3. **Software Detection:** A message is detected by software that is created to detect different methods of steganography.

If a steg-analyst wants an effective attack, he or she must understand and acquire the related technology and information. However, sometimes even though the attacker has enough information, the embedded message may still be difficult to extract. Brute force can be successful in detecting or extracting the hidden information, but it requires much processing time to achieve this intent (Katzenbeisser & Petitcolas, 2000).

A GENERAL MODEL OF INFORMATION-HIDING TECHNOLOGY

The general model of an information-hiding system is given in Figure 2 (Barni & Bartolini, 2004). In order to increase security, in the embedding process, the data *m* is embedded into the carrier C through the key *k*. In general, the security of the cryptosystem cannot depend on the algorithm but on the key used (Barni & Bartolini). The carrier C may be an image, an audio file, or a piece of video. The embedding process can be classified into two groups. The first is the spatial-domain technique (Lou & Liu, 2002; Lou, Liu, & Tso, 2004; Lou & Yin, 2002), which embeds a message by directly modifying the pixel values of images. The least significant bit (LSB) method is the simplest technique. Its advantage lies in its lower computational complexity because it does not need to perform signal transformation. However, the disadvantage is its lower security and weakness to common attacks. The second embedding process is the transform-domain technique (Lee & Chen, 2002; Shieh, Lou, & Tso, 2005), which embeds a message by modulating the coefficients of the transform domain, such as through the discrete cosine transform (DCT) and discrete wavelet transform (DWT) techniques. In general, embedding the watermark into a transform domain can give more imperceptibility, security, and robustness than a spatial domain.

The second part of Figure 2 is the transmission channel. This part describes the carrier that covers the data through the channel, and may be manipulated by intentional or unintentional attacks. An intentional attack means the explicit intent of destroying the hidden carrier, including a steganalysis attack, active or passive attack, collusion attack, counterfeit attack, and so forth. An unintentional attack means the undergoing of signal processing, including filtering, lossy compression, blurring, sharpening, and so forth. Table 2 summarizes some of the attack modes (Anderson & Petitcolas, 1998; Katzenbeisser & Petitcolas, 2000; Kutter & Petitcolas, 1999).

The last part of Figure 2 is the process of information retrieval. Steganography schemes can retrieve the hidden data by using the key without the original carrier and data. Watermarking schemes for watermark extraction depends on whether the original carrier is necessary or not. In general, the schemes that require the original carrier for the watermark-extraction process are robust against the attacks of signal processing. Furthermore, the schemes are not feasible in practice such as in DVD copy protection, where the original information may not be available

Figure 2. The general mode of an information-hiding system

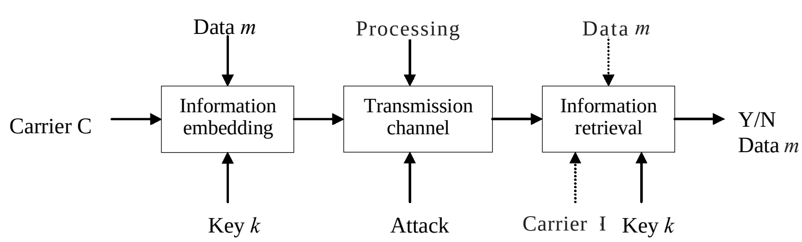

Table 2. A summary of the attack modes

- Steganalysis attack (active attack, passive attack)
- Filtering (blurring, sharpening, low-pass filtering, etc.)
- Noise adding
- Lossy compression
- Geometric transforming (translation, rotation, scaling)
- Data reduction (cropping, histogram modification)
- Data composition (logo insertion, scene composition)
- D/A and A/D conversion (print-scan, analog TV transmission)
- Transcoding (BMP to JPEG, H.263 to MPEG2)
- IBM attack
- Mosaic attack
- Statistical averaging
- Collusion attack
- Copy attack
- Counterfeit attack
- Multiple watermark
- Tampering
- Protocol attack
- Statistical attack
- Common-cover-carrier attack
- Overmarking
- Jitter attack

for watermark detection. On the other hand, the schemes that do not require the original carrier for the watermark-extraction process, called blind detection, are more feasible in that situation. However, the schemes have lower robustness than the former ones.

INFORMATION-HIDING SCHEMES

Classical information-hiding carriers include tablets, hollow heels, images under stamps, tiny photographs, word arrangements, and so forth. With the progression of computer techniques, the hidden carriers are transferred to digital types. These digital carriers are widely applied to information hiding, and many different technologies have been proposed. The schemes include the following (Johnson et al., 2001).

1. **Hiding in Text:** A document may be modified to conceal information by manipulating the positions of lines and words. HTML (hypertext markup language) files can be used to carry information because adding spaces, extra line breaks, invisible characters, and tabs are ignored by the browser. The extra spaces and lines are not perceptible until the source code of the Web page is revealed. Another example is open code or null cipher, which has been mentioned above.
2. **Hiding in Disk Space:** The way to find unused space is not readily apparent to an observer. For example, early Windows 95, drive formatted as FAT16, without compression used cluster sizes of around 32K. That means the minimum space allocated to a file is 32K. If a file is 2K, then an additional 30K is wasted due to the way storage space is allocated. Another scheme is to create a hidden file in the file system. If the user knows the file name and password, then access is granted to the file. No evidence of the file exists in the system.
3. **Hiding in a Network Packet:** Inherent characteristics in network protocols can be used to hide information. For example, the header of the TCP/IP (transmission-control protocol/Internet protocol) packet has some unused space and other features that can be manipulated to hide information.
4. **Hiding in Software and Circuitry:** Data can be hidden in a carrier based on the physical arrangement of the work. The arrangement itself may be an embedded signature that is unique to the creator (e.g., the layout of code distribution in a program or electronic circuits on a board). The intent is to identify the origin, and it cannot be removed without significant change to the work.
5. **Hiding in Images, Audio, and Video:** There are many different schemes for hiding information in images, audio, and video. These schemes may include hiding information in unused space such as the header of a file. Embedding techniques can range from the placement of information in imperceptible levels, the manipulation of the compression algorithm, the manipulation of the masking model, to the modification of carrier characteristics.

SOFTWARE OF INFORMATION HIDING

Many information-hiding software are available on the Internet. SandMark is a steganographic tool developed by the University of Arizona for software watermarking, tamper proofing, and code obfuscation of Java byte code. The ultimate goal of the project is to implement and study the effectiveness of all known software-protection algorithms. Currently, the tool incorporates several dynamic and static watermarking algorithms, a large collection of obfuscation algorithms, a code optimizer, and tools for viewing and analyzing Java byte code. Software-watermarking algorithms can be used to embed a customer identification number (a fingerprint) into a Java program in order to trace software pirates.

In recent years, the broadcast-monitoring technique has given rise to a lot of interests in copyright protection. Many film owners hope to get accurate information on when and where their films are broadcast. This is also a problem crying out for a solution. The Teletrax video-watermarking system is a broadcast-video-monitoring system that embeds a watermark in video content to monitor how broadcast material is used around the world and even to identify the source of these copies.

Moreover, the cryptanalysis technique is also getting respect. Stegdetect is an automated tool for detecting messages in an image. It is capable of detecting several different steganographic methods to embed hidden information in JPEG images. The detectable schemes include Jsteg, Jphide, Invisible Secrets, Outguess 01.3b, and F5. Tables 3 and 4 summarize some software of the technology.

FUTURE TRENDS

With the development of digital technologies, it has become necessary to protect multimedia content from unauthorized usage. Recently, there are two fundamental technologies, encryption and digital watermarking, that have been identified for protecting copyrighted multimedia content on the Internet.

The protection of digital intellectual property has motivated most of the research in the fields. There are many other applications of increasing interest to both the academic and business communities. Moreover, many researchers are also interested in hiding information or, conversely, in preventing others form doing so.

There exists a number of image-processing-based benchmark and cryptanalysis software. However, it is a question if these techniques can successfully destroy the existing information-hiding schemes. Moreover, these techniques still need to be improved due to the lack of modular researching results (such as the software for statistical attacks).

Regarding the security issue, if an attacker understands the algorithm of a scheme without obtaining any other information, such as the key, the scheme is supposed to be secure (Anderson & Petitcolas, 1998). However, with the development of computer techniques, the speed of cryptanalysis is more and more rapid. Thus, the issue of security will be more important.

The problem of digital-content piracy has become more and more critical, and major content producers are seeing their businesses drastically reduced because of the way in which digital content can be copied and distributed. This is the reason why digital rights management (DRM) is currently garnering much attention from the industry and academia (Barni & Bartolini, 2004).

Table 5 summarizes some of current research topics of information-hiding technology.

Table 5. A summary of current research topics

• Anonymous communications
• Covert channels in computer systems
• Detection of hidden information
• Digital elections
• Information-hiding aspects of privacy and confidentiality
• Low-probability-of-interception communications
• Steganography and steganalysis
• Subliminal channels in cryptographic protocols
• Watermarking for the protection of intellectual property
• Authentication of multimedia
• Robust watermarking and fingerprinting of multimedia
• Software protection
• Stego-engineering
• Digital cash and electronic commerce
• Digital forensic and forensic analysis of digital multimedia
• Attacks to watermarking security
• Digital rights management
• New applications, legal aspects, and security issues (including encryption, tamper resistance, watermarking, fingerprinting, etc.)
• Identification of digital content
• Security analysis of existing watermarking schemes
• Proposal of secure, practical watermarking algorithms
• Lossless data embedding
• Image database
• Informational-theoretical aspects of data hiding
• Practical systems with aspects of data hiding
• Watermarking quality evaluation and benchmarks
• Data-hiding applications in biometrics
• Embedding and attack software for data hiding

CONCLUSION

Information-hiding technology is not only an ancient art, but is also existent in the development of computer technology, which has brought a new vision. Though the development of computer networks has made the exchange of information easier, information-hiding technology is an effective tool for protecting personal information, rights, and benefits. The critical issues discussed in this article offer many implications and challenges to businesses, academia, and governments. With greater emphasis being placed on this technology and its capabilities, these issues must be dealt with continuously without delay, and as the new technology continues to develop, newer issues will arise and present new challenges to the user.

KEY TERMS

Collusion Attack: By averaging together the carriers of hidden information, the watermarks may be canceled out.

Cover-Medium: A medium that does not contain any message.

Digital Watermark: It is a process that secretly embeds a message, such as a logo or data about the authorship, into multimedia. The watermark information still can be detected or extracted after suffering from attacks. Its major intent is establishing an identity of multimedia to prevent unauthorized use.

Fingerprint: It is also called a label. It is a feature of the carrier and is used to distinguish it from other carriers. Moreover, it allows the copyrighted owner to trace pirates if the carrier is redisseminated illegally. The major difference between watermarking and fingerprinting is whether the identity of the transmitter or that of the recipient is embedded in the carrier.

Fragile: After a message is embedded into a carrier, the hidden message is destroyed if the carrier is destroyed or modified. The scheme is not suitable to prove a legal copyright but useful to detect a carrier tampered with.

Imperceptibility: After a message is hidden into carrier, it is difficult for a viewer or listener to distinguish between the carrier that contains the hidden message and those that do not.

Robustness: It is the resistant ability of a hidden message against various attacks; that is, a message that is hid in a carrier can be reliably detected after the carrier has been attacked.

Steganalysis: Discovering the existence of hidden information. Hence, its major intent is to discover hidden information and break the security of the carrier.

Steganography: Hiding the existence of a message by hiding information into various carriers. The major intent is to prevent the detection of hidden information.

Stego-Medium: The medium after hiding a secret message into a cover medium.

Evolution of Marketing to E-Marketing

Anesh Maniraj Singh
University of KwaZulu-Natal, South Africa

INTRODUCTION

The Internet was initially developed for military purposes but soon grew into an academic tool intended to disseminate research from one institution to another. In the 1990s, the Internet was introduced into the business arena and has steadily grown into a very important business tool that has helped businesses to achieve and improve on their strategic goals. The Internet has created new revenue streams; it has broken geographic boundaries to new markets and has ushered in a new level of convenience. The Internet has not only impacted on the overall organisation, but it has also impacted on functional areas such as finance, production, human resources, and marketing. This article examines the extent to which marketing has changed as a result of the Internet.

BACKGROUND

What is Marketing?

Marketing is often confused with advertising or sales, and many people believe that marketing, advertising, and sales are one and the same and hence use the terms synonymously. Marketing, however, is the overarching discipline that encompasses advertising, sales, research, and other activities. Kotler (2003) defined marketing as "the art of identifying and understanding customer needs, and creating solutions that deliver satisfaction to the customers." Perrault and McCarthy (2000) defined marketing as a set of activities to accomplish the organisations goals by anticipating customer needs and supplying them with need satisfying goods and services. According to Singh (2001), the central themes that emanate from these definitions are need identification, need satisfaction, and profit, which he terms the *marketing equation*. The marketing equation assumes, ceteris paribus, tha, if organisations can identify customer's needs and satisfy them, then quantities demanded would increase, resulting in a profit for the organisation. Need identification is generally based on market research such as surveys, focus groups, and observation. In attempting to satisfy the customers need, marketers employ the Marketing Mix, or the 4P's of Marketing, to develop their offering. The 4Ps are Product, Price, Place, and Promotion (Perrault & McCarthy, 2000). The four activities of the Marketing Mix revolve around the consumer. The 4Ps are like baking a cake—quantities can be adjusted, based on the organisations resources. However, a change in one activity will affect others; for example, an increase in promotion expenses will result in an increase in price. How does any of this relate to the Internet?

INTERNET MARKETING

Many articles and books are being written about Internet marketing and e-marketing to guide marketers to look to the Internet to develop new markets and exploit the purchasing power of the global consumer. In essence, Internet marketing involves using the Internet to perform marketing activities. In order to explain this, the concepts explained earlier—that is, need identification, need satisfaction, and the marketing mix—will be discussed in relation to the Internet.

NEED IDENTIFICATION

The Internet has speeded up the need-identification phase. The World Wide Web (hereafter referred to as the Web) has become a very effective market and marketing research tool. Using traditional marketing research methods has proven unreliable; customers rush through surveys conducted in person and often do not return postal surveys. Focus group members often do not arrive for the session, and some even disrupt the session. The Internet makes data collection more reliable, whereby questionnaires are sent directly to the customer. Responses are returned almost immediately. However, this is dependant on the customer's willingness to fill in the questionnaire and to return it. Another limiting factor is access; the Internet market is a very small community, which limits online research to Internet users only (Strauss, El-Ansary, & Frost, 2005). Chat sessions online are quick and easy to arrange and do not incur costs of bringing people together in one venue. However, online anonymity makes it difficult to determine who is on the other end. This could skew the results obtained.

Figure 1. The buying decision process (Adapted from Kotler, 2003)

Market and marketing information can be purchased online from many reputable market-research houses. Information is also available for free online from public and government departments. Internet service providers and other Web-based organisations are willing to sell or make information available free of charge.

NEED SATISFACTION

When purchasing high-involvement products such as appliances, electronics, clothing, perfumes, and motor vehicles, the consumer generally follows a buying decision process (see Figure 1).

The Internet serves as an invaluable tool in the consumer's information search phase and post purchase behaviour. It also plays a lesser role in the evaluation of alternatives and the actual purchase. Making business information available is one of the most important ways of satisfying one's customers. The Internet makes information easily accessible, and it is information that gives the customer greater control over the purchase (Peters, 1999). Detailed online information assists the customer in making an informed decision. The Internet also makes the information search easier with the multitude of search engines that can locate sites that contain the information being sought by the customer. According to Ries (2000), one of the benefits of the Internet is that it provides the consumer with price comparisons, which is most beneficial to customers who are price sensitive.

Some Web sites known as infomediaries have features that aid the consumer's evaluation of their product choices, prices and features (Awad, 2004; Schneider, 2004). Some infomediaries also assist the customer with the purchase of the product by linking the customer to a store's Web page, where the customer will conclude the purchase by filling in delivery details and credit card particulars to complete the purchase.

Postpurchase behaviour, such as, queries and complaints can be handled a lot quicker, as a result of the Internet. Web sites allow feedback from customers. Contact via e-mail is quick, cheap, and easy and facilitates immediate handling of complaints (Reedy, Schullo, & Zimmerman, 2000). Some organisations preempt customer queries based on previous feedback and develop a frequently asked questions database. Companies assign Web pages to contain frequently asked questions and their answers (Perrault & McCarthy 2000, Strauss et al., 2005).

THE MARKETING MIX

It is evident that the Internet has made it possible to identify and to help satisfy customer's needs. However, it has also impacted on the marketing mix. All four components of the mix have been affected.

Product

According to Bickerton, Bickerton, and Pardesi (1996) customers do not purchase the product, they purchase the benefits. The Internet makes it possible for a company to extol the benefits of their product or service at minimal cost. Detailed information, such as product specifications, alternate uses, demonstrations, and instructions are available online. However, getting the customer to use a firm's Web site is a challenge for e-marketers.

Branding is often one of the product benefits that consumers look for, and e-branding has attracted extensive debate. E-brands are unique brands to the Internet such as Amazon, Yahoo!, and eBay, or they could be aliases for offline brands such as Egg, which is the online arm of Prudential Insurance Company. According to Moodley (2000), establishing e-brands and more importantly, e-brand loyalty is an extremely difficult task. This notion has been supported by Cohen (1999), who is of the opinion that the Web defies all brand logic: What is successful off-line does not enjoy the same success online. It is hard to encourage loyalty, because customers are worried that once the organisation makes the money, the site will be gone. Bickerton et al. (1996) are of the opinion that established non-Internet brands have an advantage over their competitors when they market on the Internet. However, strong off-line brands do not always translate easily to the Web. This is supported by Ries (2000), who wrote that "taking your real world name and putting it on the Internet, is fundamentally wrong" (Ries, 2000, p. 1); for example, Nike, one of the world's biggest and best known brands, does not enjoy the same success online. The values that are imbued in Nike's offline messages of speed, and agility, are absent on the web. Except for the swoosh, the site is slow and takes a long time to process pictures, which contradicts Nike's main selling points. It is difficult to take an offline brand and replicate it online (Cohen, 1999). Developing Internet branding is difficult because of the following:

- There are no visual cues, such as an eye catching pair of earrings in a store window, to direct one to a site. A brand is invisible until you input it into your browser.
- It does not allow touching, feeling, and testing.
- It does not provide a smile and a cup of coffee, the personal touches that build brand loyalty. (Ries, 2000)

Furthermore, physical environments contribute to the value of a brand. It is impossible to capture on a computer screen the smells of perfumes, freshly baked bread, aromatic spices, and freshly ground coffee as one walks through a supermarket.

According to Ries (2000), organisations need to create news surrounding their site. They need to launch a "massive publicity campaign" and then use advertising as reminders. In developing Web brands, organisations need to:

- be like Yahoo, Amazon.com and Ebay;
- be unique by having abstract names, which are hard to imitate;
- be consistent and give the same service to all customers;
- be focussed; that is, the brand must mean the same thing to everyone, like Fedex means overnight delivery and Woolworths means quality; and
- be in it for the long haul by building loyalty over a long term period. (E-Brands. Brand … 2000)

Building brands, however, is not enough. E-brands are a living entity that needs nurturing. Firms must constantly monitor, respond to inputs, and update their brands to ensure their survival (Komenar, 1996).

Price

The rules for pricing on the Internet are no different from the rules of pricing in traditional organisations. Cost recovery is still paramount for the success of the Internet organisation. According to Reedy et al. (2000), Web pricing levels the playing field when dealing with manufacturers and retailers, and the Internet may turn out to be a price equaliser rather than a price cutter. Internet pricing is more transparent (Strauss et al., 2005). The Internet provides customers with instant price comparisons, forcing Internet retailers to have a price orientation (Ries, 2000). According to Lambin (2000), the Internet market is too perfect for products: consumers have full knowledge of prices and worldwide comparisons of seller's offerings. Therefore, competing on price is not enough: sellers have to develop strong brands to ensure continued sales.

The Internet has been able to lower prices as a result of lower overheads (Ries, 2000). The virtual organisation does not require large premises, inventories and staff. These cost savings translate to lower prices for the customer. Priceline.com lets the customer offer a price that he or she is willing to pay for an airline ticket, and the site searches for the match (Peters, 1999). Pricing is in the hands of the customer. If the price is not right, it is cheaper a click away. No longer will the seller have the upper hand in the mysteries of pricing (Reedy et al., 2000), because the consumer now controls pricing more immediately and more directly (Komenar, 1996).

Place

Several hundred manufacturers are using Web sites for marketing, buying, or selling goods and services to other businesses (Roberts, 2000). The Internet is more than just a new sales channel (Peters, 1999). *Cybermarketing* is the term used to describe Internet marketing. Cybermarketing involves selling in market space rather than in a market place (Kotler & Armstrong, 1999). Virtual stores and virtual organisations are mushrooming every day. According to Haag, Cummings, and Dawkins (2000), "virtual organisations are a network of independent vendors linked together by Information Technology to exploit market opportunities by sharing skills, costs and market access." The Internet has made it possible to bring stores and manufacturers closer to the customer. In fact, the Web has made the physical distance between buyer and seller immaterial (Rai, Chandra, & True, 1999).

Direct selling from the manufacturer to the consumer in the traditional market is logistically unsound. However, the Internet makes direct selling a more viable option (Bickerton et al., 1996). Dell Computer Corporation is able to keep ahead of its competitors because of its effective use of the supply chain (King & Conner, 2000). The Internet has made it possible to eliminate the middleman. However, the Web has introduced its own middleman, known as *metamediaries* (Strauss & Frost, 2001). Metamediaries assemble the content and information centred on a theme such as weddings, parties, and other lifestyle products and services.

Besides threatening traditional businesses, the Internet has given rise to the virtual mall, also known as *cybermalls*. The cybermall, like traditional malls, leases space to vendors to conduct business, whilst the mall looks after advertising and maintenance of the site (Alderman, 1996). The advantages of joining a cybermall include the possibility of attracting new customers and developing a brand identity and brand loyalty that may benefit vendors of that mall (Alderman, 1996). Vendors belonging to a mall with a strong brand may not need to develop a brand of its own. Cybermalls, however, add to the vendor's costs, which affects pricing.

Bricks-and-mortar businesses may be threatened by virtual organisations, but, they will not be replaced entirely. Traditional stores may grow smaller as cybershopping increases, but as long as poverty and illiteracy exist, physical stores will continue to exist.

Promotion

Guiltinan and Paul (1991) defined promotion as the activities associated with marketing communications. Grant (1999) collectively called marketing communications MARCOM. She states further that MARCOM is one of the business areas that is experiencing dramatic changes in strategy and execution due to the Internet. The Internet serves as a new channel for marketing communication, and it is changing the nature of what can be done to promote a company and its products (Grant, 1999).

Personal Selling

According to Kotler (2003), the market will see a decline in travelling salespeople as a result of the Web. The Internet is replacing salespeople, clerks, brokers, and other middlemen by serving the customer directly. Merril Lynch is confident that its future is on the internet, to the extent that the jobs of 14,800 stockbrokers are at risk (Graham, 2000). Robertson (cited in Ochman, 2000), however, stated that customers will gather information and intelligence on prices from the Internet, but to conclude the deal, they still want the reassurance of a traditional handshake that one does not get over the Internet.

Direct Marketing

The Internet provides an additional channel for home shopping (Cravens, 2000). E-mail-based catalogues cost less to produce than physical catalogues printed on glossy paper. Delivery is quicker, more accurate, and even cheaper than the postal service. The cost of sending a thousand e-mails is the same as sending one (Grant, 1999). Video, sound, and detailed information are adding a new dimension to flat traditional brochures (Grant, 1999).

Publicity

As mentioned previously, Ries (2000) is of the opinion that organisations need to gain publicity first before getting onto the Net. Getting publicity on the home pages of CNN, Financial Times, and Independent Online, Web versions of popular news media, increases the credibility of a press release, or any other newsworthy activities of a firm.

Just like traditional media, publicity on the Net is also short lived and is only effective whilst it is still "hot news."

Sales Promotion

The effectiveness of sales promotions on the Web is no different from normal promotions. Web promotions also rely on incentives in the form of electronic coupons, special offers, free accessories and contests, amongst others, to generate sales. Taste testing however, is not possible, which could affect the sale of new food products.

According to Strauss and Frost (2001), e-coupons are big business. Electronic coupons can either be printed, or used in normal stores, or they can be redeemed online at virtual stores. Electronic coupons create commitment (Mohammed, Fisher, Jaworski, & Cahill, 2002).

Loyalty awards can also be accumulated for Web purchases (Grant, 1999). Internet organisations could also offer customers rewards for introducing new e-customers. This is known as *word-of-click* or *viral marketing*, the same as *word-of-mouth* advertising.

Contests, which are normally expensive, are cost effective on the Internet and are able to generate invaluable information, such as biographical and contact details of contestants, which could be used later as sales leads (Grant, 1999).

According to Silver (2000), businesses should apply the "bonus pile on" (p. 2). Adding "free" extras makes the price seem a lot less expensive than the perceived added value that the customer is receiving. Internet "freebies" could include personalised e-mail addresses, Web space for a year, software, and subscriptions to electronic magazines.

Knight (2000) recommended that a successful online sales promotion must be a part of the overall marketing campaign to ensure consistency. He also advises that the promotion should run for a limited time only. Start and finishing dates must be set and adhered to, in order to give the firm control of the promotion. One promotion is not enough. There must be constant activity which creates a vibe around a promotion.

Advertising

When advertising on the Internet first appeared, many critics said it would never last. However, it is here to stay and is gaining momentum. American Internet advertising spending in 1997 amounted to $907 million (Advertising on the Internet, 2000). This figure in 2004 grew to $2.1 billion (Rashed, 2005). The Internet is the best and most effective way of advertising in the new millennium (Advertising on the Internet, 2000). Internet advertising is also the cheapest form of advertising, as there is no limit to the amount of information that can be distributed (Rai et al., 1999). The Internet changes advertising in that it is a new channel for advertising, and it offers new places for placing advertisements (Grant, 1999). The Internet has extensive international reach and is the permanent ambassador of the firm. There are two types of Internet advertising, namely, own Web-page advertising and paid advertising.

Paid advertising is similar to regular advertising, except that it can be either space or time based or both. Banner adverts are strips of information that appear either as fixed features on a Web page, or they appear as animations that float across the top of the screen. A static banner price is determined by the space it occupies on a web page, and an animated banner price is determined by the time it takes to flash the message across the screen, and the space that the banner occupies. Banners need to be as accurate and concise as possible, with a link to the advertiser's site. A boring banner can be easily clicked away, hence losing a potential buyer. Interstitial advertising is an effective means of occupying an Internet user whilst he or she waits for something to happen, such as the download of files (Grant, 1999).

Web-page advertising is the best option in terms of cost versus benefit (Rai et al., 1999). The development and hosting costs of a Web site are a fraction of a full advertising campaign (Advertising on the Internet, 2000). A Web site can attract or repel customers with a single mouse click. Therefore, Web sites have to be developed in such a manner that they grab and hold the attention of the consumer. Having a Web site is not enough. The site has to be monitored and maintained, and it needs to be supported with traditional media, by publishing the site address in normal adverts, on company stationery, and on all other promotional tools (Lambin, 2000; Tiedt, 2000; Wilson, 2000).

Unless one is looking for a Web site that they were referred to, or saw in some other medium, everything on the Web is invisible. This statement raises questions with regards the effectiveness of Internet advertising. The effectiveness of Internet advertising is best measured in relation to other media. Table 1 illustrates the effectiveness of Internet advertising in relation to television and newspaper advertising (Barker & Gronne, 1996).

Reach is the size of audience that can be reached by the medium. Selectivity is the precision with which the advertising reaches the target audience. Feedback is the ease with which feedback is given to the advertiser. Cost is the expense that is incurred in reaching the audience and capacity is the amount of information disseminated by the medium. It is evident from Table 1 that the Internet is an effective advertising medium. Internet advertising is especially effective as a medium for the transfer of large volumes of information to a select audience, with instant feedback at the lowest cost, and the effectiveness of which is measured almost instantly. However, the reach of Internet advertising is limited to those who can afford the technology. The Internet has changed the way marketing activities are conducted. The greatest impact has been on the marketing mix. Will Marketing change anymore?

FUTURE TRENDS

Traditional Marketing as discussed in this article is aimed at mass markets and uses a one size fits all approach. E-Marketing in the form of customer relationship marketing (CRM) takes a personalised approach to individual customers (Strauss & Frost, 2001). CRM enables marketers to use technology to develop databases of individual customer's needs, wants, and preferences. Based on the information, marketers can develop products that are best suited to the individual. Banks are using their extensive databases to develop individual banking profiles of customers, which they then use to offer the customer more

Table 1. Effectiveness of advertising media (Adapted from Barker & Gronne, 1996)

	Internet	Television	Newspaper
Reach	Low	Very High	High
Selectivity	High	Low	Medium
Feedback	Very High	Very Low	Low
Capacity	Very High	Low	Medium
Cost	Very Low	Very High	High

credit, investment opportunities and even send them customised birthday cards. With the trend towards the mobile Internet, advertisers will be able to send adverts to mobile devices. Fast-food outlets stand to gain immensely from mobile marketing and mobile ordering systems. According to Ankeney (2001), research indicates that a 6-second increase in transaction speed can boost a fast-food franchise's revenues by 1%, therefore being able to order fast foods on a mobile device before reaching the outlet could benefit both the consumer and the supplier.

CONCLUSION

This article has highlighted the fact that the Internet is a revolution. It has redefined the way that business is conducted. However, when one reads the media, people talk about e-strategies, e-business plans, and e-marketing plans among others. Businesses need to remember that the Internet has not captured the entire world population and therefore they need to serve those markets using traditional means. Furthermore, the Internet is just a new medium for conducting business across the globe. Therefore, sticking to basic principles of business, such as identifying customers needs, satisfying those needs, recovering cost, and treating the customer as a king or queen are still essential to business success. An e-marketing plan has to form a part of the marketing plan, which has to form a part of the overall business strategy. Electronic marketing is here to stay. Marketers need to embrace the trend and find ways and means to exploit it to the mutual benefit of the customer and the organisation.

KEY TERMS

Customer Relationship Management: The use of technology especially databases that help customers profile individual customers in order to provide them with customized products and services.

Electronic Marketing: Conducting marketing activities on any electronic device, including cell phones, PDAs, laptop computers, and fax machines.

Internet: The Internet is the technology that facilitates global communication using computers. It is a worldwide system of computer networks in which any one computer can get information from any other connected computer linked to the Internet.

Internet Marketing: Conducting marketing activities on the Internet.

Market Research: An activity that is carried out to determine the potential customers who are willing and able to purchase a firms products or services.

Marketing Research: An activity carried out among existing customers to determine their level of satisfaction with the firm's products or services. Marketing research is also carried out to determine the effectiveness of a firm's marketing activities.

World Wide Web (Web): The Web is an application that runs on the Internet, and is a collection of electronic documents, or Web pages, that can be viewed on your computer using a Web browser. The words Internet and Web are used synonymously, although by definition they are very different.

The Evolution of Trust in Business-to-Business E-Commerce

Pauline Ratnasingam
Central Missouri State University, USA

INTRODUCTION

E-commerce is defined as a means of conducting business electronically via online transactions among trading partners. Forrester Research predicted that B2B (business-to-business) e-commerce could be worth $5.7 trillion by the end of 2004. This study aims to examine the evolution of e-technologies and its impact on trust. Trust refers to reliance on and confidence in one's business partner (Mayer, Davis, & Schoorman, 1995). We discuss the evolution of e-technologies in light of the evolution of trust in technology trust (or transactional trust) and relationship trust or (relational trust). Electronic data interchange (EDI) was the prominent technology used in the 1970s and '80s. As we approached the 21st century and with the advent of the Internet, businesses feared that the lack of presence on the Internet would hinder their competitive and strategic advantages. Internet competition in most industries is forcing businesses to search for ways to improve product quality, customer service, and operation efficiency in supply chain management (SCM) in order to remain competitive. Today e-commerce has moved beyond EDI via value-added networks (VANs) by leveraging into the Internet and extending into Web technologies. The Internet is transforming and reshaping the nature of interorganizational commerce by enabling new types of interorganizational relationships. The business benefits include lower costs and more flexible systems that provide a facilitating structure for virtual relationships, enabling the easier identification of suppliers and products and more integrated supply chain management (Dai & Kaufmann, 2000). The Internet has impacted the SCM e-commerce environment by creating a centralized, global business and management strategy (e.g., make to order, assemble to order, and make to stock), and online real-time, distributed information processing to the desktop, thereby providing total supply-chain information visibility and the ability to manage information not only within firms, but also across firms and industries.

On the other hand, uncertainties, technical complexities, and concerns about trust have kept many firms from participating actively in B2B e-commerce. Uncertainties reduce the confidence both in the reliability of online B2B transactions and more importantly in the trading parties themselves. In a survey of 60 procurement trading partners involved in supply chain management at U.S. firms conducted by New York-based Jupiter Media Metrix Inc. in 2001, the findings indicated that 45% of the trading partners suggest a lack of trust prevented them from buying goods and trading online more frequently. In the next section we discuss the evolution of e-technologies, followed by its role in supply chain management and impact on trust.

THE EVOLUTION OF E-TECHNOLOGIES AND TRUST

We discuss the evolution of e-technologies from traditional EDI via VANs to Internet-based EDI, extranets, e-marketplaces, and Web services commonly used in supply-chain activities today. Further, we link these e-technologies and their impact on trust. The study provides a novel discussion on how management is affected by using e-technologies for SCM activities. More importantly, we discuss how the evolution of different types of e-technologies impacts the evolution of trust. The next section describes the e-technologies.

Traditional EDI via Value-Added Networks

The traditional EDI-via-VANs technology has been used for almost three decades and has brought its users significant advantages resulting in increased productivity and efficiency. EDI is defined as the computer-to-computer exchange of intercompany business documents and information through standard interfaces that requires hardware, software, and communications technology that permit computers to transfer the data electronically (such as purchase orders, invoices, shipping notices, and price lists).

Organizations that used EDI relied mostly on VANs and private messaging networks, both characterized by relatively high costs and limited connectivity. As an automated information exchange, EDI standardizes documents such as purchase orders, invoices, and shipping documents into an agreed-upon open-coded format. Connectivity to VANs was available only for large organizations that relied mostly on mailbox services. VANs were considered too expensive to implement, and smaller suppliers were pressured to adopt EDI (Langfield-Smith & Greenwood, 1998). Furthermore, recent research reflects reluctance on the part of traditional EDI trading partners to adopt the Internet due to the newness of the Internet technology, potential Internet legislations, the lack of Internet standards, and the lack of reliability and security of data transmission within the Internet environment.

Internet-Based EDI

Alternatively, Internet-based EDI, with significantly fewer implementation constraints, plays an important role in extending EDI benefits to a wider spectrum of businesses. Internet-based EDI differs from traditional EDI as it uses proprietary flat files in HTML (hypertext markup language) formats and it establishes two types of connections. The first is a direct connection that requires front-end translation software to transmit and display documents or interfaces with existing in-house application systems. Second is through a third-party Internet VAN (IVAN) that sets up a Web page to perform translations and exchanges among trading partners.

What was once cost effective for only large corporations conducting e-commerce in EDI format is today feasible for all organizations through Internet commerce applications (using Internet-based EDI, intranets, extranets, e-marketplaces, and Web services). E-technologies promote accessibility, availability, and universality, thereby allowing trading partners to interact with one another easily. Furthermore, the Internet provides smaller suppliers with an easy, inexpensive method of accessing data in addition to providing a ubiquitous reach and real-time access to information.

Extranets

Extranets are Internet-based applications that use standard protocols, middleware, and browser software to fulfill functional requirements and support supply-chain operations. Extranets serve as information communication technologies that integrate internal and external communications along the supply chain. The applications improve firm competitiveness by increasing the efficiency of internal and external communications and organizations, and by facilitating new and improved products and services. Furthermore, it is used to support information sharing among registered trading partners. For example, when orders come into an extranet system, the lead time for delivering the products is composed of order-processing times, material lead times, assembly lead times, distribution lead times, transportation times, and installation times.

E-Marketplaces

White and Daniel (2003) describe e-marketplaces as Web-based systems that enable automated transactions, trading, or collaboration between business partners. An electronic marketplace is an interorganizational system that allows participating buyers and sellers to exchange information about processes, products, and services in the supply chain. Furthermore, Bakos (1998) suggests that the key tasks of e-marketplaces are matching buyers and sellers, aggregating and facilitating buyers' demands and sellers' products, and acting as agents of trust.

Web Services

Web services are modular Internet-based business functions that perform specific business tasks to facilitate business interactions within and beyond the organization. They are flexible, decentralized, open, unmonitored, shared Internet-based applications that allow firms to create new products and services faster than existing methods that consist of the dynamic assembly of loosely coupled components (e-services, legacy data; Fieldman, 2002; Fonseca, 2002). Web services bring requesters, providers, and brokers together, thereby connecting people, applications, and data (Fieldman). They are primarily technical, enabling e-collaborations among value-chain partners. Web services promise to increase flexibility, agility, and competitiveness as well as opportunities to reduce development cost and time. Early adopters of Web services include high-velocity industries, such as insurance, financial services, and high-technology industries. These industries are viewed as a set of diverse trading partners (including suppliers and customers) working closely together in a highly competitive market that requires continuous innovation to maintain competitive advantage (Paratech International, 2001). In the next section, we discuss how e-technologies impact supply chain management.

The Role of E-Technologies in Supply Chain Management

SCM is a network of facilities that procures raw materials, transforms them into intermediate subassemblies and final products, and then delivers the products to customers through a distribution system. The Internet provides a platform for electronic inventory management, production planning, purchasing, distribution management, and payment systems (Anderson & Lee, 2003). For example, in the automotive industry, SCM involves balancing reliable customer delivery with manufacturing and inventory-management costs in order to effectively perform the order-fulfillment cycle time, inventory level, and cost. The main activities include material processing such as blanking, stamping, and information processing to forecast and plan production for each supplier, manufacturer, and assembler. Coordination among trading partners is critical due to interdependencies that include the shipment of steel sheets to the stamping plant and the shipment of doors, roofs, hoods, and minor parts. The overall objective is to minimize the inventory levels necessary to maintain reasonable order-fulfillment cycle times, taking into consideration the demand, process, and supply uncertainties across the supply chain. E-technologies also offer several secondary services including integrating the purchasing, distribution, and inventory processes, thereby streamlining the entire transaction process and allowing better inventory management, quality control, and supply chain management. Buyers experience effective e-procurement collaborative activities through better and more informed decisions in selecting suppliers and products, through superior planning and forecasting, and by obtaining more competitive pricing, better delivery terms, and higher product quality in the supply chain. Information on products, prices, businesses, and services in electronic databases are available to registered trading partners anytime from anywhere in the world. Furthermore, firms are using Web-based tools to make decisions and validate their trading partners (Domke-Damonte & Lensen, 2002). For example, Freightquote.com, a Lenexa provider of online freight management services, is using The Dun & Bradstreet Corporation in Murray Hill, NJ, to access the Global Decision Maker Web site for real-time recommendations on whether to grant credit. Therefore, both the internal and external integration of e-technologies is important for effective SCM. While internal integration involves interconnection with a variety of applications such as order entry, invoicing, billing, and payment transfers, external integration facilitates e-commerce transactions with trading partners such as suppliers, customers, government units, and financial institutions (Claycomb & Frankwick, 2004). Effective SCM and competition in the global economy demands trustworthy trading partners. In the next section, we discuss the role of trust in using e-technologies.

The Role of Trust in Using E-Technologies

The extant literature on relationship marketing defines trust as being that the partner's word is reliable and that a party will fulfill its obligations. Economists and sociologists have been interested in how institutions are created to reduce the anxiety and uncertainty associated with transactions (e.g., Zucker, 1986). Trust in general involves uncertainty and dependency, as online transactions and exchange relationships are not only characterized by uncertainties, but also by anonymity, lack of control, and potential opportunism, making risk and trust crucial elements of e-commerce. Relational marketing includes activities directed toward establishing, developing, and maintaining successful relational exchanges. Relational exchanges include supplier partnerships (goods suppliers, just in time, and total quality management), lateral partnerships (competitors, technology alliances, nonprofit organizations, government), buyer partnerships (ultimate customers and intermediate customers), and internal partnerships (functional departments, employees, and business units).

Institutionally based trust production uses formal mechanisms and does not rest on personal characteristics or on past history of exchange (Zucker, 1986). Similarly, Grabner-Krauter and Kaluscha (2003) suggest that one important reason for the importance of trust in e-commerce is the fact that in a virtual environment, the degree of uncertainty of economic transactions can bring about several risks caused by the implicit uncertainty of using open technological infrastructures for the exchange of information (system-dependent uncertainty), or can be explained by the conduct or behavior of actors who are involved in the online transaction (transaction-specific uncertainty).

We propose that in B2B e-commerce relationships, technical solutions and security services provide impersonal assurances that contribute to expectations, intentions, and behaviors. Behaviors and intentions (i.e., intentions to continue in the e-commerce relationship) is a predictor of actual behavior (i.e., relationship continuity). This is consistent with Zucker (1986): Technology trust can be viewed as a form of institution-based trust. It is created in an impersonal economic environment (without familiarity) with similarity (communality). Trust forms not because people know each other personally, but because institutional structures that are akin to policies, auditing, and recourse are embedded in the e-commerce technology. Hence, we propose two types of trust—technology trust and relationship trust—discussed in the next section followed by types of communications.

Technology Trust

We refer to this impersonal form of system trust as technology trust. Technology trust is derived from the security mechanisms and standardized, routine business processes embedded in e-commerce technologies. The foundations of technology trust are the technical safeguards, protective measures, and control governance mechanisms that aim to provide reliable transactions through standardized, routine processes and detective mechanisms embedded in the e-commerce technology. We define technology trust as the subjective probability by which organizations believe that the underlying technology infrastructure is capable of facilitating transactions according to their confident expectations.

Relationship Trust

Relationship trust refers to the conduct and behaviors of actors involved in online transactions. Relationship trust is defined as the subjective probability with which organizational members collectively assess that a particular transaction will occur according to their confident expectations. It is derived from the interpersonal component of e-commerce relationships. Behaviors reflect reliability, integrity, and dependability as well as knowledge and understanding of the e-commerce system. Unique to e-commerce relationships, relationship trust is evidenced when a partner makes available real-time information. Trading partners have access to supply-chain databases containing information such as demand forecasts, sales data, inventory data, production data, and distribution data.

What is Communications?

Morgan and Hunt (1994) suggest that a major precursor of relationship trust is communication, which is defined as "the formal as well as informal sharing of meaningful timely information between firms" (Anderson & Narus, 1990, p. 44). Previous research suggests that quality communication is related to satisfaction with the partner, intentions to continue a relationship, and a willingness to provide referrals (Morgan & Hunt; Sawhney & Zabin, 2002). MacNeil (1981) acknowledges that honest and open lines of communications encourage continued growth and close ties between partners. Furthermore, Doney and Cannon (1997) suggest that a focal firm may confer trustworthiness upon a partner through the provision of positive statements about its experience with the partner. Likewise, Anderson and Narus (p. 45) suggest a positive link between trust and communication, and noted that the "accumulation of trust leads to better communication." Morgan and Hunt suggest that effective communication leads to relationship commitment, defined as an exchange partner believing that an ongoing relationship with another is so important as to warrant maximum efforts at maintaining it.

Types of Communications

There are two forms of communication in e-commerce relationships, namely the transactional and relational components of communication. The transactional component of communication is reflected in the more formal and precise reporting of outcomes and results. Transactional attributes of communication include the accuracy, timeliness, adequacy, correctness, and credibility of information exchanged between the partners (Mohr & Spekman, 1994). We suggest that technology trust sets the stage for initial trust. From a transactional perspective, trust in the technology contributes to satisfaction, commitment, and intentions to continue.

In contrast, the relational component of communication is reflected in the bargaining and negotiation between the partners. Similar to the information-sharing and participation aspects of communication identified by Mohr and Spekman (1994), trading partners share information and engage in joint planning and goal setting. The intent is to engage in conversations that become increasingly revealing to set the stage for the reciprocal sharing of information and increased risk taking. The higher the trust the buyers have in their suppliers, the more they will be inclined to exhibit positive behaviors, keep promises, and show care and concern. We argue that the role of relationship trust supports a positive relationship evidenced by cooperation, information sharing, satisfaction, and commitment leading to relationship continuity. Similarly, previous research suggests that there is a positive relationship between trust and commitment (Doney & Cannon, 1997; Ganesan, 1994). Table 1 presents the different types of e-technologies applied in B2B e-commerce and links their impact on the role of management and trust.

CONCLUSION

This study explored the role of e-technologies in supply chain management and its impact on the role of communication for management and trust. The study contributes to theory by extending the existing literature on e-commerce and trust. Furthermore, the study also contributes to practice as e-commerce practitioners will be made aware of the evolving nature of technology, management, and the role of trust. Future research should aim to examine each type of e-technology in greater depth as multiple case studies in order to derive a generic model showing the link between the evolution of different types of e-technologies and trust.

Table 1. Evolution of e-technologies and trust

E-Technologies	**Role of Management**	**Impact on Trust**
Traditional EDI via VANs from 1970s onward	Focus on structural arrangements in the form of trading agreements, policies, and procedures for the governance of standardized, structured transactions. The focus is on implementing the transactional component of communication so that EDI messages can be transmitted in an orderly fashion.	Buyers are likely to experience high technology trust as the focus is on implementing compatible IT infrastructures to facilitate suppliers to send EDI transactions. Low relationship trust was experienced when the smaller suppliers were coerced to adopt EDI (particularly in the automotive industry) even though EDI was expensive and inflexible.
Internet-based EDI from mid-'90s onward	Focus is on implementing the Internet IT infrastructure that facilitates the integration of Internet-based EDI. The focus is on both the transactional and relational components of communications as trading partners need to be trained to use the Internet-based EDI application, in addition to formulating uniform standards of operations.	Buyers are likely to experience high technology trust as the focus is on implementing EDI with proprietary systems in HTML formats. Furthermore, buyers also make an effort to build their relationships, and they experience medium relationship trust as trading partners experienced a cost-effective manner of engaging in e-commerce.
Extranets in mid-'90s	Focus on training their registered trading partners on their product characteristics including asset specificity and complexity, in addition to building relationships. The emphasis here is on the relational component of communication as the buyer would like to lock its supplier for long-term relationships.	Buyers are likely to experience high technology trust as the focus is on implementing compatible technologies and training trading partners to use the system correctly. Furthermore, they are likely to experience high relationship trust as the supplier wants to retain the buyers by providing high-quality service. Buyers had to register in order to have access to the buyer extranet system.
E-marketplaces at turn of the 21st century	Focus on building relationships and implementing compatible systems in order to expand their market's situational characteristics such as bargaining power, liquidity, product availability, uncertainty, and trust. The focus is on the relational component of communication as buyers would like to retain their suppliers.	Trading partners are likely to experience high technology trust as the focus is in maintaining a compatible system to interact. Likewise, trading partners are likely to experience medium relationship trust due to the global reach in which trading partners have access to multiple buyers and suppliers.
Web services in the 21st century	Focus on providing quality services and relationship building in addition to the firm's characteristics that include e-procurement activities such as switching costs, and purchase formalization and centralization. The focus is on both the transactional and relational components of communication.	Trading partners are likely to experience high technology trust as the focus is on implementing compatible systems in order to facilitate online transactions. Likewise, they are likely to experience high relationship trust as service providers want to maintain and retain their trading partners for long-term investments.

KEY TERMS

Electronic Data Interchange (EDI): The computer-to-computer exchange of intercompany business documents and information through standard interfaces, which requires hardware, software, and communications technology that permit those computers to transfer the data electronically (such as purchase orders, invoices, medical claims, and price lists).

E-Marketplaces: Web-based systems that enable automated transactions, trading, or collaboration between business partners. It is an interorganizational information system that allows the participating buyers and sellers to exchange information about prices and product offerings.

Extranets: Internet-based applications that use standard protocols, middleware, and browser software that fulfill functional requirements to support supply-chain operations.

Internet-Based EDI: An alternative to traditional EDI that uses proprietary systems in HTML format.

Relationship Trust: The subjective probability with which organizational members collectively assess that a particular transaction will occur according to their confident expectations.

Technology Trust: The subjective probability by which organizations believe that the underlying technology infrastructure is capable of facilitating transactions according to their confident expectations.

Web Services: Modular Internet-based business functions that perform specific business tasks to facilitate business interactions within and beyond the organization.

INTRODUCTION

Among the many important contributions that information technology (IT) applications provide to organizations, Internet based applications may be considered the most important for strategic purposes, according to different authors like Porter (2001).

Initially, companies tried many different alternatives for using the great potential of the Web and a great number of completely new businesses that were enabled by the new technology. However, there were many failures (not only successes) and the situation has changed since the late 1990s. Thus, the time of experimentation is over and a business-oriented approach is required (Chen & Tan, 2004; Souitaris & Cohen, 2003). The Internet has indeed represented an opportunity, if properly used, for small and for big enterprises anywhere in the world (Drew, 2003; Kula & Tatoglu, 2003; Wresch, 2003).

This article describes the initial steps of an ongoing research that intends to compare the phases of Web dissemination in organizations with the adoption stages of traditional computer systems, based on Nolan's six stage model (Nolan, 1979). This approach could help describe and predict the integration of WWW into the work of organizations as well as provide a basis for improving management policies and decisions (Laurindo, Carvalho, & Shimizu, 2003).

Nolan's model (Nolan, 1979) is still an important and widespread known reference. In 1977, ARPANet (the network that gave origin to the Internet) had only 107 hosts (Ruthfield, 1995). This number increased to 317 million of hosts in January of 2005 (ISC, 2005).

This article is based in secondary data collection, some interviews with professionals from companies present on the Web, research on Web sites, in addition to a bibliography about the issue.

BACKGROUND

Nolan's Four Stages Theory

Gibson and Nolan (1974) presented a theory where the evolution of computer utilization was divided in four stages:

1. **Initiation:** New concept, exploring the possibilities of technology use.
2. **Expansion:** Some applications are developed. People are required for developments.
3. **Formalization:** Costs begin to be considered. Some effective controls are developed.
4. **Maturity:** The technology is being well integrated and managed.

The Six Stages of a Reviewed Theory

Nolan (1979) reviewed his pioneering theory and published a new study, showing the evolution of computer implementation in an organization as happening in six stages, and that is known as stages theory:

1. **Initiation:** When the first computers are purchased for labor reduction and reduce paper handling.
2. **Contagion:** When IT is expanded to other functions like invoice, inventories, and checks emission. There isn't, however, the concept of information integration.
3. **Control:** The growth of the use of information systems in the organization is explosive. IT department is professionally administered.
4. **Integration:** The restructuring demanded by the previous stage is completed in response to the pressure for better administration; information sys-

tems are guided to support needs of different managerial levels. Information has better quality as a direct result of centralization of the IT department under a single administrative structure and as a consequence of the use of databases management systems.

5. **Data Administration:** Is dominated by database technology. IT department recognizes that information is a very valuable resource that should be accessible by all users along the organization.
6. **Maturity:** Information is considered as patrimony of the organization. Users are active and responsible, and IT growth is planned and organized. Applications portfolio is complete and its structure reflects the organization and their information flow.

WEAVING THE STAGES

The introduction of the Web in companies has followed, in some way, a similar pattern established on Nolan's stage theory. As it is usually possible to take advantage of the structure and resources of preexisting IT applications, the first initial elementary steps are generally soon overcome. Web applications implementation usually begins when the company already can be classified in the integration stage of computer implementation (Anghern, 1997).

Seybold and Marshak (1998) establish that there are five stages for e-business initiatives: enterprise information (*brochureware*); customer support and interaction; electronic transactions support; customer's personalized interactions; and community promotion. Galliers and Sutherland (1994) defined six stages: *ad hocery*; starting the foundation; centralized dictatorship; democratic dialectic and cooperation; entrepreneurial opportunity; and integrated harmonious relationships. Anghern (1997) proposed the idea of four virtual spaces that companies would successively pass in the Internet: information, communication, distribution, and transaction. McKay, Marshal, and Prananto (2000) suggested a model named SOG-e (stages of growth for e-business), where the stages are defined as: no presence, static online presence; interactive online presence; Internet commerce; internal integration; and external integration.

This article proposes a classification that follows the same evolutionary classification, integrated with Nolan's stages.

Beginning the Weaving

The Internet's first use in companies is usually e-mail, a demand of personal and inter-organizational communication. Initially, own domains are not used, but access provider domains. However, as soon as own domain is registered, initiation in the Web begins, what usually happens timidly from isolated initiatives. Commonly it is made by IT professionals, since they know how to deal with the Web, and they can easily learn HTML.

Web pages are designed by professionals with technical, but no "artistic" skills. Thus, pages are usually visually poor, with graphic elements collected from other sites and with animation usually generating visual conflicts that are not always coherent when coupled with the presented content.

It is not just the form that doesn't adhere to company business. Also content often reflects the taste of the person that made the pages, with links to sites that are unrelated to company objectives and concerns.

Publication is usually made with several "under construction" areas awaiting information of other departments, which are never received, since executives of the company still do not clearly visualize or understand Internet potential (Evans & Wurster, 1999).

An example is the site of a small electronic manufacturer, which produces switching power supplies. This company sells as an OEM manufacturer and does not have final user customers. Many products are developed under customer specification and main clients are in the electronic products industry. This manufacturer has several product families, and its site (an own domain site) is a collection of static pages showing these products. There are no search engine or database queries to find specific characteristics. The page design can be considered adequate, with some appeal, although there are some "under construction" pages. The site is disconnected from the business: it is only a "show room". There are no private pages for specific customers and the only way to contact the company is by e-mail or phone.

Contamination

With the intensification of domestic and professional Internet use, companies and managers pay attention to the need for better site structure and for more accurate information. IT professionals are demanded for these requirements; however, they are not prepared to cope with these desires while simultaneously performing their habitual activities.

Each executive has his or her own idea of how to use the Internet. They start to understand the Web as a resource to generate financial incomes; although, it is not clear to them how it can be done. However, due to lack of coordination, no project really is able to achieve expressive results.

In order to implement the Web in a company, Internet training is provided to IT personnel; although, this, by itself, doesn't represent an effective site evolution for the lack of specific coordination. WYSIWYG software is adopted by IT professionals, which makes possible the visualization of pages independently of HTML knowledge.

One example is a nonprofit organization and partner of a university. It works in the industrial engineering field and has the following activities: specialization courses, consulting services, and quality certification. The site is a collection of several static pages with almost no user interaction. These pages work like an organization's services catalog, and it is hard to find what one is looking for. There is an electronic bulletin that is a Web copy of the paper bulletin published every three months. The only dynamic activity is student registration for the courses, but it is not connected with the internal ERP system.

Controlled Net

The recruiting of a Web master marks the beginning of a more professional approach of Net utilization. This professional is still subordinate to the IT department, but begins to work as an interface between the IT department and other business areas, particularly the marketing department, which identifies the Web as not just an information vehicle, but also a sales channel. By the first time, there is an effective interest with site's design. Sites development turned out to be considered a cost center and to be made by contracted companies as advertisement and/or design agencies. Meanwhile, the development of intranets is analyzed. It is still a turbulent stage, but objectives begin to be more clearly delineated. Some companies started to create their first visual identity and proceedings handbooks.

A possible example is the site of a producer of paper goods, as envelopes and letter papers. Its first site was developed in 1998 and just showed the address and an icon "talk with us". Its second generation was developed by an advertisement company, which defined a visual identity and created a user-friendly and visually elaborate portal providing news related to paper goods and also showing its products and specifications. Although the company sells only to re-sellers, the site is still not used as a B2B solution. However, the marketing department is pressuring the Web master to finish the development of one solution to sell using the Internet.

Net Business Integration

Company objectives are better defined. The site is developed and managed by professionals (Anghern, 1997). Many companies structured their own Internet department with Web designers, although developments are in agreement with advertisement agencies in order to establish a corporate communication identity. Coordination of this department is usually done by the marketing department. Flash technology use is intensified, with elaborate animations and programming resources integrated, in addition to dynamic pages, which makes interactive sessions possible. Depending on the company's activities, e-business sites are developed, such as virtual stores and Web EDI.

Intranets are more carefully developed, containing diversified information using resources of databases, such as procedures and manuals, product catalogs, documents relative to ISO 9000 series, as well as, according to company activity, some pages with internal news, like announcements of employee birthdays and trips or the arrival of new employees.

The next example is a large international power tools manufacturer, which makes products like chainsaws, line trimmers, and brush cutters. It has a well-structured site that is easy to navigate, with a full online catalog. There is general information like company history, customer services (as a safety manual), and other product orientation. A "tips and tricks" section has several interesting comments for final users like "tip of the month: the right way to plant fruit trees", showing that the company wants to "*capture*" clients' attention by publishing issues of interest to them, although there is no direct retail sale. It is possible to find dealers around the world. Some countries have a dealer of private communication for B2B (business to business) operation.

Web Data Administration

All Internet resources are already assimilated. Depending on the company activity, firms adopt B2C (business to consumer) and/or B2B (business to business).

In B2C, the most frequent utilization is virtual stores, which use complex procedures to guarantee that sales are securely made (Belanger, Janine, Hiller, & Smith, 2002). Stock availability and respective and continuous updating are included in these procedures; validation of credit cards; the "basket"; etc. Different technologies compete: internally developed, acquired, or obtained through alliances. Electronic auction is another form of B2C, where buyers can obtain desired products in specific sites. In B2B, there are several forms of relationships with members of a supply chain. Since the traditional EDI (electronic data interchange) based on Internet's resources and capillarity, until extranets, where business partners can be linked for orders emission; stocks inquiry; Web EDI; etc. There is an intensive dissemination of the use of data bases and XML language, what makes possible to share information and documents through the Web. Intranets are increasingly used in collaborative activities. Vertical portals, also known as e-hubs (Kaplan & Sawhney, 2000), allow wider relationships in the supply chain. They are vertical virtual markets, providing information and services for a specific industry (Christiaanse, Diepen, & Damsgaard, 2004).

Big B2C companies are representative examples. Many of them were born during the Internet boom. All these companies are working in a similar way. The graphical interface is absolutely friendly, and usually, it is very easy to find the desired product. The customer can choose a product from a catalog where he or she can also see the stock quantity, put it in a "basket" together with other products, and the system calculates the final price, including freight. The system is able to notify the customer when the goods will be delivered and provides the customer with step-by-step e-mail notifications of what is happening with his or her purchase order (like credit approved, stock picking, in dispatch, etc.). Some similar sites do it so automatically that there is no tneed to show options for asking questions. The system manages everything.

Web Maturity

The slogan of Web maturity could be "everything by Internet, from any place, at any moment." It is not just for allowing database access, or for purchasing orders emission, but for truly managing via the Web. Applications are totally based in application service provider (ASP), which are organizations that host those applications, making possible their use for several companies that pay a fee for the time used. They are accessed through the Internet, mainly by the use of VPN (virtual private network), a kind of virtual net. Applications are based on Web technology. XML language and .NET technology (from Microsoft) are widely used. This resource allows systems like ERP to be shared, not just inside of organizations, but also selectively, by partners of the value system.

An example is the site of one of the biggest hospitals in Brazil. The site was launched in 2004 with the goal of offering services to hospital users and providing support for its doctors. It is easy to navigate, with good flash animations. Using it as a service for hospital users, he or she can obtain exam results using a password defined when he or she goes to the laboratory. The doctor can read the results at any time from any place to provide more efficient care.

On the subject of preventive care, users can learn which steps to follow in order to be prepared for exams, like the length of a fasting period or the duration of a urine collection, for example. Regarding materning, there is e-learning for pregnant women in order to prepare them for childbirth. It is possible to access a Web TV with movies, which uses a laical language where the user can not only learn about diseases and their corresponding treatments, but also see interviews with leaders and other personalities. The intranet is a good complement for the site. From the intranet it is possible to control in real-time the beds on hospital rooms. It is possible to know if a bed is occupied or not and if the patient is being fed, etc. Also by intranet, doctors have access to a phone book and e-mail addresses of colleagues with information including whether he or she is working in the hospital and his or her position in the building.

All administrative controls are ERP based and on the intranet. Besides, they can be accessed by authorized people. Intranet is not only accessed on LAN, but also by hospital employees from any where using the Internet.

FUTURE TRENDS

Mobility is the key word. Wi-Fi solutions are disseminating, with hotspots covering wide areas and technological convergence of equipments that combine all kind of communication resources. They provide access to the Internet not only from any place, at any moment, but also by any kind of wired or wireless connections (Mennecke & Strader, 2003).

The growth of the Internet makes possible knowledge accumulation in an almost limitless way. No other media can do that. Thus, this will be the Web's greatest role: to serve as a constant and permanent knowledge accumulator.

Meanwhile, another important front for Internet expansion will be e-government, which encompasses income tax declaration, filling in documents, registration, online reverse auctions, among many other different and increasingly available applications. The Internet has enabled a more service-oriented approach to government activities. In addition, in the near future, other possibilities, like elections via the Web can even assist citizens in participating in political activities (Steyaert, 2004; Tapscott, 2001).

CONCLUSION

The Internet, according to Porter (2001), is the most important IT platform to emphasize a distinctive strategy. The different phases of its use in organizations can help one to understand how to use it successfully. However some authors, like Tapscott (2001), understand that the Internet revolutionized the way business is performed.

This article discussed of the idea of a stage model for Internet use.

Nolan's stage model faces some criticisms, like Smithson and Hirscheim (1998), which consider this model to be poorly action oriented and classify it as only a diagnosis tool. But in a turbulent environment like that of modern markets, an analytic tool that can quickly provide good insight into and understanding of a company's situation can be a powerful aid to correct both operations and strategy orientation. This is the potential of the application of the stage model in Web utilization.

The model proposed in this article should be further observed in future empirical studies, which would allow for its enhancement and refinement.

KEY TERMS

B2B (Business-to-Business): Business made electronically (mainly by Internet) between companies by the selling or purchasing of goods or services. It includes the data interchange.

B2C (Business-to-Consumer): Is the retail selling made via the Internet.

E-Business: "Electronic business", or a business made via the Internet, not only selling or buying, but also supporting customers and connecting the supply chain.

E-Commerce: "Electronic commerce" means selling and buying of products and services via the Internet.

EDI: "Electronic data interchange". A standard message layout used on computer-to-computer commercial data interchange. Traditional EDI uses an electronic method called VAN (value added network). However, it is increasingly adopting Internet protocol.

E-Hubs: Virtual markets among companies (B2B marketplaces or B2B information brokers).

Information Technology (IT): Is the comprehensive and diversified set of technologies for information processing, as software, hardware, and telecommunications.

Web EDI: Is the "electronic data interchange" made through Internet Web pages.

Web TV: Are movies, interviews, or shows transmitted via the Internet.

Exploiting Public Sector Information through Innovative E-Government Policies

Ioannis P. Chochliouros
Hellenic Telecommunications Organization S.A. (OTE), Greece

Anastasia S. Spiliopoulou-Chochliourou
Hellenic Telecommunications Organization S.A. (OTE), Greece

INTRODUCTION

The digital, knowledge-based economy (European Commission, 2003a) has a strong impact on the life of all citizens at the global level. Under suitable terms and/or appropriate conditions, it can be a powerful "engine" for growth, competitiveness, and jobs, while at the same time it improves living standards.

The multiplicity of innovative Information Society (Dutta, Paua, & Lanvin, 2004) tools has led to unprecedented possibilities to combine data taken from different and various sources into added-value products and services. To this perspective, public sector information can be an important "prime" material for relevant applications.

For the specific framework of the European Union (EU), the public sector information (European Commission, 1998) plays a very important role in its social and economic models by supporting high levels of welfare for citizens, ensuring socioeconomic cohesion, and sustaining the functioning of a competitive and fully liberalized market environment. In particular, the public sector engages in a wide range of activities, varying from education, healthcare, and social security, to protecting consumers and strengthening the environment. Consequently, financial and business information is collected by a number of ministries and other appropriate organizations.

Company registers, usually required by law in many Member States, are also maintained by the public sector. Legal information (in particular concerning legislation and jurisprudence) and administrative information constitute another example, while patent offices are usually public sector bodies. Scientific, technical, cultural, and medical information is extensively collected by public research institutions and public archives. Geographical information relevant to transport and tourism (e.g., maps, road traffic situation) is also available in corresponding public agencies. Furthermore, tourist information is gathered and published by public sector bodies at different levels of government.

Learning how to manage and to exploit all relevant information produced and stored could create a very high level of public value (and this is probably an unavoidable step towards a future user-centered government). Even greater potential benefits can result if governments, authorities, and/or organizations actively participate in the development of the knowledge-based society, in the true sense to create public-shared spaces for the creation and the delivery of various forms of "knowledge."

However, today there are still some "barriers" preventing the full "exploitation" of public sector information at the European level. These may originate from diversities either in language or in pricing issues, or in (administrative) rules and/or practices, such as differences in replying time, the refusal to transmit the information in digital format, the need to prove that the information is not limited by data-protection rules, and exclusive deals that already exist between public and private firms.

In fact, Europe's public sector (Cap Gemini Ernst & Young, 2004) is today at a crossroads, in front of numerous global challenging conditions, institutional change, and the profound impact of new technologies in a background which evolves very rapidly. Expectation is growing that, as it is a major economic performer for boosting growth and innovation, the public sector can (and will) play a strong role in realizing the Lisbon strategy (European Commission, 2000; European Council, 2003) for economic, social, and environmental renewal. It should be expected that the public sector would become more productive, cut the "red tape," eliminate queues, and offer services of improved quality.

Simultaneously, the European public sector will, over the next decade, undergo a number of transitions (such as increasing cultural and religious diversity, aging of the population, and changing living, working, and consumption patterns) that will require new services as well as innovative ways of delivering the existing ones. In particular, the public sector should "close" the demographic deficit, restore democratic ownership, and cope with demographic change (e.g., aging, immigration, etc.). Other perspectives may be relevant to safeguard liberty, justice, and security. The public administrations are now facing (with a medium- to long-term time horizon) very power-fully the challenge (DG Information Society of the European Commission, 2001) of improving the efficiency, productivity, and quality of their offerings, to respond to all the forthcoming needs and demands. This may result in new ways of delivering services to citizens and businesses while coping with various domains, especially if considering initiatives to extend the internal market and to deepen convergence in enlargement (OECD, 2003; IDA eGovernment Observatory, 2002; Chochliouros & Spiliopoulou-Chochliourou, 2003a). This option also implicates special perspectives such as identity management, advanced public electronic services, deployment of dynamic and personalized services, and exploitation of innovation in technology.

BACKGROUND

The initial concept of electronic government (e-government) took off a few years ago, mostly as the "*mirror image*" of electronic commerce (e-commerce) in the public sector. However, the e-government has now become an explicit component of public sector reform as a fundamental instrument to increase efficiency, strengthen competitiveness, and enhance modernization.

In particular, e-government can be now estimated (European Commission, 2003c) as: "…the use of information and communication technologies (ICTs) in public administrations combined with organizational change and new skills in order to improve public services and democratic processes and strengthen support to public policies."

Experiences and up-to-date practices have very clearly demonstrated that relevant activities can refer to a great diversity of functions (European Institute of Public Administration, 2003), including, *inter-alia*:

- Electronic public services (e-services) to end-users, either citizens or corporate businesses; these could include applications, facilities, and/or additional electronic features related to government *online* presence/access and the provision of *online* services, customs' services, value-added taxes, *online* job search, *online* requests for personal documents, *online* book search in public libraries, and so forth.
- Electronic procurement (e-procurement)—that is, the means for the realization of *online purchases*. The adoption of electronic public procurement systems is driven by the need to reduce costs and favor purchases in large volumes, thus limiting the number of contracts. Although such an option can be occasionally included in e-services (as a specific modular component), it may follow completely different implementation dynamics. In fact, it is currently promoted by higher-level administrations and typically requires considerable internal government reorganization. Early experiences seem to suggest extra benefits in terms of cost savings and improvement of transparency, however there are still strong "resistances" by local stakeholders, threatened by the concentration of purchase activities and other constituencies.
- Electronic democracy (e-democracy), in a way to support the genuine participation of citizens in politics. Although still in its "infancy" and at elementary levels (with some pioneer experiences especially in northern Europe), e-democracy formulates a very promising expectation for the future.

E-GOVERNMENT AS THE "VEHICLE" FOR EXPLOITING "PUBLIC VALUE"

In fact, e-government implicates the use of emerging technologies to transform public administrations and to improve radically the way they work with their customers, be they citizens, enterprises, or other administrations. The e-government is now a key vehicle for the implementation and achievement of "higher policy" objectives. It is unlikely that relevant objectives on the single market freedoms, industrial policy, liberalization and competition, sustainable development, and security across the EU can be achieved (Chochliouros & Spiliopoulou-Chochliourou, 2003a) unless such interoperable services are swiftly implemented.

This places e-government at the "core" of public management renovation and reform, where technology is used as a strategic tool to modernize structures, processes, the regulatory framework (Chochliouros & Spiliopoulou-Chochliourou, 2003b), human resources, and the culture of public administrations to provide better government and, ultimately, increased "public value."

The creation of public value is a broad term that includes a multiplicity of democratic, social, economic, environmental, and governance roles. Some quite indicative but concrete examples may refer to: (a) the provision of public administration and public services (such as health, education, and social care); (b) the development and the implementation of policies, accompanied by an appropriate regulatory framework to reflect real market needs; (c) the supervision and the management of public finances; (d) the guarantee of democratic political processes, gender equality, social inclusion, and personal security; and (e) the management of environmental sustainability and development.

The target for the provision of better government depends on a variety of factors including, but not limited to, existing and developing governmental structures and processes, cost benefits and reductions, effectiveness, improved quality of services, accountability, transparency and openness, and greater participative governance and adequate accessibility, especially to avoid "digital divide" events (Department of Economic and Social Affairs of the UN, 2003).

In particular, present challenges are focused on opportunities to design, apply, and exploit methods, means, and/or other "tools" essential for new public management activities, especially focusing on the centrality of users' needs. Core drivers of such a revolutionary process could be: (a) the need to improve efficiency, productivity, and quality of public services without increasing budgets; and (b) the need to satisfy citizens' expectations of new standards of service provision allowing flexibility, personalization, and full availability, as in the private sector.

It becomes evident that e-government can be a "catalyst" to realize a more efficient administration, transforming the "balance of power" between government levels (supranational, national, regional, local) and functions. So it improves the development and implementation of public policies and helps the public sector to cope with the conflicting demands of delivering more and better services with fewer resources. While technology cannot transform "bad" procedures into good "ones," e-government creates the *choice* for the public sector to do its tasks differently. Therefore, electronic government marks "the most dramatic shift in governance in generations and offers a fundamental restructuring of the way government operates and interacts with citizens" (Holmes, 2001).

OPTIONS FOR STRUCTURING THE NECESSARY UNDERLYING PREREQUISITES

All fundamental related activities are currently built on two main but interrelated developments. The first can be estimated as the business models adopted in the recent past by the (private) enterprise sector. These were largely concerned with obtaining competitive advantage by diverse activities such as continuous process improvement, a focus on core competencies, and the reorganization of internal processes. The public and their political representatives now expect public administration to be as efficient, fast, and effective in achieving its goal, as is the private enterprise sector.

The second domain of activities is related to the effective use (Wauters, 2003) of a wide range of information and communications technologies, of which the Internet is the most "visible." The combination of advanced ICTs in the support of new ways of working in public administration, together with the "enhanced" provision of information and interactive services, accessible over different "channels" and infrastructures, is the foundation of e-government. This vision is very exciting as it progresses beyond the "simplistic" image of communication technologies, considered as "tools" for an additional delivery channel of public services. On the contrary, it constitutes a new vision of the role of government, which exploits the potential of technical innovation, without falling in the trap of any particular technological determinism. Modernizing government through ICTs is not the only driver of change in the public administration. The whole socio-political system is shifting, to incorporate new and innovative options of the evolution performed. This "variable geometry of power" scenario lends credibility to the perspective of an increasingly networked government.

In essence, interoperability between infrastructures, facilities, applications, and equipment is a fundamental requirement (European Commission, 2003b), from both the economic and technical perspectives, for the development of efficient and effective services at both the pan-European and national levels (also including the regional and local ones). Interoperability is not simply a technical issue concerned with linking up various systems; it goes beyond, to include the sharing of information between networks and the reorganization of administrative processes to support the seamless delivery of e-government services. Such a framework, which can be defined as the "wider" set of policies, standards, and guidelines describing the way in which organizations have agreed, or should agree, to do business with each other, is to provide the specifications and the guiding principles for joining together the information systems of public administrations across the EU.

FUTURE TRENDS

Apart from intergovernmental relationships (also including the local, regional, national, and EU dimensions), all principal applications currently refer to government-to-citizens (G2C) and government-to-businesses (G2B) relationships. Citizens and enterprises can greatly benefit from a sophisticated provision of various forms of public sector information on Internet-based platforms and infrastructures.

Making public sector information online available for reuse (where allowed and always under the specific requirements imposed by a proper legal framework) enables businesses (also including small and medium-sized enterprises (SMEs)) to develop attractive and competitive offers. Meanwhile, a minimum "set" of common rules could take away investment failures and most part of any probable uncertainty, to enhance the offering of suitable products.

Current trends (IDA eGovernment Observatory, 2002) promote the need to incorporate, in the delivery chain, a growing number of "intermediaries," which will play an increasing role in the delivery of public services and will ensure openness and competitiveness. Services, however, should be addressed to the citizen-centric, especially in terms of availability, usability, flexibility, and pricing.

Citizens are becoming accustomed to ever-faster response times and ever-higher quality of products-services from the private sector (OECD, 2003). Consequently, they expect to have the same (or similar) levels of performance from the public administrations. Obscure procedures, long queues, having to re-enter information that is already held by the administration, and "one-size-fits-all" approaches are all practices that are increasingly criticized. In order to face the appearing challenges (Millard, Iversen, Kubicek, Westholm, & Cimander, 2004), public service provision should be expected to become more user friendly and personalized, adapted to the specific needs of the individuals. Moreover, it needs to be "inclusive," and all citizens have to be adequately served, independently of their skills and capabilities, income, or geographical location. The public sector cannot "choose" its clients, contrary to the private sector (nor can the public usually choose whether or not to be clients of the public sector).

The e-government evolution should also address the needs of enterprises for reducing cost transactions, supporting competition in a global economic environment, and increasing speed, simplicity, and scalability. Meanwhile, the promotion of fair-trading and appropriate pricing schemes in the market(s), in order to guarantee a minimum of certainty and transparency, will be a principal factor to forward an efficient penetration of e-government. In order to respond, *properly,* to the forthcoming challenges, the enterprise sector should, with appropriate support from the EU authorities, develop fully interoperable e-business solutions.

Interoperability, therefore, for both public and enterprise sectors, will be at the heart of all the suggested policies. This implicates combined considerations at various levels, such as: (a) the technical level, which is concerned with technical issues of linking "Internet-type" technologies and systems, the definition of "open" interfaces (with appropriate standards and specifications), and realizing communications; (b) the organizational level, which deals with modeling business processes, aligning information architectures to organizational goals, and helping business processes to cooperate, to extend their activities, and to include suppliers, (business) partners, and customers; and (c) the semantics level, which is concerned with ensuring that the precise meaning of exchanged information is understandable by any other relevant application; this also entails agreement on, for example, ways to discover, represent, and give context to information, and it will allow automated tools to share and process data, even when they have been designed independently.

Citizens and businesses expect authorities to become more accountable for the management of their financial contributions and taxes to the state. They also demand more transparency of decision making (especially in the fight against corruption and fraud) and democratic involvement in all phases of policy development. More specifically, through online forums, virtual discussion rooms, and electronic voting, citizens can be able to express their views, directly question the decision makers, and so contribute with an informed opinion to the democratic process.

This constitutes an improvement towards more transparent, accountable, and open public institutions.

To ensure creation, development, and implementation of appropriate e-government- based services (Millard, 2003), the latter should be accompanied by joint actions to build up experience and validate advanced solutions for profitable collaborations. This concerns common approaches to key aspects of seamless pan-European service provision such as accessibility, user identification, security, interoperability, also including data definitions and procedures. As far as appropriate, pan-European e-government services should be integrated and interactive.

CONCLUSION

Public sector information covers a great variety of activities, while its improved use could turn all relevant resources into a valuable asset for European citizens, businesses, and administrations alike. In particular, with the advent of the Internet, governments have started exploring how they can maximize the value of their information resources.

Consequently, numerous recent European initiatives have been focused on stimulating services, applications, and content that can create new markets, reduce costs, and eventually increase productivity throughout the economy. In such a complex environment, electronic government can be a significant factor, mainly to promote solutions for an effective exploitation of the disposed information. The expected development encompasses the provision of better public administration; more efficient, transparent, open, and participative governance; and the implementation of more democratic political processes.

E-government has emerged as a means for improving government, and ultimately, for increasing public value (Centeno, van Bavel, & Burgelman, 2004). However, clearer understanding on how, and in what areas, can efficiently contribute to maintain and strengthen good governance in the knowledge society. In particular, recent development is now entering a new phase, fully characterized by the "re-engineering" of governmental processes, at all possible levels of administration, for better treatment of information.

E-government should have a strategic focus: the complete achievement of the "Lisbon goals" for realizing an appropriate "electronic Europe" capable of sustainable economic growth, and ensuring that businesses and citizens derive the maximum benefit from any progress in ICTs (European Commission, 2000; European Council, 2003). This will also contribute to the reduction of barriers to the internal market for services and mobility, effective implementation of national policies, and broader regional or local development.

Moreover, e-government should be oriented to satisfy user needs in two parallel options: (a) for living, working, and doing business; and (b) as "users" of administrative services, as taxpayers, and as interactive participants in democracy.

Public administrations can provide major key contributions to improve Europe's competitiveness, growth, innovation, and employment rates, as well as social cohesion (European Commission, 2001b).

KEY TERMS

E-Democracy: The utilization of electronic communications technologies, such as the Internet, in enhancing democratic processes within a democratic republic or a representative democracy. It is a political development still in its infancy, as well as the subject of much debate and activity within government, civic-oriented groups, and societies around the world. E-democracy also includes within its scope electronic voting.

E-Government: The use of information and communication technologies in public administrations, combined with organizational change and new skills in order to improve public services and democratic processes, and strengthen support to public policies.

E-Procurement: The means for the realization of *online purchases*, by using appropriate electronic communications services and infrastructures.

Information and Communication Technology (ICT): A sector including a great variety of technologies such as desktop and laptop computers, software, peripherals, and connections to the Internet that are intended to fulfill information processing and communications functions.

Interoperability Framework: Not simply a purely technical issue concerned with linking up various systems, but the "wider" set of policies, measures, standards, practices, and guidelines describing the way in which various organizations have agreed, or should agree, to do business with each other.

Knowledge-Based Economy: A form of modern economy referring to a specific structural transformation, where the fast creation of new knowledge and the improvement of access to various knowledge bases increasingly constitute the main resource for greater efficiency, novelty, and competitiveness.

Public Value: Any form of value created by governments though the provision of services, the passing of laws and regulations, and other actions. It also involves all the short-term and long-term contributions made by public administrations to society and the economy. Furthermore, it includes efficiency gains by better internal performance and, most importantly, the multiplier social and economic effects such as: (1) social development and inclusion, (2) enabling companies to lower their administrative costs and become more competitive, and (3) strengthening innovation across the economy.

Failure of Furniture.com

INTRODUCTION

The growing U.S. furniture and home furnishing market is highly segmented (Bransten, 2000). Although many large manufactures and retailers have 100 years or longer history in this industry, none of them dominate the market.

In the e-commerce boom starting from mid 1990s, many companies began to use the Internet as a new channel selling furniture to customers. Among those new online furniture businesses, some were traditional furniture retailers setting up a Web site as an additional channel reaching customers, and others were pure-play e-tailers, owning only online presences but no physical stores.

This article traces the history of furniture.com, a once-famous pure-play retailer in the furniture retail industry, and analyzes the reasons of its failure theoretically. We believe that the narrative and the analysis will provide valuable insights for pure-play e-tailer managers from many aspects, including product selection, online and offline services, and management of relationships with suppliers, etc.

THE HISTORY OF FURNITURE.COM

A Start-Up Backed by High-Profile Financial Institutions

In June 1998, Steve Rothschild launched furnituresite.com. In November 1998, Andrew Brooks replaced Steve Rothschild as CEO and changed the name of the company to furniture.com in January 1999. Furniture.com funded $13 million in the first round of financing in June 1998 (Sandoval, 2000). In the following year, the company successfully carried out its second and third round of financing, which brought the total capital raised to more than $50 million (Cox, 1999B).

Products and Services

Furniture.com was a pure-play furniture e-tailer, owning only online store but no physical stores. According to SEC filing, furniture.com offered furnishings for every room, as well as outdoor furniture, mattresses and accessories. It offered products from over 200 manufacturers. Furniture.com had no inventory or warehouses and its products were delivered to customers directly from manufacturers.

Furniture.com was one of the leaders of online service revolution. It attempted to use Internet-related technologies to improve customers' online experiences. It provided an excellent cyber magazine about decorating that is comparable with print offerings such as Home. Furniture.com Web site also offered customers with personalized newsletters and personalized Web pages. Another feature on furniture.com was instant messenger. When customers shopping online had any questions about furniture or decoration, they could reach an online expert design consultant and ask specific questions (Mullaney 1999, 2001). The Web site enabled customers to create a drawing of a room and then drop furniture into it to visualize how well the furniture will work. Offline, furniture.com provided free delivery and set-up through a Red-Carpet Program.

However, some of these online features were not implemented as promised. Customers complained that the consultants behind instant messenger often could not give feedback instantly, and sometimes gave answers that seemed like they did not read and understand the questions entirely, likely due to dealing with too many customers simultaneously (Mullaney, 1999). As far as offline operations went, furniture.com got many complaints about late delivery and missing merchandise. In April 2000, it canceled its free shipping and charged a flat $95 shipping fee for all purchases (Iovine, 2000).

National Brand Name Campaign

In spring 1999, furniture.com launched a $5 million-plus national brand name advertising campaign inviting customers "to love their rooms" with help from "the best way to shop for furniture" (Cox, 1999A). The campaign consisted of three ads airing on radio stations and in daily newspapers in over a dozen of the largest metro markets in the U.S. (Cox, 1999A). The ad launch was the first element in a major brand building program, which furniture.com planned to invest "tens of millions of dollars" in offline and online adverting, strategic partnership, and other marketing initiatives (Cox, 1999A).

In the national brand name building campaign, furniture.com signed marketing alliances with AOL, Yahoo!, GO Network, and affiliated marketer Be Free Inc (Cox, 1999D). In July 1999, it signed advertising agreements with Lycos and MSN, in which it secured presence on the MSN Shopping site and placed banner advertisements on MSN Home Advisor and Women Central. It gained presence in the Real Estate, Home, Business, and Arts and Entertainment areas on Lycos. Under the agreement, furniture.com also gained a significant presence on HotBot, as well as other Tripod communities (Cox, 1999E).

In August 1999, furniture.com appointed the New York office of British advertising agency Bartle Bogle Hegarty to handle its U.S. brand building advertising account. This time the spending "easily eclipsed" the $5 million radio and print campaign it ran that spring (Cox, 1999C). In October 1999, furniture.com introduced George the cat, "the world's toughest furniture critic" as the icon of a $20 million integrated national branding campaign (Cox, 1999F). Furniture.com's advertisements aired on NBC, CBS, and ABC as well as HGTV, E! Entertainment Television, and other cable stations. In print, the ads appeared in shelter, lifestyle, and weekly magazines; and in national and general market newspapers (Cox, 1999F).

The Failure of IPO and the Bankruptcy of Furniture.com

In January 2000, furniture.com filed with Securities and Exchange Commission for an initial public offering (IPO). The offering was initially led by Goldman, Sach & Co. Although furniture.com had a loss of $43.7 million on sales; $10.9 million in 1999, the company expected to raise a maximum of $50 million according to its SEC filing.

In March 2000, Goldman Sachs dropped out of the IPO. Due to the unfavorable market situation, furniture.com withdrew its planned IPO in June. Three days later after the withdrawal, furniture.com slashed its work force by 41%. A spokesman said 80 employees lost their jobs and the layoffs were "part of an overall program to reduce costs and accelerate furniture.com to profitability" (Enos, 2000).

After it canceled the original planned IPO, furniture.com turned to a new round of private financing and got $27 million from CMGI. In CNET news in July 2000 (Sandoval, 2000), a former employee in furniture.com described the situation at that time: "In a desperate attempt to impress potential investors, the e-tail company staged an elaborate show in May for two Idealab executives taking a tour of its headquarter in Framingham, Mass. Accountants, human resources workers, and engineers were ordered to sit in the company's call center and "look busy" helping imaginary customers while speaking into dead phone lines." Such theatrics paid off temporarily. A month later, furniture.com managed to stave off bankruptcy by the narrowest of margins after receiving $27 million from CMGI, Bessemer Venture Partners, and other investment companies (Sandoval, 2000).

Despite the success of private financing, the company ceased operations and entered Chapter 11 bankruptcy because of lack of funding and a harsh market only three months later in November 2000 (Enos, 2000).

The Businesses of Other Furniture E-Tailers

The collapse of furniture.com was not solitary. Its other two strongest competitors HomePortfolio.com and Living.com shut down before furniture.com did so.

In an article in Home Office Computing in March 2001 (Syarto, 2001), five online furniture Web sites were recommended as stable furniture sites. Three of them were running on the bricks-and-clicks model. Those surviving pure-play furniture e-tailers are mentioned as having a "well thought-out customer service model." While most pure-play furniture e-tailers dropped out, traditional furniture retailers began to take a phased approach to the Internet. They first provided product information and gathered customer data, and later began to sell products online. One of the successful cases has been Ethan Allen.

Failures of Furniture.com in the Press

The failure of furniture.com received a lot of attention in the press. Some articles were about complaints from furnitures.com customers. The customers complained that design consultants supporting the Web site could not answer messages as quickly as they promised. More importantly, customers experienced painful problems such as late delivery and missing parts when making purchases from furniture.com (Mullaney, 2001). From the industry perspective, some commentators felt that furniture and home furnishing e-tailer chose wrong items to sell online since furniture purchase is infrequent and high-priced, and most furniture is too big to be delivered through UPS. Moreover, a Web site cannot be touchy-feely and so customers cannot bounce on a mattress, for instance, when they make a purchase decision. Weak back-end office and a flawed business model are also causes for the failures. Another reason mentioned was too much spending on marketing and information infrastructure (Sandoval, 2000).

Rebirth of Furniture.com

At the time this article is written, five years have passed since the bankruptcy of furniture.com. During this period, furniture.com has been reincarnated and back to business. A group of former employees bought the domain name in October, 2001 (Sandoval, 2002). Carl Prindle, a senior vice president for the former furniture.com, assumed the president of the new company (Cox, 2000G). Furniture.com was re-launched in April, 2002 with a new business model (Regan, 2002). The company planned to form alliances with experienced furniture stores and its first two partners were Seaman's Furniture and Levitz Home Furnishings, two of the largest furniture retailers in U.S. The new furniture.com attempted to take advantage of their partners' marketing support, production, and distribution capabilities. The company also turned to click-and-mortar from pure-play business model. Customers of the new site can enter their zip code and then only products available in the near area will be shown on the Web site, ensuring fast furniture delivery. The descriptions and analysis in this article are restricted to the furniture.com that went bankruptcy in 2000.

THEORETICAL ANALYSIS OF FAILURE OF FURNITURE.COM

First of all, furniture.com failed because it entered an unattractive industry. The $60 billion-a-year U.S. furniture retailer industry is fragmented and difficult to manage (Bransten, 2000). Michael Porter provided a five forces framework that can be used to analyze an industry's relative attractiveness from five different dimensions, including the bargaining power of customers, the bargaining power of suppliers, the potential new entrants, the substitute products or services, and the intra-industry rivalry (Porter, 1980). Analyzing the pure-play retailer furniture industry based on the five forces model, we find that it is not an attractive industry (see Figure 1, Porter's Five Forces Model for furniture.com). First, the bargaining power of customers is high. Most people buy furniture infrequently and they have many choices. Second, the bargaining power of suppliers is high. Most furniture manufacturers have their own distribution systems in place and do not have the desire to incorporate new online e-tailers into their established distribution chain. Third, although there are no substitute products for furniture from the product stand point, there are substitute services that allow customers to shop for furniture in different ways. If customers are not happy with pure-play furniture e-tailers, they can easily turn to traditional furniture stores or click-and-mortar furniture retailers. Fourth, the entry barrier is low and the potential new entrants are numerous. At the time of e-commerce boom, both traditional and new start-up e-commerce furniture retailers were trying to enter the online furniture market. Fifth, the intra-industry rivalry is severe both in terms of the online furniture retailer industry or the general furniture industry. During the time that furniture.com was in business, there were several other high-profile furniture e-tailers running with the same business model, including living.com and HomePortfolio.com. These two companies also filed for bankruptcy in late 2000 (Enos, 2000). Even some established traditional furniture retailers had difficult time. Bransten (2000) reported, "Heilig-Meyers Co., a big furniture retailer, filed for bankruptcy-court protection from creditors in August 2000. Restoration Hardware, Inc. a home furnishings chain based in Corte Madera, Calif., slumped in September 2000."

Figure 1. Porter's "Five Forces Model" for funiture.com

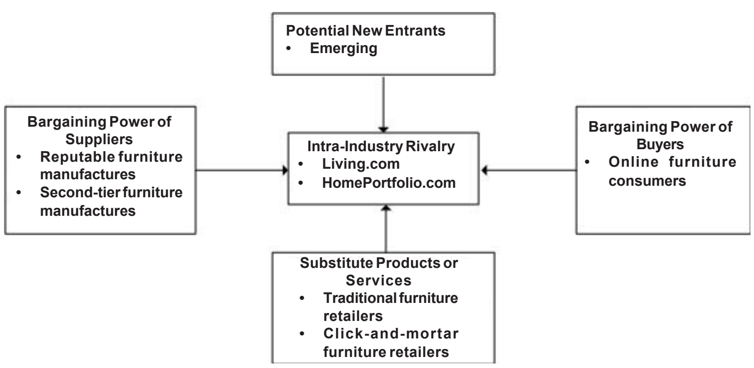

Figure 2. Direct-to-customer model—Furniture.com (Adapted from Perter Weill and Michael R. Vitale, Place to Space, Migrating to Ebusiness Models. Boston: Harvard Business School Press, p. 109, 2001.)

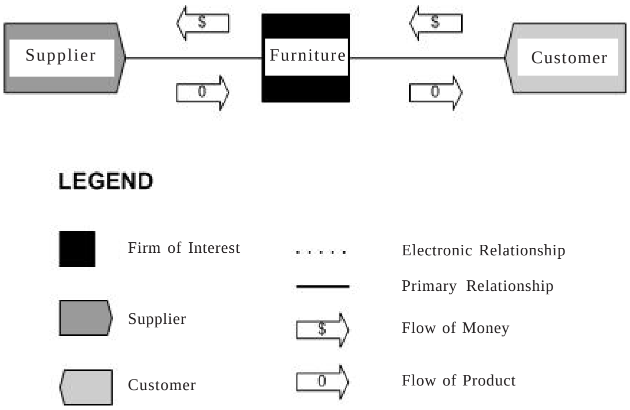

Second, furniture.com failed because it did not succeed in teaming up with reputable furniture manufactures. Afuah and Tucci (2001) proposed a framework for strategies of building business models for e-commerce. According to their framework, when the technology for running business is imitable and the complementary assets are held tightly and important, the suitable strategy is "team up." In the case of furniture.com, the technology to build a Web site selling furniture is highly imitable, evidenced by the large number of emerging furniture e-tailers during the 1999-2000 period. The complementary assets, such as brand name, alliances with good suppliers, and excellent customer services, were critical to the success of business and difficult to acquire. Therefore, forming a solid alliance with reputable furniture manufacturers possessing complementary assets is the appropriate business strategy.

What was troublesome, however, was that reputable traditional furniture manufacturers were not only pure-play e-tailers' potential upstream suppliers, but some of them were also e-tailers' direct competitors. Meanwhile, the traditional retailers in the furniture industry restricted their manufacturers from teaming up with pure-play e-tailers. For example, Iovine (2000) reported, "Stanley, a leading manufacturer, agreed to put its furniture on living.com but pulled it off less than two weeks later after complaints from retailers who felt they were being betrayed. They said that they had to invest in floor samples and advertising, then watch while customers stopped by, kicked the tires, and went and ordered the items on the Web."

The third reason causing furniture.com's failure is that it did not focus on building good back-end office and high-quality customer services. According to the categorization of e-commerce business models by Weill and Vitale (2001), furniture.com was running on "direct to customer" model. One of the core competencies of this business model is managing and integrating online and offline business processes to assure customer value because customer of direct-to-customer firms want fast service and instant gratification (Weill & Vitale 2001). Focusing and spending too much on marketing campaign, furniture.com had poor performance on customer services. It was a good idea to set up instant messenger and make design consultants available online to customers, but the results of implementation were not satisfying. Customers often waited for 15 minutes or more to get an answer to an "instant message" (Mullaney, 1999). Late delivery, missing shipments, damaged merchandise, and botched assembly efforts happened frequently offline (Sandoval, 2000).

The fourth reason why furniture.com failed is that it overspent on brand name building. From resource-based view of the firm, resources that can contribute to creating and sustaining competitive advantages must have three characteristics: (1) the resource is heterogeneously distributed among firms, (2) imperfectly mobile, and (3) hard to be imitated, acquired, or stolen (Mata & Fuerst, 1995). Brand name has the three above characteristics and therefore is a valuable asset for pure-play e-tailers to create and sustain the competitive advantage. However, brand name should be gained at a reasonable cost. According to Securities and Exchange Commission documents, furniture.com pulled in revenues of \$10.9 million in 1999 but lost \$46 million. One possible reason is that it spent \$33.9 million on marketing. This number was triple its sales and almost triple what it spent on product development and general administrative costs combined. Advertisement spending should generally be no greater that 20% of sales according to expert opinion (Kemp, 2000).

PRACTICAL IMPLICATIONS FOR MANAGERS OF E-TAILERS

The experiences of furniture.com are a good lesson for e-tailers, especially pure play e-tailers.

First, choosing the right items to sell plays an important role in online retail industry. A big difference exists between a \$50 book and \$1500 furniture. An in-depth survey on the market and the consumer behaviors should be conducted before making decisions on the choice of products. Furniture may not always be suitable for selling online for several obvious reasons. A Web site is not a good medium for providing customers with a touchy-feely experience. People hesitate to purchase high-priced items without seeing them beforehand. In addition, most furniture is so large that they cannot easily be delivered via UPS or other shipment carriers, leaving delivery a problem to be solved by the e-tailer itself (Sandoval, 2000).

CarMax and others have shown that high ticket items can be marketed on the Web, but it is equally true that physical sites help to leverage the Web for this firm. Furniture.com had none of these advantages.

Second, e-tailer managers need to select the appropriate schematics to evaluate the success of their business. In the years 1999 and 2000, most of the e-tailers evaluated their business success with the number of visitors of the Web site. For example, it was reported that 772,000 unique visitors stopped by furniture.com in September 1999 and this was considered a sign of success of the business. However, it was unknown how many visitors made a purchase and how much they bought. Using "eyeball" tallies to evaluate or predict business success is not reliable. Other factors to appraise business are needed. Good sets of such measures are profitability, profitability predictor, and component attributes (Afuah & Tucci, 2001).

Third, acquiring brand name awareness and other complementary assets should be conducted at a reasonable cost. Furniture.com and its competitor living.com both spent huge amounts of money on marketing campaigns to acquire customers and build their brand names. In August 1999, furniture.com named an advertising agency to handle its U.S. brand-building advertising account and while spending specifics were not disclosed, the retailer said it will "easily eclipse" a $5 million radio and print campaign it ran in the spring (Cox, 1999C). At the end of 1999, furniture.com planned to increase ad spending in 2000, though at that time it only had $31.4 million in cash on hand (Kemp, 2000).

The fourth lesson for e-tailer managers is that excellent services and good back-end offices are still critical success factors in the retail industry, and it is no exception for online retailers. A killer Web site is not the sole factor leading to success. Providing products and services in high quality and effectively managing distribution are also important.

KEY TERMS

Click-and-Mortar: An e-commerce company that has both online presence and physical store.

Direct-to-Customer: An e-commerce business model that connects manufacturers with customers directly by bypassing intermediaries with Internet-related technology.

E-Tailer: An online retail store.

Five Forces Model: A theoretical framework proposed by Michael Porter that can be used to analyze the relative attractiveness of an industry from five different dimensions.

Instant Messenger: An information technology that enable people to send real-time text messages.

Online Services: Services that are provided online, such as personalized newsletter, instant messenger, etc.

Pure-Play: An e-commerce company that only has online presence but no physical store.

Category: Applications of E-Technologies

Forecasting the Stock Market with ANNs and Autonomous Agents

Cristiano Leite Castro
University of Belo Horizonte, Brazil

Antônio Pádua Braga
Federal University of Minas Gerais, Brazil

INTRODUCTION AND BACKGROUND OF ORGANIZATION

Investment strategies usually aim at achieving maximum profitability what, according to current management theory (Refenes, Burgess, & Bentz, 1997), can be obtained by the construction of well balanced investment portfolios that seek to maximum return and minimum risks.

In order to provide users with information to plan a good investment portfolio, we present an e-commerce Web site solution that enables users to estimate in advance investments return and risks. The application, which is based on computational intelligence techniques, aims at forecasting and divulging the share prices of the main companies listed in the stock market.

Artificial neural networks (ANNs) (Haykin, 1999) that have been used successfully in many other financial time series applications (Braga, Carvalho, Lurdemir, Almeida, & Lacerda, 2002; Refenes, et al., 1997; Zhang, 2003) were used as the main forecasting engine of the system. Autonomous agents (Paolucci, Sycara, & Kawamura, 2003; Russel & Norvig, 1995) are responsible for collecting, on a daily basis, information regarding sale and purchase of shares. The information collected is then used by the ANN to forecast future stock market trends and closing values. The Web site offers free of charge services, such as access to forecasting charts, simulation of investments and general guidelines for buying and selling shares.

DESCRIPTION OF E-COMMERCE, E-GOVERNMENT, AND/OR MOBILE COMMERCE

The application consists of an intelligent system capable of anticipating share prices of the main companies listed in the stock market. This task entails daily collection of market information for calculation time series future values. The data collected is used as exogenous variables of the neural model.

Autonomous agents are responsible for collecting data, divulging forecast indexes on the Web site and generating dynamic Web pages that interact with the data repository. Since they are activated daily, the agents behave as an autonomous intelligent system capable of operating without the intervention of the user or programmer. The *Sections* that follow describe the main techniques that form the structure of the e-commerce application: Artificial Neural Networks and Autonomous Agents.

Artificial Neural Networks

Artificial neural networks (ANNs) (Bishop, 1995; Haykin, 1999) have been widely used to forecast financial time series in the last few years (Berardi & Zhang, 2003; Cao & Tay, 2003; Zhang, 2003). Characteristics inherent to neural models such as learning and generalization based on a set of data and universality in the approximation of linear and non-linear multi-variable continuous functions (Cybenko, 1988) make ANNs a very attractive tool for modeling and forecasting non-stationary time series, such as stock market values.

The forecasting models were based on multi layer perceptron (MLP) feed-forward networks (Haykin, 1999) that consist of a set of sensorial input units, one or two hidden (intermediate) layers and an output layer of computational elements (neurons). The entry signal propagates from the inputs to the outputs through each network layer. Figure 1 illustrates a MLP with two hidden layers.

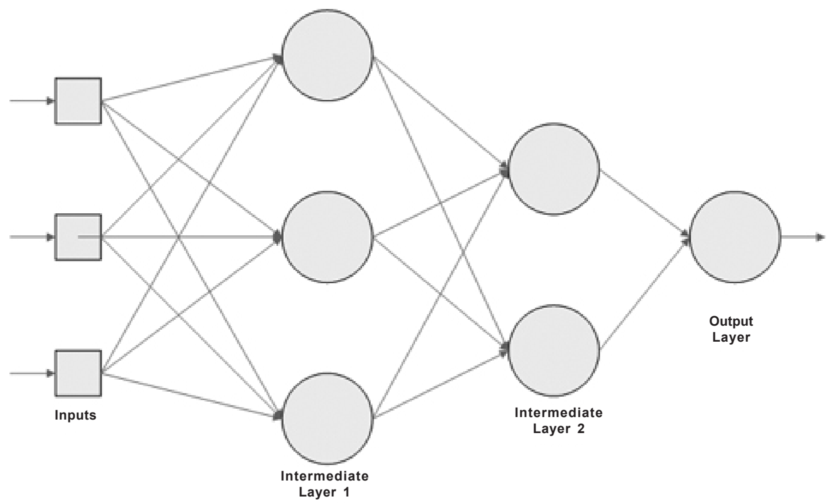
In forecasting financial time series, the inputs of the MLP network are the independent or exogenous variables. The functional relationship estimated by an MLP network can be defined by the *equation* (Zhang, Patuwo, & Hu, 1998):

$$y = f(x_1, x_2, ..., x_p),$$

where $x_1, x_2, ..., x_p$ are the independent variables p and y is the dependent variable. In this sense, this feed-forward neural model is functionally equivalent to a nonlinear regression model.

F

Figure 1. Typical MLP network with two hidden layers



Usually, in time series forecasting models, the inputs correspond to the exogenous variables delayed in time and the output to the future value predicted. This input-output functional mapping implemented by the neural network can be described by the *equation* (Zhang et al., 1998):

$$yt_1 = f(x_{1t}, x_{1t-1}, \ldots, x_{1t-\mathrm{m}}, x_{2t}, x_{2t-1}, \ldots, x_{2t-n}, \ldots y_t, y_{t-1}, \ldots, y_{t-p})$$

where the indexes *t, t-1, ..., t–p* represent the delays of time in relation to *t*; x_1 and x_2 are exogenous variables. Therefore, the MLP network can be seen as a nonlinear regression model for time series forecasting (Brockwell & Davis, 1996). The neural models developed use past values of the series as well as explanatory exogenous variables collected from Internet sites in order to predict future values.

The training process of an MLP network consists of defining the adequate values of the synaptic weights *w* and bias *b* present in the acyclic arcs that provide the links between the units (sensorial or computational) of the adjacent layers (Haykin, 1999). The knowledge acquired by the network during training is stored in these elements. Training of MLPs is supervised (Haykin, 1999) and each desired response (target) for each input pattern (example) is available in the training data. A training algorithm is used to search the values of the weights *w* and bias *b*, by minimizing an error measure such as the sum of square errors (SSE) or the sum of mean square errors (MSE) (Zhang et al., 1998). As a result, the training problem of an MLP network can be seen as a problem of non-linear minimization of a cost function (Bishop, 1995). Typically, an objective function (SSE) to be minimized during the training process is described by the equation:

$$E = \frac{1}{2}\sum_{i=1}^{N}\left(y_i - a_i\right)^2,$$

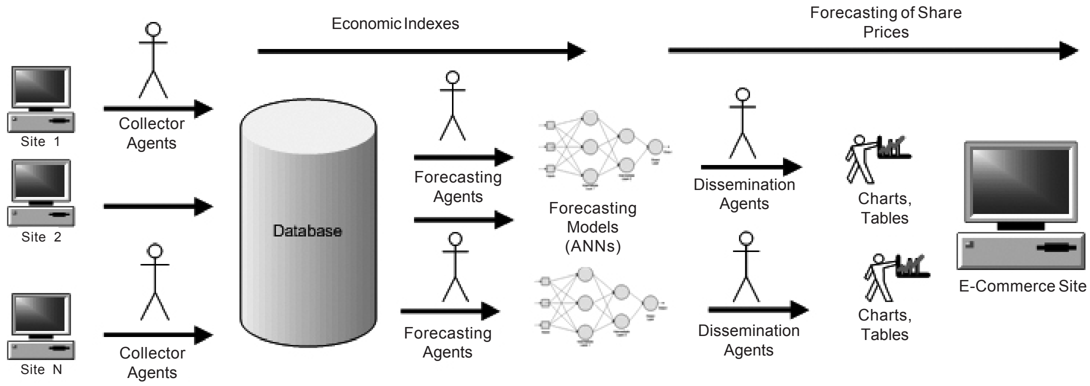
where a_i is the current output of the network, y_i is the desired output and N corresponds to the number of samples in the training set. There are a number of algorithms based on optimization methods for training MLPs, such as, for example, the Backpropagation algorithm (Rumelhart, Hinton, & Willians, 1986), the Levenberg Marquardt algorithm (Hagan & Menhaj, 1994), the GRG2 algorithm (Lasdon & Waren, 1986) and the MOBJ algorithm (Teixeira, Braga, Takahashi, & Saldanha, 1999).

Autonomous Agents

According to Russel and Norvig (1995) "an agent is anything that can be viewed as perceiving its environment through sensors and acting upon that environment through actuators" (p. 32). An autonomous agent is a software component capable of working for the performance of tasks to the benefit of its users (Paolucci et al., 2003).

The ideal architecture of an agent will directly depend on the type of task it performs and on the environment it is in (Nilsson, 1998). The autonomous agents forming the intelligent system can be classified as information or Internet agents introduced following a demand for tools capable of helping managing the boom of information on the Internet. They manage and collect information from a wide variety of sources. They are programs capable of retrieving information from remote Web sites by means of Internet protocols (Paolucci et al., 2003), storing it in a data

Figure 2. Detailed structure of the intelligent system



repository and using it for executing specific tasks. The following Section offers a detailed description of how the e-commerce solution proposed by our organization works.

How the E-Commerce Web Site Works

Figure 2 presents a schematic overview of the intelligent system illustrating the activities of autonomous agents.

The collector agents are responsible for collecting the information from the Web and for its storage in a database, thus putting together a repository of the time series. This is carried out by monitoring economic Web sites with the aim of collecting economic indexes. The function of the agents that retrieve information is to navigate the Internet searching for pages and extract the desired information from them.

Based on the data stored in the repository of the time series, the forecasting agents are responsible for pre-processing the data so that they can be used in the ANN forecasting models. The agents provide each forecasting neural model with the required input variables in order to predict future values. Finally, the predicted values are also stored in the data repository.

In the last stage, dissemination agents generate dynamic pages from the information stored in the database. These agents are activated upon the action of the forecasting agents.

The pages generated by the dissemination agents provide the user with a forecast of the share prices of the main companies listed in the stock market, in the form of charts and tables. Apart from that, they divulge the variation trends of the quote in relation to previous values.

The agents are capable of calculating the percentile error of the forecasting and to generate illustrative forecasting charts containing real and predicted values. The agents also generate a table comparing the values along with the percentile of errors in the form of a histogram. All this guarantees that the user has a means to evaluate the reliability of the forecasting yielded by the intelligent system.

Each of the stages described previously are under the responsibility of specialized agents that interact with the forecasting models. These agents work independently, that is, their tasks are performed without the intervention of the user or the programmer.

IMPACT OF E-COMMERCE IN THE ORGANIZATION

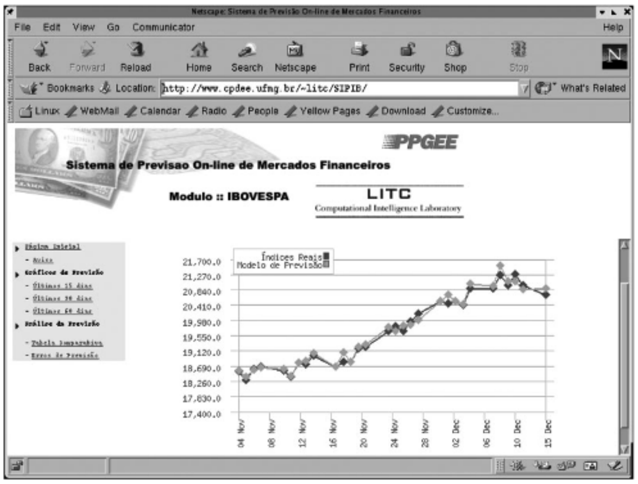
The use of computational intelligence (artificial neural networks and autonomous agents) tools in the development of the e-commerce application led to the construction of a Web site that offers its users a wide range of free-of-charge services:

1. Visual access to dynamic charts and tables containing the predicted values of the share prices.
2. Simulation of investments by means of the construction of a virtual portfolio.
3. Help in making decisions when trading with shares.
4. Statistical analysis of system performance by means of reliability tests, tables and histograms showing the results.
5. Following the news and values of the main economic indicators.
6. Following stock market trends.

Figure 3 illustrates the dynamic chart comparing the forecast values and the real values produced by the Web site.

The inclusion of the intelligent system to the organization's Web site is a differential in itself. More than just an informative Web site, the application devel-

Figure 3. Interface of the Web site with forecasting chart



oped makes it possible for advanced estimates of share prices to be made. In accordance with current theories for planning investment portfolios, the Web site offers support to the planning of high-profit and low-risk investments.

The reliability test offered on the Web site guarantees its trustworthiness, which makes it a reference for banking institutions, investors, economists and financial advisors.

CONCLUSION

The article described an e-commerce application that makes use of an intelligent system capable of forecasting and divulging the quote of the main companies listed in the stock market.

The structure of the intelligent system comprises the interaction between the Autonomous Agents and forecasting models based on artificial neural networks (ANNs). This Web site owes its success to the wide range of resources offered by this intelligent system.

The application described demonstrated that companies can use computational intelligence techniques to offer e-commerce solutions, while making their sites even more attractive to their users with the expansion of services offered.

KEY TERMS

Artificial Neural Networks (ANNs): Parallel distributed processor formed by single processing units that has a natural capacity of storing experimental knowledge and to make it available for use. Artificial neural networks are designed to model complex problems such as time series forecasting, pattern recognition, etc.

Autonomous Agents: Software components capable of working for the performance of tasks to the benefit of its users. An agent is anything that can be viewed as perceiving its environment through sensors and acting upon that environment through actuators.

Forecasting Models: Computational and/or mathematical models that simulate time series behavior with the purpose of forecasting their future values.

Information Agents: Programs capable of retrieving information from remote Web sites by means of Internet protocols, storing it in a data repository and using it for executing specific tasks.

Investment Portfolio: Set of investments (sale and purchase of shares) in a determined period of time. The portfolio keeps a history of operations in the stock market. The construction of an optimal portfolio requires a priori estimates of asset returns and risk.

Multi-Layer Perceptron Feed-Forward Networks: Type of neural networks topology. Set of sensorial input units, one or more hidden (intermediate) layers and an output layer of computational elements (neurons). The entry signal propagates from the inputs to the outputs through each network layer.

Supervised Training: Learning process of artificial neural networks where each desired response (target) for each input pattern (example) is available in the training data.

Training Algorithm: Learning process of artificial neural networks whose function consists on defining the adequate values of the synaptic weights w and bias b, by minimizing an error measure such as the sum of square errors (SSE) or the sum of mean square errors (MSE).

Gambling Over the Internet

Clare Brindley
University of Central Lancashire, UK

INTRODUCTION

Gambling providers have begun to exploit the Internet as a vehicle for marketing their products and services. This article discusses the increase in *Internet gambling* and how the gambling industry has exploited technology to make market gains. Gambling on the Internet is a billion-dollar industry, with online lotteries and pools generating more than half of the total market value (i.e., $1.66 billion). There is a plethora of gambling opportunities, such as casino games and online games, and horse and event betting, although inevitably some of the rules of the games have had to be adapted to operate via the new medium. The home-based nature of *interactive* gambling means that consumers are no longer restricted by opening hours, social status, or membership requirements, and are able to choose from a wide selection of gambling sites. The nature of the response by gambling organizations to the changes in consumer behavior has depended on the willingness of providers to become online providers, domestic and/or international *legislation*, and of course Internet service provision, all of which will differ depending on the gambling products offered.

BACKGROUND

Recently, van't Veer (1998, p. 4) provided a definition of interactive gaming that encapsulates its attributes:

…the player can participate at any time and at any pace without the intervention of a third party, not completely free of charge, which are provided with the aid of information technology and means of telecommunication beyond the scope of the traditional supply structure and which give the player, at the discretion of the provider, the opportunity to perform all actions necessary for participation such that he [or she] is able to win prizes.

A recent report suggests a surge in online gambling, mostly in the form of electronic sales of lottery and pool tickets. Forrester Research (as cited in Wall, 2000) estimated that more than 1 million Internet users visit gambling sites. Datamonitor estimates that Europeans gamble $55 million a year via the Internet (http://www.e-web.com). In global terms, Balestra (2004) estimated that by the end of 2004, the Internet gambling industry would be a $7.4 billion industry.

Cyber gambling is possible via two technologies: the Internet and digital television. Interactive services are possible because of digital television's utilization of a new bandwidth that allows interactive services. It is anticipated that digital TV will create between 120 and 200 new channels, allowing target marketing to become more directed. Further developments in the use of *WAP* (wireless application protocol) technology create opportunities for gambling via the telephone. Indeed, Eurobet in the Summer of 2000 gave away WAP phones on its UK Web site (http://www.eurobet.co.uk) after identifying a synergy between betting and WAP (Revolution, 2000). Such technological innovations will increase the penetration of access to the Internet, and thus the development of gambling sites becomes a potentially more lucrative opportunity. As the National Gambling Impact Study Commission (1999, p. 5.3) reported, "the rapid increase in sites is likely the result of the financial success of existing operations." Technological capability coupled with credible gambling sites appearing in more regulated environments will rapidly increase the proportion of gambling transacted over the Internet (Michener, Gregory, & Swatman, 1999).

Interactive Gaming and Communications (USA) was the first company to accept a wager over the Net on May 11, 1995, with 18 different casino games, online access to the National Indian Lottery, and plans to launch an Internet sports book. The Yahoo! search engine in January 2005 revealed 100 casino categories, containing 9.46 million casino sites (http://yahoo.com). The Internet Gaming Commission identifies 850 Internet gaming establishments operating in more than 30 countries, 125 of which are not licensed (http://www.internet.commission.com). Rolling Good Times (http://www.rgtonline.com) offers links to approximately 1,000 Internet sites that offer some sort of betting. These varying estimates of the number of online gambling sites supports the National Gambling Impact Study Commission (1999) finding that the lack of a central register of Internet gambling sites makes calculating the number of sites virtually impossible.

Gambling via interactive technology is underpinned by two recent changes in consumer behavior. First, access to and familiarity with interactive technology is becoming increasingly commonplace, for example, through the use of ATMs (automated teller machines) and telephone bank transactions, and the growth of Internet service providers (ISPs). The National Gambling Impact Study Commission (1999) argued that the increasing use of the Internet and growing consumer confidence in conducting online financial transactions have led to a greater number of people willing to engage in Internet gambling.

THE IMPACT OF INTERACTIVE GAMBLING

The ease of use of the technology and pathways through the sites are important. Providers need to recognize that an extensive effort on education is likely to be required. The National Gambling Impact Study Commission (1999, p. 53) found that "the design and pace of the online games have advanced dramatically over the past few years, as has the ease of use. Gambling sites now feature interactive games…and walk customers through a virtual tour of the site…" This finding supports the view that the effective delivery of the service will depend on participants acquiring and displaying appropriate skills (Mudie & Cottam, 1993). For example, to enhance the adoption of ATMs, "it was necessary to familiarize customers with the new technology properly, as well as aid them in overcoming the depersonalization of a formerly personal service" (Grove, Fisk, & Bitner as cited in Gabbott & Hogg, 1997, p. 139). This lack of personal contact may affect players' confidence and trust in the service. Hence, the Interactive Entertainment Group's online casino site (http://www.geishalounge.com) uses a geisha as a guide through the site to mirror the service aspects of a typical casino. The organization argues that a high level of customer service supports the customers' need for instant feedback, given the adrenaline buzz of gambling ("Casino Puts Focus on Sophistication," 1999).

The marketing of interactive gambling appears to be a classic marketing case study. The new medium of the Internet has offered providers with a different marketing channel for their gaming products. Rather than the development of new games, the familiar gambling activities of casinos, lotteries, and sports betting have been adapted to operate on this new medium. Moreover, the nature of the technology means that the providers have readily accessible databases of customer information that will enhance future product developments and aid the retention of customers by relationships with their target groups.

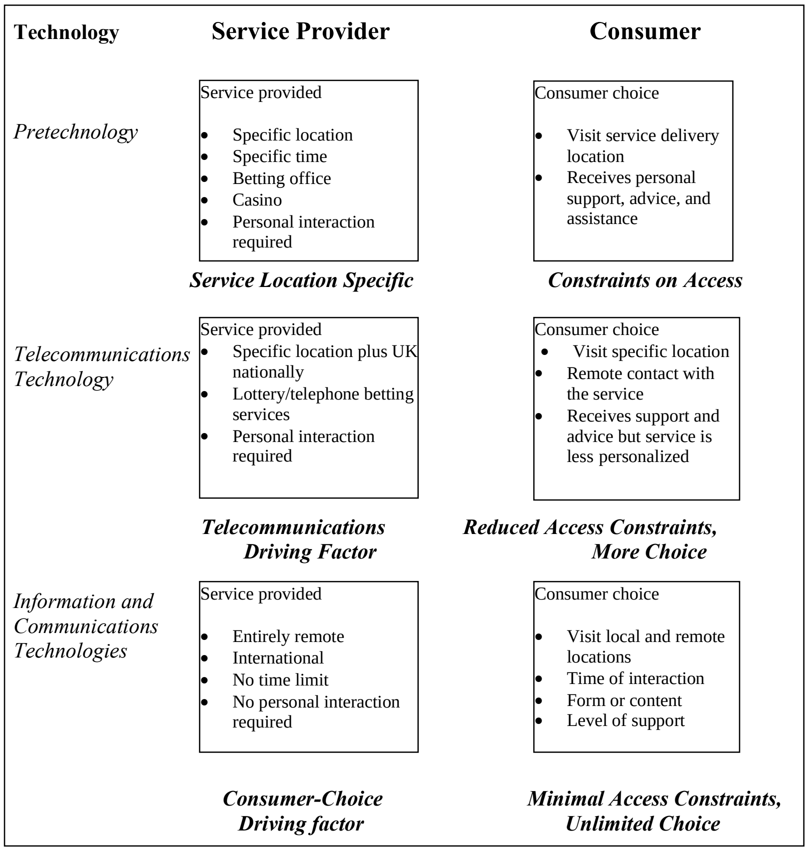
Internet gambling is currently largely unregulated and uncontrolled. The potential of gambling on credit, persons under 18 gambling, and criminal involvement are all areas of concern (Gaming Board for Great Britain, 1997). Under UK law (1968 Gaming Act), there is no problem with Internet betting; however, establishing an Internet casino host in the United Kingdom is illegal (http://www.gbgb.org.uk/faq). In Australia, legislation on Internet gambling (The Queensland Interactive Gambling Player Protection Act 1998) has been introduced (Michener et al., 1999). The U.S. response has been to make Internet gambling illegal under the auspices of the 1961 Federal Wire Act, which prohibits the use of the telephone to place sports betting. Indeed, the co-owner of an Antigua-based sports-betting operation has recently been found guilty in New York under the 1961 act and was sentenced to a 2-year jail term (Daneshku & Garrahan, 2000). However, the 1961 statute does not specifically deal with the Internet; hence, the Internet Gambling Prohibition Act successfully passed through the Senate in November 1999. The act was proposed by an Arizona senator, who argued:

Gambling is either heavily regulated or expressly prohibited in the States. On the Internet it is neither. Given the tremendous potential abuse, addiction and access by minors, on-line gambling should be prohibited. My bill will protect children from logging on to the family computer, "borrowing" the family credit card and losing the family home, all before their parents get home. (http://www.senate.gov/kyl)

The lack of a regulatory framework means that interactive services have the potential of supporting criminal activity through games or money laundering (Carruthers, 2004). This harks back to Ploscowe (1963, p. 654) who argued that "gambling gold" underpinned organized crime ventures and "hoodlums" had a prominent role in many forms of gambling, for example, slots, lotteries, casinos, bingo, and numbers. The Internet offers a return to criminal involvement in the gambling market.

Endler and Davis (1999), McMillan and Grabosky (1998), Michener et al. (1999), and the National Gambling Impact Study Commission (1999) have all discussed the negative criminal impacts of Internet gambling, particularly in regard to money laundering. Indeed, the need for regulatory control is important to McMillan and Grabosky because they argue that cyber gambling eclipses the notion of community control that characterized traditional gambling. For Watson, Liddell, Moore, and Eshee (2004), the legalization and regulation of Internet gambling should be through existing land-based casinos. Endler and Davis suggest that legal redress must be at an international level, and they argue for regulation based on perception and trust, with trust to be exemplified by a mechanism to distinguish reputable games. This argument provides an interesting dimension to the relationship between provider and player.

Figure 1. The impact of ICTs on the gambling supply chain



The Internet Gaming Commission, an independent body launched by an American, offers the online gambler a categorization of sites based on bet sizes and odds, and offers a bulletin board and dispute-resolution section (http://www.Internet.commission.com). The industry is involved in a similar labeling exercise through the use of the GamCare symbol on registered sites. GamCare, the National Association for Gambling Care, is a registered charity whose aim is to promote responsible attitudes to gambling (http://www.gamcare.org.uk). For example, http://www.premier5.com/game, the URL of an Internet sports-betting site, points to a document that incorporates information regarding GamCare, including a help-line number and useful tips for those who access its site and believe that their gambling is a problem.

In summary, there are concerns in regard to money laundering, underage gambling, problem gambling, the abuse of databases, the hacking of credit-card details, and the retrieval of gambling debts and payouts of winnings. Coupled with this is the view that the Internet is a democratic medium that should not be subject to legislation. However, existing statutes do not appear to be entirely applicable to the Internet. Van't Veer (1998) identified three approaches to regulation, which he termed the American, the European, and the Australian approaches. The European approach is to utilize domestic legislation. The American approach could be seen as punitive in that its basis appears to be that online gaming is bad. The Australian approach has been to introduce legislation to protect the player and to provide tax revenues. Thus, the approaches range from strict control to laissez-faire (McMillan & Grabosky, 1998).

Traditionally, to participate in gambling, customers had to visit a particular venue (e.g., a casino, racetrack, betting shop, bingo hall). They were restricted by tangible barriers, such as opening times and membership rules, and the intangible barriers of societal taboos and unspoken rules of the game that made it difficult for the uninitiated to participate. ICT developments mean that gambling can be supplied online to a purchaser at home, at work, while traveling, or at leisure venues. Through access to the Internet, gamblers can readily access a number of gambling sites, provided by different organizations, and can play a variety of games. The supplier-buyer relationship, while being distant, can also be personalized through the format of the technology, for example, by "welcome back" messages that address the user by name. Promotions can be personally targeted to the individual gambler.

The impact of ICTs on the gambling supply chain is shown in a diagrammatic format in Figure 1. The consumer can choose from a number of providers, decide what and when to play, and have play tailored to his or her specific needs.

FUTURE TRENDS

It is perhaps inevitable that future innovations in gambling will take advantage of the opportunities provided by technological developments and the consequent change in purchase behavior. The rapid development of technologies, such as mobile devices with more user-friendly screens and keyboards, will aid the market penetration of interactive gambling. Provider databases contain appropriate marketing information that will support the increased personalization of gambling opportunities. For example, if a customer already receives text alerts about his or her favorite team's soccer results, then the customer could also be encouraged to place wagers on the outcome of particular soccer matches involving that team.

To retain consumers as gamblers, gambling organizations will have to develop relationships with them. Gaining access to players will in turn involve gambling sites engaging with others in the supply chain, for example, platform providers, complementary service-product providers, and so forth. The nature of the transactions (i.e., money transfers potentially between partners who do not know for sure the locations of each other) suggests that trust will be a key aspect of the relationship.

CONCLUSION

The potential for gaming to drive the widespread usage of the Internet has been likened to pornography's role in popularizing the home ownership of videocassette recorders. Data shows that gaming attracts lower income people more than it does the wealthy. Thus, gaming might be the application that drives online usage from the economic and academic elite to all levels of society (Rose, 1998). Online gaming might be one of the few services that can directly generate the billions of dollars in revenue that will be needed to finance the cost of developing the information superhighway infrastructure (Mermigas as cited in Janower, 1996).

When home-based access to the Internet becomes the norm, the perception of interactive gambling as a popular leisure activity is also likely to become the norm. There is an obvious synergy between gambling products and experiences, and technology.

Internet gambling sites have achieved success by providing access using a number of different platforms and easy links around the sites. Perception barriers surrounding the term gambling or betting have been recognized, and there is an emphasis on fun, flutter, and sweepstakes. Access and perception barriers have been overcome by the development of games based on the target market's interests, for example, particular sports, television programs, and so forth. The promotion of Internet sites utilizes a company's established brand presence, prize funds, and affiliate marketing schemes.

Participants in the gambling industry have demonstrated their recognition of the need to adapt supply-chain arrangements to meet the needs of existing and new market segments. Changes in customer and consumer attitudes and purchasing behavior provide the opportunities for such adaptation, while ICTs provide the catalyst and the conduit.

KEY TERMS

Affiliate Marketing: When companies use third parties to provide services on their behalf. The affiliates may deliver customer lists or customers to the main company in return for a commission payment or cross-selling opportunity.

Brand Presence: The presence of a product offering that is distinguished from its competitors through the use of a symbol, design, or characteristic, or a combination of these.

Cyber Gambling: Gambling that takes place using an interactive technology such as the Internet or digital television.

Gambling: A leisure activity in which money is staked with the anticipation of making a gain and/or winning a prize.

Information and Communication Technologies (ICTs): Used to describe the diverse range of technological developments (e.g., computer storage and retrieval, computing capacity, wired communications, wireless communications, portable technologies) that have enhanced the internal and external activities of organizations.

Supply Chain: A network of organizations that provide goods or services to each other.

Trust: The reliance and confidence in the behavior between one or more partners involved in a trading relationship.

Global Marketing on the Internet

José Manuel Ortega Egea
University of Almería, Spain

Manuel Recio Menéndez
University of Almería, Spain

INTRODUCTION

One of the most differential characteristics between the Internet and other traditional media relates to the relatively easier "global market reach" enabled on this new medium. Internet technologies foster direct, fast, and flexible communication between producers, suppliers, and final customers across countries (Bridges, Goldsmith, & Hofacker, 2005).

The Internet global reach is likely to have relevant implications for both business-to-consumer (B2C) and business-to-business (B2B) markets. Internet-related technologies are also argued to have "equalizing effects" (Cavusgil, 2002; Hamill, 1997; Samiee, 1998a), as skills and information assets tend to be more critical factors than financial resources or firm size in order to achieve success in global e-markets. Nevertheless, companies will necessarily have to face important challenges and risks in this new global business environment.

Global marketing practices are especially likely to be changed by the introduction of Internet technologies, owing to the differential characteristics of the Internet medium—speed, ubiquity, interactivity, and two-way communication. This article examines the impact of Internet technologies on global marketing activities: global e-marketing.

BACKGROUND

Global E-Markets

Internet markets have special characteristics that will change significantly the way products and services are marketed and distributed through traditional domestic and international distribution channels.

Internet-Based Technologies and Traditional Media for Cross-Border Communications

Although Internet uptake among businesses and consumers has not yet reached the penetration levels of more traditional communication channels (e.g., telephone or fax), the usefulness of online services is expected to increase substantially in the near future (Leek, Turnbull, & Naudé, 2003).

Diverse technologies are available to develop global Internet marketing strategies:

- Among current technologies, the Web and related services, such as e-mail, online forums, newsletters, or chat services, are powerful vehicles for global marketing communications. E-mail is currently the world's most widely used online service among businesses and consumers (Hamill, 1997), and it is expected to become the most useful method for global business communication (Leek et al., 2003).
- Other technological solutions also offer great potential for global e-marketing communications, such as electronic data interchange (EDI), work flow and groupware systems, intranets, extranets, peer-to-peer (P2P) technologies, and other data transfer systems (Cavusgil, 2002).

The relevance of the Internet as a global marketing channel will depend on the added value that it provides compared to traditional media. While certain communication methods will be gradually replaced by more efficient online ones, online and off-line communication systems are expected to coexist in the future.

Global Market Reach

On the Internet, both consumers and businesses can benefit from the access and exchange of information across national and regional boundaries. Diverse authors explicitly recognize the relevance of the Internet global market reach, arguing that the Internet will become an essential element of global marketing strategies (Lazer & Shaw, 2000; Samiee, 1998b).

The Internet and Web promise an easier and cheaper global market presence, "regardless of company size" (Bennett, 1997). Less time and financial resources are required to market goods and services to worldwide customers over the Internet, compared to other distribution channels. The Internet global reach has the potential to increase the variety of products available in different national markets (Deshpandé, 2000).

Quelch and Klein (1996) argue that companies with an online presence become automatically multinationals. However, certain companies, especially SMCs, which have traditionally served only their domestic markets, may have extended their potential customer base on the Internet, but not deliberately. Such companies may not be aware of the Internet's suitability for building international relationships (Hornby, Goulding, & Poon, 2002; Melewar, Hunt, & Bridgewater, 2001; Samiee, 1998b).

Adoption of Internet-Related Technologies: Growth Trends in Different Countries

The term "digital divide" (Ngini, Furnell, & Ghita, 2002) is currently used to refer to national and regional differences in the Internet adoption levels of consumers and companies. Such differences limit significantly the potential benefits to be obtained in Internet markets by international companies and consumers.

Although regional differences are being progressively reduced, Internet adoption and the development of digital infrastructures are still higher in the United States. It must also be noted that Internet markets are developing in uneven patterns around the world—that is, lower Internet penetration and lower availability of broadband Internet access in certain regions (Crosby & Johnson, 2002).

The following regional trends can be observed, with regard to the development of Internet markets (Javalgi & Ramsey, 2001): The United States is still leading, with regard to the number of Internet users and online transactions. Europe is around 10-15 months behind the United States in terms of Internet use, but is the worldwide leader in the use of mobile devices. China is the fastest growing Internet market in Asia, and will account for a large share of the global Internet market.

According to market estimations by Forrester Research for the year 2004, the regional distribution of worldwide e-commerce will be as follows: the U.S. will account for 47% of worldwide e-commerce, Asia/Pacific-countries 24.3%, Europe 22.6%, and Latin America 1.2%.

GLOBAL E-MARKETING

Challenges and Risks

More challenges and risks are involved in global markets than in domestic markets. Diverse issues have been identified in previous research as barriers for the success of global e-marketing communications (Cavusgil, 2002; Eid & Trueman, 2002; Melewar et al., 2001; Samiee, 1998a):

Infrastructural Issues in Foreign Markets

Infrastructural constraints limit the potential success of global e-commerce and e-marketing communications. Global e-marketers should assess the availability and requirements of both technological and commercial infrastructures in the target markets.

Technological Infrastructures in Target Markets

It is critical for companies to evaluate the development of technological and telecommunication infrastructures in countries targeted through the Internet. The suitability of the Internet channel for marketing communications will be lower in those countries with less developed telecommunications infrastructure or unaffordable prices for Internet access.

Firms' Own Technological Infrastructures

Managers need to make the right decisions on the development of their own technological infrastructures, such as setting up their own Web servers or contracting with an ISP, necessary bandwidth, and so forth (Javalgi & Ramsey, 2001).

Commercial and Support Infrastructures

Two main factors are likely to influence success in this regard:

- Availability of local offices and representation (Bennett, 1997; Samiee, 1998a). Setting up local offices can be a costly strategy. Other solutions include contracting the services of local distributors.
- Sophistication of foreign markets' commercial infrastructure—for example, local availability of banks and financial institutions, and providers of computer and Internet services (Javalgi & Ramsey, 2001).

Structural Issues

Consumer Resources

- **PC Ownership:** The international availability and adoption of computer equipment enabling Internet access is required to support the development of e-commerce on a global scale (Javalgi & Ramsey, 2001; Samiee, 1998a). While personal computers are widely available in developed countries, the purchase of PCs is less affordable for consumers in less developed countries.

- **Staff and Consumers' Skills:** The effective use of Internet technologies for global e-commerce demands threshold levels of skills by both companies' staff and consumers. Educational and technological skills (e.g., familiarity with PCs and Internet technologies) and a proper understanding of foreign markets (e.g., linguistic and specific skills to deal with foreign customers and partners) are required in order to fully benefit from the use of the Internet for global marketing communications (Javalgi & Ramsey, 2001).

Geographic Location

Location and geographic constraints are less relevant to commercial success on the Internet, because of the Internet potential for building an integrated worldwide network of people and organizations, regardless of where they are situated (Angelides, 1997; Bennett, 1997; Cavusgil, 2002; Lazer & Shaw, 2000; Samiee, 1998a). Nevertheless, the Internet does not alleviate certain difficulties involved in foreign markets, such as perceived market risk or distribution and logistic complexities.

Government Regulations

Because of cross-border information flows on the Internet, governments will play a key role in the development of Internet markets. On the Internet, global marketers will have to deal with diverse national regulations, and bilateral and multilateral agreements (Tran & Atkinson, 2002; Zugelder, Flaherty, & Johnson, 2000). There is little international homogenization on such issues as consumer protection, intellectual property issues, taxation and pricing, product regulations, limitations to global information flows, restrictions to imports and exports, security and privacy regulations, or censorship.

Payment Systems

There are significant differences in the commonly used payment systems in different countries: while certain payment methods are preferred by consumers from some countries, such payment systems may not be even available or safe enough in other regions (Guillén, 2002). For example, more recently developed payment methods such as e-cash have only been introduced into certain local markets, and few consumers already use these systems (Hornby et al., 2002).

The decision on the acceptable payment methods is crucial for companies conducting transactions over the Internet. E-sellers should be flexible with regard to the accepted payment systems in different national markets.

Cultural Factors

A key decision in global marketing relates to the extent to which marketing communications should be standardized or localized across countries. The global information flows on the Internet have been argued to contribute to an increasing globalization and homogenization of consumers' preferences (Bennett, 1997). Other authors conversely argue that, along with opportunities, the Internet global markets involve significant complexities associated with the diversity of cultures (Samiee, 1998b).

Fully standardized marketing communications are very difficult to apply. Depending on the product and the sector, varying degrees of local responsiveness may be necessary (Guillén, 2002). Owing to the easy global market access through the Internet, there is a risk that global e-marketers overlook the potential implications of regional and cultural differences for effectiveness of their global e-marketing communications (Quelch & Klein, 1996).

Organizational Barriers

Organizational barriers arise from the difficulties and resources required to engage in global marketing. The application of Internet technologies to commercial activities involves the integration and adaptation of the firm's technology, business processes, and staff, according to the characteristics of the online environment and the target markets.

Information Management

Another challenge for online companies may be the effective management of the sheer amount of diverse data available on the Internet (e.g., information on customers' preferences and online behavior or diverse reports and market analyses).

Web Sites' Development and Maintenance Costs

Though the Internet significantly reduces the financial requirements for global marketing communications, the costs involved in effective Web site development and maintenance are not negligible, ranging from $300,000 for promotional sites to $3.4 million for shopping sites (Samiee, 1998a, 1998b).

The maintenance of effective Web sites is an ongoing process, and depending on the purposes and the degree of Web site localization, the total costs of global marketing on the Web may be too high for smaller companies with limited financial resources.

Operational and Procedural Problems

Further problems posed by the global implications of Internet markets relate to dealing with operational and procedural problems (Samiee, 1998a). Such problems are largely transaction specific and include such practical problems as dealing with documentation and paperwork, international logistics, and managing payments in different currencies.

Global E-Marketing Strategies

This section reviews the most significant changes introduced by Internet technologies into the development of global marketing activities. The authors strive to offer a thorough analysis of the potential effects of global online information flows on marketing practices.

Global E-Market Segmentation

Market segmentation on the Internet will differ significantly from traditional consumer and business segmentation. On the Internet, potential customers are easier to target and reach on a global scale. The peculiarities of the Internet for market segmentation have been referred to as "mass customization" or "personalization" (Goldsmith, 1999; Lazer & Shaw, 2000): it incorporates the best of mass markets (e.g., global market reach), together with huge possibilities for individual customization (identification of "segments of one").

Internet technological capabilities allow marketers to identify the individual customer's preferences and accordingly customize marketing communications. On the Web, it is easier for marketers to analyze and track consumers' shopping behavior than in off-line markets. Diverse online services help companies gain an overview of the needs and preferences of people from different cultures (Melewar et al., 2001).

The Global E-Marketing Mix

Global Online Promotion

The decision on the degree of standardization vs. localization is critical for the effectiveness of global online advertising. Online marketers should not underestimate the need for advertising localization on the Internet, depending on the target market characteristics (e.g., developing multilingual Web sites).

Samiee (1998b) points out that the Internet global nature may promote standardized advertising approaches, which may reduce the effectiveness of online advertising campaigns in different countries. Recent research shows that there are no universal values to which standardized advertising can appeal (De Mooij, 2003).

Global Branding on the Web

The Internet offers great opportunities for branding and image building, previously unavailable in offline business environments. The information transparency and international reach, facilitated by Internet technologies, enable companies to build a worldwide identity much faster than in off-line settings (Cavusgil, 2002).

Reputation and branding-related issues are expected to be as relevant on the Internet as in physical markets (Guillén, 2002). Image building is critical for international customers to be aware of a company's existence. Furthermore, "trust" is one of the most decisive factors for online shopping adoption, so companies should not expect international Internet users to purchase "unfamiliar brands through unknown vendors in the foreseeable future" (Samiee, 1998b).

White (1997) argues that consumers should not be expected to purchase from international Web sites if they do not perceive unique benefits in the products offered on those Web sites, compared to the products available through local Web sites.

Branding through Web Sites

The management of a global brand and corporate logo on the Internet is an important challenge to be managed by e-companies. As in traditional markets, companies may decide to use a single brand or multiple brands. On the Internet, Web sites are the most powerful branding medium, and various approaches to Web site development are available, according to the desired degree of identification between (1) product or services brands, (2) global Web sites, and (3) corporate identity (Quelch & Klein, 1996):

- Centralization of all product lines on a single Web site.
- Multiple local Web sites for a single brand.
- Different Web sites for each brand.
- Development of local Web sites by independent sellers or intermediaries.

Pricing Strategies

Effective pricing on the Internet represents a great challenge for companies operating on a global basis. The Web increases consumer power to acquire information and compare prices between domestic and international service providers (Deshpandé, 2000; Lazer & Shaw, 2000).

Diverse possibilities are available for online sellers to track online buyers' behavior (e.g., cookies, IP tracking, or data mining), which can significantly contribute to price discrimination attempts, based not only on traditionally used criteria, such as geographic location of customers and prospects, but on the individual consumer's behavior (Guillén, 2002). Price discrimination strategies involve certain risks that may arise if consumers become aware of price differences between countries.

Among others, challenges to global e-pricing strategies include: (1) global standardization of promotions (e.g., Mother's Day is celebrated on different dates internationally); (2) national differences in price sensitivity; (3) customer dissatisfaction because of price discrimination; (4) faster competitors' reactions to online pricing strategies; (5) pricing regulations; (6) currencies to quote prices; and (7) information related to applicable shipping charges and local taxes.

Distribution

In both domestic and global markets, distribution is a critical determinant of customer satisfaction with online shopping services. Based on the production country and the served markets, companies will have to develop an appropriate distribution channel (Samiee, 1998b): for example, online sellers may decide to keep their own product inventory, or make arrangements with suppliers that ship the products directly to the customers.

Online Disintermediation

Certain authors suggest that companies accessing foreign markets through the Internet will not need to rely on local intermediaries, because customers from those markets can find information about a wider variety of products on the Internet than in local markets (Javalgi & Ramsey, 2001; Quelch & Klein, 1996). The Internet channel, though, does not solve logistic problems associated with the distribution of tangible products to international markets. Because of these restrictions, companies will need to carefully manage logistics and transport issues in foreign markets.

Distribution Fulfillment

The fulfillment of international orders is one of the most important challenges faced by global e-sellers. Most of the problems related to international order fulfillment are associated with the required logistics to distribute tangible goods in foreign markets. Conversely, the Internet is a very suitable medium for the distribution of information and "digitizable" products.

International customers not receiving or receiving late the products they have ordered and paid for online will surely not consider those companies for future purchases. The attitudes toward online purchasing could also be damaged, owing to such unsatisfactory online shopping experiences. Global e-sellers should find logistical solutions, which ensure a smooth and cost-effective distribution to foreign customers.

Product

Global online marketers should assess and emphasize the unique advantages of their own products and services in local markets, compared to those available through traditional channels (Quelch & Klein, 1996; White, 1997).

On the Internet, international customers will benefit from a wider product variety. Some products, not distributed in certain local markets, will usually be available for purchase online. Consumers from such markets can access foreign Web sites for purchases.

Niche Products

Smaller companies with limited financial resources can gain easier access to international markets through the Internet. Quelch and Klein (1996) suggest that companies with specialized offerings, thanks to the Internet, will be able to gather the necessary number of customers.

Product Development and Product Design

The benefits provided by the Internet for product development include easier identification of customer needs, individual product customization, and global and faster product testing (Eid & Trueman, 2002). The Internet helps in the design of products that match customers' preferences by incorporating the views and tastes of global customers into the product design and product development phases. Product design and product development processes can be improved by forming virtual teams, which integrate knowledge from different countries (Cavusgil, 2002).

FUTURE TRENDS

Because of the relatively recent development of Internet technologies, further research is needed to clarify the challenges and most suitable global e-marketing strategies in different countries (e.g., standardization vs. localization approaches). Country-specific studies should provide useful insights into the preferred characteristics of e-marketing communications in different regions.

Researchers should emphasize the global implications of the e-marketing research topics, such as those referring to the elements of the e-marketing mix.

CONCLUSION

The Internet provides great opportunities for global market access to companies of different sizes. Lower access costs to foreign markets, as well as better knowledge of global consumers' preferences, are two of the main improvements offered by Internet technologies, compared to traditional distribution channels.

Nevertheless, online companies will have to deal with complex market conditions related to the existence of national and regional differences in the target markets' economic, infrastructural, cultural, legal, and political characteristics. Diverse structural issues, such as current regional differences in Internet usage, should also be taken into account by online marketers in their global e-marketing strategies (Mahajan, Pratini De Moraes, & Wind, 2000). Other challenges to be carefully managed by online marketers relate to organizational issues, such as ensuring a smooth distribution, integrating the Internet into the companies' global marketing strategies, coordinating online and off-line distribution channels, or evaluating the need for local representation in the local market (Samiee, 1998b). The most suitable strategies to cope with structural and organizational problems will be highly dependent on both the characteristics of the target market and the offered products or services.

Internet technologies provide great improvements in global market segmentation and market selection, which is likely to increase the effectiveness of online companies' global e-marketing efforts. The Internet channel will also have a significant impact on the diverse elements of the companies' global marketing (e-marketing) mix. Internet technologies will introduce significant changes into the pricing, promotion, distribution, and product elements of the marketing mix. Most of the improvements provided by Internet technologies relate to higher possibilities for adaptation, according to the preferences of the individual customer.

It seems clear that the Internet should not be regarded as a panacea for global market access. According to diverse recent investigations, localization of marketing communications is expected to be further necessary on the Internet in order to account for local markets' differential characteristics. The improved possibilities for global market research offered by the Internet should help companies find a balance between standardization vs. localization approaches, according to the target market's specific characteristics. Global e-marketers should prove their skills in finding a balance between the higher effectiveness of localization approaches and cost advantages provided by standardization strategies.

KEY TERMS

Global E-Market Segmentation: Process leading to the identification of homogeneous consumer groups in the global Internet markets.

Global E-Marketing: Marketing efforts undertaken by companies outside their domestic market.

Global E-Marketing Mix: Combination of elements (promotion, price, place, and product) used by online companies to market their products/services on a global scale.

Internet: Global communications network consisting of thousands of interconnected networks.

Online Shopping: Purchases carried out through the Internet channel.

Niche Product: Specialized offering with a limited customer base.

Web: World Wide Web, or resources on the Internet that are using the hypertext transfer protocol (HTTP).

Governing Health Care with IT

Reima Suomi
Turku School of Economics and Business Administration, Finland

INTRODUCTION

The pressures for the health care industry are well known and very similar in all developed countries: altering populations, shortage of resources as it comes to staff and financial resources from the taxpayers, higher sensitivity of the population for health issues, new and emerging diseases, just to name a few. Underdeveloped countries have different problems, but they also have the advantage of being able to learn from the lessons and actions the developed countries made already, maybe decades ago. On the other hand, many solutions also exist, but they all make the environment even more difficult to manage: possibilities of networking, booming medical and health-related research and knowledge produced by it, alternative care-taking solutions, new and expensive treats and medicines, and promises of the biotechnology.

From the public authorities point of view, the solution might be easy: outsource as much as you can out of this mess. Usually, the first ones to go are marginal operational activities, such as laundry, cleaning, and catering services. It is easy to add information systems to this list, but we believe this is often done without a careful enough consideration. Outsourcing is often seen as a trendy, obvious, and easy solution, which has been supported by financial facts on the short run. Many examples show that even in the case of operational information systems outsourcing can become a costly option, not to speak of lost possibilities for organizational learning and competitive positioning through mastering of information technology.

In this article, we discuss how information technology and health care industry work together. Information technology is a valuable resource that must be managed within the health care industry. At the same time, information technology has the potential to renew the whole industry. Good practices in both must be supported by good IT governance.

Health care is a big resource user in every country. In Table 1 we have percentages of health care expenditures in relation to gross domestic product in selected countries, where the percentage is very high (WHO, 2004). As one can see, the cost explosion phenomenon hits both rich and poor countries, even though the wealthiest countries are well presented in the list.

Table 1. Top 20 percentages of health care expenditure in relation to gross domestic product in 2001 in selected countries (WHO, 2004)

USA	13.9
Lebanon	12.2
Cambodia	11.8
Switzerland	11.0
Uruguay	10.9
Germany	10.8
Timor-Leste	9.8
Marshall Islands	9.8
France	9.6
Jordan	9.5
Argentina	9.5
Canada	9.5
Greece	9.4
Surimare	9.4
Australia	9.2
Palau	9.2
Portugal	9.2
Iceland	9.2
Croatia	9.0
Belgium	8.9

Health care costs can be born by different parties within a national economy. Shares of different potential cost carriers vary from national economy to economy:

- The national government, directly or through different indirect arrangements such as separate funds or public insurance institutions
- Municipalities or other local public actors
- Private insurance institutions
- Employers
- The patients themselves

For example, in the United States, the raising costs of health care born by the employers have been a topic of much academic and industry discussion (Berry, Mirabito, & Berwick, 2004). Sadly enough, there is controversial evidence whether information technology can lower the total costs of running health services (Ammenwerth, Gräber, Herrmann, Bürkle, & König, 2003; Ko & Osei-Bryson, 2004).

There are few other forces than modern information technology that could cut down costs in the health care industry. In addition to cost cutting, information technology can provide extended productivity and is an ingredient in the processes that cumulate towards better care practices. But advantages from information technology are not to be harvested without constant focus on IT governance issues in the industry.

BACKGROUND

We have found the following reasons for the late adoption of modern information technology in the health care sector (Suomi, 2000):

- Fragmented industry structure
- Weak customers
- Strong professional culture of medical care personnel
- Hierarchical organization structures
- Handcrafting traditions
- One-sided education
- Big national differences in processes

We will next discuss each of these issues in greater detail.

Fragmented Industry Structure

Good competitors and customers are a key to success for any company and industry (Porter, 1990). Unfortunately, the health care sector has not been able to enjoy from neither of them. For a long time health care has been considered as a faceless public service, where normal competitive forces are not in effect. Health care organizations have not felt each other as competitors, and neither have they documented productive cooperative behavior. First with penetrating privatization the situation is starting to change.

Weak Customers

As it comes to customers, most often they get into touch with the industry when in a critical and sensitive situation, where bargaining power is very low. Bad service has just to be suffered. First during the last few years the concept "customer" has started to substitute the word "patient." Regulative bodies have become active in this respect, and for example in Finland a special patient-ombudsman has been institutionalized and legislation on patient reclamation and insurance has been introduced. In general, new technology is seen as a method to empower patients (Beun, 2003).

Strong Professional Culture of Medical Care Personnel

Professional cultures can have a profound outcome on organizational outcome. Within the health care sector, there are many strong professional cultures, the strongest of them being those of doctors and those of the nurses. People seeking to these professions usually value human interaction, and are not much up for abstract systems such as computers.

Hierarchical Organization Structures

A part of hospital organization has always been a strong hierarchical, professional and specialized structure. Work on the computers, unfortunately, is low on the hierarchy list, especially of course in the activities of keying in patient data that would be a natural thing to do for the doctors. As EITO (1995, p. 46) put it: "*for many Health Care applications, the most difficult obstacles can be social and cultural.*" It is well known that information system development and application can be very difficult or at least different from less bureaucratic organizations than the health care.

Handcrafting Traditions

Even when we conclude that health care is a very information intensive industry, it has not been considered as such one. A good doctor is valued because of his handcrafting skills, especially in surgery, and it is not being understood that behind the handcraft operations a vast amount of knowledge is needed. Some, anyway, have understood that human body is the most complex entity in the world and of which information and knowledge has been collected over thousands of years.

One-Sided Education

Education of health care personnel has traditionally not focused on computer skills. Even the classical university tradition has kept medical and natural science (and thus computer) faculties apart from each other. Fortunately, during the last years, the drive for deeper cooperation between different science fields has begun to bear fruit.

Big National Differences in Processes

Patient care is very culturally bound, and especially the administrative processes behind vary greatly from one country to another. This, of course, makes standardization very difficult and the industry a bad target for suppliers of standard software and platforms. Neither do we have any dominant players in the field that would behave in the market as strong customers and trend setters.

Currently, however, not even the health care industry can not escape the tsunami of modern IT. IT has to be governed within the industry and IT and governance structures meet in two ways. At one side, IT enables new governance structures for the health care industry. On the other, it is an object needing governing. As both sectors offer a multitude of new possibilities, innovations are called for in the industry.

IT governance thinking matures in organizations as any other discipline. Van Grembergen, De Haes, and Guldentops (2003) defined the following stages in their IT Governance Maturity Model:

- Nonexistent
- Initial/ad-hoc
- Repeatable but Intuitive
- Defined Process
- Managed and Measurable
- Optimized

Needless to say, in the health care industry, IT governance thinking is nonexistent or initial/ad hoc in the best situation.

HEALTH CARE, GOVERNANCE, AND IT

The Meaning of IT Governance Structure in Health Care

IT is an old acronym for information technology. Very often it is now replaced with the term *ICT,* referring to information and communication technology. This is to emphasize the communication services that are developing very fast, such as the Internet and mobile services. The letter "C" is often upgraded to the second dimension—alongside communication it can refer to contents. IT or IT governance is defined (IT Governance Institute, 2001) as follows:

IT governance is the responsibility of the board of directors and executive management. It is an integral part of enterprise governance and consists of the leadership and organizational structures and processes that ensure that the organization's IT sustains and extends the organization's strategies and objectives. (p. 10)

For many there is a temptation to understand governance as just a synonym for *management*. This is an oversimplification. Management is a goal-oriented activity, whereas governance is often given from outside, and organizations just have to live with it. This is not to say, that all governance structures would be beyond management control: most governance structures management can influence—at least on the long run. The long run is a key term in many aspects: When referring to governance structures, we talk about structures that are semipermanent and are not changed very frequently. *Structure* is a term closer to *architecture* than to *infrastructure*: governance structures are architectural terms, and are then implemented into infrastructures through different organizational forms. Therefore, the terms *organization form* and *governance structure* are not synonyms. Organizational forms are more formal and touch upon one organization, whereas governance structures are found in a richer selection of forms and organize themselves over a number of organizations. Table 2 summarizes our discussion here.

Governance structures are present in almost any human decision making situation. In Table 3, we have a collection of key aspects of IT governance structure issues in health care.

IT AS A TOOL TO BE GOVERNED IN HEALTH CARE

Information and communication technology needs management in health care organizations as in any other organization. Yet the issue seems to be very difficult for

Table 2. Comparison of terms management, organizational form, and governance structure

	Management	Organizational Form	Governance Structure
Time perspective	Short	Medium	Long
Focus	Action	Internal organization	Interorganizational structures
Management Control	In action	Easy	Difficult
Metaphor	Communication channels	Infrastructure	Architecture
Character	Concrete	Formal	Abstract

the health care organizations. Morrissey (2003, p. 6) paid attention to the fact that health care organizational culture is often hostile to new information technology: *"The expression 'Culture eats Strategy for lunch' has never been more accurate than with physician order entry."* At the same time he documents the frustrations many hospitals and health care organizations have felt in the case of information technology: "*We have bought enough technology and we're not getting the expected value out of it.*" Haux, Ammenwerth, Herzog, and Knaup (2002, p. 19) have paid attention to the weak management of information technology and systems in health care organizations: "*The health care institutions, especially hospitals, must emphasize professional information management more strongly in their organizations.*"

Ross and Rockart (1996) have defined the following success factors for successful IT management:

- Achieve two-way strategic alignment
- Develop effective relationships with line management
- Deliver and implement new systems
- Build and manage infrastructure
- Reskill the IT organization
- Manage vendor partnerships
- Build high performance
- Redesign and manage the federal IT organization

Next, we discuss these issues in the health care IT context.

Two-way strategic alignment means that the organizational strategy affects the IT strategy, and vice versa. The current tumult of health care IT is partly a result of the fact that the effect of IT on health care processes has been denied for too long.

Effective relationship with line management means that communication is fluent and the parties aim at common goals. Effective communication needs a common language. Unfortunately, medical people and IT professionals do not always speak the same language. The applications the staff members use are the face of the information technology to the whole organization. A deliberate balance with investments to the infrastructure as well is needed. Functional applications can not be built on a flimsy base, but overinvestment in infrastructure is always a danger threatening organizations (Broadbent, 1999). Typical key applications of a hospital are electronic patient records (EPRs) and picture archiving and communication systems (PACSs).

Even in the health care organizational environment, IT professionals are under constant educational and skill renewal pressure. One of the big challenges meeting them is that patient data must move over traditional organizational boundaries and therefore must be able to deliver professional services in networked and often virtual organizational settings. The same issue is central in the management of vendor relationships: health care organization's IT staff must be able to integrate solutions from several vendors or, even better, they must be able to put enough pressure to vendors to self integrate their solutions.

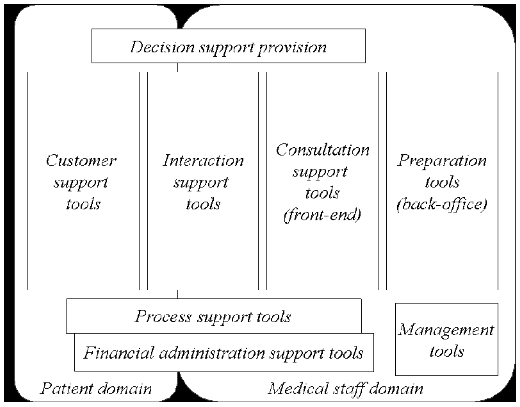
Performance of IT solutions is dependent on many factors. Typical critical resources are time and money. Lack of money can be seen in undersized hardware and software solutions, and lack of IT-professionals time culminates in bad designs for the solutions.

Federal IT organization means that there are both centralized and decentralized IT units in the organizations. Even in big hospitals there is usually just one big IT unit. The federal structure problematic comes more into the foreground in the interorganizational settings of systems.

Table 3. IT governance structure issues in health care

IT as an enabler
Health-related information on the Web
Private-public sector cooperation
Allocation of patients to different levels of care
Customer contacts distribution between electronic and classical means
Ownership, structure and allocation of patient, population-level and other critical data
Electronic forums for patients to interact
Electronic prescription systems
IT as an object to be governed
New legislation needs because of the new data processing possibilities
Data privacy and security
Structure and status of the information resource management in health care units
IT-general management partnership
Sourcing decisions of IT
Charging arrangements on IT-services

Figure 1. Classification of IT tools in health care



IT AS A TOOL FOR GOVERNANCE IN HEALTH CARE

How can information technology help in governing health care? We can approach this issue by taking a look at the application areas of IT in health care organizations. We propose the classification as shown in Figure 1, as adapted from (Suomi, 2000). The classification is a conceptual one, and actual information systems met in health care settings might fit several categories of the framework's systems.

The heart of our classification is in the interaction between the medical personnel and the patient, a kind of basic value-adding chain. In addition to the basic value chain in the middle of the figure, there are certain supporting functions and systems needed.

The figure divides the systems into systems for the use by the patient/customer (patient domain) and by the medical staff (medical staff domain).

We further differentiate between two basic use scenarios of these systems:

1. (patient) self-care scenario
2. (patient-medical staff) interaction scenario

In addition we have the activities of the health care professional or organization, that are not connected to any specific individual patient interaction, but they are of less interest for our analysis here.

SELF-CARE SCENARIO

The self-care scenario means that the patient tries to manage his or her disease or illness without individual professional help. Decision support provision in the self-care scenario helps in self-diagnosis and in deciding whether professional help is needed or not. Internet-provided information is a key component in this category.

Customer support tools help the patient with the daily management of the disease or illness. For example, easy-to-use tools to make different measurements (such as blood pressure) belong to this category. Process support tools are related tools, but focus in the self-care scenario more on the total life cycle of the disease. An example might be computerized tools for keeping track of different measurements. Financial administration tools help in managing the disease or illness condition financially.

INTERACTION SCENARIO

In the patient-medical staff interaction scenario, decision support helps to diagnose the patient and to decide what kind of care he or she needs. Now the decision is made in cooperation between the medical staff and the patient, not just by the patient, as in the self-care scenario.

Customer support tools are used in the same way as in the self-care scenario, but there they also help the patient to prepare for the interaction with the medical professionals.

Interaction support tools are active in the situations where the medical staff and the patient meet. This meeting can take many forms: it can be a physical meeting, a virtual meeting through electronic means, or some combination of these. Doctors often want to keep physical meetings technology free, but technology can help even in these cases, say to facilitate communication in the case of sense disabilities or language problems. In a virtual meeting, different systems such as phone or e-mail services belong to this category as well as those different applications of telemedicine.

Consultation support tools and preparation tools are to be used by the medical staff. Consultation support tools help the medical staff members during an individual customer consultation, whereas preparation tools are active outside the actual customer interaction. An example of consultation support systems might be a system used to support surgery operations.

In our analysis, the information domains are important. Customer support tools contain information for the patient and are used by him or her. Interaction support tools contain joint information and are used by both patients and medical staff. Consultation support tools contain patient-specific information that is targeted just for the medical staff.

To clarify the proposed value chain, take the example of a laboratory test. For the test, the customer might have to prepare himself or herself by not eating anything. The customer might obtain this information the hospital's

Web site or a customer-support tool. An electronic patient card that would help in identifying the patient during the testing would be an interaction support tool. Analyzing the test would be a back-office function for the preparation tools. Analyzing the laboratory results and working out how to tell the results of the test to the customer in a comprehensive way could be facilitated by a consultation support tool.

Process support tools in the interaction scenario help in organizing the interactions between the patient and the medical staff (e.g., different consultation time reservation, queue management systems). Financial administration of the patient-medical staff interaction is one part of this. Electronic systems for handling prescriptions also belong to this category.

Finally, a health care organization has to maintain a lot of management routines that are not connected to any individual patients. Resource planning and management systems and statistics keeping are examples of this domain.

The information in Figure 1 is not to say that the different health care systems would be independent isles of automation. All the systems included in the figure should be integrated by a comprehensive electronic patient record.

FUTURE TRENDS

In Table 4, we list the most dramatic changes we will see in the health care sector because of modern IT and the challenges these changes cast on the IT governance.

One of the biggest changes in the industry is that information related to health, diseases, sickness, and medicines is not scarce. Internet is a rich source of such information, at different levels of expertise, and in different languages. The gap between what information is available and what a health care professional should know is growing fast (Weaver, 2002); similarly, the pressures for laymen to know about medical issues grow. Decision support is needed more than ever in this plentitude of information. Different solutions should be found to differentiate right information from wrong, especially in the case of information targeted for laymen, such as most of the information found on the Internet.

Free information will shift the power balance between health professionals and patients: More often, the patients are the best experts on their disease, and self-care will grow in importance. Systems to support self-care must be developed. Different electronic forums or virtual communities will offer the patients forums to share experiences and peer advice, to the healthy ones as well as to the chronic and acute sick (Utbult, 2000).

If the patients get more empowered, they should too get more responsibility. Health care information systems should not just keep track of medical staff decisions, the decisions taken by the patients should also be recorded to the systems.

Similarly, the interaction between the patients and health care professionals is going to change: Electronic means are going to take share from face-to-face meetings (Cain, Sarasohn-Kahn, & Wayne, 2000; Gilson, 2003). A key survival factor for all the electronic sources of health information and all communication channels to be used by

Table 4. Future changes in the field of health care introduced by modern IT and the challenges to IT governance produced by them

Future changes in the field of health care introduced by modern IT	**Challenges to IT governance**
The amount of free medical information will grow very fast	Mechanisms to rate different information sources have to be developed
Patient self-care will grow in importance	Systems to support self-care must be developed
Patient empowerment will gain in importance	Customer rights and decisions must be tracked in medical information systems
Interaction between patients and medical staff will increasingly turn away from physical meetings to electronic means	Electronic means to facilitate patient-medical staff communication must be developed
Data collected about patients will grow in amount and quality	Data privacy needs even more concern
Medicalization of the society	Medical and other information systems will have to be linked sophistically
Costs of medical care will continue to raise	Cost monitoring will grow in importance
Focus should turn from individual care-taking episodes and consultations to long-term care-taking relationships and processes	Pressures to develop electronic patient records
Resources of the area will not grow as fast as demand	Information systems must be used for process redesign

the patients is how they can build and sustain customer/patient trust (Luo & Najdawi, 2004).

Medicalisation of the society (Conrad, 1992) is a strong trend. Increasingly more issues in human life are seen as belonging to the sphere of medical expertise. If and when we accept this trend, medical decision makers need information about our lives in many aspects. As patient data can be electronically cumulated into huge databases, these databases can be used for different statistical, research, and other purposes. This calls for care and proper legislation giving the ramifications for data usage. For example, often the need of integrating data about one's health and social life arises, if effective care is looked for. Needless to say, we enter a difficult area where data privacy issues gain in importance.

Science and industry will continue to produce increasingly effective cure methods and medicines, but not always without increased costs. It is clear that not everyone can be granted the best possible care with public finances. Systems for keeping track of costs and making cost-informed care-taking decisions will be needed in the future.

For organizing patient flows through the health care system modern IT offers many possibilities. A key issue is to follow the long-term development of the patient, not to focus just on short-term episodes of care. This puts pressures on the electronic patient record systems.

Resources can be saved or wasted through care-taking decisions. It is for sure that in many nations the total share of health care costs is at its top already, so current resources should be used more efficiently. Efficiency, among other things, means that patients are taken care of in the best and most effective places, be they public or private, and of right level of expertise. This all calls for extensive process redesign and system support for that. Should patient data be all the time available anywhere though electronic means, would the Healthcare Supply Chain be much more effective (More & McGrath, 2001).

CONCLUSION

Health is undoubtedly among the most important issues for all people. In a modern society, the threats towards health are changing all the time, but at the same time the possibilities to maintain health and to cure illnesses also grow exponentially. The task is to make needs and solutions to meet in an effective way. This is about information and communication technologies and governance structures.

Modern IT allows health care organizations to structure themselves in new, innovative ways and simultaneously to empower the customers to interact with the organizations, with fellow patients and information sources in revolutionary new ways. In this environment, health care professionals too have to adjust their roles.

Managing and building governance structures for IT in health care organizations is not that much different from other organizations. Even in health care organizations the scope and status of information resource management has to be decided. Issues such as sourcing decisions, charging arrangements and data privacy and security issues all deserve their attention. There are, anyway, certain problems that need to be solved in this area:

- Data privacy and security needs are extremely important and might sometimes conflict with optimal care.
- As the area is new, legislation is often lagging behind.
- The field is a meeting place for two strong professional cultures, that of medical doctors and IT professionals, which might bring along difficulties.

KEY TERMS

Electronic Patient Record: All health-related information related to a patient in electronic form, assembled as a single entity.

Electronic Prescription: Prescriptions created and handled in electronic form in an integrated information system.

Health Care Supply Chain: A managed set of activities related to the health care activity of a patient organized so that all information needed is all the time available and that the participants in the chain have a complete picture of the total process.

Picture Archiving and Communication System: A system for capturing, storing and distributing medical images. These systems are fast turning from storing analog images to storing digital images.

Sourcing Decision: Whether to buy goods/services from the market or to make them self—alone or in different alliances.

Virtual Community: A social aggregation on the Internet when people interact long enough to form personal relationships.

Graphical Content on Mobile Devices

Heidrun Schumann
University of Rostock, Germany

INTRODUCTION

The enthusiasm for mobile computing is still unbroken as a year on year increase of 51% in the overall global shipments of mobile devices in the fourth quarter of 2004 has shown (Canalys.com, 2005). With 300 million new subscribers in 2004 alone, 27% of the world's population now has access to mobile communications (Svanberg, 2005). A mobile device is a natural multi-functional device and the opportunity to handle multimedia data is only the first step on a long way. Although the development of mobile devices has already made great progress, handling graphical data is still expensive due to the limited resources in mobile environments. Especially if large graphics must be processed limits are quickly reached. However, it is necessary to provide effective and appealing graphical representations for successful m-commerce.

The aim of this article is to derive major limitations of current mobile hardware and to show how large graphical content can be appropriately processed on such devices. Since visual content can be described either by vector (SVG, Flash) or raster data (Bmp, Gif), both approaches are explained and particular properties are shown. Based on experimental results, this enables us to give guidelines for the appropriate handling of large graphical contents in m-commerce applications.

This contribution is structured as follows: in the section titled "Background", properties of current mobile devices are reviewed and the displaying pipeline together with basic principles of vector and raster images is explained. These statements form the basis for our tests and comparisons in the "Main Discussions" section and statements for future work in the "Future Trends" section. Since there are huge differences in the performance in the handling of vector and raster images, we close our contribution by giving implementation guidelines for applications presenting large graphical content on mobile devices ("Conclusion"). "References" and "Key Terms" serve to provide sources for cited literature and definitions for related terms.

BACKGROUND

Recent Work

Effectively representing information by graphical means is a key issue in m-commerce applications. Many publications describe the processing of graphical content in mobile environments, but they are rather limited to WWW-browsers (Joshi et al., 1996), interaction issues (Rekimoto, 1996) or other specific problems (Rist, 2001; Want et al., 2002; Karstens, Rosenbaum, & Schumann, 2003). Nevertheless, these publications neither describe the actual efforts needed to process the used graphical data, nor do they consider the nature of the content description actually used. Due to limitations of mobile devices, this can be of crucial interest since each kind of data is processed differently, which might even render an accepted approach impossible if provided resources are exceeded. This has been shown in (Rosenbaum & Tominski, 2003) by a comprehensive investigation of the processing and display pipeline of mobile hardware.

Related Limitations of Mobile Devices

Due to fast progression in this research field, properties of mobile devices change quickly. Thus, current limitations regarding the handling of large images are not the same as a few years ago (Rosenbaum & Tominski, 2003). We found, that some constrains still exist (e.g., screen size/resolution, processing power), whereas some have strongly decreased (storage space) or have been overcome (lack of color). To give the reader an impression of current hardware, we compiled a list of important properties of current mobile devices (Table 1). Since classic tablet-PCs or Laptops are more aligned to stationary systems than to light-weight mobile assistants, they have not been considered.

Table 1. Specifications of different mobile devices (03/2005)

Screen Dimension

The relatively small screen dimension is one of the major drawbacks of mobile devices if large graphical content is to be presented. The display size of current devices varies dependent on the respective device class and spreads from 2 to 5 inches screen diagonal, which is by far less than what is offered by common stationary devices. Thus, the available space for presenting images is very limited and most parts of the content might be hidden. Interestingly, some mobiles offer a second, smaller display to show additional data.

Screen Resolution

The pixel density of mobile displays is rather high. Some devices offer a resolution of 800×600 by a screen dimension of only 5 inches. This leads to a very detailed presentation of the content. Nevertheless, this property is limited by the human visual system, which can resolve visual content only up to a certain extent (Hubel, 1988; Wandell, 1995). Thus, the provided space to display data is and will be by far lower compared to stationary gadgets.

Processing Power

The appropriate handling of graphical content is heavily affected by the available processing power. Due to the dimensions of mobile devices, it is not possible to include hardware with performance similar to stationary devices. This is mainly due to the limited energy supply. Although the speed of current systems has increased a lot, the performance regarding data processing is innately much slower. An interesting trend is the use of additional GPUs to improve the processing of graphical data. Currently, they are only provided by two devices specialized on gaming (Gizmondo) or highly detailed output (Sony VAIO), but are expected to be supported by other devices too. The advent of such additional peripherals will strongly enhance the handling of visual content in the near future (Rasmusson, Dahlgren, Gustafsson, & Nilsson, 2004).

Other Limitations

As predicted in (Rosenbaum & Tominski, 2003), nowadays mobile devices offer by far more storage space than two years ago (Table 1). Thus, limitations in image handling are mostly overcome and might only occur if many images must be handled or stored at same time. Minor limitations, as user interaction and data transmission, do not influence content presentation and are considered to be out of scope for this article.

Presenting Graphical Content on Mobile Devices

Working with mobile hardware causes a variety of problems due to limited capabilities of such devices. In this section we want to review basic steps of the display pipeline for graphical data together with important properties and requirements which should be fulfilled to allow a convenient and effortless exploration process. This gives us clues for later examinations and statements.

Before graphical content can be shown on screen, it must pass the display pipeline. First, it must be loaded to memory. Here, properties like *file size* and *file format* play an important role. Since the content is often encoded, *loading* can be further split in pure *file reading* and the following *decoding* in memory. Based on this, more detailed statements can be derived about affected properties of the device. After the loading step, the content is stored in an internal memory representation (IMR) forming the basis for the later display. There are different approaches for such internal representations, which can even coexist at the same time. The IMR itself is mainly influenced by the properties *image dimension* and *precision*, but also by image content. The final pipeline step shows the whole or part of the IMR on screen. Here, all current devices make use of a discrete raster display with a certain *screen resolution.* Since there are rather different approaches for the IMR, their demands on the display step vary heavily and are worth being examined.

Arbitrary graphical content can be described by either raster or vector graphics. Due to the fact that each approach uses completely different ways to describe graphical content, they require different resources at the respective pipeline steps.

Raster graphics are used in areas where content is rather complex, (e.g., in digital photography). When using raster graphics, image content is described by pixels arranged on a regular 2D-grid of certain *image dimension* and *precision*. Each pixel is independent from others regarding its color, which causes a quite large *file size* if using spatially extensive graphics at high precision. Thus, raster data is often stored in compressed representation (e.g., in PNG- or JPEG-format), only sometimes uncompressed (e.g., in BMP-format). The used *file format* heavily influences the time to load the content, whereby formats producing a small *file size* need generally more processing power for decoding, but are faster to read. However, the structure of the resulting IMR, mostly a bitmap, is the same, and no conversion is necessary to map the IMR to display. Nevertheless, additional modifications (e.g., for zooming operations) might influence the presentation quality.

Vector graphics use simple geometric primitives and their attributes to describe image content. Due to this principle, it is necessary that the graphical content can be appropriately described by such primitives, (e.g., in technical drawings). Content described by vector primitives is often smaller than raster data. Thus, *file size* is also smaller, and the demand for processing power while loading is little. This might not always be the case, and depends strongly on the *number* and *complexity of primitives*. In contrast to raster graphics, the IMR can be rather different for vector data. The most obvious approach is to store a description of the vector primitives and to render them directly to screen at display time (*direct drawing*). Here, the *number of primitives* and *complexity* are the main properties to consider. To achieve differently zoomed as well as panned views, a transformation matrix is preliminarily applied to primitives. By doing so, no information is lost and the visual appearance is very good. Unfortunately, this is costly in terms of processing power, especially if the *number of primitives* is large, and can be even worse if *primitive complexity* is high. To reduce these needs, it might be useful to render the whole content after decoding to an IMR-bitmap. Thus, similar results as for raster data can be achieved for display time. We refer to this approach as *indirect drawing*. Common *file formats* to store vector graphics in mobile environments are Macromedia Flash (Besley & Bhangal, 2003) and SVG (Scalable Vector Graphics) (W3C, 2001).

It has been proposed that while exploring large raster or vector graphics on mobile devices, two main requirements should be fulfilled (Rosenbaum & Tominski, 2003):

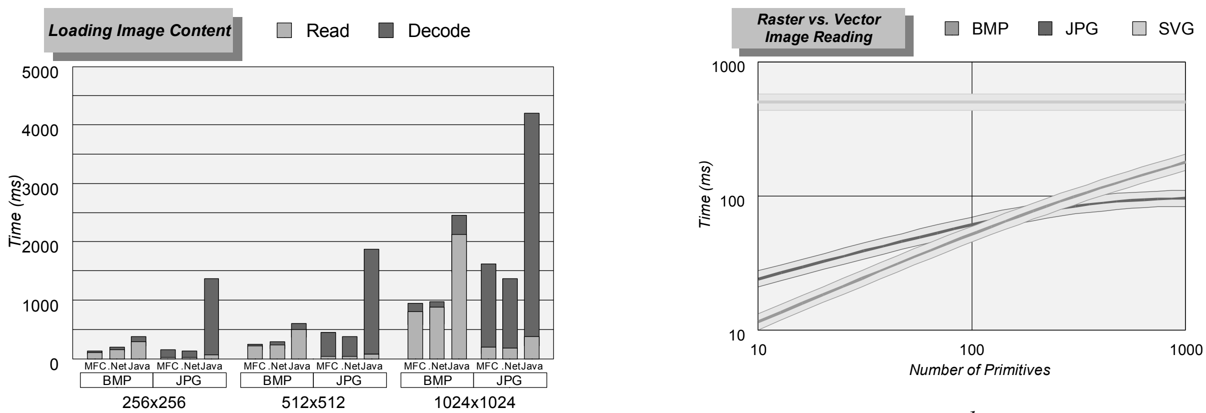
- High presentation quality
- Short presentation and update time

The degree of accomplishment of these requirements varies for raster and vector graphics, hardware capabilities, and user interaction. Regarding interaction, we constrain our statements to the elementary zoom and pan approach since more sophisticated techniques are mostly a combination of the different options offered by this method. Interaction further requires the distinction in *presentation* and *update time*. While presentation time spreads from loading until displaying, update time only considers the time to display the IMR.

MAIN DISCUSSIONS

In this section, we present results derived from our experiments with large graphical contents described by raster and vector images in m-commerce environments. The results are taken by using a modern LOOX 720 running with Pocket PC2003 and providing average performance compared to the devices listed in Table 1. To extent the applicability of the statements, we used different programming environments–MFC (Microsoft Foundation Classes), .Net Compact Framework, and Java to also consider their rather varying performance. *Presentation quality*, *presentation time*, and *update time* are the key points we are focusing on.

Figure 1. (a) Loading time of graphical content using raster images of different dimension and format, and (b) Pure reading time of vector and raster images with varying content.



b.

a.

Presentation Quality

A high presentation quality is mandatory for creating successful m-commerce applications. Such high quality representations can be achieved if the graphical content can be rendered to the display without loss of information.

For raster graphics some loss of information occurs if content must be scaled, (e.g., for zooming). If so, we got the worst results if build-in system functions were used. Especially when downscaling, pixels are simply omitted without regarding their color. Better results can be achieved by using the more complex filtered scaling, which on the other hand strains the computational abilities of the mobile device.

In case of vector graphics, panning and scaling operations are lossless (i.e., do not cause loss of information). However, there is a slight decrease in quality due to the rasterization necessary to map primitives to IMR/screen. This might be reduced by using anti-aliasing techniques, which again come at a computational cost.

Presentation and Update Time

Fast access to graphical information is another issue in m-commerce applications. Before presenting an image it must be loaded and mapped to IMR. To meaningfully compare raster graphics, examples of different *image dimension* were selected. As shown in Figure 1(a), loading time increases linearly with *image dimension*. Since the used *image format* does strongly influence processing time, we measured properties of BMP- and JPEG-images. JPEG-encoded images are much smaller than BMP-images, and can be read more than 10 times faster. While *file size* of BMP-images depends only on *image dimension*, it might vary for JPEG-images. If image content changes, compression ratio and *file size* are influenced, which also affects the time to read the image (Figure 1b).

To evaluate loading time, decoding of image content must also be considered. Since image content in BMP-files is stored uncompressed, no additional efforts are necessary. Not surprisingly, JPEG-images need significantly more time for decompression than for reading. Thus, loading time for JPEG-images increases dramatically and is, in overall, higher than for BMP-images. As shown in Figure 1a the testbed implementations based on MFC and .Net achieve similar results and outperform Java by a factor of about two.

For vector images, it is more difficult to derive statements regarding loading time. While for raster images creating an IMR is straightforward, vector images must be parsed and analyzed. Here, loading time depends even stronger on the used *file format*. If using Macromedia Flash, which is based on an optimized and even compressed binary description, files are fast to read. Contrary, SVG is based on XML grammar, and thus *file size* is bigger and processing the content is more expensive. Hence, loading SVG-files is innately slower than loading Flash. Due to the absence of a freely available SDK for accessing Flash-files, we restricted our measurements to the reading of SVG-files (Figure 1b). As assumed, reading time is highly correlated with the *number of primitives*.

As shown in Figure 1b, the time to load raster graphics is only loosely coupled with the content. Contrary, loading vector graphics depends strongly on the *number of primitives*. Thus, if only a few primitives are processed, vector graphics are faster to read than raster graphics. The break-even in our example is reached by using slightly more than 150 primitives. The concrete value also de-

Figure 2. Direct drawing of vector primitives with different complexity

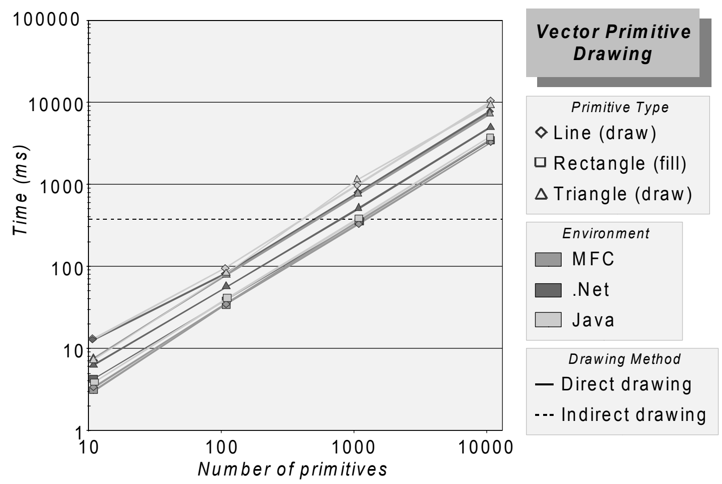


Figure 3. Performance of scaling operations for (a) raster- and (b) vector graphics

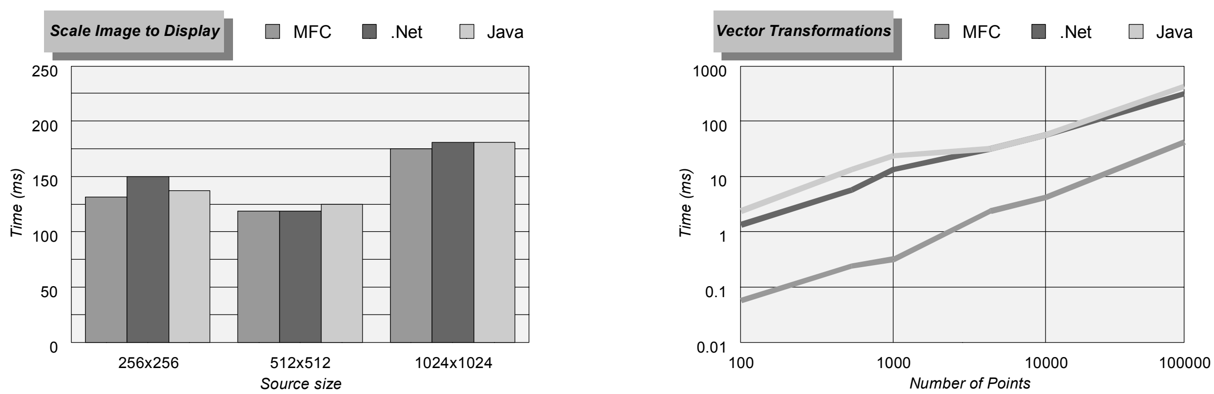

a. *b.*

pends on *primitive complexity*. If more or complex primitives are needed to describe the content, (e.g., to build a texture), better results are achieved by using raster data.

When the content is available in IMR, it can be shown on screen. As described above, the IMR of raster data can be rendered directly to display. Thus, update time mainly depends on *screen resolution*. For the handheld used, processing takes approximately 130ms in all tested environments. This update time stays constant even if *image dimension* exceeds *screen resolution*. Obviously, if *image dimension* is lower than *screen resolution*, a faster update time can be achieved. This also applies for *indirect drawing* of vector data, where only the IMR-bitmap must be transferred to screen (Figure 2). Thus, the same fast update times can be achieved. Since all primitives have already been drawn to the IMR-bitmap and been discarded, update time is completely independent from *primitives complexity*.

To simulate common applications for *direct drawing* of vector images, we measured the display time of several types of graphical primitives. As shown in Figure 2, update time increases depending on *primitive number* and *complexity*, whereby drawing triangles takes the most time. There are also differences depending on the used programming environment. Here, MFC performs best in most of the tests, but the advantage over .Net is often marginal. Contrary, Java is up to twice as slow.

Regarding an interactive exploration using zoom and pan, we examined how panning and different scaling operations affect update times. Since for panning simply a different image part is shown, there is no difference regarding update time for raster data. However, zooming is different and time to transform the content depends heavily on *image dimension* and *screen resolution.* To show this, we measured the time required to scale images of different *image dimension* to *screen resolution* (Figure 3a). Surprisingly, all programming environments achieve similar results. Nevertheless, more complex scaling techniques are slower than straightforward approaches.

Panning and zooming for vector primitives is realized by using a transformation matrix. In order to compare scaling, we measured how long such matrix multiplications take. This depends especially on *primitive number*, respectively points. If more points must be transformed, it takes more time to process them. As shown in Figure 3b, integer vector transformations can be computed rather fast on mobile devices. As expected, calculations in double precision are much slower. The fastest transformations are achieved by the MFC-implementation.

FUTURE TRENDS

The mobile sector is subject to rapid development of the belonging hardware. Thus, computational power of mobile devices will also increase and the application area of vector graphics will surely expand. The inclusion of additional GPUs in current devices seems to back this outlook. Furthermore, more sophisticated compression approaches for raster images, as JPEG2000, require more computing power to be processed. Nevertheless, they provide better performance, and even more interesting, many additional features for interactive imaging (Rosenbaum & Schumann, 2005). Thus, our conclusions given in the next section might still be valid for the near future.

CONCLUSION

Summarizing, we stated the properties of current mobile hardware to show still existing limitations of such devices. This gave us the motivation to review the displaying pipeline together with important properties of vector and raster data in order to derive statements for an appropriate handling of graphical content in such environments. Based on this, concrete tests and comparisons have been conducted and lead to the following statements when to use raster or vector data in m-commerce applications:

- **Graphics loading**
  - Loading time depends strongly on the used file format.
  - Loading raster data is generally fast but requires additional computational efforts if content must be decompressed.
  - Loading vector data is fast for up to about 150 primitives.
- **Graphics rendering**
  - Drawing raster data is fast on mobile devices.
  - Rendering vector primitives directly to display is generally slow and depends on primitive number and complexity.
  - Rendering vector primitives indirectly using an IMR-bitmap achieves fast update times.
- **Quality**
  - Simple scaling of raster data is fast but leads to low quality presentations.
  - Scaling vector graphics by integer matrix multiplications is very fast and achieves high quality.
- **Development environment**
  - Implementations based on MFC are fastest.
  - .Net and Java implementations often achieve a similar performance

Our claim was also to answer in which circumstances raster or vector data are more suitable for presentation of large graphical contents on mobile devices. We found that both classes have their eligibility depending on the content and external demands, like quality vs. response time. In case of simple graphics, which can be described by less than 150 primitives, vector graphics performed best. Vector graphics also offer better quality than raster graphics. On the other hand, our measures show that raster graphics are better suited if large and complex graphics must be presented, since their system requirements are content independent. They are simply not as complex as vector graphics, and thus, easier to handle. Due to this, they fit to current mobile hardware, and we favor raster graphics to describe graphical content in such environments.

KEY TERMS

Displaying Pipeline: Collective term for the different stages which must be passed to show *graphical content* on screen.

Graphical Content: Information represented by an image, perceived via the human visual system.

Image Format: Used to permanently store *graphical content*, based on the use of *raster graphics* or *vector graphics.*

Limitations (of *Mobile Devices*): Hardware restrictions mostly imposed by the application area, main limitations are processing power, screen dimensions and transmission bandwidth.

Mobile Devices: Gadgets not needed to be attached for a certain place, mostly subject to certain *limitations.*

Raster Graphics: Approach for the description of *graphical content* by color points arranged on a regular pixel grid.

Update Time: Time necessary to draw *graphical content* to display, the update step is part of the *displaying pipeline.*

Vector Graphics: Approach for the description of *graphical content* by *vector primitives.*

Vector Primitive: Geometrical object with certain properties, mostly belonging to one of the basic classes: point, line, or triangle.

High Availability and Data Consistency for Three-Tier Enterprise Applications

Wenbing Zhao
Cleveland State University, USA

Louise E. Moser
University of California, Santa Barbara, USA

P. Michael Melliar-Smith
University of California, Santa Barbara, USA

INTRODUCTION

Enterprise applications, such as those for e-commerce and e-government, are becoming more and more critical to our economy and society. Such applications need to provide continuous service, 24 hours a day, 7 days a week. Any disruption in service, including both planned and unplanned downtime, can result in negative financial and social effects. Consequently, high availability and data consistency are critically important for enterprise applications.

Enterprise applications are typically implemented as three-tier applications. A three-tier application consists of clients in the front tier, servers that perform the business logic processing in the middle tier, and database systems that store the application data in the backend tier, as shown in Figure 1.

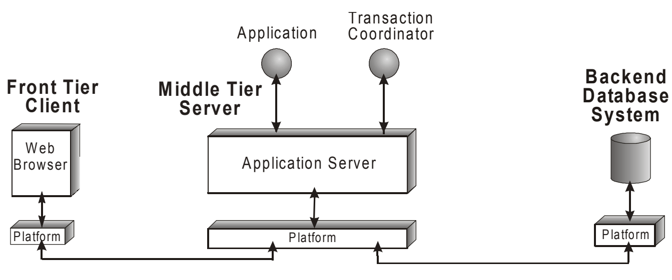
Within the middle tier, a server application typically uses a transaction processing programming model. When a server application receives a client's request, it initiates one or more transactions, which often are distributed transactions. When it finishes processing the request, the server application commits the transaction, stores the resulting state in the backend database, and returns the result to the client.

A fault in the middle tier might cause the abort of a transaction and/or prevent the client from knowing the outcome of the transaction. A fault in the backend tier has similar consequences. In some cases, the problems can be a lot worse. For example, a software design fault, or an inappropriate heuristic decision, might introduce inconsistency in the data stored in the database, which can take a long time to fix.

Two alternative recovery strategies, namely roll-backward and roll-forward, can be employed to tolerate and recover from a fault. In roll-backward recovery, the state of the application that has been modified by a set of unfinished operations is reversed by restoring it to a previous consistent state. This strategy is used in transaction processing systems. In roll-forward recovery, critical components, processes, or objects are replicated on multiple computers so that if one of the replicas fails, the other replicas continue to provide service, which enables the system to advance despite the fault. Many applications that require continuous availability take the roll-forward approach. Replication is commonly employed in the backend tier to increase the reliability of the database system.

There has been intense research (Frolund & Guerraoui, 2002; Zhao, Moser, & Melliar-Smith, 2005a) on the seamless integration of the roll-backward and roll-forward strategies in software infrastructures for three-tier enterprise applications, to achieve high availability and data consistency. *High availability* is a measure of the uptime

Figure 1. A three-tier enterprise application



of a system, and typically means five nines (99.999%) or better, which corresponds to 5.25 minutes of planned and unplanned downtime per year. *Data consistency* means that the application state stored in the database remains consistent after a transaction commits. Both transactions and replication require consistency, as the applications execute operations that change their states. Transactions require data consistency, and replication requires replica consistency.

BACKGROUND

Transaction Processing

A transaction is a set of operations on the application state (Gray & Reuter, 1993) that exhibit the following ACID properties:

- **Atomicity:** Either all the operations succeed in which case the transaction commits, or none of the operations is carried out in which case the transaction aborts.
- **Consistency:** If the application state is consistent at the beginning of a transaction, the application state remains consistent after the transaction commits.
- **Isolation:** One transaction does not read or overwrite intermediate results produced by another transaction—that is, the transactions appear to execute serially.
- **Durability:** The updates to the application state become permanent (or persist) once the transaction is committed, even if a fault occurs.

A transaction processing (TP) system typically consists of a TP monitor, communication channels, database servers, operating systems, and applications. A TP monitor provides tools, mechanisms, and application programming interfaces (APIs) to ease or automate the application programming, execution, and administration of the transactions.

When a transaction involves operations on more than one computer, it is called a *distributed transaction*. In a distributed transaction, an atomic commit protocol is necessary, so that the ACID properties hold for the state at all of the computers involved in the transaction. The most popular atomic commit protocol is the two-phase commit (2PC) protocol.

The 2PC protocol involves a transaction coordinator, which drives the protocol, and one or more transaction participants, which control the application state to be persisted. The 2PC protocol involves two phases of message passing. In the first phase, the coordinator sends a request to *prepare* to all of the participants. If a participant can successfully write its update to persistent storage, so that it can perform the update even in the presence of a fault, the participant responds to the coordinator with a "Yes" vote. At this point, the participant is *prepared*. If the coordinator collects "Yes" votes from all of the participants, it decides to *commit* the transaction. If the coordinator receives even a single "No" vote, or if a participant does not respond and is timed out, the coordinator decides to *abort* the transaction. In the second phase, the coordinator *notifies* the participants of its decision. Each participant then either commits or aborts the transaction locally and sends an acknowledgment to the coordinator. The coordinator can *forget* the transaction once it receives acknowledgments from all of the participants in the second phase.

Because of its simplicity and efficiency under fault-free conditions, the 2PC protocol has been adopted as the atomic commit protocol for many distributed transaction processing specifications, including the XOpen/XA specification (The Open Group, 1992) and the CORBA OTS specification (Object Management Group, 2000). The 2PC protocol is used by essentially every commercial TP monitor and database server for distributed transaction coordination within a single enterprise.

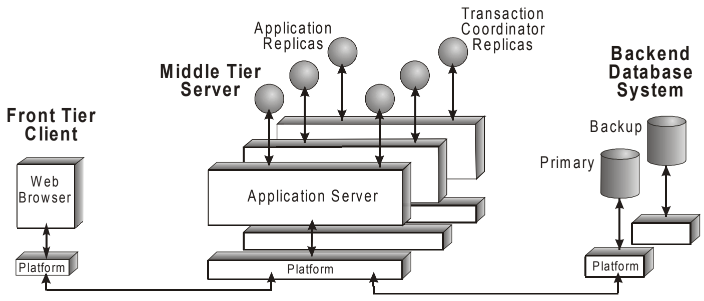
Replication

Component, process, or object replication, based on the virtual synchrony model (Birman & van Renesse, 1994) is often regarded as orthogonal to transaction processing. Critical components of a distributed system are replicated to achieve the required reliability and availability, so that the failure of one of the replicas will not bring down the entire system.

Active replication, passive replication, and semi-active replication are the most common replication strategies, which are defined as follows (Powell, 1991):

- **Active Replication:** All replicas perform exactly the same actions in the same order and output their results.
- **Passive Replication:** Only one replica (the primary) executes in response to the client's requests. Passive replication has two variations: warm passive replication and cold passive replication. In warm passive replication, the primary periodically checkpoints its state at the other executing replicas (the backups). In cold passive replication, the backups are not launched until the primary is detected to have failed.
- **Semi-Active Replication:** Semi-active replication is a hybrid of the active and passive replication strat-

Figure 2. The use of both replication and transaction processing for three-tier enterprise applications



egies. In semi-active replication, both the primary and the backup replicas execute the operations, but the backups follow the directives of the primary, and only the primary outputs the results.

To provide a single copy image to the other components in the distributed system, and to maintain replica consistency, systems that provide replication use a fault tolerance infrastructure to manage the replicated objects. The most challenging aspect of replication-based fault tolerance is maintaining replica consistency (Narasimhan, Moser, & Melliar-Smith, 2002), as methods are invoked on the replicas, as the states of the replicas change, and as faults occur. The basic strategy for maintaining replica consistency is to start the replicas in the same state and to ensure that they perform the same operations in the same order. In such a fault tolerance infrastructure, a multicast group communication system (Melliar-Smith & Moser, 1999) is typically used to provide reliable totally ordered multicasting of messages and group membership services.

THREE-TIER ENTERPRISE APPLICATIONS

To provide high availability and data consistency for three-tier enterprise applications by integrating replication and transaction processing, one must consider the client tier, the middle tier containing the server applications, and the backend tier containing the database system, which are discussed below. The use of both replication and transaction processing for three-tier enterprise applications is shown in Figure 2.

The Client Tier

The client tier of a three-tier enterprise application typically consists of Web browsers and is notoriously unreliable. A Web browser might freeze or crash unexpectedly due to software bugs in the browser or in the operating system on which the browser runs. The user of a Web browser might decide to quit without giving appropriate notice to the server. In addition, the network connection between the client tier and the server in the middle tier might break unexpectedly.

Developers of enterprise applications have been well aware of these problems and have often incorporated specific solutions into their applications. From the server's point of view, there are two concerns. First, valuable server-side resources should not be wasted if the client crashes, or becomes inactive, or quits. Second, service should be provided to the clients, preferably with exactly-once semantics, even if the client fails briefly, as long as it can recover later.

The first concern is typically addressed by creating a session each time a client logs in and by keeping the session open only while the client is active. When the session is closed, all server-side resources, such as database connections, are garbage-collected or reused by other clients' sessions.

The second concern is often addressed by using a technique called "cookies." A cookie is a small string that is generated by a Web server as a byproduct of a client's request, sent with the server's response to the client, and stored at the client's computer, usually in a separate file. Later requests from the same client to the same server carry the cookies created earlier, so that the server can recognize the client. Sometimes, cookies can be used to detect duplicate requests to the server. For example, a cookie can be generated by a Web server immediately before a client initiates an online payment. If for any reason the client retries the online payment, the same cookie would be used by the client's requests. The server can easily recognize this by storing the cookie with the first online payment request and by comparing the cookie in the duplicate request with the one it stored. If the server cannot guarantee exactly-once semantics, the server should provide enough information to the client, so that the client can determine if an earlier attempt succeeded.

The Middle Tier

The middle-tier server applications interact with the clients directly and execute according to predetermined application business logic. Therefore, it is important to provide fault tolerance in the middle tier.

For large enterprise applications, a transaction often spans several database systems, which requires the middle tier to run transaction monitoring middleware to coordinate the commitment of distributed transactions. Typically, the 2PC protocol is used for distributed transaction coordination within a single enterprise. The 2PC protocol is a blocking protocol in that the transaction participants might be blocked for an extended period of time waiting to commit or abort a transaction, if the transaction coordinator is temporarily inaccessible. Although practical implementations of the 2PC protocol allow a participant to make heuristic decisions regarding the outcome of a transaction, continued processing without waiting for the coordinator to recover can compromise the consistency of the data. In principle, such inconsistencies can be addressed by the applications; however, application-specific solutions are usually provided in ad-hoc manners and are expensive to design, implement, and maintain. Several non-blocking commit protocols have been developed (Skeen, 1981). Very few of them, if any, have been incorporated into commercial TP systems because of excessive complexity and high overhead.

An enterprise application can benefit in several ways if replication is incorporated into the middle tier.

- By replicating the application objects, a fault in an application object is masked so that the ongoing transactions in which the object is involved are not aborted, and thus, the probability of committing a transaction is increased.
- By replicating the transaction coordinator, a fault in the transaction coordinator does not roll back or block a transaction, thus avoiding typical problems involved with the use of the 2PC protocol.
- In some cases, such as deadlock avoidance, a transaction must be aborted. A fault tolerance infrastructure, if properly designed, can automatically retry the aborted transaction using message logs, checkpoints, and message replay. This retry further reduces the probability of propagating the effects of an aborted transaction to a client.

There are two aspects that one must address in building a fault tolerance infrastructure that provides both high availability and data consistency, replication, and recovery.

Replication

To ensure replica consistency, it is necessary that incoming messages are delivered to each replica reliably in the same order. This requirement is typically achieved by using a multicast group communication protocol (Melliar-Smith & Moser, 1999) that ensures virtual synchrony (Birman & van Renesse, 1994). Without virtual synchrony, requests might be delivered more than once and, if a fault occurs, some requests might not be delivered at all.

In addition to the message ordering requirement, other sources of replica non-determinism must be masked or sanitized by the fault tolerance infrastructure, particularly for stateful replicas. Examples of other sources of replica non-determinism are multithreading and clock-related operations.

A fault tolerance infrastructure that provides both high availability and data consistency replicates both the application objects and the transaction coordinator of the TP monitor in the middle tier. Protecting the application objects against faults, by replication, reduces the risk that a transaction is aborted if the application objects fail. Similarly, protecting the transaction coordinator against faults, by replication, reduces the risk that a transaction becomes blocked if the coordinator fails.

Even though the application objects can be made largely stateless by recording all important state in the database in the backend tier, the transaction coordinator is intrinsically stateful—that is, it generates unique identifiers for new transactions and it keeps track of the state of ongoing transactions. For each transaction, the transaction coordinator writes its decision to commit or abort a transaction to stable storage when it has received acknowledgments from all of the other coordinator replicas that they have received “Yes” votes from all of the participants. To ensure that the persistent data are not compromised by replication of the transaction coordinator, the disk-write operations carried out by the replicas of the coordinator must be synchronized.

In principle, a uniform reliable totally ordered multicast group communication protocol (Schiper & Sandoz, 1993) should be used for replica synchronization and recovery when there are visible side effects of operations resulting from message delivery, such as disk-write operations. However, a uniform reliable totally ordered multicast significantly impacts the latency of message delivery and, therefore, functionally similar synchronization mechanisms are often used. A drawback of the latter approach is that it is necessary to identify the places where such synchronization mechanisms are needed, and to design and implement those mechanisms.

Recovery

Recovery includes incorporating a new replica into the system and restarting a replica that failed. In a replicated transaction processing system, it is desirable to retry an aborted transaction automatically, as a way to recover the system in a consistent manner using the roll-forward recovery strategy.

The recovery is made possible by periodically checkpointing the state of a replica and logging incoming messages. A checkpoint of a replica can also be taken on demand. When a new or restarted replica is introduced into the system, the infrastructure determines a synchronization point after which new incoming messages are logged at the new or restarted replica. The most recent checkpoint and the logged messages before the synchronization point are transferred to the new or restarted replica. The checkpoint is then applied to the new or restarted replica and the logged messages are replayed to bring the replica up to date.

When the infrastructure becomes aware that a transaction has been aborted, it sends a notification to all of the participants in the transaction (including the initiator). Then the infrastructure resets the states of the application objects involved in the aborted transaction by applying the most recent checkpoints and replaying the logged messages up to, but not including, the message that took the objects into the transaction. It discards the logged messages within the aborted transaction. Finally, the infrastructure replays the message that initiated the transaction at the initiator.

The Backend Tier

Replication has long been used in database systems to improve reliability and availability. Early studies have shown that traditional replication techniques where updates are propagated from the primary to the backups *before* a transaction is committed (often termed *eager replication*) are too expensive and prone to deadlock when used in database systems (Gray & Reuter, 1993).

Consequently, commercial database systems make a tradeoff that compromises correctness and consistency of replication to achieve better performance (Vaysburd, 1999). A typical approach is to commit transactions at the primary without delay and then asynchronously transfer the transaction log from the primary to the backups (often termed *lazy replication*). If the primary fails, a backup will take over (termed *failover*). However, the most recently committed transactions might be lost during the failover. Moreover, the old primary and the new primary might make incompatible decisions. Reconciliation of those committed conflicting transactions typically require manual intervention.

Recent results suggest that eager database replication that uses an efficient reliable totally ordered multicast protocol (Kemme & Alonso, 2000) might be a more promising approach for achieving high availability and data consistency without compromising either consistency or efficiency.

FUTURE TRENDS

Existing transactional database systems are easy to use and very effective within a single enterprise. Many enterprise applications, however, span multiple enterprises. Transaction processing systems include protocols to allow distributed transactions and two-phase commit across multiple enterprises. Those protocols are, however, almost never used, because they impose a risk that a fault in one enterprise can block activities in another enterprise and can render data inaccessible.

Instead, transactions are strictly local, and compensating transactions (Garcia-Molina & Salem, 1987) are created to undo the effects of committed transactions. If a transaction in one enterprise aborts, compensating transactions are invoked to undo corresponding activities in other enterprises. Unfortunately, compensating transactions are highly application specific, and are difficult to program and test.

An alternative strategy for the future (Zhao et al., 2005b) involves strictly local transactions and roll-backward recovery to maintain data consistency, and replication and roll-forward recovery for communication between enterprises to maintain high availability and data consistency. This strategy avoids the use of compensating transactions by employing a reservation-based extended transaction protocol that coordinates business activities. Each task within a business activity involves two steps, where each step executes as a separate traditional short-running transaction. The first step involves an explicit reservation of resources. The second step involves the confirmation or cancellation of the reservation. As distributed applications that span multiple enterprises become more widespread, such strategies will become more important.

CONCLUSION

High availability and data consistency are essential for enterprise applications, particularly for e-commerce and e-government. Such enterprise applications must be continuously available to their clients, and should strive to ensure exactly once invocation semantics. Providing high availability and data consistency involves careful design and programming of the applications, replication of critical components (namely, the transaction coordinator and stateful application objects of the middle-tier servers), and replication of the backend database systems.

KEY TERMS

Data Consistency: When the application state stored in the database remains consistent after a transaction commits.

Fault Tolerance: The ability to provide continuous service, even in the presence of faults, using replication, or redundancy, to mask faults.

High Availability (HA): A measure of the uptime of a system; typically means five nines (99.999%) or better, which corresponds to 5.25 minutes of planned and unplanned downtime per year.

Multicast Group Communication Protocol: Provides reliable totally ordered delivery of messages that are multicast to all replicas of a component, process, or object.

Recovery (Roll-Backward, Roll-Forward): Recovery includes incorporating a new replica into the system and restarting a replica that failed. With roll-backward recovery, the state of the application that has been modified by a set of unfinished operations is reversed by restoring it to a previous consistent value. With roll-forward recovery, critical components, processes, or objects are replicated on multiple computers so that if one of the replicas fails, the other replicas continue to provide service, which enables the system to advance despite faults.

Replication (Active, Passive, Semi-Active): With replication, multiple copies of an application program execute as multiple components, processes, or objects on different computers. In active replication, all of the replicas execute the operations and output their results. In passive replication, only one replica, the primary replica, executes the operations, and one or more backups stand ready to perform the operations if the primary fails. In semi-active replication, both the primary and the backup replicas execute the operations, but the backups follow the directives of the primary, and only the primary outputs the results.

Three-Tier Application: Consists of clients in the front tier, servers that perform the application business logic processing in the middle tier, and databases that store the application data in the backend tier.

Transaction Processing: An application programming paradigm that is based on the notion of a transaction. A transaction is a set of operations on the application state that exhibit the atomicity, consistency, isolation, and durability (ACID) properties.

Two-Phase Commit (2PC) Protocol: The most popular atomic commit protocol; it is so named because it involves two phases of message passing, a transaction coordinator, which drives the protocol, and one or more transaction participants, which control the application state to be persisted.

History of E-Commerce

Yan Tian

Temple University, USA

INTRODUCTION

E-commerce or electronic commerce, also known as e-business, refers to the transaction of goods and services through electronic communications. Although the general public has become familiar with e-commerce only in the last decade or so, e-commerce has actually been around for over 30 years. There are two basic types of e-commerce: business-to-business (B2B) and business-to-consumer (B2C). In B2B, companies conduct business with their suppliers, distributors, and other partners through electronic networks. In B2C, companies sell products and services to consumers. Although B2C is the better known to the general public, B2B is the form that actually dominates e-commerce in terms of revenue.[1]

The concept of e-commerce is related to notions of Internet economy and digital economy. All these concepts relate to the use of new information and communication technologies for economic activities, but with different focuses. Internet economy refers to the economic activities that generate revenue from the Internet or Internet-related products or services (Costa, 2001). Therefore, pre-Internet e-commerce, as will be detailed in the following section, cannot be called Internet economy. On the other hand, some activities, such as building Internet connections for commercial purposes, are a part of Internet economy, but they are not necessarily e-commerce. Digital economy is based on digital technologies such as computer, software, and digital networks. In most cases, digital economy is the same as e-commerce. However, not all activities in the digital economy are e-commerce activities. For example, purchasing computer gear from a storefront retailer is not an activity of e-commerce, although it certainly is a key component of the digital economy. Hence, e-commerce, Internet economy, and digital economy are closely related but have different concepts.

E-commerce has been perhaps one of the most prevalent terms in this digital era. Although e-commerce was once looked upon simply as an expressway to wealth, it has actually transformed the way people conduct business. An historical analysis of e-commerce will provide insights into the evolution of the application of information and communication technologies in the commercial arena. Furthermore, an analysis of the evolution of e-commerce in the past as well as its present state will enable us to project future trends in e-commerce.

THE INFANCY OF E-COMMERCE: BEFORE 1995

E-commerce was made possible by the development of electronic data interchange (EDI), the exchange of business documents from one computer to another in a standard format. EDI originated in the mid-1960s, when companies in transportation and some retail industries were attempting to create "paperless" offices. In the mid-1970s, EDI was formalized by the Accredited Standards Committee of industry representatives, and more varied companies began to adopt EDI through the 1970s and 1980s. As the first generation of e-commerce, EDI allowed companies to exchange information, place orders, and conduct electronic funds transfer through computers (Sawanibi, 2001). However, the diffusion of EDI was slow. By the late 1990s, less than one percent of companies in Europe and in the United States had adopted EDI (Timmers, 1999). The huge expense for getting connected to an EDI network and some technical problems limited the diffusion of EDI.

The second generation of e-commerce is characterized by the transaction of goods and services through the Internet, which started as a research tool, but has generally evolved into a commercial tool. The inception of the Internet can be traced back to the 1960s, when the Advanced Research Projects Agency Computer Network (ARPANET), the precursor to the Internet, was established for research in high technology areas. The nodes of ARPANET increased from 4 in 1969 to 15 in 1971. The term *Internet* actually did not come into use until 1982, when the number of hosts on the ARPANET rose to 213. Then, in 1983, the Internet Protocol (IP) became the only approved way to transmit data on the Net, enabling all computers to exchange information equally. In 1986, the National Science Foundation (NSF), a government agency, launched the NSFNET, with the purpose of providing high-speed communication links between major supercomputer centers across the United States. The backbone of the NSFNET then became the cornerstone of the TCP/IP-based Internet (Anthes, 1994).

By the end of the 1980s, the Internet had still maintained its noncommercial nature, and all of its networks were based on the free use of the NSFNET backbone, directly or indirectly. The primary users were still scientists and engineers working for the government or for universities. As a matter of fact, academics or researchers were the only ones capable of using the Internet, because a sophisticated understanding of computer science and a high level of computer skills were necessary for Internet use at that time (Eccleson, 1999).

It was the development of a graphical user interface (GUI) and the navigability of the World Wide Web (WWW) that changed the nature of Internet use. In the early 1990s, the creation of the hypertext markup language (HTML), with specifications for uniform resource locators (URLs) enabled the Web to evolve into the environment that we know today. The Internet was therefore taken "out of the realm of technical mystique and into common usage" as it became usable for ordinary people without sophisticated understanding of computer science and techniques (Eccleson, 1999, p. 70). Hence, with the increasing number of Internet users, the Internet became attractive to the business world.

Perhaps the most significant milestone, however, came in 1991, when NSFNET decided to lift commercial restrictions on the use of the network, and thereby opened up opportunities for e-commerce. Advanced Network & Services (ANS), established by IBM, MCI Communications Corp., and Merit Network, Inc., provided Internet connection to commercial users without government restrictions on commercial traffic online. In addition, a portion of the money from these commercial applications was used to upgrade the network infrastructure. In 1993, Mosaic, one of the first Internet browsers, was released, and with Mosaic's graphical interface and rapid proliferation, the Internet became more user-friendly and visually appealing. One year later, Netscape released its Navigator browser, hand in so doing ushered in the golden age of e-commerce.

THE "GOLDEN AGE" OF E-COMMERCE: FROM 1995 TO 1999

In 1995, ANS was sold to America Online, which marked "a transition of backbone infrastructure from federal funding to full private commercialization operation of the Internet" (Kim, 1998, p. 283). With NSF's subsidy removed, private companies took a leading role on the Internet (Kim, 1998). Commercial use of the Internet gradually became the dominant pattern of Internet use in the mid-1990s. The term *e-commerce* came into popular use in 1995, signifying the rapid development of commercial applications of the Internet.

Also in 1995, Amazon.com, the world's largest online bookstore, was launched. Just 1 year later, it became a multimillion dollar business with a database of 1.1 million books searchable by title, author, subject, or keyword, and favored by both publishers and customers. Two months after Amazon's debut, eBay, the world's first online auction site, was launched. In 1996, Dell began to sell personal computers directly to consumers on the Internet and, in 1997, the commercial domain (.com) replaced the educational domain (.edu) as the largest in use (Kim, 1998). The Internet became the fastest growing technology in economic history. Investors, businesses, and consumers alike were attracted by e-commerce during that period.

From 1995 to 1999, many companies built their Web presence and began to conduct transactions online. In 1996, e-commerce transactions in the United States resulted in $707 million in revenue, which increased to $2.6 billion in 1997, and $5.8 billion in 1998 (Fellenstein & Wood, pp. 9-10). From October 1998 to April 2000, more than 300 Internet companies made initial public offerings (IPOs; Cassidy, 2002, p. 192). There were approximately 600,000 e-commerce sites in the United States by the end of 2000 (Dholakia et al., 2002, p. 5). Advertising on the Internet also increased from $267 million in 1996 to $907 million in 1997 and to $3 billion in 1999. The sales of Amazon increased from less than $16 million in 1996 to $1.6 billion in 1999, and the daily sales of Dell increased from under $1 million to $40 million in less than 3 years (Costa, 2001, p. 34).

The growth of e-commerce coincided with the changes in the regulation of the Internet. Throughout the mid-1980s to 1995, the Internet's main backbone was comprised by the NSFnet, a wide-area network developed under the auspices of the National Science Foundation (NSF). NSFnet replaced ARPANET as the main government network linking universities and research facilities. In 1995, however, the NSF dismantled NSFnet and replaced it with a commercial Internet backbone. In that process, the National Science Foundation (NSF) decided to award a monopoly contract to a partnership between the Information Sciences Institute (ISI) and Network Solutions, Inc., to operate IP numbers and domain registration services from 1992 to 1997. At the same time, the NSF implemented a new backbone called very high-speed Backbone Network Service (vBNS), which served as a testing ground for the next generation of Internet technologies.

In 1996, a blue ribbon international panel formed by the Internet Society (ISOC) took over the root server, which is a domain name system (DNS) name server that points to all the top-level domains, and the International Ad Hoc Committee (IAHC) was charted with a plan to form a monopoly registry administration of the DNS on a nonprofit basis. While DNS was looked at as "public resource" by some researchers then (Par, 2003, p. 131), others believed that multiple, competing groups co-owned this resource (Mueller, 1999). In 1997, as the NSF decided to terminate its contract with Network Solutions, the IAHC collapsed.

With the increasing pressure of commercial interests over trademark "squatting," (Par, 2003, p. 131), the U.S. Department of Commerce issued the White Paper in 1997 to transfer the management of the DNS to a new private, not-for-profit corporation. In 1998 the Internet Corporation for Assigned Names and Numbers (ICANN) was formed, which represented a "substantial shift in power to control the Internet from government to private industry" (Fuller, 2001). ICANN made decisions such as allowing more competition among registrars and instituting mandatory arbitration for trademark claims during its first two years of life, which had a significant impact on the development of e-commerce during that period.

THE BURST OF THE DOT-COM BUBBLE: 2000 AND 2001

The "gold rush" of the late 1990s came to be known as the "dot-com bubble," and 2000 and 2001 saw the bursting of that bubble. From March 10 to April 14, 2000, the NASDAQ, the high-tech stock exchange, dropped 34.2%, and the Dow Jones Composite Internet Index dropped 53.6%. The stock price for all the 20 leading Internet stocks dropped, including Amazon.com by 29.9%, eBay by 27.9%, Internet Capital by 72.1%, and VeriSign by 59.2% (Cassidy, 2002, pp. 292-293). This crash quickly cooled the e-commerce frenzy. Many Internet companies were forced to cancel their IPOs, and companies such as Boo.com and Value America had to file for bankruptcy (Cassidy, 2002). According to the *Fortune* magazine, 384 dot-coms "passed on" in 2001 (Adams, 2004, p. 105). In the San Francisco Bay Area, 80% of dot-coms went out of business in 2000 and 2001, which led to a loss of 30,000 jobs directly related to the Internet (Nevaer, 2002, p. xii).

The dot-com crash in 2000 and 2001 has been attributed to the unrealistic expectations for e-commerce and Internet companies. The stocks for Internet companies were overvalued. Exaggerated projections by Silicon Valley, Wall Street, journalists, and government officers all contributed to the inflation of the dot-com bubble. The bubble finally burst, which meant decreases in investment, a slow-down in economic and productivity growth, and decreasing corporate revenues (Cassidy, 2002).

Ironically, despite the bankruptcy of many Internet companies, e-commerce sales actually increased in the year 2000 and 2001. According to the Department of Commerce (2001), estimated retail e-commerce sales in the fourth quarter of 1999 were $5.27 billion, increasing to $8.88 billion in the fourth quarter of 2000 and to $10.04 billion in the fourth quarter of 2001. The estimated total e-commerce sales for 2001 were $32.6 billion, a 19.3% increase compared with the total e-commerce sales for 2000. The increase of e-commerce sales during the dot-com crash suggests that although e-commerce and Internet companies may have been overvalued in the 1990s, e-commerce itself was still viable and growing.

THE RESURGENCE OF E-COMMERCE: 2002 TO THE PRESENT

E-commerce continued to grow after the burst of the dot-com bubble. Some Internet companies that survived the 2000 and 2001 crash have become very successful. For example, Amazon.com has won some of highest customer satisfaction scores in the history of retail industry. eBay has significant sales in second-hand cars, which were once looked upon as inappropriate commodities for online transactions. Wal-Mart, the world's largest storefront retailer, conducts all the business with suppliers through a B2B network (*The Economist,* 2004). Estimated total e-commerce sales reached $45.6 million for 2002 and $54.9 billion for 2003 (Department of Commerce, 2002, 2003). This trend continued in 2004, with e-commerce sales for the third quarter of 2004 estimated to have increased 21.5% from the same period in 2003 (Department of Commerce, 2004).

However, e-commerce still does not represent a large proportion of the economy. E-commerce sales are less than 2% of the total sales in the United States (Department of Commerce, 2004). Although there is plenty of opportunity for growth, the development of e-commerce is limited by factors such as universal access, privacy and security concerns, and Internet fraud. These limitations must be adequately addressed to ensure strong growth in e-commerce.

With the resurgence of e-commerce, regulation of e-commerce deserves special attention. Consumer protection, user agreements, contracts, and privacy in e-commerce all present new concerns regarding regulation of commercial activities (Füstös & López, 2004), particularly as e-commerce contributes to the globalization of economic activity. For example, whereas the European

Union emphasizes consumer's rights, the United States is more focused on protecting freedom of expression and intellectual property (Füstös & López, 2004). Nevertheless, laws such as the U.S. Anticybersquatting Consumer Protection Act (ACPA) and the Electronic Signature in Global and National Commerce Act have been passed to protect the flow of commerce in cyberspace (Füstös & López, 2004; Schneider, 2004). To protect intellectual property in e-commerce, the World Intellectual Property Association (WIPO) developed the Uniform Domain Name Dispute Resolution (UNDR) polity to help settle disputes regarding domain names. In addition, organizations such as the Secure Digital Music Initiative (SDMI), with members of companies related to the information technology industry and music recording industry, are working on protecting intellectual property of digital products (Schneider, 2004).

Controversy has also emerged regarding the collection of sales-tax revenue in this new business environment. E-commerce is believed to contribute to the loss of revenue of state and local government, because states cannot effectively collect sales and use taxes on transactions through the Internet. Organizations such as the National Governors Association and National Conference of State Legislatures have been working under the Streamlined Sales and Use Tax Agreement to create a uniform system to administer and collect remote sales taxes (Government Finance Review, 2004). All of these examples illustrate the array of issues for the regulation of e-commerce. However, with the challenges e-commerce presents to traditional legal jurisdiction, privacy and security of transactions, tariffs, and taxation (Cordy, 2003), careful examination of laws and policies will be needed to assure the growth of e-commerce.

FUTURE TRENDS IN E-COMMERCE

M-commerce, or mobile commerce, is an important growth area for e-commerce. M-commerce refers to the process of using mobile devices such as mobile phones or wireless PDAs to conduct business transactions. With 1.5 billion mobile users in the world, and 140 million in the United States (Cellular Online, 2004), m-commerce is becoming a significant aspect of e-commerce. With m-commerce, the nature of mobile devices changes from pure communication tools to transactional tools. M-commerce has already found important applications in industries such as financial management, travel services, and entertainment (Schone, 2004). M-commerce will be adopted by an increasing number of industries, given its capacity to facilitate interactions between companies and consumers, create mobile virtual malls, and tailor products and services according to customers' purchasing habits in real time. It is estimated by ARC Group that approximately 546 million mobile device users will spend approximately $40 billion on m-commerce by 2007 (Schone, 2004).

The globalizing economy presents additional opportunities for e-commerce. The global Internet population is more diversified than ever before. With the rapid increase of Internet population in countries other than the United States, e-commerce on a global scale becomes necessary as well as feasible. Leading companies in e-commerce have realized this. EBay, for example, built a Chinese service, which has become the biggest e-commerce site in China (*The Economist,* 2004). Another example is Amazon.com, which hired ThinkAmerican, a "cultural portal," to translate and customize its Japanese Web pages to comport with the Japanese culture. As leading e-commerce companies in the United States are extending their business to overseas markets, e-commerce is thriving in many countries around the world. According to Forrester Research, global e-commerce would reach $6.8 trillion by 2004, with North America representing 50.9% (the United States, 47%), Asia/Pacific representing 24.3%, Europe representing 22.6%, and Latin America representing 1.2% (Global Reach, 2004). Forrester also predicted that, although the United States and North America are currently leading in online transactions, Asia and European nations would become more active in e-commerce in the coming years. With the Internet's inherent "globality," global e-commerce pushes e-commerce into its next phase.

As one of the most influential economic forms in our age, significant research will continue to focus on e-commerce. Historical and economic studies will examine the impact of the evolution of the infrastructures, technologies, strategies, and regulation of e-commerce. With the rapid development of m-commerce and global e-commerce, future research will consider implications of advancements in global telecommunications, mobile communications as well as the influence of cross-cultural content and practices.

CONCLUSION

Despite the dramatic rise and fall of Internet companies, e-commerce has demonstrated continuous growth in sales. E-commerce has significant implications for the companies and customers involved as well as society at large. For companies, e-commerce can improve efficiency and productivity. Furthermore, e-commerce allows employees to have more access to information and services, which can help to maintain a healthy corporate culture. For customers, e-commerce provides a very convenient way to transact many kinds of business 24 hours a day, 7 days a week. For society, e-commerce can help to accelerate their economic growth and opportunities, but at the same time may pose challenges and concerns in terms of surveillance and privacy.

The burst of the dot-com bubble may actually have brought about a more rational and sustainable approach to e-commerce. However, as e-commerce grows, we will continue to witness changes in the way people conceive of organizations, transactions, and communications with a dramatic rethinking of time and space considerations in economic activities.

KEY TERMS

Digital Economy: Economy based on digital technologies such as computer, software, and digital networks.

Dot-Com Bubble: The exaggerated enthusiasm in Internet companies with the overvaluation of high-technology stocks in the late 1990s.

Dot-Com Company: A company that conducts its primary business on the Internet. It is called dot-com company because the company's URL ends with ".com."

Dot-Com Crash: The stock market crash of Internet companies in 2000 and 2001, many of which failed during the crash. Those companies were overvalued before the crash.

E-Commerce (Electronic Commerce): The transaction of goods and services through electronic communications. E-commerce has two primary forms: B2B (business to business) and B2C (business to consumer).

EDI (Electronic Data Interchange): Exchange of business documents through computer networks in a standard format. It was the first generation of e-commerce, applied in B2B transactions before the availability of the Internet in its present form.

Internet Economy: Economy with revenues from the Internet or Internet-related products or services.

M-Commerce (Mobile Electronic Commerce): Using mobile devices (e.g., cell phones and PDAs) to conduct business transactions.

ENDNOTE

1 Most studies classify e-commerce into two categories: B2B and B2C. However, some researchers use a four-type categorization of e-commerce: B2B, B2C, C2B (e.g., guru.com), and C2C (e.g., eBay). See Dholakia, Fritz, Dholakia, and Mundorf (2002, p. 4).

Hypermedia and Associated Concepts

Michael Lang
National University of Ireland, Galway, Ireland

INTRODUCTION

There has been considerable speculation of late that the design of hypermedia and Web-based systems warrants new methods different from those used in conventional software design (Kautz & Nørbjerg, 2003). However, much confusion abounds within this debate because fundamental concepts such as hypermedia, multimedia, and Web-based systems are rarely explicitly defined and it is often unclear what is actually meant. This article explains the following interrelated terms: multimedia, interactive multimedia, digital multimedia, interactive digital multimedia, hypertext, hypermedia, and Web-based systems. Such clarification is important because for research results to be comparable and scholarly discourse to be logical, there must be a common language.

BACKGROUND

The conceptual origins of hypermedia may be traced to a seminal postwar paper by Vannevar Bush (1945) titled "As We May Think" in which he set forth his vision of an information-management device called Memex. Inspired by Bush's ideas, Douglas Engelbart (1962/1991) wrote him a letter in 1962 about the concept of "an integrated man-machine working relationship, where close, continuous interaction with a computer avails the human of radically changed information-handling and -portrayal skills" (p. 237). This concept was realised as the Augment/NLS (online system) system, famously demonstrated in San Francisco in 1968. Featuring hypertext, split-screen windows, mouse-based input, and interactive, cooperative work using voice and video connections, it was a major milestone in the evolution of computing. Meanwhile, Ted Nelson (1965) was working at Xanadu on a computer-based file system "that would have every feature a novelist or absent-minded professor could want, holding everything he wanted in just the complicated way he wanted it held" (p. 85). Like Engelbart, Nelson (1987) was concerned not just with the support of individual work, but also collaborative information sharing. His vision was of a system in which "any user should be able to follow origins and links of material across boundaries of documents, servers, networks, and individual implementations" (p. 243).

Although there were notable advances in hypermedia technologies during the 1980s, it was not until 1991 when Tim Berners-Lee of CERN (European Centre for Nuclear Research) released his World Wide Web project into the public domain that a universal, unified environment such as envisaged by Nelson (1965) came into being. The Web is a global hypertext system founded upon the hypertext markup language (HTML), hypertext transfer protocol (HTTP), and uniform resource locators (URLs). In its earlier forms, the Web had basic architectural limitations and could only be properly regarded as a primitive, constrained hypermedia implementation. Through the emergence in recent years of standards such as the extensible markup language (XML), XML linking language (XLink), document object model (DOM), synchronized multimedia integration language (SMIL), and Web distributed authoring and versioning (WebDAV), as well as additional functionality provided by the common gateway interface (CGI), Java, plug-ins, and middleware applications, the Web is now moving closer to an idealized hypermedia environment (Bulterman & Rutledge, 2004; W3C, 2001, 2004).

EXPLANATION OF TERMS AND CONCEPTS

Multimedia

Hypermedia is formed by the convergence of two traditionally separate streams of research, namely, multimedia and hypertext. In order to better explain the concept of hypermedia, one must consider both of these streams. This section deals with multimedia; the next deals with hypertext.

Multimedia desktop computing is a relatively new concept, having only been around for a decade or so. The lack of a clear, consistent, commonly agreed-upon definition of multimedia is oft lamented. Simplistic definitions refer to the blending of sound, music, images, and other media into a synchronized whole. However, according to such a definition, the origins of multimedia would extend back to prehistorical cave ceremonies. More recently, the composer Wagner integrated various media into his Gesamtkünstwerk (Total Art Work) performances in the

1870s. By the 1960s, the term multimedia, alternatively known as cross-media, was being used to refer to live demonstrations by human speakers supported by combinations of slide projectors, motion-picture projectors, and audio-tape players.

To distinguish from artistic works, audiovisual presentations, theatre, and other noncomputer-based multimedia, one may use the term digital multimedia, meaning that the application is fully controlled by digital computers (Fluckiger, 1995). A further refinement of the definition of multimedia is the notion of interactive multimedia. Interactive multimedia systems enable end users to choose the information they see and receive by actively engaging with the system. In contrast, traditional television and comparable technologies such as videotape are passive because the end user has no control over the timing, sequence, or content and is not able or intended to interact (Dustdar & Angelides, 1998). However, interactivity is not unique to digital media. It has long been a feature of traditional media such as newspapers where readers must scan a page and decide what articles to read and in what sequence. For the sake of precision, the term interactive digital multimedia is therefore preferable to multimedia or interactive multimedia.

Another related and much misused term that warrants clarification is new media, defined by Williams, Strover, and Grant (1994) as applications of microelectronics, computers, and telecommunications that offer new services or enhancements of old ones. Considered thus, it is a broad term that comprises technologies such as videophones, electronic bulletin boards, and interactive television, though narrow interpretations often treat new media as synonymous with the World Wide Web (McMillan, 2002).

Figure 1 shows a simple diagrammatic representation of the overlapping relationships between multimedia, interactive media, digital media or new media, and interactive digital multimedia. Not all digital media can be regarded as multimedia; for example, SMS (short messaging service) messaging is digital but uses text only, unlike digital television that uses a combination of media (i.e., digital multimedia). Likewise, some applications of interactive media cannot be classified as multimedia.

Hypertext and Hypermedia

The term hypertext was coined by Nelson (1965), meaning "a body of written or pictorial material interconnected in such a complex way that it could not conveniently be presented or represented on paper" (p. 96). In technical parlance, Smith and Weiss (1988) define hypertext as "an approach to information management in which data is stored in a network of nodes connected by links" (p. 816). These nodes can contain text, graphics, audio, and video as well as source code or other forms of data. Hyperlinks, sometimes called hotspots or buttons, may take the form of one or more contiguous words in a passage of text, a picture or diagram or segment thereof, an interface object such as a button, or a segment of a media object. The point at which a hyperlink is located within a node is referred to as an anchor. The destination point of a hyperlink is also known as an anchor. Nodes are sometimes alternatively referred to as targets, pages, documents, cards, or frames. These technical terms are illustrated in Figure 2.

Figure 3 depicts the relationships between hypertext, hypermedia, interactive digital multimedia, and Web-based systems. In keeping with other authors (Vaughan, 2001), hypermedia is treated as a subset of interactive digital multimedia. Here, as elsewhere (Conklin, 1987; Fluckiger, 1995), hypermedia is also regarded as a specialized extension of the more general class of hypertext in the sense that hypermedia incorporates information of any type or format as opposed to just textual data. There is, however, some difference of opinion on this distinction, and the terms hypertext and hypermedia are often used interchangeably as though equivalent. This is understandable given that Nelson's (1965) definition of hypertext as earlier mentioned clearly does not preclude the use of multimedia data types. Indeed, Nelson alluded to the possibility of arranging nontextual media such as films and sound recordings into nonlinear sequences, but referred to such objects as hypermedia.

Figure 1. Associations in multimedia terminology

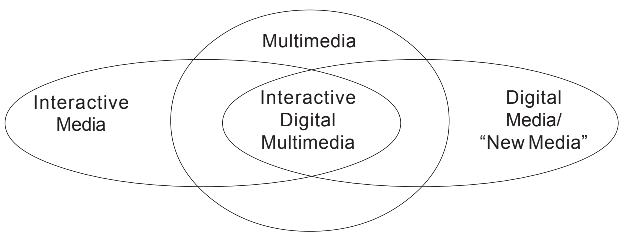

Figure 2. Nodes, anchors, and hyperlinks

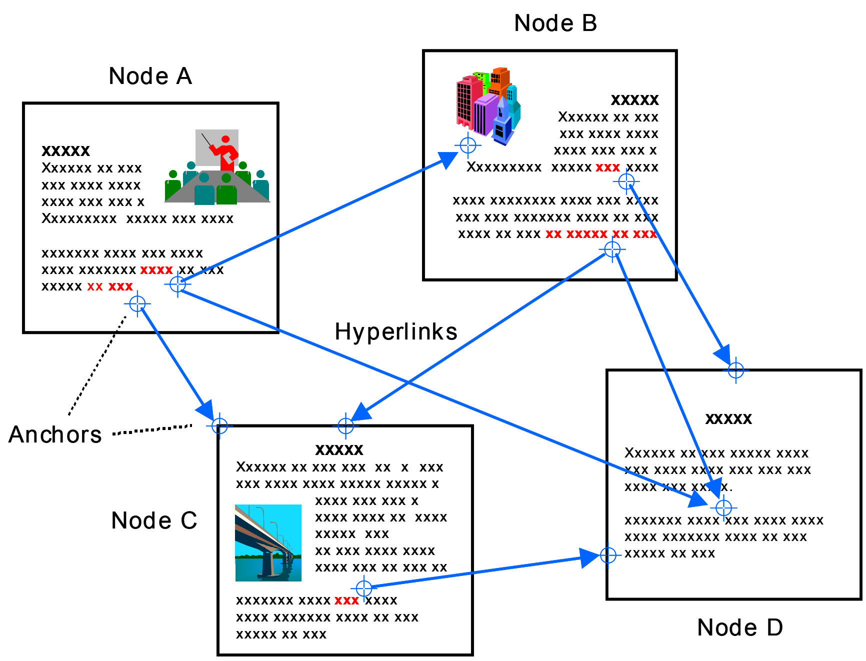

Figure 3. Associations between hypermedia and related concepts

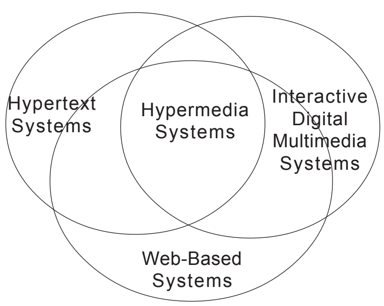


Descriptions of hypermedia generally agree upon the following principal definitive aspects:

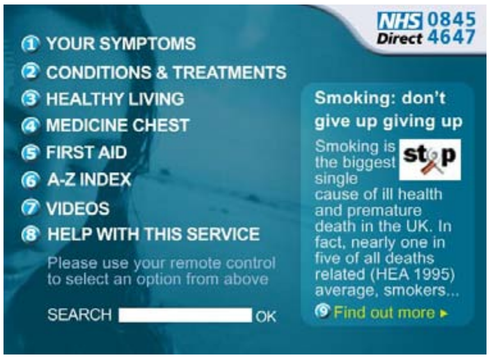
- information structures comprising a set of associated nodes in which the end user requires only a single node at a time;
- nonlinear navigation mechanisms, based upon these associative information structures, that support both casual browsing and purposeful self-directed navigation;
- support for multiple media types and formats; and
- interactive, visual, media-rich user interfaces.

Narrower, more rigorous definitions of hypermedia emphasize additional aspects such as support for end-user annotations, a tailored presentation, the synchronization of time-based media (e.g., audio, video, animation), explicit representations of the network structure within the user interface, scalability, extensibility, interoperability and openness, independence from proprietary standards and technologies, and internationalization. In actuality, these are ideals that remain largely unachieved by most modern hypermedia systems.

In terms of application functionality, it is difficult if not impossible to specify an all-encompassing set of features that sets hypermedia apart from more conventional applications. Typical features of hypermedia applications are hyperlinks, graphical user interfaces (GUIs), integration with back-end databases and systems, dynamically generated pages, and frequently changing content. Many features of hypermedia are now incorporated into a diversity of applications including databases, spreadsheets, and word processors. However, hypermedia applications are recognizably different from conventional applications because they have much richer user interfaces and more complex and flexible navigation mechanisms. To best explain these aspects, a number of screenshots of hypermedia applications are presented in the following pages.

Figure 4 depicts the start-up screen for an interactive television application developed for the UK National

Figure 4. Interactive television application of UK NHS

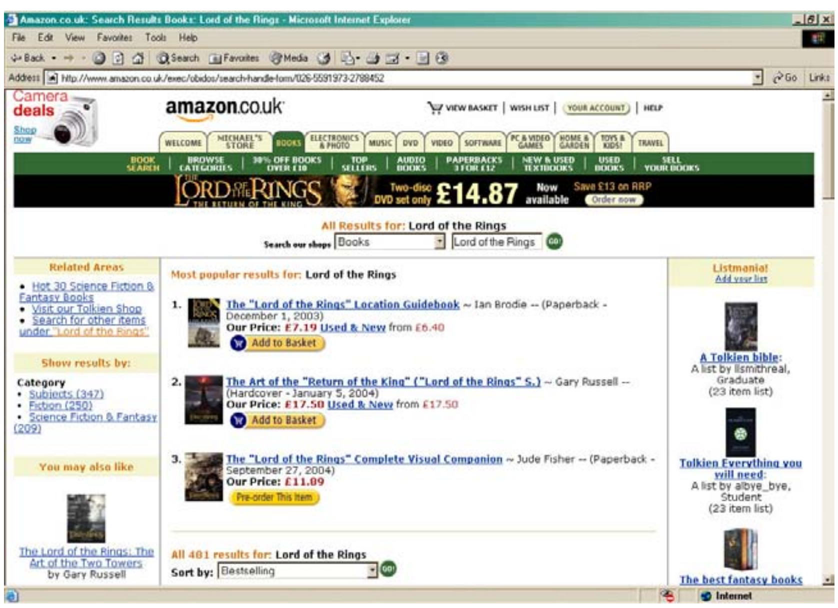


Health Service (NHS). The media types used are text and photographs supplemented by video on demand, and the application is driven by a back-end database with extensive information. Interactive television applications such as this might loosely be considered hypermedia because they include the basic features: support for self-directed navigation and browsing or searching, modular information units, a visual interface, and the use of multiple media. Previous generations of TV-based information services, such as teletext, lacked these essential features and therefore could not be regarded as hypermedia.

However, one would normally expect a hypermedia system to have a more media-rich interface than the UK NHS application. To illustrate this point, Figure 5 shows a screen from a Web-based system widely admired as an example of good design: that of Amazon UK. The variety of navigation mechanisms (e.g., high-level menus, multiple in-line hotspots), highly graphical nature of the interface, and media richness are immediately striking features, as can likewise be remarked of the Web site of Raidio Teilifís Éireann, Ireland's national broadcaster (Figure 6). Both these examples would certainly be regarded as hypermedia applications, even by strict definitions. Media-rich Web sites such as these typically use back-end databases or content-management tools to dynamically generate pages. This is in marked contrast to conventional GUI database information systems where the user interface normally consists of hard-coded, fixed-position elements, content is generally plain-text fields, and navigation mechanisms are basic. Such systems do not qualify as hypermedia, and they still would not if merely ported to the Web without the addition of essential enhancements such as hyperlinks between records and support for nontextual data.

Another common type of hypermedia applications, which preceded the take-off of multimedia desktop computing and the Web in the mid-1990s, is online help systems and electronic documentation. Notably, Microsoft Windows help files bear the file extension CHM, an acronym for compiled HTML. Looking at the example in Figure 7, standard hypermedia features are again obvious: support for purposeful navigation (through the contents or by searching the index) or browsing, cross-referenced nodes of information (visible in the right panel), and support for multiple media (text, graphics, links to video, etc.). Yet another application of hypermedia is electronic encyclopedias. Figure 8 shows a screenshot of one such example: Microsoft Encarta. As with printed encyclopedias, articles contain cross-references to other articles and there is an index of contents. However, media types

Figure 5. Web site of Amazon UK



are richer, including not just text, graphics, and photographs, but also audiovisual data.

Web-Based Systems

In recent years, there has been a flurry of interest in the design of Web-based systems, much of it based upon the premise that by definition they are fundamentally different from so-called traditional or conventional systems. The debate is clouded by confusion over the meaning of the phrase Web-based system, variants of which include Web-based application, Web application, Web-like application, WebApps, Webware, Web-based information system, Web information system, Web-enabled information system, Internet-based information system, and Web site (Holck, 2003).

Starting with the most familiar of these, Web sites date from the early days of the Web and historically denoted static sets of pages, so-called brochureware, whose purpose was to establish a Web presence for external marketing and corporate branding purposes. This notion of a Web site as a unidirectional information-publishing medium is quite different from a Web-based information system, which one would normally expect to be integrated with back-end transaction-processing databases and whose function is to support organisational work. However, many informational Web sites that initially started as brochureware now feature back-end databases, dynami-

Figure 6. Web site of Raidio Teilifís Éireann

Figure 7. Online help for a Microsoft Windows application

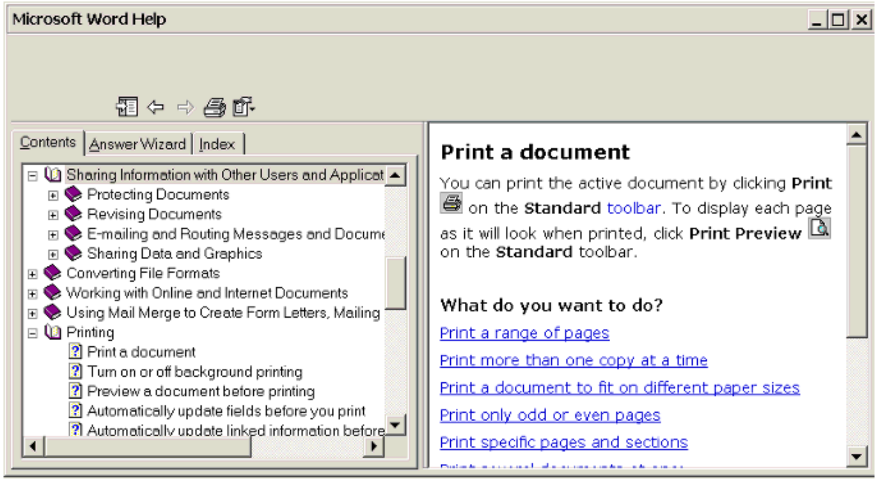


Figure 8. Microsoft Encarta encyclopedia

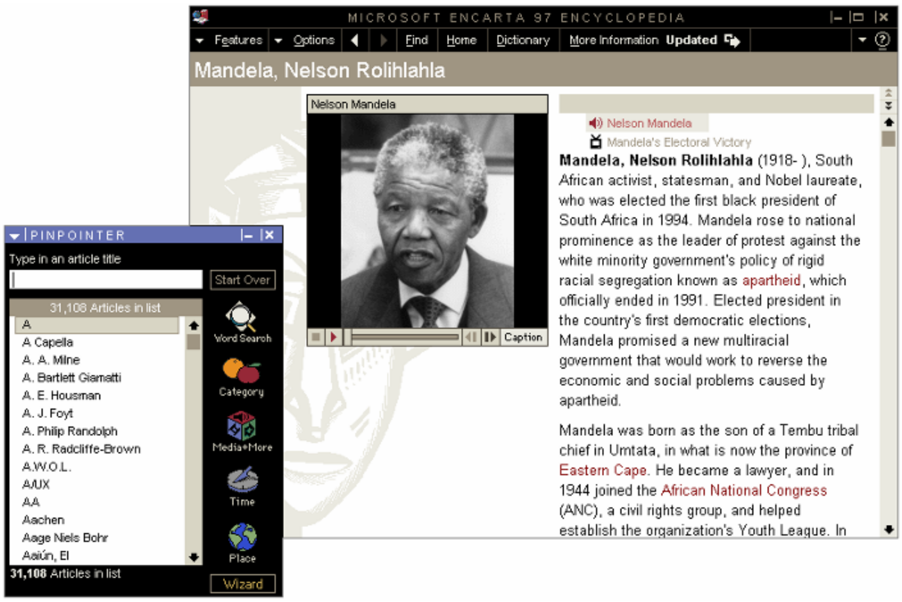

cally generated pages, and support for real-time transactions, and as such have become fully fledged software applications. Thus, there is no longer a clear distinction between the terms Web site and Web-based application or Web-based system.

Web-based system is a very loose term that in its broadest sense could be construed to embrace all applications that somehow rely upon the World Wide Web as a platform for execution. That could include not just interactive Web sites, but also Web crawlers, agents, middleware, daemons, and systems software. In a narrow sense, Web-based system is generally taken to mean information systems for which human-computer interaction is mediated through a Web-browser interface. Clearly, this is not a de facto fundamental difference. Indeed, Lockwood and Constantine (1999, p. 78) make the point that "current development tools make it easy to 'browserize' almost anything," so little if any redesign may be required to effect the basic migration of a system to the Web. For example, some intranet projects have been as straightforward as Web-enabling existing back-end applications such as Lotus Notes databases. This migration can be as simple as moving a set of files to a Web server. It is therefore obvious that although a system may be said to be Web-based, this does not necessarily imply it is any different from a non-Web-based system as regards software design considerations. Indeed, it may be argued that Web-based is just an adjective that does not fundamentally alter the meaning of the term information system when prefixed to it (Barry & Brown, 2003). The opinion of this author is that it is only when Web-based systems take on additional hypermedia functionality (such as enhanced navigation and multimedia content) that they present design challenges substantively different from those encountered in the design of conventional systems such as enterprise databases, interorganisational systems, or distributed client-server networks (Lang, 2005).

FUTURE TRENDS

Current implementations of hypermedia still have some way to go to reach the ideal functionality of a true hypermedia system, and perhaps most current hypermedia systems should properly be regarded as graphical hypertext systems. Many of the futuristic ideas speculatively set forth by Bush (1945) have been somehow implemented, but others remain as yet aspirational. Much research is ongoing into advanced multimedia features such as digital taste (e.g., electronic tongues), digital touch (e.g., haptic devices), digital smell (e.g., olfactory delivery devices, electronic noses), digital speech (e.g., voice recognition, text to speech), digital audio (e.g., spatial sound), virtual reality, wearable computers, and cybernetics, and it will be interesting to see how these features become integrated into future hypermedia systems (Güven & Feiner, 2003; Roberts, 2004; W3C, 2003; Washburn & Jones, 2004).

CONCLUSION

This article set forth definitions of interactive digital multimedia, hypertext, hypermedia, and Web-based systems, and explored the relationships between these and other associated concepts. It is argued that the term Web-based system of itself is not very meaningful from a software designer's point of view because merely by stating that a system is Web-based does not necessarily imply that radically different design methods or approaches are required above and beyond those that would be engaged for a comparable non-Web-based system. Indeed, Web-based system may soon become a redundant anachronism. It is likely that over time most systems will be ported to the Web and that Web-based interfaces will become the norm. If most systems were to become Web based and most information devices (mobile phones, PDAs [personal digital assistants], televisions, etc.) were to become Web enabled, it is likely that Web-based systems would simply be called systems! A recent example of such a change in computing language is multimedia PC (personal computer), a popular term from the early 1990s that is now defunct because multimedia functionality has become a standard feature of modern PCs.

Murugesan, Deshpande, Hansen, and Ginige (1999, p. 1) speak of "a pressing need for disciplined approaches and new methods and tools" taking into account "the unique features of the new medium" that is the Web. However, misguided assumptions of newness have been common throughout the history of software design. Rather than unnecessarily reinventing design methods and approaches for interactive Web-based systems, it may be beneficial to draw upon the legacy of design experiences from earlier generations of hypermedia and interactive digital multimedia systems. Researchers should aspire to produce timeless contributions, and accordingly, it is preferable to consider interactive Web-site design within the broader banner of hypermedia design, not just because hypermedia system is a less ambiguous term than Web-based system, but moreover because hypermedia is a more enduring concept and embraces technologies that predate the Web (e.g., online help, encyclopedia CD-ROMs [compact disc read-only memory]) as well as those that follow the Web (e.g., WAP [wireless application protocol] and interactive TV applications). Web design should therefore be properly thought of as situated along an evolutionary timeline reaching back to CD-ROM authoring, and extending in the future to new generations of interactive digital multimedia.

KEY TERMS

Hypermedia: Often taken as synonymous with hypertext, but some authors use the term hypermedia to refer to hypertext systems that contain not just text data, but also graphics, animation, video, audio, and other media.

Hypertext: An approach to information management in which data is stored as a network of interrelated nodes that may be purposefully navigated or casually browsed in a nonlinear sequence by means of various user-selected paths.

Interactive Digital Multimedia: Interactive digital multimedia systems enable end users to customize and select the information they see and receive by actively engaging with the system (e.g., tourism kiosk, interactive television), as opposed to passive multimedia where the end user has no control over the timing, sequence, or content (e.g., videotape, linear presentation).

Multimedia: Broadly defined, multimedia is the blending of sound, music, images, and other media into a synchronized whole. A more precise term is digital multimedia, meaning the computer-controlled integration of text, graphics, still and moving images, animation, sounds, and any other medium where every type of information can be represented, stored, transmitted, and processed digitally.

Web-Based Systems: A loose term that in its broadest sense embraces all software systems that somehow rely upon the World Wide Web as a platform for execution. In a narrow sense, it is generally taken to mean systems for which human-computer interaction is mediated through a Web-browser interface.

XML (Extensible Markup Language): A mechanism for encoding data into computer-understandable forms, useful for applications such as business-to-business electronic document interchange via the World Wide Web.

ICT Applications in Aviation

T. T. Wong
The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

Globalization of the social economy will further increase during the 21st century. The mission of international air transportation will become more important, and all airports around the world will have a significant role to play. Furthermore, it is predicted that air transportation demand in the world will double over the next 15 years.

In the meantime, since the September 11, 2001 terrorist attacks on the United States, the environment surrounding the aviation industry has become very severe and has caused adverse impact to the entire aviation industry. Security at airports has been reinforced in all aspects, significantly deteriorated on-time performance, caused mass congestion at the airport, and caused a drastic increase in aviation management and operational costs.

Owing to these issues, the aviation industry in recent years has seen a need to improve both convenience to passengers and security measures, and at the same time improve on-time performance in the most economical manner.

In connection with this trend, the International Air Transport Association (IATA) has been promoting the Simplifying Passenger Travel project to facilitate the process of international travel for next-generation air transportation. Information and communication technologies (ICTs) have an especially significant role to play here, for it is only with the strategic, widespread, intensive, and innovative use of ICT in future airport development polices and programs that the ambitious agenda of passenger convenience and airport security becomes much more possible to achieve. But this involves the need not only to unleash the potential of ICT per se, but also the need to ensure that an enabling environment and capacities that can facilitate its aviation applications are in place.

BACKGROUND

To find out how ICT applications can facilitate air passenger convenience and aviation security, one can evaluate the extent to which the needs of air passengers and the airport authority are met.

Air Passenger Needs

Travel Planning

Through any 3G mobile phone, one can use the in-built videoconferencing facility with his business partners or friends to discuss a travel plan. Once an itinerary has been agreed, one can access the Web site of travel agents and ask for quotes from different airlines regarding routes and accommodation types.

Through e-mail and/or short message service (SMS) messages from the travel agent, the traveler can use his PC, mobile phone, or personal digital assistant (PDA) to find out a plan most suitable to him.

One can then purchase electronic air and rail tickets through the Internet banking service (using his e-certificate). In cities like Hong Kong, mobile e-certificates are issued to individuals to authenticate the online identity of subscribers, and to provide a secure and trusted environment for the conduct of online transactions, such as secure e-mail services, online government services, online entertainment services, online stock trading, and online banking services.

Nowadays in places like Japan, one can also send electronic passport information to an Authorized Agent for the purpose of getting an entry visa for the destination countries. Having matched the data provided by the air traveler to other systems such as law enforcement and intelligence databases, the authorized agent would issue an electronic visa to the traveler in a short time. Also, the traveler can have the choice of traveling hands-free. This means that one can arrange with the concerned airline before travel so that a delivery company would pick up the traveler's baggage at an agreed time before departure.

Commencement of Traveling

Before Departure

On the day before departure, the traveler may need to buy some gifts, and he can access one of the virtual shops at the airport and pick it up on the day of departure.

Assume that a traveler wants to travel hands-free, a delivery company would be asked by the airline to contact him for the purpose of picking up his baggage for delivery to the airport. In order to check the airline and flight number from the e-ticket, the driver could check the traveler's mobile phone by means of his portable identity (ID) terminal. When the driver does this, the ID terminal automatically sends the baggage information to the airline's computer system. Upon arrival at the airport, the baggage will then be transferred to the baggage handling system for security inspection and subsequently delivered to the aircraft.

Departing for Airport and E-Check In

On the day of departure, when the traveler arrives at the rail station, he can pass through the rail ticket gates simply by holding his mobile phone in contact with the designated scanner so that the built-in IC chips could be scanned.

On moving into the passenger terminal, while the traveler is waiting for his friends at an Internet cafe, he may use his PDA or 3G mobile phone to watch a movie. When it is time for boarding, the group would expect to check in quickly through the automatic check-in kiosks, which are installed with one of the International Civil Aviation Organization (ICAO)-endorsed biometrics for passenger identification and passport control.

Arrival at the Destination Airport

When the destination airport is installed with an advance passenger information (API) system, the API data (collected from a passenger's machine-readable e-passport) will be sent by the airline to destination airport, enabling the customs/immigration officials at the airport to organize their clearance process in advance of the arrival of the flight. One instance is the eAPIS Online Transmission System, developed by the United States Customs & Border Protection for commercial operators to submit Advance Passenger Information System (APIS) data and Master Crew Lists (MCLs). With this system, the customs/immigration officials at the destination airport are able to focus on previously selected passengers, significantly reducing the wait time for the majority of passengers and enhancing the quality of the clearance process regarding the inspection of suspected aliens or illegal immigrants.

Upon arrival at the destination airport, one may want to learn about the tourist promotion programs; this can be obtained via the electronic translation facility provided at the airport. By means of his PDA, the passenger can download useful tourist information for getting around in the destination.

Aviation Security Needs

Identity Verification

In air travel there is an increasing need for accurate and efficient verification of passenger identity. Technologies which allow for stronger access control and strengthened document integrity will be welcome by most airports. In May 2003, the use of contactless technology was endorsed as the next generation of data storage for passports by the Air Transport Committee of the ICAO Council (ICAO, 2003a).

In recent years, there has been a steady increase in the testing and piloting of biometrics. Biometrics are unique, measurable characteristics or traits of a human being for automatically recognizing or verifying identity (OECD, 2004). The primary purpose of biometrics is to allow for identity verification (also called authentication) or "confirming identity" (ICAO, 2003b), where a one-to-one match is intended to establish the validity of a claimed identity by comparing a verification template to an enrolment template.

In the context of international travel, facial recognition, fingerprint, and iris scan appear to be the three primary candidates (Mariano, 2001; Fonseca, 2002; *Aviation Daily,* 2002; Krempl & Smith, 2002; Pietrucha, 2002; Basu, 2002; Cooley, 2003; Fisher, 2003; Mainichi Shimbun, 2003; Swissinfo, 2003).

The stability and uniqueness of the fingerprint are well established. The largest application of fingerprint technology is in automated fingerprint identification systems (AFISs) used by police forces in over 30 countries. Iris identification technology involves the acquisition, analysis, and comparison of the unique details contained in the intricate patterns of the furrows and ridges of the iris. This non-intrusive technology offers a high reliability rate for one-to-one verification. Facial recognition technology utilizes distinctive features of the human face in order to perform a biometrics match. Even though two individuals may look alike, the unique physiological patterns of their facial features will be different. A comparison of these three ICAO-endorsed biometrics is shown in Table 1.

Better Resource Utilization

Some countries start implementing trusted passenger programs to expedite the security screening of passengers who participate in such programs, thereby allowing security screening personnel to focus on those passengers who should be subject to more extensive screening (U.S. Congress, 2001).

Table 1. A comparison of ICAO-preferred biometrics

	Facial Recognition	Fingerprint	Iris Scan
Pros	Public acceptability; Ease of use; Useful for watch list	Mature technology; High accuracy; Stable over time; Large database	High accuracy; Stable over time
Cons	Accuracy; Controversial; Questions as to effects of aging over time	Low public acceptability	Very new technology; Not yet user friendly

Determining Suspected Identity

A one-to-many match is intended to check the biometric characteristics of a person against an existing enrollee dataset (e.g., check against a watch list, prevention of multiple enrollments). This security need could be achieved through a combination of biometrics and wireless surveillance technologies.

Real-Time Baggage Tracking

In response to the need for increasing levels of aviation security coupled with higher customer satisfaction levels, international airports are expected to provide real-time baggage tracking capability.

As shown, it can be seen that most passenger and aviation security needs can be achieved through the application of contactless smart card technology, 3G mobile, radio frequency identification (RFID), and wireless surveillance technologies.

ICT SYSTEMS IN AVIATION

A brief description of the features of the key ICT systems applicable in aviation is given below.

Contactless Smart Card Technology (CSCT)

A contactless smart card includes an embedded smart card secure microcontroller or equivalent intelligence, internal memory, and a small antenna; it communicates with a reader through a contactless radio frequency (RF) interface. Contactless smart card technology is used in applications that need to protect personal information and/or deliver fast, secure transactions, such as transit fare payment cards, government and corporate identification cards, documents such as electronic passports and visas, and financial payment cards. Contactless smart cards have the ability to securely manage, store, and provide access to data on the card, perform on-card functions (e.g., encryption), and interact intelligently with a contactless smart card reader. To facilitate airport security screening, electronic passports are expected to be issued by governments in the near future.

Radio Frequency Identification (RFID) Technology

RFID uses an integrated microchip and antenna that reads information. The combination of the chip and antenna is called an RFID transponder, tag, or inlet. When the RFID transponder is placed in the field of an RFID reader, information is transmitted to the reader and processed by a computer. Unlike bar code data storage, line-of-sight communication is not necessary.

Attached to physical objects, including baggage, air cargo, cartons, pallets, and containers, the RFID tags uniquely identify objects. Readers receive data from the RFID tags via radio frequency waves once the tags are within reading range. It is anticipated that by means of RFID tags, air travelers will be allowed to make advance arrangements to have their luggage picked up at home, so they can check in at the departure airport and board their flights unencumbered, and claim their bags at the destination airport.

Third-Generation (3G) Mobile Technology

3G brings together two powerful forces: wideband radio communications and Internet protocol-based services. Together, these lay the groundwork for advanced mobile Internet services, including personalized portals, "infotainment," mobile commerce, and unified messaging, encompassing high-speed data, superior quality voice and video, and location-based services.

Making 3G a reality depends on technology developments in different areas. These include amendments to the radio interface to support wideband communications and in the core network. For instance, General Packet

Radio Service (GPRS) is an enhancement to existing Global System for Mobile Communications (GSM) and Time Division Multiple Access (TDMA) networks that introduce packet data transmission, enabling "always on" mobility. This means that users can choose to be permanently logged on to e-mail, Internet access, and other services, but do not have to pay for these services unless sending or receiving information. Supporting technologies, such as Wireless Application Protocol and Bluetooth, also have an important role to play.

Wireless Surveillance Technology

There are several serious problems with using traditional coaxial or even high-tech fiber-optic cables to transmit video images from the surveillance cameras to the stations at which the images are monitored and/or recorded. Cables are easily damaged or severed by accidents or saboteurs, and thus require nearly constant monitoring, maintenance, and repair. Furthermore, cables cannot be strung over long distances without sacrificing image quality or having to build expensive booster stations along the way. The use of cable thus necessitates the close physical proximity of the monitoring stations to the areas under video surveillance. But proximity might be undesirable if the surveillance is intended to be covert or impossible if the subjects of surveillance (e.g., criminals or suspected terrorists) are constantly on the move.

To search for suspected persons against a watch list, wireless video surveillance can be used in airports. There are several means by which live video images can be transmitted without the use of cables or wires: lasers, radar signals, and radio (all of which are "microwaves," differing only in frequency on the spectrum). The most commonly used microwave is radio-frequency. In America, many law enforcement agencies use radio signals to transmit, relay, and receive live video images. Their use of wireless cameras can either be covert or overt. In covert operations ("stake-outs"), the cameras are usually small devices that beam their signals over short distances (usually to an unmarked van or car parked nearby) from hidden, semi-permanent locations on or near the suspects. In overt operations ("routine patrols"), the cameras are usually large devices that beam their signals over relatively long distances.

IMPACT OF ICT IN AVIATION

More Onsite Tests

More onsite tests in respect of the new ICT systems will cause considerable air passenger and cargo delays. For instance, the Transportation Security Administration (TSA) in the United States is conducting tests on a variety of advanced technologies, including state-of-the-art video surveillance, RFID cards, iris scan readers, and hand geometry readers, to protect against unwanted guests attempting to enter restricted areas of the airport.

Similarly, for a baggage-handling system using RFID, onsite testing must be carried out carefully if multiple sources of electromagnetic interference (EMI) are to be identified, such as other readers, other tags, wireless LANs, and data transmission systems.

Future Technological Research

Technological research of a more or less exotic nature will continue, but technological issues will not be the main ones. In fact, a large proportion of the technologies that will supply the markets of tomorrow already exist. Instead, efforts shall focus primarily on consolidating existing technologies, and on addressing issues outlined here.

ICT Product Development

This includes:

- reinforcing RFID scanners to support non-routine operating environments (primarily temperature, lighting, and humidity);
- developing non-participatory scanning techniques (surveillance by remote identification);
- improving techniques for detecting biometric artifacts (false fingers, false iris, life-size facial photographs);
- three-dimensional face imaging and development of tools for using existing photo archives; and
- performance improvements, and in particular a considerable reduction in "Failure to Enrol" and "False Rejection Rate"—this is essential for the airport security control.

Merger of Technologies

The current telecommunications scenario is, in fact, characterized by a global system fast converging towards the idea of virtual home/office environment, this trend being also fuelled by the evolution that the future wireless/mobile applications are experiencing. The user, while moving, feels the exigency of being continuously and efficiently connected to multimedia information systems and databases scattered across a fixed interconnected backbone (mainly characterized by ICT).

Two aspects highlighted by Honkasalo, Pehkonen, Niemi, and Leino (2002) are worth noting. First, the typical demand for information that users want to access is characterized by heavy data files and applications, calling for fast transmission capability. Second, airports are typical hot spots in which the widely cited exigency of high bandwidth data traffic access is strongly felt, while the overall radio coverage furnished by the mobile access systems to the fixed backbone could be insufficient (Saltkintzis, Fors, & Pazhyannu, 2002). This is mainly due to the fact that the standardization efforts relevant to the third generation of mobile systems focused on the development of a system supporting a wide-area wireless coverage and a high degree of user mobility, but with a maximum target capacity of 2 Mbit/s only.

A further interesting networking configuration that will surely play an important role in the next-generation communications environment is represented by WLAN islands roaming across 3G cellular networks, such as in the case of WLANs deployed either in airplanes or ships.

Therefore, the overall envisaged architecture of the next generation will be likely characterized by the presence of wired and wireless access technologies, such as Ethernet (802.3) for wired access, Wi-Fi (802.11) for wireless LAN access, and wideband code-division multiple access (W-CDMA) for cellular access. In such a scenario, the customer will get guaranteed quality-of-service levels on an end-to-end basis, while he/she is freely and transparently roaming from segment to segment.

Behavioral Issues

The implementation of information systems is affected by the way people perceive these systems and how people behave. ICT systems are no exception. Resistance to change is another important issue. It is a major behavioral factor that can have a significant impact on the implementation of proposed ICT systems.

Over the last few years, ICT has gained tremendous publicity. The general level of expectations regarding the system held both by top management and users may now be too high. Over-expectations may hinder the successful implementation of an ICT system.

Cultural Issues

People may not have confidence in a new ICT system because it is relatively new to them. It may take them a long time to understand and trust the technology.

Business Process Issues

As is the case with most breakthrough technologies in aviation, implementing new ICT products or systems can require the fundamental redesigning of business processes if optimal benefits from using such products or systems are to be obtained.

Data Management Issues

ICT systems such as RFID capture and deal with enormous volumes of data. We need to filter out the useless data, identify what needs to be stored, and consider how and where to store data.

Security Issues

An ICT system such as RFID could make possible an omnipresent state of surveillance. The security and integrity of information and the privacy of cargo customers are always primary issues surrounding the adoption of RFID.

Legal Issues

The traditional doctrines of privacy protection agencies, such as those relating to proportionality, purpose, and traces, will be challenged by the spreading use of biometrics and the many new ICT products used by the police. Resolving these issues will require responsible communication and education on the part of all players: privacy protection agencies, governments, citizens, and the industry. Solutions will be based on careful choices of legal and technical approaches.

FUTURE TRENDS

Despite the promise associated with ICT, as shown above there are still many formidable obstacles to its adoption. In particular, technological, financial, and cultural issues must be addressed before the benefits can be realized in aviation.

For instance, in the case of RFID, technological issues relating to laws of physics must be managed. Although radio waves can pass through most articles, metal and liquids are problematic. In addition, there are multiple sources of potential background interference, as RFID tags and readers attempt their two-way communication. For communication to take place, hardware must be tuned to specific radio wave frequencies, but frequency availability is not consistent worldwide. Accuracy and encryption are other technological challenges facing RFID today.

Although RFID is already used in many applications today, its current costs preclude widespread adoption on low margin items. To some extent, cost is a technological problem, but even if hardware issues are resolved on a unit basis, there will still be substantial costs associated with retooling baggage handling systems, air cargo terminals, warehouses, and trucks with RFID equipment. In addition, the full benefit of RFID will be realized only when personnel can be redirected from the menial work of scanning, searching, and verifying a product, to the more complex work of anticipating problems and collaborating on solutions. This will require substantial retraining. In the short run, start-up costs will receive the most attention, but in the long run, there will be substantial costs involved in maintaining and upgrading software, hardware, and data needs.

Similarly, wireless video technology is a risky business for two reasons: (1) though such transmissions are often "modulated" or otherwise encrypted, they are nevertheless sent on "open," non-secured frequencies, and so can be intercepted and, given time, decoded; and (2) airport staff routinely stationed near the transmitters can suffer serious health problems if over-exposed to microwave radiation.

On the other hand, it is clear that contactless smart card technologies have a bright future ahead of them in the world's regulatory scene. As the need for increased security and privacy becomes apparent to policymakers and citizens, the possible uses and actual implementation of smart cards will radically grow. The potential areas of application are almost limitless.

CONCLUSION

Through the application of proposed ICT in the aviation industry, one would anticipate the following passenger convenience and aviation security enhancements:

- **Comprehensive Airport Information via Mobile Devices:** Airport facility guides, flight information, and user location information via Global Positioning System functions, and tourist information in other languages.
- **Facilitated Airport Procedures:** E-ticket services using mobile phones with IC chips, automated departure procedures, and biometric technology will allow passengers to complete their procedures smoothly and safely.
- **Airport Internet Access:** With the installation of wireless LAN facilities and Internet cafes, airport users will have easy access to broadband Internet services.
- **Real-Time Baggage Handling System:** The use of RFID tags will reduce the incidence of lost baggage and allow passengers to travel from their home to their destination without being burdened by luggage.
- **Better Aviation Security:** In conjunction with ICAO-endorsed biometrics, CSCT is an excellent privacy-enabling solution for applications that need to protect personal information and ensure that communication with the contactless device is secure. The on-chip intelligence uniquely enables systems that use CSCT to comply with mandatory privacy and security guidelines, as well as deliver the speed and convenience of contactless communication. Also, through wireless surveillance technology, less airport crimes would occur.

ACKNOWLEDGMENT

The author wishes to thank The Hong Kong Polytechnic University for supporting this research project.

KEY TERMS

3G: Abbreviation for "third-generation" mobile telephone technology. The services associated with 3G provide the ability to transfer both voice data (a telephone call) and non-voice data (such as downloading information, exchanging e-mail, and instant messaging).

Asynchronous Transfer Mode (ATM): A network technology based on transferring data in cells or packets of a fixed size. The small, constant cell size allows ATM equipment to transmit video, audio, and computer data over the same network, and assure that no single type of data hogs the line.

Biometrics: Usually refers to technologies for measuring and analyzing human physiological characteristics such as fingerprints, eye retinas and irises, voice patterns, facial patterns, and hand measurements, especially for authentication purposes. In a typical IT biometric system, a person registers with the system when one or more of his physiological characteristics are obtained, processed by a numerical algorithm, and entered into a database. Ideally, when he logs in, all of his features match 100%; then when someone else tries to log in, she does not fully match, so the system will not allow her to log in.

General Packet Radio Service (GPRS): A packet-linked technology that enables high-speed wireless Internet and other data communications. GPRS provides more than four times greater speed than conventional GSM systems. Using a packet data service, subscribers are always connected and always online so services will be easy and quick to access.

Quality of Service (QoS): A networking term that specifies a guaranteed throughput level. One of the biggest advantages of ATM over competing technologies such as Frame Relay and Fast Ethernet is that it supports QoS levels. This allows ATM providers to guarantee to their customers that end-to-end latency will not exceed a specified level.

W-CDMA: A wideband spread-spectrum 3G mobile telecommunication air interface that utilizes code division multiple access (or CDMA, the general multiplexing scheme).

Wi-Fi: Abbreviation for "Wireless Fidelity"; a set of product compatibility standards for WLAN based on the IEEE 802.11 specifications. Wi-Fi was intended to be used for mobile devices and LANs, but is now often used for Internet access. It enables a person with a wireless-enabled computer or PDA to connect to the Internet when in proximity of an access point.

Identifying E-Business Options

Albert Boonstra
University of Groningen, The Netherlands

Bert de Brock
University of Groningen, The Netherlands

INTRODUCTION

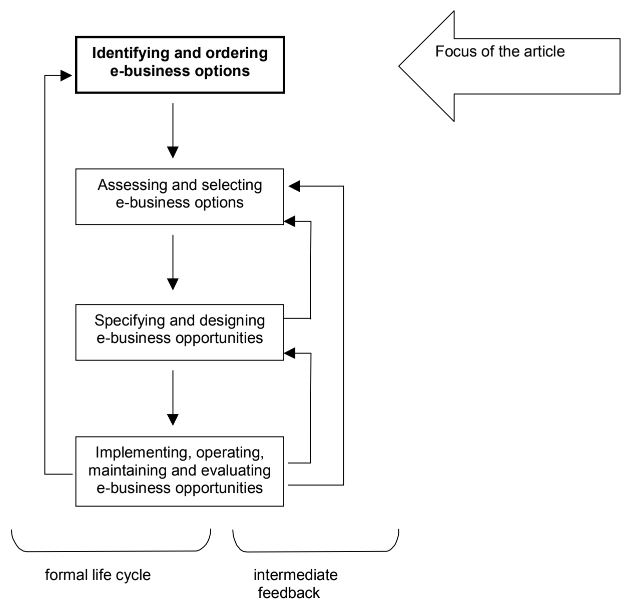
The past few years, many organizations have been using the Internet in quite arbitrary and experimental ways. This phase, which can be considered as a period of learning and experimentation, has created a need for a more systematic approach to the identification, the ordering and the assessment of e-business options. It is the objective of this paper to address this need by presenting a methodology that aims at supporting management in using alternative e-business applications in the first stage of the decision-making process.

Figure 1 shows how a systematic decision-making process can be organized by using e-business options. The steps are based on Simon's intelligence, design, and choice trichotomy (Simon, 1960). First, alternative e-business options have to be identified and ordered. Then the possible options have to be assessed and selected. After this stage the selected opportunities have to be specified and designed. Next, implementation, operation, maintenance, and evaluation may follow. In Figure 1 this is called the "formal life cycle". We will apply the word "e-business option" referring to the possibility to use an electronic network for a business purpose. An e-business opportunity is defined here as an assessed and selected e-business option.

In practice, different intermediate feedback activities, interrupts, delays and adjustments are often necessary to reconsider earlier steps (Mintzberg, Raisinghani, & Théorêt, 1976). This is—among other reasons—because decision-making processes of this kind take place in dynamic environments and decisions are made in political contexts (Pettigrew, 2002). Moreover, participants in decision-making processes are often lacking the necessary information to make well-considered decisions right from the start (Miller, Hickson, & Wilson, 1996). In Figure 1 these activities are called "intermediate feedback".

The methodology presented in this article focuses mainly on the first stage of the decision-making process: the identification of e-business options and the ordering of these options. Further, the focus is only on e-business options in the context of an organization and its current or new external stakeholders.

Figure 1. Focus of the article in the light of the desicion-making context



The methodology helps identify e-business options, describe them in a global way by specifying each option in six dimensions, and order them according to organization- dependent priorities. Only after management has assessed and selected an option can this option be specified more precisely in order to design an application (see also Figure 1).

This methodology aims at contributing to practice as well as to theory. Practitioners, such as (e-business) managers and (e-business) consultants, can use the methodology to identify and order e-business options in a systematic rather than an intuitive, imitating or precedent-based way. This methodology can also be used to challenge certain e-business strategies or to consider unconventional alternatives.

The contribution to theory is based on the fact that many existing e-business frameworks are directed at the assessment of certain e-business alternatives, but that general approaches addressing the identification of e-business options from scratch, are still scarce. This argument will be explained in the next section.

BACKGROUND

Although Chung-Shing Lee's contribution (2001) of providing a framework to evaluate e-commerce business models is useful, evaluation can only take place after the identification of options, which is the focus of this article.

Barua, Konana, Whinston, and Yin, (2001) introduce an e-business value model that supports management in determining where to deploy organizational resources by highlighting specific areas of opportunity. Barua et al. also emphasize that organizations should not merely concentrate on the existing products or services. They suggest that the Internet may open up opportunities to reach new customers and to introduce new products or services.

The ideas of Barua are in line with those of Ansoff (1965), who identifies product market areas to be focused on by organizations. Ansoff suggests that two important strategic questions of organizations are: (1) whether they should focus only on their existing markets and customers or also on new markets and customers, and (2) whether they should merely focus on existing products and services or also on the development of new ones. With respect to e-business these two fundamental questions are highly relevant, since the Internet makes many organizations rethink their product-market combinations fundamentally. Therefore, these two questions are addressed in the approach as described in this article.

Straub and Klein (2001) build on these ideas by stating that e-commerce can produce three categories of effects: first-order, second-order, and third-order effects. First-order effects involve reducing costs and increasing productivity. Second-order effects concern the pursuit of new markets and improving services, and third order effects lead to far-reaching transformations affecting goods and services, ways of targeting as well as distribution (Andal, Cartwright, & Yip, 2003). These issues are also addressed in the methodology as described in this article; they will be identified explicitly.

We can conclude that there are already a considerable number of models that can be used to assess and evaluate current e-business applications and measure their readiness for the future. However, there seems to be a lack of approaches that can help analysts generate options and future directions regarding utilizing the Internet. The approach as described in this article aims at making suggestions with respect to how such a methodology could take form.

METHODOLOGY

Dimensions and Elements

Organizations can use the Internet as a means of communication with the outside world in different ways. These different ways can be analyzed by distinguishing among the following dimensions: stakeholders groups, stakeholders' statuses, channel strategies, communication modes, product/service groups and product/service statuses.

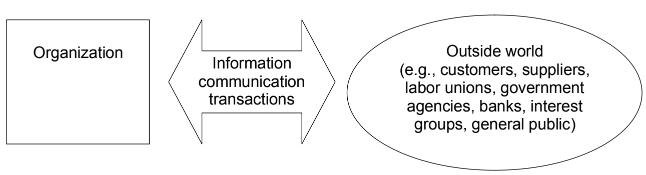
These dimensions are derived from the elementary notion that organizations can be perceived as open systems. In order to survive, good relations have to be established with parties in the outside world. For that reason, organizations exchange information to relevant parties in that outside world. These communications may lead to transactions. See Figure 2.

In order to generate potential e-business options, it has to be identified with which parties in the outside world the organization intends to exchange information. These can be current or new parties, since electronic networks can also be used to extend the reach of organizations. When this outside world has been identified, the way of using electronic networks has to be considered. Here we can identify communication modes, channel strategies and (current or new) products and services. These dimensions are further explained in the next paragraph.

Dimension #1: (External) Stakeholders Groups

Organizations exchange information and communicate with all external stakeholders, who can be divided in *business partners* and *other stakeholders*. It is relevant

Figure 2. Organization as an open system



to distinguish between business partners and other external stakeholders because the communication mode between the organization and these two kinds of stakeholders groups is different (see also the paragraph on communication modes). With business partners, an organization has both a transactional (including monetary) exchange relation and an informational and communicational relation. Business partners include customers, suppliers, banks, insurance companies, shareholders, and governments (e.g., concerning taxes, licenses, and regulations).

With other external stakeholders, organizations only have an informational or communicational relation. Examples are the press, special interest groups, (e.g., environmental groups), and the general public. The number of external stakeholders groups is organization-dependent: the user of our methodology has to map out and group all external stakeholders who may be relevant to the analysis.

Some relevant questions with respect to stakeholders are:

- What are the current groups of business partners?
- What are the current groups of other stakeholders?

Dimension #2: Stakeholder Statuses

We distinguish between two statuses, namely *current* and *new*. By using the Internet, an organization can transform or extend its business with respect to new stakeholders. New stakeholders can be new customers, new suppliers, new banks, or even new governments. New customers can be reached by entering new markets (market extension) or by disintermediating current intermediaries and, in this way, targeting final consumers. The same applies to suppliers. By using electronic marketplaces, organizations can broaden their suppliers' base or disintermediate backward to replace suppliers by the initial producers of the supplies.

Some relevant questions with respect to stakeholder statuses are:

- Could the organization reach new business partners by using the Internet?
- Could the organization reach new other stakeholders by using the Internet?

Dimension #3: Channel Strategies

In this article we distinguish between Internet channels and non-Internet channels (although our methodology also allows further refinements). Organizations can choose to use the Internet as an exclusive medium for communication exchange purposes with one or more (groups of) stakeholders. This is called a single-channel Internet strategy. The alternative is to combine the Internet with non-Internet channels. This is called a multi-channel strategy.

Some relevant questions with respect to channel strategies are:

- Can the organization use the Internet as a single-channel strategy to reach a current group of business partners?
- Can the organization use the Internet as an additional-channel strategy to reach a new group of business partners?
- Can the organization use the Internet as a single-channel strategy to reach a current group of current other stakeholders?

Dimension #4: Communication Modes

We distinguish among *informational*, *interactional,* and *transactional* communication modes. Informational means a one-sided provision of information, (e.g., by putting a product catalogue on the Internet). Interactional means a two-sided information exchange, (e.g., by enabling customers to ask questions). Transactional means the exchange of products or services or the agreement about such an exchange, (e.g., to order a product and to pay over the Internet). Interactional mode includes informational mode; transactional mode includes interactional and, hence also informational mode (Grover & Ramanlal, 2004).

A relevant question with respect to communication modes is:

- Could the organization use the Internet to provide information, to exchange information or to engage in transactions?

Dimension #5: Product (and Service) Groups

Organizations can use the Internet to buy or to market their products and/or services. The number of product/service groups is organization-dependent: the user of our methodology has to map out and to group all current products and services that may be relevant to the analysis.

Some relevant questions with respect to product/service groups are:

- What are the current or new final products and services and could the Internet be used to facilitate the buying or selling process?
- What are the current or new inputs and could the Internet be used to facilitate the buying process?

Dimension #6: Product (and Service) Statuses

We distinguish between two statuses, namely *current* and *new*. Organizations can use the Internet to buy or sell their current products and services, but they can also transform or extend business by buying or marketing new products or new services on the Internet. Many products can be extended or transformed by using the Internet.

A relevant question with respect to product statuses is:

- What are possible new final products/services and inputs?
- Could the Internet be used to facilitate the buying or selling process of new products or services?

Examples of a Newspaper Publisher

A publisher of a regional newspaper has many options with regard to using the Internet. We will use the different dimensions of our methodology to describe four of these options. These options are also shown in Table 2.

- **Example 1:** The publisher may choose to put the contents of (a part of) the newspaper on the Internet as an additional service for his current subscribers (extension of current product to current customers, multi-channel).
- **Example 2:** The publisher may choose to put the contents of (a part of) the newspaper on the Internet as a service extension to his current products for current subscribers as well as new clients.
- **Example 3:** The publisher may choose to develop a new single-channel Internet newspaper, using special Internet features (e.g., interactivity, news on demand) to reach new customers (new product, new customers, single-channel Internet).
- **Example 4:** The publisher may choose to develop an Internet newspaper, based on a current newspaper, using special Internet features as a free new service for current subscribers and a chargeable service for new Internet customers (the English newspaper *The Economist* makes use of this option).

To illustrate the different dimensions of an e-business option, the e-business options in this example are generated in an arbitrary way. Many other options are also possible. In the next sections we will show how options can be generated and ordered in a systematic manner.

Generating Potential Options

In order to systematically generate potential e-business options once the (company-dependent) elements of all dimensions are determined, a closer look is required at the structure of the description of the potential options. In our view, the following general format can be used to describe all potential options:

<communication mode> ***options concerning*** <product status> <product group> ***with*** <stakeholder status> <stakeholders group> ***using a*** <channel strategy>

All possible combinations of values applied to the six variables in the general format then make up the complete set of potential options. If p is the number of product/service groups and s is the number of stakeholders groups that are distinguished by the organization concerned, this will lead to 2 * 2 * 2 * 3 * p * s (i.e., 24 * p * s) potential options. So it is obvious that these potential options can be generated in a systematic manner, namely by straight-

Table 1. Examples of some e-business options of a newspaper publisher

Example nr	**Stakeholders Groups and statuses** *Dimension # 1, # 2*	**Channel strategies** *Dimension #3*	**Communication modes** *Dimension #4*	**Product and service groups** *Dimension #5*	**Product and service statuses** *Dimension #6*
1	Current subscribers	Internet *and* traditional newspaper = multichannel	Information	Content of current newspaper	Current
2	Current subscribers and New clients	Internet *and* traditional newspaper = multichannel	Information	Content of current newspaper	Current
3	New customers	Internet single-channel	Transaction	Newspaper	New
4	Current subscribers and New customers	Internet and traditional newspaper = Multichannel	Interaction for current subscribers, transaction for Internet/only customers	Current newspaper, adapted	New

Table 2. Dimensions of e-business options

Dimension	Dimension order
Stakeholders groups	6
Product groups	5
Channel strategies	1
Communication modes	4
Stakeholder statuses	2
Product statuses	3

Table 3. Elements of e-business options

Element	Dimension	Elements order
Customers	Stakeholders groups	1
Suppliers	Stakeholders groups	2
Shareholders	Stakeholders groups	3
Banks	Stakeholders groups	4
Governments	Stakeholders groups	5
Physical goods	Product groups	3
Digital products	Product groups	1
Services	Product groups	2
Single-channel Internet strategy	Channel strategies	1
Multi-channel strategy	Channel strategies	2
Informational	Communication modes	1
Interactional	Communication modes	2
Transactional	Communication modes	3
Current	Stakeholder statuses	1
New	Stakeholder statuses	2
Current	Product statuses	1
New	Product statuses	2

forwardly combining each possible element with each of the six dimensions. Each combination results in a potential option.

Rather than writing out these 24 * p * s potential options by hand, they can also be generated by means of a tool. The tool can consist of a database with a *Dimensions* table containing the six dimensions and an *Elements* table containing all (2 + 2 + 2 + 3 + p + s) elements per dimension. A sample content of such a database will be shown in the next section. Furthermore, the database has to have a reporting facility which, based on the joining of these two tables, can generate the 24 * p * s descriptions of the potential options in our general format.

Ordering Potential Options

The potential options can be ordered by adding the ordered dimensions to the ordered elements within each dimension. The ordering of the dimensions and their elements implicitly implies an ordering of the generated options. The next example should make this clear.

Example

Suppose that the publisher distinguishes three general product groups (Physical goods, Digital products, and Services) as well as five stakeholders groups (Customers, Suppliers, Shareholders, Banks, and Governments). After choosing one particular way of ordering the dimensions and the elements within each dimension, the contents of our two database tables could be as shown in Tables 2 and 3.

This means that in this example we will first consider:

- *Informational options concerning current digital products for current customers using a single-channel Internet strategy*
- Then, similar options for the other stakeholders groups (4 groups in this case),
- then, similar options for the other product groups (2 groups in this case),
- then, similar options for the other communication modes (2 modes in this case),
- then, similar options for the *new* products,
- then, similar options for the *new* stakeholders, and,
- finally, similar options for the other channel strategy.
- We will obtain the descriptions of potential options by simply placing the respective elements into the general format that we introduced earlier.
- In our example, this generates 360 potential options (namely, 5 * 3 * 3 * 2 * 2 * 2).

Different criteria can be used for ordering the different elements. One criterion may be to prioritize from current to new. This means that potential options, including current stakeholders, current products, and multi-channel strategies, appear at a higher place on the list than potential options including new stakeholders, new products and single-channel strategies. This is in accordance with Straub et al. (2001) who state that Internet applications tend to move from first-order to second-order and then to third-order effects (see the background section). If a company chooses to follow this pattern, the list will first suggest the less risky options.

Another approach may be to look for a strategic fit. If a company intends to reach new groups of customers, it is reasonable to give new stakeholders groups a higher ranking. The same applies when an organization intends to use the Internet to launch new (Internet-based) products or services. In that case, these new products and services should get a higher priority. If the company-dependent elements are identified in the right way, the list will, in any case, provide all potential options.

Once the list of potential options has been generated and ordered, a list of valid options has to be composed.

The difference between a potential and a valid option is determined by whether a potential option is possible. This means that impossibilities have to be eliminated from the list. To give an example: it is impossible to deliver a bottle of orange juice over the Internet. So delivering orange juice over the Internet is a potential option, but not a valid one. Ordering orange juice over the Internet is a potential option as well as a valid one, since it is actually possible.

However, not all (valid) options will make sense from a business perspective. This means that options have to be assessed, often by using a range of criteria. So once the list of valid options has been acquired, the next stage of assessment can begin (see Figure 2).

Tool Support

The approach as described in this article will be supported by a tool that enables one to easily:

- Record the product/service groups and the stakeholders groups (organization-dependent);
- Generate the potential e-business options; and
- Order the e-business options.

The tool will consist of a database, which contains the proper:

- Data structures (tables) already containing all organization-independent data;
- Forms to enter and update the organization-dependent data (i.e., the product/service groups and the stakeholders groups); and
- Reporting facility to generate and order the potential e-business options.

E-business consultants, managers, and business analysts can use this tool to support the process of business improvement of organizations. The methodology suggests conventional as well as highly unconventional approaches to the use of the Internet and helps people specify certain directions of e-business-related change.

This approach, including this tool, can be used in interviews and workshops to generate and discuss directions of change that may improve final decision-making.

FUTURE WORK

When the options are identified and ordered, they have to be assessed on the basis of one or more criteria (see Figure 1). These criteria are organization-dependent. Many organizations use multi-criteria methods (Grimbergen et al., 2001; Parker, Benson, & Trainor, 1988) to assess IT investment alternatives, including e-business options. We intend to extend the methodology as described in this article by incorporating this next step. To support this next step, a tool will be developed. This tool should, among other things, enable an organization to record the results of the assessment and selection process. So, our methodology will then aim at covering and supporting the first two stages of the e-business decision-making process as depicted in Figure 1.

A prototype of the methodology as described in this article has been applied in two organizations. We intend to describe these cases and extend this case base with the objective to refine and improve our methodology.

CONCLUSION

It can be concluded that there is already a considerable number of models for assessing current e-business applications and for measuring the readiness of e-business for the future. However, there is a lack of approaches that can help consultants, managers and academics to generate new options and new directions regarding utilizing the Internet and other new (electronic) communication channels. In this article, such an approach has been offered, including a tool that supports this goal. The approach contributes to a more creative and systematic way of decision-making with respect to e-business. It describes the more trivial as well as the highly unconventional e-business options in a global but complete and systematic way. These descriptions lead to an extensive list of potential options. This list can serve as the basis for further systematic decision-making and may stimulate people to make conscious and well-considered e-business decisions. Further, the approach could be extended so that the assessment and selection processes are incorporated as well. Finally, these processes could also be supported by a tool.

KEY TERMS

E-Business Opportunity: An assessed and selected e-business option.

E-Business Option: A possibility to use an electronic network for a business purpose.

E-Business Value Model: A model which conveys to management where to focus organizational resources by highlighting specific areas of opportunity.

External Stakeholders: Organizations exchange information and communicate with all external stakeholders, who can be divided in *business partners* and *other stakeholders*.

Internet Option: A possibility to use the Internet for a business purpose.

Implementing CRM Systems in Online Enterprises

Călin Gurău
Groupe Sup. de Co. Montpellier, France

INTRODUCTION

Companies are increasingly embracing customer relationship management (*CRM*) as a major element of corporate strategy, for two important reasons: new technologies now enable companies to target chosen market segments, microsegments, or individual customers more precisely; and new marketing thinking has recognised the limitations of traditional marketing and the potential of more customer-focused, process-oriented perspectives (Payne, 2002; Ragins, & Greco, 2003).

The first *CRM* procedures were implemented to provide more efficient customer transactions. The gradual shift from transaction to interaction, as a long-term process, required the implementation of analytical marketing procedures, based on databases and data processing technology. Brobst and Rareyk (2004) outlined the evolution of analytical *CRM*, identifying five distinct stages (see Table 1). The interactive marketing stage is possible only using the *Internet* as a *CRM* strategic channel—which allows real-time, continuous collection, analysis, and use of data to adapt the company's offer and communication to the individual profile and behaviour of the customer. The introduction and use of *CRM* in the online environment requires a complex process of planning, analysis, strategy design and implementation. This article presents a model for the implementation of a customer-centric strategy in online businesses, discussing the advantages and the challenges of this new system.

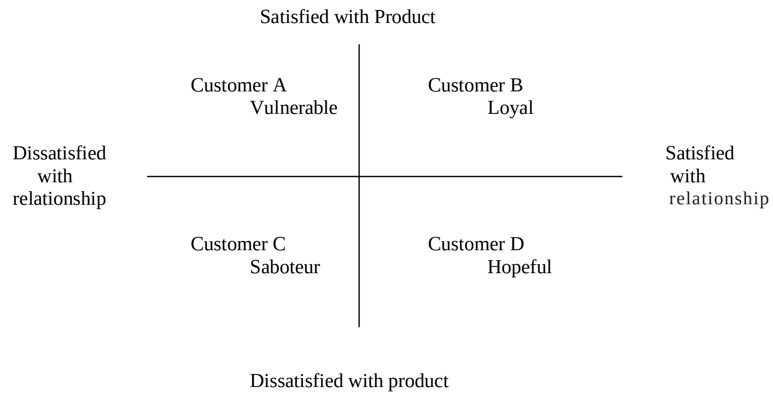
BACKGROUND

The *Internet* user has the opportunity to switch the suppliers with several mouse clicks, to compare price and products on a worldwide basis, and to select without external pressure the best available offer. The winning combination of low price/high quality product does not work properly on the *Internet* because the same offer may be available at hundreds of other online retailers

Table 1. The five stages of analytical CRM (From Brobst & Rareyk, 2004)

Stage of analytical CRM	**Main Strategic Orientation**	**Challenges**
Mass marketing	Create a database of customers improving the effectiveness of mass marketing operations and reducing the costs of blanket marketing campaigns	Data and database quality—reliability and elimination of double entries
Segment marketing	Deliver product offers differentiated by customer segment. Use ad hoc analysis to develop an understanding of customer segments and design product offerings appropriate to each segment	The capacity to dynamically segment the market based of various criteria applied to the customer database. Performance management and proactive capacity planning for the database is a prerequisite to success
Target marketing	Treat each customer as an individual. Every customer and prospect is scored based on their propensity to buy and targeted accordingly	The introduction of data-mining technology combined with the calculation of customer lifetime value
Event-based marketing	Focuses on enabling personalised marketing communication driven by individual behaviour patterns.	The implementation of "software event detectives," to identify events relevant for customer relationship and then initiate personalised communications in response to such events. Events detection implies more frequent data acquisition and updating
Interactive marketing	Real-time interaction with customers, adapted to their profile, behaviour, and reactions	Integration of analytical and operational CRM—databases connected with customer management applications

Figure 1. The eLoyalty Matrix (Adapted from Conway & Fitzpatrick, 1999)



(Wundermann, 2001). The only possibility to increase the competitive advantage of online retailing is to create not only product-related satisfaction but also customer-firm relationship satisfaction (Bradshaw & Brash, 2001).

The eLoyalty Matrix (see Figure 1), an economic model developed at eLoyalty (Conway & Fitzpatrick, 1999), considers the situation of a company-customer long-term relationship, in which, to a given moment, various types of customers experience a variation in the level of satisfaction determined by relationship and/or product strategies.

Customer A is satisfied with the product purchased, but dissatisfied with his or her relationship with the company. This customer type is vulnerable to switching. The customer/company relationship profoundly affects how a product or company is viewed and affects customer behaviour. Properly managed and serviced, this category of customer can become a significant source of future transactions and move into the loyalty quadrant.

Customer B is very satisfied with the product and the relationship with the company. The company can count on his or her repeat purchase and will most likely benefit from referral business via positive word of mouth.

Customer C is a saboteur to the organisation. Because of a negative experience, these customers will never buy from the company again, and they can also discourage other potential customers from ever interacting with the company.

Customer D was not satisfied with the product but is hopeful that the next purchase will be satisfactory. A good relationship creates a reservoir of goodwill upon which the customer is willing to give the company another chance. However, the good relationship cannot represent an absolute deterrent of customer defection, and the company needs to take urgent measures to adapt its product offer to the customer's needs before it is too late.

As the eLoyalty Matrix indicates, *CRM* implementation represents the key to increasing customer loyalty in the digital environment (Lindström & Andersen, 2000; Reichheld & Schefter, 2000). Despite a rising consciousness about the importance of loyalty marketing, 70% of online retailers lack operational strategies for cultivating their all-important customer relationships (FollowUp.Net, 1999).

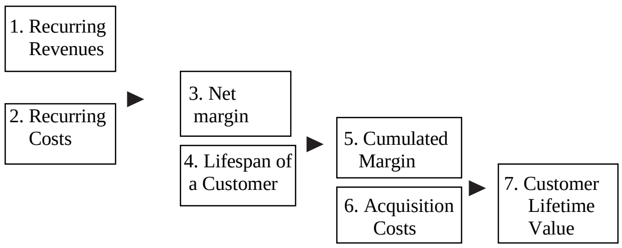
The implementation of an efficient customer relationship management strategy requires the introduction of a customer-focused organisational culture (Rheault & Sheridan, 2002). The key operations for building an effective *CRM* strategy include the following (Conway & Fitzpatrick, 1999):

- identifying the characteristics of the main customer segments;
- modelling the current and the potential value of each customer;
- creating proactive strategies and operational plans, or business rules, which will support the desired experience for the customer, starting with the highest value customers; and
- redesigning the organisation, processes, technology, and reward system to implement the relationship strategies.

The strategic planning process of an e-business organisation needs to be adjusted to the needs of a *customer-centric culture*. This adjustment has two major stages:

1. Implementing the tools of the *CRM* system within the operational structure of the firm
2. Introducing customer-centric values, objectives and procedures in the organisational culture

Figure 2. Seven-step process to measure customer lifetime value (Adapted from Bacuvier, 2001).



IMPLEMENTING THE CRM SYSTEM

Before the strategic planning process can be applied to customer centric procedures, the firm needs to put in place the tools and procedures to collect relevant information about its customers, to process efficiently this information, and to segment the market. The implementation of customer-centric systems comprises a number of essential stages.

Collecting Customer Information

As the *CRM* system is based on a customer's profile and transaction history, the company needs to collect information about its customers. The implementation of *CRM* procedures requires the existence of historical data that are used to identify the main market segments and create an accurate customer profile. These data are available either though online automated systems that register the history of customer-firm interaction (historical data) and/or buying the necessary data from a third party (usually a specialised market research agency). The collected data is stored in databases and is then accessed for processing.

Calculating the Customer Lifetime Value (CLV)

The *CLV* consists in taking into account the total financial contribution (i.e., revenues minus costs) of a customer over his or her entire life of a business relationship with the company. Despite its simplicity, the measurement of *CLV* requires great care. All cash flows involved in the process have to be identified and measured on a detailed level and allocated precisely to each customer or type of customer. The diagram in Figure 2 represents a concise seven-step approach to measure *CLV* (Bacuvier, 2001).

The calculation of the customer lifetime value is not problem free. However, most of these problems can be successfully solved, taking into consideration two main issues:

- The company applying this method has to clearly define from the beginning the purpose of using customer lifetime value analysis and the expected benefits.
- The problems raised by the customer lifetime value analysis are often industry and company specific, and as a result the company has to select the most appropriate way to apply this concept in its particular situation.

Despite its utility, it should be kept in mind that the calculation and application of *CLV* has all the limitations of a method that uses old or present data to predict future consumer behaviour. Its use is based on the existence of consumption tendencies that, although evolve in time, have a certain stability on short to medium term.

Value Segmentation

Segmentation is the key to understand the lifetime value of a specific customer, and to apply the most appropriate customer management strategy (Gurău, 2003). As a result of the customer lifetime value calculation, the company's clients can be segmented in terms of profitability, using dimensions that are discriminating either on the revenue side (e.g., usage intensity and behaviour) or on the cost side (e.g., products purchased, channel used, intensity of customer care usage and service levels). Using this analysis, the company can have a complete mapping of the "wells" of value creation and "pits" of value destruction of the business and an understanding of why they are such.

To be effective, customer behaviour profiling needs to be connected with customer *segmentation* on different value categories, using *CLV* (Ness, Schroeck, Letendre, & Wilmar, 2001). The connection between customer value and customer behaviour can be highlighted creating a relationship equity matrix (Conway & Fitzpatrick, 1999).

Table 2. Differentiated combinations of strategic approach for various customer segments

Value/Loyalty	**High Value**	**Low Value**
Loyal	Retain	Conquer Increase revenues Reduce recurring costs Reduce acquisition costs
Disloyal	Retain Reduce acquisition costs	Increase revenues Reduce recurring costs

Analysing the matrix, the strategic priority of each segment is easily identifiable.

Customer E, high-value but disloyal, represents a group that deserves the greatest amount of attention. The company is at risk of losing profitable, influential customers.

Customer F is what makes the company successful at present. Companies must pay great attention to this group as a way of expressing appreciation for their ongoing business and recognising their importance.

Customer G, low value and disloyal, does not represent a group with long-term potential. If he or she chose to switch suppliers, the economic loss will be minimal for the company. This customer is usually opportunistic and price oriented.

Customer H, low value but loyal, can be over-serviced, and therefore unprofitable for the company in the long term.

The analysis and the definition of each customer segment in terms of profitability will depend on each firm's profile and strategic objectives. The *customer life cycle* also needs to be taken into consideration. Sometimes, the low value/loyal customers can evolve into highly profitable customers, either through increased purchase or through positive referrals.

Strategies for Profit Maximisation

Considering the procedure of *CLV* calculation, in any business there are essentially five levers of customer value creation (Bacuvier, 2001):

1. **Conquer:** Acquire new customers with positive customer values or who contribute to spread the fixed costs over a wider basis.
2. **Increase Revenues:** Generate more revenues from existing customers at each transaction.
3. **Retain:** Increase the loyalty of customers in order to extend their individual lifetime with the company.
4. **Reduce Recurring Costs:** Improve the efficiency of operations in order to reduce the cost of serving each customer.
5. **Reduce Acquisition Costs:** Improve the process of attracting new customers.

These five strategies should be used differently for each customer segment, in order to optimise the potential of value creation. Table 2 proposes differentiated combinations of strategic approach for the four customer segments defined in the relationship equity matrix.

Figure 3. The relationship equity matrix (adapted from Conway & Fitzpatrick, 1999)

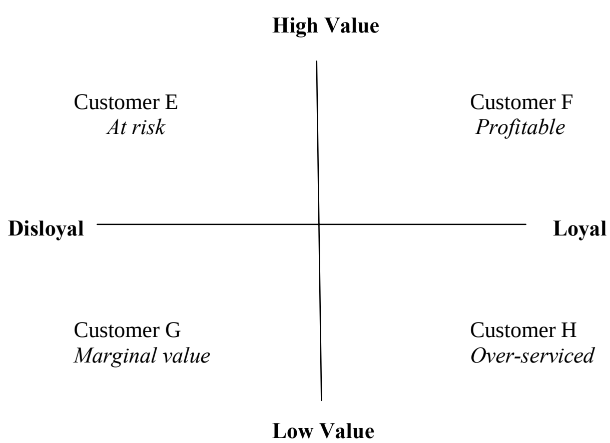


Table 3. The key changes triggered by CRM implementation (Adapted from Forsyth, 1999)

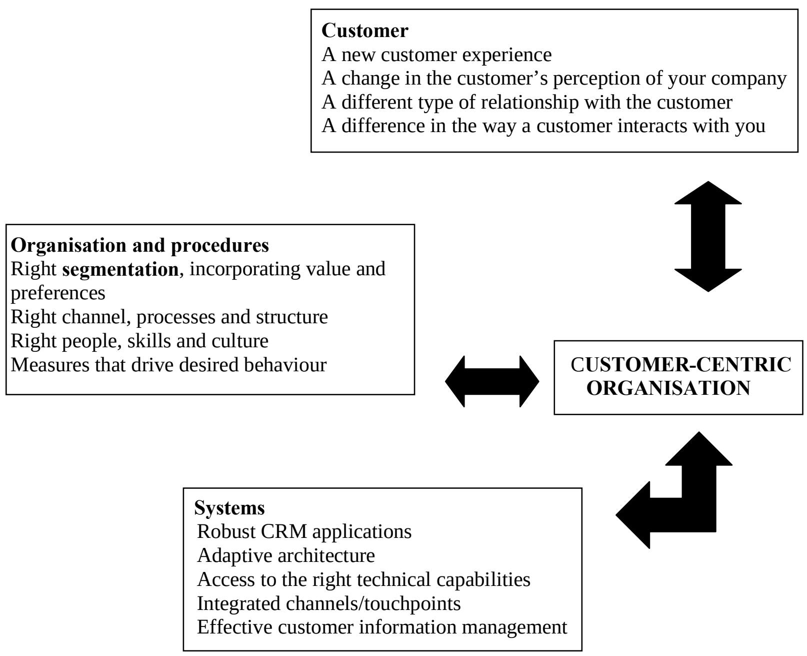
Organisational	Managing Change	Sales and Marketing	Technical
Incorporating "customer" into the business planning cycle	Changing the boundaries of marketing, sales, and communication channels	Incorporating "customer" into marketing decisions and sales operations	Providing an evolving, user-friendly CRM system
Setting customer-related objectives	Changing the customer culture to be customer oriented rather than product focused	Centralising control of the sales and marketing process	Building the CRM database from the operational or "legacy" systems
Multifunction teams required to implement customer relationship programs	Implementing a process of "continuous change"	Learning the new skills of CRM-based marketing	Providing a cost-effective environment with good performance

Figure 4. The CRM journey—Realizing full value (Adapted from Forsyth, 1999)



The main goal of this stage in the strategic planning process is to understand the characteristics of customer segments and to identify the correct mix of operational activities, capable to optimise the value of each customer segment.

Implementing a Customer-Centric Corporate Culture

Once the customers segments have been identified and prioritised in terms of profitability, it is possible to redesign the corporate culture of the business organisation around a customer-centric approach.

The redesign of the corporate culture as customer-centric (see Table 3) needs to simultaneously transform and adjust (a) the technological systems and procedures used to deal with customers (information collection systems, customer databases, customer segmentation, customer relationship strategies and their implementation); (b) the internal operations and processes within the organisation (hierarchical structure, links and collaboration between different organisational departments, structure of managerial functions and responsibilities); and (c) the values and the objectives of the organisation (application of the customer lifetime value concept, mass customisation, pursuing an increase of customer satisfaction in order to retain and increase the return value of each client, differentiation through consistent customer service). In customer-centric online organisations, the integration of analytical and operational *CRM* tools offers the possibility to identify, assess and define precisely the main customer segments in terms of profitability, and to build predictive customer profiles. The planning process should incorporate both strategic and operational perspectives, creating continuity and consistency among various organisational levels. The implementation process becomes more flexible, offering the possibility of a quick adjustment at the level of individual customer campaign.

The integration of customers' databases with data mining tools and customer management applications permits the effective management of customer interaction at individual level. Intelligent software agents can be used, for example, to identify particular events relevant for customer relationship, and then activate customer management software that automatically sends an e-mail message to the targeted client. By integrating intelligent agents and e-*CRM* technology, customer communication can be fully or partially automated using a single knowledge base via a variety of independent electronic channels such as online chat, e-mail or SMS messaging.

FUTURE TRENDS

This article attempted to present, analyse and assess the advantages and the challenges of *CRM* system implementation, and to propose a model to redesign the organisational structure in this context. This model can provide beneficial information both for academics and practitioners:

1. On the basis of this theoretical framework, future research projects can be initiated to analyse the specific procedure of introducing a *customer-centric culture* in various *CRM*-based online organisations.
2. The model can be used by managers and business practitioners to reflect on the advantages/problems of implementing a *CRM* system in their organisation and to identify the main aspects regarding the adaptation of the business process to the new organisational structure.

CONCLUSION

The flexible and interactive nature of the Internet offers the possibility to collect a vast amount of data about online customers and their interaction with the company. Processing this data provides a good basis to segment the market precisely, to predict the behaviour of customers, and to implement one-to-one marketing campaigns.

On the other hand, the volatility of online markets requires an increased focus on customer relationship and customer loyalty. Research shows that a 5% increase in customer retention can increase the company profits with 20% to 100% (Reichheld, Markey, & Hopton, 2000). In this situation, *CRM* processes become a major element of corporate strategy for digital organisations.

The applicability of the traditional approach to marketing in the online business environment has been increasingly questioned and criticised in recent years. This approach emphasised the management of key marketing mix elements such as product, price, promotion, and place within the functional context of the marketing department in order to create a winning offer. The new *CRM* approach, whilst recognising the importance of the marketing mix, reflects the need to create an integrated cross-functional focus on customer-firm interaction (Winer, 2001).

The implementation of the *CRM* model will restructure the whole enterprise, creating new procedures for market research, strategic planning, operational implementation, and managerial control. Considering the magnitude of change, an organisation needs to assess its core business and consider the form of CRM that is more appropriate for its structure and market. Then, having identified the present and the future focus of CRM, the organisation has to access and implement the appropriate information architecture to enable their *CRM* strategy (see Figure 4).

Ultimately, the organisation's success in *CRM* will involve creating an appropriate strategic vision of the future, making the appropriate choice of applications, creatively using appropriate analytical techniques to exploit the data, and, finally, incorporating the customer-centric procedures into a flexible organisational process at the corporate level (Payne, 2001).

KEY TERMS

Customer-Centric Approach: Organisational strategy that aims to explore and understand customers' needs and motivations and to restructure all organisational processes to provide superior value to consumers.

Customer Lifetime Value: The total net income a company can expect from a customer during the entire period of customer-company interaction.

Customer Management Software: Software application that allows the company to interact with multiple customer segments and to send them personalised offers.

Customer Relationship Management: An organisational strategy that starts, maintains, and optimizes relationships to increase the loyalty of customers.

Data Mining Tools: Software applications that extract predictive information from large databases, which can then be analyzed to enhance corporate data resources and generate predictions regarding business trends and customer behaviour.

Online Customer Relationship Management: The methodologies, software, and Internet capabilities that help a company manage customer relationships in an efficient and organised manner.

Relationship Equity Matrix: Analytical model developed by Conway and Fitzpatrick (1999) that allows a representation of various consumer categories and of the associated CRM operations performed by the company.

Category: Concepts, Trends, and Challenges

Indexing Mobile Objects

Panayiotis Bozanis
University of Thessaly, Greece

INTRODUCTION

The past few years have shown a significant increase in the volume and diversity of data stored in database management systems. Among these are spatiotemporal data, one of the faster developing categories of data. This phenomenon can be attributed to the flurry of application development concerning continuously evolving spatial objects in several areas: mobile communication systems, military equipment in battlefields, air traffic, truck fleets, and others.

In standard database applications, data remain unchanged unless an update is explicitly stated. Applying this mode of operation to constantly moving objects would require frequent updates to be performed; otherwise, the database would be inaccurate and unreliable. In order to capture continuous movement and to avoid unnecessary updates, object positions are stored as time-dependent functions, requiring updates only when a function parameter changes. The moving objects are considered responsible for updating the database about alterations in their movement. In the following article is a short review on basic indexing schemes for accommodating moving objects in database systems so that complex queries about their location in the past, present, and future can be served.

BACKGROUND

The indexes developed for moving objects can be classified according to criteria such as the kind of supported queries, the type of the accommodated objects, and their applicability to various-use cases. This article focuses on the last criterion. Thus, an index is characterized as *practical* when it has been implemented and experimentally investigated. Otherwise, it is *theoretical*, and its main utility is indicating inherent complexities. The following addresses practical indexes.

Database Representation

Most applications usually assume objects of fixed shape and volume and are interested only in their location as a geometric point at various instances in time. The optimal way to register such spatiotemporal information depends on its intended use, which is either the postprocessing of the recorded data, or the exploration of current and future locations.

In the first case, object trajectories must be indexed. The trajectories are usually calculated by the linear interpolation of sampled locations, both to accommodate storage limitations but also—more important—because of the very nature of the data generators (e.g., GPS equipment generates discrete location data). As a result, each trajectory consists of a sequence of connected line segments in the three-dimensional space, for which semantically related line segments must be indexed. This indexing operation requires cautious extensions to spatial indexes (Gaede & Günther, 1998).

In the second case, the object position is considered as a time function x(t). Usually x(t) is modeled as a linear *parametric* function of time:

$$x(t) = x(t_{ref}) + v(t-t_{ref}),$$

specified by two parameters: the *reference position* x(t_{ref}) at a specific time t_{ref}, and the *velocity vector* **v**, which defines a space *dual* to the *time-location* space.

Query Types

Location-Based Queries

Location-based queries are further categorized into *range* and *nearest-neighbor (NN)* or *proximity* queries. A range query is characterized as (i) *time-slice* or *snapshot* when, given a hyper-rectangle *r* located at time *t*, it asks for all moving objects contained in *r* at that time; (ii) *window* when it requests reporting all objects crossing a hyper-rectangle *r* during a time interval $\mathbf{t}=[t_s,t_e]$; and (iii) *moving* when it specifies a trapezoid τ by connecting a hyper-rectangle r_1 at time t_s and a hyper-rectangle r_2 at time t_e and inquires all objects crossing τ.

On the other hand, nearest-neighbor queries request the nearest moving object to a given location at time *t* or during a time interval $\mathbf{t} = [t_s,t_e]$. The generalization this type of queries demands the *k nearest-neighbors* (kNN). Sometimes, *reversed nearest neighbor* (RNN) searching is required for reporting all objects having a given object as their nearest neighbor.

Trajectory-Based Queries

Trajectory-based queries concern (i) information about the semantics of the movement (e.g., objects entering, leaving, crossing, and bypassing a region during a given time instance or interval). For example, "*find all mobile phones entering a particular cell between 2 p.m. and 5 p.m. today*"; and (ii) Derived or navigational information, such as travelled distance, velocity, and so forth; for example, "*report all objects whose travelled distance between 2 p.m. and 5 p.m. 3 days ago was smaller than 40 mph.*"

Continuous Queries

Continuous queries considers that the range or point query is also moving: "*find all my nearest restaurants as I drive towards the current direction for the next 5 minutes*." Despite its conceptual simplicity, these queries are inherently complex, because they are equivalent to constantly posing location-based queries.

Soundness-Enriched Queries

Soundness-enriched queries demands answers enriched with validity (temporal or spatial) information; namely, the future time t at which the result expires, and the change that will occur at time t. For instance when one asks "*report the pharmacy nearest to my position as I am now moving,*" the database will return the nearest pharmacy ID i, the future time t that i ceases to be the closest pharmacy and a new pharmacy $i2$ that would be the next nearest one at time t. Alternatively, the database returns a validity region r around the query position, within which the answer remains valid. Returning to the example, i will be accompanied by the region for which it is the nearest.

This class aims at reducing the number of generated queries: Because the query and the server responses are delivered via a wireless network, the extra information could spare network bandwidth, because the user will release new inquiries only when it is absolutely necessary.

MOBILE OBJECT INDEXING

Practical indexes can be classified into two subcategories according to the time dimension: The structures capable of answering queries about the present and the future belong to the first group, and the second one comprises indexes serving inquires about the past. The presentation of the indexes will focus on (i) the type of the queries they support; and (ii) the main performance and implementation characteristics they exhibit. Table 1 summarizes the presentation.

Querying About the Present and Future

The members of this grouping are further classified based on three types of supporting inquiries:

Structures Supporting Range Queries

Kollios, Gunopoulos and Tsotras (1999b) suggested solutions for one- and two-dimensional range querying that

Table 1. Categorization of presented indexes

Querying about the Present and Future	
Query	**Index**
Range	Kollios et al. (1999b)
	Šaltenis et al. (2000)

	Porkaew et al. (2001)
	Hadjieleftheriou et al. (2002)
	Lazaridis et al. (2002)
Aggregating	Papadias et al. (2002)
	Tao et al. (2004)
	Sun et al. (2004)

employ mathematical transformation and use either off-the-shelf spatial indexes (e.g., the R-tree; Gaede & Günther, 1998), or simplex range searching in the two-dimensional dual space.

In Šaltenis, Jensen, Leutenegger, and Lopez (2000), the TPR-tree—a time-parameterized version of the R*-tree (Gaede & Günther, 1998) for objects moving with constant velocities in one-, two- and three-dimensional space—was introduced, which became the de facto spatial index for time-slice, window, and moving queries. The TPR-tree is a practical and well-tested solution that avoids the dual space technique and the reduction to higher dimensional spaces. TPR-tree algorithms were extended in Benetis, Jensen, Karciauskas, and Šaltenis (2002) so that two-dimensional NN and RNN queries for a query point q during a time interval $\mathbf{t}$ can be served.

Further improvements where introduced as the TPR*-tree (Tao, Papadias, & Sun, 2003), which exhibits new insertion and deletion algorithms based on a novel cost model. Extensive experimentation proved the superiority of the TPR*-tree: The average query cost is almost five times less, and the average update cost is nearly constant. Thus, the TPR*-tree can be characterized as the state-of-the-art index for serving range queries. However, this fact does not invalidate the practicality of the TPR-tree, especially when one accepts to trade the administration cost for index maintenance for the ability to answer two-dimensional NN and RNN queries.

Structures Supporting Nearest Neighbor Queries

The members of this subcategory are distinguished as follows:

- **Simple Proximity Indexes:** Kollios, Gunopoulos, and Tsotras (1999a) suggested preliminary practical solutions for dealing with the simple problem of locating the nearest moving neighbor of a static query in the plane. The generality of the approach also permits locating nearest-neighbors within a specified time interval and for restricted data movement in fixed routes.

  On the other hand, Aggarwal and Agrawal (2003) introduced methods for indexing moving objects with nonlinear trajectories in arbitrary dimensions, such as d-dimensional parabolic trajectories, that satisfy the convex hull property. The convex hull property relates the locality in parametric space to the locality in the positions of objects, and, thus, suggests the employment of standard indexes (e.g., the R*-tree).
- **Continuous Proximity Indexes:** Song and Roussopoulos (2001) studied the kNN problem for a moving query point and static data points and introduced algorithms that extend static kNN queries, capitalizing on the fact that, when the query point moves to a new position, some part of the previous answer also belongs to the new one. The proposed algorithms can be implemented easily, a fact that one should consider when using off-the-shelf R-trees.

  Continuous kNN search in a static data set organized as an R-tree T has been studied by Tao, Papadias, and Shen (2002). The authors observed that when the query point is moving on a line segment, it is sufficient to use a bound-and-bound traversal of T that employs heuristic node pruning rules. The extensive experimental evaluation of this method confirms its usefulness.

  Finally, Iwerks, Samet, and Smith (2003) presented algorithms for answering continuous kNN queries on a constantly moving point set, whose members can change either location or velocity. In general, their approach is quite interesting and extends naturally the repertoire of mobile NN-queries but, as the authors noticed, further research is needed for fine tuning.

Structures Supporting Soundness-Enriched Inquires

This class of indexes returns either temporal or spatial validity information which specifies the conditions under which the answer remains effective, in addition to the answer itself. The solutions devised so far are relatively simple, but also quite promising for further development and research:

- **Time-Parameterized Queries:** Tao and Papadias (2002) introduced the time-parameterized (TP) queries that return, along with the answer set, its expiration time and the event that invalidates it. The authors also demonstrate how TP queries can be used to answer continuous *spatiotemporal* and *earliest event* queries: The first type refers to the case when one should provide results for a given time span, as they are generated. The second type asks for the evaluation of the earliest time in the future a specified event could take place; for example, in the scene of moving point objects and query point q, find the first time q catches a point.
- **Validity Queries:** Zheng and Lee (2001) considered the problem of enabling mobile clients to

determine the validity of query results according to their current location. Thus, the number of client queries—and therefore the network traffic—is reduced: The server returns the answer along with a validity region *r* within which there is no alteration of the answer, allowing clients to issue subsequent queries only when they leave *r*. Zhang, Zhu, Papadias, Tao, and Lee (2003) dealt with validity NN, kNN and window queries. For the first two cases, they suggested algorithms that implicitly calculate the validity region. The third case—window queries—is reduced to determining the maximal rectangle around the center of the window inside which the result remains unchanged and then appropriately refining it.

Querying the Past

Historical databases on moving objects accommodate spatiotemporal information, which can be processed to either *report* or *enumerate* all objects satisfying certain spatial and temporal conditions. In the first case, the corresponding indexes are characterized as *reporting* and in the second, as *aggregating* or *enumerating*.

Reporting Indexes

In Pfoser, Jensen, and Theodoridis (2000) the STR-tree and the TB-tree are proposed. Both treat spatiotemporal queries on mobile object trajectories without future prediction. The first index constitutes an extension of the R-tree; lines belonging to the same trajectory are kept closely together and time is the main dimension. In contrast, the TB-tree serves spatiotemporal queries by properly cutting every trajectory into pieces which it stores cautiously. Experimental evaluation of the index proved its efficiency, with further tuning of its performance achieved in Pfoser and Jensen (2001): In the presence of constraints by the infrastructure environment (such as roads, lakes, etc.), one can employ a proper segmentation of the original query range in a set of subranges and eliminate dead space.

The case of indexing moving objects whose extent may change was treated in (Hadjieleftheriou, Kollios, Tsotras, & Gunopoulos, 2002). The authors approximated the object movement with a minimum bounding rectangle (MBR). In addition, in order to eliminate empty space and overlap they artificially split every trajectory in pieces and insert those into a partially persistent R-tree. Porkaew, Lazaridis, and Mehrotta (2001) also approximated trajectories by MBRs stored in an R-tree and proposed algorithms for combinations of spatial and temporal range, NN, and kNN queries.

Lazaridis, Porkaew, and Mehrotra (2002) also approximated trajectories by MBRs stored in an R-tree and suggested algorithms for moving window queries with known (*predictive*) and unknown (*nonpredictive*) moving patterns. In short, they use a priority queue along with specific intersection conditions which guide and prune the search of the R-tree.

Aggregating or Enumerating Indexes

Papadias, Tao, Kalnis, and Zhang (2002) introduced three indexes for answering aggregate queries in spatiotemporal databases, the aRB-tree, the aHRB-tree and the a3DRB-tree. The first (aggregate RB-tree) refers to the case of fixed spatial dimensions whereby one needs to maintain historical summary data. For dynamic regions the authors propose the latter two indexes: aggregate historical RB-tree (aHRB-tree), which uses a node copying technique, and aggregate 3DRB-tree (a3DRB-tree), which is applicable when all region changes are known in advance.

The aforementioned indexes have a “defect”: If an object remains in the query region for several time stamps during the query interval, then it will also participate in the answer several times. Because the “distinct counting” property is very crucial in many decision-making queries—such as traffic analysis and mobile-phone-users’ statistics—Tao, Kollios, Considine, Li, and Papadias (2004) suggested algorithms that replace the direct counting of the objects by FM sketches. In this way, the resultant structure becomes *approximate* and of bounded probability failure, but it can also be properly extended to support distinct sum queries and spatiotemporal association rules extraction.

Finally, the first approach to support approximate queries about the past, present, and future was recently reported in Sun, Papadias, Tao, and Liu (2004), which introduced (i) the adaptive multidimensional grid-based histogram (AMH) for answering present time queries, and (ii) the application of the exponential smoothing—a time-series forecasting method—for serving queries about the future based on recent historical data.

FUTURE TRENDS

As can be seen in previous short review of contemporary solutions in this area of research, some very interesting topics arise that require further consideration. One area deserving attention is that of designing indexes capable of capturing the uncertainty of a moving object’s location. This uncertainty arises due to the combination of network delays and continuity of motion. Preliminary work by Trajcevski, Wolson, Zhang, and Chamberlain (2002) partially addresses modelling and querying in this domain. In addition, it would be very interesting to efficiently manipulate nonlinear trajectories since the scope of indexable moving objects would be significantly extended.

Another appealing subject, especially for extending mobile application capabilities, is the design of indexing structures capable of serving "mixed" queries concerning the past and future of movement; the approach in Sun et al. (2004) can be considered as a first attempt towards this direction. Along this same line of research, the incremental valuation of validity queries is also very intriguing.

Finally, it would be very helpful from an engineering perspective (i) to test and evaluate indexes with real datasets—until now, every experimental investigation is conducted with "semireal" data whose movement component is generated; and (ii) to design efficient updating algorithms for the indexes, which deviate from the usual 'deletion and reinsertion' practice, introducing perhaps a trade-off between either the query time or the accuracy of the result and the update time.

CONCLUSION

A broad category of applications, emerging from the technological advances that occurred in the last years in telecommunications and hardware, constitute the framework known as "mobile computing." A key issue in such a framework is the fast and timely access to a constantly changing data set. This fact indicates the crucial role of indexing moving objects. Provided in this study is a review of some contemporary solutions for this area of research from the application perspective and presented some very interesting topics for further consideration.

KEY TERMS

Database Management Systems: Software systems for organizing the information in a database in a way that permits data input, verification, storage, retrieval, and combination.

Indexing: To create an external memory data structure in order to speed up search and retrieval of information.

Mobile Computing: The infrastructure, both networking and software applications, that permits networked devices to be moved freely within the broadcast coverage area, contacting others, and conducting computations.

Moving Object: Any object (e.g., automobile, vessel, pedestrian) equipped with a location-detection device.

Query: A request to retrieve data from a database.

Spatiotemporal Data: Multidimensional data with spatial (two- or three-dimensional) and time dimensions.

Trajectory: A set of multidimensional points which define the route of a moving object during a time interval.

Information Assurance in E-Healthcare

Sherrie D. Cannoy
The University of North Carolina at Greensboro, USA

A. F. Salam
The University of North Carolina at Greensboro, USA

INTRODUCTION

There is growing concern that the healthcare industry has not adopted IT systems as widely and effectively as other industries. Healthcare technological advances generally emerge from the clinical and medical areas rather than clerical and administrative. The healthcare industry is perceived to be 10 to 15 years behind other industries in its use of information technology (Raghupathi & Tan, 1997). Incorporating new technology into the healthcare organization's processes is risky because of the potential for patient information being disclosed. The purpose of this study is to investigate the information assurance factors involved with security regulations and electronic medical record initiatives—a first necessary step in making the healthcare industry more efficient. Noncompliance of a healthcare organization's employees with security and privacy policies (i.e., information assurance) can result in legal and financial difficulties, as well as irreparable damage to an organization's reputation. To implement electronic medical initiatives, it is vital that an organization has compliance with security and privacy policies.

E-health technology is a relatively current phenomenon. There are two types of distance-related healthcare that are technology driven. Telehealth is known for involving telemedicine—medicine practiced over a distance, with the impetus of control being in the physician's hands (Maheu, 2000). E-health involves the patient or physician actively searching for information or a service, usually via the Internet (Maheu). Electronic medical records fall into the e-health category because the physician, healthcare partners, and patient would be able to access the information through an Internet connection.

Security and information assurance are critical factors in implementing e-health technologies. There is a lack of a well-developed theoretical framework in which to understand information assurance factors in e-healthcare. The theory of reasoned action (TRA) and technology acceptance model (TAM) enable a conceptual model of information assurance and compliance to be formed in the context of healthcare security and privacy policy. The relationship between behavior and intentions, attitudes, beliefs, and external factors has been supported in previous research and will provide a framework for ensuring compliance to security and privacy policies in healthcare organizations so that HIPAA (Health Insurance Portability and Accountability Act) regulations are enforced and electronic medical records (EMRs) can be securely implemented.

Traditionally, records in the healthcare industry have been paper based, enabling strict accessibility to records. This allowed for confidentiality of information to be practically ensured. The uniqueness of healthcare records and the sensitive information they contain is specific to the industry. Over the many years that medical records have been kept, those involved in the field have undertaken a self-imposed rule of stringently protecting the patient information while providing quality care.

The patient's expectation for confidentiality of personally identifiable medical records is also critical. According to Rindfleisch (1997, pp. 95-96), in his study of healthcare IT privacy, the threats to patient information confidentiality are inside the patient-care institution; from within secondary user settings which may exploit data; or from outsider intrusion into medical information. Rindfleisch (1997) examined specific disclosures which could release sensitive information such as emotional problems, fertility and abortions, sexually transmitted diseases, substance abuse, genetic predispositions to disease—all of which could cause embarrassment and could affect insurability, child custody cases, and employment.

The process of healthcare treatment includes not only the patient and physician but also nurses, office staff who send out bills and insurance claims, the insurance company, billing clearinghouses, pharmacies, and any other companies to which these processes can be outsourced. There is an estimate that states as many as 400 people may have access to your personal medical information throughout the typical care process (Mercuri, 2004). The government is also a partner in national health concerns, and also maintains databases containing information on contagious diseases, cancer registries, organ donations, and other healthcare information of national interest. (See http://www.fedstats.gov/programs/health.html for a listing of the databases.)

With the advent of government mandates such as EMRs and HIPAA regulations, the increased accessibility of sensitive records requires intense effort to create policies that limit access for those who are authorized. Although there is an area of information economics which views information as an asset that can be numerically valued for its benefit, the same perspective has not been adopted in healthcare. Especially in the United States, clinical information and patient care are considered proprietary (Hagland, 2004). There is no specific associated cost with one's medical information—what damage is done when one's medical information has been utilized improperly? Even though damages are ill-defined, there are regulations and standards for emerging technology in healthcare. The two most current important security and privacy issues involve HIPAA regulation and the government mandate for EMRs.

BACKGROUND

The HIPAA Regulation . . .

HIPAA was enacted in 1996 and covers insurance reform for ensuring preexisting coverage when changing jobs as well as the standardization of electronic transmissions. It consists of two components, the Security Rule and the Privacy Rule. If the rules are not enacted, there are severe financial penalties enforced by the government (Mercuri, 2004). Also, an organization risks having internal employees disclose information that would be of a confidential nature to patients, which could result in legal consequences.

The Privacy Rule (Markus, 2004) focuses on the use and disclosure of medical information, specifically that which is personally identifiable, also known as protected health information (PHI) in the industry. The goal of the Privacy Rule is to ensure protection of PHI across transmissions to health partners (insurance companies, billing clearinghouses, etc.). This requires the patient to fill out the Notice of Privacy Practices Patient Acknowledgment form, which suggests that the patient has read the HIPAA privacy information and allows the patient to determine the people to which one's PHI can be disclosed.

The Security Rule requires that PHI be protected specifically in electronic storage and transmissions. Implications for HIPAA compliance have been intense. Developing standards and security encryptions for existing software, as well as ensuring that third-party partners are compliant, has been time-consuming and costly. However, Privacy and Security Rule compliance will be critical for successful implementation of electronic medical record infrastructure.

Electronic Medical Records

An electronic medical record (EMR) contains a patient's medical history with a physician. The capture of one's medical information can be made available to authorized users such as other physicians, pharmacists, insurance companies, and the government. Due to the inherent virtualization of the record, the physician's office or hospital will not have physical control as they have in the past. Therefore, security measures, mainly technical components, are critical to EMR implementation. EMR records will also fall under the HIPAA Privacy and Security Rules. Since the healthcare industry has been reluctant to implement EMR plans for cost, security, or other reasons, the government has taken an active role to encourage development of EMRs through financial incentives. Healthcare and IT organizations are also collaborating to develop standards (Mercuri, 2004).

Measures Needed for Better Management

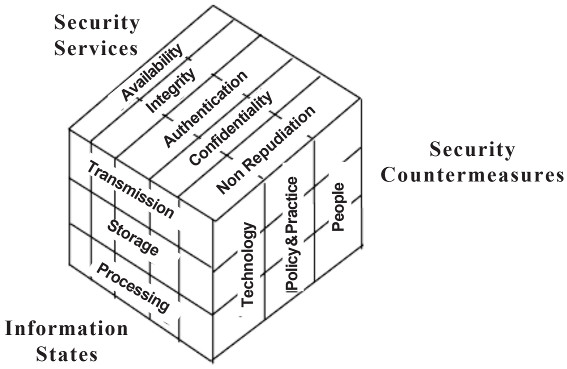
Handling of sensitive information will be vital to understanding the compliance for HIPAA regulation, as well as for the implementation of EMRs. With information now being stored and transmitted electronically, a new paradigm exists for power over the information. How organizations measure the success of HIPAA compliance will reflect on how sensitive information is handled. However, it is uncertain how the healthcare industry monitors this. The old adage of "what is not measured is not managed" comes to mind and one wonders if compliance will be monitored after training is administered and policies are implemented. The purpose of this study is to develop a preliminary framework of issues that determine compliance to information assurance and security policies.

Information Assurance

Figure 1 (from Maconachy, Schou, Ragsdale, & Welch, 2001) in which the aspects of information assurance are depicted. They discuss information assurance as an expansion of the "coverage, responsibilities, and accountability of security professionals" which includes "proactive offensive activities" (p. 307).

Aspects of security services, information, and security countermeasures fall under the information assurance (IA) umbrella. The focus of IA is integrating the relationships between these, since a weakness in one would result in a weakness in the entire system. The information can be either currently in storage, in processing, or in transmission mode. The Security Services are carried not only by technological details such as availability of the system,

Figure 1. Information assurance model (From Maconachy, Schou, Ragsdale, & Welch, 2001)



integrity of the data, authentication of users, and confidentiality, but by operations and procedures, and, most importantly, people. People "are the heart and soul of secure systems ... and require awareness, literacy, training, and education in sound security practices for the system to be secured" (Maconachy et al., p. 308). Whether or not a person follows a policy and uses the IA technology will determine how secure the system ultimately will be.

In terms of healthcare, information assurance provides a well-developed model in which to integrate the technological and behavioral issues in e-Healthcare security and privacy context. E-healthcare will be successful only if information assurance is carefully planned and monitored for compliance. In the premise offered for this research, information assurance is inherent in security and privacy policy compliance, and provides the structure for integrating the variety of research areas involved. Therefore, a theoretically-sound framework for incorporating TRA and TAM in the context of healthcare information assurance is proposed to bridge the gap between policy creation and policy compliance. This area has not been researched previously and will provide an important contribution to e-healthcare implementation in the industry, especially in bridging the gap between the technical and behavioral aspects of e-healthcare information assurance.

Government resources from Health and Human Services and associated National Institute for Standards and Technology (NIST) are helpful in framing the variables into a model for information assurance and compliance. The Department of Health and Human Services developed *Delivering Consumer-Centric and Info-Rich Healthcare: Framework for Strategic Action* (Thompson & Brailer, 2004), which discusses the readiness for change in healthcare, as well as a framework for action and leadership. NIST offers policy and security frameworks as well as healthcare tools and other assistance for both the clinical and administrative aspects (see http://www.nist.gov/public_affairs/healthcare.htm).

Healthcare Culture, Security, Compliance, and Information Assurance

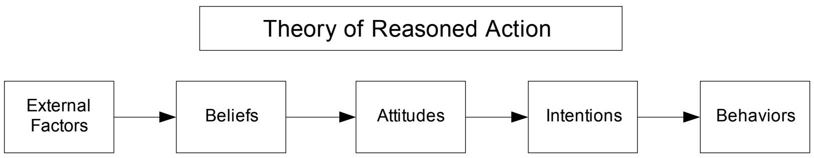
It is often stated that an organization is only as strong as the weakest link. "When you start bringing in the users, your system is going to be as trustworthy as the least trustworthy person who touches it" (Baldwin, 2000). The opportunity with HIPAA and EMRs is to realize that privacy and security of PHI must be managed in a technologically driven environment. This supports our premise that, although technological tools can aid in monitoring security and privacy compliance, they cannot provide the comprehensive measure—comprehensive adoption includes people issues. Trish Markus (2004) questioned the establishment of a "culture of compliance," which advocates the management involvement and commitment through communication and training procedures. Mercuri (2004) quoted a chief information officer as stating that HIPAA "compliance is not sold in a bottle," therefore, "providing employees with policies and procedures for their job classification and requiring them to read and sign off on them" is not adequate (p. 27). Culture includes a shared vision and a positive link to company strategy. Indeed, organizational culture can determine if compliant attitudes, intentions, and behaviors will become second nature (Gue, 2002).

Theory-Based Research

Academic research in the healthcare area has been specific, usually technology-related versus theory building and testing. TRA and TAM are utilized for the purpose of this research because the factors including a person's attitudes, beliefs, and intention to adopt a technology such as EMRs and to examine one's intentions to comply with information assurance policy associated with those EMRs. Hu, Chau, and Tulu et al. (1999, 2002, 2003) researched TAM in the context of healthcare technology adoption, with mixed results. In their 1999 telemedicine study Hu et al. found that TAM is adequate, with exception to TAM's explanation of attitude and intention. Perceived usefulness was significant on intention to use telemedicine. For the physician to perceive telemedicine as being useful, Hu et al. (1999) suggested that proper user training is essential. Attitude also significantly influenced physician behavioral intention.

In similar studies, TRA was utilized and was extended in information technology usage. Amoako-Gyampah and

Figure 2. Diagram of the theory of reasoned action



Salam (2004) measured constructs for ERP (enterprise resource planning) project communication, training, belief in the project benefits, attitude towards ERP system, perceived usefulness, ease of use, and behavioral intention to predict usage of ERP systems. TAM was extended to external variables of project communication, beliefs in ERP system benefits, and training. Findings were significant for project communication and training affect on beliefs in the system benefits. Also, shared beliefs strongly affected both PU (perceived usefulness) and PEU (perceived ease of use) in the ERP setting.

An example of TRA utilization in another study by Salam, Iyer, Palvia, and Singh (2005) examined associations between the formation of trust, technology usage, and development of a relationship with a vendor website. It suggests that managers develop factors that affect the trustworthiness of their companies. This correlates to managing the factors that affect compliance with security and privacy policies.

Capturing Information Assurance Issues in Healthcare IT Policy Implementation

The widely accepted theory of TRA has been utilized often to support the causal relationships between external factors, beliefs, attitudes, intentions, and behavior. TAM is a TRA spin-off and has supported the intention to use, perceived usefulness, and behavior when adopting new technology. This same theoretical basis can be used to examine the acceptance and compliance behavior of users who are to adopt new organizational policy. In the context of information assurance, the TRA model will capture the compliance of healthcare security and privacy policies (see Figure 2).

Our premise is that through one's external factors, beliefs, attitudes, and intentions, one will decide to either comply or not comply with security and privacy policies. We will examine the context of compliance with security and privacy policies within the TRA, because the user of the policy will, in essence, determine the success of such policies and compliance with HIPAA. The user can be defined as the physician, clerical staff member, IT staff, administrative staff, nursing staff, and so forth.

COMPONENTS OF THE FRAMEWORK

Organizational Culture

The main components of organizational culture which relate to information assurance compliance are management commitment and its enforcement of IA Policies. The extent to which management seems committed and is willing to enforce IA policies will affect how strongly one believes in management commitment and its enforcement of those policies.

Figure 3. Diagram of the technology acceptance model

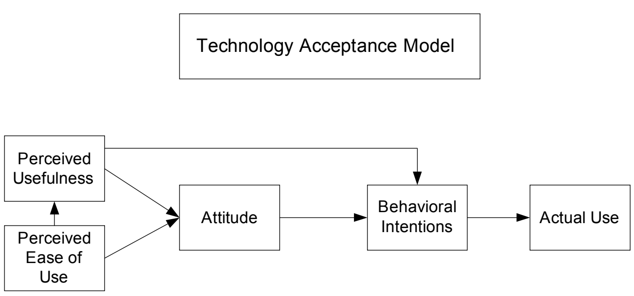


Figure 4. A conceptual framework for applying the theory of reasoned action and the technology acceptance model in e-healthcare information assurance

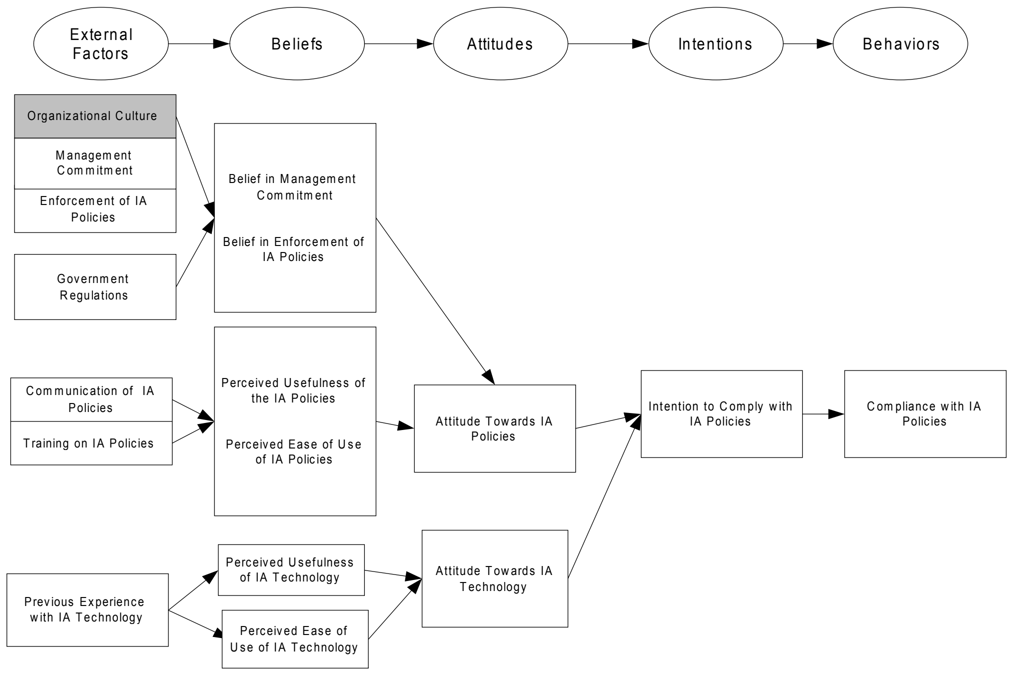

Government Regulations

Government regulations such as HIPAA and mandates such as EMRs will affect how strongly the management of healthcare organizations is committed to communicating and enforcing information assurance policies.

Training and Communication

Amoako-Gyampah and Salam (2004) found in their research on ERP implementation that Training and Communication influence the beliefs on attitude and its mediation effects on the intention to use an ERP system. Accordingly, training on IA Policies and the communication of those policies should also have an influence on the perceived ease of use and perceived usefulness of such policies. If employees feel that training is helpful in information assurance and compliance, employers may be urged to offer further training, even in the maintenance phase, so that information assurance can be increased as much as possible. If the policies are communicated often, and in various ways, especially in how they are important and relate ensuring security and privacy of patient information, employees should be more apt to find it beneficial to use and comply with the policies.

Previous Experience with IA Technology

The TAM model is appropriate and supported in demonstrating the influence between a person's prior experience with a technology and how useful and easy that technology will be to use. Much of the research has shown that this perception of usefulness and ease of use enables one to develop attitudes towards that technology in order to determine whether they will use the technology (Davis, 1989; Venkatesh & Davis, 2000). In this case, the attitude towards technology will affect one's behavior and choice to comply with the policies. If the implementation of information assurance and security policies involves technological barriers that decrease functionality of the technology or are too difficult to manage, the user is less likely to use the technology, therefore, less likely to comply with the policy.

This framework captures how factors such as organizational culture, government regulations, training, policy, and previous experience lead to belief, attitude, and intention formation regarding IA policy compliance behavior. Belief systems such as management commitment, enforcement of policy, the ease of use and perceived usefulness of IA policy and technology, shape one's attitude towards IA technology and policy. This attitude development then affects one's intention to comply with IA policies and, therefore, actual compliance behavior.

FUTURE TRENDS IN E-HEALTHCARE

The environment for healthcare is changing rapidly, and the processes involved will transform how patient care is conducted. Along with the implementation of EMRs, the ultimate goal is the EHR (electronic health record), which will include the consolidation of a patient's lifetime health records from each healthcare provider. This EHR is a virtual roadmap that guides the physician in the journey to medical decision-making. Having this information at hand, even available via handheld devices, makes critical information available to physicians to share data while geographically dispersed. This is the dawn of telemedicine, which is already gaining popularity in New Zealand and Australia. Smart card technology is emerging as a new technology which can be applied to enable patients to carry their own virtual medical charts in their pockets (Raghupathi & Tan, 2002).

There are additional legal and financial issues to be handled in the future. The legal aspects of implementing telemedicine and EMRs need clarification. Who owns the EMR? Who will be responsible for attempts at unauthorized access? Will the patient be allowed to view and edit their EMRs—for example, add their living will or organ donor preferences (Pyper, Amery, Watson, Thomas, & Crook, 2001)? If a vendor is utilized to store healthcare data for an organization, what happens to the data if the company goes out of business (Songini & Dash, 2000)? Will insurance companies consider telemedicine consults for payment?

These legal, financial, and technical issues will need to be resolved so that the transformation of healthcare processes are successful and patient care is administered in the most appropriate manner possible, regardless of how, where, and what information is utilized to make the most informed medical decisions.

CONCLUSION

The contribution of this research is to propose a theoretically sound framework in which behavior and technology are analyzed in compliance and information assurance in e-healthcare. This will enable future research in moving the field forward in healthcare information assurance research and practice. The next step in this research is to examine how healthcare organizations can measure the success of security and privacy policy compliance to achieve an information assurance threshold. The importance of understanding compliance within this context will be critical to determining the success of security and privacy policies.

KEY TERMS

Confidentiality: Not releasing or disclosing information to unauthorized individuals, entities, or processes (Fariborz, Navathe, Sharp, & Enslow, 2003).

EMR: electronic medical record; also known as EHR (electronic health record), CMR (computerized medical record) or CPR (computer-based patient record). There are subtle differences between these; for example, EHR is often used specifically for ambulatory care records (Marietti, 1998).

HIPAA: Health Insurance Portability and Accountability Act (1996) requires the secretary of health and human services to publicize standards for the electronic exchange, privacy, and security of health information.

- **Privacy Rule:** addresses the need for healthcare organizations to allow patients to choose how their information is disclosed
- **Security Rule:** addresses the security of electronic transmission of medical information

Information Assurance: Information operations that protect and defend information and systems by ensuring their availability, integrity, authentication, confidentiality, and nonrepudiation (Maconachy, Schou, Ragsdale, & Welch, 2001).

NIST: National Institute of Standards and Technology

- NIST was founded in 1901 and is a non-regulatory federal agency within the U.S. Commerce Department's Technology Administration. NIST's mission is to develop and promote measurement, standards, and technology to enhance productivity, facilitate trade, and improve the quality of life. (see www.nist.gov)

Privacy: The rights of individuals regarding collection, storage, processing and use in decision making about personal information about themselves (Turn, 1999).

Security: A collection of policies, procedures, and safeguards that help maintain integrity and availability of information systems and control access to their contents (Rindfleisch, 1997).

Telemedicine: "When physicians use electronic communication and information technologies to provide or support clinical care from a distance" (Patel & Rushefshy, 2002, p. 328).

Information Integration for Relationship Management

Robert S. Moore
Mississippi State University, USA

Merrill Warkentin
Mississippi State University, USA

Melissa Moore
Mississippi State University, USA

INTRODUCTION

In the past 20 years, an explosion in the ability of firms to acquire and integrate vast amounts of electronic customer information has occurred. For example, in the early 1990s, Lotus Development Corporation introduced, then withdrew a software product called *MarketPlace: Households* from the market after widespread public concern. The $695 product had a searchable database of 120 million Americans, containing their names, addresses, estimated incomes, consumer preferences, and other personal details. Fast forward to 2005, and companies like ChoicePoint Inc. hold personal information on virtually every single American and sell it over the Internet. Though the ability to technologically acquire and manage information has been possible since the mid 1960s, it was not until the 1990s that the Internet allowed even the smallest of firms to collect, purchase, and integrate information about potential customers. This "interactive information integration" capability is a process of consolidating and managing customer information from all available sources. The recent proliferation of affordable client devices such as desktop computing combined with advances in telecommunication (broadband, mobile devices, etc.) in the early part of the 21st century has enabled this trend to continue and grow.

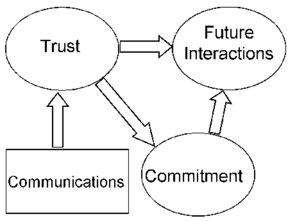
Optimally, marketplace information is used to develop need-based offerings generated from specific individual-level data. These customized solutions can lead to long-term profitable relationships for both customers and firms. However, the level of acceptance of the collection and use of personal information varies among consumers, and the human and technological ability of firms to properly secure information is not perfect. Miscues, such as ChoicePoint's report that personal data for more than 140,000 people had been stolen and Time Warner's report that data tapes containing information on more than 600,000 past and present employees was lost (Perez & Brooks 2005), affect attitudes toward the collection and use of personal information, particularly in marketing communications.

BACKGROUND

Within the span of only a few years, marketers have witnessed an explosion in the number of available electronic communication vehicles. These new media channels include the firm's Web site, directed online advertisements placed on Web pages, commercially oriented e-mails, text messaging, and direct communication to mobile devices (e.g., smart phones and PDAs). In each of these communication media, the collection and use of personal information can influence the development of relationships between firms and individual consumers. Firms differentiating themselves by better targeting their messages must collect and use personal information.

However, the willingness to provide information is not the same for all consumers (Berendt, Günther, & Spiekermann, 2005) and perceptions of appropriate use of information falls along an *intrusion continuum* (Petty, 2003), with some individuals advocating a right to privacy and strongly opposed to any information collection processes, while others appreciate that personal information use is a prerequisite for improved service and value. Firms consider consumer information as a resource to be used internally and shared with strategic partners (third parties). Internal use allows integration of seemingly disparate customer information into meaningful user profiles, which are used to develop highly personalized communications. Information from consumers comes knowingly (i.e., through filling out online forms) or unknowingly (i.e.,

Figure 1. Marketing communication's role in building relationships



online behavior tracking). Yet, individuals are often unaware of the information's accuracy, how the information is used, or who has access to it.

We present an interdisciplinary synthesis of recent research concerning information integration use in relationship marketing in the emerging electronic marketing communications arena. We present our perspective of how different levels of information acquisition and integration used in electronic marketing communications impact consumer perceptions and relationship building, couched with a discussion of recent legal and policy issues related to online privacy. We conclude with a discussion of future trends and implications of electronic marketing communications, coupled with privacy concerns on perceptions and subsequent customer relationships.

RELATIONSHIP MARKETING

Researchers in the field of marketing have adopted a relationship-based philosophy toward marketplace interactions. Firms have moved from generic mass marketing communications toward highly individualized targeted communications. Figure 1 provides a general illustration of marketing communications' effect in the relationship marketing process. The purpose of targeted communications is the formation of relationship commitment from customers. As committed customers, they are more likely to stay with the firm, speak positively about the firm, and disclose information to the firm, leading to even more targeted communications.

With electronic communications overall, developing trust is seen as an important step in the relationship building process (Lee & Turban, 2001). Trust is accepted to be essential in the development of successful relationships (Morgan & Hunt, 1994; Garbarino & Johnson, 1999). Trust leads an individual to believe that the company will "…perform actions that will result in positive outcomes … as well as not take unexpected actions that result in negative outcomes" (Anderson & Narus, 1990, p. 45).

In marketplace interactions, trust is necessary before one is willing to share personal information. However, for the Internet, because it is a relatively new means for engaging in commercial and communication activity, uncertainty and risk are often noted as reasons for an individual's reluctance to provide information, and trust is essential (Suh & Han, 2003).

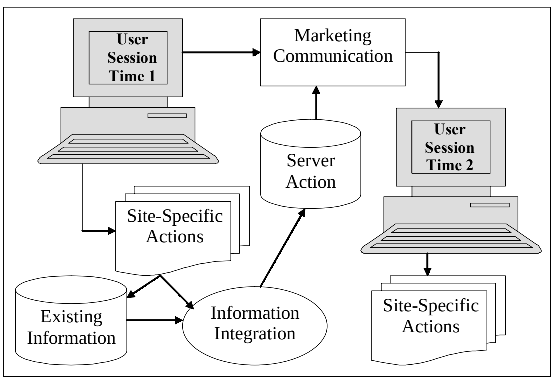
Role of Communication in Relationship Marketing

Communication, or information exchange, is an important antecedent of trust in relationship marketing (Morgan & Hunt, 1994). Marketing communications in the electronic environment are any actions that result in electronically based information being shared between an individual and a firm. Therefore, electronic communication is more than just firm-created communications and encompasses individual actions such as visiting a firm's Web site, sending e-mail, receiving newsletters, filling out forms, engaging in text messaging with service personnel, tracking a package, or responding to an offer sent via short messaging service (SMS) or mobile text messaging. Such a broad definition allows that any electronically enabled interaction between the firm and an individual is viewed as a communication act.

INFORMATION INTEGRATION AND MARKETING COMMUNICATIONS

The integration of information is a powerful tool for developing personalized marketing communications (Peltier, Schibrowsky, Schultz, & Davis, 2002). Information integration, as illustrated in Figure 2, is a technology-

Figure 2. Information use to create personalized marketing communications



based approach that assimilates relevant data from internal and external sources to develop an offering from the firm (Jhingran, Mattos, & Pirahesh, 2002).

As an Internet user begins his or her session, information is collected based on current actions and previously stored information. This information is then integrated to offer a marketing communication to the user. The user's response is collected to be used to calibrate and modify future communications (Gatarski, 2002; Sherman & Deighton, 2001).

Existing Information

This encompasses any information that has been collected previously about or from a particular user. An individual firm may have access to data about a user's purchasing history, demographics, or financial status, but also data regarding previous usage patterns on the Internet (Bhat, Bevans, & Sengupta, 2002), as well as communications that the user may have had with the company through telephone conversations, e-mails, chat room comments, responses to previous communication, or from contracted secondary sources (Romano, Donovan, Chen, & Nunamaker, 2003).

Site-Specific Information

Beyond collection of information related to a specific purchase (e.g., name and items purchased), we refer to technological tools to obtain real-time information about a user. The use of client- and server-side technologies allows the specific actions in a current Internet session to be tracked and recorded.

Cookies are the most prevalent client-side technology. Cookies are small text files which are capable of tracking and recording information such as the specific visited Web page URLs and information provided to such Web sites. Alternatively, server-side technologies are managed at the company's servers. Log files keep track of items such as which Web pages are called and how long a page is kept open. Web bugs combine the capabilities of server log files and cookies by tracking users across participating Web sites. Web bugs not only track behavior on a single Web site, but can also be used to track behavior across Web sites over time.

Information Integration

This is the ability to efficiently and systematically combine information from many sources. With the large amount of information that is available, the ability of firms to integrate and extract situation-specific data and apply them in a targeted communication is a valuable asset which can provide the firm with a strategic competitive advantage (Roth, Wolfson, Kleewein, & Nelin, 2002).

Server Actions

In terms of Internet marketing communications, the information integration process utilizes information resources to have the server react differently for each customer or a customer group. The precision to which the server reacts is driven by the amount of information integration used to form a profile (Wiedmann, Buxel, & Walsh, 2002). A profile may include not just demographic data, but also psychographic information (Peltier et al., 2002). Peltier et al. (2002) further provide that marketing communications can be developed to match the purchasing needs of that segment of each profiled segment.

Marketing Communications

Since the early 1990s (Blattberg & Deighton, 1991), firms have used technology and proprietary customer data as the basis for developing new product sales forecasts. Today, most electronic marketing communication efforts of firms are matched with some aspect of the individual (Raghu, Kannan, Rao, & Whinston, 2001). These efforts include both asynchronous and synchronous communication formats. Asynchronous formats are exemplified by brand-building Web sites in which the visitor interacts with the brand itself, online advertisements which are ads placed on content sites (Zhou & Bao, 2002), and opt-in commercially oriented e-mails (Krishnamurthy, 2001a) or unsolicited e-mails (a.k.a., "spam"). Telecommunication advances have also led to the emergence of synchronous formats of communication, such as wireless communication technologies which include instant messaging (IM) also known as text messaging, and communication to mobile devices, such as smart phones and PDAs, particularly in Asia (Fowler, 2005). Information integration is essential for these mobile communication strategies to be successful. The communications represent building blocks in the relationship. However, the degree to which these communications are accepted by users and contribute to a relationship depends on whether the individual has given the marketer permission to use that information (Godin, 1999; Krishnamurthy, 2001b).

Permission marketing suggests consumers will be more accepting of a message if they agreed to receive it (Godin, 1999). Krishnamurthy (2001b) extended this concept with *permission intensity*—a combination of a user's willingness to receive a message and the leeway they allow the marketer to use personal information.

A real issue with using technology to create personalized communications is that individuals may not know their personal information collected or how it is used. Consider the following events:

- **May 2000:** FTC recommends that Congress take action to create legislation for all commercially oriented Web sites to comply with "the fair information practice principles—consisting of notice, choice, access and security" on the collection and usage of personal information (FTC, 2000).
- **January 2002:** Eli Lily and Company settles with the FTC after an e-mail containing the e-mail addresses of all 669 subscribers to its Prozac medication reminder service was sent to the entire list inadvertently in the "To:" field (FTC, 2002).
- **August 2002:** DoubleClick Inc., the nation's leading Internet advertising service, settles with 10 states for $450,000 over their privacy practices of tracking online behavior through cookies and Web bugs (Culberg & Reilly, 2002).
- **February 2003:** The largest fine ever assessed by the FTC was on Mrs. Fields Cookies and Hershey Foods Corporation ($185,000) for collecting personal information from children without parental consent in violation of COPPA (FTC, 2003).
- **April 2005:** New York Attorney General Eliot Spitzer files suit against Intermix Media for downloading spyware and adware to users' PCs without warning or with misleading disclaimers (Richmond, 2005).

As the above stories verify, the clash between personal information and business use of technology is ongoing. Technological improvements have made it much easier and cheaper for virtually any firm to obtain personal information (Rust, Kannan, & Peng, 2002). There is a constant tradeoff between a communication's value and personal privacy (Foxman & Kilcoyne, 1993).

A key influencer of why an individual is willing to give information is the reputation of the firm (Andrade, Kalcheva, & Weitz, 2002). The more reputable a firm is perceived to be, the less concern an individual has over the collection of personal information. Additionally, the more complete and comprehensive a firm's privacy policy, the less concern an individual has over information collection and use (Culnan, 2000; Milne & Culnan, 2002). Unfortunately, the content of privacy policies of even the most popular Web sites is difficult to comprehend, which affects the policy's usefulness (Milne & Culnan, 2002).

FUTURE TRENDS

Information integration trends fall along two streams—advances in technology and behavioral issues relating to privacy concerns. A potential means of increasing consumer trust in a firm's privacy standards is through the use of seals of approval. Seals of approval from trusted third parties may lead to increased trust in an Internet firm's operation, as suggested by Miyazaki and Krishnamurthy (2002). However, Internet-based seals of approval are not well known by users, and one study found that even if they are aware of the seal's legitimacy, less than half reported that the seal affects their purchasing decisions (Head & Hassanein, 2002). Therefore, there appears to be a limited role in using third-party seals to allay an individual's privacy concerns. An alternative to third-party seals of approval may be effective co-branding through the use of affiliate programs. A reputable, trusted firm that offers affiliate programs needs to be careful in too freely allowing affiliates which may not adhere to the same level of customer orientation in their quest for increased sales.

In terms of public policy, a specific mechanism that potentially could improve user trust is the widespread adoption of the World Wide Web consortium's Platform for Privacy Preferences (P3P). P3P allows a user's stated privacy preferences to be compared with a Web site's information collection practices. When the firm wants more information than the individual has stated as preferences, the user would be notified (Powell, 2002).

Technologically, the 21st century is likely to witness new and unforeseen convergences of electronic devices. For example, the physical locations of technology to track and record information is moving away from the firm and toward the individual, as illustrated by U.S. approval in October 2004 of an implantable chip that could contain an individual's medical history. The use of radio frequency identification (RFID) chips to track the movement of individual products is yet another example of this shift. So-called "location-aware" applications may provide marketers with the ability to directly target users (via communication to their mobile devices) who are at specific locations, such as outside a specific shop or at a specific mall. Convergences and applications such as these may require individuals, businesses, and governments to take proactive positions on acceptable circumstances for personal information use and perhaps even on the question of who owns personal information.

CONCLUSION

The preceding sections have synthesized recent literature concerning the integration of electronic communications in the development of customer-firm relationships. We have discussed the importance of marketing communications for firms as they attempt to build trust and acquire long-term (repeat) customers. Firms want positive relationships with customers since these customers are likely to speak positively about the firm, purchase again from the firm, and trust the firm enough to share valuable personal information.

At the individual level, research indicates that individuals' level of concern for privacy is likely to influence acceptance of marketing communications. Additionally, the threshold of privacy intrusion perception may rise with the increased sharing of traditionally sensitive personal information such as medical or financial information than with less sensitive data such as purchasing patterns or electronic behavior. However, with the availability of seamless, real-time information integration, many individuals may not know how, who, or when their personal information is being shared between parties or is being used to create marketing communications, and privacy concerns may not surface. As consumers learn that their personal information is being collected without their knowledge and is being used in the development of electronic communications, especially when the communication uses personal information and is intrusive, there is potential for a backlash against the message sponsor and even against the technology itself. This may lead to grassroots efforts to change public policy, as more consumer interest groups push for legislative action at all levels of government.

KEY TERMS

Client Side: Activities that occur on the user's computer, which may interact with the server. (Note that "clients" may now include mobile devices, such as smart phones and PDAs.)

Customer Relationship Management (CRM): Methods and technology-based capabilities that help an enterprise proactively manage customer relationships to deliver value to customers. CRM typically involves tracking individual customer behavior over time (in a database) so that the resulting knowledge (typically mined from clickstream data, purchase histories, etc.) can be used to configure solutions tailored to each individual customer's preferences, needs, and desires. This process of personalizing each customer's experience is often termed "mass customization."

Information Integration: The process of consolidating and managing customer information from all available sources. Also called customer data integration.

Permission Intensity: Composed of two elements, the amount of information an individual provides an organization and the permission to use the information to develop personalized communications.

Permission Marketing: The act of requesting customer approval before sending a marketing communication.

Relationship Commitment: The degree to which either party of a commercial relationship (firm or customer) is likely to remain in the relationship.

Relationship Marketing: The process of creating a long-term beneficial commercial relationship between a firm and a customer through the use of individualized interactive communications and offerings.

Server Side: Activities that occur on an organization's Web server, which may interact with multiple clients.

Information Privacy and E-Technologies

Edward J. Szewczak
Canisius College, USA

INTRODUCTION

The use of various e-technologies for e-commerce, e-government, and mobile commerce is characterized by the collection of personal information—both routinely as well as surreptitiously—and the possibility of misuse of that information. Various uses of e-technologies that collect or disseminate personal information include corporate and government databases, e-mail, and wireless communications. (For a discussion of clickstream tracking and spyware, hardware and software watermarks, and biometric devices, see Szewczak, 2005) The main challenge to personal information privacy is the surreptitious monitoring of user behavior without the user's consent and the possible misuse of the collected information resulting in financial and personal harm to the user. In light of this reality, people limit their use of e-technologies, even to the point of limiting the success of e-commerce (Szewczak, 2004). Our focus is primarily on e-technology use in the United States of America, though clearly e-technology is global in nature and poses challenges and issues for societies around the world. Also, in light of the 9/11 terrorist attacks on the World Trade Center and the Pentagon and the U.S. government's response to them, the issue of information privacy takes on a new urgency (for more information, see www.privacyinternational.org).

THE IMPORTANCE OF INFORMATION PRIVACY

The results of a 1998 survey conducted by Louis Harris & Associates, Inc., revealed that worries about protecting personal information ranked as the top reason why people are generally avoiding the Web (Hammonds, 1998). A survey by NFO Interactive (for more information, see www.nfoi.com) found that the safekeeping of online consumer personal information was the main reason people chose not to shop online.

Furthermore, TNS and TRUSTe's quarterly study of consumer attitudes and behaviors on privacy topics found that many Web users are skeptical of the necessity of giving their personal information to online businesses and do not like registering at Web sites they visit. Forty-three percent of those surveyed stated they did not trust companies to not share personal information (e.g., see www.TRUSTe.org/articles/quarterly_index1.php). The misuse of credit card data for activities such as identity theft is a major concern (Westin, 2003). Identity theft involves the surreptitious assumption of a person's identity to secure bank loans, credit cards, and mortgages in that person's name. Victims usually do not have to pay for credit card purchases made in their name, although they may be liable in thefts involving other types of loans. It can take months and years for innocent victims to restore their damaged credit histories. Some identity thieves assume the identities of whole companies, using an employer identification number to secure commercial loans, corporate leases, or expensive office products. The Federal Bureau of Investigation claims that many identity thefts originate in Russia, Romania, and West Africa (O'Brien, 2004b).

Failed Internet companies such as Boo.com, Toysmart.com, and CraftShop.com have either sold or have tried to sell customer data that may include phone numbers, credit card numbers, home address and statistics on shopping habits, even though they had previously met Internet privacy monitor Truste's criteria for safeguarding customer information privacy. The rationale for the selling was to appease creditors (Sandoval, 2000). Selling customer data is in direct opposition to the top Internet privacy issue as identified by Dhillon and Moores (2001).

In his excellent study on privacy in the information age, Cate (1997) adopted the definition of privacy as "the claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others" Westin (1967, p. 7). Westin's and Cate's definition is interesting, because it allows for flexibility in discussing privacy within the context of e-technologies. Whereas many people worry about divulging personal information electronically, other people seem more than willing to give it away, trading their personal information for personal benefits such as free shipping and coupons (Kuchinskas, 2000). Personalized service is the main benefit. A Web site can save a shopper time and money by storing and recalling a user's tastes and buying habits (Baig, Stepanek, & Gross, 1999). Microsoft's Passport is designed to allow a user to visit many Web sites without reentering personal information at each site (Clark, 2001). Internet service providers are willing to allow Web users cheaper access to the Internet, provided the users are amenable to having their online behavior tracked for marketing purposes by specialized software (Angwin, 2000). SBC Communications has told its customers that it will take away discounts for its popular offerings like high-speed Internet access if they choose not to have their personal information shared among the company's subsidiaries (Lazarus, 2004).

E-TECHNOLOGY CHALLENGES TO INFORMATION PRIVACY

Corporate and Government Databases

The practice of gathering personal information about customers and citizens by corporations and governments is well established. Software is available that is dedicated to analyzing data collected by company Web sites, direct-mail operations, customer service, retail stores, and field sales. Web analysis and marketing software enable Web companies to take data about customers stored in large databases and offer these customers merchandise based on past buying behavior, either actual or inferred. It also enables targeted marketing to individuals using e-mail. Governments routinely collect personal information from official records of births, deaths, marriages, divorces, property sales, business licenses, legal proceedings, and driving records. Many of the databases containing this information are going online (Bott, 2000; Cropper, 2005). Personal information that were once stored in filing cabinets in attorneys' offices, hospitals and financial institutions can now be accessed with a click of a mouse (I. Armstrong, 2002).

Public records, however relevant for ensuring fairness in government action, may be accessed online to acquire personal information about a wide variety of topics including a person's lifestyle or sexual history which may be included in court documents (e.g., divorce decrees). The same is true for private medical records if an insurance holder sues over payment claims. The problem is compounded by the fact that counties have sold information in bulk to commercial companies that repackage it or resell it to other companies or to individuals (Leach, 2004). Although most states require information like Social Security numbers be concealed before documents are made available online, it is impractical and sometimes impossible to catch every instance (Ogles, 2004).

Internet service providers maintain archives of Internet message boards. Even users who adopt pseudonyms to protect their identities when expressing opinions may be identified through logs of Internet access, length of time online, time of day the Web was surfed, and credit card numbers used to shop (Bedell, 2001).

The deregulation of the financial services industry provided by the Gramm-Leach-Bliley Act (GLB) has made it possible for banks, insurance companies, and investment companies to begin working together to offer various financial products to consumers. Personal financial information that was kept separate before deregulation can now be aggregated. In fact the ability to mine customer data is one of the driving forces behind the creation of large financial conglomerates. Services can be offered to customers based on their information profiles. Large credit bureaus such as Equifax and Trans Union have traditionally been a source of information about a person's credit worthiness. Their databases contain information such as a person's age, address, and occupation. Credit bureaus sell personal information to retailers and other businesses (Westin, 2000a).

Like personal financial information, medical information is for most people a very private matter. Despite this fact, there is a wealth of personal medical data in government and institutional databases. As *Consumer Reports* (Westin, 2000b, p. 23) noted:

The federal government maintains electronic files of hundreds of millions of Medicare claims. And every state aggregates medical data on its inhabitants, including registries of births, deaths, immunizations, and communicable diseases. But most states go much further. Thirty-seven mandate collection of electronic records of every hospital discharge. Thirty-nine maintain registries of every newly diagnosed case of cancer. Most of these databases are available to any member of the public who asks for them and can operate the database software required to read and manipulate them.

Much of personal health information available to the public is volunteered by individuals responding to 800 numbers, coupon offers, rebate offers, and Web-site registration. Much of the information is included in commercial databases like Behavior-Bank sponsored by Experian, one of the world's largest direct-mail database companies. This information is sold to clients interested in categories of health problems, such as bladder control or high cholesterol. The Medical Information Bureau (MIB) is a database of medical information shared by insurance companies. If a person has a medical condition that an insurance company considers significant, the company will report that information to the MIB, where medical conditions are represented by codes (for more information, see www.privacyrights.org).

E-Mail

E-mail accounts for 70% of all network traffic, yet only 10% of it is protected by security measures. Thus, it is susceptible to tampering and snooping (L. Armstrong, 2000; Weingarten & Weingarten, 2002). In many companies, employee e-mail communications are routinely monitored. Despite the fact that most companies had policies alerting employees that they were subject to monitoring, 25% surveyed had fired employees based on evidence collected during monitoring (Seglin, 2000). Hackers can also be a problem. Programs can be surreptitiously installed that monitor a user's keystrokes. The keystrokes can be sent across the Internet to a computer that logs everything that is typed for later use (Glass, 2000).

Google, Inc., released an e-mail service called Gmail, which searches for certain words in users' incoming messages, then displays text ads related to those words. Not only do users find the targeted ads a nuisance, privacy advocates object to the fact that perhaps thousands of a user's messages may be stored on Google's servers over time, where the user has little control over them. These stored messages may be combined with records of a user's search activity captured using clickstream tracking and spyware to create a detailed portrait of a user (Delaney, 2004; Wildstrom, 2004).

Another threat to information privacy related to e-mail is phishing. Phishing uses e-mail messages to entice unsuspecting consumers to Web sites that resemble the home pages of trusted banks and credit card issuers. Web site visitors are then induced to reveal passwords and bank account, Social Security, and credit card numbers (O'Brien, 2004a). Phishers profit by acquiring personal financial information and working with international crime syndicates to fence stolen data. They cover their tracks by routing e-mail and Web sites through multiple Internet hosts located throughout the world (Krebs, 2004).

Wireless Communications

Echelon, a monitoring operation run by the U.S. National Security Agency, uses satellite technology to listen in on virtually all international and (to a limited degree) local wireless communications, including phone calls, faxes, e-mail, and all radio signals. Echelon is designed primarily for nonmilitary targets, including governments, organizations, and businesses around the globe (Port & Resch, 1999). Various consumer services, such as GM's satellite-based Onstar and wireless tollbooth collection systems such as EZ-Pass and FasTrak can monitor and record a traveler's activities (for more information, see www.cdt.org/privacy).

Wireless advertising poses a host of challenges for privacy advocates. Wireless service providers know customers' names, cell phone numbers, home or office addresses, and the location from where a customer is calling as well as the number a customer is calling. Each phone has a unique identifier that can be used to record where in the physical world someone travels while using the cell phone (Petersen, 2000). The Federal Communications Commission requires cell phone service providers to be able to identify the location of a caller who dials 911, the emergency number, using Global Positioning System (GPS) technology or triangulation based on the distance of a cell phone's signal to nearby cellular towers. Because a cell phone service provider can track the location of a 911 call, it can track the location of any other call as well (for more information, see www.privacyrights.org).

Five major U.S. wireless carriers have proposed the development of a 411 directory of wireless mobile phone numbers to satisfy the needs of small businesses that use wireless phones as their primary mode of communication with their customers. A national survey conducted by TNS showed that 53% of mobile phone users are against the establishment of such a 411 directory. 56% of respondents would opt-out of publishing their numbers (www.TRUSTe.org/About/Press_Release/12-07-04.php).

Radio frequency identification (RFID) devices transmit identification numbers on request from a compatible reader using radio frequencies. RFID devices are tiny and easily concealable in consumer items such as clothing, cosmetics and tires (www.Junkbusters.com/rfid.html). They are becoming an indispensable technology in supply-chain management. For example, Wal-Mart has adopted an electronic product code to track pallets and cases coming through its dock doors (see www.Walmartstores.com). Ultra high frequency RFID tags provide faster data-transfer speeds and longer read ranges. Some RFID readers can read data transmitted by many different RFID tags, enabling retailers to compile a more complete profile of shoppers than is possible by scanning bar codes of products a consumer purchases. Some technology experts predict that a network of millions of RFID receivers will be placed strategically in airports, seaports, highways, distribution centers, warehouses, retail stores, and homes to collect, process and evaluate consumers' behavior. It could be used by governments to monitor the activities of its citizens (see Electronic Privacy Information Center, 2005).

FUTURE TRENDS

How the information privacy issue is ultimately resolved will be decided by the values inherent in a society. Because privacy issues have been addressed in court and precedents established in state and common law, it seems likely that the information privacy issue will be resolved in the world's legislatures and resulting laws enforced in the courts (Lessig, 1999). At the federal government level, the U.S. has seen the passage of the Health Insurance Portability and Accountability Act that prohibits unauthorized disclosures of personal medical information, punishable by a fine up to $250,000 and 10 years in jail (Lueck, 2003). The GLB requires that a financial institution give its customers a privacy policy (for an interesting recent study of Internet privacy policies of the 50 largest U.S. companies, see Plesak, 2005), the right to opt-out of the sale of personal data to third parties, and safeguards to prevent fraudulent access to financial information (see Privacy Rights Clearinghouse, 2004).

CONCLUSION

Various uses of e-technology that collect or disseminate personal information include corporate and government databases, e-mail, and wireless communications. The challenges to information privacy posed by the various forms of e-technology are not the result of the technology itself, rather it is the uses of the technology that pose the threat to the integrity of information privacy. In particular, the surreptitious monitoring of user behavior without the user's consent and the possible misuse of the collected information pose the biggest threats. Unless information privacy is adequately safeguarded, both individuals and businesses will experience unwanted consequences.

KEY TERMS

Biometrics: The use of technological devices to identify people through scans of their faces, hands, fingers, eyes, or voice.

Clickstream Tracking: The use of software to monitor when people use the Internet and what sites they visit.

Global Positioning System: Satellite technology that locates people and objects on earth with high accuracy.

Hardware and Software Watermarks: Unique identifiers (e.g., a serial number) embedded in computer equipment and programs.

Identity Theft: The stealing and use of a person's identity through the acquisition of personal information without that person's knowledge or permission.

Personal Information: Information about, or peculiar to, a certain person or individual.

Phishing: Using e-mail to entice unsuspecting consumers to Web sites resembling those of trusted banks and credit card issuers with a view toward collecting personal information.

Privacy: The claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others (Westin, 1967).

Radio Frequency Identification: Devices that transmit identification numbers on request from a compatible reader using radio frequencies.

Spyware: Software that installs itself on computers when programs are downloaded and that tracks each user click, usually without the user's knowledge or permission.

Information Security for Legal Safety

Andreas Mitrakas
European Network and Information Security Agency (ENISA), Greece

INTRODUCTION

The growing use of information technology in sensitive daily transactions highlights the significance of information security to protect information assets. Vulnerabilities associated with public and private transactions pose challenges that government, private organizations, and individuals are compelled to respond to by adopting appropriate protection measures. Information security responds to the need of transacting parties for confidentiality, integrity, and availability of resources (Pfleeger, 2000). Information security is required in transactions carried out among, businesses, public administrations, and citizens. An organizational response to information security threats includes setting up and implementing appropriate policy frameworks that are typically endorsed by agreement. Beyond organizational objectives lies an emerging legal framework instigated by the role of information security as a means to safeguard information assets that are socially significant. Organizations are often required to implement information security measures mandated by industry regulations or legislation, such as in electronic banking transactions. The scope of these legal and regulatory requirements is to mitigate potential risk that entails liabilities for shareholders, employees, customers, trading partners, or other third parties involved in a transaction. Information security and its subsequent regulation are equally important for public services. In e-government services made available to citizens and businesses, information security ensures e-government transactions. The remainder of this article presents an overview of the prevailing legal and policy issues that are currently associated with information security.

BACKGROUND

Electronic transactions typically require a high level of assurance with respect to the content and management of the transaction, the authentication of the trade partners, threats against enterprise resources, and so forth. The following presents a brief and non-exhaustive overview of the regulatory background on information security. If not properly treated, security risks may nurture liability risks for the parties who fail to adopt security countermeasures. Liability in this regard might emanate from general legal requirements or as it has become increasingly apparent from specific legislation that addresses specific security matters. The evidential value of electronic documents, for example, can be challenged as long as the contents of the transaction and the conditions under which it was carried out cannot be ascertained (Mitrakas, 1997). Information security can also function as negative proof of actions that are under investigation in a digital forensics process.

The *U.S. National Information Systems Security Glossary* defines information security as "the protection of information systems against unauthorized access to or modification of information, whether in storage, in processing, or in transit, and against the denial of service to authorized users or the provision of service to unauthorized users, including those measures necessary to detect, document, and counter such threats" (1992, p. 38). Information security threats can be distinguished in categories such as the following:

- **Natural threats**, which are described by terms such as *acts of God*, sometimes described as *force majeure*; for example, unforeseen events such as a flood or an earthquake.
- **Accidental threats** caused by the actors involved, such as, for example, missing out in a plan or a procedure.
- **Intentional threats** by actors directly or indirectly involved, such as, for example the deletion of data with the intent to transfer funds without authorization.

Although threats might carry liability or criminal consequences to the implicated parties, the basis for information security in law is the legal duty of care that transacting parties must show in their daily or business dealings (Lindup & Lindup, 2003). The duty of care is yet more significant in situations where a party acts under a certain capacity or in a trade. There are situations, however, whereby the law mandates certain information security measures in order to protect against information threats, such as, for example, in the case of processing personal data. In such cases, there is a set of duties of the implicated personal data controller to implement security safeguards on personal data stored or processed (Directive 95/46/EC of the European Parliament and of the Council of 24 October 1995 on the protection of personal data and on the free movement of such data, p. 31).

Information security objectives must be associated with the acts at hand and strive to detect the implementation of the following principles with the evidence in hand:

- Confidentiality ensuring that information is accessible only to those authorized to have access, according to the International Standards Organization (ISO). Confidentiality is typically ensured through encryption.
- Integrity is the condition that exists when data are unchanged from their sources and have not been modified, altered, or destroyed at any operation according to an expectation of data quality.
- Availability of data is the degree to which a system is operable and in a committable state at the start of an assignment.
- Accountability of parties involved for acts performed being held to account, scrutinised, and required to give an account. Especially in white collar crime, accountability is often associated with governance.

Whereas the aforementioned principles might only be fully observed within highly organized environments that operate on the basis of audited security policies and practices (e.g., in white-collar crime investigated in a corporation) in other less organized environments odd data has to be put in context through social methods and mundane practices to pinpoint actions in the crime under investigation. To determine information security measures, it is typically required that a risk assessment is carried out by measuring two quantities of risk the magnitude of the potential loss, and the probability that the loss will occur. Prior to a risk assessment, it is advisable to carry out a vulnerability assessment by identifying and quantifying vulnerabilities in a system that seeks network and information security measures (Dunn & Wigert, 2004).

Information security is an enabler to ascertain basic rights, such as the right to confidentiality, personal data protection, trade secrets, and so forth. In information society, information security is gradually becoming a significant factor upon which basic rights depend in order to be exercised by all members of the society. Information security as such is not a right in itself; there is no such thing as a right to information security. This article argues that although information security is an instrument to exercise and enjoy other basic rights and freedoms, it should be encouraged and afforded protection in a meaningful way (Dworkin, 1977). Within the European Union, internal market rules that sometimes depend on information-society services rely on information security in order to take meaningful effect. Conditions regarding the encouragement and exercising of information security include, for example, exceptions with regard to crime investigation through digital forensics, lawful interception, and so forth. A balance, however, must be sought to ensure that legitimate users are granted sufficient access to information security resources and that they are not unnecessarily constrained in the choice of information security resources that evolved over time. The commercial use of public networks has resulted in a surge of regulation concerning an array of issues, among which information security plays a lynchpin role (Rathmell & Valeri, 2002). It is important to stress that information security regulation is twofold in the following situations:

- Addressing risks associated with an attacker carrying out an illegal act, such as hacking or spreading viruses.
- Setting out the requirements for the party that is attacked to take out appropriate measures mitigating risks or face the consequences.

LEGAL CONSIDERATIONS

Information security has emerged as a legal requirement in order to ensure, for example, the legitimate use of computer resources; protection against cyber-crime, and compliance in critical areas such as electronic signatures, personal data protection, and so forth. At an international level, the legal framework of information security includes the UNCITRAL Model Law on Electronic Signatures (United Nations, 2001), which recommends that countries adopt laws allowing the enforceability of electronic signatures, subject to a risk assessment with regard to reliability and trustworthiness. Similarly, the OECD Information Security Guidelines (2002) aim at creating a culture of security by effectively managing risk (Ward, 2003). When carrying out risk assessments, it is necessary to consider legal risks in the audit processes.

Information security is necessary to control risk in transactions. An information security approach and information security rules allow for the assessment of threats and mitigation of risk. Whereas a threat is the possibility of hindering the operation of an information system, risk is the probability that a threat might materialize. The principles of proportionality and reasonableness have been enshrined in the EU Directive 95/46/EC on the protection of individuals with regard to the processing of personal data and on the free movement of such data. Privacy protection requires the setup of discreet environments to process personal data in a way that leaking such data to another environment can never go undetected. An example includes the use of social security numbers; for example, as a business identifier or as reliable input in building identification profiles that are merged into comprehensive databases. The duty to maintain the confidentiality of data that is stored within or exchanged between information systems is another necessary condition that concerns service providers and users of data alike because failure to protect implies liability consequences for the implicated parties.

Regarding data protection, Directive 2002/58/EC of the European Parliament and Council, concerning the processing of personal data and the protection of privacy in the telecommunications sector, has introduced new rules for an array of issues associated with information security in electronic communications. Although the scope of the Directive is to warrant an equivalent level of protection of fundamental rights and freedoms to ensure the free movement of such data, equipment, and services across the European Union, the protection of the legitimate interests of subscribers is equally observed. The directive prohibits wiretapping and eavesdropping without the prior consent of the users concerned, with the exception of legally authorized interceptions.

Another pertinent issue for privacy is related with the use of cookies that can reveal user behavior; Directive 2002/58/EC stipulates that member states must ensure that the use of electronic communications networks to store information or to gain access to information stored in the terminal equipment of a subscriber or user, is only allowed on condition that the subscriber or user concerned is provided with clear and comprehensive information and is offered the right to refuse such processing by the data controller. The ability to treat cookies remotely implies that, if cookies are used as tracking devices, the end user must have exclusive control over them.

Cybercrime law protects certain rights and assets such as privacy by making interception and unauthorized access illegal. To investigate cybercrime and crimes carried out with the help or by information technology, law enforcement agencies seek access to content of communications, data in transit, stored data, and authentication data. In terms of legislation, the efforts of the Council of Europe and the Organisation for Economic Cooperation and Development (OECD) can be highlighted. The Convention on Cybercrime of the Council of Europe stipulates in Article 15 that investigative powers and procedures are subject to conditions and safeguards provided for under its domestic law in a way that provides for adequate protection of human rights and liberties (Council of Europe, 2001). The protection afforded to citizens must be commensurate with the procedure or power concerned. This convention is currently nonbinding, pending ratification by national parliaments; however, it makes significant steps towards defining crimes related to computer systems.

The *OECD Cybersecurity Guidelines* stipulate that security should be implemented in a manner consistent with the values recognized by democratic societies including the freedom to exchange thoughts and ideas, the free flow of information, the confidentiality of information and communication, the appropriate protection of personal information, openness and transparency.

Some countries, however, have already initiated data retention schemes that might be further extended, in spite of concerns regarding their success. The issue of data retention requires addressing security threats such as spam because, for the time being, it is not necessarily clear whether service providers have to retain all data or selected portions of them. In the latter option, privacy considerations have to be addressed along with a duty to implement spam filters at the service-provider level.

INFORMATION SECURITY THROUGH SELF-REGULATION

In addition to the legal framework, information security is addressed through voluntary frameworks imposed by trade partners. Voluntary frameworks include policies and agreements that aim at setting out the conditions for information security safeguards within an organisation, or in transaction frameworks. A security policy lays down the rules for network information access, determines the process to enforce policies and lays out the architecture of the security environment of an organisation. At a bilateral level, the parties use service level agreements to specify the quality service they seek from their provider and ensure availability rates for their applications. Quite often, however, parties might set up security frameworks, which are activated by means of subscriber agreements that are executed individually. In this case, the service can be a generic one that does not necessarily allow for a high degree of customization (Kiefer, Wu, Wilson, & Sabett, 2004).

Additional measures such as internal policy drafting and mapping, audit, and control of enforcement are also essential to support a security framework (Caelli, Longley, & Shain, 1991; Clarke, 2004). An approach to information security includes

- Detecting and recognizing of a threat and the risks it poses through an appropriate threat analysis, a vulnerability analysis, and risk assessment;
- A strategy on a security plan and subsequent implementation; and
- An audit of the implemented security plan.

Information security can be assured through security policies that are drafted on the basis of international standards (ISO, 2000). Regardless of the form that information takes, or means by which it is shared or stored, it should always be appropriately protected. The International Standards Organisation (ISO) standard known as ISO 17799 provides recommendations and guidance for information security management. This standard provides a shared basis to develop organizational security standards and effective security management practice. Beyond businesses and financial institutions, the ISO 17799 has also been recognized as appropriate for use in government environments (Deprest & Robben, 2003).

A security policy identifies the rules and procedures that parties accessing computer resources must adhere to in order to ensure the confidentiality, integrity, and availability of data and resources as well as accountability, if required. Furthermore, a security policy formalizes an organization's security posture, describes and assigns functions and responsibilities, and identifies the incident response procedures. Voluntary security frameworks are binding to the extent that this is the intent of the parties involved. Breach of warranty in a publicized or otherwise security policy is a breach of an obligation that is likely to result into the party involved paying damages. From a legal viewpoint a security policy supports the following requirements:

- Communicates security information in binding manner by ensuring management involvement;
- Makes enforcement of a security framework possible;
- Identifies the areas of responsibility for users, administrators, and management by means of which the consequences of noncompliance are determined and is enacted by senior management; and
- Meets the requirement to protect certain rights (e.g., privacy) while contributing to enterprise productivity goals.

The components of a security policy are adapted to the type and corporate goal of an organization. Typical elements of a security policy include the following:

- **Security Definition:** A security policy includes a well-defined security vision for the organization. The security vision should convey to the readers the intent of the policy in ensuring the confidentiality, integrity, and availability of data and resources through the use of effective and established security processes and procedures. The security policy definition addresses why the security policy is implemented and what it entails in terms of the mission and the business goals of the organization.
- **Enforcement:** A security policy identifies how a security policy is enforced and how a breach is managed. This requirement is necessary in order to ensure that incidents are handled in an appropriate manner while the security policy remains binding across the organization.
- **User Access to Computer Resources:** A security policy regards the roles and responsibilities of users accessing resources on the organization's network. This section ties organizational procedures to individual roles and aims at controlling the acts or omissions of the human factor in secure processes. Additionally, some organizations may require that other organizations meet the terms and conditions identified in the organization's security policy before granting access.

It is necessary to ensure that security policies are consistent with other applicable policies within the organisation concerned. Additional requirements of the security policy framework involve the definition of the conditions to deliver services in areas of particular interest, such as electronic signatures and data protection, for example ETSI (2001) and IETF (2003). Standards in this area provide guidance and set the framework in order to deliver services, control and rely upon electronic signatures (Mitrakas, 2005). European Union regulatory initiatives highlighted the significant effort is beginning to take shape in the European Union with regard to information security. The European Network Information Security Agency (ENISA) aims at providing support to member states, the E.U. Commission, and stakeholders with regard to information security management and policy. The Network Information Security Standardisation (NIS) Steering Group aims at liaising with the industry and ENISA in order to provide an appropriate forum for standardisation in the European Union (ETSI, 2003).

FUTURE TRENDS

Beyond legislation, the evolution of case law is expected to enhance and determine the admissibility and evidential value of data that are protected, according to specific information security policies, in those application areas in which they emerge as a requirement. Remarkably, to date there has been little done to address in a uniform manner the requirements pertaining to the legal value of information security policies. Additional requirements might seek to cover the mapping and methods on the reconciliation of information security policy frameworks in overlapping transactions especially in the field of outsourcing services. An additional area of future attention could address information security policy frameworks as they relate to applications. As present day requirements for transparency within organizations instigated by the requirements for greater corporate accountability are likely to be further raised, it is expected that online applications will increasingly become more demanding in explaining to the end user what they do and actually warranting the performance and trustworthiness of a system or service (Mitrakas, 2005). To date, general conditions and service agreements cover part of this requirement; however, a comprehensive description of the technical features and functionality of the application in a way that allows the end user to gain some insight, while protecting the vital security interests of the service provider, is needed. Tailoring information security policies further to meet the needs of particular groups of organizations is an additional expectation.

Additional requirements of a framework for information security require the definition of the conditions to deliver services in applications. Standards in this area provide guidance and set the framework in order to deliver services and control and rely upon electronic signatures (Mitrakas, 2005). In emerging technologies, and applications the definition of security threats must addresses the requirements on organizational responsibility and transparency. Additionally, self-imposed frameworks, through agreement or best practices, must also be put in place in an effort to provide guidance to trade parties and confidence to citizens. Cybercrime prevention can further extend to awareness programs as well as the development of industry specific threat and risk assessment methodologies in order to deal with current information security risks emanating from malicious attacks as well as terrorism. Additional attention can be dedicated to areas that affect large populations, such as, for example, e-government, where public interest is high.

CONCLUSION

Information security has emerged as a way to ensure the integrity, confidentiality, and availability of certain assets that are necessary to carry out transactions in an information society. Information security is a necessary instrument to allow members of the society to exercise and enjoy basic rights. Political and legal initiatives, aimed at encouraging and protecting in a meaningful way the evolution of security to protect those rights. Cross-border cooperation becomes essential to ensure the applicability and robustness of measures adopted and practices employed. An essential requirement for business level applications is to gain a common understanding of the legal implications of security in electronic communications and transactions especially with regard to threats and vulnerabilities that are successfully exploited to the detriment of a trade party that might carry liability or bear penal consequences.

Further efforts are necessary to clarify the boundaries of the legal framework application with regard to information security. Especially in new or emerging technologies and applications, further definition of security threats is needed that addresses the requirements of organizational responsibility and transparency. Additionally, self-imposed frameworks, through agreement or best practices, must also be put in place in an effort to provide guidance to trade parties and confidence to citizens. Penal law aspects can further extend to awareness programs and the development of industry-specific threat and risk assessment methodologies in order to deal with current information security risks emanating from malicious attacks and terrorism. Special emphasis can be dedicated to areas that affect large populations, such as e-government.

Harmonizing the requirements for cross-border cooperation can be facilitated by initiatives aiming at effective mutual assistance arrangements. There is an urgent need to ease the reporting and investigation of suspicious incidents and to provide information to help investigations without facing legal sanctions or complex processes. Information security is necessary as an instrument that puts into practice legal requirements; there is, however, a way to go before it can be fully leveraged in legal processes.

KEY TERMS

Accountability: Accountability of parties means holding to account, scrutinising, and being required to give an account; especially in white-collar crime, accountability is often associated with governance.

Availability: Availability of data is the degree to which a system is operable and in a committable state at the start of an assignment.

Confidentiality: Confidentiality ensures that information is accessible only to those authorized to have access and it is typically ensured through encryption.

Information Security: Information security is the protection of information systems against unauthorized access to or modification of information, whether in storage, processing or transit, and against the denial of service to authorized users or the provision of service to unauthorized users, including those measures necessary to detect, document, and counter such threats.

Integrity: Integrity is the condition that exists when data is unchanged from its source and has not been modified, altered, or destroyed at any operation according to an expectation of data quality.

Risk Assessment: Risk assessment is determined by measuring two quantities of risk, the magnitude of the potential loss, and the probability that the loss will occur.

Security Policy: Security policy is a document that lays out the rules for network information access, determines the process to enforce policies and lays out the architecture of the security environment of an organisation.

Vulnerability Assessment: Vulnerability assessment is the identification and quantification of vulnerabilities in a system that seeks network and information security measures.

Inherent E-Commerce Barriers for SMEs

Sushil K. Sharma
Ball State University, USA

INTRODUCTION

Electronic commerce (e-commerce) is the fastest growing industry the world over and it impacts business, international trade, and national economies. The number of nations who are offering e-commerce solutions is increasing every year. Despite the downturn in the Internet economy represented by the crash of many "dot-com" companies, several forecasts continue to predict huge potential in global e-commerce over the next several years (Deschoolmeester & Van, 2000). For example, global business-to-business (B2B) commerce over the Internet is expected to reach between U.S. $2 trillion to about U.S. $10 trillion by 2004 (http://www.emarketer.com/ereports/ecommerce_b2b/welcome.html). Large businesses have found e-commerce a tool for exponential economic growth but small businesses are still far from the e-commerce revolution because of inherent problems in generally acquiring the basic e-commerce infrastructure and expertise. Governments of many nations are providing support and incentives for small and medium enterprises (SMEs) to use e-commerce platforms to expand globally to sell their products or trade online with other businesses, but the e-adoption campaign for SMEs to invest in online services has not been encouraging (A Study Report on Thailand, 2001; Sharma & Wickramasinghe, 2004; Sharma, Wickramasinghe, & Gupta, 2004). E-commerce certainly has been streamlining supply-chain activities, speeding inventory turnover, and reducing cycle times, yet SMEs don't appear to be in the forefront of the e-commerce movement. SMEs have modernized and automated the way they do business and have been exploiting Internet technology to expand their reach and communication with their partners, suppliers, and customers, however, their use of such ICT tools is limited to mostly administrative matters (Beal, 2000; Ihlström & Nilsson, 2000). Many of the medium scale enterprises are using the Internet and ICT only for office automation such as word-processing, spreadsheets, accounting, and payroll (Poon & Swatman, 1997). SMEs in Asia have yet to take the actual plunge into e-commerce, are still skeptical of the e-commerce hype, and are reluctant to embrace much of the required technology (Haynes, Becherer, & Helms, 1998; Mehrtens, Cragg, & Mills, 2001). E-commerce is still relatively a new playing field for SMEs (Chau & Turner, 2002; Sugasawa & Liyanage, 1999).

BACKGROUND

There are few studies conducted for examining e-commerce adoption by SMEs in Asia. (APEC, 1999; Beal, 2000; Sharma & Wickramasinghe, 2004). Hasio presents a qualitative study of the barriers faced by SMEs to introduce B2B e-commerce in Singapore. The investigation employs an interpretative approach that draws on the theory of "technological frames". The results of Hasio's study highlights four key factors that explain the adoption difficulties: lack of familiarity (with technology), risk aversion, lack of trust, and incongruent cultural practice. Similar to Hasio, Dhawan, and associates (Dhawan et al., 2000) examining the problems associated with building B2B e-marketplaces for SMEs. Both these studies were more focused on EDI aspects and B2B commerce rather than business-to-customers (B2C). However, all these studies conducted on this subject enhanced our understanding of the adoption difficulties involved in e-commerce.

As e-commerce is becoming the way to trade, it is the large corporations that are exploiting their finances and technical expertise to jump into this electronic abyss whereas, SMEs are finding too many obstacles to participate in e-commerce (Ihlström & Nilsson, 2000; Tan & Ouyand, 2003; Walczuch, Van, & Lundgren, 2000). Following a review of the current literature, this article describes the key factors that are hindering SMEs' participation in e-commerce and the obstacles to SMEs for e-adoption. Although this study is limited to Asia, many of the findings do contribute significantly to the factors hindering all SMEs' e-adoption efforts.

OBSTACLES OR BARRIERS TO THE ADOPTION OF E-COMMERCE

Asian governments are actively encouraging the diffusion of e-commerce in SMEs as a way to improve their competitiveness and access to new markets. Many initiatives have been taken such as: raising awareness, establishing development centers, creating business access points, and providing education and training programs. Despite all these, they continue to encounter numerous obstacles to adoption of e-commerce (APEC, 1999; Sharma, Wickramasinghe, & Gupta, 2004; Sharma & Wickramasinghe, 2004; Thong, 2001; Thong, Yap, & Raman, 1996).

Lack of Awareness

The primary obstacle to adoption of e-commerce among SMEs is lack of awareness of e-commerce, and the availability and access to telecom infrastructure at a reasonable cost (APEC, 1999). The SMEs are not aware of the current developments or the role they could play in this new marketplace. Personnel involved in SMEs find e-commerce literature too technical and complicated. Unless, the governments or other agencies simplify technical information for them, SMEs can not adopt e-commerce concepts and begin implementation. English as a common language of an e-commerce is a big barrier in many Asian countries since the people involved conduct their business using the local language. The lack of awareness is closely linked to the fact that SMEs in Asia are usually slower in adopting new technologies given the often high investments necessary. Many of the Asian SMEs are also less risk taking and not ready to experiment (Sharma & Wickramasinghe, 2004).

Poor Customers, Suppliers, and Business Partners' Base

Another obstacle experienced by Asian SMEs is the lack of a critical mass among customers, suppliers, and business partners. The lack of a critical mass of these stakeholders is due to either ignorance or fear of a lack of security and privacy when using electronic means. The e-commerce infrastructure is very poor in Asian countries and online shopping is not yet very popular among masses. Due to low use of e-commerce, there are few customers and suppliers using e-commerce and this acts as a discouraging factor for SMEs to join the e-commerce revolution (APEC, 1999). Until sufficient numbers of their main local customers or suppliers participate in online commerce activities, there is little incentive for individual SMEs to become engaged in e-commerce themselves. In Asian countries, SMEs cited several factors contributing to low levels of customer e-commerce use including: language barriers and low levels of English fluency, lack of familiarity with e-commerce technologies, a cultural preference for more traditional trade practices involving face-to-face contact between buyer and seller, and continued preference for the use of cash in transactions (APEC, 1999; A Study Report on Thailand, 2001; Beal, 2000; Turpin, 2000; Sharma et al., 2004; Sharma & Wickramasinghe, 2004).

Trust and Confidence

Lack of trust and confidence in various aspects of the electronic marketplace was identified as another main obstacle to the growth of the e-commerce market in general, and for SME engagement in e-commerce in particular. SMEs fear doing business with international marketplaces, due to cultural backgrounds, and a fear of being deceived, due to lack of knowledge of new technologies. The security issue is perceived as very important across the Asian region, and the majority of SMEs have the fear of electronics. Security may not be a serious problem but due to the low level of technology diffusion and awareness among SMEs, it is still a psychological barrier for SMEs (APEC, 1999; Beal, 2000; Turpin, 2000). Many of these SMEs owners do not have technical backgrounds, and they are not convinced that the technology standards such as encryption etc. exist to protect them. Due to perceived security fears, SMEs are not willing to use electronic payment systems. Credit cards and e-checks are still a distant dream for many of them. Security, legal, and liability issues were often identified as very important concerns of participating SMEs in Asia (APEC, 1999; Sharma et al., 2004; Sharma & Wickramasinghe, 2004).

Lack of Legal and Regulatory Framework

The lack of a comprehensive and acceptable legal and regulatory framework is an issue for Asian SMEs. Many of the Asian countries still do not have laws for electronic contracts, invoices, and other types of documentation in place. Few countries have taken the lead but the majority of others are still in formulating laws. E-commerce demands several legal and liability issues to be addressed before it is widely accepted by SMEs and others in the Asia. Conducting business through electronic networks raises numerous legal questions that include: the legal status and enforceability of electronic contracts; the legal jurisdiction of international e-commerce transactions; intellectual property rights and copyright protection for digital content; the privacy of personal data; and the validity of electronic "evidence" in legal disputes (APEC, 1999). Unless these issues are addressed, Asian SMEs may not choose e-commerce as a medium for their business. Asian SMEs also have concerns about international legal protection such as global patent applicability, global taxation, and consumer protection (APEC, 1999; A Study Report on Thailand, 2001; Beal, 2000; Turpin 2000).

Taxation

Asian SMEs are more concerned about taxation because many of them like to avoid taxes. Also, taxation processes in these countries are not transparent and are often subject to the discretion of evaluators. Malpractice is common practice to avoid taxes and SMEs do not want to adopt other countries tax laws which they anticipate could be more stringent. SMEs also lack the guidance of lawyers since many of then can not afford the high fees. The application of existing taxation on commerce conducted over the Internet requires that tax principles be consistent with the established principles of international taxation, neutral with respect to other forms of commerce, avoid inconsistent national tax jurisdictions and double taxation, and simple to administer and easy to understand (Hall, 1995; Sharma et al., 2004; Sharma & Wickramasinghe, 2004). It is apparent that much needs to be accomplished before these taxation laws can be implemented.

Lack of Knowledge of E-Commerce

Asian SMEs lack extensive knowledge of e-commerce technologies and that itself is one of the big obstacles for their participation and engagement in e-commerce. Due to a lack of knowledge of e-commerce technologies, there is an internal resistance to change, and skepticism of the benefits of e-commerce among SMEs. E-commerce demands fundamental shifts in business strategies, operations, and technologies. Many participating SMEs indicated that they have limited access to information about the business models and technologies that are the basis of e-commerce success. Lack of knowledgeable staff in SMEs is also responsible for non-adoption of e-commerce. An issue often cited by participating Asian SMEs was the general lack of success stories available to demonstrate that e-commerce can be successfully implemented by firms that are similar in some way to their own (APEC, 1999). Many SMEs are not willing to engage in e-commerce because they fear that there will be many who will copy their ideas and approaches overnight if they disclose their implementation of e-commerce (Bennet, Polkinghorne, Pearce, & Hudson, 1999; Chau & Turner, 2001).

Poor Information Infrastructure Access, Quality, and High Costs

Despite the cost reduction of Internet-based technology, implementing e-commerce solutions still represents a considerable and costly challenge for most SMEs in Asia (Chapman, James-Moore, Szczygiel, & Thompson, 2000). Large corporations with more funding, more attainable skills, and with strengths in building solid business strategies, can afford e-commerce deployment. Most SMEs typically with less cash, a shortage of IT expertise, and necessary infrastructure, are not able to afford e-commerce (Hall, 1995). The level of information infrastructure to support e-commerce applications differs greatly among the Asian countries from very poor to moderate. Most of the SMEs have connected to the Internet, but have simply opened a homepage and an e-mail address (APEC, 1999; A Study Report on Thailand, 2001; Beal, 2000; Turpin, 2000). The cost of telecommunication infrastructure for requisite bandwidth is also beyond the reach of many of the SMEs. Most of the Asian countries suffer poor infrastructure of electricity and energy. There are many parts of Asia where getting 4-5 hours electricity in a day itself is an issue, therefore, SMEs can not think of engaging in e-commerce. Additionally, telecommunication access and usage costs are still prohibitively high in most Asian countries, and are seen as a major obstacle among SMEs for e-adoption (APEC, 1999; Sharma et al., 2004; Sharma & Wickramasinghe, 2004).

Weak Payment and Delivery Systems

Although Asia's Internet players are rushing to promote e-commerce as a creative business mode for the new economy, few of them can break through the last-mile barriers to online purchasing. These barriers have been attributed to the lack of a standard credit system and an effective express network, two critical elements for the operation of online shopping and business transaction. Very few SMEs—those that are technology developers themselves—support electronic cash, electronic checks, and micro-payment. The majority of customers and suppliers do not use credit cards for their payments in Asian countries. Therefore, the development of electronic payment systems, including the use of credit cards, is limited. Since a credit card culture is not present in the society, both credit card companies and consumers shy away from using credit cards for transactions. The financial network of banks and other institutions do not have their databases integrated and available online (APEC, 1999; A Study Report on Thailand, 2001; Beal, 2000; Turpin 2000).

Asian countries do not have strong road, rail, and air network to support an e-commerce delivery system. Further, many postal systems are not as efficient as is found in developed countries. Due to the poor quality and limitations of the postal delivery and other distribution channels, the speedy delivery of products and services is not possible. Thus, consumers do not perceive the benefits of e-commerce reducing costs and fast delivery (Sharma et al., 2004; Sharma & Wickramasinghe, 2004).

FUTURE TRENDS

Current trends and developments suggest accelerating change for smaller businesses in the future. New technologies, organizational structures, and a move by entrepreneurs to more knowledge-based service businesses, are likely to increase productivity and profitability. It is important that the SMEs have sufficient ICTs infrastructure and skilled manpower to handle the challenge of competing in knowledge economy. More studies need to be conducted to examine how inherent barriers for SMEs for e-commerce can be removed. Networks, knowledge, and relationships have become crucial assets to business survival in the new economy. Research indicates that network building is a major new source of competitive advantage and an essential regional and indeed global management requirement (Levy & Powell, 2000). Because regional policies encourage inter-firm alliances and the development of regional economic communities, the fostering of a culture of connectivity, networking, learning, and trust between regional small and medium-size tourism enterprises may offer a potential solution for a win-win situation. It is suggested that SMEs would benefit from increased information flow through regional networking and cooperative e-marketing campaigns to enhance market visibility, global positioning, and strategic leverage in the new economy (Ho, 2001).

CONCLUSION

SMEs in Asian countries can become more competitive by promoting the development and use of e-commerce. The governments have to encourage the development of Internet Service Providers (ISPs), liberalization, and regulatory reform to increase competition in the provision of telecommunications services and encourage lower rates and service innovation. Measures should be taken to promote greater awareness of the opportunities and benefits of e-commerce for SMEs, such as training and skills development programs, and the distribution of best practices. The government should enhance the climate for investment to attract and retain venture capital and investment in SMEs with potential for rapid growth (Bode & Burn, 2002). Asian countries should initiate specific measure to build e-commerce capabilities among SMEs through seminars, workshops, training, or other activities that build awareness of e-commerce issues and concerns of SMEs. Continued emphasis by governments of these countries and other multilateral organizations on e-commerce will be important and necessary.

KEY TERMS

E-Business (Electronic Business): The conduct of business on the Internet. It is a more generic term than e-commerce because it refers to not only buying and selling, but also electronically back end integration with other business processes such as servicing customers and collaborating with business partners.

E-Commerce (Electronic Commerce): Defined as the conduct of buying and selling of products and services by businesses and consumers over the Internet. E simply means anything done electronically, usually via the Internet. E-commerce is the means of selling goods and services on the Internet.

ICTs (Information and Communication Technologies): Includes telecommunication technologies, such as telephony, cable, satellite, and radio, as well as digital technologies, such as computers, information networks, internet, and software.

Knowledge Economy: The knowledge-based economy is all about adding ideas to products and turning new ideas into new products. Relationships with trading partners, customers, and suppliers, distribution networks, intellectual property, patents, image, etc., are all elements of a knowledge economy. These elements represent intellectual capital.

SCM (Supply Chain Management): Defined as process or processes involved for the supply of items and services from vendor through to customer.

SMEs: There is no consensus on the definition of SMEs throughout the Asia-Pacific region due to the differences in the general economic development within each country and their prevailing social conditions. Various indices are used by member economies, among them: number of employees; invested capital; total amount of assets; sales volume; and production capability.

Innovation Translation and E-Commerce in SMEs

Arthur Tatnall
Victoria University, Australia

Stephen Burgess
Victoria University, Australia

INTRODUCTION

Adoption of a new technology cannot be automatically assumed. The implementation of an e-commerce system in a small to medium enterprise (SME) necessitates change in the way the business operates, and so should be considered as an innovation and studied using innovation theory. In this article we argue that the decision to adopt, or not to adopt a new technology, has more to do with the interactions and associations of both human and nonhuman actors involved in the project than with the characteristics of the technology.

As e-commerce necessarily involves interactions of people and technology, any study of how it is used by SMEs must be considered in a socio-technical context for its true complexity to be revealed (Tatnall & Burgess, 2005). This complexity is due, to a considerable degree, to the interconnected parts played by human actors and by the multitude of nonhuman entities involved: small business managers, sales people, procurement staff, computers, software, Web browsers, Internet service providers, modems and Web portals are only some of the many heterogeneous components of an e-commerce system. In this article we will argue that the complexity of these systems is best seen and understood by taking this heterogeneity into account and finding a way to give due regard to both human and nonhuman aspects. The implementation of an e-commerce system in an SME necessitates change in the way the business operates and we contend that this is best studied in the light of innovation theory. In this article we examine how innovation translation, informed by actor-network theory, can be usefully applied in analysis of the adoption, or nonadoption, of e-commerce. We illustrate this in two Australian case studies.

ACTOR-NETWORK THEORY

One view of the adoption of electronic commerce by an SME suggests that decisions are made primarily based on their perceptions of the characteristics of the technology concerned. Innovation diffusion (Rogers, 1995) uses this approach and a researcher would probably begin by looking for characteristics of the specific e-commerce technology to be adopted, and the advantages and problems associated with its use. We contend that while there may be some validity in such an approach, it is unlikely to provide the complete explanation as it would miss other influences due to interpersonal and interbusiness interactions, and to the background of the people involved. We further suggest that this is particularly the case in SMEs, where the more formal adoption procedures generally used in larger companies often do not apply.

We argue that actor-network theory (ANT) has much to offer in a situation like this. A researcher using an actor-network approach to study innovation would concentrate on issues of network formation, investigating the human and nonhuman actors and the alliances and networks they build up. They would investigate how the strength of these alliances may have enticed the small business to make the adoption or, on the other hand, to have deterred them from doing so (Tatnall, 2002; Tatnall & Gilding 1999). Although some research approaches to technological innovation treat the social and the technical in entirely different ways, actor-network theory proposes instead a socio-technical account in which neither social nor technical positions are privileged.

In our experience it is often the case that when a small business is considering a technological innovation it is interested in *only some aspects* of this innovation and not others (Tatnall 2002; Tatnall & Burgess, 2002). In actor-network terms it needs to *translate* (Callon, 1986) this piece of technology into a form where it can be adopted, which may mean choosing some elements of the technology and leaving out others. What results is that the innovation finally adopted is not the innovation in its original form, but a translation of it into a form that is suitable for use by the recipient small business (Tatnall, 2002).

Unlike the more formal procedures used by larger organisations, in many instances a small business proprietor will adopt e-commerce because a friend is using it, or because they know a competitor is using it, or because a son or daughter learned about it at school (Burgess, 2002; Tatnall, 2002). The nature of each small business, the interbusiness interactions in which they engage, and the backgrounds and interests of particular individuals in each are also likely to have an important affect that would, most likely, have been ignored by the essentialist approach offered by innovation diffusion. Actor-network theory, in examining alliances and networks of human and nonhuman actors, provides a good foundation from which small business adoption and use of e-commerce can be researched. The ANT approach will be further amplified in the case studies that follow, particularly in respect of the identification of actors and networks (Tatnall, 2005).

THE CASE STUDIES

Each of the case studies that follow will include a discussion, under the umbrella of actor-network theory, of the approach taken by each of these SMEs to the adoption, or nonadoption, of e-commerce. In each case, data for the study was obtained through a series of semistructured interviews (2001, 2002) with the proprietors and personnel of the businesses involved. The data was then subjected to an ANT analysis in which actors and networks were identified and interactions were traced. The approach used in ANT to identify and trace networks is to "follow the actors" (Latour, 1996, p. 10) and investigate the leads each new actor suggests. This means that it is primarily the actors themselves, and not the researcher, that determine the direction taken by the investigation.

Adoption of the Bizewest Portal by a Storage and Transport Company

Company Background

In June 2000 the Western Region Economic Development Organisation (WREDO), in Melbourne, Australia, received a government grant for a project to set up a B-B portal (Pliaskin & Tatnall, 2005). This innovative project was to create a horizontal portal, *Bizewest*, which would enable the whole range of small to medium enterprises in Melbourne's west to engage in an increased number of e-commerce transactions with each other. An important aspect of the development was youth involvement, and students from local high schools who were studying information technology related subjects, were to be given the opportunity to consult with SMEs on a one-to-one basis in the development of their Web pages for the portal. Bizewest became operational in June 2001.

The business to be considered here is a medium-sized Melbourne company with about 50 employees that stores frozen food and transports it to supermarkets and other locations around the country. An interview with the general manager, who is also owner of the business, was conducted soon after his company adopted the Bizewest portal. When asked whether the company had already begun to make use of B-B e-commerce, he replied that they "do a little bit of it at the moment," and went on to describe how the company had only recently got all the computers in their office networked, and how this meant that they could now link all their staff to the portal.

Description of E-Commerce in the Company

Clients of the business include both small and large companies from many parts of the world, and it has dealt online with some of the larger ones now for over two years. In one case the firm is directly online with their client's stock so that they can facilitate all their freezing work. The general manager has found, however, that many companies are slow coming online and suggests this is because they are not really sure what systems to use. The general manager has been involved with the local industry group for over 12 years and was no stranger to innovation and change. When approached by WREDO to be involved in the Bizewest project he indicated that he would. When asked if he had any specific expectations for Bizewest, he said that he did not, but that he thought it was "a really good idea." He indicated that he thought it was great for the region in giving local businesses a chance to work with one another. When asked about the benefits he saw in adopting the portal he stated these in terms of time savings and better service.

A major reason that the company adopted the portal was the hope that it would provide a better opportunity to deal with people in the local region. The general manager thinks that it is going to provide many benefits for everybody, not just his company, and this is important to him. He thinks that use of the portal will change his business by enabling it to use people in the local region, and that "working together for the benefit of everybody" will be advantageous for the region. Another factor that prompted the adoption of the portal was being able to involve school students in creating the company's web pages. With a long interest in the community and in education, the general manager saw this as important.

ANT Analysis of the E-Commerce Adoption

It is clear from the study that the transport company has "not really been into computers," and has only recently started coming to grips with this technology. Although the manager had some idea of the benefits to his company of using the portal, he had no clear plan for using it. It was just "a really good idea." The reasons he adopted this innovation thus had little to do with the characteristics of this technology, and much more to do with his involvement with the local business community and because of his belief that the portal had the potential to improve business in the region. As someone with a long-term interest in education, he was persuaded by the use of school students in developing the Web sites: he saw this as a good reason to get involved.

Among the actors contributing to this adoption are: the general manager himself, the local community, the local school students, the western region, WREDO, office staff of the company, the company's larger customers, and the portal. The community and the region, in particular, should also be seen as networks that could be dissected into a large number of individual actors if this was required. As far as the general manager was concerned, the portal was definitely a black box, the contents of which he did not really want to investigate.

Impact of the Portal

The general manager had a wider view of business that just his own, and was especially interested in fostering business in the local community and in the region. He saw the Bizewest portal primarily in terms of a means of achieving greater participation of business in the region and in getting SMEs in the region to work together for their mutual benefit. He certainly wanted to make use of a B-B portal, but his main interest was in one that would get the local business community working together. He was thus most interested in a translation of the portal to become a means of achieving greater business cooperation and community involvement within the western region.

Nonadoption of E-Commerce by a Small Chartered Accountancy Firm

Company Background

The second case is of a small chartered accountancy firm, which is a family business in the western suburbs of Melbourne. Employees of the business are the main accountant, who has a degree in accounting and is a CPA, the main accountant's father—who previously ran the business but, as he is not qualified, is limited these days mainly to supporting the taxation side of the business; another accountant (CPA), and a full-time secretary. The firm offers services that are typical of a small accounting business: advice on basic accountancy and bookkeeping for small businesses; preparation and lodgement of taxation returns; taxation advice; investment and financial planning advice and advice on the use of accounting software. Its clients include both individuals and small businesses.

Description of E-Commerce in the Company

For a while, some members of the business had been debating whether to set up a Web site. The business does have an Internet connection, which they use for basic research and to connect to the Web site of the Australian Society of Certified Practicing Accountants. The employees of the business are happy to interact via electronic mail with customers who wish to do so. All of the employees were comfortable with using computers, Microsoft Office software, accounting software, dedicated financial analysis software and with browsing the Internet.

The decision about whether or not to set up a Web site seemed to come down to two major opposing viewpoints. The first viewpoint, held by the main accountant, was that a Web site was the way of the future and customers would expect it. Some competitors also already had one. The opposite viewpoint, held by the father, was that it is a waste of time and money, that there was nothing you could put on a Web site that customers would want anyway, and "who is going to do it?" Other members of the business seemed quite apathetic about the whole matter. Undeterred, the main accountant investigated the cost of a Web site with a few local ISPs, and found that it was relatively low. He also discovered a few new terms, such as *domain name*, *URL*, *traffic costs*, and so forth, which were a little off-putting. One of the ISPs asked who would be responsible for uploading the Web site content to keep it current, at which point the main accountant "felt a hot flush come over him." He found the terminology to be quite intimidating, even with his computer expertise. In the end, the final decision was to wait and see for another twelve months and then review the decision. In the meantime, the secretary was given the task of following up possible sources of expertise, either consultants or training materials, so that any future investigation may not seem so daunting.

ANT Analysis of the Nonadoption of E-Commerce

The initial conflict of interest between father and son produced a stalemate. The apathy of the other members, if anything, supported the argument of the father: "they don't care, so why bother?" The ISPs did not help themselves by failing to recognise that they had a potential customer who they turned away with technical jargon. It seems that in this instance, the Web site was never given a chance to effectively negotiate its own position. It had to rely on human actors within the business who were not quite sure of its capabilities, and actors in the ISP who did not understand the needs of the main accountant. Another outcome of the negotiations was that the overall question: Would the Web site result in extra profits for the business? was never actually asked. Although the decision has been postponed for the short term, have the accountants really helped any future negotiations by selecting the secretary to investigate further sources of information? The main accountant believes that the secretary is "very self-sufficient" and will "probably do it better than any of us could anyway." One of the problems in this case is that the operations of an ISP in setting up the Web site fall within the notion of a black box. The business has little idea of how the process operates, and probably even less now that they have spoken to the ISPs.

Nonimpact of the Internet Connection

For this business, the potential Web site could not be translated into a form where it could be adopted; it was not suitable for adoption from the viewpoint of the actors involved. The main accountant was the prime motivator in attempting to define the problem and to discover the solution: he defined the problematisation, but not well enough to gain acceptance of the innovation. Other human actors in the business failed to see that there was a problem at all, which made the process difficult from the start. The main accountant also was a prime mover in attempting to impose identities and roles on the other actors, by initiating discussions with the ISPs. Attempts at interesting and attracting other human actors in the business by coming between them and the potential Web site failed somewhat. In addition, attempts by the ISP to put themselves between the potential Web site and main accountant failed miserably. There was never much chance of enrolment occurring once the ISPs were involved with the main accountant. He had enough difficulty trying to get other human actors in the business to yield before having self-doubts introduced by the ISPs.

CONCLUSION

In this article we have given two examples of adoption/nonadoption of e-commerce technology and considered how they could be explained by ANT. Each business described was interested in some aspects of e-commerce, but not in all aspects. They each attempted, one successfully and one not so successfully, to translate e-commerce into a form they could adopt. They each attempted to choose some elements and to leave others out: to *translate* the technology into a form suitable for them.

Each of these situations point to the fact that decisions on the adoption of electronic commerce technologies are often made on the basis of more than just the characteristics of the technology, and that in many cases these characteristics are not especially significant in the decision making process, particularly in SMEs. In each instance an actor-network approach therefore offers a useful explanation of why a particular e-commerce initiative was or was not adopted. An innovation diffusion approach to investigating each of the potential adoptions looked for explanations for the uptake, or lack of uptake, primarily in the characteristics and properties of the technology. In our view, the decision to adopt, or not to adopt, has more to do with the interactions and associations of both human and nonhuman actors involved in the project rather with characteristics of the technology.

The main use made of any research approach such as ANT is in the study of past events, and ANT makes no claim to be able to predict what may happen in the future. We suggest, however, that ANT analysis can identify some pointers towards the successful introduction of an innovation, and the change management associate with this. The key to successful change management, it would thus seem, involves allowing for these interactions and for the socio-technical nature of the process.

KEY TERMS

Actor-Network Theory: An approach to research in which networks associations and interactions between actors (both human and nonhuman) and are the basis for investigation.

Community Portals: Often set up by community groups or based around special group interests, they attempt to foster the concept of a virtual community.

Electronic Commerce: Computers, communications technologies and information systems used by people to improve the ways in which they do business.

Horizontal Industry Portals: Portals utilised by a broad base of users across a horizontal market.

Innovation Translation: A theory of innovation in which, instead of using an innovation in the form it is proposed, potential adopters *translate* into a form that suits their needs.

Small to Medium Enterprise: Those businesses with 1 to 20 employees—small, and 21 to 50 employees—medium.

Web Portal: A special Web site designed to act as a gateway to give access to other sites.

INTRODUCTION

In general terms, electronic government (or digital government) refers to the selection, implementation, and use of information and communication technologies in government settings (Dawes & Pardo, 2002; Fountain, 2001; Garson, 2004; Moon, 2002). E-government research is a transdisciplinary endeavor including traditions such as public administration, public policy, management information systems, operations management, and information science.

Partially because of the novelty of the concept, but also because of its multidisciplinary nature, the concept of e-government is still a work in progress. The purpose of this article is to review different definitions and conceptual approaches to electronic government, analyzing their conceptual amplitude and distinguishing characteristics. The article presents a comprehensive definition of electronic government based on current definitions and a well-established theoretical framework in public administration. The article ends with a brief discussion of some future trends in electronic government.

BACKGROUND: UNDERSTANDING THE E-GOVERNMENT CONCEPT

This section contains a literature review from which it was possible to identify three different approaches to defining electronic government. The first approach proposes direct definitions containing the main elements and characteristics of electronic government, while the second de-

Table 1. A summary of the main characteristics found in e-government definitions (Adapted from Gil-García and Luna-Reyes, 2003)

Characteristic		Sources
Use of ICTs	Using electronic means or information technologies	(American Society for Public Administration [ASPA], 2001; Carbo & Williams, 2004; Cook & LaVigne, 2002; Edmiston, 2003; Galindo, 2002; Ho, 2002; LaVigne, 2002; Organisation for Economic Co-operation and Development [OECD], 2003; UNPAN, 2002; Zweers & Planqué, 2001)
	Specifically the Internet	(Choudrie, Ghinea, & Weerakkody, 2004; Edmiston, 2003; Galindo, 2002; UNPAN, 2002)
	Anytime, anyplace	(Zweers & Planqué, 2001)
To support government actions	Provision of information and knowledge	(ASPA, 2001; Ho, 2002; UNPAN, 2002; Zweers & Planqué, 2001)
	Provision of services (including complete transactions)	(ASPA, 2001; Carbo & Williams, 2004; Choudrie et al., 2004; Cook & LaVigne, 2002; Edmiston, 2003; Finger & Pécoud, 2003; Ho, 2002; LaVigne, 2002; OECD, 2003; Zweers & Planqué, 2001)
	Provision of products	(Zweers & Planqué, 2001)
	Governmental actions/daily administration/better government/intergovernmental collaboration	(Cloete, 2003; Cook & LaVigne, 2002; Edmiston, 2003; Ho, 2002; LaVigne, 2002; OECD, 2003; UNPAN, 2002)
To improve relations or citizen engagement	Relations between authorities and citizens	(Galindo, 2002)
	Exert political rights, citizen engagement	(Carbo & Williams, 2004; Fountain, 2003; Galindo, 2002)
Following a strategy oriented to add value	Adding value to participants in transaction	(Zweers & Planqué, 2001)
	Developing strategy to use technology, more important than the technology itself	(Choudrie et al., 2004; Grönlund, 2001)

fines the concept by enumerating different stakeholder-oriented applications of e-government. Finally, the third approach defines electronic government from an evolutionary perspective.

Definitional Approach: Some Characteristics of E-Government

A rich variety of electronic government definitions were found in a review of the existing literature. As shown in Table 1, it is possible to summarize most of the current definitions of electronic government using four basic elements. Electronic government is characterized by (a) the use of ICTs (computer networks, Internet, faxes, and telephones), (b) the support of governmental actions (to provide information, services, products, administration), (c) the improvement of governmental relationships with citizens (through the creation of new communication channels or the promotion of citizen engagement in the political or administrative process), and (d) the following of a strategy oriented to add value to the participants in the process.

Within this same approach, a complementary way to explain electronic government involves classifying applications according to different types of government actions. These applications can be organized in several ways; for example, Perri 6 (2001) uses three main groups of government activities: (a) electronic services, (b) electronic democracy, and (c) electronic governance. Other authors contend the concept of electronic government incorporates four fundamental dimensions of activity: (a) electronic services, (b) electronic democracy, (c) electronic commerce, and (d) electronic management (Cook & LaVigne, 2002).

Electronic services and electronic commerce are associated with the provision of government services by electronic means. Electronic management includes a great variety of elements such as intergovernmental collaboration, government systems development, training, marketing, information management, and citizen-relationship management (e.g., call centers). Public participation and electronic voting characterize electronic democracy. Finally, electronic governance concerns support for policy design and decision making as well as institutional development and administration.

Stakeholder-Oriented Approach: Different Applications of E-Government

Another approach to understanding electronic government consists of classifying e-government applications according to relations among government and other entities (Hiller & Bélanger, 2001; Moon, 2002; Schelin, 2003). In this perspective, electronic government consists of using the Internet as a tool to facilitate and improve governmental interchanges with different constituencies or stakeholders. The three main relations identified in the literature are with citizens (G2C, government-to-citizen), private organizations (G2B, government-to-business), or other governments (G2G, government-to-government) (Hiller & Bélanger, 2001; Holmes, 2001; Schelin, 2003).

Some researchers call for more specificity in interactions due to the importance and peculiarities of certain types of relationships (Hiller & Bélanger, 2001). These authors add (a) government-to-individuals as part of the political process (G2IP), stressing the importance of the democratic process, (b) government-to-companies in the market (G2BMKT), emphasizing economic interchange between government and companies, and (c) government-to-employees (G2E), differentiating the relationship of government with its employees from those with citizens in general.

Evolutionary Approach: E-Government Stages

A third way of understanding electronic government follows an evolutionary approach, identifying different stages of development in e-government initiatives (Hiller & Bélanger, 2001; Layne & Lee, 2001; Martinez-Moyano & Gil-García, 2003; Reddick, 2004; United Nations [UN] Division of Public Economics and Public Administration & ASPA, 2002). Some of these approaches restrict e-government to those projects with a certain extent of development. In the following, we describe two influential models.

Layne and Lee (2001) present a model of four stages that encompass the development of a totally functional electronic government: (a) cataloguing, (b) transaction, (c) vertical integration, and (d) horizontal integration. The first stage (cataloguing) focuses on the classification or cataloguing of government information and its presentation using Web pages. Projects in the second stage (transaction) facilitate interaction between the citizens and the government by providing products and services online. Projects in the stage of vertical integration include the integration of services from governmental organizations at different levels of government that have a common function among their responsibilities. Finally, horizontal integration consists of a radical transformation in government organizations to provide a one-stop window or a vestibule of state that provides all the information, products, and services that citizens require (Gant, Gant, & Johnson, 2002).

The Division of Public Economy and Public Administration of the United Nations and the American Society for

Public Administration (2002) developed another useful evolutionary view of electronic government. They suggested a five-stage model: (a) initial presence, (b) extended presence, (c) interactive presence, (d) transactional presence, and (e) totally integrated presence. Initial presence and extended presence both refer to information presentation with different levels of size and complexity (similar to cataloguing). Interactive and transactional presence consist of the existence of a portal that organizes and presents services and information offered by several government agencies in terms of citizen needs (similar to transaction). A totally integrated presence is closely related to both vertical and horizontal integration.

AN INTEGRATIVE VIEW TO THE E-GOVERNMENT CONCEPT

After a review of the main approaches to the concept of e-government, the main goal of this section is to briefly assess the strengths and weaknesses of each approach.[1] Taking into consideration a well-established theoretical framework in public administration, the section finishes with an e-government view based on previous approaches and their mapping onto the theory.

The evolutionary approach to e-government is described in terms that limit the e-government concept mainly to Web applications. In addition, some evolutionary approaches imply that only projects with a certain level of development can be considered electronic government. Although it is true that most computer-based e-government applications will be housed within a Web environment, we think it is very important to extend the concept of e-government to any use of ICTs.

The stakeholder-oriented approach considers mostly external relationships (i.e., from the government to another entity outside the government). Although many applications are oriented to improve the way in which government relates to other entities, e-government applications can also serve to improve internal operations and management as well as citizen engagement and public accountability.

From our initial description of each approach, it seems the definitional approaches include a wider spectrum of e-government applications in a less restrictive way. Given the limitations of the evolutionary and stakeholder-oriented approaches described in previous paragraphs, we consider the definitional approach to be the most adequate to understand the concept of e-government. However, the comprehensiveness of this approach makes it difficult to select which elements are theoretically and practically important.

Nearly all the authors address the improvement of government services as a fundamental element of electronic government (e-services). A smaller number of academics and practitioners consider ICT's potential to improve and change internal operations and management as an important element of e-government (e-management). Few of these authors acknowledge the value of information technologies for promoting and preserving democratic values (e-democracy). Finally, almost no one has clearly related electronic government to the design of public policies that facilitate and promote the development of IT initiatives and the information society, that is, electronic public policy (e-policy).

Table 2. Mapping e-government elements to public-administration theory (Adapted from Gil-García and Luna-Reyes, 2003)

Approaches to Public Administration	E-Government Categories	E-Government Elements	Sources
Managerial	E-Services	E-Services, E-Commerce	(6, 2001; ASPA, 2001; Carbo & Williams, 2004; Cook & LaVigne, 2002; Galindo, 2002; Hiller & Bélanger, 2001; Holmes, 2001; LaVigne, 2002; Layne & Lee, 2001; Moon, 2002; OECD, 2003; Schelin, 2003; Scholl, 2002; UN Division of Public Economics and Public Administration & ASPA, 2002; UNPAN, 2002; Zweers & Planqué, 2001)
	E-Management	E-Management, E-Personnel, E-Procurement	(Cook & LaVigne, 2002; Finger & Pécoud, 2003; Grönlund, 2001; Hiller & Bélanger, 2001; Holmes, 2001; LaVigne, 2002; Layne & Lee, 2001; Moon, 2002; OECDE, 2003; Rocheleau, 2003; Schelin, 2003; Scholl, 2002; UNPAN, 2002)
Political	E-Democracy	E-Democracy, E-Participation, E-Voting, E-Transparency	(6, 2001; Carbo & Williams, 2004; Cook & LaVigne, 2002; Fountain, 2003; Galindo, 2002; Hiller & Bélanger, 2001; OECDE, 2003; Scholl, 2002)
Legal	E-Policy	E-Policy, E-Governance	(6, 2001; Finger & Pécoud, 2003)

According to Rosenbloom (1998), there are three relatively distinct approaches to public administration: the managerial, political, and legal. Each of these views emphasizes different but complementary aspects of government. By mapping e-government elements to this theoretical framework, most of the elements can be grouped into e-management and e-democracy as corresponding to the managerial and political views (see Table 2).

However, it seems necessary to also include the legal view (e-policy). Governments also create regulatory and legal frameworks for the information revolution to happen. In addition, information-technology policies have been identified as key factors in the success of e-government initiatives (Dawes & Nelson, 1995; Fletcher, 2004).

Although applying Rosenbloom's (1998) framework to e-government applications would include e-services as a part of the managerial view or e-management, we would like to separate out e-services because of the customer orientation of the New Public Management perspective, which makes them different from managerial concerns. In the e-commerce arena, e-services are actually forming a new paradigm that transforms the way industries provide services, where the customer is at the center and technology constitutes an enabler for organizational transformation. The e-services view looks to the outside (customers) instead of the inside (technology and management) (Rust & Kannan, 2003), searching for the organizational transformation that allows a one-stop government-integrated service (Wimmer, 2002).

A definition of electronic government that claims to be useful for academic research and governmental policies and actions must take into consideration at least the previous four elements: e-services, e-management, e-democracy, and e-policy (as shown in Table 2). Thus, electronic government is the selection, implementation, and use of information and communication technologies in government to provide public services, improve managerial effectiveness, and promote democratic values and mechanisms, as well as the development of a regulatory framework that facilitates information-intensive initiatives and fosters the knowledge society (Gil-García & Luna-Reyes, 2003). Accordingly, e-government policies are not only about IT projects in government, but also about creating the conditions for their successful development.

Although this definition is still a work in progress, it accounts for most of the theoretical elements found in the literature; it is also sufficiently pragmatic to guide e-government strategy and policy development.

FUTURE TRENDS

Current trends in electronic government research are associated with increasing the adoption of e-government by citizens (Carter & Belanger, 2004). Some research related to this adoption process explores the importance of citizen trust in government as an adoption factor (Warkentin, Gefen, Pavlou, & Rose, 2002), but also studies the problem of citizen access to ICTs and information resources, known as the digital divide (Compaine, 2001; Luna-Reyes & Maxwell, 2003). Future trends in the digital-divide research arena will focus not only on the existence of the gap and how to close it, but also on the true benefits related to its closing (Jackson, Von Eye, Barbatsis, Biocca, Fitzgerald, & Zhao, 2004).

Current emerging trends in e-commerce research and practice will also impact the future of e-government such as user orientation and service quality (Aichholzer, 2004; Roy, 2003) or outsourcing (Chen & Perry, 2003). Some of these trends are related to the definition of e-services as a new commerce paradigm. From these new perspectives, a Web service "supports direct interactions with other software agents using XML [extensible markup language] messages exchanged via Internet-based protocols" (Ferris & Farrell, 2003, p. 31). Research about other technical standards (Borras, 2004; Landsbergen & Wolken, 2001) and open-source alternatives (Butler, Feller, Pope, Barry, & Murphy, 2004) is also taking place.

In this way, e-services will be based on reducing costs and increasing efficiency (Brown, 2001; La Porte, Demchak, & Friis, 2001), but also on building a profitable customer relationship (Rust & Kannan, 2003). E-services are mobile (PDAs [personal digital assistants], cell phones, etc.), flexible, and interactive (i.e., a series of interactive building blocks that help a customer to do the task) so as to allow the creation of sets of interacting applications around service areas (Hoffman, 2003).

In the future, this trend will facilitate the organization of government services as multichannel delivery (Aichholzer, 2004) in terms of life events such as getting married or moving to make one-stop government a reality (Wimmer, 2002), requiring complex interorganizational collaboration (Dawes & Préfontaine, 2003). However, the impacts of these trends on e-commerce have to be carefully considered by the public manager because of differences in customer relationships and IT investment between the public and private sectors (Rocheleau & Wu, 2002). Finally, security and privacy are also important challenges for the current and future development of e-government (Aichholzer, 2004) and e-democracy applications (Weinstein, 2000).

CONCLUSION

The dynamic nature of ICTs has greatly affected the development of the e-government concept. From the first use of mainframes and minicomputers to increasingly powerful networks and Web-based applications, governments have attempted to obtain benefits from the new technologies while avoiding problems. This evolution and increased complexity have been reflected in the terms used to refer to the relationships between government and ICTs. Public information systems, government information management, and e-government are some examples of a trend in which concepts attempt to capture the essence of emergent technologies.

It seems clear this tendency will continue in the near future so that the e-government concept and its definition will soon be in transition. Understanding the dynamics and complexity inherent to e-government as a concept and reality is very important for both the development of sound theories and the implementation of successful e-government projects. The research community continues a fruitful discussion and debate that will surely contribute to the strengthening of e-government as a distinct field of study.

KEY TERMS

E-Government: The selection, implementation, and use of information and communication technologies in government to provide public services, improve managerial effectiveness, and promote democratic values and mechanisms, as well as the development of a regulatory framework that facilitates information-intensive initiatives and fosters the knowledge society.

E-Government Internet Security: Technological tools, standards, policies, and other decisions concerning the security of the information and systems used by government organizations or in public-sector settings.

E-Government Portal: An interagency or intergovernment Web site that integrates information and services at a single point of entrance and can be customized according to different constituencies.

E-Government Stages: In an evolutionary approach, e-government stages are the different steps in the development of e-government. Normally, they follow a logical progression of increased technological sophistication over time.

ICTs: Information and communication technologies include hardware, software, and networks as well as the social and organizational structures needed to support their adequate functioning.

Public Services: Information and services provided by government agencies and other organizations working within the public sphere.

Web Service: "Software application identified by a URI, whose interfaces and bindings are capable of being defined, described and discovered as XML artifacts" (Ferris & Farrell, 2003, p. 31).

ENDNOTE

1 It is important to clarify that this integrative approach to e-government is conceptual in nature. Readers interested in implementation issues and success factors can consult Basu (2004), Dawes and Pardo (2002), Gil-García and Pardo (in press), Kaaya (2004), Kaylor, Deshazo, and Van Eck (2001), Martin and Byrne (2003), Mittal et al. Intelligent Product Brokering and Preference Tracking Services

Sheng-Uei Guan
National University of Singapore, Singapore

BACKGROUND

It has been projected that electronic commerce conducted via mobile devices such as cellular phones and PDAs will become a whopping $25 billion market worldwide by 2006 (Frost & Sullivan, 2002). Some of the driving factors behind mobile commerce (m-commerce) have been attributed to the compactness and high-penetration rate of these mobile devices.

Despite all the hype and promises about m-commerce, however, several main issues will have to be resolved (Morris & Dickinson, 2001; Nwana & Ndumu, 1996, 1997). Clumsy user interfaces, cumbersome application, low speeds, flaky connections, and expensive services have soured many who have tried m-commerce, and security and privacy concerns have also dampened enthusiasms for m-commerce.

Taking these concerns into account, the developers will have to offer something unique. One of the potential killer applications for m-commerce could be intelligent programs that are able to search and retrieve a personalized set of products from the Internet for their users. These programs are called software agents. Agent-based e-commerce has emerged and software agents have demonstrated tremendous potential in conducting transactional tasks via the Internet.

According to the model from the Maes's group (Guttman & Maes, 1999), the consumer buying behavior (CBB) can be divided into six stages, namely, need identification, product brokering, merchant brokering, negotiation, payment and delivery, and product service and evaluation. Among these stages, product brokering plays an important role. It involves gathering product or service information, filtering information, recommending products, and so forth.

A user searching for a particular product on the Internet will normally have to use popular search engines and enter keywords that describe the product. These search engines will process these keywords and generate a large number of links for the user to visit. Neither the search engine nor the Web site knows the preference of the user and therefore might provide information that is irrelevant to the user. Hence, user preference tracking becomes one of the fundamental tasks of product-brokering agents.

Agents act on behalf of their users by carrying out delegated tasks automatically. A product-brokering agent will search for the products in the background with minimal user intervention, thereby allowing the user to concentrate on other aspects of the transaction, such as product purchase, bidding, negotiation, and so forth. The agent could be programmed with the user's preferences in mind and filter out irrelevant products automatically. The agent could also detect shifts in the user's interests and adjust accordingly to suit the user. Personalized product-brokering agents require a profile of the user in order to function effectively. The agent would also have to be responsive to changes in the user's interests and be able to search and extract relevant information from outside sources.

At MIT Media Labs, Maes and Sheth (Maes, 1994; Sheth & Maes, 1993) came up with a system to filter and retrieve a personalized set of USENET articles for a particular user by creating and evolving a population of information filtering agents using genetic algorithms (Holland, 1973). Genetic algorithms have been widely used in various applications (Chen & Shahabi, 2002; Farhoodi & Fingar, 1997a). Their superior and flexible performance has motivated their use in software agents.

Some keywords will be provided by the user that represents the user's interests. Weights are also assigned to each keyword, and the agents will use them to search and retrieve articles from the relevant newsgroups. After reading the articles, the user can either give a positive or negative feedback to the agents via a simple GUI. Positive feedback increases the fitness of the appropriate agents and also the weights of the relevant keywords (vice versa for negative feedback). In the background, the system periodically creates new generations of agents from the fitter species while eliminating the weaker ones. Initial results obtained from their experiments showed that the agents are capable of tracking its user's interests and recommend mostly relevant articles.

Whereas the researchers at MIT required the user to input their preferences into the system before a profile could be created, Crabtree and Soltysiak (1998) believed that the user's profile could be generated automatically by monitoring the user's Web and e-mail habits, thereby reducing the need for user-supplied keywords.

Crabtree and Soltysiak's approach was to extract high-information-bearing words that occur frequently in the documents opened by the user. This is achieved by using a text summarizer that can generate a set of keywords to describe the document and can also determine the information value of each keyword. A clustering algorithm is then employed to help identify user's interests, and some heuristics are used to ensure that the program could perform as much of the classification of interest clusters as possible.

However, they (Crabtree & Soltysiak, 1998) have not been completely successful in their own experiments. The researchers admitted that it would be very difficult for the system to classify all the user's interests without the user's help. Nevertheless, they believed that their program has taken a step in the right direction by learning user's interest with minimal human intervention.

Widyantoro, Ioerger, and Yen (2003) proposed a method to keep track of changes in user interests from a document stream. Their method integrates a pseudorelevance feedback mechanism, an assumption about the persistence of user interests, and incremental method for data clustering. They claimed that their method significantly improves the performances of existing user-interest-tracking systems without requiring additional, actual relevance judgments. Kiss and Quinqueton (2001) also presented a machine learning method designed to predict preference knowledge in a multiagent context.

A new product-brokering agent usually does not have sufficient information to recommend any products to the user, and therefore it has to get product information from somewhere else. A good source of information will be the Internet. In order to do that, a method suggested by Pant and Menczer (2002) involves inplementing a population of Web crawlers called InfoSpiders that searches the World Wide Web on behalf of the user. Information on the Internet will be gathered based on the user's query and will then be indexed accordingly. These agents initially rely on traditional search engines to obtain a starting set of URLs that are relevant to the user's query. The agents will then visit these Web sites and decode their contents before deciding where to go next. The decoding process includes parsing the Web page, looking at a small set of words around each hyperlink, and giving a score based on their relevance to the user. The link with the highest score is then selected, and the agent visits the Web site.

DESCRIPTION OF INTELLIGENT PRODUCT-BROKERING AGENTS

Intelligent product-brokering agents, a new design and implementation of product-brokering agents, is briefly presented here (Guan, Ngoo, & Zhu, 2002, 2003). The intelligent ontology-based product-brokering agents implemented are capable of providing a personalized service for their users. They learn user preferences over time and recommend products that might interest the user. This work has two main features: One feature is that the product brokering is closely integrated with user preference tracking, and the other feature is that a genetic algorithm is used to adjust parameters to track user preferences.

Some assumptions have been made about the system, such as that the user is a rational person and will select a product rationally and that the value a user places on a product can be calculated, such as the price of product. Before the product brokering agent is able to explore the Internet and retrieve product information for the user, the agent needs to have some prior knowledge, such as the URL of some relevant Web sites, keywords, or some quantifiable attributes that can be used to describe the product. It could be tedious if the user has to enter such information into the agents when he or she wants to search for a particular product. An alternative to this is to create a product ontology, which involves defining the meaning of each term that is used to describe the product, their valid range of values, and their relationship with one another.

In this design, each agent will have an evaluation function that will be used to calculate the value of each product. Products that have a higher value will have a higher chance of been recommended by the agent. This evaluation function has some tunable parameters that characterize the user's preferences for a particular category of products.

Before recommending a product to the user, the agent should first be able to evaluate which product would best fit the user's requirements. A proposed method is to use some quantifiable attributes, such as performance, cost, and so forth, to evaluate the products. As an example, two weights—perf_weight (the weight of the performance of the product) and cost_weight (the weight allocated to the product cost)—represent the weights that the user could give to each attribute. These two parameters are actually used to represent the user's preferences and are incorporated inside the agent. If perf_weight has a higher value, it means that the user place more emphasis on the performance of the product. Likewise, if the user has a higher value for cost_weight, it means that the user is more concerned about the cost of the product.

When an agent is created, these two weights will be initialized based on some heuristics and would be used to calculate the value of each product found in the agent's database. The agent will then rank the products according to their values and select the top products to be presented to the user. The two weights will be allowed to change during agent evolution.

During user feedback, each agent in the system will select the top products in its database and adds them into a recommended list. A sorting function is implemented to allow the user to sort the list according to his preferences. When the user selects a product that he likes, all the agents in the system will be informed about the user's selection.

The agents will take note of the product that the user has selected and searches for that product inside its own database. At this stage, each agent would have already assigned a product value to each product in its database. To determine the amount of points to award to an agent, it will be asked to rank the products in an ascending order according to this value.

The agent's fitness is obtained by averaging the number of points earned by the agent in the previous generations. A new agent would start off with some default fitness. To keep track of the agent's performances, each agent will have a fitness history list that used to store the fitness of an agent for each generation. Hence, after an agent has been awarded some points, it will calculate its new fitness and inserts the value into the fitness-history list.

During the evolution process, weaker agents will copy over all the parameters of the fitter agents. Then, they will try to adjust the newly acquired parameters to better reflect the user's requirements. First, it will use the newly acquired parameters to reevaluate all the products found inside its new database. Then the agent will select the best product based on these new parameters. If it is the same as the user selected product, no further changes will be required but some small and random mutations in the parameters will be allowed.

IMPACT OF INTELLIGENT PRODUCT BROKERING AGENTS

To evaluate the performance of the implemented system, some experiments have been conducted to see if the system is able to detect a change in the user's preference and how fast the system will be able to respond to these changes. This could be observed by looking at the average fitness of all the agents in the system. The average fitness of all the agents should remain high if the system is able to track and respond to the changes effectively. The detailed results can be found in Guan et al. (2003). It has been found that the implemented system is capable of tracking the gradual changes in users' preferences.

CONCLUSION

With the development of software-agent technology and soft-computing techniques, agent-based e-commerce has attracted more interests. With the assistance of the intelligent agents, product brokering on the Web will become more accessible, and users may benefit from some killer applications. The GA-based product-brokering agent described in this article can intelligently track user preferences and adjust the parameters to track the preferences. Experiments have shown that the evolutionary intelligent agents are capable of tracking changes in user preferences. One weakness of the GA-based agent approach, however, is the incapability of the agent to know generic user interests, such as preference for a lighter color, for instance, which has not been preprogrammed into the agent.

Furthermore, the system is also user friendly in that the agent will learn user preferences through the user-feedback process. Although the user may not necessarily know his or her own preferences in the beginning, through agent recommendation, the user will make his or her choices, which helps the agent learn.

Further work on this topic includes care for security issues when the agents are distributed over a network. Also important is the capability of an agent to track drastic and dramatic changes in user preference. The application of fuzzy decision making to agents is another important future research direction as this will enable an agent to evaluate subjective and intangible products.

KEY TERMS

Electronic Commerce: Electronic commerce, or e-commerce, consists of the buying, selling, marketing, and servicing of products or services over computer networks. The information technology industry might see it as an electronic business application aimed at commercial transactions.

Genetic Algorithms: A genetic algorithm (GA) is a heuristic agent used to find approximate solutions to difficult-to-solve problems through application of the principles of evolutionary biology to computer science.

Intelligent Programs: Programs that are intelligent in some sense, using learning, adaptive, or evolutionary algorithms.

M-Commerce: M-commerce, or mobile commerce, stands for electronic commerce made through mobile devices.

Product Brokering: In commerce, a product broker is a party that mediates between a buyer and a seller. A broker who also acts as a seller or as a buyer becomes a principal party to the deal.

Relevance: Relevance is a score assigned to a search result, representing how well the result matches the search query. In many cases, a result's relevance determines the order in which the result is presented to the user.

Software Agents: A software agent is a piece of autonomous, or semiautonomous proactive and reactive, computer software. Many individual communicative software agents may form a multiagent system.

Interaction Standards in E-Business

Stephen Hawk
University of Wisconsin, Parkside, USA

Weijun Zheng
University of Wisconsin, Parkside, USA

INTRODUCTION

A standard is a framework of specifications that has been approved by a recognized standards organization (de jure standard), is accepted as a de facto standard by the industry or belongs to the open standards (Hawkins, Mansell, & Skea, 1995). According to Rotem, Olken, and Shear (2001), there are two types of communication standards encountered in the e-business: infrastructure type standards and interaction type standards. Infrastructure type standards such as TCP/IP are important for almost any application that uses the Internet and are not the focus of this chapter. Interaction type standards address communication content and interfaces between e-business systems with the goals of facilitating system interoperability and process integration. These standards cover issues such as data dictionaries, message structure, and remote object invocation.

BACKGROUND

E-business interaction standards began in the 1980s with the emergence of electronic data interchange (EDI). EDI's structured document format enabled the systems of one firm to directly communicate with those of other firms. This earlier form of business-to-business (B2B) e-commerce, however, was difficult for small-to-medium enterprises to adopt due to its high cost and complexity (Chau & Jim, 2002).

With the growth of the Internet-based e-commerce, there was increasing need for business systems to be able to communicate with each other over the Internet. The need for systems of different organizations to interact with each other in ways beyond just sending structured documents also emerged. For instance, the systems of one organization may need to invoke the processes of systems of another organization. With the increasing reliance on the Internet as a medium for conducting business, it is likely that interaction standards will become an important element in e-business systems. This article provides an overview of these standards.

E-business partners have interactions at different levels of society. Accordingly, e-business standardization can happen from individual level and company level to industry or association level and national level (Verman, 1973). Due to the huge number of these standards bodies, this article has chosen standards bodies or groups at international level as its discussion targets.

TYPES OF INTERACTION OF STANDARDS

Most e-business interaction standards can be categorized into one of the following five categories: message structure, data dictionary data guidelines, remote object invocation, registries/repositories, and business processes. The following describes each of these areas and some of the main standards that have been developed in them.

Message Structure

Despite the emergence of successors, traditional EDI continues to be widely used. An EDI message consists of a series of data elements, each representing a single fact, such as a product ID or price, separated by a delimiter. The entire series is called a data segment. One or more data segments framed by a header and trailer form a transaction set. This is what is sent via EDI and is equivalent to a message. This message would tend to consist of what would normally be contained in a typical business document.

The main version of EDI used in the United States follows the ANSI Accredited Standards Committee (ASC) X12 standard developed by the Data Interchange Standards Association. Since 1987, chartered by ANSI, the Data Interchange Standards Association (DISA) has served as the secretariat for the X12 standards development process. ASC X12's strategy direction is to "embrace collaboration with domestic and international organizations while continuing to forge ahead to ensure ASC X12 member companies' electronic data interchange (EDI) requirements are met" (Cover, 2003). A closely related international standard UN/EDIFACT was developed by the United Nations Centre for Facilitation of Procedures and Practices for Administration, Commerce and Transport (UN/CEFACT). ASC X12 and UN/EDIFACT are closely coordinated standards.

ebXML (electronic business XML) is an emerging, open and Internet-based standard that is supplanting traditional EDI. ebXML is intended for the exchange of business documents globally among firms of any size, and in any location, by securely exchanging of XML-based messages (Chiu, 2002). ebXML is the result of a project that was jointly launched by UN/CEFACT and the Organization for the Advancement of Structured Information Standards (OASIS, 2005). OASIS is a not-for-profit international consortium of vendors, users and specialists whose membership includes 75 companies, including major IT vendors and trade associations throughout the world.

Since ebXML uses existing standards such as HTTP, TCP/IP, MIME, SMTP, FTP, and XML, it can be deployed on virtually any platform. This, along with the use of the Internet instead of proprietary networks makes ebXML relatively inexpensive and easy to use.

BizTalk, an alternative to ebXML is a result of an industry initiative headed by Microsoft to promote XML as the data exchange language for e-commerce and application integration on the Internet. While not a standards body per se, the group is fostering a common XML message-passing architecture to tie systems together. In the BizTalk Framework, a message is embedded inside an envelope that includes additional information such as origin, purpose, and destination.

Data Dictionaries

Data dictionary standards may include guidelines about how specific elements are represented or which segments of data may coexist, or are mutually exclusive. Such guidelines appear in the EDI and RosettaNet message standards. The following are some standards related to data dictionaries:

1. ASC X12 data element dictionary represents the collection of basic building blocks on which all electronic data interchange (EDI) transaction sets are constructed.
2. The UN/EDIFACT data dictionary defines each data element and its cross-reference to all UN/EDIFACT messages in which it's used, including all available codes and attributes.
3. RosettaNet is a nonprofit consortium dedicated to the development and deployment of standard electronic business interfaces (Hamilton, 2004). These standards include common partner interface process (PIP) and data dictionaries. RosettaNet encodes messages as well-formed XML documents. RosettaNet was formed in 1998 by leading companies in the electronic sector, is a nonprofit consortium of more than 500 organizations working to create open e-business standard. Because RosettaNet is widely supported by companies in the IT industry, its standards are expected to be widely adopted. Once adopted, there is some evidence showing that interaction standards such as RosettaNet have considerable potential for altering the way firms in industries interact with each other (Malhotra, Gosain, & El Sawy 2005).
4. The Open Applications Group (OAG) has developed the business object document (BOD) architecture that provides the framework to communicate messages or business documents. BOD consists of two major components: control layer and business data layer. The OAG work group has provided the specification to develop a set of OAG-compliant document type definitions (DTDs) to support their eXtensible Markup Language (XML) messaging requirement. Both the XML messages and its DTDs make up the BOD.
5. The ebXML core components project team is working on a method to develop a common business data dictionary. The goal is to develop a syntactical neutral data dictionary where it can support numerous syntax such as XML, X12, EDIFACT, etc. This is a work in progress.

Remove Object Invocation

Trading partners often need interoperability among their systems. The dominant standards in these areas are Microsoft's component object model (COM) and COM+, common object request broker architecture (CORBA) by OMG, and Sun's Enterprise JavaBeans (EJBs).

SOAP (simple object access protocol) provides methods for a program running under one operating system to communicate with a program in the same or another operating system using the hypertext transfer protocol (HTTP) and XML as the mechanisms for information exchange (Alexander & Zhang, 2005). SOAP specifies how to encode an HTTP header and an XML file so that a program in one computer can call a program in another computer and pass it information. It also specifies how the called program can return a response. Because HTTP requests normally are allowed to pass through firewalls, SOAP communications are typically able to communicate with programs anywhere.

Registries/Repositories

These can be viewed as large databases of information about schemas, DTDs, and services offered. Examples of registry standards are UDDI, Total-espeak by HP, and ebRIM, the ebXML registry information model (Rotem et al., 2001).

UDDI (universal description, discovery, and integration) for example, is based on XML. It provides a registry for businesses to list themselves on the Internet. Its goal is to simplify transactions by helping companies to find each other on the Internet, and increase the interoperability of their systems (Newcomer, 2002). UDDI can be viewed as an online version of a telephone book's white and yellow pages. UDDI allows businesses to list themselves by name, product, location, or the Web services they offer. Efforts to develop UDDI were led by the firms Microsoft, IBM, and Ariba.

Also based on XML, WSDL (Web services description language) is a language for describing services offered by businesses. WSDL provide a mechanism for accessing these services electronically. WSDL is used by UDDI for businesses to describe themselves.

Business Processes

A tighter integration is sometimes required among complete business processes or workflows. For example, a purchase order workflow at Company A needs to invoke an acknowledgment process and inventory search process at Company B.

In addition to its involvement with data dictionary standards, RosettaNet is also involved in standards for defining business processes. Its partner interface processes (PIPs) defines business processes between trading partners. PIPs fit into seven Clusters, or groups of core business processes, that represent the backbone of the trading network. Each cluster is broken down into Segments—cross-enterprise processes involving more than one type of trading partner.

STANDARDS BODIES

It has been noted that several industry lead standards organizations or "forums" have been formed (Mähönen, 1999). This indicates a tendency towards standardization carried out by different industry groups in the field of e-business. Table 1 shows some of the major standards setting bodies and some of the standards each is involved in.

FUTURE TRENDS

Today's XML based e-business starts from 80s EDI. At that time, many big companies intended EDI to integrate business functions for automatically delivery of the data. EDI based on ASC X12 and UN/EDIFACT currently has a large installed base; the volume of EDI transactions and integration with core business processes will continue to make it a widely implemented standard for e-business. The introduction of the XML in late 90s point e-business in a new direction. XML-based e-business standardization begins with an ambitious vision: to transform all information system into interpretable ones to business partners or even the society. Newer interaction models, usually based on XML appear in a number of

standards that have reached different levels of maturity and adoption. The ebXML framework, for instances, does not seem close to "critical mass" status for e-business yet. The status of other XML-based e-business standards is also not yet stable. The mature, stable form of some has yet to appear; their ultimate levels of adoption are anything but certain. A problem with adopting these standards is the fact that since they are not yet stable, their adoption can be risky. Additionally, in many cases, the related technology could have become almost antiquated by the time the standard is published (Egyedi, 2000; March & Olsen, 1989).

CONCLUSION

It is worthwhile to note here that the standardization of e-business is a combination of vision and action. Beginning with EDI, e-business interaction standards are developing through newer standards largely based on XML These standards by and large address interactions between companies or organizations. The standards groups often had problems to define their scope in the same terms because of the larger scale or volume of activity required to justify the expense of the systems to support these standards. Collaboration or coordination among standards groups are therefore strongly encouraged by the industries and proved to be a good approach to facilitate the convergence of e-business standards. As relationships between parties become redefined, standards groups also need to consider broadening the scope of their standards to include both intra- and inter-enterprise transactions. With companies outsourcing more administrative functions, these internal exchanges can become intercompany messages almost overnight (Kotok, 2001).

According to Rotem et al. (2001), there are really two strategies to deal with multiple e-business standards and their standards bodies. The firms can either choose a set of standards to support natively in all applications and systems and expect the rest of the world to comply as RosettaNet did or they have to build a translation capability that allows the organization to accommodate multiple evolving standards.

Whichever strategies the company chooses seems to be strongly affected by the industry structure it exists. Mature industries tend to have already converged on a set of dominant standards—either official or de facto. Emerging industries tread on shifting sands and new standards come and go like the wind. For companies whose business network extends across industry boundaries, they face a mess of standards; for example, semiconductor manufacturing industry will need to accommodate multiple standards as they transact with the automotive, aerospace, and consumer goods markets.

Some industries can have one or a few dominant player that can dictate standards to suppliers (e.g., Boeing in aircraft, Wal-Mart in retail, and the big three in automotive). For the rest players of those industries, the best strategy will be following dominant players to gain second move advantages. In other industries without dominant players, it may be possible for firms to influence standards development by creating the structures to work together collectively in order to gain influence (Reimers & Lee, 2005).

Similarly, if there is a single or a consortium of, dominant IT vendors that serve the industry, it or they may be able to drive standards adoption. The adoption of the same standards has also been quick in some instances and slow in others. ebXML, for instance, has been adopted by the automotive industry as e-business exchange standards. But in semiconductor industry, due to the existence of RosettaNet, the shifting to ebXML is expected to be slow. Furthermore, the role of government in a heavily regulated industry can not be ignored.

KEY TERMS

DTD (Document Type Definition): Provides guidelines about how specific elements in a document are represented or which segments of data may coexist, or are mutually exclusive.

ebXML (Electronic Business XML): An EDI standard intended to supplant X12 and UN/EDIFACT. Based on eXtensible Markup Language (XML) and using standard Internet protocols, it is expected to lower the cost and difficulty of setting up and using EDI, thereby expanding its use to small and medium sized enterprises.

EDI (Electronic Data Interchange): A standard, structured format for exchanging business data.

Interaction Standards: Interaction standards are primarily used in business transactions. These standards address communication content and interfaces in e-business.

RosettaNet: Open e-business standards, encompassing data dictionaries, implementation framework, and XML-based business message schemas and process specifications.

SOAP (Simple Object Access Protocol): A standard for remote object invocation that uses HTTP and XML.

UDDI (Universal Description, Discovery, and Integration): Provides a registry for businesses to list themselves on the Internet. It functions as an online version of a telephone book's white and yellow pages.

UN/EDIFACT: An international EDI standard that is similar to, and based on X12. Its syntax is somewhat different from X12's but it follows the same basic principles and architecture.

WSDL (Web Services Description Language): Describes services offered by businesses, providing mechanisms for accessing these services. WSDL is used by UDDI.

X12: The X12 EDI standard defines the data structure and content for business transactions transmitted between information systems with dictionaries that specify name, length of data field, description, data type, and meaning.

Internet and Access to Scholarly Publications

INTRODUCTION

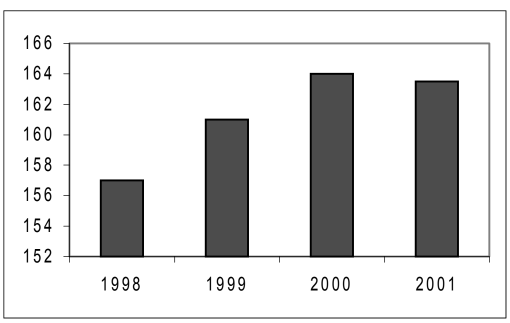
"If I have seen further it is by standing upon the shoulders of giants." The famous statement of Sir Isaac Newton demonstrates that the progress of science relies on the dissemination of discoveries and scientific knowledge. Even though scientific progress is not strictly cumulative (Kuhn, 1970), information sharing is the heart of this progress.

In the Gutenberg era, researchers had no alternative: Publishers were the only way to reach readers. The development of e-commerce and of digital networks led to the post-Gutenberg era, and offers a powerful alternative that can lead in the long term to a new organization of scientific publications (Harnad, 1999). As well as e-commerce is revolutionizing the distribution of cultural goods (particularly music), the distribution of scientific knowledge through the Internet should contribute to the emergence of a new economic model.

BACKGROUND

The growing complexity of modern science induces a growing need of knowledge-dissemination media. The number of academic journals is very difficult to estimate, but according to "Ulrich's International Periodicals Directory" (http://www.ulrichsweb.com), there were about 164,000 scientific periodicals in 2001 in all disciplines (see Figure 1).

Figure 1. Number of periodicals (thousands) published worldwide from 1998 to 2001 (Source: "Ulrich's International Periodicals Directory")



The largest publishers like Elsevier-Reed, Blackwell, or Wiley own most of these journals. Over the last 20 years, commercial firms—especially the largest ones—have raised prices at a rate that cannot be justified by cost or quality increase (McCabe, 2000). The evolution of the median cost of serials is summarized in Table 1; it is now 3 times higher than it was in the mid-'80s.

Former president of the University of California, Richard C. Atkinson, recently stated, "University librarians are now being forced to work with faculty members to choose more of the publications they can do *without*" (Atkinson, 2003, p. 1). As a consequence, in the USA, Figure 2 shows the following.

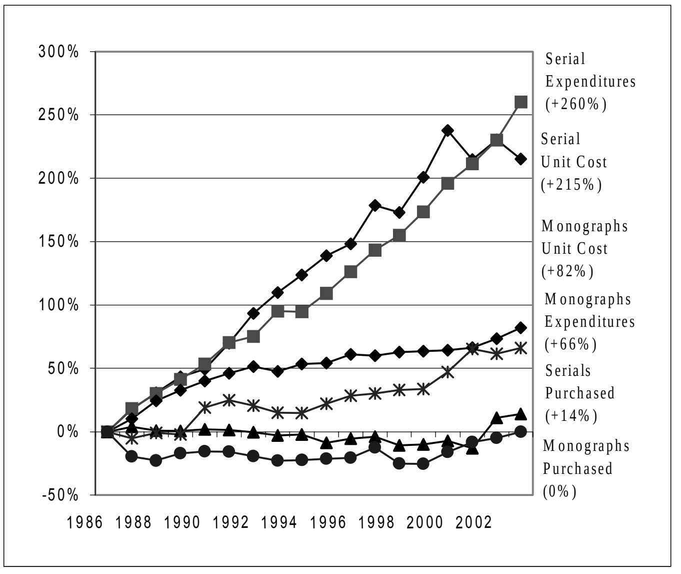
1. Acquisition expenditures have tremendously grown.
2. Part of the budgets had to be reallocated from monographs to journals.

The rise of journal prices has multiple origins, one of the most important being provisions to invest in electronic publications (Chartron & Salaun, 2000). The electronic publication, which should reduce costs, is now a source of cost increase. These provisions are nevertheless insufficient to explain the current prices. Elsevier-Reed's gross-profit margin is estimated at 32% (Wellen, 2004). Such Microsoft-like margins are very unusual and demonstrate the inefficiency of the scientific-publication market. There are four main reasons for this inefficiency.

Table 1. Evolution of the median value of serial unit cost from 1986 to 2003 (Source: Association of Research Libraries (ARL, 2004))

Year	Serial Unit Cost	Annual Percentage Changes	Cumulative Percentage Changes
1986	$ 89.77	N/A	N/A
1988	$ 117.25	10.94%	30.60%
1990	$ 134.09	4.18%	49.36%
1992	$ 173.67	13.93%	93.46%
1994	$ 200.85	6.67%	123.72%
1996	$ 222.89	3.95%	148.28%
1998	$ 245.05	-1.97%	172.96%
2000	$ 303.19	12.30%	237.73%
2001	$ 282.54	-6.81%	214.72%
2002	$ 296.50	4.94%	230.27%
2003	$ 283.08	-4.53%	215.32%

Figure 2. Monograph and serial costs in ARL libraries from 1986 to 2003 (Source: ARL, 2004)



- Researchers publish to popularize their works and to improve peers' recognition (which has a great impact on their careers). They are "giveaway authors" (Harnad, 2001) and do not receive any royalties or fees. Furthermore, they do not have to pay to access to scientific information since all the expenses are paid by academic libraries. Authors are then not concerned with the prices of journals; they only consider the reputation and the citation impact of the journals they publish in.
- The demand is price inelastic (that is, prices have few impact on the volume of the demand) since prices are not important for researchers, and journals are not easily substitutable.
- Libraries evolve on a commercial market, but do not have any commercial approach. They buy up to their budget limit and not according to any price equilibrium.
- The multiplication of mergers among publishers has strongly contributed to the increase of prices (McCabe, 2000).

Moreover, commercial publishers now have a growing aggressive commercial attitude with, for example, journal bundling that obliges libraries to buy journals they do not need if they want to subscribe to prestigious must-have journals. The Big Deal (Frazier, 2001)—an online aggregation of journals—is so expensive and restrictive that prestigious universities like Stanford or Cornell created sensation in late 2003 by canceling their Big Deal subscriptions (Wellen, 2004).

Symptomatic of this evolution, the new CEO (chief executive officer) of Elsevier-Reed previously worked in firms operating in highly competitive markets like Procter & Gamble and Guiness (Wellcome Trust, 2003).

In this context, public research institutions pay twice for scientific knowledge. They pay researchers who publish freely, and publishers to have access to journals (Anderson, 2004).

The growing conflict between researchers, who aim at disseminating their works as widely as possible, and libraries, which have a limited budget on the one hand, and publishers, who mainly have financial objectives on the other hand, gave rise to the accelerated development of the practice of open access to electronic publications. Governments concerned about research budgets are more and more interested in that movement and try to support it. At the end of January 2004, OECD ministers "recognized that fostering broader, open access to and wide use of research data will enhance the quality and productivity of science systems worldwide. They therefore adopted a Declaration on Access to Research Data from Public Funding" (OECD, 2004). One of the principles of this declaration is to promote openness, that is, open access to public-funding research.

THE OPEN-ACCESS MOVEMENT: TOWARD A NEW ECONOMIC MODEL OF SCIENTIFIC PUBLICATIONS

According to Harnad (1999), the new organization of scientific publications will be based on open access to electronic publications. Beginning with self-archiving and repositories, the open-access movement is now moving toward free electronic publications.

Self-Archiving

From the very beginning, scientists have exchanged information, consulted peers about a given idea, or tested colleagues' reactions to an innovative concept. Up to the second half of the last century, the main transmission tool was private correspondence via postal mail. With the development of the Internet and electronic communications, informal exchanges have exploded since it is now easy and very common to contact a researcher by e-mail to ask him or her for a copy of a given work.

In order to ease informal exchanges and to increase their visibility, many researchers have used the Internet for a long time to self-archive their works, that is, to make either preprints (before refereeing) or postprints (after refereeing) available on their own (personal or institutional) Web site.

Due to the pressure of the open-access movement, the copyright policy of journals and publishers has changed a lot over the last years. Project RoMEO (Rights Metadata for Open Archiving, http://www.lboro.ac.uk/departments/ls/disresearch/romeo/) lists publishers' copyright-transfer agreements. Figure 3 shows that 83% of the 10,673 journals listed in September 2004 now accept at least preprint archiving. This percentage was only 55% in 2003.

Self-archiving undoubtedly increases visibility but, since these archives can only be found through usual search engines, their access is very difficult without the knowledge of the existence of a given work.

Repositories

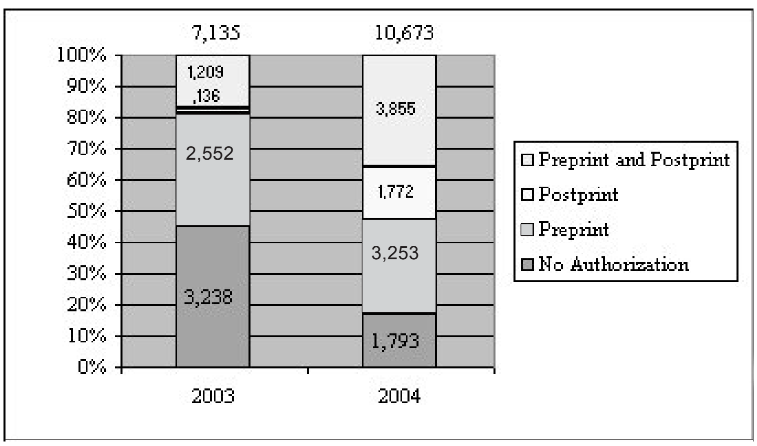
The success of self-archiving and the difficulty to find self-archived works led Paul Ginsparg, then physicist at the Los Alamos National Laboratory, to initiate in 1991 the *arXiv* archives (http://www.arXiv.org). It aimed at centralizing and easing access to free electronic publications by asking researchers to archive their works in *arXiv*. With such tools, publications are no longer dispersed among many Web sites and are available at once. There are now more than 300,000 articles in *arXiv* with a submission rate of about 3,500 papers per month.

Following this pioneer, other high-level archives emerged. Some of the most important being the following.

- **Cogprints** (http://cogprints.ecs.soton.ac.uk) specialized in cognitive sciences.
- **PubMed Central** (http://www.pubmedcentral.gov/) specialized in life sciences.
- **Repec** (http://www.repec.org/) and **WoPEc** (http://netec.mcc.ac.uk/WoPEc.html) specialized in economics.
- **Math-Net** (http://www.math-net.org/) specialized in mathematics.
- **NCSTRL** (http://www.ncstrl.org/) and **CiteSeer** (http://citeseer.ist.psu.edu/) specialized in computer science.

The development of repositories and self-archives led to a standardization need, and the proliferation of repositories induced the need of services permitting search across multiple repositories. Repositories also

Figure 3. Evolution of journals' self-archiving policies from 2003 to 2004 (Source: Project RoMEO)



needed capabilities to properly identify and copy articles stored in other repositories (Lynch, 2001). These needs, identified by Herbert van de Sompel, led to the Open Archives Initiative (OAI, http://www.openarchives.org), initiated by P. Ginsparg in 1999 with The Santa Fe Convention of the Open Archives Initiative. The Open Archives Initiative designed specific metadata tagging standards to make archives easily harvestable. Even though the Open Archives Metadata Harvesting Protocol is mainly used by free repositories, it is also employed by servers housing commercial products (the term open refers to the technical architecture, not to free contents).

Specific directories like OAIster (http://www.oaister.org) or Eprints.org (http://www.eprints.org) now provide lists of OAI-compliant archives. This initiative has known tremendous success, notably because the implementation of a repository is technically relatively easy (Crow, 2002). In February 2005, OAIster managed more than 5 million records originated from more than 400 institutions.

Online Journals

Considering the success of e-commerce and e-distribution, a great deal of publishers has decided to make their journals available online. Apart from their usual paper editions, these journals try to improve their diffusion and reputations.

Some publishers or institutions also decided to adopt a more radical solution, that is, purely electronic journals. Considering the prices of printing and postal diffusion, electronic publications can reduce the cost of journals (Wellcome Trust, 2003). Publishers only have to support the organization of the review process and the cost of diffusion tools (software and hardware).

Access to electronic articles originated in classical or electronic journals is usually reserved to subscribers, but a growing number of them are now free on certain conditions (such as time-delayed release). In February 2005, the *Directory of Open Access Journals* (http://www.doaj.org) listed more than 1,400 journals in all disciplines.

One of the reasons of the growing success of open-access journals is that open-access articles have a greater citation impact than others. Studying 119,924 conference articles in computer science and related disciplines, Lawrence (2001) found that the number of citations of open-access articles was 2.6 times greater than the number for off-line articles. A recent study based on the ISI CD-ROM citation database concluded that for the year 2001, the citation impact in all physics fields was 5.5 times higher for open-access articles (Brody, Stamerjohanns, Vallières, Harnad, Gingras, & Oppenheim, 2004).

The Search for a New Economic Model

The transition to electronic journals reduces the costs but is of course insufficient to economically validate the open-access model. Apart from subsidy-based free journals, a growing economic model is based on the payment by the authors' institutions. An author-paid model is substituted for the classical subscriber-paid system.

A recent study by the Wellcome Trust (2004) tries to compare the costs of classical subscriber-paid journals and electronic author-paid journals. The results are summarized in Table 2.

The structure of fixed costs is similar for both types of journals (editorial costs, review costs, articles preparation, etc.), but fixed costs are estimated higher for author-paid journals because they have to cover the administration of the charging system to authors. Variable costs differ since the marginal cost of electronic distribution is very low. According to Wellcome Trust (2004, p. 4):

In terms of costs of production, system costs and the implication of those for levels of fees, the author-pays

Table 2. Estimates of journal cost: (a) Eight articles reviewed for each article accepted; (b) Two articles reviewed for each article accepted (Source: Wellcome Trust, 2004)

Cost Element	Subscriber-Paid Journal Cost in U.S. $		Author-Paid Journal Cost in U.S. $	
	Good to High Quality Journal[(a)]	Medium Quality Journal[(b)]	Good to High Quality Journal[(a)]	Medium Quality Journal[(b)]
First-Copy Costs per Article	1,500	750	1,500	750
Fixed Costs per Article	1,650	825	1,850	925
Variable Costs per Article	1,100	600	100	100
Total Costs per Article	**2,750**	**1,425**	**1,950**	**1,025**

model is a viable option. Open-access author-pays models appear to be less costly and to have the potential to serve the scientific community successfully.

One of the first author-funded journals was the *New Journal of Physics* (NJP) launched at the end of 1998 (Haynes, 1999). This journal requires authors of published papers to pay a publication fee of £300. The beginnings were difficult since online journals were not considered as 100% serious, but NJP is now ranked 14 of 68 titles in the physics-multidisciplinary category of ISI's *Journal Citation Reports* (Haynes, 2004).

The most prestigious initiative yet is that of the Public Library of Science (PLoS, http://www.plos.org) founded in October 2000 by Nobel Prize recipient Harold E. Varmus, Patrick O. Brown from Stanford University, and Michael Eisen from the University of California, Berkeley. They received a $9 million grant from the Gordon and Betty Moore foundation and launched a high-level journal, *PLoS Biology*, in October 2003. *PLoS Biology* charges authors about $1,500 per accepted article, but, thanks to an equalization system, publications in *PLoS Biology* can be affordable for any laboratory in developing countries (Delbecq, 2004).

The NJP as well as *PLoS Biology* do not cover their direct costs yet with author fees and strongly rely on subsidies. The NJP should increase the number of published articles by 150%, the proportion of authors paying articles from the present 60% to 95%, and the fee from the present £400 to £600 in order to cover its costs (Haynes, 2004).

The economic model of free publications then remains to be constructed. A pure author-paid system cannot be implemented immediately. Prosser (2003) proposes a transition model in which journals would give authors two options.

- To pay for publication and the article will then be freely available.
- Not to pay for publication and the article will only be available to subscribers.

According to Prosser, the numerous advantages of open access, particularly in terms of visibility and citation frequency (Harnad, 2004), should lead to a growing share of author-paid articles.

Prosser's model as well as the propositions of the Open Society Institute (Crow & Goldstein, 2004) remain to be validated. No open-access journal covered its fixed costs yet, and the solutions to bring them to financial equilibrium are still to be invented. Furthermore, the open-access model undoubtedly has undesired effects.

- Many scientific societies live on their publications. These nonprofit organizations use the publication incomes to finance conferences or scholarships. The development of open access could threaten their activities.
- By succeeding, the open-access movement may threaten the largest publishers. They should be tempted to concentrate their publications on core collections. Loosing economies of scale from successful publications, the cost of marginal highly specialized journals could explode (Okerson, 2003).
- The author-paid model could result in a simple shift from library subscription to research budgets. In 2003, Duke University published about 4,500 papers. If authors had paid $1,500 per article, the total cost of $6.75 million would have been close to the current budget for journals, which is about $6.6 million (Guterman, 2004).
- Author-paid journals will inevitably be tempted to accept a growing number of articles in order to cover their fixed costs; the global quality of these publications could then decrease.
- Authors who do not have the budget to finance a publication might look to think tanks and corporations to find extra funding. These scientific works will paradoxically be more influenced by political and commercial agendas (Wellen, 2004).

FUTURE TRENDS

Open access is by no way a panacea. It is not economically viable yet and could have important undesired effects. Nevertheless, the pressure induced on commercial publishers is now very high and they no longer can ignore this movement. It is now very difficult to imagine that in a decade or more, commercial publications will disappear and be replaced by free publications, but the open-access movement will undoubtedly brake the exploding dynamic of prices. The future equilibrium will inevitably associate commercial and open-access publications, opening the way toward a more efficient market of scholarly publications.

CONCLUSION

The *Journal of Comparative Neurology* costs $18,000 a year; *Brain Research* costs about $21,000 and *Nuclear Physics A* and *B* more than $23,000 (Guterman, 2004). Such exploding prices explain the growing conflict between academics and publishers. The development of the open-access movement is then not the mere consequence of the diffusion of the Internet, but also a clear symptom of the inefficiency of the current market. The debate on free publications remains very passionate and is not always rational, but its great merit is to raise an important issue. By modifying the balance of power between researchers and publishers, the success of the open-access movement and the development of e-commerce and e-distribution will ease scientific knowledge dissemination, reduce the information gap between wealthy and low-budget institutions, and help the advent of an efficient market.

KEY TERMS

Big Deal: Online aggregation of journals offered by publishers. Big Deal can oblige libraries to subscribe to marginal journals to have access to must-have journals.

Metadata Tagging Standards: Standard format of keywords used while self-archiving to identify, classify, and retrieve the archived works.

OAI-PMH: The Open Archives Initiative Protocol for Metadata Harvesting provides a standard framework for metadata harvesting.

Open Access Journals: Freely available online scholarly journals. Some of them are purely electronic journals, and others are classical ones offering a free electronic version (http://www.doaj.org).

Open Archives Initiative: Initiated by the American physicist P. Grinsparg in 1999, the OAI designed metadata tagging standards (http://www.openarchives.org).

Postprint: Scientific work modified after peer review.

Preprint: Scientific work before peer review.

Public Library of Science: Organization founded in October 2000 committed to make scientific literature a freely available resource. Nobel Prize recipient Harold E. Varmus is cofounder and chairman of the board of PLoS (http://www.plos.org).

Repository: Database where researchers self-archive their works, either preprints or postprints. The Open Archives Initiative proposes standards to allow access to different repositories.

Self-Archiving: Consists of depositing researcher works in a repository. The researcher is generally responsible for the format of the deposit and particularly for its conformance to the archive standards.

Internet in a Commodity Mining Company

Pat Foley
University of Melbourne, Australia

Danny Samson
University of Melbourne, Australia

BACKGROUND OF THE BUSINESS

On August 16, 1999, the world's first Internet commodity exchange-traded metals sale took place when WMC, an Australian resources company, sold five tons of cobalt at $18.25 a pound. Some metal traders had been buying and selling steel through Web sites, however, commodity exchange-traded metals had lagged behind the steel industry in the use of e-commerce, with most nonferrous companies and exchanges offering only information on products and services through the Web while continuing to trade using standard processes. WMC had introduced electronic commerce to one of the world's oldest industries and became the first metal producer to use the Internet to support the marketing of nonferrous metals. This was only the beginning for WMC.

In the mid- and late 1990s, high-technology e-stocks boomed. There were excited discussions about a new economy that was commonly presumed to be immune to the cyclical problems that confronted the resource sector. As the resource shares were declining, commentators were talking about an Internet gold rush. A new-economy gold fever had gripped investors. Mining companies were treated as relics of an old economy. They were seen as old-economy companies using rusting-edge practices that reflected their dinosaur-sized machinery. It seemed inconceivable that a mining company could sell a larger tonnage of product over the Internet than Amazon.com and make a profit that Amazon had not yet achieved.

DESCRIPTION OF THE BUSINESS

WMC was Australia's third-largest publicly listed resource company.[1] Established as an Australian gold-exploration and -mining company in 1933, WMC Limited became a major global minerals explorer and producer with business interests in 16 countries. It had four competitive and world-class core businesses: copper and uranium, alumina, nickel, and fertilizers. The 2000 annual report (http://www.wmc.com.au) recorded 3,483 employees, and with contractors, the total number of staff was 5,212. At the end of the 2001 financial year, it had a market capitalization of approximately $10 billion.

Selling Cobalt in the New Economy

In 1999, Peter Johnston was 4 years into his role as executive general manager of WMC's nickel division and was frustrated with a problem endemic to the world cobalt market. The Metals Bulletin, a London mining magazine, had for decades provided the only publicly posted cobalt price. However, the published price was rarely current when a deal was done so the cobalt market lacked transparency and as a result pricing was an issue. Then London-based marketing executive Roger McSweeney presented Johnston with a "brainwave," a radical suggestion to sell cobalt over the Internet. The mining sector, mired in tradition, had not embraced e-commerce. Initial discussions had started on developing e-marketplaces for suppliers to the industry, but these had not progressed.

It was the result of a recent restructuring that placed Johnston in the joint role of head of WMC's nickel division as well as head of information technology, which enabled informal discussion about the advantages of Internet enabling WMC's business practices to occur. There was a volley of e-mails between WMC technology experts in Perth and senior executives in different parts of the world, and buoyed with the assurance "We can do it in 4 weeks," Johnston decided to champion the idea. He felt that the project had little strategic risk as cobalt was a niche market for WMC. In 1999, they produced only 700 to 800 tons a year as a nickel by-product.

Internet selling of commodity items was common in other industries, so it was quickly decided that it was technically feasible and that a viable pilot could be mounted for $100,000. Overcoming mild skepticism by Hugh Morgan, WMC's CEO (chief executive officer), it was decided that this initiative could be accomplished in a short time frame and might offer WMC some strategic advantage. The decision was made to test cobalt sales on the Internet. Within days of posting cobalt on a hastily created Web site, WMC not only sold all the cobalt it was offering, but had also increased its customer base. Customers who had previously dealt with metal brokers were now dealing directly with WMC.

Is There Any Money in This?

Starr (2003) considers the operations-management aspects of e-business from a retailing perspective. In order to do this, he has considered the cost of B2C (business-to-consumer) Internet operations and used Webvan as a case study, in which the operating costs simply precluded that company from achieving a break-even point, leading it to bankruptcy. While very many companies were burning cash fast on their e-initiatives, WMC was moving forward with sensible business strategies that made use of these Internet technologies.

Like many mining companies, WMC was dominated by strategies that aim to enhance cost efficiency. Competition in such commodity markets is traditionally seen as being based on cost. However, the Internet pilot quickly led to an expansion in WMC's strategic thinking. Senior management rapidly realized that the Internet created an opportunity for a resource company to differentiate on customer service. This customer-service focus also minimized the historical role and cost of intermediaries. This insight gave birth to what WMC was later to call its e-WMC initiative. At this stage, a full e-strategy was not formulated, but it soon emerged organically. The first step in this growth was Johnston's realization that one Internet success could be followed by another.

Four weeks after the first cobalt Internet sale, WMC posted its surplus nickel on the Web site and had a similar response. In 1999, WMC was selling about 60,000 tons of nickel a year under long-term contracts and an additional 10% to the on-the-spot market. WMC was also getting up to 3% more for the nickel sold on the Internet than nickel sold to a metal trader. The degree of success of the WMC Web site, particularly with North American customers, came as a surprise. It also surprised the entire metal world, and WMC was quick to take advantage of this success. The opportunity was not only to sell products to customers more efficiently, but also to change the nature of its customer relationships.

There was little downside to the initiative. The London Metal Exchange (LME) was supportive because WMC used it for benchmark prices, and 90% of its business is in trading financial derivatives anyway. WMC's customers were very happy because Internet-sourced sales cut transaction times down to about a minute since availability, pricing, and shipping details that had formerly been negotiated over the phone could now be posted online. However, metal traders who brokered the transactions for the on-the-spot market, and had previously been paid commission on these transactions, were not as happy. They were being disintermediated.

Initially, it had been assumed that long-term contractual customers would not be interested in using the Internet. This assumption was soon proved wrong. Long-term contractual customers started to use the Web site to top up their requirements and to make requests for additional information. By 2000, this pilot project had caused a change in WMC's strategic thinking. The new strategy was to gain leverage from an initiative started 5 years before.

Getting Ready without Really Knowing It

In 1995, WMC started an information-integrity program. At the time there was no indication that 5 years later this initiative would become a key building block of its e-commerce strategy. The program used an SAP platform to establish a standard system and consistent language for the management of information within WMC. Unlike many mining companies, it would remove a host of legacy systems that had been used in different locations, businesses, and countries worldwide. SAP was chosen to be the common platform across all its operations worldwide.

In September 1996, WMC started the implementation of its information-integrity program group-wide. The aim was to implement standard processes throughout the entire group underpinned by SAP. Even while it was being installed, WMC was able to cut its level of inventory and gain a better understanding of the operations of its plant and equipment. One of the earliest advantages was the consolidation of the group's contracts with various suppliers.

Like many organizations, different divisions within WMC used disparate information systems. This presented problems in product ordering and inventory control since the systems at each of the sites coded inventory in its own manner. This effectively guaranteed that an integrated overview of inventory throughout the group was next to impossible. The advantages from being part of a group were not being realized. Not only did WMC realize stock control and inventory efficiencies with a central inventory-management system for the entire group, it also centralized stock ordering and received direct financial savings. Its inventory-management flexibility also improved the movement of goods between WMC's Australian sites since the common system automatically updated values in the financial-accounting, asset-accounting, and control databases.

Through SAP, ERP (enterprise resource planning) was seen as having the potential to be a key building block for WMC's e-commerce strategy. In early 2000, it was unclear how the pieces of this e-commerce strategy jigsaw would come together, however by 2001, what would be called e-WMC was beginning to take shape.

e-WMC Customers

Rotondaro (2002) points to the importance of understanding the clients' or customers' expectations in designing the offer, particularly the e-business offer. This applies to both B2C and B2B (business-to-business) applications and focuses on the items that create and satisfy customer satisfaction.

The e-WMC initiative applies Internet technologies to facilitate business between WMC and third parties. It allows collaboration with customers and suppliers to achieve specified business objectives such as reducing administrative costs and extending the opportunity for supplier participation. In the area of sales and marketing, WMC recognizes that the Internet is a major tool in communicating with the marketplace, strengthening relationships with existing customers and helping to form relationships with new customers.

The e-WMC initiative started with the Cobalt Open Sales System (COSS) Web site in mid-1999. Subsequently, it established the Nickel Internet Marketing System (NIMS), the Copper Sales Information System (CopperSIS), and an Internet tendering site, and it was also one of the founding companies of the metals and mining procurement initiative Quadrem (http://www.quadrem.com).

From its trial in August 1999, the Cobalt Internet sales site developed into WMC's COSS to provide customers worldwide with quick and easy access to its cobalt product and prices. The current availability for WMC's products is updated daily. The provision of a spot market for small sales had resulted in continued premium prices for WMC. By 2002, this site had emerged globally as a leading cobalt price indicator and industry reference.

Similarly, the nickel Internet site matured into the NIMS. The site aims to provide buyers with quick and easy access to the availability and premiums for WMC's refined nickel products by location. Through NIMS, WMC is able to actively participate in the on-the-spot and near-term nickel market, and to expand its nickel customer base by reaching nickel consumers worldwide via the Internet. It is able to post details of product type, quantities available, and premiums by location.

WMC's CopperSIS was commissioned in June 2000. The strategy behind CopperSIS is to offer customers information instantaneously that is of value to them while at the same time reducing transaction costs for WMC and the customer. CopperSIS enables customers with direct access to real-time data affecting their own copper deliveries 24 hours a day, 7 days a week, overcoming time-zone constraints. Access to CopperSIS is restricted to WMC's current copper customers and controlled via individual user-name and password protection.

The aim of CopperSIS is to provide WMC's copper customers access to their own contracts, and delivery, shipping, and billing records live from data stored within WMC. CopperSIS also provides online availability of uncommitted spot copper quantities to the existing customer base, LME pricing records, and copper-industry news stories supplied by Reuters. This site allowed WMC to leverage the capabilities of WMC's SAP system. WMC's experience with CopperSIS, especially how it can integrate its e-WMC strategy with its information-integrity initiative, became a key building block for its next development in e-business.

During 2001, as part of WMC's growing e-capability, its fertilizer business also made significant progress with two e-business projects. The first was creating a new WMC fertilizer Internet site. This site supports the Queensland Fertilizer Operations (the wholesale sales group), the Aussie Gold product range, and HiFert (the retail sales group). The customer-management system provides a secure portal that enables wholesale customers to

- view product specifications,
- view current product prices,
- update demand forecasts,
- view current delivery plans, and
- view live contract, order, delivery, and billing information from WMC's SAP system.

The second project is an online system for HiFert agents to enter orders directly into WMC's system. This will eliminate the need for HiFert personnel to manually enter orders from some 100,000 faxes a year. Completed in December 2001, the system was rolled out to 60 agents in 2002.

E-Procurement in the Mining Industry

Cagno, Di Giulio, and Trucco (2004) point out procurement savings through e-procurement to be worth 7 to 10% of cost reduction in overall purchasing costs. They also point out that this can represent 60% of the company's annual revenue as a saving. The procurement is, according to Cagno et al. (Cagno, 2004, p. 25), "[l]ikely to lead to profound restructuring of operational practice and management of internal processes."

In the late 1990s, the metals industry, along with many other industries, saw the opportunities that e-commerce could provide. At this time there was also plenty of venture capital to back e-commerce ventures, which led to the establishment of several metal-trading sites spanning from copper to steel and offering different grades of metals. Since then, quite a few online ventures have closed down due either to a lack of funding or to a lack of trading volume.

Aluminium.com, which specialized in the online trading of all grades of aluminum, closed operations in June 2001 after its venture capitalist Divine InterVentures stopped funding. MetalSpectrum, an online marketplace for aluminum, stainless and carbon steel, copper, brass, and other specialty metals, was launched in May 2000 with the financial backing and participation of several leading metal-industry companies. Reasons given for MetalSpectrum's failure were market conditions and slow user adoption.

WMC was one of the 14 founding shareholders of Quadrem, also known as the Mining and Metals Procurement Marketplace. In 1999, this market was estimated to be worth $200 billion. The Web site provides product search, requisitioning, order tracking, tendering, contract options, and data warehousing, as well as sophisticated and consolidated management of contracts and logistics.

Carter (2003) has suggested that innovations that are made possible via e-commerce have led the industry to substantially embrace more efficient e-business-based practices. He points to the success of Quadrem, which is a global e-marketplace for the natural resources sector transacting more than $1.5 billion of business in 2003 and involving 1,800 trading partners with an annual growth rate of 30% in the past year. Quadrem involves 3,500 suppliers and a large number of mainstream mining procurement activities.

The original vision of the Mining and Metals Procurement Marketplace was to create a platform to bring together mining, metals, and minerals producers and suppliers in more than 100 countries, and to provide unrivaled access to procurement sources worldwide. The Mining and Metals Procurement Marketplace was to be a global, Internet-based marketplace that delivers procurement solutions to the mining, minerals, and metals industry. It aimed to reduce costs and improve efficiencies across the supply chain while simultaneously eliminating the costs inherent in proprietary or disparate information technologies. Similar to Aluminium.com and MetalSpectrum, the goal of the Marketplace, as it was then called, was to generate sustainable value for all participants through streamlined transaction and business processes.

In June 2000, Accenture was selected as the launch phase consultant, and 35 senior executives were seconded to Los Angeles from Quadrem's 14 foundation organizations to start buyer outreach efforts. In July 2000, they undertook a global technology review, and in August 2000 selected Commerce One and SAP as the preferred technology vendors and begun building the e-marketplace platform in September of that year. The Mining and Metals Procurement Marketplace initiative spurred Commerce One and SAP to form a strategic partnership in September 2000, whereby SAP would use Commerce One technology and integrate it into its enterprise software. In October 2000, the Mining and Metals Procurement Marketplace initiative changed its name to Quadrem. Some commentators thought that with the change of the name, the concept had gone the same way as Aluminium.com and MetalSpectrum.

Mackay, Altmann, and McMichael (2003, p. 51) suggest that the "dominant form of adoption of E business strategies is to be found in the business to business forms of e-commerce." They point to the importance of customer relationships and customer intimacy through the sharing of information and stock replenishment practices as important factors in Australia's development of e-commerce strategies. WMC was clearly approaching e-business to achieve both marketing and procurement advantages.

In 1999, Quadrem's aim was highly ambitious: to have 2,500 suppliers worldwide by the end of 2001. Although the early targets proved overly optimistic by April 2002, there were 1,050 signed suppliers and 21 buying organizations. A number of suppliers joined Quadrem because their existing customers were some of the 14 founding members. Suppliers were concerned by about reverse auctions or group buying on Quadrem.

WMC has used Quadrem, which had cost it about $20 million by the middle of 2001, to increase data accuracy and reduce transaction, inventory, and associated costs. It has also improved sourcing and logistics, and reduced the cost of inputs such as chemicals, commodities, and services. With the increasing integration of Quadrem with its SAP ERP system, WMC can place an order in its in-house system and route it through Quadrem, and then the supplier can pick up the orders from its company mailbox on the site. However, often suppliers still process their orders manually.

WMC is increasingly using Quadrem for sourcing supplies for major capital projects. This can represent 20 to 30% of their annual purchases. Part of their procurement savings has come through the standardization of mining components by the Quadrem shareholder group. It has enhanced communications and knowledge sharing among the Quadrem shareholder group, its employees, and the market participants.

In addition to Quadrem as a procurement channel, WMC also has its own online tendering site to provide suppliers with online access to information regarding future tenders, current open tenders and expressions of interest, and tenders that have been closed and awarded. The site aims to facilitate the tendering process by ensuring that information and tender documents are available immediately, submissions are made online, and the processing time of retrieval, evaluation, and notification of tender awarding is reduced.

WMC's Next Steps

WMC has continued to develop its Web-based capabilities and further integrate customers and suppliers into its business, aiming to take out costs and create customer value. SAP, which has been seen as a traditional ERP company, and Commerce One, which has been an e-procurement and marketplace-building specialist, have had a long association with WMC: SAP since 1995 as part of WMC's information-integrity initiative and Commerce One as a consultant on its Internet sites. Since 2000, both Commerce One and SAP were also preferred technology providers to Quadrem. As a result of Quadrem and other projects, SAP and Commerce One have developed Enterprise Buyer Professional, a high-end procurement application, though some commentators are concerned about the long-term viability of this relationship. As SAP expands its interest in e-procurement integration, it is enabled to overcome problems that have confronted ERP companies.

WMC's SAP e-procurement goes beyond simple catalog ordering to automating all stages of a business transaction over the Internet for both ad hoc and strategic purchasing. Business intelligence tools help to optimize procurement policies and strategies, and provide a strong basis for negotiating with suppliers. By automating the entire procurement cycle from requisition to payment, WMC will reduce the cost of goods procured as well as processing and production costs while also increasing purchasing efficiency. This will occur because fewer employees will be required to check and process invoices. WMC will also be able to consolidate contracts with vendors, negotiate lower prices, and cut the paperwork required for orders, as well as reducing order lead times.

With the adoption of Enterprise Buyer Professional, WMC will be able to build on its existing SAP systems, which are integrated worldwide, and extend its existing e-commerce capabilities, including the following:

- **Streamlined procurement.** Users can automatically generate and approve purchase orders using the robust work-flow engine and reconcile purchase transactions with accounting in real time.
- **Strategic sourcing.** Users can centralize contract management to support global purchasing activities and to manage strategic suppliers. Purchasing departments can automatically implement global purchasing agreements while the execution of day-to-day procurement responsibilities shifts to employees, simultaneously increasing purchasing power and reducing procurement costs.
- **Competitive online bidding.** Users can solicit competitive bids from new and established suppliers anywhere in the world, enabling companies to obtain the highest quality goods and services at the lowest prices.
- **Sophisticated integrated analytics.** Extensive reporting capabilities, such as monitoring and analyzing vendor and cost-center trends, allow for more effective negotiation of agreements and the rapid adjustment of buying patterns.
- **Integration of buying and selling sites.** The real-time integration of buyer-side and seller-side applications allows users to manage every step in the requisition-to-payment process from within a single, Web-based environment.
- **Mobile access.** This function allows the strategic procurement of goods and services from almost any mobile device.

LESSONS LEARNED

WMC's 1999 Internet cobalt sale success developed its belief that discovering and developing market opportunities for its businesses was a way of adding value. Like many mining companies, WMC was dominated by strategies that aimed to enhance cost efficiency. Competition in such commodity markets is traditionally seen as being based on cost. However, the pilot quickly led to an expansion in WMC's strategic thinking. WMC realized that the Internet created an opportunity for a resource company to differentiate on customer service. This customer service focus also minimized the historical role and cost of intermediaries. The Internet, if used well, could enhance both its customer-service focus and also its cost efficiency. This insight gave birth to what WMC would call its e-WMC initiative. No full e-strategy was formulated at that stage, but it quickly emerged organically and was able to build on an earlier data-integrity initiative.

WMC aims to broaden the geographical spread of sales by ensuring that it is a preferred and preeminent supplier, providing excellent service and quality products. It also believes the most successful companies will be those that effectively leverage the Internet to automate, streamline, and integrate their business processes to enhance customer relationships. As part of its cost efficiency strategy to position unit-production costs in the lowest quartile, WMC is building and using Internet-based communication systems to improve operational performance, reduce costs, and create new value for stakeholders. Nevertheless, it is conscious of cost efficiency and has set itself with the ongoing task of conducting rigorous reviews to determine which of the rapid technological developments in e-business delivers real benefits.

KEY TERMS

Disintermediation: Going around a player in a supply chain, as in rendering that player redundant.

E-Procurement: Using the Internet and related technologies to facilitate procurement.

E-Strategy: The use of the Internet and related technologies to add power to or reconfigure a business strategy.

Intermediary: A party that acts as an agent in transactions or markets.

Old Economy: The economy from before, or not using the Internet and related technologies to exchange information or value.

Portal: Way of entering into an Internet site.

Procurement: Arranging for the supply and purchase of goods or services.

ENDNOTE

1. It has since split into two separately listed entities: WMR and Alumina.

Internet Pharmacies

Philip Rosson
Dalhousie University, Canada

INTRODUCTION

The advent of Internet technology has affected the pharmaceutical industry in at least two ways. First, *existing* companies have implemented Internet solutions for efficiency and performance reasons. These solutions may convey benefits across the entire manufacturer—wholesaler—pharmacy supply chain (e.g., inventory tracking and management), or focus at one level (e.g., providing customer information from a pharmacy Web site). Second, *new* businesses have been established to capitalize on the opportunities made possible by Internet technology. The new businesses may be related to others, as in the case where storefront pharmacies have established online companies to expand their market scope.

Two other new business types represent more radical change and are controversial. The first uses the Internet to deliver information about specific drugs through spam (unsolicited commercial or bulk e-mail). Relatively little is known about such pharmacies, although they account for a large and growing proportion of all spam (PRWeb, 2004). They often promote dubious products and cures, may not require a prescription, and actual delivery is not assured (Barrett, 2001). Some customers buy from such pharmacies in spite of these problems. Because there is a dearth of research on pharmacies using spam, and given that their ethics and standards are at best highly questionable, they are not considered here.

A second type of pharmacy has gained prominence since 1999. The Internet pharmacies in question are start-ups that operate wholly online and have no connection to existing pharmacies. For the most part, these Internet pharmacies export prescription drugs from a lower cost country to one or more where higher costs prevail. In North America, many Internet pharmacies have sprung up in western Canada to supply drugs to U.S. consumers. International trade in prescription drugs is also seen elsewhere, again motivated by different price levels.[1] The North America experience is discussed next.

Canadian Internet pharmacies have achieved success since 1999, but face an uncertain future. Their emergence is traced below and the major points of controversy identified. The analysis reveals that the application of Internet technology in these pharmacies was quite straightforward. More problematic is the complex, political environment in which Internet pharmacies operate, and the fact that the strategy adopted challenges established legal and ethical standards. These issues are addressed in the final sections where the future of Internet pharmacies is examined.

BACKGROUND

When price differences exist between markets, new supply channels sometimes emerge to exploit the opportunity. This practice is labeled "gray marketing" or "parallel trade." This section begins by defining these terms and explaining why price differences for prescription drugs exist between Canada and the United States. Then attention turns to the exploitation of these price differences through technology. Canadian entrepreneurs have combined Internet and other technologies to enable U.S. customers to buy their prescription drugs in a simple, efficient and secure manner.

Pricing Differences

Gray marketing involves the selling of trademarked goods through channels of distribution that are not authorized by the trademark holders (Duhan & Sheffert, 1988, p. 76). In order for gray markets to work, there must be a source of supply, easy access from one market to another, and sufficient price differentials to make the business profitable (Eagle, Kitchen, & Rose, 2003). Gray marketing is a growing problem in many industries and locations (Mathur, 1995), imposing costs on the affected parties, including a dilution of exclusivity, free riding, damage to channel relationships, undermining segmented pricing schemes, reputation, and legal liability (Antia, Bergen, & Dutton, 2004, pp. 65-66). Parallel trade is the term frequently used when gray marketing is international in its scope.

Prescription drugs lend themselves to gray marketing/parallel trade. For the most part, they are readily available, ship easily, and are priced differently in proximate markets. North America provides a good example of this situation. The drugs on sale in Canada are essentially the same branded products as those offered in the United States. The high value-to-weight ratio means that distribution of the product is straightforward. In fact, many of the prescription drugs available in Canada are manufactured in the United States and shipped to Canadian wholesalers for onward distribution to pharmacies. Yet Canadian and U.S. prescription drug prices vary significantly. This results from different regulatory regimes. In the US, drug manufacturers are essentially free to set their prices without interference from government. In Canada, governments influence prices. At the federal level, the Patented Medicine Prices Review Board (PMPRB) ensures that drug prices charged by manufacturers are not excessive. In 2001, PMPRB reported that drug prices were 69% higher in the United States than Canada (Gross, 2003). Canadian provinces also influence prices through a formulary, which list drugs that are reimbursable under Pharmacare programs.[2] In this way, provinces provide incentives for pharmaceutical companies to set prices at levels that are financially attractive for inclusion in the formulary. Thus, the necessary conditions for parallel trade in prescription drugs—a ready supply, good access, and sharp price differences—exist in the case of Canada and the United States.

Internet Pharmacies

How have Canadian entrepreneurs capitalized on the opportunity described above to sell prescription drugs to U.S. customers? Recognizing that this would require customer change, they designed business processes to make interactions simple, efficient, and secure. E-commerce technology plays a vital role, but the fax machine, mail and courier systems are also important, particularly in the transmission of prescription and medical information and in product shipment.

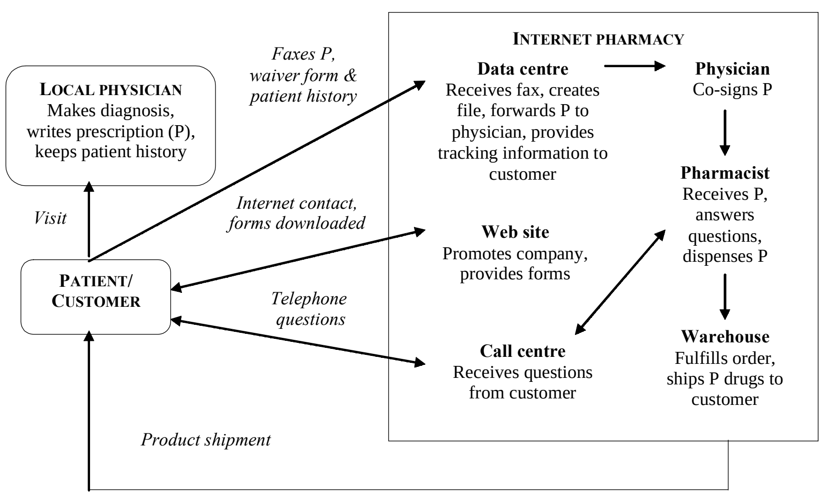
Customer contact is usually made through a Web site that provides information about the pharmacy and a searchable product database. After finding the prescription drug required and downloading the necessary documents, the customer mails or faxes a completed order form, liability waiver and prescription to the Internet pharmacy (see Figure 1). The information is transmitted from the pharmacy data centre to a physician (licensed in Canada and paid by the pharmacy) to review the information and write a Canadian prescription. This step is a legal requirement. The prescription then goes to the pharmacist to be dispensed. New prescriptions usually take two to three weeks to fill and be delivered, whereas refills take 1 to 2 weeks. Any questions are handled through the pharmacy call centre. Internet pharmacies source the drugs they sell through the normal supply chain. In other words, they purchase product from pharmaceutical wholesalers in Canada, which are supplied by multinational manufacturers.

The number of Canadian Internet pharmacies has grown from four in 1999, to 120 in 2003. The new industry is particularly associated with the province of Manitoba (55 pharmacies), with others located in Alberta and British Columbia. It is estimated that Internet pharmacies' sales to U.S. consumers in 2003 were in the $566 to $605 million range, more than twice those achieved in 2002 (Hollis & Anis, 2004).

STAKEHOLDER ISSUES

Attention now turns to the response of various stakeholders to Internet pharmacies and their parallel trade operations. Reactions of the following groups are described—U.S. customers, pharmaceutical companies, legal and political groups, medical and pharmacy bodies,

Figure 1. Prescription drug transaction process (Adapted from Janega, 2003)



and local communities. This is followed by an assessment of the current position faced by Internet pharmacies.

U.S. Customers

Although some U.S. citizens knew that it was possible to buy cheaper prescription drugs in Canada and made purchases on trips across the border, the Internet has increased knowledge and buying. The Web sites of senior citizen groups, advocacy organizations, politicians, and others, provide useful information and document the contrasting prices for prescription drugs. The Web sites of Internet pharmacies have also contributed to changed purchasing, especially among older, poorer and uninsured Americans seeking lower prices. U.S. senior citizens are reported to account for 89% of the sales of Internet pharmacies in Manitoba (Manitoba International Pharmacists Association, 2005). However, even though Canadian Internet pharmacies have expanded sales to U.S. customers sharply, this business is a small fraction of the $200 billion spent annually on prescription drugs in the United States (Hawaleshka, 2004).

Pharmaceutical Companies

The success of Internet pharmacies has provoked a strong response from pharmaceutical companies. GlaxoSmithKline plc (Glaxo) was the first to take action, arguing that imported drugs were illegal, potentially unsafe, and provided no legal recourse in the event of a problem. The company's view was that questions of drug affordability were better handled through changes to Medicare rather than by imports from other countries. Glaxo cut off supplies of its more popular drugs to Canadian Internet pharmacies that were suspected of exporting to U.S. customers (Zehr, 2003a). Other manufacturers[3] followed Glaxo's example, so that by 2004, five of the world's largest 11 pharmaceutical manufacturers had taken action against Canadian Internet pharmacies.

This response was criticized in some quarters. Noting that half of the pharmaceutical industry's sales and most of its profits were generated in the U.S., some saw these actions simply as an attempt to protect a critical market (Harris, 2003). Consumer groups, in particular, viewed the financial returns and spending of the pharmaceutical industry to be excessive (Alliance for Retired Americans, 2003). The industry defended its profit record, explaining that drug research was expensive and risky and required substantial investment.[4]

Legal and Political Groups

Technically, the parallel trade described above contravened the U.S. Food Drug and Cosmetic Act. However, the Food and Drug Administration (FDA) seldom cracked down on prescription drugs moving by mail or courier.[5] Given the discrepancy—between what the U.S. Food Drug and Cosmetic Act said, and what the FDA did at the border—U.S. customers did not think they were doing anything wrong.

The cross-border trade in prescription drugs provoked differing political responses over time. Initially, most governments and politicians saw it as a minor disruption of normal business patterns. Later, the trade was seen to be a reaction to the health care situation in the United States and, as government officials paid greater attention to this problem, Internet pharmacies gained greater prominence.

At the federal level, President George W. Bush identified Medicare as a priority item to be dealt with prior to the 2004 presidential election. Medicare does not cover prescription drugs and, given high and escalating prices, this was seen as a problem. Two similar versions of a bill to change Medicare were passed through the House of Representatives and Senate in June 2003. Effective 2006, prescription drug coverage would become available to seniors either directly through Medicare or via a private insurer (Toner & Pear, 2003). An amendment added to the bill was the Pharmaceutical Market Access Act of 2003. This was a final bargaining chip in the political maneuvering that took place towards the end of the Medicare debate. The amendment permits imports from 25 nations, including Canada. However drug import bills had been approved in the past but never implemented (Zehr, 2003b).

State and city governments were also concerned about drug prices. Medical coverage (including drugs) for the poorest Americans was provided through Medicaid, which was largely funded by states. These costs were proving very difficult to finance given the worsening budget situation of many states. States and cities also had employee and retiree benefit programs to finance. Accordingly, several states and cities were examining different ways to control drug spending, including buying from Canadian Internet pharmacies. These were difficult decisions for, while no elected official could ignore vulnerable groups (such as senior citizens and the uninsured), the drug industry was a powerful force.[6]

Health Canada is the federal government department responsible for the approval and review of drugs in Canada. Until 2004, it took no position on the Internet pharmacy issue. If there was a problem in the U.S., its position was that this should be dealt with by appropriate import regulations.

Medical and Pharmacy Bodies

The activities of Internet pharmacies were of interest to numerous medical and pharmacy bodies in Canada at both national and provincial levels, including Colleges of Physicians and Surgeons, Colleges of Pharmacists, associations representing physicians and pharmacists, and regulatory organizations. Perhaps most important were the Colleges that governed medical and pharmacy professionals. These ensured that appropriate standards of practice were maintained through functions such as policy setting, licensing, monitoring, and investigating complaints.

Pharmacy groups viewed Internet pharmacies differently. At the national level and in some provinces, the cross-border trade in drugs was felt to be illegal and raise questions of consumer safety. In other provinces, however, a contrasting view was apparent, making for a mixed response to Internet pharmacies across Canada. Some saw the response to be "soft" (reflecting a confused and conflicted position on the part of pharmacists) and "slow" (showing that associations were unable to keep pace with entrepreneurs).

Physician associations in Canada were also implicated in Internet pharmacy developments. Once again, different regulations made for a variety of responses. Generally, provincial Colleges of Physicians required that patients be examined before prescriptions could be written. In Alberta, British Columbia and Manitoba, however, any registered Canadian physician was permitted to sign a prescription. This enabled Internet pharmacies to recruit physicians to review and co-sign prescriptions for US customers quite widely.

Local Stakeholders

Internet pharmacies deliver many benefits to the communities in which they are located. In Manitoba, for example, Internet pharmacies employed 1,500 people and had annual sales of $400 million (Manitoba International Pharmacists Association, 2005). The Manitoba government strongly supported the industry, viewing it as a prime example of how innovation and entrepreneurship could generate wealth and jobs. However, others claimed that Internet pharmacies had created shortages of certain drugs locally, driven up pharmacist salaries, and hired away pharmacists from local hospitals.

Stakeholder views about Internet pharmacies are polarized. On the one hand, many U.S. customers and some pharmacists, physicians, and politicians strongly support Internet pharmacies. On the other hand, the pharmaceutical industry, as well as other pharmacists, physicians, and politicians are vocal in their opposition to the practices of these organizations. In 2004, Internet pharmacies came under increasing pressure. These developments are outlined next.

FUTURE TRENDS

The future prospects for Canadian Internet pharmacies became increasingly unclear in 2004. Several developments conspired against Internet pharmacies. The first development was strictly financial. The U.S. dollar depreciated by about 20% against the Canadian dollar over a 2-year period from January 2003. Thus, when Internet pharmacies translated their prices from Canadian to U.S. dollars, the posted drug prices were more expensive and somewhat less attractive to U.S. customers. A second development was commercial and involved supply cutbacks by pharmaceutical manufacturers. These restrictions had more impact over time as the number of participating companies grew. The restrictions meant that (a) it was harder for Internet pharmacies to source some drugs, (b) when drugs were secured from nontraditional and more distant locations (e.g., Europe and Asia) they were invariably more expensive, and (c) out-of-stock situations were sometimes experienced. A third development was the stronger regulatory stance taken by medical and pharmacy bodies, which began to censure physicians and pharmacists who did not comply with professional standards. A fourth development was that the Canadian federal government was taking a more active interest in Internet pharmacies. The initial "hands-off" stance appeared to be changing. A new Minister of Health spoke about the ethics of physicians co-signing United States prescriptions, and about the importance of ensuring adequate supplies of drugs for Canadians. The U.S. government continued to argue that parallel trade in drugs created safety risks for consumers. Officials pressed this point during President George W. Bush's visit to Ottawa in the fall of 2004.[7] By January 2005, it was reported that the Government of Canada was developing policy that would essentially close down Internet pharmacies. Whether this would involve new or changed regulations was important since the former would prove more difficult for Prime Minister Martin's minority government to enact (Associated Press, 2005).

The response of Internet pharmacies to the uncertainties of late 2003 and 2004 varied. With business proving to be more difficult, some business had closed while others consolidated their operations. The experiences of the last few years had alerted some companies to the need for contingency planning. In some cases this meant planning to source much more from overseas suppliers, while others were considering moving operations totally outside of Canada (McAfee, 2004). Some Internet pharmacies continued to believe that Canadian regulators and governments would not bring an end to an industry that employed Internet technology to satisfy the prescription drug needs of disadvantaged U.S. consumers.

A final comment deserves mention. The debate about Internet pharmacies would benefit from greater research attention. The major contributors to the extant literature are journalists and various interest groups. With the exception of a number of government reports (e.g., GAO, 2004), few attempts have been made to examine this new industry in a systematic and scientific manner (e.g., London School of Economics, 2003; Schmidt & Pioch, 2003; Yang, Peterson, & Huang, 2001).

CONCLUSION

The emergence and early development of Internet pharmacies has been traced. Price differences and Internet technology made it possible for Canadian entrepreneurs to sell prescription drugs to U.S. customers. Although Internet pharmacies have grown quickly by satisfying a need for less expensive drugs, the sustainability of their operations is in doubt. Several factors explain this situation, including the complex and political nature of the health care environment, the power of pharmaceutical manufacturers, and the fact that Internet pharmacies use a business model that technically contravenes the law and professional standards for physicians and pharmacists.

KEY TERMS

Formulary: A list of drugs that are approved for use under a given health insurance program.

Gray Marketing: Occurs when products are sold through nonauthorized channels of distribution.

Internet Pharmacy: A pharmacy that has no storefront presence and where the Internet is a key technology for serving customers.

Medicaid: A U.S. federal and state health insurance program designed to provide access to health services for persons below a certain income level.

Medicare: A U.S. federal health insurance program designed to provide health care for the elderly and the disabled.

Parallel Trade: Occurs when a product is purchased by an intermediary in one country (at a low price) and then exported to another (high price) country.

Pharmaceutical Manufacturers: Companies that are involved in the discovery, production and marketing of substances used in the treatment of disease.

Pharmacy: A retail store where drugs are dispensed.

Prescription Drugs: Drugs that require written direction and authorization from a physician.

Spam: Unsolicited e-mail that is sent to large numbers of people to promote products or services.

Wholesaler: A business that distributes manufacturers' products to retailers (pharmacies) and other distributors.

ENDNOTES

1 Europe is a good example. Different pricing levels, proximate markets, and the European Union's "free movement of goods" policy means that cross-border sales of prescription drug have boomed. The European literature in this area emphasizes activity at the wholesale level (i.e., exporters selling to importers) whereas the North American literature focuses on retail activity (i.e., Canadian pharmacies selling to U.S. consumers).

2 Although the extent varied, seniors and social assistance recipients in all Canadian provinces received drug coverage.

3 These companies and their industry rank (by 2003 revenues) are Pfizer (1), GlaxoSmithKline (2), Merck (3), AstraZeneca (6), and Wyeth (11) (Contract Pharma, 2005).

4 High drug prices in the United States financed the research and development activities of the pharmaceutical industry. Some observers argued that by restricting prices, other developed western nations (such as Canada) were essentially "free riders" (Graham, 2003).

5 Nor did customs officers confiscate prescription drugs purchased by U.S. citizens for personal use on trips to Canada.

6 Governments competed to get drug companies to locate within their jurisdiction since their operations were viewed as "clean" and health care was expected to become a key driver of economic growth. The pharmaceutical industry also made large political donations (Harris, 2003).

7 In spite of the Bush Administration's opposition to drug imports, some state and city governments in the United States had begun doing business with Canadian suppliers. Further, should the Pharmaceutical Market Access Act of 2003 be approved by Congress, President Bush would face the difficult decision about whether to sign the bill.

Internet Search Engines

Radhika Jain
Georgia State University, USA

INTRODUCTION

In the context of the Internet, a search engine can be defined as a software program designed to help one access information, documents, and other content on the World Wide Web. The adoption and growth of the Internet in the last decade has been unprecedented. The World Wide Web has always been applauded for its simplicity and ease of use. This is evident looking at the extent of the knowledge one requires to build a Web page. The flexible nature of the Internet has enabled the rapid growth and adoption of it, making it hard to search for relevant information on the Web. The number of Web pages has been increasing at an astronomical pace, from around 2 million registered domains in 1995 to 233 million registered domains in 2004 (Consortium, 2004). The Internet, considered a distributed database of information, has the CRUD (create, retrieve, update, and delete) rule applied to it. While the Internet has been effective at creating, updating, and deleting content, it has considerably lacked in enabling the retrieval of relevant information. After all, there is no point in having a Web page that has little or no visibility on the Web.

Since the 1990s when the first search program was released, we have come a long way in terms of searching for information. Although we are currently witnessing a tremendous growth in search engine technology, the growth of the Internet has overtaken it, leading to a state in which the existing search engine technology is falling short.

When we apply the metrics of relevance, rigor, efficiency, and effectiveness to the search domain, it becomes very clear that we have progressed on the rigor and efficiency metrics by utilizing abundant computing power to produce faster searches with a lot of information. Rigor and efficiency are evident in the large number of indexed pages by the leading search engines (Barroso, Dean, & Holzle, 2003). However, more research needs to be done to address the relevance and effectiveness metrics. Users typically type in two to three keywords when searching, only to end up with a search result having thousands of Web pages! This has made it increasingly hard to effectively find any useful, relevant information.

Search engines face a number of challenges today requiring them to perform rigorous searches with relevant results efficiently so that they are effective. These challenges include the following ("Search Engines," 2004).

1. The Web is growing at a much faster rate than any present search engine technology can index.
2. Web pages are updated frequently, forcing search engines to revisit them periodically.
3. Dynamically generated Web sites may be slow or difficult to index, or may result in excessive results from a single Web site.
4. Many dynamically generated Web sites are not able to be indexed by search engines.
5. The commercial interests of a search engine can interfere with the order of relevant results the search engine shows.
6. Content that is behind a firewall or that is password protected is not accessible to search engines (such as those found in several digital libraries).[1]
7. Some Web sites have started using tricks such as spamdexing and cloaking to manipulate search en-

Table 1. Search engine issues and challenges

Major Challenges and Concerns	Detail
Spamdexing and cloaking	These tricks are used by Web sites to manipulate search engines to display them as the top results for a set of keywords.
Privacy and security	Search engines index all the content available on the Web without any bounds on the sensitivity of the information.
Information explosion	The Web is growing at a fast rate, with Web pages being updated very frequently, presenting challenges to search engines to index frequently and intensely.
Categorization and representation	Search engines are facing the challenge to categorize and represent the information to the user within the top few matches. The traditional sequential listing of results is posing some challenges.

gines to display them as the top results for a set of keywords. This can make the search results polluted, with more relevant links being pushed down in the result list. This is a result of the popularity of Web searches and the business potential search engines can generate today.

8. Search engines index all the content of the Web without any bounds on the sensitivity of information. This has raised a few security and privacy flags.

With the above background and challenges in mind, we lay out the article as follows. In the next section, we begin with a discussion of search engine evolution. To facilitate the examination and discussion of the search engine development's progress, we break down this discussion into the three generations of search engines. Figure 1 depicts this evolution pictorially and highlights the need for better search engine technologies. Next, we present a brief discussion on the contemporary state of search engine technology and various types of content searches available today. With this background, the next section documents various concerns about existing search engines setting the stage for better search engine technology. These concerns include information overload, relevance, representation, and categorization. Finally, we briefly address the research efforts under way to alleviate these concerns and then present our conclusion.

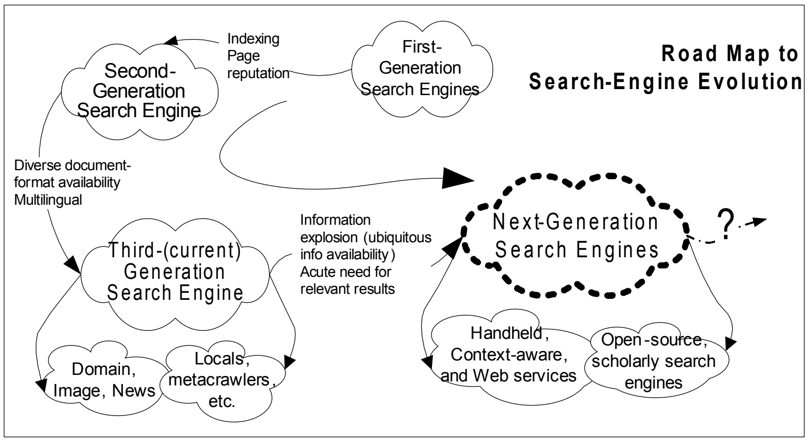
BACKGROUND OF SEARCH ENGINES

Search engines have developed from just being research projects in the early 1990s (e.g., Archie, Gopher, Veronica, and Jughead) to some of the most visited Web sites such as Google, Yahoo!, and AskJeeves (Marckini, 2001). We classify search engines as first, second, and third generation (Nobles, 2003) as a guide for discussion and not to deduce much from the classification.

First-Generation Search Engines

This generation includes the early entrants in the search domain. Search engines existed even before the invention of the World Wide Web. Search tools such as Archie and Veronica searched using FTP (file transfer protocol) and gopher protocols long before HTTP (hypertext transfer protocol) came into play. Search technology was very primitive. With Archie one could search for file names, while with Veronica, one could search for text files and file names. The World Wide Web and its standards enabled the development of robots and crawler or spider software that "wandered" around the Web to index all the links it could find to perform a search on them later. MIT's World Wide Web wanderer's launch in 1993 was the first of many spiders such as RSBE, WWWworm, and Jumpstation. ALIWEB (Archie-Like Indexing of the Web) debuted in 1994; instead of relying on a Web spider to create an index, it relied on webmasters of participating Web sites to post their own index information for each Web page that they wanted to be listed. Thus, ALIWEB gave webmasters their first opportunity to use META tags to position their sites on a search tool. This gave birth to the META tag within the HTML (hypertext markup language) header of a Web page. The popularity of the Web and introduction of Web browsers such as Netscape and Internet Explorer gave rise to the development of search engines with Web interfaces such as Yahoo!, WebCrawler, Lycos, and Galaxy. This in turn gave rise to the second generation of search engines, discussed next.

Figure 1. Search-engine evolution



Second-Generation Search Engines

The development of metasearch engines improved the efficiency of searches by indexing the Web and providing effective searches based on page reputation. Other major components include link-click popularity, temporal tracking, and link quality. These components resulted due to the outburst in the number of Web pages that appeared on the Web. There was a major shift from search engines simply being rigorous in searching the Web to providing relevant results to the user. Thus, the major change in the second-generation search engines involved the use of algorithms to display the ordering of results that are relevant. This also saw the rise of term vectors, stats analysis, cache data, and context in which two-word keyword pairs were extracted from a Web page to better categorize it. PageRank is an algorithm used by Google to rank Web pages to match a given search string (Brin & Page, 1998). It computes a recursive figure of merit for Web pages based on the weighted sum of the pages linked to them. PageRank thus derives from human-generated links and correlates well with human concepts of importance. Previous keyword-based methods of ranking results relied solely on the number of times the term appeared on the Web page. Similar algorithms are used by other search engines such as Yahoo!, AltaVista, Infoseek, and AskJeeves.

Third-Generation Search Engines

The third generation of search engines includes search engines that exhibit the capability of performing domain-specific searches such as searches for news, directories, images, newsgroups, and deals and prices. The search is also extended to search documents other than HTML pages to document formats such as .pdf, .doc, .xls, .ppt, and .ps, among several others. Personalized searches are gaining attention as envisioned by Amazon's A9 and AskJeeves' MyJeeves. Third-generation search engines also have the capability to perform multilingual searches on Web pages. In the next section, we elaborate further on these third-generation search engines and the related terminology. We further drill down on the third or contemporary search engine technology to give readers a feel of what can be achieved with the existing search technologies.

CONTEMPORARY STATE OF SEARCH ENGINE TECHNOLOGY

This section provides a brief discussion on various content searches possible with contemporary search engines. Search engines traditionally searched the text on Web pages. This obviously limited the searches as most Web pages today have a number of pages that are in different file formats such as .pdf, .ppt, and .doc, to name a few. The search engines today search the text within all these and other file formats that were not accessible earlier. The search has also expanded to other domains such as images, news, newsgroups, and directories.

Images

Image search engines look for images that are relevant to certain criteria. The search engine usually analyzes the text adjacent to the image, the image caption, and other criteria to identify the image content. An image search facility is provided by many search engines including Google, Yahoo!, MSN, and AskJeeves. There are also beta 3-D image search engines available. The commercial availability of such search engines and 3-D content could allow researchers and designers from across the world to look for design documents rather than creating them anew (Bergstein, 2004).

News

News search engines look for news Web sites around the world. The articles from Web sites that are recognized as news Web sites by the search engines are searched according to the relevant keywords in them. Topics are updated continuously throughout the day so that new stories appear at the top of the results. Also, features such as the ability to sort by date or relevance offer extra flexibility to the user to sort the results according to his or her preference.

Locals

A search restricted to a particular physical location is called a location-specific search. This is useful when one needs to find stores and services around a particular neighborhood. In this case, the search engine analyzes the content in its index of Web pages and combines this information with yellow-pages data to provide the local search experience. For example, if a user says, "I need an Italian restaurant that is close to where I live," the search engine can provide the user with information on Italian restaurants' addresses, phone numbers, ratings, and, more importantly, their distances from where the user lives. This is done by combining information from the yellow pages and the zip code. Recently, Amazon's search engine A9 introduced similar yellow-page searches with images of the actual location of the store.

Apart from the ones mentioned above, there are numerous other searches provided by contemporary search engines, including searches that are specific to universities, languages, catalogs, deals and public services, maps, research articles, specific file formats, and so forth.

SEARCH ENGINE CONCERNS

In the following subsections, we discuss various concerns that should be taken into consideration and addressed to provide and locate relevant search results for the increasingly information-ravening Web users.

Information Overload and Relevance

While search engine technology has improved over the years, making searches and finding information relatively effortless, the pace of information explosion has endlessly surpassed the improvements made in search engine technologies. Increasingly, people from all over the world are getting access to the Internet and realizing the potential of it. Many of them have now started to bring their businesses online to gain visibility in this highly competitive and dynamic business world. Furthermore, as a result of various technological advances, the retrieval, production, and distribution of information has become easier than ever. This has certainly led to an enormous increase in the amount of information available to the consumers of a search engine, and often times it has led to irrelevant, unclear, and inaccurate data fragments. It is common knowledge that in today's information age, information and knowledge are power and having more of them is considered a good thing. However, with the unprecedented rate at which new Web pages are added to the World Wide Web on a regular basis, even the most tech-savvy user groups find it almost difficult (if not impossible) to sift through the search results to identify relevant information. This concern has been accurately captured in the recent Delphi survey (Delphi Group, 2002) of knowledge workers:

[Business] professionals typically spend at least 25% of their day searching for information and 61% of them believe they have a less than 75% chance of finding the information they need. The main impediments to finding this information are poor tools (28%) and concerns about the volatility or rate of change of the information (35%).

Ackoff (1967) quite accurately identified this phenomenon of the overabundance of irrelevant information decades ago while critiquing the assumptions behind most management information systems. Information overload is becoming a challenging problem to address as we reach the point of saturation. Effects of too much information include anxiety, poor decision making, difficulties in memorizing and remembering, and reduced attention spans resulting in poor performance of the task at hand (Delphi Group, 2002). This suggests that search engines need to continuously evolve their search strategies to keep up with information overload. From the earlier discussion on the generations of search engines, it is apparent that search engine developers have been proactively taking steps to identify new and more effective strategies to optimize search results.

Categorization and Representation

Currently, most search engines display their results sequentially, with the most relevant results at the top of the list while the least relevant results are at the bottom toward the end of list. Search engines determine the relevance of the search results based on various criteria such as keyword matches and page ranks. This approach does not truly take into consideration the context of the user to provide the ranking of the search result. The daunting task of locating a relevant page and related result categories is left to the user.

Furthermore, currently, most popular search engines do not provide any categorization or clustering of search results, which adds to the difficulty of locating a relevant Web page from a plethora of apparently pertinent Web pages. Search engines such as Vivisimo and Kartoo take an interesting approach to the categorization and representation of search results. Kartoo is a metasearch engine that presents its search results visually on a map represented by more or less important Web pages depending upon their relevance. When the pointer is moved over these pages, concerned keywords are highlighted and links connecting the highlighted page to other relevant pages are displayed. Similar techniques of displaying result categories visually can be used for mobile devices to alleviate the problems caused by smaller screen sizes.

In the next section, we extend this discussion by alluding the reader's attention to context-aware searches that can help achieve highly relevant searches.

FUTURE POTENTIAL OF SEARCH ENGINES

While extant search engines serve the basic purpose of searching and finding desired information on the Web, it is apparent that there is still some room for improvement. There has been a growing amount of interest in the applicability of context-aware technologies in the field of search engines. Users rarely search in isolation, but rather always in some context; hence, the search results returned by the search engines need to be appropriate to particular places, times, people, schedules, usage patterns, and preferences. Context awareness refers to the properties of the system that make it aware of this contextual information from its surroundings and help the search engine adapt its behavior accordingly. Heer, Peddemors, and Lankhorst (2002) break down the contextual indicators into the following categories: the spatial, the temporal, environmental information and social situations, nearby resources, the availability of resources, physiological measurements, the user's current task and the overall task information, the user's information need, the user's model of information seeking, and historical context patterns (Jones & Brown, 2004).

With contextual indicators acting as filters, one can potentially retrieve a much better set of relevant results. Currently, the most popular contextual information being used for the same purpose is the user profile. However, we believe that by making use of a much richer set of contextual information, more effective searches can be performed. This context-aware search problem becomes interesting with the increasing popularity of handheld devices that have limited resources in terms of screen size, and battery and computing power. Handheld devices have been primarily used to support more task-oriented uses and to perform highly specific information-retrieval tasks (Syed, 2004). Thus, when performing searches using such devices, the need to obtain more relevant results is acute to enhance the mobile user's experience. The mobility of the handheld user provides for a much richer contextual setting, which, when taken into consideration, can help filter a number of irrelevant search results (Syed). Based upon the context of the search, the same word may have different meanings in different contexts. Thus, a search engine should be able to incorporate such contextual semantic information in order to improve the effectiveness of the search results retrieved.

Finally, before concluding, we would like to point the reader's attention to open-source search engine technology (e.g., Buntine et al., 2004; Hook, 2003), which is becoming a serious competitor to commercial search engines. Additionally, there are several attempts under way by the leading search engine giants, publishers, libraries, and academics to make scholarly literature easily accessible and searchable (Summann & Lossau, 2004).

KEY TERMS

Cloaking: Another means of spamdexing in which sites provide a different page to the search engine spider than the one that will be seen by human users.

Context: Everything—social, cultural, political, and historical factors—that surrounds a particular event. These are the forces of influence at play when the event actually occurs. Greater knowledge of the context of a thing leads to a deeper understanding of and a more balanced perspective on its nature.

Information Overload: The availability of excess information beyond that which is desired or needed by a user, requiring nonproductive processing.

Metasearch Engine: A search engine that sends search keywords to different search engines and blends together the search results from these search engines as one resultant list.

PageRank: An algorithm that Google uses to rank Web pages that match a given search string.

Spamdexing: The promotion of irrelevant commercial pages by taking advantage of the search algorithms used by search engines.

ENDNOTE

1 The absence of those relevant results may mislead users to assume the nonexistence of any such results.

Internet Technologies in Factory Automation

Thorsten Blecker
Hamburg University of Technology (TUHH), Germany

INTRODUCTION

One of the most important changes in the technological and economic environment of industrial firms is the increasing diffusion and strongly increasing commercial use of Internet technologies in manufacturing. Both formal and empirical studies verified the significant increase in productivity through intraorganizational applications of modern information and communication technologies in manufacturing processes (Barua & Lee, 2001).

Early industrial applications of Internet technologies were limited to single, unconnected solutions for distributed Computer-Aided Design (CAD) systems or telecooperation. Now Internet technologies may reach into the automation and control levels of every assembly line. Therefore, it is not surprising that applications of Internet technologies in production processes on the shop floor increase, and automation-technology suppliers combine Internet technologies more and more into their products. While production concepts, such as lean production, world-class manufacturing, and agile manufacturing, inevitably disregard this development, new production concepts arise that fundamentally consider the application of Internet technologies on the shop floor.

BACKGROUND

Internet Technologies for Manufacturing

Usually the term Internet technologies is understood in the context of the well-known Internet as the technological basis of a global information and communication network. Often, there is no differentiation between company internal and external applications. Indeed, the WWW (World Wide Web) is the most popular, and for almost everyone an observable application of Internet technologies. However, the term Internet technologies does not prejudge an external relevance. Yet, the internal application of these technologies focuses on intranets for office information systems. In the future, the main industrial application area of Internet technologies is in field-area networks (FANs).

FANs are real-time, capable networks on the field level (shop floor) of industrial firms' communication systems for the interconnection of automation devices, for example, assembly lines, production cells, or single machines (e.g., Schnell, 2003). Requirements for the FAN are, in particular, real-time ability, a high transmission speed, high reliability, and electro-magnetic compatibility. Depending on the nature of the business and the underlying technological concept, different types of FANs are applied. For our purposes, we can differentiate two major groups of FAN: (a) a FAN that is based on field buses, and (b) a FAN that is based on Internet technologies. Field buses are a substitute for the individual wiring of sensors and actuators within automation technologies. They offer a continuous communication infrastructure on the field level. Those that are well known include, for example, systems such as Profibus, DeviceNet, CAN Open, and SERCOS. The second group represents the industrial application of Internet technologies and is mainly based on (industrial) Ethernet.

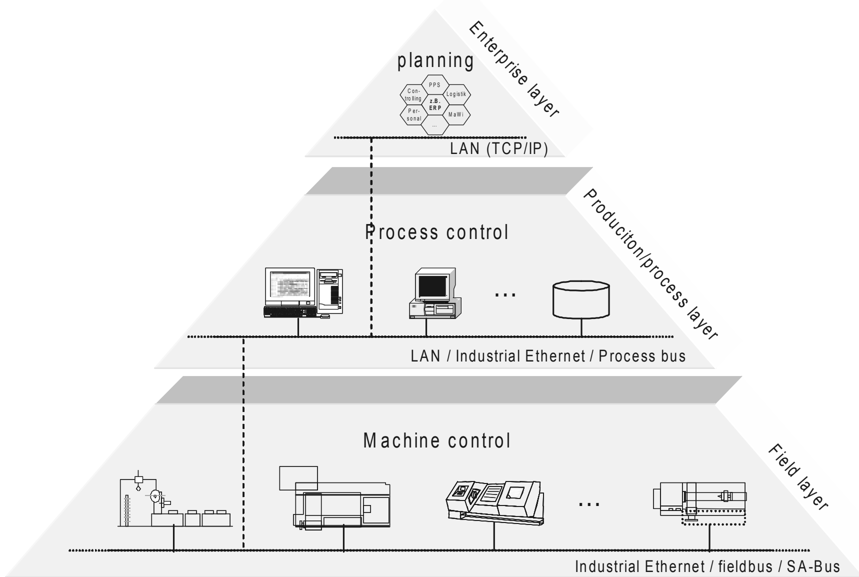
INDUSTRIAL APPLICATION OF INTERNET TECHNOLOGIES

Applicability of Internet Technologies

For the research of the network infrastructures in production environments, a hierarchical arrangement has to be carried out on the implemented network and/or bus systems on the different layers of the enterprise. An automation pyramid most adequately represents this hierarchical arrangement. Although there are automation pyramids with up to seven layers in engineer-scientific literature (e.g., Schnell, 2003), the three-layer pyramid in Figure 1 provides a good overview of the different industrial applications of Internet technologies.

The highest layer is the enterprise layer, in which the enterprise planning occurs, for example, within an enterprise resource planning (ERP) system. In this environment that is mainly dominated by office applications, local-area networks (LANs) are applied, for example, based on Ethernet and the TCP/IP (transmission-control protocol/Internet protocol) suite. This layer is cross-linked with the production and/or process layer. On this layer,

Figure 1. Automation pyramid (Blecker, 2005)



manufacturing execution systems (MESs), for example, are applied to provide a logical connection between the planning and production process layers. Furthermore, production-near dispositive tasks are processed by the production control. Control centres are implemented here. Industrial field-bus systems (process busses) are employed as the network infrastructure. From a technical viewpoint, Ethernet networks and/or the local-area networks of the office environments are also purposeful on the production or process level (Schnell, 2003). Recently, Internet technologies were implemented based on the industrial Ethernet. The real-time equipment on the field level are cross-linked often with the aid of field buses, for example, the different variants of ProfiBus.

Yet, field buses as a traditional network technology are still dominating in production processes, for example, the ProfiBus concept of Siemens Automation & Drives Group. In the future, Internet-based FAN will complement or even replace field buses. Since 1985, industrial firms have utilized Ethernet on the shop floor. Industrial Ethernet especially reduces the technological limits that have existed up to now to the applicability of Internet-based FAN or even the replacement of field buses. Industrial Ethernet is based on the relevant international standards (e.g., IEEE 802.3). It is adjusted to the specific environmental conditions, for example, regarding electromagnetic compatibility, shaking, moisture, and chemical resistance. In some sectors, Ethernet and industrial Ethernet are already the de facto standards, for example, in the automotive industry, process industry, and plant engineering.

The technological improvement of industrial Ethernet and/or Internet technologies in general does not necessarily enable a total replacement of field buses. On the one hand, some applications or existing machinery still need FANs that are based on field buses. On the other hand, field buses such as ProfiBus evolve toward a convergent, interconnective infrastructure, for example, as in ProfiNet. Hence, even where Ethernet cannot replace field buses, Internet technologies connect the different assembly lines together and transfer detailed data from the shop floor to the office and vice versa. Internet technologies are especially useful for the networking of production lines with each other, as well as for the data transfer from the technical systems in the production to the enterprise systems in the administration and vice versa as it is shown by numerous initiatives in factory automation. Consequently, a comprehensive application of Internet-based FAN enables the expansion of existing intranets in office automation to all production processes, especially manufacturing. Enabling technologies, such as Web services, active technologies, and industrial frameworks (based on .NET or Sun ONE), will support intelligent manufacturing technologies and a homogeneous network from offices on the enterprise level to manufacturing devices on the field level. These platforms have an enormous potential to reduce (transaction) costs within the production system (Blecker, 2005). Therefore, Internet technologies become a ubiquitous network: an omnipresent information infrastructure in the complete industrial firm.

Industrial Applications in Practice

Siemens Automation & Drives Group propagates today a communication network for automation control that not only allows a networking within the production processes, but also a networking of the field level with the office environment. This network also provides the accessibility of single machines and plants. This approach is called SIMATIC NET. It should guarantee the continuity of industrial communication networks in an enterprise, and provide possibilities for teleservice and control of machines and plants. Furthermore, Siemens and other providers strive for acquiring the ability to employ the existing facilities without modifications. For this purpose, the fieldbus-centred ProfiBus approach was developed toward the integrative concept ProfiNet based on industrial Ethernet (e.g., Profibus International, 2003a, 2003b).

A further example was introduced under the name Interface for Distributed Automation (IDA) in the year 2000. This hierarchy-free network on the field level is based on (industrial) Ethernet and the TCP/IP suite. IDA cross-links automation technologies with each other as well as systems of the office environments, a potential intranet and even Internet when it is appropriate (Schnell, 2003). In spite of its decentralized organizational structure, it enables distributed problem solving on the field level as well as upright integration that reaches the enterprise level in terms of enterprise application integration (EAI).

A competing but promising approach of Internet technologies in manufacturing is the most often implemented standard Modbus TCP/IP of Schneider Electric SA (Volz, 2003). This approach is also based on the application of Ethernet and TCP/IP in the automation technology. Modbus TCP/IP uses its own well-specified port within the normal stack. It was introduced by the regulation authorities (Internet Engineering Task Foce [IETF]) of the Internet as an official standard for Internet technologies. From this it follows that in all worldwide relevant operating systems, a protocol is applied automatically that was developed for automation technologies of industrial processes (Schnell, 2003). Therefore, it is theoretically possible to cross-link every computer with networks in manufacturing, the last step being the convergence of office applications and production networks. In the future, a further essential advantage may result through the fusion of the IDA group and the Modbus organization to a common group by October 2003. They try to define hierarchy-less, decentralized networks on the field level, which allow a very flexible communication infrastructure with high interconnectivity both inside and outside the company. Schneider Electric SA presents a first commercial solution under the name Transparent Factory or Transparent Ready.

Further examples from practice that illustrate the application of Internet technologies are the pilot systems of the Control Web approach of KUKA GmbH, Bosch GmbH, Trumpf GmbH & Co. KG, and other factory-automation suppliers. The essential features of this approach are the comprehensive use of Ethernet at the field level, the application of personal computers for automation control, and the integration of Web servers based on embedded systems into the automation systems. In order to ensure communication and/or operate the system, Web browsers are used. The first plants in the automotive industry that consistently utilize Internet technologies in manufacturing according to the approach developed by KUKA and the others were implemented by 2005 (Ebert & Klüger, 2003).

Recapitulating, the technological shift from traditional FAN such as Profibus to Internet-based FAN may connect office information systems with the automation and control level of every assembly line. It is not surprising that applications of Internet technologies in production processes increase, and that many suppliers of automation technology combine Internet technologies into their products. This leads to a convergence of the traditional production systems and Internet technologies (Blecker, 2005). It explicates the unification of technologies with different features to a homogeneous service bundle, thereby requiring the revision of traditional production concepts or even the development of new ones. For example, the interconnection of assembly lines as well as the sharing of detailed data with corporate Ethernet networks leads to a direct communication between ERP and production planning and control (PPC), MESs, and automation technologies in the sense of EAI. Because of the resulting high availability of real-time data from the shop-floor equipment, new (production) planning and control mechanisms as well as continuous information and communication structures between administrative and production systems arise.

EMERGING ISSUES OF INTERNET TECHNOLOGIES IN PRODUCTION CONCEPTS

The application of Internet technologies at the field level leads to an interconnection and networking of automation infrastructure (e.g., machine controls) on the shop floor, and information systems (e.g., ERP) that are involved in the production process. However, in order to profit from the potential benefits of Internet technologies in manufacturing and to achieve competitive advantages, adequate production concepts must be applied (Blecker & Graf, 2003a). Early examples of Internet-based or Internet-oriented production concepts are Atherton's (1999) idea of Java-based applications in factory automation, the concept of information-based manufacturing (Shaw, 2001), the e-factory (Beavers, 2001), and so forth. A more recent approach is the concept of Web-integrated manufacturing, which describes the general application of Internet technologies in manufacturing, for example, agent-based systems, Java, Jini, and Service Object Access Protocol (SOAP). It was developed during the international research project Plant Automation Based on Distributed Systems (PABADIS, 2001) that uses this approach as a theoretical basis and aims at the development of decentralized, distributed systems of office communication within the machine control on the shop floor. This is supposed to lead to highly flexible, adaptive, and simply reconfigurable production systems (Huang & Mak, 2003). Reconfigurable production systems combine the advantages of high-productive and highly flexible systems because they can be adapted immediately regarding their structure, functionality, and capacity, as well as their inherent technology, to changing demands.

A more comprehensive concept of Internet-technology applications in production processes has to focus on a more consistent and continuous application of Internet technologies in industrial firms. Furthermore, it has to deal with the current evolutions of the production technique as well as operations management. We mainly expect that such a concept does not solely focus on the consequences of Internet technologies for the shop floor. It has to take into account the new options of Internet technologies in operations management and their effects on the strategic and operative management of industrial firms, too. Such a concept is Web-based manufacturing (Blecker, 2005). It is based on the continuous and global application of multimedia Internet technologies in the technical and managerial processes concerning industrial production, and it reaches from the office into the automation level.

Web-based manufacturing assumes that it is generally necessary to change over from obsolete computer-integrated production concepts (Computer Integrated Manufacturing [CIM]) to Internet-based ones. A major difference between both philosophies is that CIM focuses on a centralistic integration of different, dislocated subsystems of planning and operation of production processes. The intense application of Internet technologies in the production processes and/or their combination with automation technologies reduces the central coordination and control as well as the formerly forced heteronomy of the actors in production processes. Instead, decentralized coordination and operation mechanisms as well as an at least partial self-determination of the actors become possible. This means that industrial firms can apply already-known concepts of decentralized PPC and partially autonomous automation technologies more effectively.

FUTURE TRENDS

Three main future trends should be pointed out. First, Internet technologies will increasingly penetrate manufacturing processes and technologies. The projects and approaches developed by the IDA group and the Modbus organization will especially lead to the convergence of production and Internet technologies. For example, Modbus has its own port in the TCP/IP stack so that worldwide every personal computer with access to the Internet can be interconnected via this automation-technology approach. A second trend is that Internet technologies will be directly implemented on the shop floor, for example, in networking dislocated assembly lines, and will allow an interconnection of manufacturing systems with supporting management systems, e.g., PPC. Due to this evolution of direct IP-supported networking (down to the machinery level), an increase of distributed services in production processes and a convergence of the traditional production and operation systems and Internet technologies are possible. From this follows the third trend. In the resulting convergent Internet-based infrastructure, it is possible to implement multiagent systems on the shop floor that will replace the manufacturing execution systems that are up to now often applied (e.g., PABADIS, 2001). In addition, both multiagent systems and Internet technologies on the shop floor are considered to be key factors of a mass-customizing production system (Baker, Van Dyke, & Kultuhan, 1999; Blecker & Graf, 2003b).

CONCLUSION

Internet technologies and the potential fields for their applications in production processes evolve very rapidly. Internet technologies will increasingly replace the traditional field buses in the coming years. Therefore, the intraorganizational application of Internet technologies will be the generic networking infrastructure for production processes in the future. Web-based manufacturing especially opens new options for enterprises and creates sustainable competitive advantages.

From a technical point of view, the realization of Web-based manufacturing is already possible without problems as it can be shown through the high number of practice-relevant projects and implemented island solutions. The combinations of robotics and Internet technologies have been demonstrated for a long time. Additionally, the importance of Internet technologies in automation systems as a crucial basis for the achievement of a competitive advantage and the realization of new manufacturing concepts is undisputed at least within engineering. Even industrial practice confirms the high potentials of Internet technologies in production processes. Many firms recognized that the usage of Internet technologies could contribute to an improvement of their competitive positions, and have already developed the first approaches of Internet-based production concepts. From the point of view of business administration, the development of the already-known approaches to a comprehensive concept of Web-based manufacturing is necessary.

KEY TERMS

Convergence: Uniting the functions of heterogeneous technologies with different features to form a homogeneous service bundle.

Enterprise Application Integration: Application of aligned processes, software and hardware tools, methodologies, and technologies aimed at interconnecting and consolidating all computer applications, data, and business processes in order to achieve a friction-free network that allows real-time data exchange as well as easy management and (re)configuration activities.

Field-Area Network: Real-time network on the field level (shop floor) of industrial firms' communication systems for the interconnection of automation devices, for example, assembly lines, production cells, or single machines. Depending on the nature of the business, different types of FANs are applied, which are either based on field buses or Internet technologies. Well-known FANs are, for example, Profibus, DeviceNet, CAN Open, and SERCOS.

Industrial Ethernet: Special type of Ethernet for field-area networks based on the relevant international standards (e.g., IEEE 802.3). It is adjusted to the specific environmental conditions in industrial production systems, for example, regarding electromagnetic compatibility, shaking, moisture, and chemical resistance.

Internet Technologies: Family of technologies suitable for exchanging structured data through package-oriented transmissions on heterogeneous platforms, in particular, protocols, programming languages, hardware, and software.

Manufacturing: Specific form of production processes based on mechanical technologies and activities.

Production: Function of (industrial) firms consisting of creating a transformation system and combining internal and external resources by applying technological and conceptual procedures in order to generate goods and services for further possessing and/or as a marketable output for serving the customer.

Production Concept: In theory, a well-founded guiding idea based on empirical knowledge, where it is appropriate, on the organization, planning, control, and evolution of production systems with the main objective of enhancing the competitiveness of the firm.

Production System: Subsystem of the enterprise for the transformation of input factors, for example, goods and services, into output factors, for example, tangible goods and services, in order to satisfy a customer need. The production system itself consists of two basic subsystems: the management subsystem and the operation subsystem. These subsystems are interconnected and interwoven by an information system. The operation subsystem deals with the original transformation processes and includes all facilities, machines, logistical equipment, and employees (blue-collar workers). The management subsystem is responsible for the short-run (operational) design, planning, and control of the entire operation subsystem.

Web-Based Manufacturing: Production concept aiming at easily reconfigurable, highly flexible production systems based among other things on the comprehensive application of Internet-based field-area networks and convergent automation technologies (Blecker, 2005).

Internet-Based Marine Maintenance Information System

T. T. Wong
The Hong Kong Polytechnic University, Hong Kong

W. K. Chan
The Hong Kong Police Force, Hong Kong

INTRODUCTION

The Marine Region of the Hong Kong Police Force is responsible for policing the waters and 262 islands that lie within the 1,651 square kilometers of the Hong Kong Special Administrative Region (HKSAR). In addition to routine policing, the Marine Region has responsibilities in other diverse areas like quarantine, immigration, conservancy, and also port and maritime regulations (Hong Kong Police Force, 2005). The Region is now managing a police fleet of over 140 vessels of various classes. A modern police vessel is a complex, technologically advanced, and highly automated machine. As such, the Marine Region Support Bureau (MRSB) insisted that it must be maintained at the highest possible levels of operational availability while its life cycle operating and maintenance costs should be kept at a minimum. To achieve this aim, this article addresses the need to effectively implement a marine maintenance information system.

Traditionally, the defects and maintenance data of the fleet were collected and recorded by the crew in writing, and then the maintenance records were used as the basis for maintenance decisions by the MRSB and the Hong Kong Government Dockyard. With the paper-based recording procedure, the following problems often occur:

- There are missing data due to unintentional negligence or uncertainty about the nature of the equipment failure or damage,
- errors occurred during the coding of failure information, and
- there is difficulty in deciding whether repair tasks performed were routine servicing or corrective maintenance.

To minimize such problems, it was decided that the processes of crew logbook entry and failure coding procedures would be replaced by direct input to the desktops of MRSB and the Government Dockyard through portable communication devices such as personal digital assistants (PDAs) and laptops, which can easily be obtained at reasonable costs locally.

Currently, virtual private networks (VPNs) provide one of the most cost-effective ways for users to access organization networks while in Hong Kong waters. They are also an effective way of joining together the main office with remote depots using the public Internet. Three types of VPNs are being used.

1. **Intranet VPN:** This VPN can securely connect the desktops of the MRSB and the HKSAR Government Dockyard over the intranet, with all data traffic being encrypted.
2. **Extranet VPN:** Besides the functions provided by the intranet VPN, this network provides access to the MIS to preferred maintenance contractors. Data are accessible only over secure encrypted connections, with all contractor users authenticated.
3. **Remote-Access VPN:** For this network, authorized users are able to access the MRSB and HKSAR Government Dockyard MIS anytime from anywhere. With the aid of wireless PDAs, this facilitates decision making on the spot and is limited to decision makers such as the police superintendent.

A preliminary attempt at developing a Web-based maintenance management information system was carried out for a small fleet of patrol vessels (Wong & Chan, 2002), and due to the nonmodular structure, a major difficulty was found in the modification and extension of the system framework. Recent advances in VPN technology indicate that VPN WANs (wide area networks) are now faster, cheaper, and more reliable than traditional WAN technologies. For a successful implementation of the IMIS, an efficient framework is needed to achieve the automaton of diagnostic processes and the integration of inspection and maintenance information under a secure communication infrastructure. Prior to an elaboration on the design of the proposed model, a brief review of object-oriented technologies (OOTs) is shown in the following section.

OBJECT-ORIENTED TECHNOLOGIES

Many object-oriented methods have been proposed over the years. In an object-oriented paradigm, a system is defined in terms of objects. The object-oriented method represents a model of a system that is based on real-world entities. Objects can represent systems, defects, or functions that individuals or organizations play. OOTs employ the principle of inheriting characteristics or attributes from superclass objects. The inheritance mechanism of an OOT supports the reusability of software and simplifies design. In the literature, various object-oriented approaches to design, model, and develop management information systems have been noted.

The concepts and methodology of an architecture for developing agroenvironmental models based on reusable components are proposed by Papajorgji, Beck, and Braga (2004). The unified modeling language (UML) is used to specify the system model and components at a high level of abstraction. UML interfaces are used to define the behavior of components that can be implemented using standard object-oriented programming languages such as Java. Distributed components can be created using the common object broker architecture (CORBA), remote method invocation (RMI), or Web-services technologies, which enable components at different geographic locations to communicate.

Accumulated information about design and process failures recorded through failure mode and effect analysis (FMEA) provides detailed knowledge for future product and process design. However, the way the knowledge is captured poses considerable difficulties for reuse. Teoh and Case (2004) have contributed to the reuse of FMEA knowledge through a knowledge-modeling approach. An object-oriented approach has been used to create an FMEA model. The FMEA model is assisted by functional reasoning techniques to enable automatic FMEA generation from historical data. The reasoning technique also provides a means for the creation of new knowledge.

Dynamic simulations of energy systems are essential when it comes to the transient analysis and design of complex plants. In their work, Wischhusen and Schmitz described the advantages of the transient simulation method in the optimization process of energy systems (Wischhusen & Schmitz, 2004). The object-oriented model of a heat exchanger is presented utilizing the modeling language Modelica.

In software reuse, which is an important approach to improving the practice of software engineering, many factors may hinder reusing software artifacts. Among those factors are the availability of software artifacts at a different level of abstraction and a method to classify and retrieve them. Ali and Du (2004) proposed an approach based on a faceted classification scheme for the classification and retrieval of software design artifacts, namely object-oriented design (OOD) models, thus facilitating their reuse. Six facets—domain, abstractions, responsibilities, collaborations, design view, and asset type—have been defined to constitute the classification and retrieval attributes. Each of the facets describes one aspect of an OOD model. It contains a number of predefined terms chosen through the analysis of various software systems specifications. The selected terms of each facet are arranged on a conceptual graph to aid the retrieval process.

Amongst all possibly desired endeavors for e-commerce, research has shown that the effective management of customer relationships is a major source for keeping competitive differentiation. In their work, Lin and Lee (2004) has proposed an object-oriented analysis method for the development of such a customer-relationship management information system (CRMIS). The approach starts with the identification of prospect customers and their desired behaviors under preferable execution environments, and ends with the specification of the system—the internal objects and entities that collaborate to satisfy these behaviors and environments. The method used is the case-driven approach with UML utilized and extended as its tool.

Role-based access control (RBAC) provides flexibility to security management over the traditional approach of using user and group identifiers. In RBAC, access privileges are given to roles rather than to individual users. Users acquire the corresponding permissions when playing different roles. Roles can be defined simply as labels, but such an approach lacks the support to allow users to automatically change roles under different contexts; using a static method also adds administrative overhead in role assignment. In e-commerce and other cooperative computing environments, access to shared resources has to be controlled in the context of the entire business process; it is therefore necessary to model dynamic roles as a function of resource attributes and contextual information.

Afgan, Coelho, and Carvalho (1998) describe the development of an expert system for detecting boiler-tube leakage. The leakage-detection expert system is designed in a knowledge-base environment, comprising the knowledge base containing facts, information on how to reason with these facts, and inference mechanisms able to convert information from the knowledge base into user-requested information. The knowledge base is based on the object-oriented structure with the definition of the object Leakage. The object class Leakage is composed of subclasses Sensor and Cases. The inference procedure uses a set of procedural processes in the preparation of diagnostic variables reading for the decision-making process. A fuzzification process is used for the conversion of actual diagnostic values into semantic values.

Shi and Deng (2000) intend to develop a construction scheduling and planning method, named the object-oriented resource-based planning method (ORPM), for meeting the different requirements at various planning stages. Object-oriented representation is adopted for modeling construction activities. Each object has attribute values to detail the required conditions to construct the activity, such as logical dependency and the resource demands.

In their paper, Lim and Chiang (2004) propose an object-oriented global data model that can accommodate attribute and relationship instance heterogeneities in integrated databases. The proposed model has been designed to allow database integrators and end users to query both the local and resolved instance values using the same query language throughout the derivation and evolution phases of database integration. Coupled with the suggested model, they also define a set of local-to-global database mapping rules that can detect new heterogeneities among databases and resolve instance heterogeneities if situations permit.

Chudoba, Butenweg, and Peiffer (2004) describe concepts used in the development of a technical information system for supporting the collaborative material research of textile-reinforced concrete (TRC). The technical information system works as a database-powered Internet server with a transparent definition of the product and process model. These models have been formally specified by using the unified modeling language (Fowler, 2004) and implemented by defining class hierarchies and methods in an object-oriented database system employing the technique of object-relational mapping.

In functionally decentralized organizations, operational data are usually dispersed in individual departments; thus, the departmental decisions are made separately on the basis of limited information and perspective. Huh and Kim (2004) propose an object-oriented data model for developing a collaborative model management system that facilitates not only the sharing of mathematical models among multiple departments, but also the coordinating and propagating of ongoing changes in the models on a real-time basis. A prototype system is developed at KAIST for a commercial object-oriented database system called ObjectStore using the C++ programming language.

DESIGN OF INTERNET-BASED OBJECT-ORIENTED MODEL

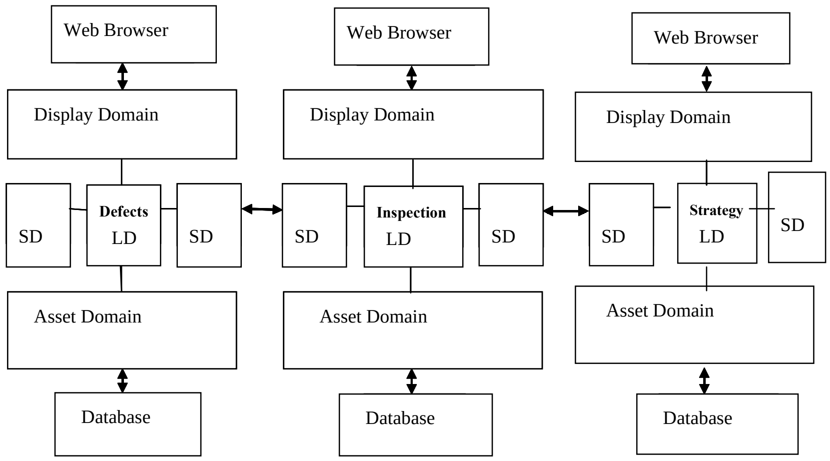
In this study, the authors modified the implementation of the HPD-OO model (K. C. Ng, Ip, & Lee, 1999) with Internet-based technology, which they called the Internet-Based Object-Oriented Model (IBOOM). IBOOM provides the framework and the interface necessary to build the marine police-fleet MIS. By using advanced development techniques, the IBOOM model, which provides an integration solution for all the objects of an MIS, is developed. The proposed architecture adopts object-oriented technology, which aims to enhance the scalability and configuration of the system. The proposed IBOOM model comprises four main object domains: (a) the logic domain (LD), (b) asset domain (AD), (c) display domain (DD), and (d) service domain (SD). The four domain-specific objects of the architecture are characterized by their high degree of flexibility, taking advantage of the object technology. The high level of integration of the individual applications assures the security and consistency of data throughout the Internet. Each object will carry out a unique and complete operational function. For example, an inspection system is a single object. Diagnostic procedures and essential test data such as the temperature, pressure, corrosion rates, and so forth are all defined within that object. Another object such as the Strategy object can interchange information with the Inspection object through the interface provided by the SD.

The IBOOM model is divided into two distinct layers. These are the real-object layer that defines the user's conceptual view and the application layer that defines the MRSB resources view. The real-object layer belongs to the display domain while the application layer exists in the logic domain. The user's conceptual model of an object is not a direct reflection of the application model. The application model is represented as an IDEF model (J. K. C. Ng & Ip, 2003). The IDEF model is a master blueprint defining all of the maintenance entities, relationships, and attributes that must be maintained to preserve the integrity of the MRSB information resources.

The DD is concentrated on the interaction with the user and on managing the user's interface. The LD is focused on managing the MRSB resources (e.g., physical-asset registers) that users share, in particular, the application logic. Only the LD can directly interact with the asset domain. The AD is an interface to the relational database server (e.g., Informix, Oracle, SQL Server, etc.) that manages the storage of data. This domain is also responsible for the preparation of maintenance reports, graphs, or queries. The following sections describe the key elements of the proposed system architecture.

A feature of the proposed model is that each IBOOM object shows only the portion of the master blueprint that is relevant to the maintenance activity in which the user is engaged. The conceptual model of an IBOOM object takes the shape of a hierarchical composite object that is identified by the root subject entity. Each function in the MIS system can be modeled with a single IBOOM

Figure 1. Interaction between three IBOOM objects: Defects, Inspection, and Strategy



object. In Figure 1, three IBOOM objects are illustrated, including the Defects object, Inspection object, and Strategy object. The internal communication of these three objects is by the means of message passing through the SD. The most up-to-date marine police-fleet information, such as routine servicing dates, is shown on the user's Web browser by the DD. In order to retrieve the real-time data, the LD requests the DD to extract all the necessary data from the MRSB database engine by the database query generated from the LD. The function and features of the model components are elaborated in the following sections. All the data passing through the database server and Web browsers are being secured by encryption.

MODEL IMPLEMENTATION

Logic Domain

The LD is the central processing unit of the model. Functions of this domain include the following.

- Generating display mimics
- Providing program logic
- Communicating and synchronizing with databases
- Processing service requests from the service agent
- Routing regional requests to the request agent

The application components of the LD are entities, relationships, elements, transactions, and databases. The LD also acts as the interchange between the Web server on the open network and the database server on the private network. It is used to manage the MRSB database, maintain its integrity in order to maximize the usefulness of it, and provide program logic to cater for the maintenance operation. This domain is designed to retrieve data in a variety of useful ways and update the database in a safe and controlled manner. It also ensures that the event-driven processes are triggered and the users obtain up-to-date data in their workstations. The implementation of the IDEF model is the backbone of the LD architecture. The entities of the object and relationships object receive a message, process it, and return a reply. The relationship object in the LD is also responsible for spreading the event-driven maintenance process. It also provides a query method that will produce a list of the systems' relationships. The query specifies which column to include, the task requesting criteria, and the quality specification. Moreover, the relationship object can assign the sequential key to the entity by querying the database. The relationship object can also be used to resolve concurrency locks and register interest.

Asset Domain

The AD is a standard interface for accessing the physical-asset databases. It is the only interface in the system that is responsible for retrieving, manipulating, and updating data directly to and from the database system through a transaction object, which is the controller of all database updating activities. The function of a transaction object is to ensure that the database is always recoverable to a logically consistent state. The transaction agent can be aborted at anytime and the updates can be rolled back when an error signal is detected by any object. The AD is used to provide multiple and different database systems support. It isolates the LD from the physical asset database so different asset database systems can cooperate seamlessly and simultaneously. Moreover, the AD acts as the only channel for database access that separates the physical-asset database from the Internet connection such that the asset database is protected from illegal access and security is achieved.

One of the major advantages of the AD is to allow scalability; the systems developed by system integrators who make use of the model have the advantage of universal database support, ranging from personal file-mapping databases to high-end client-server database engines. This domain is also responsible for preparing reports, graphs, or queries. It comprises three components, namely, the presenter, extractor, and analyzer. The presenter is used to display all the reports, graphs, or queries to the user through all available media (e.g., screen, printer). The extractor can communicate with the LD through a database object by calling the database management system (DBMS) to perform all SQL operations. The analyzer assimilates the data and prepares them for presentation. All of the calculation and sorting operations for a report are performed by this component.

Display Domain

The DD is mainly concentrated on the manipulation of the Internet-based user interface and on the interaction with the user, that is, the Web browser. The DD is the standard man-machine interface employed by the Web browser. The concept of this domain is simple: The DD uses a Web browser as the client to access all applications. Texts, graphics, animations, multimedia effects, charts, and dynamic data are all presented with the help of a Web browser. This design is based on a thin-client architecture.

This means that no application resides on the client; all application development is performed on the server. This architecture reduces the application maintenance effort and the total cost of ownership of the MIS system, and it allows worldwide maintenance service providers to be connected to the system with no configuration effort.

Service Domain

The SD consists of two agents; they are the service provider agent and the demand agent. The service provider agent is an external communication interface that enables the LD to release its public services for another MOOM object. Another object can request a service from the supply agent of any object through its own demand agent. Generally, the supply agent together with the demand agent provides a standard communication protocol for interobject communication. An important reason for having the supply agent is that it can help to facilitate the model. The supply agent is the only channel through which another object can make a request. Hence, it is easier for system integrators to develop their own services on top of the standard architecture. The demand agent is an external communication interface that enables the IBOOM objects to request information from global objects. Once a maintenance request is made, the demand agent will seek for the information through an intelligent routing mechanism based on the client-server II technology. The demand agent can be considered as an intelligent router for information interchange. The intelligent agent is used to determine load balancing; heavy loading services can be downsized into concurrent services on the Internet or intranet. This approach can highly reduce the server hunting condition. It also provides manageability since services are now treated as global objects. With the help of the client-server II technology, the system integrator can develop his or her own services without knowing the details and physical location of the dependent services.

FUTURE TRENDS

The capabilities of PDAs will advance rapidly. Based on the current rate of technology advances, the expected capabilities of PDAs can be estimated. Advances in computers, communications, networking, and consumer electronics technologies will make the PDA capabilities 5 to 10 times better than current products in several years. Most PDAs will have e-mail and Internet access and other communication capabilities. Connection to corporate networks via VPNs will be standard for office PDAs. Short-range wireless capabilities via Bluetooth and/or IEEE 802.11 are especially important because they will provide wireless broadband access to PDAs. Many PDAs will have a digital camera for low-end video conferencing and to take still pictures. Some PDAs will also have scanners for collecting printed information or scanning bar codes. PDA memory size will grow by 16 to 32 times in several years. Processor performance will improve by at least 5 times, and more like 10 to 20 times for PDAs. All these technological forecasts will certainly lead to the further development of MIS implementation frameworks.

CONCLUSION

This article emphasizes the importance of automating marine-equipment diagnostic processes and the integration of inspection and maintenance strategy information under a secure communication infrastructure. With the aid of object-oriented technologies, an Internet-based maintenance model named IBOOM was developed for the Hong Kong Marine Police fleet. Object-oriented systems have a natural structure for modular design: objects, subsystems, frameworks, and so on. Thus, OO systems are easier to modify since changes are neatly encapsulated. It is anticipated that through such an Internet-based OO maintenance approach, the performance of transportation fleet such as police vehicles, hospital ambulances, container trucks, and so forth can be greatly enhanced. Such a practical application in the logistics sector illustrates one of the significant contributions of ICT research and developments to the society (Khosrow-Pour, 2003).

KEY TERMS

Class: A class is a blueprint or prototype that defines the variables and the methods common to all objects of a certain kind.

Inheritance: A class inherits its state and behavior from its superclass. Inheritance provides a powerful and natural mechanism for organizing and structuring software programs.

Interface: An interface is a contract in the form of a collection of methods and constant declarations. When a class implements an interface, it promises to implement all of the methods declared in that interface.

Message: Software objects interact and communicate with each other using messages.

Object: An object is a software bundle of related variables and methods. Generally, something is an object if it has a name, properties associated with it, and messages that it can understand. Object-oriented programming involves modeling the software system as a set of interacting (conceptual) objects in object-oriented design, then implementing (coding) the design using an object-oriented programming language with (programming-language) objects.

Superclass: A class that is used to derive other classes. A superclass is also called a parent class or base class. The classes that are derived from a superclass are known as child classes or derived classes. A superclass allows for a generic interface to specialize functionality through the use of virtual functions.

Knowledge Creation in Online Communities

INTRODUCTION

The emergence of online communities has brought a profound impact on human interaction and methods of information exchange in society. More than one-third of all U.S. Internet users have turned to mass, large-scale communication systems such as e-mail, mailing lists, instant messaging, chat rooms, Web stores, customer service sites, and threaded discussion systems such as USENET (Preece, 2002). Reflecting this prominent phenomenon, there have been a considerable number of studies focused on online communities and communications. This article focuses on the factors and dynamics of the knowledge creation process in online communities, relying on Nonaka's Socialization-Externalization-Combination-Internalization (SECI) Model (1994). Based on that framework, this article discusses the factors that affect knowledge creation and sharing in online communities.

The rest of this article is organized as follows. The characteristics of online communities are discussed in the "Background" section. The section titled "Dynamics of Knowledge Creation and Sharing in Online Communities" reviews the existing concepts and the SECI model of knowledge creation, and extends that model to include the online community context. We further discuss the effects of important factors on knowledge creation and sharing in online communities. The section "Future Trends" suggests further research opportunities in the area. The final section summarizes and concludes the article.

BACKGROUND

Definition and Components

The online community—otherwise known as the "virtual community" or the "cyber community"—has provided efficient and comprehensive ways of communication (Andrews, 2002). It has been proposed that this new form of community is not subject to the same constraints as traditional social structures (Butler, 2001) due to its unique characteristics.

Online communities can be defined as "groups of people who communicate and interact with each other via electronic media" (Romn, Pliskin, & Clarke, 1997). Online communities possess several unique characteristics that offer opportunities for knowledge creation and sharing activities. An online community provides participants with an opportunity to engage in *many-to-many communication.* This allows access to an unlimited number of counterparts, avoiding limitations embedded in face-to-face community contexts (Butler, 2001). In addition, online communities offer *asynchronous communication opportunities* to those who want to reflect, compose, and review correspondence at their own convenience. Asynchronous communication refers to the timing of interaction engagement (e.g., response), without regard to physical constraints such as geographical distance and physical time to deliver information. This kind of asynchronous communication is not an opportunity in a conventional face-to-face community setting (Bieber et al., 2002; Preece, 2002).

An online community creates a unique environment where some of the common interaction methods in the face-to-face communication are eliminated, or replaced with substitutes. In online communities, social presence cues represented by verbal and visual recognition might be eliminated, and *anonymity* takes the place of such cues (Sia, Tan, & Wei, 2002). Anonymity may encourage people to be more open to sharing their feelings and opinions and freeing them from social pressure to follow group norms. In a similar context, Siegel, Dubrovsky, and Kiesler (1986) found that a computer-mediated communication (CMC) lacking communication cues leads to a more equalized participation level among participants than a CMC with high social presence (Siegel, Dubrovsky, & Kiesler, 1986). The anonymity of online communities, hence, results in an increase of membership size. Anonymity leads to increased benefits for community members and positive effects on members' willingness to participate in knowledge creation and sharing with more novel and valid arguments.

DYNAMICS OF KNOWLEDGE CREATION AND SHARING IN ONLINE COMMUNITIES

Knowledge Creation in Online Communities

In order to understand the phenomenon of knowledge creation and sharing in online communities, we rely on Nonaka's pioneering framework of knowledge creation (Nonaka, 1994). Nonaka suggests two dimensions of knowledge; explicit and tacit. *Tacit knowledge* is highly personal and hard to formalize, making it difficult to communicate or share with others, whereas *explicit knowledge* can be expressed in words and numbers, and shared in the form of data, formulae, specifications, and other "explicit" forms of information such that can be readily transmitted between individuals formally and systematically (Nonaka & Konno, 1998). From the combination of these two dimensions, Nonaka proposed four modes of knowledge conversion, *socialization*, *externalization*, *internalization,* and *combination*, and formulated the process of knowledge creation as shifts among these four modes in light of the interactions among organizational members with regard to their levels of knowledge created through such processes (Bieber et al., 2002; Nonaka, 1994; Nonaka & Konno, 1998).

Socialization (from Tacit to Tacit Knowledge)

Socialization involves the sharing of tacit knowledge between individuals. Due to the nature of tacit knowledge, socialization is carried out through "joint activities" among members of an organization, such as working or living in the same environment, rather than through the media of verbal or written expression of knowledge (Nonaka & Konno, 1998). Socialization is an initial stage of knowledge creation in the conventional, offline context, in which tacit knowledge is shared among members. In the online community, however, socialization hardly takes place due to: (1) the anonymity of members and (2) a verbal or written medium as the fundamental communication tool. Both verbal and written media are suitable for explicit knowledge but not for tacit knowledge. In online communities, the advantages of socialization can be substituted by an immediate online accessibility that would be facilitated by anonymity and many-to-many communication characteristics of an online community.

Externalization (from Tacit to Explicit Knowledge)

Externalization is the transformation of tacit knowledge into a form that is comprehensible by others, and at the same time exchangeable with them. (Nonaka & Konno, 1998) Externalization, therefore, involves the process of articulation of shared tacit knowledge in socialization mode, wherein a piece of "shared" tacit knowledge is converted into a piece of "shared" explicit knowledge. This "shared" explicit knowledge is then used as a building block for synthesizing more complex knowledge through the next mode in sequence (i.e., "combination mode").

Externalization is the most prominent mode of knowledge creation and sharing in an online community context. It is the initiating phase in an online context. This is because most knowledge creation and sharing initially take place by either articulating a need for certain specific knowledge, or by converting personal tacit knowledge into communicable explicit knowledge as responses to those needs.

Combination (from Explicit to Explicit Knowledge)

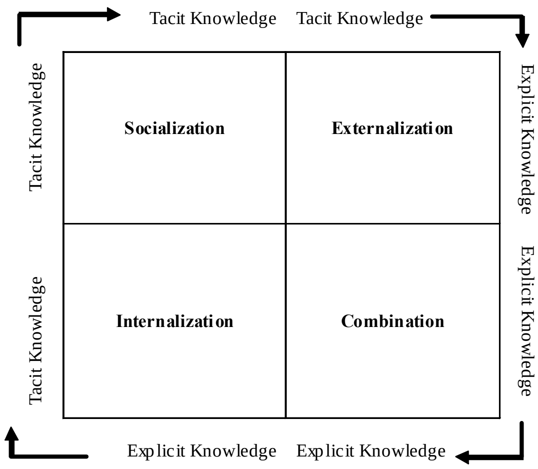
Combination involves creating "newer" explicit knowledge from "new" explicit knowledge generated in externalization mode by reconfiguring existing information through sorting, adding, re-categorizing, and re-contextualizing knowledge (Nonaka, 1994). In other words, combination mode is the stage where explicit knowledge created in the previous externalization mode is systemized, and thus, generates more complex sets of explicit knowledge.

Combination takes place in an online community in the same way as in a conventional physical community. Exchanged explicit knowledge from the previous externalization mode is sorted, added, re-categorized, and re-contextualized through the process of arguing and counter-arguing along the threads of knowledge creation in an online community context.

Internalization (from Explicit to Tacit Knowledge)

Internalization is the process of converting newly created explicit knowledge into tacit knowledge. It requires an individual to identify which organizational knowledge is

Figure 1. SECI model and the four modes of knowledge creation (Nonaka & Konno, 1998)



relevant, which requires finding one's self in a larger entity of oneself (Nonaka & Konno, 1998).

Internalization rarely takes place in an online community due to the nature of the communication tools. This does not necessarily mean that internalization is not happening at individual level in an online context. The conversion of explicit knowledge into tacit knowledge at an individual level still takes place. However, internalization at "organizational level" (e.g., any type of physical social structure such as a department of a company, or the company itself) does not occur since it is neither necessary nor plausible in online communities.

The four modes of knowledge creation are presented in Figure 1. In essence, the SECI model suggests that knowledge creation in an organizational context is represented by an ongoing repeated spiral procedure of interaction between tacit and explicit knowledge. The SECI model provides a useful insight and has implications for the investigation of knowledge creation in online community.

Knowledge Sharing in Online Communities

In this section, we examine the factors that may affect knowledge sharing in online communities. Those are trust, motivation, membership size, and anonymity.

Trust

Trust is the baseline from which socialization of tacit knowledge begins to take place among individuals (Nonaka, 1994). In general, trust can be developed when there is a history of favorable past interactions that lead participants to expect positive future interactions (Preece, 2002). Trust has been emphasized as a pre-requirement of knowledge sharing (Nonaka, 1994). Constructive collaboration involves time-consuming and painstaking interaction for the members to create knowledge through the four modes of knowledge conversion. Without mutual trust among the community members, it would be difficult to facilitate constructive collaboration.

In contrast to traditional face-to-face communications, trust in online communities is in part influenced by anonymity, which is one of the unique characteristics of an online community. As previously stated, anonymity brings the potential of greater group size, thereby bringing a larger potential pool of resources. A lack of trust combined with the comfort of anonymity, however, fosters the temptation to free-ride on the efforts of others (Smith, 2002). Furthermore, most online communities lack the physical social cues of the face-to-face world due to anonymity (Andrews, 2002). Online communities, therefore, need to be supported by technology to attenuate the negative effect of anonymity on trust issues, while maximizing the positive effects of anonymity such as inducing people to be more willing to contribute (Sia et al., 2002).

Figure 2 shows the visualization of social cues in an online community. The visualization tools present a graphical representation of participating members' presence and timeline history as a social proxy (a minimalist visualization of people and their activities). The members in conversation are shown within the circle, and the members logged on but in other rooms are positioned outside the circle. When the members talk or listen, their dots move to the inner periphery of the circle, and then

Figure 2. An example of graphical presentation of social cue (babble system)

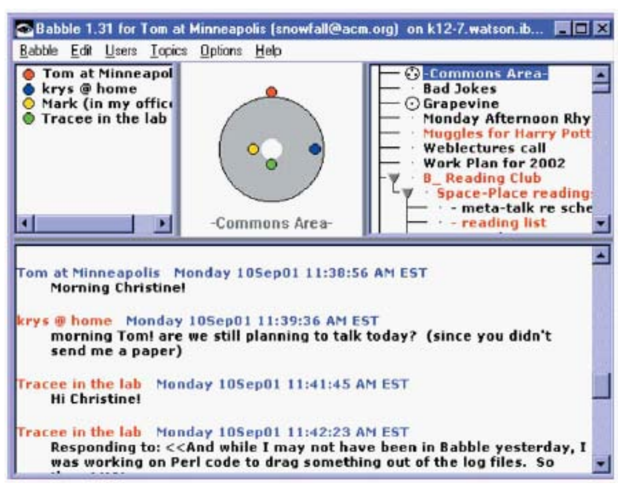


Figure 3. NETSCAN search page (Source:http://netscan.research.microsoft.com)

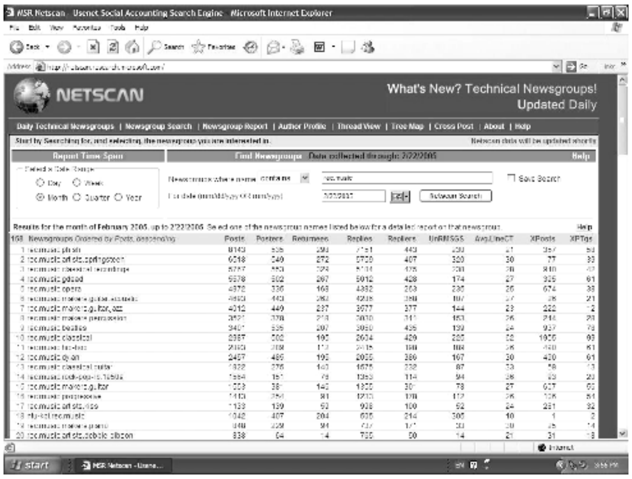

Figure 4. Thread tracker (Source: http://netscan.research.microsoft.com)

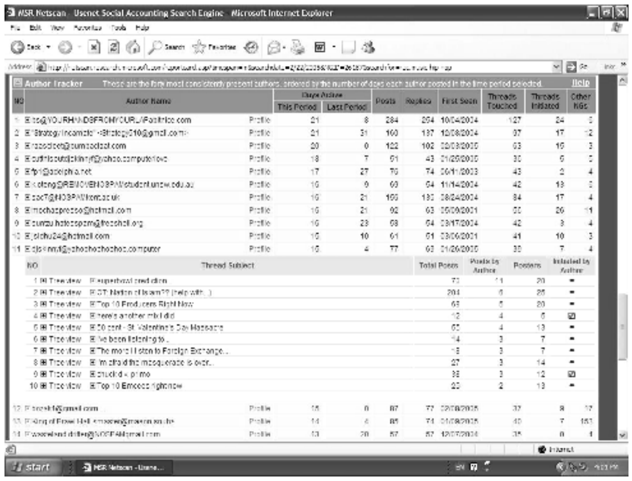


gradually drift back out to the edge over. This approach can help with the trust-related drawbacks of online communities. A member may develop trust for others by observing their visualized actions using this tool (Erickson, Halverson, Kellogg, Laff, & Wolf, 2002).

Motivation

Motivation to participate in the knowledge sharing process has emerged as an issue of interest. The SECI Model suggests that a knowledge sharing community can be effective when it is under a certain authority by which a structured compensation to members is arranged based on members' aggregated benefits from, and contributions to, that community. However, in an online community, motivation becomes questionable when a knowledge contributor is unknown to the recipient, and they may never communicate other than online. The usual obligation of reciprocity between two individuals is, therefore, not quite feasible in an online community context. (Wang & Fesenmaier, 2003).

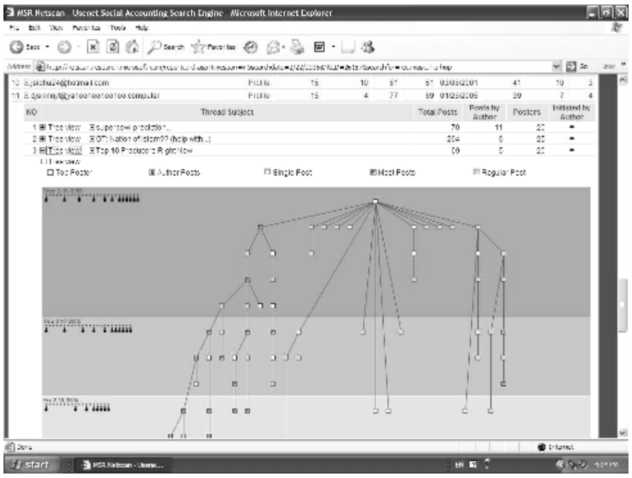
An unstated premise of online communities is that sharing knowledge with an unknown recipient usually involves an implied obligation to repay the favor at some time in the future (Wang & Fesenmaier, 2003). The motivation for members of an online community to participate in the process of knowledge creation and sharing is based on an implied agreement of, "I'll do this for you now, knowing that somewhere down the road you will do something for me" (Wang & Fesenmaier, 2003).

Variety and Membership Size

Since an individual's tacit knowledge forms the basis of knowledge creation, the variety of an individual's experience constitutes one of the most important factors in determining the quality of tacit knowledge (Nonaka, 1994). However, in a large online community, any single individual's experience may be found in other members, and so the significance of any individual's experience may be reduced.

Whether through conventional face-to-face settings or online contexts, social structures can be sustainable when they provide benefits that outweigh the costs of obtaining those benefits (Butler, 2001). In general, the cost of knowledge sharing in online communities decreases exponentially as the number of possible interactions increases (Butler, 2001). But the benefits increase exponentially, and these benefits accrue from a theoretically unlimited number of counterparts—many-to-many communication. As a result, the cost of obtaining knowledge by participating in knowledge sharing in an online community tends to be much lower than that incurred in a traditional face-to-face communication context. For example, the value of knowledge offered to members of an online community is amplified because an unlimited number of people might use or make copies of the information (Wang & Fesenmaier, 2003). The potential benefit from such knowledge is also increased due to the great variety of experiences from a potentially unlimited number of interaction counterparts. The potential benefits are further increased by "asynchronous communication" since

Figure 5. Author Tracker (Source: http://netscan.research.microsoft.com)



the knowledge resource pool can be extended across the time dimension. The benefits from an unlimited interaction counterparts is not restricted to participants concurrently engaged in the communication, but extended to participants from the past (by obtaining knowledge posted in the past), and possibly into the future (by getting replies from participants at a later time).

Since members provide the primary resource for knowledge creation and sharing in an online community, the size of membership may be a meaningful measure of resource availability (Butler, 2001). Greater resource availability from larger memberships provides a motivation for participation, which in turn can lead to an even greater membership size. Hence, membership size affects knowledge creation and sharing in that a greater number of members are associated with more effective and efficient knowledge creation and sharing. However, there are some negative consequences of online communities with very large memberships, because of the complexity involved in managing communications. Various online community technologies such as "thread tracker" and "author tracker" play a role in mitigating the negative effects of the community group size (Smith, 2002). Those applications allow members to obtain relevant information and to track communication history records, thus attenuating the negative effects of membership size and enabling its benefits to be realized (Figures 3-5).

Anonymity

Anonymity is an indispensable property of an online community, which may lead to increases in membership size that, in turn, would lead to the greater success of the community. It has a positive effect on the member's willingness to participate in knowledge creation and sharing. On the contrary, anonymity may have a negative effect on trust. Such negative effects can be mitigated by the use of appropriate Web application programs. The advantages of such technologies in association with trust have been addressed in the previous section (i.e., the "Trust" section).

FUTURE TRENDS

An online community is a form of a socio-technical system (a combination of technologies, people, and social practices) (Bruckman, 2002) that supports knowledge creation and sharing. While specific Internet technologies are useful, more opportunities for successful knowledge creation and sharing exist through efficient community collaboration (Bruckman, 2002). The current article identified four prominent factors that affect knowledge creation and sharing in online communities. Further empirical investigations on the success factors and dynamics of online communities are needed to develop a comprehensive theoretical framework.

CONCLUSION

This article examined the four factors, *trust, motivation, membership size, and anonymity,* that are critical in online communities. This article further addressed the nature and dynamics of the factors involved, and explores knowledge creation and sharing in online communities, relying on the SECI Model. This study offers a fundamental framework for an understanding of the dynamic effects of online communities.

Online communities have been considered a technology or business driven phenomenon. Recently, a number of studies have examined the possibilities and potential of online communities as an alternative way of knowledge creation and sharing. These studies, however, do not address the knowledge creation and sharing activities forming the basis of massive, large-scale knowledge management systems. By examining the important factors and dynamics of knowledge creation and sharing in online communities, this article provides useful insights for both researchers and practitioners.

KEY TERMS

Anonymity: Anonymity refers to the lack of the identity due to the eliminated social cues (e.g., visual or verbal indication of communication partner's presence in the social interaction circumstance). Anonymity may encourage people to be more open to sharing their feelings and opinions, freeing them from social pressure to follow norms of groups in which they are involved.

Asynchronous Communication Opportunity: The asynchronous communication opportunity refers to the provision of the choice between immediate interaction and asynchronous interaction in terms of the timing of interaction engagement (e.g., response) without physical constraints such as geographical distance and physical time to deliver the information (e.g., such constraints in conventional mailing system).

Computer-Mediated Communication Systems (CMCS): Computer Mediated Communications Systems are computer based systems that enable entry, storage, processing, distribution, and reception of digitized information (Kahai & Cooper, 1999). CMCS include computer conferencing systems, electronic and voice mail systems, group decision support systems, and text retrieval systems.

Explicit Knowledge: A type of knowledge that can be expressed in words and numbers, and shared in the form of data, scientific formulae, specifications, manuals, and the like. This type of knowledge can be readily transmitted between individuals both formally and systematically (Nonaka & Konno, 1998).

Online Community: The Online Community otherwise known as the 'Virtual Community' or the 'Cyber Community' can be defined as "groups of people who communicate and interact with each other via electronic media" (Romn et al., 1997). Online communities possess several unique characteristics that create substantial benefits for knowledge creating and sharing activities; the immediate engagement in many-to-many communications; the opportunity for benefits arising from asynchronous communication, and from anonymous communications.

SECI Model of Knowledge Creation: A knowledge creation model proposed by Nonaka (Nonaka, 1994) in which knowledge creation is viewed as a spiraling process of interactions between explicit and tacit knowledge, and the interactions between these kinds of knowledge lead to the creation of new knowledge. Four modes of knowledge creation are proposed in this model: Socialization, Externalization, Combination, and Internalization (Nonaka & Konno, 1998).

Socio-Technical System: A socio-technical system is a system composed of technical and social subsystems, or a combination of technologies, people, and social practices (Bruckman, 2002). Examples of socio-technical system in a virtual context would be found in online communities such as USENET.

Tacit Knowledge: A type of knowledge that is highly personal and hard to formalize, making it difficult to communicate or share with others. Subjective insights, intuitions, and hunches may fall into this category of knowledge (Nonaka & Konno, 1998).

Lessons from Dot-Com Boom and Bust

INTRODUCTION

The dot-com industry began in the early 1990s as a collection of startup companies using the Internet as their primary means to conduct business. These companies typically used the ".com" suffix in their company names, such as Amazon.com, and proliferated in the late 90's with the massive investments in Internet-related stocks and enterprises. But with the failure and consolidation of many of these companies their numbers have since dwindled.

The catastrophic collapse of the dot-coms that shook the U.S. economy started in May 2000. More than 210 dot-com companies failed in 2000 (Hirakubo & Friedman, 2002) and a total of 762 dot-coms closed for the period January 2000 to December 2001 (Pather, Erwin, & Remenyi, 2003). Since many of these dot-coms began to lay off their staff, the unemployment rate also increased from 3.9% to 6% by 2002 (Callahan & Garrison, 2003; Howard, 2001).

The dot-com bubble burst because the boom was based on the false premise that new technology would eliminate the need for brick-and-mortar stores as this new business model would supplant the old one, thereby converting the "Old Economy," which is based on the production of physical goods into a "New Economy," which is based on heavy use of information and communication technology (Rauch, 2001). Although a great deal can be learned from examining the dot-com successes, it is equally important to study reasons for the failures. Examining the mistakes made by the dot-coms can provide insight into the evolution of e-commerce as a means of conducting business and furthermore help to form the basis on which new strategies can be developed for the future e-commerce environment.

BACKGROUND

In the 1990s, the commercialization of the Internet started a revolution in the way business is conducted. In particular, the growth of the World Wide Web has offered a unique opportunity for many companies to increase efficiency, forge better customer relationships, and expand their markets through "global visibility" (Medjahed, Benatallah, Bouguettaya, Ngu, & Elmagarmid, 2003). These advantages have led many companies to move their primary operations to the Web. According to CNN and BBC reports, an estimated 20 million Web-based companies came into existence (Pather, Erwin, & Remenyi, 2003). With the flourishing of these companies, the economy faced a new challenge: business transaction over the Internet, or e-commerce. In the early stages of e-commerce, however, the terms Web-based company, Internet-based company, and dot-com company were all used interchangeably to refer to the same sort of online retailer.

As traditional and new companies continued to establish themselves as online retailers, mass media often exaggerated the enthusiasm with such one-liners as "Be Digital or Be Toast!", "Get Web or Be Dead!", and "Dot-Com or Be Gone" (as cited in Pather et al., 2003). At the same time, as the number of Internet users increased exponentially, and online shopping became a popular consumer activity. According to Giga Information Group (2000), it was once estimated that U.S. online retail sales would increase from $26 billion in 1999 to $152 billion in 2002 and $233 billion in 2004. Another prediction suggested that consumers would spend $200 billion on the Internet in 2005 (Chartier, 2000).

Investors also showed their enthusiasm for Web-based companies. In 1999, venture investments in Internet-related businesses exploded, increasing to nearly $20 billion from $3.4 billion in 1998. This was due to the fact that many investors considered technological innovation to be the promising "future value" of a company. Subramani and Walden (2003) confirmed that the public announcement of a company's e-commerce initiative would enhance the market value of that company and thus create value for the company's stockholders. In fact, rather than measuring business performance in traditional ways, many investors demonstrated little concern about gains and losses in profit margins. One recurring comment was that "as long as an e-commerce business 'makes sense' (it does not need to 'make cents'), it may still be backed by numerous investors" (Chan, Lee, Dillon, & Chang, 2001, p. 7).

With the massive investments, the U.S. economy experienced the dot-com boom or dot-com bubble in the late 1990s. The height of the boom was characterized by an enormous increase in stock prices, especially in the prices of Internet-related stocks. Starting in January 1997, the dot-com industry stimulated NASDAQ and thus surpassed expectations with record high after record high. In the period of just one year (1997-1998), America Online's stock rose by 593%, and Yahoo!'s by 584%. Amazing growth occurred in Amazon.com, with a 970% increase. The NASDAQ also showed inflation. Within only six months (September 1999 to March 2000) it showed an 83% increase (Callahan & Garrison, 2003).

However, in early 2000 the stock market witnessed a bubble ready to burst. This burst led to the rapid decline in the value of Internet-related stocks. In the weeks and days that followed the burst, the stock market bounced up and down randomly. For instance, on March 10, 2000 NASDAQ closed above 5,000, but dropped three days later by almost 500 points. On March 22, NASDAQ jumped to 4, 864.75 with a 3% increase and was back to almost 5,000 points at the end of week. However, the overall cycle of NASDAQ during March 10 to April 14 showed a 34.2% decline. More importantly, though, the stock prices for all the 20 leading Internet stocks fell (Cassidy, 2002). For instance, Amazon.com dropped by 29.9%, eBay by 27.9%, Yahoo! by 34.8%, and TheStreet.com by 54.3%.

The first factor contributing to the dot-com collapse was the frenzied buying of Internet-related stocks without serious consideration of whether the companies were actually fiscally sound with strong management plans. This impulsive buying sent the main U.S. market indices (especially the tech-heavy NASDAQ) soaring from a low 1541.80 in late 1998 to a high of 5000 in early 2000.

With this inflation in NASDAQ and in the Dow, many believed that the dot-coms constituted a prime investment opportunity and that technology itself was a good business plan. This idea led to significant growth of the Internet-related sector of the stock market through the overvaluing of stock prices.

The second factor was that investment firms involved in launching IPOs undervalued the initial stock offering, depriving the startups of vital capital resources. For example, Priceline.com went public on March 31, 1999 and initially had an IPO of $16, with an initial public offering of 10 million shares. However, Priceline.com opened the first day of trading at $81.00 with a high of $95.94 and achieved market value of $9.8 billion, the highest first-day ever achieved by an Internet company (Business Magazines & Media Inc., 1999). If the firm had priced the IPO at $30.00, it could have made $300 million instead of $160 million (which it made at the initial IPO). One reason for such undervaluation was the lack of know-how in deciding the true value of dot-coms with complicated situations. Given that Priceline.com had profit and revenues of only $35 million, and there was no justification for predicting the potential market value: "One person who took part in the Prieline.com pricing meeting likened the process of valuing Internet companies to throwing darts" (Cassidy, 2002, p. 216). This scenario was repeated throughout the dot-com industry as billions of dollars were lost in IPOs by the undervaluation of these stocks.

Although the stock market's bounce resulted in many dot-com meltdowns, there are a number of other reasons why many dot-com companies have been unsuccessful at making a profit. One of these reasons is that most dot-com companies did not have a sound business strategy that provided a clear plan.

DOT-COM FAILURES

In some cases, failure was due to financial problems. Most of the so-called B2C (Business to Consumer) companies had spent far too much money marketing themselves to consumers, but had not yet turned a profit. Many dot-coms failed because they spent too much when the company was founded and then simply ran out of money. For instance, Boo.com, founded in 1999, targeted women under 30 who are interested in trendy clothing. The site promised that it would be "working diligently over the next few weeks to position Boo as the ultimate global fashion portal—to deliver all the great things you loved about Boo." But that portal never reached its target audience.

Boo.com's attempt to reach a global community of online "fashion-conscious consumers" made them the first victim in the NASDAQ crash. On May 17, 2000, five months after its Web site launched, Boo.com shut down and filed for bankruptcy. Boo.com's failure was generally credited to its expensive marketing budgets, high technology costs and ambitious Web site. When Boo's Web site launched in November 1999, it was slow because it was graphic heavy as well as inaccessible to some Apple users.

However, one crucial factor leading to Boo's bankruptcy was its failure to make a profit. Boo.com spent $185 million in 18 months to create brand value, but total sales were only $1.1 million in the three months, between February and April 2000 (Cassidy, 2002). In the "old" economy, stock performance correlates with earnings—the more money a company makes, the higher its stock price should increase. But in the "new" economy of the dot-com bubble, investors assumed that market share comes first and profits follow. Boo.com relied heavily on venture capital but revenue did not follow, its failure was inevitable. When NASDAQ began to drop quickly, investors became reluctant to invest in unproven dot-coms (Hirakubo & Friedman, 2002) and these companies failed to secure additional funding.

Another issue for dot-coms was massive spending on media marketing to build e-brand. For instance, Pets.com spent $2.2 million on a 30-second television ad in the 1999 Super Bowl. Another example is the Internet toy retailer, Toysmart.com. Walt Disney Co., the owner of Toysmart.com, spent over $20 million in marketing in 1999 to build the Toysmart brand but the company failed to bring a unique service to their customers and ceased operations on May 19, 2000. Although Walt Disney planned to provide another $25 million before Toysmart.com shut down, this dot-com could not survive under pressure from other toy retailers like EToys.com, toysrus.com and Amazon.com, which all provide wider toy selections.

In some cases, dot-com failures were due to a flawed business model. Many dot-com companies simply failed to create value for their customers and failed to differentiate themselves in a competitive market. Especially apparent was that "over-saturation" became a problem in small markets when companies failed to create a real need for their services (Hirakubo & Friedman, 2002). Wolverton (2000) points out, for example, that there were too many online pet stores with similar names (e.g., Pets.com, Petstore.com, etc.). Such a situation led to a number of collapses among dot-com startups. In November 7, 2000, Pets.com, founded in 1998, announced that it was shutting down its retail operations and laying off at least 255 employees. Pets.com's chairman stated "it is well known that this is a very, very difficult environment for business-to-consumer Internet companies. With no better offers and avenues effectively exhausted, we felt that the best option was an orderly wind-down with the objective to try to return something to the shareholders" (Cassidy, 2002, p. 303). Also, considering that pet food is available at just about any neighborhood grocery store, few people have a reason to shop online. Other online pet stores such as Petopeia.com and PetsMart.com were forced to cancel their IPOs as well.

DOT-COM SUCCESSES

Not all dot-coms were failures during the dot-com crash, and a number of successful dot-coms still exist, including Amazon.com (books, music, movies, and more), eBay.com (online auction), and Drugstore.com (pharmacy, health and beauty aids). The successful companies have learned to modify their business models and to continue finding new ways of making a profit. One of the widely accepted marketing strategies is "relationship" marketing—building relationships with customers. Hirakubo and Friedman (2002) argue that because buyers and sellers are considered as partners in relationship marketing, this partnership promotes long-term growth for the company and increases service satisfaction for customers. These advantages, in turn, bring successful brand management. This scenario is at the core of Amazon.com's success story.

Launched in July 1995, Amazon.com went public in May 1997. Its online sales increased from $66 million in 1997 to $252.9 million in 1998, with a 283% increase. By the beginning of 1999 Amazon.com achieved market value of $6 billion (Saunders, 1999). As a well-branded company, the strength of Amazon.com was in its successfully developing a sense of community among its users, thereby enhancing its relationships with consumers. For instance, Amazon.com encourages customers to write and submit product reviews and allows customers to rate each other's reviews thereby creating a sense of participation. Amazon also uses "suggestive selling". Once a customer sets up an account and starts to make purchases, Amazon.com uses information on those purchases to suggest other products that may be of interest to that customer. For instance, "Recommendation Center" on Amazon.com offers customized products and services by suggesting books by the same author or similar subjects to ones the customer has already purchased. These customer-focused services make possible for the first-time purchaser to be converted to a frequent purchaser. In fact, the loyal customers who repeatedly shopped online generated more than 70% of Amazon.com's sales (Hirakubo & Friedman, 2002).

eBay.com is another example of dot-com success. It was launched in 1995 as the first online auction in the world. Like Amazon, eBay's important assets are its well-known brand and its efforts to build community among customers. For instance, eBay provides online forums where customers (i.e., sellers) talk to and help each other. At www.ebay.com/community, sellers can access hundreds of announcements, join chat groups, and participate in discussion boards and question-and-answer boards where they can exchange opinions and advice with other sellers. Through these activities loyal customers are encouraged to bring in new customers, provide information to the company, and offer assistance to other customers. With such services eBay was profitable from the first month and showed phenomenal growth in revenue over a short time period. eBay went public in September 1998, and its stock rose by 163.2% on the first day of trading (Elms, Bellomo, & Elad, 2005). In twelve months eBay had sales worth $30.5 million and revenue of $1.4 million. In 2002, with an estimated 85% share of the online auction market and 69 million registered users worldwide, eBay made a profit of $250 million (Walker, 2003).

Amazon and eBay survived the dot-com bubble and bust. While many other dot-com failures have been unsuccessful at building their brands, Amazon's and eBay's most important assets are their unique brands. This suggests then that the difference between the dot-com failures and the dot-com successes is that the failures spent too much on marketing themselves to consumers, while the successes promoted relationship marketing.

FUTURE TRENDS

Despite the dot-coms boom and bust, e-commerce sales are reported to be increasing with an extremely promising future. According to reports by the U.S. Department of Commerce (2001-2004), total e-commerce sales continued to increase in recent years. The estimated total e-commerce sales were $32.6 billion for 2001. With an increase of 26.9% from 2001 this figure was $45.6 billion for 2002, $54.9 billion for 2003 (with an increase of 26.3% from 2002), and $69.2 billion for 2004 (with an increase of 23.5% from 2003). Such growth in e-commerce suggests that dot-com survivors from the past moved to the next stage of their life-cycle as the economy has been revitalized.

An important growth trend in the post-dot com age is that organizations have embraced the concept of a portal. As ultimate e-commerce platforms, portals are, generally speaking, Web directory sites like Yahoo!, and have common elements including: reference information, directories of links to topic-related or selected Web sites, and communication channels (e.g., chat, bulletin boards, etc.) and news (O'Leary, 2002).

Corporate marketers are now seeing the potential of their Web sites, and their Web sites are becoming the new portals. Some corporate portals, particularly business-to-consumer portals, demonstrate many creative variations on the basic portal elements. For instance, Pampers.com provides reference and "ask-an-expert" information on babies and parenting. Content using the "community" concept is also popular on corporate portals.

Forums such as bulletin boards, discussion, or live chats are offered as a means to gain users' "stickiness" (i.e., repeated visits by users) on their portal sites.

Despite the dot-com crash there still remains an optimistic expectation that the dot-com industry's "leading edge will take the business to places most have not yet imaged" (Sun Professional Services, 2001, p. 1). Managing complexity—balancing issues of technology and business—will be crucial for success in the dot-com industry. In particular, the growing popularity of portal Web sites among corporations is a new challenge in the current post dot-com age.

CONCLUSION

The late 1990s witnessed the blossoming of e-commerce, as existing and start-up companies were eager to take advantage of the new possibilities. In light of the boom and bust cycle that followed, this period has been dubbed the dot-com boom. Venture capitalist investment, based on inflated estimates of earnings and stock prices, contributed to the dot-com boom. But many dot-com companies running on investment capital without profit met their demise. With the crash of the NASDAQ index, which heavily represented technology stocks in 2000, the dot-com boom went bust.

One important lesson from dot-com "meltdown" is that the Internet cannot save a flawed business model. Many dot-com companies failed because they did not have a business strategy that provided a clear path for making a profit. Despite failures, dot-coms still exist and thus demonstrate that to survive in the rapid growing e-commerce environment companies must follow "consumer-focused" strategies that provide unique products or services and build partnerships with their customers.

KEY TERMS

Business to Consumer (B2C): One form of e-commerce applications (as opposed to B2B, Business-to-business) in which the seller is a business organization and the buyer is consumer. A typical example is Amazon.com.

Dot-Com Bubble: Refers to the late 1990s during which countless dot-com companies were booming with a frenzy of investment in Internet-related technical stocks and enterprises.

Dot-Com Bust: Refers to the years 2000 to 2002, when dot-com industry collapsed and hundreds of dot-com companies went bankrupt due to the NASDAQ crash starting in March 2000.

Dot-Com Company: A company using the Internet as its primary means to conduct business. The companies typically use the ".com" suffix in company name.

IPO: Abbreviation for "Initial Public Offering." A company's first offering of its stock to the public.

New Economy: Refers to financial and economic infrastructure characterized by reliance on information technologies.

Old Economy: Based on the production of physical goods and unrelated to telecommunications or the Internet, old economy companies have little investment or involvement in the technology industry.

Portals: A Web site or Web directory site considered as an entry point to other Web sites, or relevant resources by incorporating links to subject or topic related. A typical example is Yahoo!

Relationship Marketing: The process of maintaining and enhancing relationships with customers; focusing on customer's needs, this strategy considers customers as important long-term assets.

Venture Capital: A general term to describe financing and investing for startup and early stage businesses.

Leveraging Customer Data Integration for Effective E-CRM Analytics

Thomas P. Van Dyke

Christopher D. Barko
Laboratory Corporation of America, USA

INTRODUCTION

A holistic view of the customer is a desirable resource in many organizations today. The findings from a recent DMG Consulting study confirm this reality—possessing integrated customer information is a critical success factor in 11 of the 12 business challenges facing organizations (Kharbanda & Dasgupta, 2001). To achieve a single customer view in today's marketplace often characterized by increasing global competition, shrinking product lifecycles, and decreasing customer loyalty, companies are considering customer analytical technologies to uncover previously unknown and valuable insights. These insights strengthen customer relationships through greater responsiveness and customization, thereby boosting customer loyalty. Many organizations now believe one of the fundamental instruments for creating competitive advantage is deploying information technology that supports and fosters one-to-one relationships with customers (Shoemaker, 2001). This type of customized service can be achieved through customer relationship management (CRM) and electronic CRM (e-CRM) technologies, which enable organizations to maximize their customer relationships and increase profits by leveraging people, processes, and technology for more effective acquisition, retention, and cross-selling/up-selling opportunities.

However, a holistic and integrated customer view remains elusive within most companies. Many businesses still struggle with a basic understanding of who their customers are, what they want, and what they contribute to or cost the company. This is due to the myriad of systems typically found in organizations that contain some form of customer data—CRM and database marketing, legacy and ERP (enterprise resource planning), customer service, order management, financial, call center, and sales force automation systems. In addition, integration complexity grows as organizations add external sources such as customer survey, demographic, credit, and lifestyle data. Integrating relevant data to enable a holistic view of the customer requires overcoming many obstacles, which typically encompass duplicate data, incompatible and conflicting definitions, and ownership/political battles.

BACKGROUND

The analyst firm Gartner refers to customer data integration (CDI) as the people, processes, and technologies required to create and maintain a unique, complete, and accurate customer profile and make it available to all operational systems (Shah, 2005). An effective CDI solution makes economic sense by treating the customer as a person rather than a disparate set of loosely related data sources and systems. It recognizes and analyzes how customer interactions affect every function of an organization, from sales and marketing to operations and support. As previously noted, this seemingly "simple" concept is difficult to achieve in organizations. A recent Meta Group study on customer data integration revealed that the greatest challenge in information management is integrating the wide variety of data sources required for extracting needed information (Kontzer, 2004).

To address this challenge and strengthen customer relationships, organizations are implementing organizational data mining (ODM) technologies, which are defined as technologies that leverage data mining tools to enhance the decision-making process by transforming data into valuable and actionable knowledge to gain a competitive advantage (Nemati & Barko, 2001). The growing interest in ODM and associated predictive technologies is confirmed in a recent IDC study by Henry Morris. After surveying 43 North American and European companies, Morris discovered that the median return on investment (ROI) for projects that incorporated predictive technologies was 145%, while the median ROI for projects that did not was only 89% (Stodder, 2005). This finding illustrates that predictive, customer-oriented ODM technologies such as CRM and e-CRM analytics can offer greater ROI and business value to organizations that adopt them.

CRM can be defined as the adoption, through the use of enabling technology, of customer-focused sales, marketing, and service processes (Forsyth, 2001). CRM is about deploying technology, services, and processes that connect an organization with its customers in the most reliable, efficient, and cost-effective manner while striving to create long-term, profitable relationships. CRM software provides functionality that enables a firm to make the customer the focal point of all organizational decisions. CRM technologies incorporate some of the best-in-class processes for features such as customer service, product configuration, field service, and customer analysis.

CRM has become a key process in the strengthening of customer loyalty and in helping businesses obtain greater profit from low-value customers. The manner in which companies interact with their customers has changed tremendously over the past few years. Customers no longer guarantee their loyal patronage, and this has resulted in organizations attempting to better understand them, predict their future needs, and decrease response times in fulfilling their demands. Customer retention is now widely viewed by organizations as a significant marketing strategy in creating a competitive advantage, and rightly so. Research suggests that as little as a 5% increase in retention can mean as much as a 95% boost in profit, and repeat customers generate over twice as much gross income as new customers (Winer, 2001). In addition, many business executives today have replaced their cost reduction strategies with a customer retention strategy—it costs approximately five to ten times more to acquire new customers than to retain established customers (Pan & Lee, 2003).

Similar to CRM, e-CRM can be defined as the process of acquiring a thorough understanding of an organization's online visitors and customers to create and maintain online loyalty. This loyalty must be built using the most efficient and cost-effective means, since consumers' online attention spans are short, and competing choices are great. E-CRM analytics is the process of analyzing and reporting online customer/visitor behavior patterns with the objective of acquiring and retaining customers through stronger customer relationships.

Prior research has shown that to understand online customers, a company must integrate its data from both online and off-line sources (Mena, 2001). In similar fashion, our study also demonstrates that a company cannot thoroughly understand its customers if it neglects integrating its customers' behavioral data from both the online and off-line channels. In order to have this complete customer viewpoint, it is imperative that organizations integrate data from each customer touch-point. To explore these issues further, we conducted a literature review to provide a foundation for our research. From our literature review, we developed an e-CRM framework and five propositions that demonstrate the importance of data integration in facilitating successful and valuable e-CRM analytics. The research details, findings, and their organizational implications are described below.

RESEARCH FOUNDATIONS AND FRAMEWORK

Past studies (Brancheau, Janz, & Wetherbe, 1996) have shown that data has been ranked as one of the top priorities for IT executives. With the emergence of Web technologies, the collection and storage of data, both internal and external to an organization, has increased dramatically. Internal data refers to data generated from systems within an organization, such as legacy and online transactional processing (OLTP) systems. External data refers to data that is not generated by systems within an organization, such as government census data, industry benchmark data, consumer psychographic data, and economic data. If this data is collected, integrated, and formatted properly, it can prove to be immensely beneficial to a firm in better understanding its customers (Rendlemen, 2001).

Technically, data integration can be defined as the standardization of data definitions and structures through the use of a common conceptual schema across a collection of data sources (Litwin, Mark, & Roussopoulos, 1990). This implies that data is accessible across functional areas, making data in different corporate databases available and consistent. For example, if a traditional 'bricks and mortar' company deploys a Web site and decides to integrate the Web data with its legacy systems, it has to consider various technological and design issues such as data requirements, data quality, data inconsistencies, synchronization, security, and so forth.

Even though data integration is such a complex task, organizations successfully tackling this issue have derived immense benefits from it. For example, Staples Inc. integrated all customer and sales data from their store, catalog, and online efforts into a common database (SAS Institute, 2001). Integrating all this information allows Staples' marketers to monitor and predict how customers migrate from one channel to another or how they utilize the channels to get what they need. Staples can identify what products are purchased at a store vs. their Staples Direct catalog or through their online store. This valuable information gives Staples an edge over its competition and allows marketers to (1) target specific products to customers through preferred channels, and (2) give them the ability to perform cross- and up-selling to customers across multiple channels. This leads us to our first two propositions.

Proposition 1: The more data sources a company integrates, the better the customer insight, thus creating more value for the company.

Proposition 2: Integrating online data with data from the firms' off-line operations will lead to better customer insight, thus creating more value for the company.

Timeliness of data is an important component of user satisfaction (Ballou, Wang, Pazer, & Tayi, 1998). Users need to have up-to-date information about customers' needs and preferences (Swift, 2002) to thoroughly understand and satisfy those needs. Traditional measures of customer-centric metrics such as recency, frequency, and monetary statistics need to be incorporated into the analysis. Without integrated data (from online and off-line sources), these statistics will not be accurate. Traditionally, it was acceptable for organizations to update their customer database on a monthly or quarterly basis. But in today's fast-paced electronic economy where critical decisions are made daily, companies strive for more current information, requiring systems to update their databases much more frequently (daily, hourly, or in real time). This leads us to our next proposition.

Proposition 3: Data that is more frequently refreshed will lead to better customer insight, thus creating more value for the company.

Past experiences or product quality are not the only reasons why customers make purchases. There are factors external to an organization such as new marketplace competitors, economic factors, and competitor promotions that alter our buying preferences. In his book *Web Farming,* Richard Hackathorn (1998) advocates that an organization must integrate external data into its data warehouse to gain a complete picture of its business.

Researchers have also concluded that without data about why a product was purchased, it is difficult to make accurate inferences about future customer needs. Organizations that have a myopic view of the customer risk experiencing an inference gap—they lack a multi-brand, external view of the customer that captures historical data about customer behavior and preferences across multiple organizations in an industry. Making incorrect inferences about a customer can lead to faulty marketing decisions and lost revenues. Conversely, organizations that achieve an accurate multi-brand view of the customer by integrating external data will be more effective at inferring future needs and better able to service customers due to an enhanced customer understanding (Brohman, Watson, Piccoli, & Parasuraman, 2003). Sources of external data include government databases, customer demographic and lifestyle data, credit history data, census data, and weather data. This leads us to our next proposition.

Proposition 4: Integrating external data with internal data will lead to better customer insight, thus creating more value for the company.

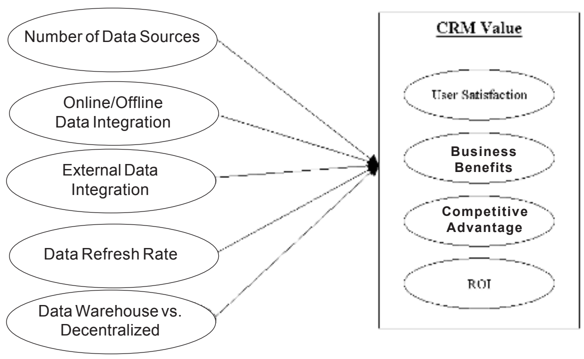
A recent Data Warehousing Institute Industry Report (Eckerson & Watson, 2001) found that organizations are challenged when integrating Web technologies into their existing legacy and IT systems. Some of the reasons behind this challenge are scalability issues, managing large clickstream databases, immaturity of technology, lack of experience, and the complexity of modeling Web data for analysis. But despite these integration challenges, the benefits realized are worth the effort.

In another survey of 800 information technology executives by the Meta Group, four out of five companies did not have a 360-degree view of their customers even though 92% of the firms surveyed ranked increasing customer knowledge as a top priority (Cooke, 2000). This study goes on to report that although business and information technology managers in these companies are interested in obtaining customer knowledge, a number of serious obstacles prevent them from doing so, such as building the right data architecture and obtaining useful analytical tools to integrate and use this data effectively. To be truly effective, an e-CRM infrastructure must provide organizations with a single view of the customer, regardless of how they are interacting with the company (Pan & Lee, 2003). Comparable research has also found that one of the fundamental requirements for a successful e-CRM solution is the consolidation of all customer-related information into a single view (Storey, Straub, Stewart, & Welke, 2000).

For successful CRM analytics, an enterprise wide, customer-centric data repository should be utilized rather than a channel-specific data repository (Beck & Summer, 2001; Swift, 2002). Vasset (2001) suggests an enterprise-wide, customer-centric data warehouse should be the foundation of any CRM initiative. This leads us to our last proposition.

Proposition 5: Deploying an enterprise-wide data warehouse as the CRM backbone will lead to better customer insight, thus creating more value for the company.

Figure 1. E-CRM value framework



Given the promise of strengthening customer relationships and enhancing profits, CRM technology is gaining greater acceptance within organizations. However, findings from recent studies suggest that organizations generally fail to support their CRM efforts with complete data (Brohman et al., 2003). As a result, considerable attention from researchers in many diverse disciplines is currently focused on implementing CRM. Although there is a growing pool of literature that addresses many aspects of the application of CRM for business solutions, there are few scholarly publications that focus on the study of CRM from an e-commerce perspective. Given the complexity of the issues involved in data integration, the enormous benefits that e-CRM can offer, and the role data integration plays in achieving e-CRM's goals, we developed an e-CRM value framework (see Figure 1) to study data integration issues and their impact on the overall value attained from e-CRM projects. Through this framework, we empirically test our five propositions to determine the impact each factor has on creating e-CRM value for an organization. The results of our analysis reveal that four of the five factors support this new framework and have a significant influence on creating value and building a competitive advantage for an organization.

Research Findings

Respondents worked in a wide variety of industries, with the majority coming from CRM/technology, transportation, healthcare, advertising, and financial industries. Job categories for respondents range from executive management to business managers to CRM professionals. These respondents were employed by an equal mix of both small and large companies. The majority of respondents were also clicks 'n bricks (Web and store) companies vs. purely Web retailers.

Our research findings strongly suggest that data integration is essential to accurately assess customer needs, thus allowing an organization to achieve greater e-CRM and business value. Four of the five propositions presented were statistically significant (proposition 3, the daily refresh rate, was not significant), suggesting our e-CRM Value Framework (excluding proposition 3) is a valid model for generating greater total benefits and a competitive advantage for organizations engaging in e-CRM projects (Nemati, Barko, & Moosa, 2003). To achieve the greatest level of benefits, we propose that organizations integrate all their customer data (online, off-line, and external) into a data warehouse or similar CRM data repository. With this architecture in place, a company is able to achieve greater profitability by obtaining a better understanding of its customers and its relationships with them.

FUTURE TRENDS

There is little debate that the volume of data captured and analyzed by organizations will continue to grow. This data explosion will likely require new data mining methods and techniques to accurately and quickly extract valuable knowledge from real-time data streams. Stanford University's continuous query language (CQL) is a variation of standard SQL (structured query language) designed for long-running, "incremental" queries over continuous data streams. The Back Side of Moore's Law (computers get 30% to 40% cheaper every year at the same performance point), along with increasing e-commerce activity, will drive the growth of both off-line and online data storage volumes, requiring more advanced and robust integration technologies. And lastly, we feel the open-source movement popular in today's database, Web server, operating system, and software development environments will eventually permeate data mining and advanced analytics, and possibly even data integration.

CONCLUSION

We have discussed the importance of customer data integration and presented a new e-CRM Value Framework to better understand how organizations can benefit. The significance of integrating data from all customer touchpoints, the number of data sources integrated, and integrating off-line, online, and external data and data architectures are discussed. Our findings suggest that despite the cost and complexity, data integration for e-CRM projects contributes to a better understanding of the customer and leads to higher ROI, a greater number of benefits, improved user satisfaction, and a greater chance of attaining a competitive advantage. Thus, when all else is equal, a company's total value increases when a company integrates data from online, off-line, and external sources. We hope that our empirical research and findings can assist practitioners and managers in identifying more efficient and effective ways of creating CRM value through customer data integration.

KEY TERMS

CDI (Customer Data Integration): The people, processes, and technologies required to create and maintain a unique, complete, and accurate customer profile and make it available to all operational systems.

CQL (Continuous Query Language): An expressive SQL-based declarative language developed by Stanford University's STREAM project for registering continuous queries against data streams.

CRM (Customer Relationship Management): The technology, services, and processes that connect an organization with its customers in the most reliable, efficient, and cost-effective manner while striving to create long-term, profitable relationships.

E-CRM (Electronic CRM): A subset of CRM that focuses on acquiring a thorough understanding of an organization's online (via the Internet) visitors and customers to create and maintain online loyalty.

E-CRM Analytics: The process of analyzing and reporting online visitor and customer behavior patterns with the objective of acquiring and retaining customers.

Moore's Law: The prediction by Intel cofounder Gordon E. Moore that the number of transistors on a microprocessor would double approximately every 24 months. To date, Moore's law has proven remarkably accurate.

ODM (Organizational Data Mining): The process of leveraging data mining tools and technologies in an organizational setting to enhance the decision-making process by transforming data into valuable and actionable knowledge to gain a competitive advantage.

Location Management and Mobility Modeling in Wireless Systems

Wenye Wang
North Carolina State University, USA

INTRODUCTION

One of the most salient features of wireless communications is that users can deploy a variety of wireless devices to communicate with others, regardless of their locations. Although mobility support provides flexibility and convenience, it introduces many challenging issues to network design, planning, and performance evaluation. With the increasing demand for multimedia applications, location-aware services, and system capacity, many recognize that modeling and management of location and mobility are becoming critical to locating mobile objects in wireless information networks. *Location management* and *mobility modeling* strongly influence the choice and performance of mobility and resource management algorithms, such as routing, handoff, and call admission control in many types of wireless networks. For these reasons, it is important to understand mobility modeling and location management mechanisms and the manner in which these mechanisms depend on the characteristics of mobile environments. This article is concerned with issues in, and methods for, location management and mobility modeling in wireless data networks.

The most distinguished features of next generation *wireless systems* can be highlighted as reliable *quality of service (QoS)* for various applications and global roaming. Since the intrinsic characteristic of mobile communications is mobility support, wireless systems must be able to locate roaming *mobile terminals (MTs)* at any time to deliver services and to maintain connections, as the MTs move from one service area to another. Location management techniques enable mobile users to move around, even between different systems with dissimilar signaling formats and protocols, while simultaneously offering them incoming calls and maintaining services in progress. Therefore, the objective of mobility modeling is to estimate the current and future locations of a mobile user upon the arrival of a connection request, which involves many parameters, such as moving speed, call duration time, distance between the last known position and destination, and geographical conditions. Location management, however, deals with the problem of how to register or update new location of a mobile user with a wireless system, and how to locate a mobile terminal given the information in system databases.

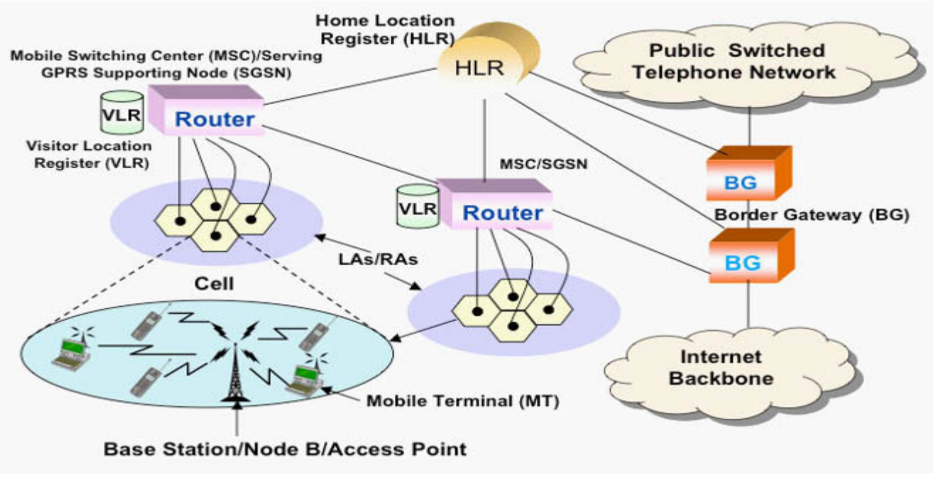
BACKGROUND

System Architecture and Problem Description

In wireless networks, each base station (BS) handles incoming and outgoing connection requests from mobile users residing within its coverage, or radio cell. A cluster of cells can be grouped together, controlled by a mobile switching center (MSC) or a serving GPRS supporting node (SGSN) in *cellular networks* such as *Universal Mobile Telecommunication System (UMTS)*. These MSCs and SGSNs are usually interconnected by wires for high-speed data transmission. The geographic coverage of a group of cells, which is also the area in the control of an MSC, is called a "location area" (LA). In wireless networks, it is very important to maintain the latest location information of each MT in the system so that a connection can be established when an incoming or an outgoing service request is received. However, mobile users change their positions over time. The identity of mobile users and their billing information are stored in a centralized database, a home location register (HLR). When an MT moves into a different region network, it must update or register with a local database, a visitor location register (VLR). In other words, the VLR in a visiting network keeps the most recent location information of a mobile user, and it will communicate with the HLR to renew location information (see Figure 1).

Location management is a technique that updates the location of MTs during the course of their movement and determines the locations of MTs for call delivery. In particular, it includes two phases: location update and *paging*. During location update or location registration, mobile terminals send location update requests to an MSC to establish or refresh their locations information in VLRs. For paging and call delivery, the system needs to search for the called MTs for message delivery. Location update and paging involve algorithms or strategies to send loca-

Figure 1. Network architecture



tion update messages and to find MTs based on known information in network databases; whereas, location registration and call delivery are related to the procedures and signaling messages.

Basic Location Update and Paging Algorithms in Cellular Networks

Location management is a two-stage process that allows wireless systems to discover the current attachment point of a mobile user for call delivery. The first stage is *location update,* or *registration*. In this stage, an MT periodically notifies a network of its new access point, allowing the network to authenticate an MT's identity and revise the user's location profile. The second stage of location management is *paging,* during which the network is queried for the user location profile so that the current position of a called MT can be found (Akyildiz et al., 1999).

The service area of a network is often divided into several LAs so that the MT informs the network when it enters a new LA by monitoring the LA identification (LAI) through public broadcast channels. Usually, MTs send location update requests when they move from one LA to another. With location update/registration, the network is able to keep track of MTs in a specific region constrained by the distance, time, or movement. An LA can be determined by retrieving an MT's record in the HLR; thus, an MT's current residing cell can be found by sending a polling message to all BSs encompassed in an LA. When an incoming call arrives, the MSC, which is associated with the LA of an MT's last registration, sends a paging message via the paging channel to the BSs with the called MT's ID. The serving BS of MT then responds to the network. As a result, the network knows in which cell an MT is residing, and an incoming call can be delivered to the MT.

In current personal communication service (PCS) systems, paging is a fundamental operation for locating an MT. As the demand for wireless services grows rapidly, the signal traffic caused by paging increases accordingly, consuming limited radio resources. In a paging process, a wireless system searches for an MT by sending poll messages to the cells close to the last reported location of the MT at the arrival of an incoming call. Delays and costs are two key factors in the paging issue (Rose & Yates, 1995; Wang Akyilidz, Stüber, & Chung, 2001). Of the two factors, *paging delay* is critical to reducing setup relay of service delivery. *Paging cost*, which is measured in terms of cells to be polled before the called MT is found, is related to the efficiency of bandwidth utilization and should be minimized under delay constraint. Many paging schemes have been proposed to resolve this conflict (Akyildiz, Xie, & Mohanty, 2004).

Mobility Modeling

A variety of mobility models exist that can find applications in different kinds of wireless networks. Because mobility models are designed to mimic the movement of mobile users in real life, many parameters need to be considered. Most of the existing mobility models describe the behaviors of mobile terminals without considering previous records. In this context, we will focus on this type of mobility model and so-called synthetic models, and we will introduce several developments that take traces or profiles into account and combinational models.

Mobility models can be categorized into different groups based on the following criteria (Bai & Helmy, 2004; Camp, Boleng, & Davies, 2002; Hong, Gerla, Pei, & Chiang, 1999; McGuire & Plataniotis, 2003):

- **Dimension:** The movement of MTs can be described in one, two, and three dimensions.
- **Scale of Mobility:** Different level of details may be used to describe a movement, including micromobility (i.e., small scale, and macromobility, such as moving from one system to another).
- **Randomness:** It depends on many unpredictable factors, such as direction, speed, and residence time in a certain area, like a cell (Nain, Towsley, Liu, & Liu, 2005).
- **Geographical Constraints:** Mobility models can be very specific for particular scenarios.
- **Destination Oriented:** Some mobility models are developed to track or describe the route or the path of a movement. For example, if it is known that a mobile user will go to a particular location, it is very likely to estimate the position and the time of his or her traveling.

It is worth mentioning that there are many mobility models, which are derived from the abovementioned models. Also, there are some hybrid models that combine two or more attributes in different models (Lin, Noubi, & Rajaraman, 2004). Several commonly used mobility models will be introduced in this article by describing their motivations, representations, and applications.

CHALLENGES AND NEW ADVANCES IN LOCATION MANAGEMENT AND MOBILITY MODELING

Dynamic Location Update and Delay-Constrained Paging

The standard LA-based location update method does not allow adaptation to the mobility characteristics of the MTs. Therefore, in recent years, there have been many efforts in designing dynamic location update and paging algorithms which take into account user mobility and optimize the total signaling cost of location update and paging. For instance, an MT can update its location or send a location registration request to a wireless network based on the distance between its current location and previous position from which the previous request is sent, which is referred to as *distance-based* location update scheme (Akyildiz, Ho, & Lin, 1996; Liang & Hass, 1999).

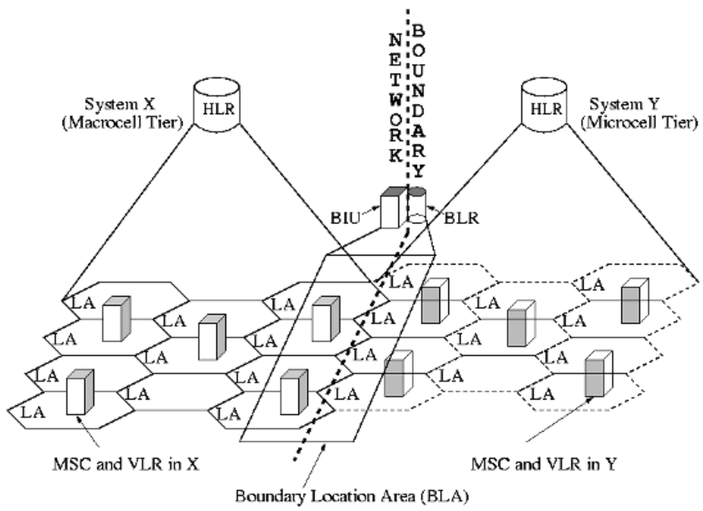
Moreover, an MT can send a registration request upon a predefined timer (i.e., an MT's location information is updated whenever a timer is expired), which was called a "time-based" scheme (Tabbane, 1997). Another location update scheme—a movement-based scheme—in which an MT performs a location update when the number of movements since the last location registration equals to a predefined threshold—a movement threshold. These schemes are aimed at designing location areas so that the total signaling overhead of location update and paging can be reduced. Considering that moving patterns differ from one use to another, some dynamic location management schemes, or mobility-based schemes, are designed based on the mobility scale. For example, location areas can also be designed based on mobility patterns in which a mobile terminal carried by a pedestrian can register its location at a small LA and can register at a large LA when that pedestrian enters a taxi, automobile, or other vehicle. The large LAs are at higher levels of the system's registration hierarchy and small LAs are at lower registration levels. Smaller LAs may consist of clusters of microcells, while larger LAs may be formed by clusters of macrocells or spot beams. The location updating rate tends to remain fixed over a wide range of terminal mobility, which is effective in avoiding excessive location updating signaling traffic (Lin & Park, 1997).

Intersystem Location Update and Paging

Diverse mobile services have stimulated an enormous number of people to deploy mobile devices, such as cellular phones and portable laptops, as their communications means for high-quality services. This demands developing effective techniques to locate and trace mobile users in order to deliver services with minimum overhead in terms of resource consumption and processing latency. Efficient location management techniques for intersystem roaming, which consists of location update/registration and paging, thus have become one of the most challenging issues for next generation wireless systems as the number of mobile users, different types of handsets, and various technologies increases (Akyildiz & Wang, 2002). As shown in Figure 2, there are two systems that may use different protocols, such as personal communication service (PCS) systems in the macrocell tier and Wi-Fi systems in the microcell tier. Each hexagon represents a location area (LA) within a stand-alone system, and each LA is composed of a cluster of microcells. The terminals are required to update their location information with the system whenever they enter a new LA; thus, the system knows the residing LA of a terminal all the time. In the macrocell tier, there may be different systems, such Global System of Mobile Communication (GSM) and Universal Mobile Telecommunication System (UMTS), in which one LA can be one macrocell.

The intersystem location update is concerned with updating the location information of an MT performing

Figure 2. Intersystem roaming: Boundary location area (BLA) and boundary location register (BLR)



intersystem roaming. The intersystem paging is concerned with searching for a called terminal roaming between different service areas. The goal of intersystem location management is to reduce signaling cost while maintaining QoS requirements. For example, reducing call loss is one of the key issues in maintaining connections of ongoing calls; decreasing paging delay is critical to reducing call set-up time. For intersystem location update, we consider a boundary region called *boundary location area* (BLA) that exists at the boundary between two systems in different tiers. As illustrated in Figure 2, systems X and Y are in the macrocell and microcell tiers, respectively. There is a home location register (HLR) for each system, and a user is permanently associated with an HLR in his or her subscribed system. The BLA is controlled by a boundary interworking unit (BIU), which is connected to MSC/SSGN in both systems. The BIU is responsible for retrieving a user's service information and transforming message formats. Also, the BIU is assumed to handle some other issues such as air interface conversion and authentication of mobile users. In addition to the concept of BLA, we designate a *boundary location register* (BLR) to be embedded in the BIU. A BLR is a database cache to maintain the roaming information of MTs moving between different systems. The roaming information of mobile terminals is captured when MTs request location registration in the BLA.

Delay-Constrained Paging Algorithms

In future wireless networks, many applications of multimedia services will have various QoS requirements, including delay, transmission rate, pricing models, and so on. As the demand for wireless services, such as e-mail, e-transactions, and Web-browse grows rapidly, the signaling traffic caused by location *tracking* increases accordingly, which consumes limited available radio resources. To improve the efficiency of bandwidth utilization, location tracking optimization cost under delay constraints is explored, which is based on a time-varying probability distribution on user location (Akyildiz et al., 2004; Fang, Chlamtac, & Lin, 2000; Hellebrandt & Mathar, 1999). The probability distribution of user location depends on factors such as mobility model, calling pattern, and so forth. In order to estimate these probabilities, many tracking schemes are designed to predict cell location probabilities and to estimate the next location of an MT accurately.

One approach to solving the optimal paging problem is to design an optimal searching sequence for polling the probable locations of a called MT, which is aimed at minimizing the signaling cost of paging under time constraint (Rose & Yates, 1995). Another method, which is independent of location probability distributions of mobile users, is proposed to satisfy delay constraint while minimizing the amount of bandwidth used for locating a mobile user (Wang et al., 2001). In this method, cells are grouped by an optimal partition algorithm and a detailed paging procedure is designed for implementations in real systems.

The mobility management issue, which is related to how to keep records of mobile users and how to utilize location information for service delivery, was discussed in this section. In the following section, mobility models that describe the movements of each mobile terminal in wireless networks are introduced.

L

Mobility Modeling

A simple but commonly used mobility model is called the "fluid-flow mobility model," which is derived from Brownian motion with a drift model (Camp et al., 2002). In this mobility model, moving direction, which can be of any direction available, is not considered. Depending on the selection or constraint of velocity, moving direction, and acceleration speed, many other mobility models are developed for different application scenarios (Mark & Zhuang, 2003). In this model, for example, mobile terminals are assumed to be uniformly distributed in the cell, and the movements of mobile users are not correlated. Moreover, the directions of these movements are uniformly distributed on $[0, 2\pi]$.

Although the fluid-flow model can describe the positions of mobile users statistically, it cannot demonstrate details of a movement. Thus, another model, the random-walk model, is developed for such an environment in which there are many entities moving in random directions with unpredictable speed. In this model, a mobile object travels from one location to a new location by randomly choosing a direction and speed. The speed is considered in a range, and the direction is chosen between $[0, 2\pi]$. In simulation, the movement is often observed in a simulation region. If a mobile terminal reaches the boundary of the simulated region, it will be "absorbed" or "bounced" off. The random walk model is basically a memoryless pattern, because it does not consider previous locations and speed values. The only factor that influences future locations and speed is the current status. There are many derivatives of random-walk models, which have been widely used in the design of wireless networks, especially for microcell or picocell systems in which moving users can freely move to neighboring cells.

The two previously described mobility models intend to represent the behaviors of mobile objects without using mobility trace files. However, because mobility trace files are mobile users' records observed in real environments, they can be used to describe moving behaviors in the real world. Toward this end, a combinational model is proposed to characterize different scales of mobility based on synthetic model and empirical results (Brown & Mohanl, 1997). This model consists of micro- and macromovements. At the micro level, it is assumed that the mobile objects move around in the vicinity of their current locations or frequently visited places, such as home and office; this micromobility is described by a random-walk model. At the macrolevel, mobile users move toward a remote destination that is based on their historical records in a wireless system.

A relatively new model, the random waypoint model, is a commonly used mobility model for simulations in wireless networks, especially for ad hoc networks (Bettstetter, Hartenstein, & Perez-Costa, 2003; Camp et al., 2002; Lin et al., 2004). A mobile node in a given simulation area randomly chooses a destination point (i.e., the "waypoint") and moves with a constant speed on a straight line to this point. After it reaches a waypoint, the mobile node will pause for a certain period of time (the "pause time") and change its speed or moving direction. It then chooses a new destination and speed and moves at constant speed to this destination, and so forth. Observing that fluid-flow models and random mobility models are memoryless models, they are not suitable to describe a movement realistically, because, in reality, a mobile user's current speed and location are correlated with their previous speed and directions. Therefore, a Gaussian-Markov model is proposed to capture the correlation of a mobile's velocity in time, in which a mobile user's current speed depends on its previous speed, with a Gaussian distribution (Liang & Hass, 1999). The Gaussian-Markov model has been used in the research of cellular networks and mobile ad hoc networks, as well.

The design a of mobility model is to accurately describe the movement pattern of a mobile object, which is random in dynamic mobile environments. The mobility models discussed can be applied in different scenarios. In

FUTURE TRENDS

Location management and mobility modeling are two major issues in supporting high-speed, real-time applica-

Table 1. Comparison of mobility models. (Their applications are marked with "x".)

	Indoor Environment	Outdoor Environment	Infrastucture (I)/ Ad hoc (A)

Random Waypoint	x	x	A
Gaussian-Markov		x	I & A

tions over wireless networks, which are of particular importance to e-mobile commerce. As more and more people are concerned with security transactions using mobile devices, location management mechanisms need to be incorporated with authentication, authorization, and accounting. In addition, to protect privacy such as user locations, it is necessary to balance the tradeoff between service satisfaction and security functions since these two requirements, in many cases, are contradictory. Meanwhile, mobility modeling will continue to be a research topic as more realistic factors are taken into account, in addition to the measurements of mobility patterns in campus or test-bed networks.

CONCLUSION

There are many challenging issues in the area of information technology, in particular, incorporating wireless systems in backbone networks for providing ubiquitous services. In this article, an overview of location management and mobility modeling in wireless networks is presented, which includes a brief introduction of the issues, current solutions, and advanced research.

KEY TERMS

Location Management: A technique that updates the location of mobile users during the course of their movement and determines the locations of mobile users for call delivery.

Location Registration: Mobile users update their location information with a wireless system.

Mobile Users: Customers who use wireless devices.

Mobility Management: A technique that maintains wireless communications of mobile users.

Mobility Models: To describe user movement in wireless networks.

Paging: A technique to locate mobile users in wireless systems.

Quality of Service: Parameters to describe system performance.

Wireless System: A system that provides service through wireless channels.

Location–Based Services in the Mobile Communications Industry

Christopher Ververidis
Athens University of Economics and Business, Greece

George C. Polyzos
Athens University of Economics and Business, Greece

INTRODUCTION

Advances in wireless communications and information technology have made the mobile Web a reality. The mobile Web is the response to the need for anytime, anywhere access to information and services. Many wireless applications have already been deployed and are available to customers via their mobile phones and wirelessly connected PDAs (personal digital assistants). However, developing the "killer" wireless application is still a goal for the industry rather than a reality. One direction for developing such applications points to location-based services (LBSs). LBSs are services that are enhanced with and depend on information about a mobile station's position. Location information by itself is not the ultimate service, but if location information is combined with content, useful services may be developed. These services offer the capability to users and machines to locate persons, vehicles, machines, and resources, as well as the possibility for users to track their own locations (GSM Association, 2003). The focus of this article is the analysis of the most critical success factors and challenges for LBS.

BACKGROUND

In order to show the domains on which LBS may have an impact, a list with the LBS categories, as defined by the Third-Generation Partnership Project (3GPPP, 2004), is presented in Table 1. Also, based on the information-delivery method, we identify three types of LBS: pull, push, and tracking services (GSM Association, 2003). In the case of a pull service, the user issues a request in order

Table 1. Standardized LBS types and corresponding application domains

Application Domain	Standardized LBS Types
Public Safety Services	Emergency Services Emergency Alert Services
Tracking Services	Person Tracking Fleet Management. Asset Management
Traffic Monitoring	Traffic Congestion Reporting
Enhanced Call Routing	Roadside Assistance Routing to Nearest Commercial Enterprise
Location Based Information Services	Traffic and public transportation information City Sightseeing Localized Advertising Mobile Yellow Pages Weather Asset and Service Finding
Entertainment and Community Services	Gaming Find Your Friend Dating Chatting Route Finding Where-am-I
Location Sensitive Charging	
Service Provider Specific Services	

to be automatically positioned and to access the LBS he or she wants. A use-case scenario demonstrating a pull service used broadly in the LBS literature (Poslad, Laamanen, Malaka, Nick, Buckle, & Zipf, 2001; Zipf, 2002) is the following. A tourist roams in a foreign city and wants to receive information about the nearest restaurants to his or her current location. Using a mobile device, the tourist issues an appropriate request (e.g., via SMS [short messaging service] or WAP [wireless application protocol]), and the network locates his or her current position and responds with a list of restaurants located near it. On the contrary, in the case of a push service, the request is issued by the service provider and not the user. A representative example of push services is location-based advertising, which informs users about products of their interest located at nearby stores. In this service, users submit their shopping-preference profiles to the service provider and allow the provider to locate and contact them with advertisements, discounts, and/or e-coupons for products of interest at nearby stores. So, in this case, the service provider is the one who pushes information to the user. Finally, in a tracking service, the basic idea is that someone (user or service) issues a request to locate other mobile stations (users, vehicles, fleets, etc.).

From a technological point of view, LBSs are split into two major categories depending on the positioning approach they use to locate mobile stations. There is the handset-based approach and the network-based approach. The former approach requires the mobile device to actively participate in the determination of its position, while the latter relies solely on the positioning capabilities of elements belonging to the mobile network. For both of these approaches, several positioning techniques have been developed or are under development. What distinguish them from one another are the accuracy they provide and the cost of their implementation. The most popular network-based positioning techniques are cell-global-identity (CGI) methods, timing advance (TA), uplink time of arrival (TOA), and angle of arrival (AOA), while the most popular handset-based positioning techniques are observed time difference of arrival (OTDOA), enhanced observed time difference (E-OTD), and assisted Global Positioning System (A-GPS; Drane, Macnaughtan, & Scott, 1998; Swedberg, 1999). The accuracy provided by some of these techniques in different coverage areas of the mobile network is presented in Table 2.

In order to understand the emergence of LBS, one has to identify the major forces that brought to the surface the need for this kind of services. There exist four major forces, namely, market forces, competition forces, technology forces, and regulatory forces. Each of them is briefly discussed in the following paragraphs.

Market Forces

Market research around the globe has documented the willingness of mobile subscribers to pay for LBS. The LBS subscriber base is forecast to reach 680 million customers globally by 2006. Predictions are that LBS will generate over $32 billion in Europe only by 2005. Numerous firms have already emerged to tap into this growing opportunity (Rao & Minakakis, 2003).

Competition Forces

Having established large customer bases, cellular-service providers will seek new ways to ensure customer loyalty by offering new types of services. Location-based services are the most promising type of these services (called value-added services). Some of the advantages for the cellular-service provider who offers location-based services are the following.

Table 2. Positioning accuracies

	CGI	E-OTD
Rural Area	1km – 35km	100m – 300m
Suburban Area	1km – 10km	50m – 150m
Urban Area	100m – 1km	50m – 150m
Dense Urban Area	100m – 1km	50m – 150m
	CGI-TA	**A-GPS**
Rural Area	550m	50m – 100m
Suburban Area	550m	30m – 100m
Urban Area	100m – 550m	10m – 20m
Dense Urban Area	100m – 550m	10m – 20m
	E-CGI	**TOA**
Rural Area	250m – 8km	85m - 100m
Suburban Area	250m – 2.5km	30m - 75m
Urban Area	50m – 550m	25m - 70m
Indoor Urban Area	50m – 550m	25m - 70m

- Innovative service provision attracts new customers and enhances existing customers' loyalty to the provider.
- Revenues increase due to the traffic generated by the use of such services.
- There is the capability to introduce new revenue streams through deals with third-party companies (that specialize in LBS implementation and/or provision) in order to sell to these companies user location information.

Technology Forces

The first location-based services are expected to be offered or are already offered to mobile-phone users via WAP, SMS, or MMS (multimedia messaging service). Every mobile phone supports the SMS feature and most of them also support WAP and MMS. The cost for such a phone is negligible nowadays. This means that many customers can instantly make use of the location services provided. In addition, the evolution from GSM (global system for mobile commications) to general packet radio service (GPRS), which means a significant increase in the available bandwidth for data communication over mobile phones (from 9.6 Kbps to over 115 Kbps), also assists the provision of LBS, which in many cases can be bandwidth demanding (not to mention the introduction of UMTS [universal mobile telecommunications system] networks in many countries). Finally, new types of phones such as media phones and "communicators" have already entered the market, giving greater capabilities for displaying information (e.g., user interfaces enhanced with photos, buttons, etc., not only text based).

Regulatory Forces

In the USA, the Federal Communications Commission has issued a directive requiring the identification of the geographical origin of an emergency call made by a mobile-phone user. According to this directive, operators should be able to provide location information for every mobile subscriber who makes an emergency call with an accuracy of 100 m 67% of the time (GSM Association Services Expert Rapporteur Group [ASERG], 2000). A similar directive has been released for the European Union.

SUCCESS FACTORS AND RESEARCH CHALLENGES IN LBS

Despite the appealing idea of using user location information to provide highly personalized and intelligent services, there are certain challenges that should be addressed in order for LBS to succeed. We can divide these challenges into three categories, namely, technological challenges, ethical challenges, and business challenges.

The main technological challenge for LBS is the capability to create easy-to-use and satisfying services. There is much talk concerning what would be the most suitable user interface and type of service (pull or push) in terms of user satisfaction. For example, in the case of push-based services, a user is not required to manually issue queries in order to get the information he or she seeks. The system automatically informs him or her based on the current location and a list of preferences listed in the user's profile. The problem is that in this way, user intent cannot be perfectly captured and the user may be frequently disturbed by out-of-context information. So, despite the easiness of usage (no or minimal interface), user satisfaction is not assured. On the other hand, in pull-based LBS, in which clients have to poll the server for updates, the users may experience difficulties in using these services because cell phones, PDAs, and wearable computers are less suitable for browsing and query-based information retrieval due to their limited input-device capabilities (Burcea & Jacobsen, 2003). All these restrictions along with the unpredictability in mobile environments (disconnections, frequent context differentiations, etc.) have to be taken very carefully into account when designing LBSs. Some of the implied requirements, as identified in Tsalgatidou, Veijalainen, Markkula, Katasonov, and Hadjiefthymiades (2003), are the following:

- A less intensive use of the mobile network and a minimal volume of transmitted data;
- The possibility of off-line operation;
- Simple and user-friendly interfaces, and limited and well-specified amounts of presented information content.

Therefore, it becomes apparent that LBS will not succeed in attracting users without implementing sophisticated techniques based on carefully designed interfaces and/or detailed knowledge of customer profiles, needs, and preferences. So, given existing technical limitations such as device capabilities, access speeds, and so forth combined with human limitations such as reduced consideration sets and the need for speed and convenience, in order for LBSs to succeed, they will need to deliver relevant, targeted, and timely information to consumers at the time and place of their choice (Rao & Minakakis, 2004).

Also, from a database perspective, LBSs raise critical challenges such as spatial and temporal query processing because the continuous movement of users or objects leads to the need for fast and frequent or continuous updates to the databases. Some of the most important database research challenges brought to the surface by LBS, as identified by Jensen, Friis-Christensen, Pedersen, Pfoser, Saltenis, and Tryfona (2001) and Saltenis and Jensen (2002), are the following.

- **Support for Nonstandard-Dimension Hierarchies:** In LBS, the geographical area may be divided into multidimensional regions following the pattern of network coverage. Until now, geographical-area representation models used by data warehouses were in the form of completely balanced trees (strict hierarchies), which cannot capture irregularities like those that frequently occur in mobile networks (e.g., the same region covered by more than one base station).
- **Support for Imprecision and Varying Precision:** Varying precision means that the location of the same user may be pinpointed with different accuracies depending on the positioning technology used while he or she is roaming from network to network. Imprecision means that the location data for the trace of a specific user may be incomplete (e.g., a user may have gone out of the network coverage or may have switched off the device for some time). So, varying precision and imprecision should be carefully handled by employing intelligent query-processing techniques, especially for queries on complete user traces.
- **Support for Movement Constraints and Transportation Networks:** Most of the time, users move on certain routes as defined by transportation networks (e.g., railways, roads, etc.) and their movement is blocked depending on the morphology of the land (e.g., mountains). The incorporation of such constraints in query resolution may offer increased positioning accuracy to LBS despite the potentially low-accuracy positioning technology used.
- **Support for Spatial Data Mining on Vehicle Movement**
- **Support for Continuous Location Change in Query-Processing Techniques**

From an ethical point of view, a critical challenge is to protect user privacy. LBS can potentially intrude on customer privacy. The adoption of LBS is highly dependent on the successful confrontation of digital frauds, attempts of intrusion in customer databases with sensitive data and profiles, and the threat of unauthorized or uncontrolled resale of location information. As underlined in Rao and Minakakis (2003, p. 63), "LBS providers must alleviate consumer privacy fears by implementing secure network and encryption technologies to curb illegal activity and by developing clear communication strategies to interact with customers and allay their fears." It has also been shown that a privacy-intruding service (for example, an always-on tracking service), despite its usability, is not desirable by users since it does not allow them to switch it off whenever they want (Barkhuus & Dey, 2003). So when designing an LBS and in order for the service to be adopted, the provider should take into account very seriously the user's concerns on privacy.

From the point of view of the regulator of the telecommunications market, new laws have to be implemented. In order to protect user privacy, there are certain laws in the United States (Wireless Communications and Public Safety Act of 1999) and the European Union (Personal Data Processing and the Protection of Privacy in the Telecommunications Sector, 97/66/EU Directive) with direct references to the way location data should be handled. However, these laws have certain deficiencies and shortcomings, and there are ongoing efforts to achieve full legislative coverage of the LBS sector.

Finally, capitalizing on the promise of LBS requires developing sustainable and viable business models for offering such services. Unfortunately, until today there has been little effort on developing a framework with which to identify the most appropriate business models for the large variety of LBSs. The major obstacle for this arises from the fact that there is a multitude of players participating in the provision of such services forming a complex value network. The main categories under which these players are grouped are the following:

- Application developers and content providers;
- Service providers and network providers;
- Hardware manufacturers.

The roles of all these different actors or players are many times conflicting if not competitive, and fairness in revenue sharing is viewed differently buy each actor. In this context, it is difficult to determine which activities should be performed by which actor (e.g., should the network operator develop its own services or outsource them to more focused application providers) or to identify which actor should be the dominant one in the business model (i.e., the operator providing access to its customer base, the content or service provider offering the actual service, or the location-technology vendor offering the enabling positioning equipment).

FUTURE TRENDS

In the new era of 2.5G, 3G, and 4G, location-based services have been recognized as one of the fastest growing areas for novel service provision in the telecommunications sector with great revenue potential. What differentiates them from traditional services is their ability to offer highly personalized, context–sensitive, and timely information to users anytime, anywhere. However, they have not yet matured enough in order to provide the so-much-anticipated killer application mainly due to technical, business, and ethical challenges that have not yet been adequately addressed. All the participants in the LBS-provision market should first understand and fix their roles within the value chain, then provide the essential guarantees for protecting user privacy, and finally develop new, intelligent ways to manipulate and present location information in order to increase user convenience and satisfaction.

CONCLUSION

We have discussed several aspects of the role of LBS in today's wireless industry. We primarily focused on technological, ethical, and business challenges imposed by LBS and provided directions for further research. User privacy protection, easy-to-use and context-aware service interfaces, sophisticated geospatial-data management techniques, and flexible business models have been identified as the most critical issues that the LBS industry should pay particular attention to in order for LBS to become a success.

KEY TERMS

A-GPS: The assisted Global Positioning System uses measurements from fixed GPS receivers scattered throughout the mobile network in order to assist a mobile phone in locating the available satellites and calculating its location.

AOA: The angle-of-arrival method measures the angle of a signal arriving at the antenna of a base station. The intersection of the projection of two calculated angles (from the antennas of two base stations) on the two-dimensional space reveals the location of the mobile phone.

CGI: Each base station in a cellular network has a unique ID that the mobile phone receives when entering the area of the base station. Cell global identity uses this unique ID in order to pinpoint the base station's area of coverage in which the mobile phone is located.

CGI-TA: Cell global identity with timing advance is a positioning method that uses the time needed for a signal to travel from the mobile phone to the base station to compute the distance between the phone and the mobile station. Along with the base station's ID, this method provides a rough estimation of the position of the phone in the base station's area of coverage.

E-OTD: The enhanced observed-time-difference method is similar to OTDOA without the need for base stations to be synchronized (additional elements are used that measure the real-time differences between base stations to correct the measurements).

MMS: The multimedia messaging service is a service giving the capability to a mobile-phone user to send a message containing any combination of images, video clips, text, and audio to another user.

OTDOA: Observed time difference of arrival is an alternative for the TOA method in which the mobile phone measures the time differences between signals from three or more base stations.

PDA: A personal digital assistant is a small, palm-sized mobile device with increased processing and viewing capabilities.

SMS: The short messaging service is a service giving the capability to a mobile-phone user to send a text message to another user.

TOA: The time-of-arrival positioning method is based on measuring the time needed by a signal transmitted by a mobile phone to reach three or more location-measurement units (LMUs). From these measurements, the distance between the phone and the LMU can be calculated as the radius of a circle with the LMU as its center. The intersection of three or more such circles gives the actual position of the mobile phone.

WAP: The wireless application protocol is a protocol for providing Internet-connectivity access to thin-client devices, such as mobile phones.

Managing Advergames

Călin Gurău
Groupe Sup. de Co. Montpellier, France

INTRODUCTION

Advergames have been defined as online games that incorporate marketing content (Dobrow, 2004). They are *interactive* games that are centered around a brand, a product, or a character associated with a brand or a product. The game can be used to demonstrate the use of a product or to associate the product with an activity or a lifestyle.

Studies conducted in the U.S. have discovered that games are extremely popular among all categories of online users. A study conducted by Jupiter Media found that in December 2003, 84.6 million people visited online gaming sites (D5 Games, 2004a). This number is projected to reach 104 million by 2007.

The preconception that only kids or teenagers are interested in *interactive* games is contradicted by findings: in the U.S., 66% of the most frequent game players are over 18 years old, and 40% of them over 35 years old, the average age of a player being 28 year old (D5 Games, 2004a). Another study conducted during December 2003-January 2004 in the U.S. has identified women over 40 years old as a major segment interested in online gaming (Arkadium, 2004)—they spend 9.1 hours per week playing games or 41% of their online time in comparison with only 6.1 hours per week, or 26% of their online time for men.

These data demonstrate the huge potential of *advergames* (Rodgers, 2004; Sennott, 2004). However, despite the hype created by this new *advertising* method, most of the information presenting advergames is professionally-oriented (DeCollibus, 2002; D5 Games, 2004b; Hartsock, 2004). Very few academic studies have been initiated to investigate the characteristics of advergames, and their influence on *consumers' perceptions* and *behavior* (Hernandez, Chapa, Minor, Maldonaldo, & Barranzuela, 2004; Nelson, 2002).

This article attempts to identify, based on the existent professional literature, the specific characteristics of an efficient advergame, and to verify the influence of advergames on players' behaviour. Therefore, the research objectives of this study are the following:

1. To present the potential of advergames.
2. To discuss the theories explaining the effect of advergames on consumers' perceptions and behaviour.
3. To analyze the influence of advergames on consumers' behaviour, using the empirical data collected through an experimental research project.

The following section of this article presents the main characteristics of advergames. Section 3 opens a theoretical debate regarding the mechanism of action of advergames on consumers' perceptions and behaviour, based on the "state of flow" and the AIDA models. The effect of advergames is empirically investigated in Section 4, which presents the results of a survey conducted in Montpellier Business School, France. The article concludes with an overview of the study and with proposition for future research.

DESCRIPTION OF ADVERGAMES

The interest in *advergames* has substantially increased in the last five years, because of its perceived advantages (FreshGames, 2002; WebResource, 2004):

- Low-cost marketing in comparison with the traditional *advertising* channels, such as TV and radio;
- A captured audience that can transmit valuable personal information about their demographic profile, behaviour, needs, attitudes and preferences;
- Customer retention: the average time spent in an advergame is 7 to 30 minutes, which cannot be reached for a classical TV advertisement.
- Viral marketing: 81% of the players will e-mail their friends to try a good game.

The advergames industry is using the format of classical computer games: the Internet user is able to access a set of instructions that describe the game, the main commands and the tastes that activate them, and then he/she is invited to start playing. Although the advergames are free, some games require registration, the data introduced by the player providing important information about the profile of the audience. Depending on their complexity, the advergames can have one or more game levels, and can be played alone or together with other participants. The score is displayed on the screen, and, in line with the viral aspect of advergames, the players are often encouraged to send information about the game to their friend and relatives, an e-mail facility being offered for this purpose. In order to increase the motivation of players, some advergames promise gifts, prizes, or promotional incentives to the best scorer(s).

The companies specialized in creating advergames have identified and presented the characteristics of an efficient advergame (D5 Games, 2004b):

- Accessible to all users, and especially to non-gamers;
- Immersive and engrossing—it should capture and hold player's attention for 5 to 30 minutes;
- Easy to understand, but challenging;
- Competitive—encouraging repeated visits;
- Relevant for the firm/brand/product that is advertised;
- Viral—to encourage communication with friends or family.

An advergame can be designed and used for various reasons, such as:

- To increase the notoriety of a firm, a brand or a product;
- To associate positive emotions with a firm, a brand or a product;
- To initiate an action of *viral marketing*;
- To introduce and facilitate a promotional campaign;
- To induce the purchasing behaviour, and therefore to increase the volume of sales; or
- All of the above.

As any other marketing communication tools, the advergame characteristics will have to correspond to: (1) the personality of the advertised brand, (2) the profile of the targeted audience, (3) the characteristics of the medium—in this case the Internet, and (4) the strategic objectives of the communication campaign.

The difficulty to concomitantly evaluate these complex variables is probably the reason for a low rationalization of the advergame development in the professional literature. The creation of an efficient advergame is still considered predominantly as a creative work, that it is difficult to describe in a formal, precise manner.

THE INFLUENCE OF ADVERGAMES ON CONSUMER PERCEPTIONS AND BEHAVIOUR

The placement of products or brand names in movies or TV shows is a relatively old technique, but the studies regarding their influence on *consumer perceptions* and *behaviour* are inconclusive (Gould, Pola, & Grabner-Krauter, 2000; Russell, 2002). The advergames present a few distinct characteristics that can eventually enhance their marketing effect:

- The advergames are selected by the player himself/herself, and are not forced upon an unwilling viewer;
- The player interacts with advergames adopting an active stance, in comparison with the passive attitude of the TV audience;
- Advergames incite the players to share the gaming experience with their friends or family.

From a marketing point of view, the advergames attempt to capture the attention of players, and then to transmit to them, in an indirect way, suggestions that aim to modify their *perceptions* regarding an enterprise, brand, or product.

The psychological fundament of this process is the inducement of the "state of flow". This concept is used by psychologists to describe a mental state in which attention is highly concentrated on a specific process, the environmental information is screened out, and the person experiences a harmonious flow of present experience (Csikszentmihalyi, 1991). The *state of flow* is known to create a state of well being, as well as increased perception and learning capacity.

The state of flow can be induced by any activity that is very interesting for a person: watching a movie, reading a book, or playing a game. The ludic activity is considered as one of the best inducers of the flow state for children, and often also for adults.

The interaction with Internet applications can also induce the state of flow in specific circumstances (King, 2003). Mihaly Csikszentmihalyi, world specialist in the state of flow, outlines that the most successful Web sites are the ones that offer interactive experiences, and not simply content.

The state of flow can be created online if the following essential conditions are combined: user motivation, user telepresence, and interactivity of the Internet application. On the other hand, the existence and the maintenance of the state of flow is a dynamic process that depends on the relation between the capabilities of the user—or player in the case of an advergame—and the level of difficulty proposed by the game. Figure 1 presents three possible scenarios of the interaction between an Internet user and an advergame.

When the capability of the player is lower than the difficulty of the advergame, the player will experience frustration and will abandon the game with a negative feeling. If the capability of the player is higher than the level of difficulty proposed by the game, a feeling of boredom is likely to result, determining the exit of the

Figure 1. The inducement of the state of flow online

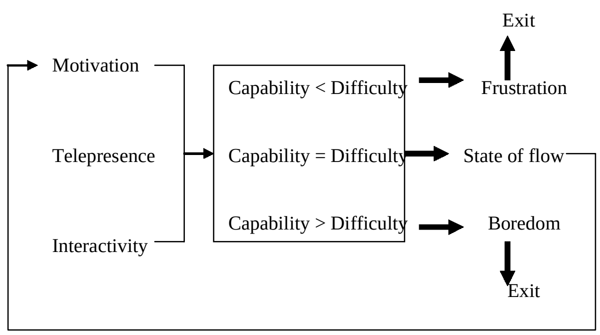

Figure 2. The possible influence of the advergame on the perceptions and behaviour of players, explained though the four phases of the AIDA model

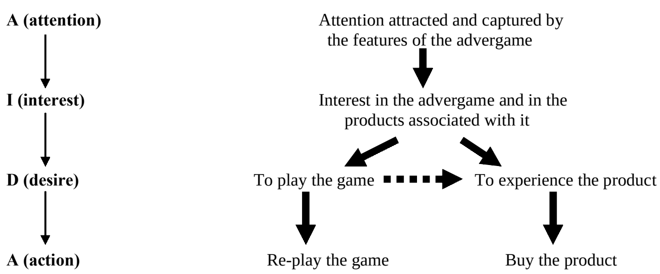


player from the advergame environment. Finally, if the level of capability of the player and the level of difficulty of the advergame match, the state of flow results and reinforces the motivation of the Internet user to revisit the site and to play again the game.

However, the situation is more complex than that. Once induced, the maintenance of the state of flow requires a constantly evolving challenge for the player, because his/her level of capability is likely to improve after playing the game a few times. This raises the problem of including in the advergame a progressive level of difficulty that can represent a dynamic challenge for players.

In terms of consumer behaviour, one of the most popular models in explaining the effect of marketing communication messages on the prospective customer can be used to investigate the possible effects of advergames. The *AIDA model* was developed by St. Elmo Lewis in the 1898, its longevity and applicability being determined by its simplicity and clarity (Fill, 2001).

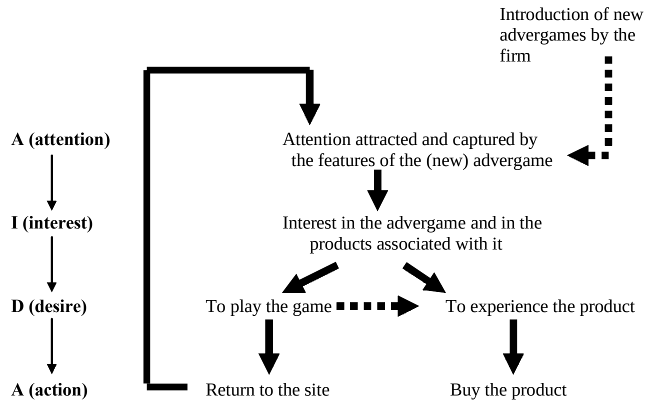
Considering the effects of advergames on the perceptions and behaviour of a player/consumer, we can define for every stage of the model a specific influence (see Figure 2).

A main problem might appear during the transition between the second (Interest) and the third stage (Desire). Some players might ignore completely the marketing dimension of the advergame and, although they continue to play, their behaviour does not evolve towards purchasing the advertised product. Ideally, the desire to play the game should influence in an indirect way the consumer's perception, creating the desire to experience the advertised product that can eventually lead to a purchasing action.

The application of the AIDA model to advergames has a number of important limitations. First of all, the presented situation corresponds to a singular interaction company-customer. Nowadays, the development of a long-term relationship between the firm and its customers has become essential for increasing and stabilizing the profitability of the company, which transforms the use of advergames in a dynamic, iterative activity (see Figure 3).

On the other hand, the viraal marketing dimension is not represented in the above model. Viral marketing describes any strategy that encourages individuals to

Figure 3. The iterative application of the AIDA model for advergames in the context of relationship marketing



pass on a marketing message to others, creating the potential for exponential growth in the message's exposure and influence (Wilson, 2000). The use of advergames corresponds well to a strategy of viral marketing, which incorporates the following principles (Wilson, 2000):

1. Give away products or services;
2. Provide for effortless transfer to others of these products/services;
3. Scale easily from a small to a very large audience;
4. Exploit common customer motivations and behaviors;
5. Utilize existing communication networks to transfer the products/services, or messages about them;
6. Take advantage of others' resources (existing users/customers).

From the perspective of the viral marketing strategy, the application of the AIDA model becomes even more complex (see Figure 4).

In order to verify the effect of advergames on players' behaviour, an experiment was designed and applied in Montpellier Business School, France. 100 first year students aged between 20 and 24 years, were asked to fill in a questionnaire about their buying habits of two competing soft drinks brands: Pepsi and Coca-Cola, as well as about their knowledge of advergames related with these two brands. In the second stage of the experiment, they were invited to access the Web sites of the two brands and to play the games available online. Finally, in the third stage of the research project, 10 days after they were asked to play the games, the students were given a second questionnaire, focused on their

Never	14	14	11	11	10	10	8	8
Total	100	00	100	100	100	100	100	100

evaluation of advergames, the effect of viral marketing induced by these games (communication with other people about these games), as well as on the evolution of their buying behaviour as a result of their exposure to advergames. The data collected were analyzed using the SPSS software.

Table 1 and 2 demonstrate that there is a statistically significant relationship between the previous knowledge about the advergame and the evaluation of the advergame, to a level of p < 0.0001. In fact, the results show a certain "fatigue" related with an already known game—for both games proposed to respondents, the large majority of people that already known the game have evaluated it neutrally, while the new players tend to appreciate them positively. This indicates the importance of novelty for an advergame; once played, the game becomes uninteresting and looses its impact on players' behaviour and perceptions.

Table 3 shows that the advergames had an important impact on the buying behaviour of respondents. The frequence of consumption for both Pepsi and Coca-Cola have increased significantly after the exposure to advergames.

In what concerns the viral marketing effect, Tables 4 and 5 show that the players who had a positive evaluation of advergames tend to transmit the information to more people than the persons that have only a neutral opinion about the advergame. Relating this finding with the information presented in Tables 1 and 2, it means that the viral effect of the advergame is directly related with its novelty and attractiveness.

An objective evaluation of the advergame relevance for the firm/brand/product advertised is difficult at this stage, because it is necessary to define a number of quantifiable criteria that can describe and assess the personality of a brand. However, future studies should investigate this dimension in order to identify the compatibility between the image of the company/brand/product and the characteristics of advergames.

M

Table 4. The influence of the evaluation of Pepsi advergames on the communication with other people

Communication / Evaluation of advergame	More than 7 people N	%	4 to 6 people N	%	1 to 3 people N	%	None N	%	Total

Total	19	100	30	100	35	100	16	100	100

Chi Square = 14.107 p = 0.003

CONCLUSION

The advergames represent an important new area of studies, related with the quick development and application of new technologies in advertising. Until now very few academic studies have been initiated on this subject, most of the secondary information about advergames use and development being provided by the professional literature.

This article attempted to present the influence of advergames on players' behaviour and perception regarding the represented products or brands. Based on a theoretical discussion of the main mechanisms that can influence consumer behaviour, an exploratory experiment was designed and implemented. The results, although limited in scope and number, show a clear relationship between the exposure to advergames and an increased consumption of the represented brands. On the other hand, the novelty and the attractiveness of advergames play an important role in the dissemination of viral information about these advergames.

The methodology applied in this project can be used in future studies, to analyze in more depth the relation between the characteristics of advergames and the image/personality of the represented brand/product, and, on the other hand, the profile of targeted players. Only on the basis of a good understanding of their mechanism of action and of their effects, the advergames can be designed and implementer more efficiently.

Managing E-Business Change

Colin G. Ash
Edith Cowan University, Australia

Janice M. Burn
Edith Cowan University, Australia

INTRODUCTION

Kalakota and Robinson (1999) state that "the creation and implementation of an e-business project is inextricably linked to the management of change" (p. 60). This requires systematic attention to learning processes, organisational culture, technology infrastructure, people and systems thinking. E-business change (eBC) is defined as the processes surrounding the effective management of different stages of online business development and growth. Guha, Grover, Kettinger, and Teng (1997) view this as an organisational initiative designed as a business project "to achieve significant breakthrough improvements in business performance" (p. 121). For example; cost reductions, responsiveness and flexibility, customer satisfaction, shareholder value, and other critical" e-business measures. Planning and managing such systems requires an integrated and multi-dimensional approach to the development of new e-business processes (Kumar & Crooks, 1999; Scheer & Habermann, 2000). Sharma (2004) recommend "a change management framework for e-business solutions" (pp. 54-69).

This article reports on the findings from multiple case studies of e-business projects in ERP enabled organisations. The summation of the findings from four case studies is captured into a pattern of generalisations for the components of an established research model. Various patterns are developed as indicators of success, trends and variance that have implications for both research and practice. This suggests an improved model of eBC management, refined in terms of the relationships between the elements of the model. Such a model would represent a comprehensive tool, for assisting managers in diagnosing the key facilitators and inhibitors of successful e-business projects for B2B interaction.

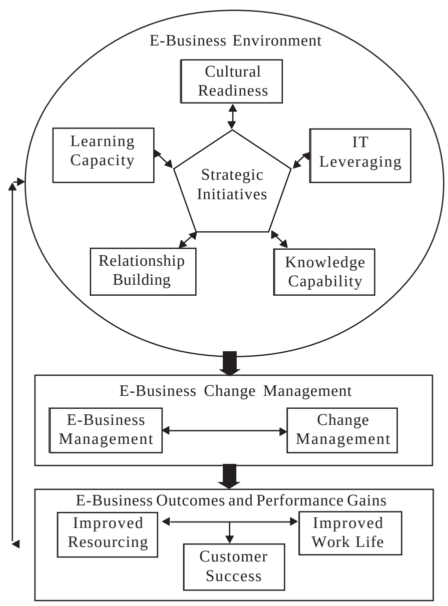
BACKGROUND

In trying to bring about e-business change: *"managers would do well to recognise the complementary nature of technology, business models, and e-business readiness throughout the value chain from their suppliers to their customers"* (Barua, Konana, Whinston, & Yin, 2001, p. 39).

Theoretical Framework

The study used an established theoretical framework (Figure 1) from business process change case-based research (Guha et al., 1997), for identifying and examining the facilitators and inhibitors of successful e-business projects. The model represented by Figure 1 was adapted from previous research on business process change by Guha et al. (1997, p. 121) to include e-business change. Also it acknowledges the existences of inter-relationships between components, as suggested by Kaplan and Norton in developing their Balanced Scorecard (2000, p. 168, 2004, p. 55).

Figure 1. Model of e-business change (Adapted from Guha et al., 1997, p. 121)



Research Approach

The research proposed three questions:

1. Which components of eBC framework facilitate and/ or inhibit success of e-business projects?
2. What are the critical success factors of e-Business projects?
3. Is the eBC framework appropriate for identifying patterns of change?

Embedded multiple case study analysis was chosen to investigate the research questions concerning the complex phenomenon of e-business change projects, in eight organisations (Yin, 1989). Embedded approaches enlist the use of multiple units of analysis: (1) the company (strategy), (2) the project team, and (3) the project. This triangulation attempts to validate primary data (Eisenhardt, 1989).

The case study selection criterion required a major e-business project, which had organisational implications. Also, as the focus was on studying antecedents to organisational performance, a set of projects having a range of B2B initiatives with variance across cases, but with the same outcome measures was required: cost reductions, responsiveness and customer satisfaction, shareholder value, and other e-business metrics (Venkatraman & Henderson, 1998, p. 34).

Case information for this study was gathered from three data sources:

1. **Primary Data:** From interviews using an established semi-structured questionnaire with questions that map the eBC items in Table 1, conducted between June and July 2000.
2. **Secondary Data:** From company documents collected or sent via e-mails in 2001.
3. **Tertiary Data:** From case articles written by authors and other researchers in 2002.

Data-collection methods included a semi-structured case protocol as; (1) a qualitative interview questionnaire, (2) multiple documents and archival records, and (3) telephone interviews. Such triangulation reduces bias and is recommended in case research (Kean & Parent, 1998, p. 308).

Case Selection

Eight cases were used for an initial assessment of the components of the eBC framework. A "Summary of Comments" table was constructed for each case by identifying key comments captured from case interviews. In each case, the components were assessed for their contribution or influence to the project success, using a 3-point scale.

Four cases out the eight that participated were selected to provide the detailed content for analysis against the eBC model. Halliburton is the representative of the four cases that exhibited little or no inter-organisational focus; that is with 'nil' B2B interaction:

- Case 1, Halliburton: [nil] business-to-employee (B2E) "Employee Tracking"
- Case 2, British Biotech: [low] business-to-supplier (B2S) "B2B Procurement"
- Case 3, Fujitsu-Siemens: [mod] business-to-customer (B2C) "Online Sales"
- Case 4, Dell & LSI: [high] B2S + B2C "B2B E-Commerce Integration"

CASE SUMMARIES

Case 1

For Halliburton, the primary beneficiaries were the off-shore project managers who needed access to the HR employee tables for personnel management and gained this through the innovative use of web-based technology. The result was one of considerable cost savings and improvement of staff resourcing through improved decision making by the project managers when working off shore. The intrinsic motivation and self-management of autonomous knowledge within the development team played an important role in the successful implementation. The emphasis was much more on collective performance rather than individual, but at the same time, development and maintenance of personal and professional reputations was a significant driver. Interestingly, while the project was rated highly successful there was strong opposition from their partner operations to implement the same system. This came from the counterpart HR staff who had not been exposed to the participative development process. The organisational management was lukewarm in their support initially, viewing the proposed system as a threat to a strongly centralised control culture. Once the benefits broke down their initial reluctance, management assumed responsibility for the success and leadership for global implementation.

We are very proud of our Web-based Personnel reporting system. (SAP project manager)

Case 2

British Biotech is a research and development stage pharmaceutical company based in the UK. Its mission is to create partnerships with pharmaceutical companies to complete the development and marketing of its compounds. The B2B Procurement project was able to ease the workload of the company's procurement department by automating the old, paper-bound purchasing process. The next step of the project was to negotiate more favourable conditions with the slimmed-down vendor base and build up closer business relationships with each one. Apart from more efficient purchasing procedures, the company's buyers have a more interesting job. Biotech's scientists should be relieved of routine paperwork, enabling them to concentrate more on research. B2B Procurement is expected to broaden day-to-day task base (Shaw, 2003).

They'll have more time to spend on nurturing relationships and working on optimisation of projects and other duties. (manager of SAP B2B project)

Case 3

Fujitsu-Siemens Computers (FSC) showed how a computer technology division within a large global organisation succeeded in making the sell-side e-business processes available over the Internet. An order and request (extranet) system was developed as an appropriate online sales system by leveraging the power of graphics and Internet technology, thus extending the reach for cross-divisional users. The efficiency gains came from speed, accuracy and security of order transactions. The primary beneficiaries were the other business partners (divisions) and independent partners. The result was one of considerable cost saving and greatly improved online sales, through any time, anywhere access (Siemens, 1999).

Interestingly, while the project was rated moderately successful the opposition came from the partner reluctance to implement the same system due to the conflict of the established offline sales channels. Further, the lack of a coordinated corporate wide strategy by the parent company was viewed as the main obstacle for uptake of the system by the business partners.

The lessons learned were two fold; (1) the use of a common platform needs the agreement of all functions, (2) The internal and external marketing of the facility is essential to the acceptance of divisional business network and to foster end-user acceptance of the technological change in business practice. Once the initial benefits broke down user reluctance, management "assumed" responsibility and leadership for a new global strategy. It highlights the need to evolve a coordinated corporate strategy and encourages the balancing of conflicting organisational knowledge when contemplating the adoption of e-business solutions.

We are beginning to recognise the potential benefits of leveraging our e-business processes and functionality through the new Web-based environment. (SBS manager)

Case 4

In 2000, Dell pioneered its first B2B "e-business integration" with an established customer company, LSI. This case demonstrates a comprehensive approach to inter-enterprise computing. This is an example of an integration architecture made possible through a variety of backend systems and procurement systems. LSI, was able to leverage its existing backend system and SAP business connector supported by Web technology to communicate directly with Dell's e-business system. The integration between LSI's SAP system and B2B e-procurement application to Dell catalogues automated the procurement of Dell products via the Internet (Dell, 2000).

We are beginning to recognise the potential benefits of leveraging our partners SAP R/3 business processes and functionality through B2B e-Commerce integration. (Dell's B2B project manager)

FINDINGS AND IMPLICATIONS

The overall findings show the Dell Corporation achieved most success, Fujitsu-Siemens Computers achieved moderate success, while Halliburton was least successful. Assuming these ratings reflect the presence of facilitators and inhibitors, then the initial findings indicate that a successful project should have facilitators in all components, including the business environment and project management, (e.g., Dell). Further there is the implication that the least successful e-business projects will have inhibitors in the areas of cultural readiness and change management practice, (e.g., Halliburton).

Evaluation of E-Business Project Success

Table 1 summarises the data captured on each construct. Consistent with the research objectives, specific probes were made concerning the constructs of each component of eBC. In addition, any construct that had a positive or negative influence on conducting eBC, or overall eBC effectiveness, was documented with either a plus (+) or a minus (–) sign. These positive or negative influences were identified and cross-validated either through direct statements by the respondents during the interview or from other data sources. In some cases, both positive and negative (+ & –) contributions were found from one component variable. For Halliburton leadership was found to exhibit (+ & –) contributions.

Table 1 is especially useful in separating those constructs that have variance across the range B2B Interactions and those that have none. For *stimuli* all four case were the same, *proactive* but reacted very differently to stimuli. To be successful, eBC management must support a *proactive* way the organisation *reacts* to the stimuli. While most successful organisations had positive characteristics, not all characteristics were seen to be equally important or indeed to directly influence success. Some constructs such as *cross-functional cooperation* were seen as "satisficing" factors, that is, they needed to be present but not necessary to be excellent. These involve components other than strategy and cultural readiness.

Lessons Learned

In Table 1, Dell is rated as the most successful project consistently showing positive facilitators in all components of the eBC model. In contrast, FSC acknowledged many inhibitors, and is rated moderately successful. Inhibitors to eBC were clustered in the areas of cultural readiness and change management.

These results confirm that the more successful projects were found to have facilitators in all components of the eBC framework, including the change environment and project management. Further, there is the implication that the least successful e-business projects will have inhibitors in both dimensions, especially in the area of cultural readiness and change management (Farhoomand, Markus, Gable, & Khan, 2004).

The cases highlight the need to evolve a coordinated corporate strategy and encourage the balancing of conflicting organisational knowledge when contemplating the adoption of e-business solutions. While this research found an important role for IT in support of eBC, the message from these case studies is that IT should not drive e-business projects.

Although all four cases reported a "proactive" response to the strategic *stimuli* construct, each reacted very differently to stimuli. In managing eBC, the organisation needs be proactive in reacting to stimuli. While the most successful organisation had positive characteristics in all components, not all characteristics were seen to be equally important or indeed to directly influence success (Markus, Axline, Petrie, & Tanis, 2000). This is viewed as a satisfying condition for success.

A MODEL FOR MANAGING E-BUSINESS CHANGE

While the study used a flat model of eBC, where all constructs in Table 1 were considered antecedents to success, the results from the case analyses suggest a more sophisticated configuration of interrelated components. A dynamic model for managing eBC is proposed for future studies where the focus is on inter-relationships between the components of eBC within three core levels of business activity: strategy, development and management.

Figure 2 represents a new conceptual framework for managing eBC distilled from the case findings. It illustrates how strategy drives developmental and management activity, management supports developments in e-business, which in turn provides feedback to strategic planning (Kaplan & Norton, 2004; Kaplan & Sawhney, 2000).

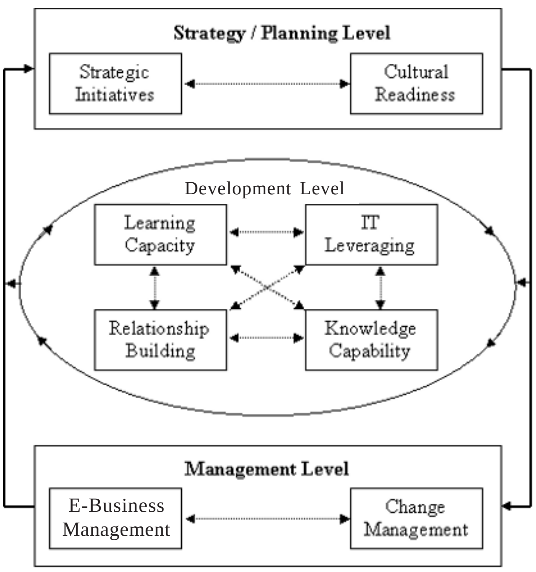
Figure 2. A model for managing e-business change



Strategy/Planning Level

Strategic Initiatives

There tends to be strategic "stimuli" ranging from competitive pressures, continued market leadership, customer expectations, employee dissatisfaction and organisation inefficiencies that trigger managers to undertake eBC:

- According to these findings, management of eBC does not have to be proactive to be successful, but rather by the way the organisation reacts to the stimuli. This is viewed as a satisficing condition for managing eBC.
- Incremental eBC can work but appears to be appropriate when risk aversion is welcomed. Also incremental projects were perceived as revolutionary in nature.
- Successful eBC projects establish an objective and unbiased team or individual champion that continues to push the organisation and groups to find new innovative processes. These champions must be empowered to implement the changes within a culture of e-business readiness (Segev & Gebauer, 2001).

Cultural Readiness

To address complexities of change, each component must be aligned, along with the enabling technology, to the strategic initiatives (Hesterbrink, 1999):

- An organisation attempting to change performance radically seems to require some "sense of urgency" in their business situation, which translates in turn into a compelling vision that is espoused throughout the organisation (Farhoomand et al., 2004).
- To overcome pockets of reluctance to change, an organisation's vision for change must provide an atmosphere of communication where individual

concerns are not seen negatively but rather welcomed (Craig & Jutla, 2000)

- An important ingredient in the right cultural mix for successful eBC is leadership from the top and initiatives from employees, together with an atmosphere of open communication, participation, committed cross-functional access to experts, and committed inter-organisational focus (Farhoomand et al., 2004).

Development Level

1. **Learning Capacity:** Successful eBC projects are enabled in organisations that:
   - have a propensity to learn from best practice and customer needs,
   - exhibit learning whereby employees individually and collectively reflect on their past experiences, modify their course when necessary, and discover new opportunities, a new culture of the learning organisation.
2. **Relationship Building:** Successful eBC projects require commitment between partner organisations to use common IT platforms and sharing of corporate information (Oliver et al., 2003).
3. **Knowledge Capability:** Successful eBC projects are enabled in organisations that leverage external information and experts, and focus on core competencies.
4. **IT Leveragability:** Successful eBC involves the coalescence of 'IT' and e-business best practice, whereby IT plays a supportive, but not always commanding role that is linked to the business case for eBC. Balanced consideration of the social, technical, and business value elements should be maintained during implementation (Hesterbrink, 1999).

Management Level

A well-defined transparent management approach should include a documented methodology of change, use objective and quantified metrics showing the value of change, continuously communicate process metrics to senior management, and possess a well-documented rollout of the new e-business design (Dell, 2000, Farhoomand et al., 2004).

To achieve this requires continuous articulation and recognition of the value of reporting results, as well as monitoring each individual's contribution and accountability to the overall company's change effort. At this individual level, concern should be placed on how the eBC will improve employee satisfaction and the quality of work life (Guha et al., 1997).

The nature of change was reported to be participative change resulting in an evolutionary change tactic. This was viewed as a "waterfall" progression of change, starting with an alleviation of dissatisfaction by employees and eventually working towards a well-managed e-business implementation from: (1) the alleviation of dissatisfaction, (2) with a vision for change, (3) by evolutionary change tactics, and (4) a well-managed process for change (Guha et al., 1997; Farhoomand et al., 2004).

FUTURE TRENDS

While the study used a flat eBC model (Figure 1) where all constructs were considered antecedents to success, a new model (Figure 2) was developed from case the findings. This dynamic model for managing eBC is recommended for use in future studies. It suggests an investigation of inter-relationships between the three levels of strategic planning, organisational development and management, as well between the components embedded within the levels.

The cases presented used an established research framework for gathering evidence to identify the factors for success of an e-business project. This research framework demonstrated its ability to examine complex phenomena. It is seen as evolutionary in nature, and was content driven. It is essentially a diagnostic tool for identifying factors contributing to success of new e-business models. It specifically useful for exploring the phenomena related to the success of learning organisations where the key issues remain as people oriented organisational issues.

CONCLUSION

The results confirm that a successful project was found to have facilitators in all components of the eBC framework, including the change environment and management practice. Further, there is the implication that the least successful e-business projects will have inhibitors in both components, especially in the area of e-business readiness and change management.

While broad generalisations from the four case studies are viewed as premature, various patterns of constructs were developed as indicators that have implications for both research and practice. These patterns represent indicators for: success, failure, a tendency to mediocrity, and variances across B2B interaction, where the latter is regarded as the most significant indicator.

The eBC framework (Figure 1) and associated semi-structured interview protocol was found to be a useful research tool for exploring the complex phenomena of eBC. A new model for managing eBC (Figure 2) is recommended to other researchers in exploring the topic further.

KEY TERMS

Change Management: The coordination and action by management required to lead the change of organisational systems and structures in order to support a new business activity or effort.

Cultural Readiness: The preparedness of an organisation's culture of its people and processes (past and present) to facilitate or inhibit change.

E-Business Change: The processes surrounding the effective management of different stages of online business development and growth.

E-Business Outcomes: E-business forces change to occur in three corporate domains; technology, process, and people–at strategic and operational levels.

E-Business Performance Gains: The improvement in; corporate resourcing, employee work life and customer satisfaction.

E-Readiness or E-Business Readiness: The preparedness of an organisation's technology, processes, and people to facilitate or inhibit e-business development.

M-Commerce Opportunities

Pouwan Lei
University of Bradford, UK

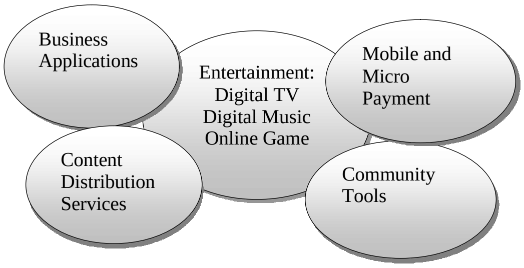
INTRODUCTION

The mobile phone industry has experienced an explosive growth in recent years. Mobile phone subscriber numbers have passed the 1.6 billion mark at the end of 2004. The emerging markets such as China, India, and Brazil contribute this growth. In China, the number of mobile subscribers has already surpassed the number of fixed landline phone subscribers. In Korea, the number of mobile phone Internet subscribers is 34.53 million people or 72% of the population in June 2004 (APEC, 2005). Mobile e-commerce (m-commerce) makes business mobility a reality. Mobile users can access the Internet at anytime and anywhere with ubiquitous, inexpensive computing infrastructure. Mobile wireless services are ranging from mobile phone networks to wireless local area networks. The service provided by mobile phone systems has achieved huge success. Mobile phone users originate from all walks of life and include almost all age groups—from teenagers to retired people. It creates a new method of personal communication without location constraints. As telecommunication technologies are converging at fast speed. We will study mobile phone and personal digital assistant (PDA) related to mobile and wireless telecommunication. Hence, m-commerce is defined as electronic commerce carried out in handheld devices such as mobile phone and PDA through mobile and wireless telecommunication networks.

BACKGROUND

E-commerce is characterized by e-marketplaces, online auction systems that act as the intermediary between buyers and sellers. On the other hand, m-commerce is more personalized and ideal for access to location based services. Many new business models have been established around the use of mobile devices. Mobile devices have the characteristics of portability, low cost, more personalization, GPS (global positioning system), voice, and so forth. The new business models include micropayment and mobile payment, content distribution services, entertainment, community communication and business services. Figure 1 illustrates m-commerce applications. Because of their existing customer base, technical expertise and familiarity with billing, mobile telephone operators are the natural candidates for the provision of mobile and micro payment services. Micropayment involves small purchases such as vending and other items. In other words, the mobile phone is used as an ATM card or debit card. Consumers can pay for purchases at convenience stores or buy train tickets using their mobile phones.

Figure 1. M-commerce applications



Content distribution services are concerned with real time information, notification (e.g., bank overdraft), using positioning systems for intelligent distribution of personalized information by location (e.g., selective advertising of locally available services and entertainment). Real-time information such as news, traffic reports, stock prices, and weather forecasts can be distributed to mobile phones via the Internet. The information is personalized to the user's interests. By using a positioning system, users can retrieve local information such as restaurants, traffic reports and shopping information. Content distribution services with a greater degree of personalization and localization can be effectively provided through a mobile portal. Localization means to supply information relevant to the current location of the user. Users' profile such as past behavior, situation and location should be taken into account for personalization and localized service provision. Notification can be sent to mobile devices too. Mobile network operators (MNOs) have a number of advantages over the other portal players (Tsalgatidou & Veijalainen, 2000). First, they have an existing customer relationship and can identify the location of the subscriber. Second, they have a billing relationship with the customers while the traditional portal does not. MNOs can act as a trusted third party and play a dominant role in m-commerce applications.

In addition, mobile phone has become a new personal entertainment medium. A wide range of entertainment services are available, which consist of online game playing, ring tones download, watching football video clips, live TV broadcasting, music download and so on. According to *Screen Digest* estimates, Korea and Japan accounted for 80% of worldwide games download revenues of Euro 380 million (*Screen Digest,* 2005). Unsurprisingly, adult mobile services and mobile gambling services are among the fast growing services. According to Juniper research, the total revenue from adult mobile services and mobile gambling services could be worth US$1billion and US$15 billion respectively by 2008 (Kowk, 2004). Law regulators have to stay ahead of the fast growing development. Community tools also generate a lot of revenue. It consists of SMS (Short Message Service) and chat. SMS broadcasting is an ideal communication tool in community. And chat allows a mobile user to keep contact with the others while he or she is on the move.

M-commerce also has a great impact on business applications, especially for companies with remote staff. Extending the existing enterprise resource planning (ERP) systems with mobile functionality will provide remote staff, such as sales personnel, with real-time corporate and management data. Time and location constraints are reduced and the capability of mobile employees is enhanced. Also it makes paperless office a reality so that off-site engineers or salesmen don't need to carry with loads of paper such as delivery note to their clients. The logistic related business also benefits from the use of mobile inventory management applications. One interesting application is "rolling inventory" (Varshney & Vetter, 2002). In this case, multiple trucks carry a large amount of inventory while on the move. Whenever a store needs certain items/goods, a nearby truck can be located and just-in-time delivery of goods can be performed. M-commerce offers tremendous potential for businesses to respond quickly in supply chains.

CHALLENGES IN M-COMMERCE

M-commerce has a number of inherent complexities as it embraces many emerging technologies: mobile wireless systems, mobile handheld devices, software, wireless protocols, and security (Ojanperä & Prasad, 2001). These technologies have rapid product cycles and quick obsolescence. M-commerce, which is more complex than e-commerce, faces a number of challenges:

1. **Economic Aspect:** The delay in 3G Mobile network operators (MNO) in implementing their systems infrastructure. The success of M-Commerce in Japan changes the concept of "free" Internet to "paid" Internet. Users are willing to pay for the service. MNOs anticipate a huge profit in taking control of the backbone of m-commerce—the wireless infrastructure. In addition, MNOs also play a dominant position in providing m-commerce applications. This has created an unreasonably high expectation from the services. Big companies in Europe, such as Deutsche Telecom, France Télécom, Spain's TelefÌnica and the United Kingdom's Vodafone spent an estimated USD125 billion to USD150 billion on 3G licenses (Garber, 2002). Many of them are burdened with high debts. In Europe, 3G was slowly rolled out in 2004 and the number of users was less than 1 million after a huge price-cut campaign.
2. **Social Aspect:** With the exception of Korea and Japan, there is a lack of interest in 3G mobile phone systems. The western European market has reached saturation point, where mobile possession rate is close to 100% in some countries. In addition, mobile users have "upgrade fatigue" (i.e., they are reluctant to upgrade their mobile phones). In 2002, the mobile phone business pushed very hard on picture messaging, which requires new expensive handsets. The response has been poor. The mobile revenue mainly comes from the voice calls and SMS messaging. Recently, Apple iPod is a big success. It transforms the music industry and shows that consumers are willing to pay for download music. In 3 GSM World Congress 2005, mobile phones operators are unveiled to team up music companies and mobile phone manufacturers to offer digital music download and play in mobile phone. MNO hopes that they can attract the customers to use their networks to download music.
3. **Standards Aspect:** The market for handheld devices is quite different from the personal computer (PC) market. For instance, Nokia, the handset manufacturer, not only produces handset hardware but also develops the Symbian software (the OS of mobile phone) together with other handset manufacturers such as Motorola. And the handset manufacturers have closed relationship with MNOs. The OS standards are under the control of handset manufactures and MNOs. Since 2002, Microsoft has provided the OS for mobile phone and PDA respectively. Though pocket PC become dominant in PDA, the smartphone system for mobile phone is disappointed. The key is to make sure that the product is attractive to MNOs (Fried, 2005).
4. **Technologies Aspects:** Security is a major issue. Mobile communications offer users many benefits

such as portability, flexibility, and increased productivity. The most significant difference between wired networks and mobile communication is that the airwave is openly exposed to intruders. The intruder eavesdrops on signalling and data connections associated with other users by using a modified mobile phone. In addition, their small size, relatively low cost, and mobility means that they are likely to be lost or stolen. Sensitive information such as the "private-key" is thus vulnerable (Karygiannis & Owens, 2002). A 3G mobile device, when connected to an IP network, is in the "always-on" mode. Both this "always-on" mode and bluetooth's "on" mode make the device susceptible to attack. Moreover, it also provides the opportunity to track a user's activity, which may be a violation of privacy.

Furthermore, handheld devices have many inherent limitations. Technological developments will increase the computing power and storage in handheld devices. However, insufficient battery life and power consumption will impede the potential growth of M-Commerce even when 3G is widely available. At present, the battery life is very short (e.g., 2-4 hours for surfing). Fuel cells may be the answer to treble the power of a mobile phone. However the liquid is inflammable, commercial viability is in doubt. Furthermore, the small screen is another limitation. PDA's have a larger screen (13cm* 8 cm), whereas the screen of a mobile phone is 7cm*5cm, which poses difficulty when surfing the Web. A low power, inexpensive, high-resolution colour display would seriously increase the growth of m-commerce.

FUTURE TRENDS

Technology has historically advanced in waves of disruption. It is the same in the telecommunications. The disruptive technologies are Wi-Fi, WiMax, mesh networks, and powerline broadband. WiFi (Wireless Fidelity) allow users to surf the Internet on moving, are proliferating at astonishing speed on a global scale. Worldwide retail chains like Starbucks and McDonald offer wireless Internet access to their customers. It offers a fast and stable connection; the data rate is several times faster than 3G. The WiFi is an important, new and disruptive technology to mobile telephone technology and it may be a watershed for all other m-commerce investment by telecom and content providers in the world of the mobile Internet (Lamont, 2001). In making use of this technology, mobile phone manufacturer (Nokia) and wireless network manufacturer (Cisco) have been working together closely to produce the Wi-Fi phone. In future, the tariff of accessing the mobile Internet will be reduced to a budget price.

WiMax (Worldwide Interoperability for Microwave Access), a low cost wireless broadband connection in wide area network (WAN) will be rolled out (Cherry, 2004). It will offer an opportunity for new mobile phone operators to enter the mobile industry. As the mobile and wireless technologies are converging, the competition will be keen in the industries. Wireless mesh networks are peer-to-peer wireless communication systems that allow two user devices to communicate directly, instead of being routed through a central switch. End user devices in a mesh network not only send their data but also act as routers or repeaters, relaying signals for other devices. Mesh wireless broadband is much cheaper and nearly half the price to Wi-Fi offering. It will substantially lowered entry barriers for green-field operators, which are new phone companies started from scratch. In addition, powerline broadband has the potential to make an impact too. It is a technology delivering high-speed Internet access into electrical outlets via common electrical grid (Buvat, 2005). The transmission rates are currently better than DSL (Digital Subscriber Line)/cable. It is important for MNO to embrace those technologies in order to maintain its competitive edge.

CONCLUSION

As the mobile and wireless technologies are evolving rapidly and sophisticated mobile phones becomes affordable, mobile commerce will become part of our daily life. Mobile Internet is ideal for particular applications and has useful characteristics that offer a range of services and content. The widespread adoption of mobile commerce is fast approaching. In business, the mobile computing is changing the logic of business; businesses have to implement effective strategies to capture and retain increasingly demanding and sophisticated customers. Business needs to think critically about how to integrate the mobile Web to the wired Web.

KEY TERMS

3.5G: It is based on a technology called, HSDPA (high-speed downlink packet access). It will be upwardly compatible with 3G W-CDMA systems, but will enable more than 10X the peak data rate and more than 6X the capacity of initial 3G systems.

Global System for Mobile Communications (GSM): It is a world standard for digital cellular communications using narrowband TDMA (Time Division Multiple Access). It is the standard most commonly used in Europe and Asia, but not in the United States.

I-Mode: It is the packet-based service for mobile phones offered by Japan's leader in wireless technology, NTT DoCoMo. The i-mode protocol uses compact HTML (cHTML) as its markup language instead of WAP's wireless markup language (WML) to provide mobile phone voice service, Internet and e-mail.

Short Message Service (SMS): It has grown very rapidly and is very popular in Europe. SMS messages are two-way alphanumeric paging messages up to 160 characters that can be sent to and from mobile phones.

The Third Generation (3G): It will bring wireless transmission speeds up to 2Mbps, which permits high-quality wireless audio and video. It comprises three primary standards: W-CDMA (wide-band code division multiple access), CDMA2000, and TD-CDMA (time division CDMA).

Wi-Fi (Wireless Fidelity): It is a popular term for 802.11b, a wireless local area network (WLAN) specified by the Institute of Electrical and Electronic Engineers (IEEE) and is based on the Ethernet protocol and CSMA/CA (carrier sense multiple access with collision avoidance) for path sharing. Wi-Fi supports a range of about 150 feet and data rates up to 11mbps.

WiMax (Worldwide Interoperability for Microwave Access): It is called 802.16 in industry standard, a wireless broadband connection in wide area network (WAN). It offers fast wireless data communications over distance up to about 30 miles.

Wireless Application Protocol (WAP): It is an open, global specification that empowers mobile users with wireless devices to easily access and interact with information and services instantly. The WAP is a standard for providing cellular phones, pagers, and other handheld devices with secure access to e-mail and text-based Web pages.

BACKGROUND OF ORGANIZATION

In the past decades, the Internet has evolved so rapidly that it makes the information-technology industry grow extremely fast. Internet-based applications such as e-commerce, e-payment, e-billing, e-learning, and so forth have tremendous influence on society: There is a trend that our society will be reshaped by the Internet. Among these applications, e-learning is one of the killer applications.

Currently, the traditional education system faces some challenges that arose from the development of the knowledge-based economy. School enrollment increases with the population growth, education levels also increase for the new economy, and the cost of higher education escalates. On the other hand, in the workforce-training market, as the information economy develops, the demand for skilled workers increases. As the technology keeps changing, the workforce needs continuous training to maintain its productivity level. Hence, both formal school-based education and continuous workforce training have become big business now, and they will be even bigger in the future (Kerrey & Isakson, 2000). A more sophisticated education model is required to take this challenge, and so e-learning came into being.

Compared to traditional classroom teaching, e-learning provides one major advantage: It makes the access of information much easier and more convenient. Hence, it makes learning of all kinds, at all levels, anytime, anyplace, at any pace a practical reality (Kolar, 2001). E-learning also gives tremendous cost savings for both instructors and learners; the learning model is shifted from instructor centered to learner centered, which focuses primarily on the needs of learners. The updating of online material is also much easier. Many e-learning systems can develop personalized and interactive applications that allow users to customize their e-learning models to their own pace, and they can truly engage the user in that they involve the simulation of real-world events and sophisticated collaboration with other learners and instructors (Quah & Chen, 2002). In our e-learning system, we incorporated mobile-agent technology to enhance the response time of information retrieval. The purpose of this incorporation is to overcome the bottleneck problem faced by many pure client-server-based systems. Since mobile agents are able to traverse from one information server to another autonomously to search for relevant documents for users, only relevant articles are sent back. This saves bandwidth and enhances the efficiency of the e-learning system. As a result, the turnaround time for user queries or information searches reduces, and the feedback from the user community is positive as the response time is shorter and users find it easier to maintain their trains of thought in their study.

DESCRIPTION OF MOBILE AGENT ASSISTED E-LEARNING SYSTEM

Mobile Agent

The server-client paradigm is popularly used in current e-learning applications. Mobile agents are an emerging technology; they make the design, implementation, and maintenance of distributed systems much easier, so they attract a great deal of interest from both industry and academia. In particular, the mobile-agent paradigm has been used to design applications ranging from distributed information retrieval to network management.

A mobile agent is an autonomous, intelligent program that can migrate from machine to machine in heterogeneous networks, searching for and interacting with services on the user's behalf. Typically, agents possess such characteristics as being autonomous, adaptive, goal oriented, collaborative, flexible, active, proactive, and so forth (Smith & Paranjape, 2000). The mobile-agent paradigm is used in distributed computing as it improves performance upon the conventional client-server paradigm.

Under the mobile-agent paradigm, any host in the network is allowed a high degree of flexibility to possess any mixture of service codes, resources, and CPU (i.e., processor) time. Its processing capabilities can be combined with local resources; the service code is not tied to a single host but rather is available throughout the network (Gray & Kotz, 2001).

Information Push and Pull Based on Mobile Agents

With the above features, the mobile-agent paradigm is suitable for distributed information retrieval and e-commerce applications.

The rapid evolution of Internet-based services causes information overloading on the Web. It has been estimated that the amount of information stored on the Internet doubles every 18 months, and the number of home pages doubles every 6 months or sooner (Yang, Yen, & Chen, 1998). Therefore, it becomes difficult for the user to find the required information or services on the Internet in the huge amount of information.

Information push and pull technologies make the delivery of information from service providers to users easier. Push technology is the process of service provision by the provider in anticipation of its use, and pull technology is the process of searching for information in the network (Quah & Lim, 2003).

Ahmad and Mori (2000) from the Tokyo Institute of Technology proposed the faded information field (FIF) architecture based on mobile-agent technology to cope with fast-changing information sources and reduce the information access time of the user. In FIF, each component such as the user, provider, and node is considered an autonomous entity. The information is distributed on these nodes, and the amount of information decreases away from the service provider as shown in Figure 1. The nodes near the service center are allocated a larger volume of information, and those farther from the central nodes are allocated a smaller volume of information.

In FIF, service providers generate push mobile agents to push information in the neighbouring nodes in faded patterns. These agents negotiate with neighbouring nodes and allocate information according to the situation and the importance level of the information. The important information is stored at more nodes, and less important information is stored in less nodes. The user looks for information with pull agents, and the pull agents navigate through the distributed nodes in FIF autonomously to find the appropriate information.

The algorithm for designing autonomous information fading takes consideration of the popularity, size, and lifetime of the information. A parameter access effort $E_g(i)$ is defined to assign the fading level to each piece of information as

$$E_g(i) = \frac{N_i \ln(d_i + 1)}{\ln(S_i + 1)}, \qquad \text{(Equation 1)}$$

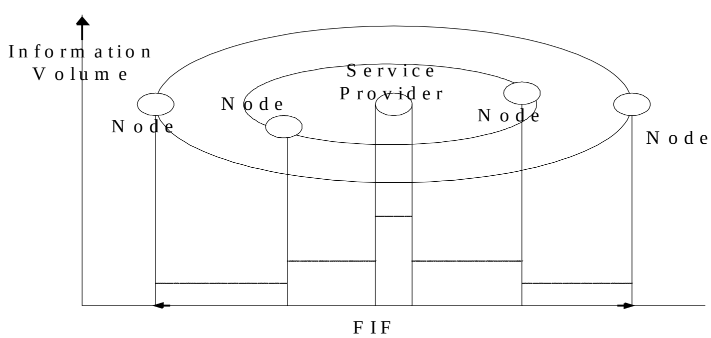
where N_i, d_i, and S_i denote the number of accesses, the lifetime, and the size of the information unit, respectively. The information having high access effort is assigned high priority and is stored on all nodes.

Through the cooperation of push agents and pull agents in FIF, the access time for the user to get the needed information is reduced since the user need not reach the service provider and can get the required information from the closer nodes. The service provider can avoid the congestion of the access, and the levels of reliability are improved.

IMPACT OF THE MOBILE AGENT ASSISTED E-LEARNING SYSTEM ON THE ORGANIZATION

We use a system architecture based on mobile agents to improve the performance of current systems. In our system, the university centers preinstalled a certain mobile-

Figure 1. Faded information field



agent base software and were connected through the agent transfer protocol (ATP) on the Internet to form a virtually huge and powerful e-learning system. The client is a networked PC (personal computer) connected to the Internet, enabling it to connect to the agent server center (ASC) to make a query to the universities on behalf of the user. The ASC will then create a mobile agent that will roam the university servers to hunt for required data. Each university center may offer some courses to users. Users may access the e-learning system through any Web browser via the Internet.

All of the university centers can be considered as different nodes in the network, and the courses are information distributed into theses different nodes. We construct an FIF to implement the information-push and -pull technology as mentioned to improve users' access time to information with a higher reliability.

The FIF system consists of logically connected nodes; information providers and users correspond to these nodes, and information allocated to these nodes decreases in amount away from the information center. That means the nodes adjacent to information center contain more information, while farther nodes contain less. As the users' demand for the subcourse materials changes dynamically over time, FIF provides an autonomous navigation mechanism by university centers through mobile agents to satisfy users' heterogeneous requirements. The university centers generate push mobile agents, and these agents carry out information fading by negotiating with the other neighbouring nodes in the network. When the push agents perform the information fading, they need to take into account the popularity, size, and lifetime of the information. They assign a priority level to each information unit: The information with higher priority is stored on more nodes, and low-priority information is stored in fewer nodes. All the nodes around the university centers are ranked by distance. The nodes with lower traffic costs are ranked as near to a university center, and those with higher traffic costs are ranked as far from a university center. The information push agents perform their tasks at a certain network off-peak time to avoid network congestion.

Through the mobile-agents-based architecture and the faded information field, the network structure is decentralized and can be extended to a larger scale easily by adding more university centers. The course materials are usually stored on more than one server so that the users can get the course materials from the nearest node, which saves information access time. When some nodes in the networks are down, users can still get course materials from other nodes, which means reliability is increased. The system is robust and fault tolerant.

Mobile Agent Based Searching

Keyword searching and text mining are popularly used among current search engines. They involve the server collecting the index of all the stored information. When a user wants to retrieve information from a server, he or she is required to enter a keyword to query the server database. The server then searches all the indexes that match the keyword entered by the user and retrieves the information accordingly (Martin & Eklund, 2000).

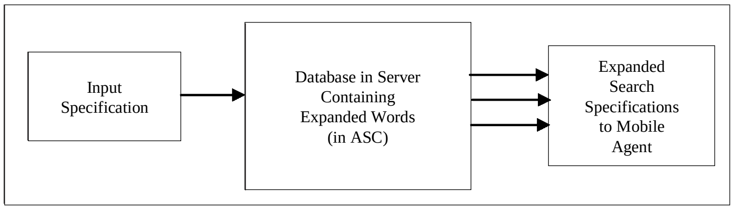
In this information-retrieval mechanism, two problems may occur. First, this mechanism is based on the assumption that the user has a good understanding about the server-stored information and can express what he or she wants to retrieve in terms of keywords correctly and accurately. If the query keyword is poorly structured or some typing error exists, the searching will not work as the user expected and may even return nothing. In order to overcome this problem, a thesaurus function is used to expand the search keys. Second, if the query causes plenty of information to be returned to the user at the client site, most likely not all the information is what the user wants, and the user needs to browse through the retrieved information and discard those pieces that are not important; this causes a waste of network bandwidth and user time also. To assist the user, the system provides a weighted keyword function to gauge the importance of each piece of retrieved information.

Adding artificial intelligence (AI) to the keyword search will improve the search quality. One approach is to do a parsing on the user-entered keywords (Katz & Yuret, 1999). This will generate several synonyms equivalent to the original keywords. When the query done with the original keywords is not satisfactory, the query based on its synonyms will be performed to return more information. Figure 2 illustrates the process of user-query expansion.

One of the AI approaches for e-learning-course search is to build Web agents (Karjoth, Lange, & Oshima, 1997); they will search for information on behalf of the user according to user preferences. The user preferences are stored in the user profile database (So, Baek, & Park, 1999). It has a learning function and can learn the user's preferences and dislikes when the user searches the Web with keyword searching.

Initially, the user enters the keywords and searches the Web. The monitor agent will save the keywords entered by user, then the search agent will start to roam on the Web searching for information (Cabri, Leonardi, & Zambonelli, 2000). When the search agent finds information at remote sites that matches the user's requirements, it will carry the information back to the user.

Figure 2. Thesaurus module



At the user site, the extraction agents will extract the keywords from the retrieved Web documents. The keyword extraction includes two methods: One is based on the frequency of a word or phrase that occurs in a Web document, and the other is based on the frequency of a word or phrase that occurs in different Web documents. The occurring frequency is computed and weighted. If it exceeds a threshold value, the word can be treated as a keyword and be saved into the user profile database together with user-entered keywords. When the user reads through the retrieved Web documents, some documents may not be what the user wants and are simply discarded. The monitor agent will monitor this and add a negative preference with a weighting to the extracted keywords. For the correctly retrieved Web documents, a positive preference weighting is added.

The next time the user does a keyword search and enters similar keywords as the previous session, the user preference database will first find all the keywords stored with positive and negative weightings and list them for the user to select as the keyword. The search priority is based on the weighting: Positive weighting indicates higher priority, and negative weighting indicates low priority. As the negative weighting exceeds a certain threshold value, the Web documents that contain such keywords will not be retrieved in future sessions.

The monitor agent, search agent, and user preference database operate in a closed feedback loop. With learning ability, the user preference database will grow larger in size as the user does keyword searches of the Web more frequently, and the search process will become more intelligent. Figure 3 shows the architecture of the search tool (Quah & Chen, 2002).

Overall Technical Architecture

In our system, the IBM Aglet workbench is used as the agent platform. Figure 4 shows the technical architecture.

The whole system consists of three layers: the front-end user machine, the back-end server, and the e-learning servers on the Web. The front end can be any PC connected to the back-end server. The back-end server has an SQL (i.e., Structured Query Language) server database storing the user account information. It is used for user verification when logging into the system, and each new user needs to register his or her account with the back-end server. The handling of these data is through CGI (i.e., Common Gateway Interface) scripts.

The addresses of all the e-learning servers on the Web that are to be visited by the searching mobile agent are also captured in the database, which forms a search directory for the searching aglet. Each e-learning-course center on the Web must preinstall the Aglet Tahiti server and has a database server to store the course materials. These e-learning centers register their addresses with the

Figure 3. AI search-engine architecture

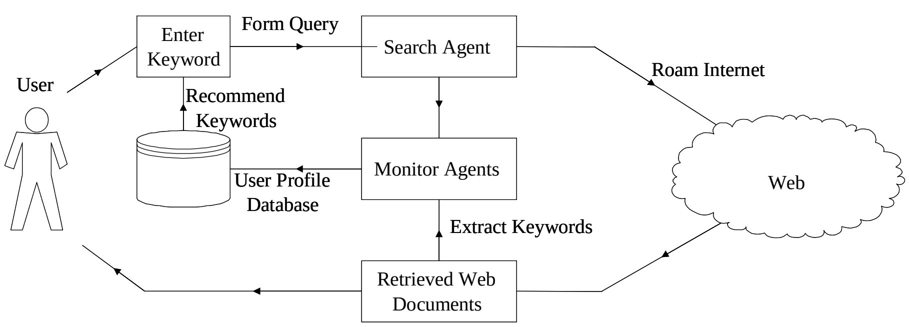


Figure 4. Overall architecture

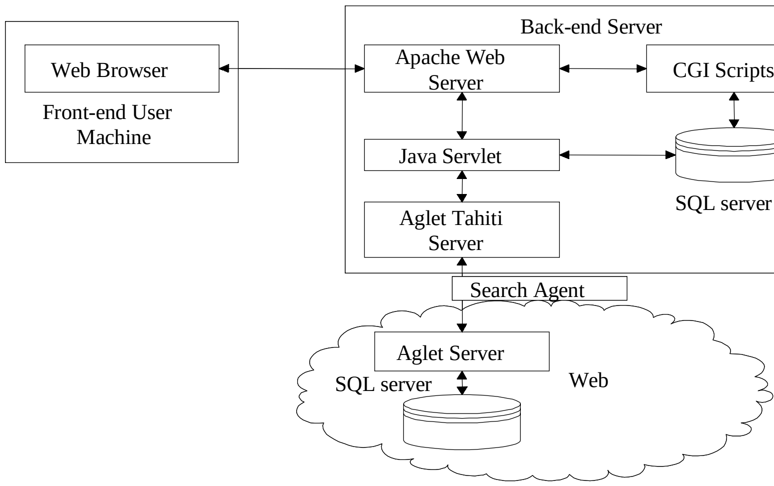


back-end server and provide context for the searching aglet to operate.

Each time the user does a search, a Java servlet will run at the back-end server, which will generate an aglet carrying the searching criteria and send it into the Web. The mobile agent will roam the Web searching for the required information on the user's behalf. When information is found, the mobile agent will send it back and continue on to visit the next aglet host in the predefined trajectory.

The retrieved information will be filtered by the thesaurus module and then presented to the user. The filtering process is a reverse process of the query-expansion process. Text-mining techniques are used to narrow down the search criteria, taking into consideration the context in which the keywords are used.

Interactive User Tracking

It was shown that the more interactive and cooperative instructors and learners are, the more effective learning will be. The user-tracking function provides an interactive environment for lecturers and students to conduct teaching and learning. This can be realized through the cooperation of static agents at student machines and static agents that sit on the e-learning central server. These two groups of agents monitor the course status for a particular student and communicate this information by message passing.

There are two types of tracking. At the lecturers' side, agents receive feedback from the student regarding the course material's effectiveness. For example, if the user-tracking report shows a high access rate of a certain course material, it may mean the difficulty level of this course material is appropriate or the course is taken by many students. On the contrary, if the access rates of certain courses are low, that may mean the courses are not very popular: Either the difficulty levels are too high or the course formats are not user friendly. With the feedback from students, the course materials can be customized to match the students' learning pace and interests.

To test the effectiveness of student learning, after the course is taken, the system also provides some randomised questions for students in the form of quizzes. The quizzes will be graded by the e-learning server, and the server will give feedback information on the grades to each student. This is realized through communications of the two groups of static agents.

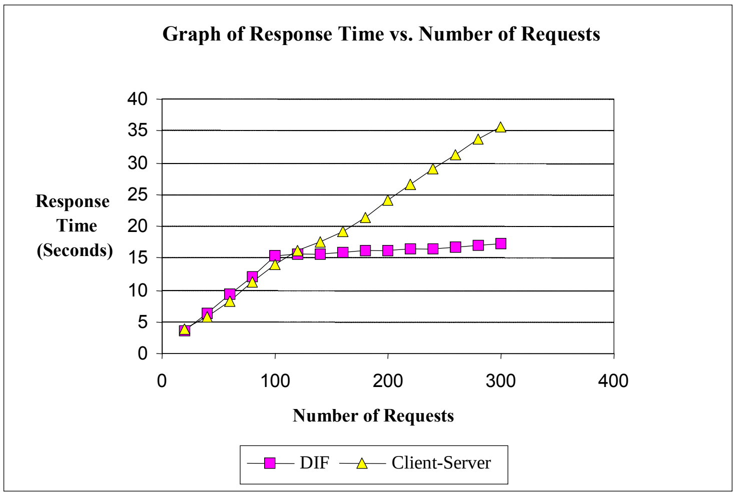
System Performance

We performed a response-time comparison (for document retrieval) between the e-learning system with mobile agents and a basic client-server system with the equivalent hardware and software components.

From the data collected, the results were plotted onto a graph to show the response time for the two systems vs. the number of requests from the user community (Figure 5). The system with mobile-agent technology (denoted as "DIF", meaning "Distributed Information Field") yields an average of 10 seconds of improvement in response time. This can be attributed to the following reasons.

- Mobile agents are not part of a stand-alone process. They are in a thread and need to work together with other programs in the agent host to complete tasks. Hence, the system is flexible and small in size. In our system, the search agent is only around 10 K, with

Figure 5. Response-time comparison



small variations depending on the user-query size, therefore the amount of time taken to transport mobile agents is small.

- Mobile agents move the query computation to the data server, so the repetitive request and response handshaking in the client-server system is eliminated. Data selection is performed at the remote server, and only the selected documents are sent to the user. However, in a client-server system, intermediate results and information need to be passed through the network between the server and client. Hence, mobile agents reduce network traffic and improve performance in terms of response time.

CONCLUSION

The experience gained from this project is largely positive. The acceptance of the Web-based e-learning system by users (students and professors) at large testifies to the strengths of the system in three aspects. First, the system exhibits intelligence in gathering and picking documents requested by users. The highly interactive Web-based design added to user friendliness. Second, the system is able to maintain good response times due to the load-balancing feature of the information-push and information-pull agents. Finally, from the technical-support group's perspective, the system is robust and fault tolerant (as multiple hosts serve as each other's backup). It is also able to withstand higher volumes of transactions and storage requirements. This will eventually convert to cost savings as the need for equipment upgrades becomes less frequent.

KEY TERMS

E-Learning: Technology-enhanced instruction whereby learners are able to progress at their own paces and choose their own learning paths.

Faded Information Field: A group of server machines connected in a topology that allows information documents to be distributed in a fashion that can improve retrieval efficiency, typically through some algorithmic computation to determine server locations.

Information Pull: The process of user access to information stored in servers linked via the Internet or an intranet.

Information Push: The process of a directory server relocating information files to active server machines within a faded information field based on the frequency of users' accesses.

Information-Retrieval Mobile Agent: A small, portable program code that can migrate from server to server and execute its master's instructions for information retrieval.

Thesaurus Module: A keyword-expansion mechanism to increase the coverage and success rate of information search using a user-entered keyword (or keywords).

User Tracking: An automated logging mechanism that stores and retrieves information on a user's progress as he or she advances through the courses on an e-learning system.

Mobile Agent–Based Auction Services

Sheng-Uei Guan
National University of Singapore, Singapore

INTRODUCTION

Electronic Commerce, a Booming Industry

There is now a gradual shift of many of the traditional business models from the real world to the Internet platform; of these models, auction service is most successful. The existence and development of numerous auction Web sites, such as eBay and OnSale Inc., have demonstrated the survivability of electronic auctions in online transactions.

However, current Web-based systems suffer from shortcomings in the following aspects:

- **Fairness and Friendliness:** Due to the different conditions of Internet connections, users across different regions may suffer from the inadequacy of limited bandwidth, especially when participating bidders are distributed across the world. This global nature also makes online auctions difficult to adapt to the potential users across the world.
- **Security and Privacy:** Security concern is one of the important issues users consider when using electronic transactions. Many users also wish to be guaranteed of privacy when doing business.
- **Intelligence and Flexibility:** The vast majority of electronic auction customers are not Internet experts but ordinary people that do not know much about the technical details. Current Web-based auction systems require too much user intervention. It would be commercially profitable if intelligent assistance is provided.

Software Agents, a Paradigm for Mobile Computing

Mobile agents refer to self-contained and identifiable computer programs that can move within the network and act on behalf of the user (Pham & Karmouch, 1998). The mobile agent paradigm as reported in the literature has two general goals: reduction of network traffic and asynchronous interaction. The mobile agent paradigm proposes to treat the network as multiple agent-friendly environments and the agents as programmatic entities that move from location to location, performing tasks for users.

Research on agent-based e-commerce is still underway (Franklin & Reiter, 1996; Guan, Ngoo, & Zhu, 2002; Guan & Yang, 2004; Guan & Zhu, 2002; Maes, Guttman, & Moukas, 1999; Poh & Guan, 2000; Subramanian, 1998; Yi, Wang, Lam, Okamoto, & Hsu, 1998). Mobile agents have demonstrated tremendous potential in conducting transactional tasks in e-commerce. The architecture proposed here is based on mobile agents. The advantages of mobility, intelligence, and autonomy of the agents are taken, which are actually representatives of their respective owners to perform the auction process. By using this framework, we wish to get rid of the previously listed disadvantages in the current online auctions. Specifically, the features of the system will be as follows:

- **Fairness:** The deficiency of bandwidth and network traffic will be overcome by taking the advantages of the mobility of software agents.
- **Autonomy:** Based on the preferences of an owner, agents can be fully automated to participate in the auction with little or no intervention from the owner.
- **Security and Privacy:** Third-party involvement is introduced to enhance the security and privacy throughout the auction. Agents are protected from malicious attacks during transportation and bidding. Furthermore, with the assistance of the coordinator and the encryption mechanism, the real identity of each participating bidder is protected.
- **Flexibility:** The architecture proposed will serve as a unified framework for various auction types as long as the bidding strategies and competing rules are well defined.

Related Work

There has been much research in agent-based auction systems. The Michigan Internet AuctionBot (http://ecommerce.media.mt.edu) sees itself as an information service that collects the bids, determines the resulting price, and notifies the participating parties about the outcome. The Fishmarket Project (http://www.iiia.csic.es/Projects/fishmarket/)evaluates a very narrow field of electronic commerce. Its main focus lies in rebuilding a commerce structure that is found in real life on downward-bidding fish markets of Spain, and it supports Dutch auction style. CASBA (Guttman, Moukas, & Maes, 1998) offers flexibility and support for all common auctions types including auctioning of multiple units. It does not have sophisticated negotiation strategies and learning mechanism to improve agent performance on the market. It is not designed with mobile agent capability. The **KASBAH** project of the AmEC Initiative (http://ecommerce.media.mit.edu/) introduced agents that negotiate following three time-constrained rules. The system itself was designed to be one huge double auction system. It is not designed with mobile agents in mind.

DESCRIPTION OF MOBILE AGENT–BASED AUCTION SYSTEMS

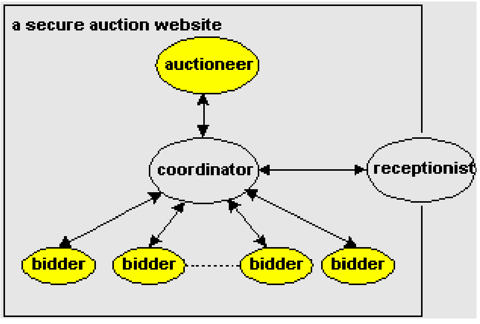
A complete auction service involves the following aspects: information shopping, auction process, payment, and shipping. In our architecture (Figure 1) however, we are only interested in the auction process and assume that auction-related information has been collected by the participants ahead of time.

Overview

In an English auction, the buyers gather together to bid for a certain product, according to the published rules and preferred strategies. In the proposed architecture, the following are typical:

- **Participants:** The auctioneer agent represents the seller of the products; the bidder agents represent potential buyers who wish to compete for the auction item; the coordinator agent is the coordinator of the auction, the receptionist agent collaborates with the coordinator and serves as the receptionist during the auction. The functions and particulars of each agent are listed in Table 1.

Figure 1. A typical auction scenario



- **Place:** The auction Web host is a secure auction environment provided by a certified third party, widely trusted by the participants.

Admission

Admission is the preparation, namely the reception of agents and the build up of the auction relationship. The admission process will be further divided into two periods: SAFER transport and auction registration. SAFER (Guan & Yang, 1999; Yang & Guan, 2000; Zhu, Guan, Yang, & Ko, 2000), has been proposed as a framework for intelligent mobile agent mediated e-commerce. Our system adopts one of the three proposed transport protocols, the supervised agent transport protocol for the secure roaming of agents to prevent agents from malicious attacks during their transportation. The agent is built up with the bidding strategies customized by the owner and carries the owner's certificate for identification purpose and his or her public/private key for encryption and signing purpose. Figure 2 illustrates the supervised agent transport protocol.

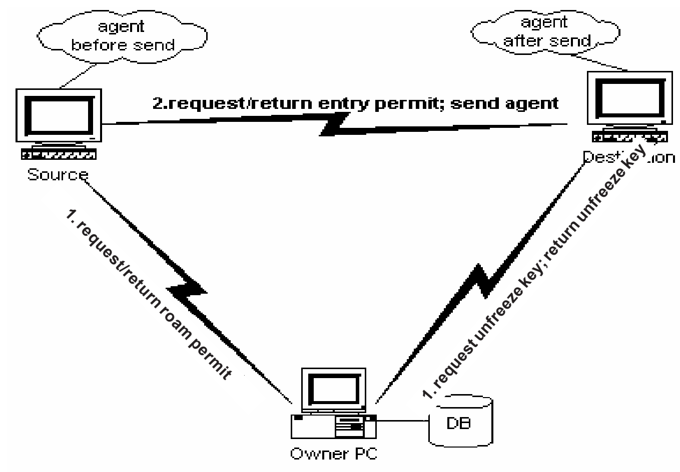
After the agents have successfully roamed to the destination, all agents are welcome by the auction receptionist. The agents then communicate with the reception-

Table 1. Functions of the participating agents

Participating Agent	Owner	Function
Auctioneer	Seller	Decide the winner
Bidders	Customers	Bid
Coordinator	Third party	Coordinate auctions
Receptionist	Third party	Receive agents

M

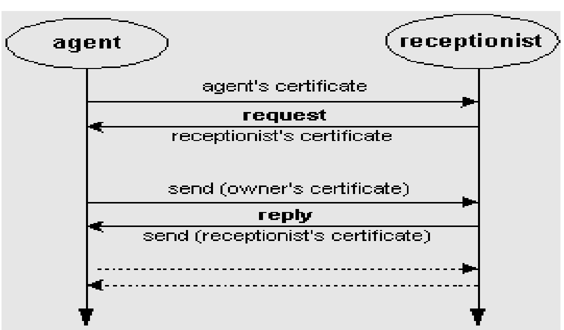
Figure 2. Supervised agent transport protocol in SAFE



ist to complete other registration formalities. Figure 3 gives a sample of the communication between agents and receptionist during registration.

The receptionist and each participating agent will check the qualifications of the others. The receptionist then requests the public key and other necessary information from a bidder for later use and will return necessary information including a unique alias to the bidder. This assigned alias will be used throughout the auction process. The bidder's real identity is kept in the receptionist's database and will not be disclosed to other participating agents including the auctioneer. When the deadline for the published admission period is due, the receptionist forwards the registration information to the coordinator, which will be used as the basis for building up an architecture regarding the competitive relationships among various agents.

Figure 3. Communication between agents and the receptionist



Bidding

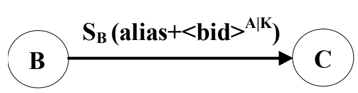
Each bidding agent is equipped with the owner-customized bidding strategies as instructions for submitting bids. The bidding period is divided into several rounds. There will be a set of predefined secure communication protocols for bidding. Let us give the following definitions before we move on to discuss the details:

- ***A, B, C, W*** denotes the auctioneer, bidder, coordinator and the final winner, respectively.
- **$<m>^{A|K}$** denotes the encryption of a message *m*, with *A*'s public key *K*;
- **$S_A(m)$** denote the digital signature of a message m by a process *A*, (i.e., with *A*'s private key)

Submitting a Bid

When a bidder decides to submit a bid in a round, the following procedures are used:

Step 1.



B prepares a message m containing its own alias and the bid, which is encrypted with the auctioneer's public key. *B* signs the message with its own private key and sends it to coordinator C.

Step 2.

$$C \xrightarrow{S_C(\langle number+\langle bid\rangle\rangle^{A|K})} A$$

Upon receiving the message from *B*, C first checks the validity of the message, generates a number (to represent the message thread in the database), and removes the alias from the message and further signs it with its own private key and sends the message to *A*.

Step 3.

A receives the message from *C* and first checks its validity with *C*'s public key. A then decrypts the original message with its own private key and gets the bid.

Broadcasting a Bid

The following procedure is used to broadcast the bid winner.

Step 1.

$$A \xrightarrow{S_A(\langle m\rangle^{A|K})} C$$

A prepares the message containing the information for the winner of a particular round, which is signed with *A*'s private key, and sends the message to *C*.

Step 2.

$$C \xrightarrow{S_C(m)} B$$

Upon receiving the message from *A, C* first checks its validity, decrypts the message and searches the information of the message in his database according to the number provided to find out the matching one to reconstruct the message, which is further signed with *C*'s own private key.

Step 3.

Bidders first check the validity of the message and then use *C*'s public key to get the information as the result of the previous round.

The coordinator together with the encryption mechanism used is instrumental in achieving the following goals:

First, the auctioneer is kept blind from the bidding process, in that the auctioneer can verify the validity of each bid, but is not able to know who has actually submitted bids. This also helps to prevent the auctioneer from linking the winner with a specific bid. This procedure ensures that the customers can bid anonymously and will not suffer from the release of their bidding information. Secondly, all the bidders are notified of the highest successful winning bid in each round, together with the alias of the originator.

Let us further consider two exceptional cases that might occur during this stage: early withdrawal and late arrival. Before an early withdrawal agent leaves, he needs to consult with the receptionist with his withdrawal and obtains permission from him so that the receptionist may forward the most updated bidding status to the coordinator. In the case of late arrivals, despite the requirement that agent must follow the standard procedure before entering the auction, it may also need to consult with the receptionist about the latest bidding situations.

Conclusion

The final stage of the auction is conclusion, in which the auctioneer announces the result of the auction and the final winner and the auctioneer identify each other to ensure nonrepudiation with the assistance of the coordinator. Based on the published rules for the auction, the auctioneer is to decide upon the closing time of the auction and select the final winner from a pool of candidates. The following procedure is used for the successful identification of the winner and the auctioneer.

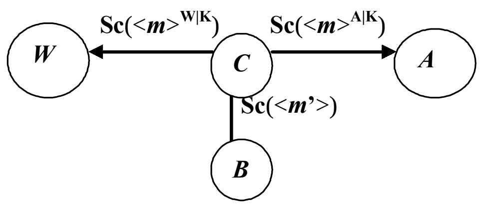
Step 1.

The auctioneer first sends a message to the coordinator to announce the close of the auction. Upon receiving the acknowledgement from the coordinator, he or she sends the result, which contains the number of the final winning message and the winning bid to the coordinator for verification:

$$A \xrightarrow{S_A(number+\langle m\rangle^{C|K})} C$$

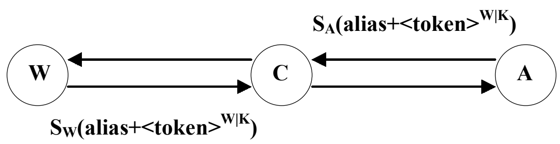
Upon receiving the message, *C* first checks the validity of the message, then retrieves the information from his database according to the number provided to find the alias of the person who submits the winning bid. The coordinator then formally announces the result of the auction.

Step 3.



The coordinator sends the signed message which contains the information and real identity of the auctioneer and the winner to each party encrypted with their own public keys respectively. The coordinator also needs to send the final result to the other participating agents. However, the message *m'* he or she sends to the losing bidders contains only an alias of the winner. Upon receiving the message, the winner and the auctioneer will first verify its authenticity and then save the information regarding identities.

Step 4.



The winner and the auctioneer exchange the identification token, which possibly includes for each party's real identity and other information, such as the agreement on the delivery of goods.

Implementation

A simple prototype has been developed and implemented to prove the feasibility of agent-based auction systems. It is deployed to ensure that security, privacy, user anonymity, and fairness are attainable in agent-based e-auctions.

The overview of the architecture is shown in Figure 4.

Descriptions of the Prototype

The three main components realized in this prototype are as follows:

1. The user interface consisting of the agent factory panel and the auction host panel;
2. The agent factory, where a bidding agent is fabricated according to the user's needs; and
3. The auction host system, whereby the auction is conducted.

Figure 5 depicts the scenario of the components implemented.

In this prototype, a user customizes an agent by setting parameters such as user identification number, maximum and minimum bids, user IP address, port number, and the desired product he or she wants to buy. When the user clicks the submit button, a Java agent is automatically generated according to these parameters. The agent is sent to the user's machine.

Running on the auction host is a multithreaded server "coordinator" that talks to the bidding agents and the auctioneer agent in a synchronized manner, as is shown in Figure 6. Once the bidding agent is invoked, it begins to establish a socket connection to its home host. The auction host will spawn child processes or threads to handle communication between bidders and auctioneer in a synchronized mode.

Implementation Issues

There are two possible ways of customizing agents:

- **Local Agents & Local Customization (LALC):** Agents are software programs downloaded and possessed by owners. Agents can be customized by the owner with his preference in bidding strategies and other specifications. The owner sends out the agent to the remote host for an auction and the

Figure 4. Auction system architecture

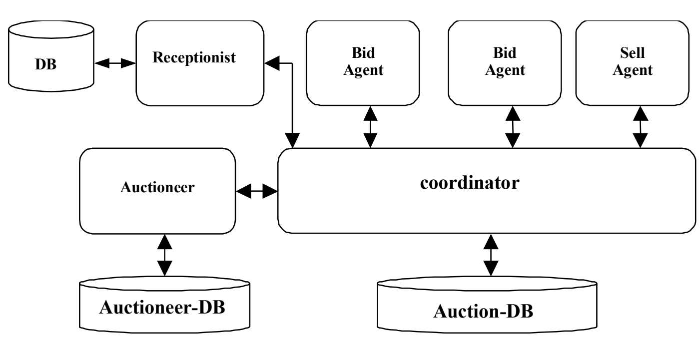


Figure 5. Implemented auction system overview

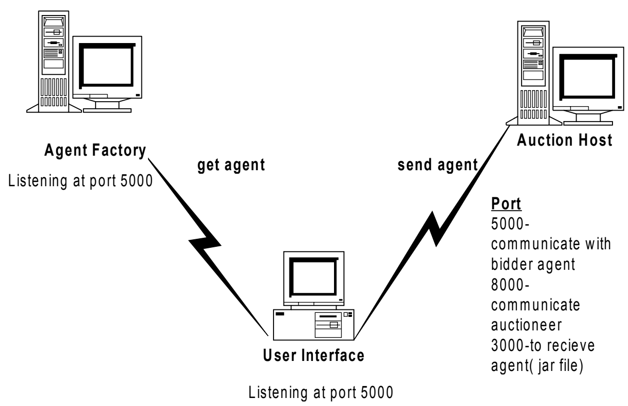

Figure 6. Multithreaded auction server

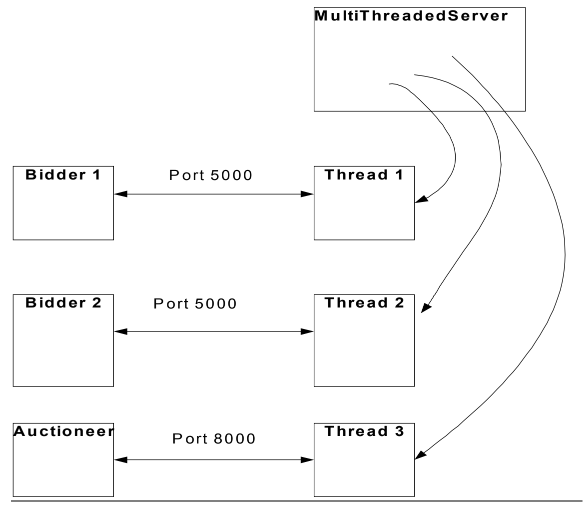

agent returns to the owner when the task is completed. The owner can still maintain communication with his bidding agent.

- **Remote Agents & Local Customization (RALC):** Agents are standalone programs which reside in the auction hosts. Users may use the browser to select the proper agent and customize it with his or her bidding strategies and other preferences by way of standard CGI forms. The user-customized agents will then be sent and automatically invoked to start the auction at the remote host. We have adopted the latter scheme in our implementation.

IMPACT OF MOBILE AGENT–BASED AUCTION SYSTEMS

The intelligence and autonomy of mobile software agents will enhance the performance of agents in auctions and reduce the workload for users. Our proposed agent-based system provides a flexible and unified structure for various types of auctions, in which both security and user anonymity are guaranteed. The proposed system is suitable when users want to be relieved from auction details or when the auction value is small. It will be useful when it is used with wireless devices, such as handphones, where users generally stay off-line and are interested in the results only.

CONCLUSION

In the previous sections, we have discussed in details the architecture for an agent-based electronic auction system. Compared to existing Web-based auctions, our proposed scheme exhibits some unique features and advantages when addressing the issues of security, privacy, fairness, and flexibility.

One of the attractive features of using software agents in an auction is its autonomy and intelligence. Given such a system, a good bidding strategy becomes the critical factor to win. A good strategy should be adaptive enough so as to respond rapidly and intelligently to the behaviors of the other partners. Agents equipped with such strategies will be “smart” while at the same time remain vigilant and faithful to their owners.

The proposed agent-based auction system may also provide an interface for future implementation with communication to devices such as wireless application protocol (WAP) phones. The proposed agent-based scheme also brings in new commercial opportunities for the Internet service providers, such as providing the programs for software agents, the design and implementation of intelligent bidding strategies, and so forth. The system will also inspire novel types of auction services that have no counterpart in the real world, enriching business content in the Internet world.

KEY TERMS

Adaptability: The ease with which software satisfies differing system constraints and user needs.

Agents: A piece of software, which acts to accomplish tasks on behalf of its user.

Anonymity: The degree to which a software system or component allows for or supports anonymous transactions.

Cryptography: The art of protecting information by transforming it (*encrypting* it) into an unreadable format, called "cipher text." Only those who possess a secret *key* can decipher (or *decrypt*) the message into plain text.

Flexibility: The ease with which a system or component can be modified for use in applications or environments, other than those for which it was specifically designed.

Mobile Banking Systems and Technologies

Cheon-Pyo Lee
Mississippi State University, USA

Merrill Warkentin
Mississippi State University, USA

INTRODUCTION

The last decade has witnessed the rapid growth of mobile communication devices and wireless technologies across the globe. The convergence of mobile devices and wireless technologies has not only changed the way many activities are conducted, but has also provided a foundation for a new type of technology-aided commerce called mobile commerce (m-commerce). As e-commerce's next evolutionary stage, m-commerce opens up new business opportunities in business-to-consumer (B2C) markets in addition to extending current operations in e-commerce and traditional brick-and-mortar businesses (Varshney & Vetter, 2002). The significant power of m-commerce is primarily a result of the anytime-anywhere connectivity of wireless devices, which provides unique experiences and services (Figge, 2004; Zwass, 2003).

One of the most promising and value-added m-commerce services is mobile banking (Lee, McGoldrick, Keeling, & Doherty, 2003; Mallat, Rossi, & Tuunainen, 2004). Mobile banking is the newest electronic delivery channel to be offered by banks in which technology has become an increasingly vital element, and it provides convenience and enhanced value to both banks and customers. With its clear benefits, mobile banking is now gaining rapid popularity in European and Asian countries with the significant market penetration of mobile handsets and the optimally designed marketing tactics of service providers (Suoranta & Mattila, 2004). However, mobile banking is still marginally adopted across the globe, and especially in the U.S., the growth appears much slower than anticipated (Mallat et al., 2004). In the United States, there are only a small number of banks that have actually introduced mobile banking services, and most other mobile banking efforts are in small-scale trials (Charny, 2001). Therefore, the technology which will be employed in the United States market has been of interest not only to financial institutions, but also to mobile technology developers and future users.

BACKGROUND

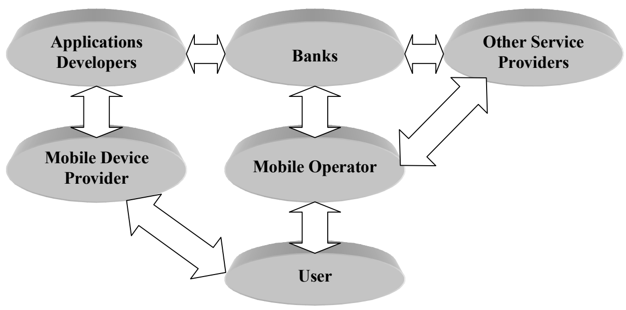
M-commerce is defined as any transaction with a monetary value—either direct or indirect—that is conducted over a wireless telecommunication network (Barnes, 2002). However, there is no clear definition for mobile banking services, so often the traditional banking services using mobile handsets (i.e., making transaction by calling a call center using a mobile phone) are considered as mobile banking services. Thus, it is very important to define a clear boundary of mobile banking service to avoid confusion. In this article, mobile banking refers to a client-server system that is specifically designed for mobile devices, allowing banking customers to use handheld devices to access their accounts, pay bills, authorize fund transfers, or perform other activities. Table 1 shows various mobile banking services currently provided.

Mobile banking has two big advantages over the narrow sense of e-banking: security and convenience (Herzberg, 2003). E-banking is based on account-holder authentication by the payment system which can fail in multiple ways but do not distinguish the source of fraud. However, mobile devices, usually with a built-in display and keyboard, are well positioned to provide a technical solution for reducing fraud and allowing the fair allocation

Table 1. Mobile banking services

• Check the balances of checking and savings accounts, investment accounts, business banking accounts, lines of credit, credit card accounts, and loan and mortgage accounts
• Electronic funds transfer (EFT)
• Pay bills and taxes
• Request a checkbook
• Inquire about check status
• Customize the statements according to the user's specific needs and requirements

Figure 1. Mobile banking life cycle (Adapted from Varshney & Vetter, 2002)



of responsibility for damages from fraud. In addition, unlike e-banking, the transactions through mobile banking can be made anywhere whether on foot or in cars, planes, or trains.

Mobile banking services began in 1999 in European and Asian countries, and have gained rapid popularity with the significant market penetration of mobile phones, the optimally designed marketing tactics of service providers, and the increased exposure to mobile technology (Suoranta & Mattila, 2004). Like many other mobile commerce services, mobile banking services are provided by several different entities, with which the customers of mobile banking services must interact to complete a successful mobile banking transaction, especially the mobile device provider, mobile operator, and content provider (Varshney & Vetter, 2002; see Figure 1). Thus, each entity in the mobile banking cycle must assist the others to attract more customers to mobile banking. The fastest way to promote the growth of mobile banking services is mutual cooperation among the entities (Datta, Pasa, & Schnitker, 2001).

Mobile Devices

The significant potential of mobile banking derives mainly from the fact that the mobile device is a familiar device which is always with the user (Mattila, 2003). Thus, satisfaction with the mobile device is a very significant factor of the mobile banking adoption decision. Mobile device in this article refers to those devices that are used to connect to mobile services (Tarasewich, Nickerson, & Warkentin, 2002). Various mobile devices are available, including mobile phones, personal digital assistants (PDAs), wireless-enabled handheld computers, laptop computers, vehicle-mounted technologies, and personal message pager devices. Among them, wireless-enabled laptops, PDAs, and handsets are currently highly preferred mobile devices for mobile banking (M-Commerce Insider, 2001). Since the use of mobile banking depends on the capabilities of mobile devices, users' satisfaction with various factors of mobile devices significantly influences their adoption of mobile banking. Some of the features of mobile devices which prevent the adoption of mobile banking are small multifunction keypads, less computation power, and limited memory and disk capacity (Siau, Lim, & Shen, 2001).

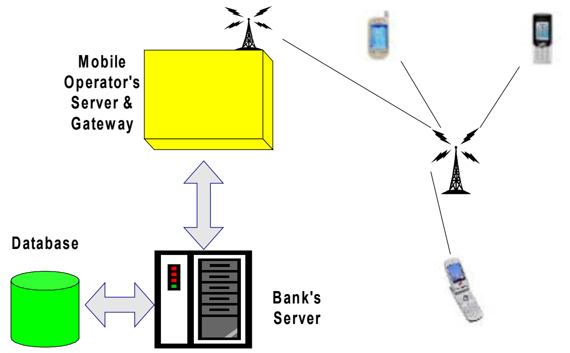
Mobile Operator

Like many other m-commerce services, mobile banking services are so new that no single company has all the expertise required to develop and deliver compelling services on its own, but many studies point out that mobile operators play a significant role since customers access their networks to perform all transactions (Donegan, 2000; Varshney, 2003). Due to the significant power of mobile operators in mobile banking services, banks often see mobile operators trying to control the financial transaction, and the relationship between banks and the mobile operator is often described as one of mutual distrust (DeZoysa, 2001). The significant power of mobile operators in the m-commerce cycle also imposes important duties to perform in support of m-commerce, such as content provider relationship management, content billing, settlement, and customer care (Buellingen & Woerter, 2004). Thus, the m-commerce users utilize the service of the mobile operator more frequently than that of any other entity, and the service attributes of mobile operators, such as call quality and tariff level, not only influence the satisfaction with the mobile operator, but also influence the adoption of mobile banking services. For instance, current pricing strategies, mainly based on time-usage, of many mobile operators are considered to prevent the mobile users from adopting mobile banking (Yeo & Huang, 2003).

Banks as Content Provider

In mobile banking services, banks are the entity providing content, which is considered one of the most important factors regardless of whether a site is Web based or wireless. Poor quality of content is considered to be significant barrier to m-commerce (Venkatesh, Ramesh, & Massey, 2003). Therefore, users increasingly choose their mobile operators on the basis of the content available, and a majority of mobile network service subscribers are willing to switch mobile operators to get better mobile content (Barnett, Hodges, & Wilshire, 2000). However, the important feature of m-commerce content is that a successful Web interface does not simply translate into a successful mobile interface (Lee & Benbasat, 2004;

Figure 2. How mobile banking services work



Venkatesh et al., 2003). Therefore, in addition to accurate and stable content, proper fonts and colors that fit into mobile device screens are also considered significant factors to attract customers to mobile banking services.

MOBILE BANKING TECHNOLOGIES

Mobile banking services are conducted by communication between the user's handset and the bank's server (see Figure 2). When the user requests a service, it is transmitted to mobile operator and forwarded to its gateway server. The server later interprets the request and forwards it to the bank's server. Then, the bank's server validates the customer for the mobile number and other information based on its database, and processes a valid request. The result is then passed on to the mobile operator's server which converts the format and transmits it to the user's mobile handset for display.

Like other entities in the mobile banking service cycle, the technologies employed for mobile banking services also play a significant role in mobile banking adoption. Various technologies have been tested and implemented in mobile banking systems, including short message service (SMS), Java, wireless application protocol (WAP), iMode, XHTML, and integrated-circuit (IC) chip. Among them, SMS and WAP have been the most popular technologies for mobile banking systems in Europe and some Asian countries (Marenzi, 2004).

Short Message Service (SMS)

An SMS mobile banking system uses the popular text-messaging service. When the customer requests information by sending an SMS containing a service command to a pre-specified number, the bank responds with a reply SMS containing the specific information. The most important feature of SMS mobile banking systems which attracts many customers is that it can be used conveniently with low cost. In addition, mobile banking with SMS enables every owner of a mobile phone to use mobile banking services. Therefore, in spite of its significant disadvantages, such as low data throughput, relatively long transaction time, limited service, and difficulty of use, SMS mobile banking services have been a dominant mobile banking technology (Kwon, 2004).

Wireless Application Protocol (WAP)

WAP has been implemented as a mobile banking technology to deliver fast and accurate banking services to customers (Lomax, 2002). WAP supports simple pages with 'menu' structures which are needed for most financial transactions (Economist, 2000). Therefore, it was popularly implemented as a major technology for mobile banking systems. However, even though WAP applications offer a greater graphical look and feel on current mobile phones, only a small percentage of the mobile users have WAP-enabled mobile devices, and only a small proportion of them actually have the knowledge of how to use them (Telephonyworld, 2004). In addition, WAP runs over circuit-switched networks in which the user is charged based on the time they spend online or how long they occupy the circuit (Yan, 2003). Since the initial connection takes a long time and there is a data call charge for browsing the service, WAP-based mobile banking service costs are usually high. Not surprisingly, WAP mobile banking service has proved too complex to use and has been replaced with less advanced technology, SMS, in many places (Zeddies, 2003).

iMode

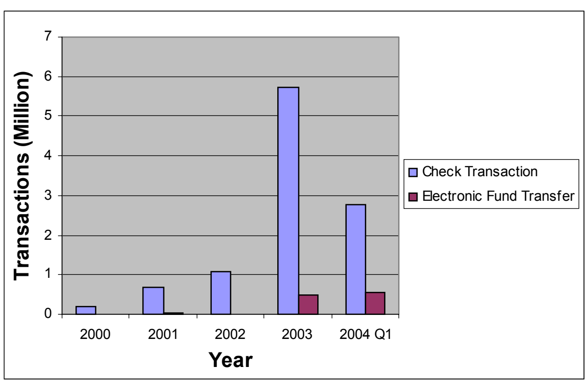
Recently some Western European banks started providing new mobile banking services using the Japanese iMode technology in the hope of revolutionizing mobile banking (Marenzi, 2004). iMode created a successful business model and gained popularity in Japan. The packet-switching iMode uses the Packet Data Cellular Protocol to speed transmission, so users pay for each packet of data rather than their time (Yan, 2003). Therefore, the cost of using iMode banking is much cheaper than WAP-based mobile banking. However, this popular interactive service neither appeals to European customers nor changes the dominant trend of SMS in Europe and Asian mobile banking markets (Marenzi, 2004).

Integrated-Circuit (IC) Chip

Like in most other countries in Asia and Europe, SMS was also the first technology employed as a mobile banking technology in South Korea, where more than 70% of its 48 million citizens carry one or more mobile handsets and one-third of all mobile phone subscribers use their handsets for m-commerce activities (Kim, 2004). However, unlike most other countries, SMS mobile banking services in South Korea, where well-advanced e-banking services are available, did not attract customers at all and was considered as a failure since not much interest was shown (Kwon, 2004). Since then, various technologies including WAP and virtual machine (VM) have been tested and used to attract customers (Korea, 2004), but customers did not display much interest. However, a new integrated-circuit (IC) chip technology provided by the nation's smallest mobile operator changed the history of mobile banking in South Korea (Kim, 2004). The new chip-based offerings were a big hit, as a total 280,000 people signed up for the new services during the first four months after its introduction in September 2003. Since then, the number of mobile banking users has dramatically increased and reached 1.1 million as of September 2004 (Korea, 2004; see Figure 3).

The most important feature of IC chip-based mobile banking is that bank account data is encrypted on a smart-card chip, so it enables customers to connect to their account quickly and securely by pressing a single button on their mobile phone. In addition, to prevent someone else from using a mobile phone or IC chip, a special password or code given by banks is required for the user to make each transaction. Another important feature of IC chip-based mobile banking systems in South Korea is that they were introduced in cooperation between banks and mobile operators (Herald, 2004). Therefore, better services, such as relatively low-cost fixed data service (around

Figure 3. The number of mobile banking transactions in South Korea (Source: www.bok.or.kr/contents_admin/info_admin/main/home/financial/payment/material/info/mobile.pdf



$7 per month), are offered to users (Kim, 2004). Korea's mobile banking service history clearly shows the significant role of technology implemented in mobile banking services.

FUTURE TRENDS

In the United States, differing technical standards and the 'called-party-pays' system somewhat inhibit the use of mobile phones and mobile commerce (Economist, 2000). However, the market has been dramatically expanded over the last two-and-a-half years. The mobile data services market in the United States has grown from nothing to a market worth an estimated $1.5 billion, and various services have been added in the m-commerce marketplace (Media, 2004). However, the majority of mobile data usage in the United States to date revolves around text messaging and low-value downloads such as ringtones (Media, 2004).

In 2004, the first for individual subscribers in the country, AT&T Wireless Services Inc., an affiliate of Japan's NTT DoCoMo Inc., started offering a mobile phone-based fast data service in the United States, enabling users to browse the Web, e-mail, and share video clips (Wireless, 2005). Sprint, another mobile operator, introduced a new mobile banking service to small and independent business owners with spring mobile loan officer (Sprint, 2004). Thus, though mobile banking services have suffered from customer disinterest, many experts insist that mobile banking will eventually become a significant channel for personal banking. One Atlanta-based bank already reported recent success in mobile banking (RCR, 2004), and a major U.S. bank found that 93% of its customers are very interested in mobile banking services (O'Connell, 2004). All the evidence suggests that if mobile banking services are provided in the proper way, they will soon be a major transaction channel for personal banking.

CONCLUSION

There are three important factors which will decide the success of mobile banking services. First is the technology, *per se*, which when implemented for mobile banking systems will significantly influence the use of mobile banking. The success of South Korea's IC chip-based mobile banking service clearly shows that a good technology ultimately appeals to customers. Secondly, it is important that the technology should be approved before it is implemented by future users. The success of SMS and the failure of WAP demonstrates that the ability to offer simple services done well has proved far more attractive than sophisticated services done poorly (Lomax, 2002). Finally, the service of all entities in a mobile commerce cycle, especially mobile operators and mobile device providers, will significantly influence the mobile banking adoption. Therefore, all the entities in a mobile banking cycle should cooperate and assist each other in order to promote the rapid growth of mobile banking.

KEY TERMS

Circuit Switching: A type of communications in which a dedicated channel (or circuit) is established for the duration of a transmission.

Integrated Circuit (IC): A small electronic device made out of a semiconductor material. Integrated circuits are used for a variety of devices, including microprocessors, audio and video equipment, and automobiles.

Mobile Banking: A client-server system that enables banking customers to use handheld devices to access their accounts, pay bills, authorize funds transfers, or perform other activities.

Mobile Commerce: Any transaction with a monetary value—either direct or indirect—that is conducted over a wireless telecommunication network.

Mobile Services: Services provided by a mobile operator that enable individual customers to access information and applications anytime-anywhere.

Packet Switching: A type of communication in which packets are individually routed between nodes, without a previously established communication path.

Wireless Application Protocol (WAP): A secure specification that allows users to access information instantly via handheld wireless devices such as mobile phones, pagers, two-way radios, smartphones, and communicators.

Mobile Caching for Location-Based Services

Jianliang Xu
Hong Kong Baptist University, Hong Kong

INTRODUCTION

Location-based services (LBS) are services that answer queries based on the locations with which the queries are associate; normally the locations where the queries are issued. With a variety of promising applications, such as local information access (e.g., traffic reports, news, and navigation maps) and nearest neighbor queries (e.g., finding the nearest restaurants) (Barbara, 1999; Ren & Dunham, 2000; D. L. Lee, Lee, Xu, & Zheng, 2002; W. C. Lee, Xu, & Zheng, 2004), LBS is emerging as an integral part of daily life.

The greatest potential of LBS is met in a mobile computing environment, where users enjoy unrestricted mobility and ubiquitous information access. For example, a traveler could issue a query like "Find the nearest hotel with a room rate below $100" from a wireless portable device in the middle of a journey. To answer such a query, however, three major challenges have to be overcome:

- **Constrained Mobile Environments:** Users in a mobile environment suffer from various constraints, such as scarce bandwidth, low-quality communication, frequent network disconnections, and limited local resources. These constraints pose a great challenge for the provision of LBS to mobile users.
- **Spatial Data:** In LBS, the answers to a query associated with different locations may be different. That is, query results are dependent on spatial properties of queries. For a query bound with a certain query location, the query result should be relevant to the query as well as valid for the bound location. This requirement adds additional complexity to traditional data management techniques such as data placement, indexing, and query processing (D. L. Lee, 2002).
- **User Movement:** The fact that a mobile user may change its location makes some tasks in LBS, such as query scheduling and cache management, particularly tough. For example, suppose that a mobile user issues a query "Find the nearest restaurant" at location *A*. If the query is not scheduled timely enough on the server, the user has moved to location *B* when he or she gets the answer *R*. However, *R* is no longer the nearest restaurant at location *B*.

Caching has been a commonly used technique for improving data access performance in a mobile computing environment (Acharya, Alonso, Franklin, & Zdonik, 1995). There are several advantages for caching data on mobile clients:

- It improves data access latency since a portion of queries, if not all, can be satisfied locally.
- It helps save energy since wireless communication is required only for cache-miss queries.
- It reduces contention on the narrow-bandwidth wireless channel and off-loads workload from the server; as such, the system throughput is improved.
- It improves data availability in circumstances where clients are disconnected or weakly connected because cached data can be used to answer queries.

However, as discussed above, the *constrains* of mobile computing environments, the *spatial* property of location-dependent data, and the *mobility* of mobile users have opened up many new research problems in client caching for LBS. This chapter discusses the research issues arising from caching of location-dependent data in a mobile environment and briefly describes several state-of-the-art solutions.

BACKGROUND

Location Model

Location plays a central role in LBS. A location needs to be specified explicitly or implicitly for any information access. The available mechanisms for identifying locations of mobile users are based on two models:

- **Geometric Model:** A location is specified as an *n*-dimensional coordinate (typically, $n = 2$ or 3); for example , the latitude/longitude pair returned by the global positioning system (GPS). The main advantage of the geometric model is its compatibility across heterogeneous systems. However, providing such fine-grained location information may involve considerable cost and complexity.

- **Symbolic Model:** The location space is divided into disjointed zones, each of which is identified by a unique name. Examples are the Cricket system (Priyantha, Chakraborty, & Balakrishnan, 2000) and the cellular infrastructure. The symbolic model is in general cheaper to deploy than the geometric model because of the lower cost of employing a coarser location granularity. Also, being discrete and well-structured, location information based on the symbolic model is easier to manage.

For ease of illustration, two notions are defined: *valid scope* and *valid scope distribution*. A dataset is a collection of data instances. The *valid scope* of a data instance is defined as the area within which this instance is the only answer with respect to a location-dependent query. With the symbolic location model, a valid scope is represented by a set of logical zone ids. With the geometric location model, a valid scope often takes the shape of a polygon in a two-dimensional space. Since a query may return different instances at different locations, it is associated with a set of valid scopes, which collectively is called the *scope distribution* of the query. To illustrate, consider a four-cell system with a wireless-cell-based location model. Suppose that the nearby restaurant for cell 1 and cell 2 is instance X, and the nearby restaurant for cell 3 and cell 4 is instance Y. Then, the valid scope of X is $\{1, 2\}$, the valid scope of Y is $\{3, 4\}$, and the scope distribution of the nearby restaurant query is $\{\{1, 2\}, \{3, 4\}\}$.

Client Caching Model

There is a cache management module in the client. Whenever an application issues a query, the local cache manager first checks whether the desired data item is in the cache. If it is a cache hit, the cache manager still needs to validate the consistency of the cached item with the master copy at the server. This process is called *cache validation*. In general, data inconsistency is incurred by data updates at the server (called *temporal-dependent invalidation*). For location-dependent information in a mobile environment, cache inconsistency can also be caused by location change of a client (called *location-dependent invalidation*). If it is a cache hit but the cached content is obsolete or invalid, or it is a cache miss, the cache manager requests the data from the server via on-demand access. When the requested data item arrives, the cache manager returns it to the user and retains a copy in the cache. The issue of *cache replacement* arises when the free cache space is not enough to accommodate a data item to be cached. It determines the victim data item(s) to be dropped from the cache in order to allocate sufficient cache space for the incoming data item.

Survey of Related Work

This section reviews the existing studies on cache invalidation and replacement strategies for mobile clients. Most of them were designed for general data services and only a few addressed the caching issues for location-dependent data. Temporal-dependent invalidation has been studied for many years (Barbara & Imielinski, 1994; Cao, 2000; Wu, Yu, & Chen, 1996). To carry out temporal-dependent invalidation, the server keeps track of the update history (for a reasonable length of time) and sends it, in the form of an invalidation report (IR), to the clients, either by periodic/aperiodic broadcasting or upon individual requests from the clients. In the basic IR approach, the server broadcasts a list of IDs for the items that have been changed within a history window. The mobile client, if active, listens to the IRs and updates its cache accordingly. Most existing temporal-dependent invalidation schemes are variations of the basic IR approach. They differ from one another mainly in the organization of IR contents and the mechanism of uplink checking. A good survey can be found in Tan et al. (2001).

Semantic data caching has been suggested for managing location-dependent query results (Dar, Franklin, Jonsson, Srivatava, & Tan, 1996; Lee, Leong, & Si, 1999), where a cached result is described with the location associated with the query. Unfortunately, the possibility was not explored that a cached data value may be valid for queries issued from locations different from that associated with the original query. As demonstrated in Zheng, Xu, and Lee (2002), the exploration of this possibility can significantly enhance the performance of location-dependent data caching. As a matter of fact, the invalidation information in the proposed methods (to be discussed later in this chapter) can be considered a kind of semantic description, which could improve cache hit rates.

Cache replacement policies for wireless environments were first studied in the *broadcast disk* project (Acharya et al., 1995; Acharya, Franklin, & Zdonik, 1996). In Acharya et al. (1995), the PIX policy takes into consideration both data access probability and broadcast frequency during replacement. In Khanna and Liberatore (2000), the Gray scheme makes replacement decisions based on both data access history and retrieval delay. Motivated by a realistic broadcast environment, an optimal cache replacement policy, called Min-SAUD, was investigated in Xu, Hu, Lee, and Lee (2004). The Min-SAUD policy incorporates various factors that affect cache performance, that is, access probability, retrieval delay, item size, update frequency, and cache validation delay.

In the studies on location-dependent data caching, data-distance based cache replacement policies, Manhattan distance (Dar et al., 1996) and FAR (Ren & Dunham, 2000), have been proposed. Under these two policies, the data that is farthest away from the client's current location is removed during replacement. However, data distance was considered alone and not integrated with other factors such as access probability. Moreover, they did not consider the factor of valid scope area.

CACHING FOR LOCATION-BASED SERVICES

Location-Dependent Cache Invalidation

When the client moves around, location-dependent data cached at a mobile client may become invalid with respect to the new location. The procedure of verifying the validity of location-dependent data with respect to the current location is referred to as *location-dependent cache invalidation*. To perform location-dependent invalidation efficiently, the idea is to make use of validity information of data instances. Specifically, the server delivers the valid scope along with a data instance to a mobile client and the client caches the data as well as its valid scope for later validity checking. The strategy involves two issues, namely validity checking time and validity information organization. Since a query result depends on the location specified with the query only, it is suggested to perform validity checking for a cached data instance until it is queried. For validity information organization, a number of schemes have been proposed (Zheng et al., 2002; Xu, Tang, & Lee, 2003). The proposed schemes can be classified into two categories according to the underlying location model employed. This section introduces two methods, that is, implicit scope information (ISI) and caching-efficiency-based method (CEB), for a symbolic and geometric location model respectively.

Implicit Scope Information (ISI)

Assume a wireless-cell-ID-based symbolic location model. Under the ISI scheme, the server enumerates the scope distributions of all items and numbers them sequentially. The valid scopes within a scope distribution are also numbered sequentially. For any instance of data item i, its valid scope is specified by a 2-tuple (SDN_i, SN_i), where SDN_i is the scope distribution number and SN_i denotes the scope number within this distribution. The 2-tuple is attached to a data instance as its valid scope. For example, suppose there are three different scope distributions (see Table 1) and data item 4 follows distribution 3. If item 4 is cached from cell 6 (i.e., CID = 6), then $SDN_4 = 3$ and $SN_4 = 3$. This implies that item 4's instance is valid in cells 6 and 7 only.

It can be observed that the size of the validity information for a data instance is small and independent of the actual number of cells in which the instance is valid. Another observation is that a set of data items may share the same scope distribution. As such, the number of scope distributions could be much smaller than the number of items in the database.

At the server-side, a *location-dependent IR* is periodically broadcast in each cell. It consists of the ordered valid scope numbers (SN) for each scope distribution in the cell. For example, in cell 8, the server broadcasts {8, 3, 4} to mobile clients, where the three numbers are the SN values in cell 8 for scope distributions 1, 2, and 3, respectively (see Table 1).

The validity checking algorithm for item i works as follows. After retrieving a location-dependent IR, the client compares the cached SN_i with the SDN_i-th SN in the location-dependent IR received. If they are the same, the cached data instance is valid. Otherwise, the data instance is invalid. For example, in cell 8, the client checks for the cached instance of data item 4 whose $SDN_4 = 3$ and $SN_4 = 3$. In the broadcast report, the SDN_4-th (i.e., third) SN equals to 4. Therefore, the client knows that the cached instance is invalid. The performance analysis conducted in Xu et al. (2003) shows that the ISI method performs close to an optimal strategy which assumes perfect location information is available on mobile clients.

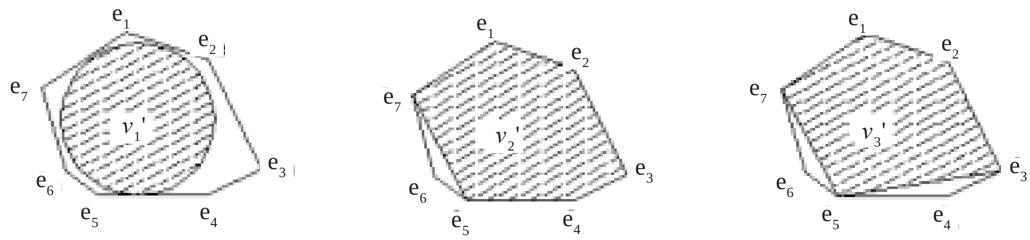
Caching-Efficiency-Based Method (CEB)

This section discusses location-dependent cache invalidation strategies for a geometric location model. Under this model, there are two basic schemes for representing valid scopes, that is, *polygonal endpoints* and *approximate circle* (Zheng et al., 2002). However, these two schemes perform poorly due to either high overhead or imprecision of the invalidation information. To enhance performance, a generic *caching-efficiency-based* (CEB)

Table 1. An example of data items with different distributions

<table>
<tr><td>Cell ID</td><td>1</td><td>2</td><td>3</td><td>4</td><td>5</td><td>6</td><td>7</td><td>8</td><td>9</td><td>10</td><td>11</td><td>12</td></tr>
<tr><td>Scope Distribution (SDN) #1</td><td>1</td><td>2</td><td>3</td><td>4</td><td>5</td><td>6</td><td>7</td><td>8</td><td>9</td><td>10</td><td>11</td><td>12</td></tr>
<tr><td>Scope Distribution (SDN) #2</td><td colspan="3">1</td><td colspan="3">2</td><td colspan="3">3</td><td colspan="3">4</td></tr>
<tr><td>Scope Distribution (SDN) #3</td><td colspan="2">1</td><td colspan="3">2</td><td colspan="2">3</td><td colspan="3">4</td><td colspan="2">5</td></tr>
</table>

Figure 1. An example of possible candidate valid scopes ($v = p(e_1,e_2,...,e_7)$)



(a)v_1'=inscribed circle of v (b)$v_2'=p(e_1, e_2, e_3, e_4, e_5, e_7)$ (c)$v_3'=p(e_1, e_2, e_3, e_5, e_7)$

method for balancing the overhead and the knowledge of valid scopes was proposed in Zheng et al. (2002).

In the CEB method, a new metric *caching efficiency* was introduced. Suppose that the valid scope of a data instance is v, and v_i' is a subregion contained in v (see Figure 1). Let s be the data size, $A(v_i')$ the area of any scope of v_i', and $O(v_i')$ the storage overhead needed to record the scope v_i'. The caching efficiency of the data instance with respect to a scope v_i' is defined as follows:

$$E(v_i') = \frac{A(v_i')/A(v)}{(s+O(v_i'))/s} = \frac{A(v_i')s}{A(v)(s+O(v_i'))}. \quad (6)$$

Let v_i' be the approximated scope information stored in the client cache. Assuming that the cache size is infinite and the probabilities of a client issuing queries at different locations are uniform, $A(v_i') / A(v)$ is the data instance's cache hit ratio when the client issues the query within the valid scope v. In contrast, $(s + O(v_i')) / s$ is the normalized overhead for achieving such a hit ratio. The rationale behind this definition is as follows. When none of the invalidation information is cached, $E(v_i')$ is 0 because the cached data is completely useless; $E(v_i')$ increases with more invalidation information attached. However, if too much overhead is therefore introduced, $E(v_i')$ would decrease again. Thus, a generic method for balancing the overhead and the precision of invalidation information works as follows:

- For a data instance with a valid scope of v, given a candidate valid scope set $V' = \{v_1', v_2',..., v_k'\}$, $v_i' \subseteq v$, $1 \le i \le k$, the CEB method chooses the scope v_i' that maximizes caching efficiency $E(v_i')$ as the valid scope to be attached to the instance.

Figure 1 illustrates an example where the valid scope of the data instance is $v = p(e_1,e_2,...,e_7)$, and v_1', v_2', v_3' are three different subregions of v, $A(v_1') / A(v) = 0.788$, $A(v_2') / A(v) = 0.970$, and $A(v_3') / A(v) = 0.910$. Assume that the data size s is 128 bytes, 8 bytes are needed to represent an endpoint, and 4 bytes for the radius of an inscribed circle; hence $O(v) = 56$, $O(v_1') = 12$, $O(v_2') = 48$, and $O(v_3') = 40$. Thus, $E(v) = 0.696$, $E(v_1') = 0.721$, $E(v_2') = 0.706$, and $E(v_3') = 0.694$. As a result, v_1' is chosen as the valid scope to be attached to the data instance. The simulation based evaluation demonstrates that the CEB method is very effective and outperforms other invalidation methods (Zheng et al., 2002).

Cache Replacement Policies

Because a mobile client has only limited cache space, cache replacement is another important issue to be tackled in client cache management. In traditional cache replacement policies, access probability is considered the most important factor that affects cache performance. A probability-based policy is to replace the data with the least access probability. However, in LBS, besides access probability, there are two other factors, namely *data distance* and *valid scope area*, which have to be considered in cache replacement strategies.

Generally, a promising cache replacement policy should choose as its victim the data item with a low access probability, a small valid scope area, and a long distance if data distance is also an influential factor. This section presents two cost-based cache replacement policies, PA and PAID, which integrate the three factors that are supposed to affect cache performance. The discussions are based on a geometric location model.

- **Probability Area (PA):** As the name suggests, the cost of a data instance under this policy is defined as the product of the access probability of the data item and the area of the attached valid scope. That is, the cost function for data instance j of item i is as follows:

$$c_{i,j} = p_i \cdot A(v'_{i,j}) \ , \quad (7)$$

where p_i is the access probability of item i and $A(v'_{i,j})$ is the area of the attached valid scope $v'_{i,j}$ for data instance j. The PA policy chooses the data with the least cost as its victim for cache replacement.

- **Probability Area Inverse Distance (PAID):** Compared with PA, this scheme further integrates the data distance factor. For the PAID policy, the cost function for data instance j of item i is defined as follows:

$$c_{i,j} = \frac{p_i \cdot A(v'_{i,j})}{D(v'_{i,j})}, \tag{8}$$

where p_i and $A(v'_{i,j})$ are defined the same as above, and $D(v'_{i,j})$ is the distance between the current location and the valid scope $v'_{i,j}$. Similar to PA, PAID ejects the data with the least cost during each replacement.

Zheng et al. (2002) have evaluated the performance of PA and PAID and demonstrated that PA and PAID substantially outperform the existing policies including LRU and FAR. In particular, consideration of the valid scope area improves performance in all settings, and consideration of the moving direction in calculating data distance is effective only for short query intervals and short moving intervals.

FUTURE TRENDS

Caching of location-dependent data opens up a new dimension of research in mobile computing. As for future work, per user based adaptive techniques can be developed since mobile clients may have different movement patterns. Besides cache invalidation and replacement schemes, it is interesting to investigate *cache prefetching* which preloads data onto the mobile client cache by taking advantage of user mobility. Furthermore, how to incorporate location-dependent data invalidation schemes and semantic caching would be an interesting topic. In addition, battery power is a scarce resource in a mobile computing environment; it is believed that power-aware cache management deserves further in-depth study.

CONCLUSION

LBS has been emerging as the result of technological advances in high-speed wireless networks, personal portable devices, and location positioning techniques. This chapter discussed client cache management issues for LBS. Two location-dependent cache invalidation methods, that is, ISI and CEB, are introduced. The cache replacement issue for location-dependent data was also investigated. Two cache replacement policies, that is, PA and PAID that consider the factors of valid scope area (for both methods) and data distance (for PAID only) and combine these factors with access probability, were presented. With an increasing popularity of LBS, caching of location-dependent data remains a fertile research area that aims to overcome inherent constraints (including power, bandwidth, storage, etc.) in a mobile environment.

KEY TERMS

Cache Invalidation: The procedure of validating whether the cached data is consistent with the master copy at the server.

Cache Replacement: The procedure of finding the victim data item(s) to be dropped from the cache in order to allocate sufficient cache space for an incoming data item.

Location-Based Services (LBS): The services that answer queries based on the locations with which the queries are associate.

Location-Dependent Cache Invalidation: The procedure of verifying the validity of cached location-dependent data with respect to the current location.

Mobile Client: A portable device that is augmented with a wireless communication interface.

Valid Scope: The area within which the data instance is the only answer with respect to a location-dependent query.

Valid Scope Distribution: The collective set of valid scopes for a data item.

Wireless Cell: The radio coverage area in which a mobile client can communicate with the wireless infrastructure.

Mobile Commerce Applications and Adoption

Krassie Petrova
Auckland University of Technology, New Zealand

INTRODUCTION

The potential advantages of mobile commerce applications have been discussed extensively in the recent literature, with many industries offering mobile services. Examples from the financial sector include instant funds transfer (mobile banking) and share trading (mobile brokerage). Commuter services such as sending schedule change alerts or using a mobile phone to pay for parking have become widespread. Applications based on the location of the user (e.g., offering mobile coupons to customers in the vicinity of a shop or a restaurant) are also being trialled (Barnes, 2002; Siau, Lim, & Shen, 2001; Varshney, Vetter, & Kalakota, 2000).

Despite the potential benefits (for example, improved customer service) mobile commerce applications have not been widely adopted across business sectors. Mobile banking illustrates the point: initially, seen as the "killer application" of mobile commerce (Kannan, Chang, & Whinston, 2001), it has now been termed a "dead end" (Semrau & Kraiss, 2001). It has also been classified as an application which has not yet matured (Mallat, Rooi, & Tuunainen, 2004). However, innovative applications continue to emerge, for example, breaking news alerts (CNN, n.d.), and a mobile tutoring service (Butte, 2004). It has become important therefore to identify the determinants of mobile commerce adoption and the emerging adoption patterns.

A significant number of results in this area have been reported in the literature. Recent examples include studies of mobile services adoption in areas characterized by relatively high penetration of mobile devices—such as Denmark (Constantiou, Damsgaard, & Knutsen, 2004), Singapore (Samtani, Leow, Lim, & Goh, 2004), and Finland (Carlsson, Hyvonen, Repo, & Walden, 2005). The identified drivers and inhibitors of mobile commerce adoption can be broadly classified as factors related to mobile infrastructure access, and factors relating to perceived consumer value. This article proposes a mobile commerce reference model which incorporates both infrastructure access and customer value and can be used to formulate research questions related to mobile commerce adoption.

The remainder of the article is organized as follows: first, mobile commerce is defined and compared to electronic commerce. The next section introduces a mobile commerce reference model and discusses mobile commerce adoption. The article continues with a review of future trends and a brief conclusion.

BACKGROUND

The definitions of mobile commerce (m-commerce) found in the literature such as the one suggested in Varshney et al. (2000), emphasize the use of mobile telephony and a handheld device to execute transactions with monetary value (i.e., exchange of funds for goods and services). M-commerce services are offered to subscribers only.

Turban, Lee, and Viehland (2004, p. 399) classify m-commerce as a subset of electronic commerce (e-commerce). However several features of m-commerce are either not found, or are not strongly manifested in e-commerce. These include "ubiquity"—which allows the user to interact with a mobile application anywhere, even when travelling or moving (Schneiderman, 2000, p. 1); "localization"—the ability of an application to offer a service specific to the location of the customer (Köhne, Totz, & Wehmeyer, 2005) and "personalization"—the ability to tailor an m-commerce activity according to a customer profile, and use the subscriber's account for payment (Siau et al., 2001).

The m-commerce characteristics described above (ubiquity, localization, and personalization) and the profile of the potential m-commerce user as a paid mobile network subscriber provide the grounds on which to differentiate between e-commerce and m-commerce. In this article, m-commerce is defined as a value-added service that enables mobile users to conduct reliable and secure transactions through specifically-designed mobile applications. The definition implies that a company or an organization offering a mobile service needs to develop and implement an appropriate business model which will incorporate the value proposition of the service, the revenue model, and the interactions of the company with business partners, suppliers and customers (Veijalainen, Terziyan, & Tirri, 2003).

MODELLING M-COMMERCE ADOPTION

Even the most innovative and creative mobile application or service will only be commercially successful if brought to customers through a business model that clearly focuses on the added value generated and offered by the application or service. Furthermore, the adoption of the application will depend on additional factors such as whether it is accessible from all locations, or whether it depends on the specific features of the handheld device—(e.g., WAP functionality or a small screen). General factors such as security awareness, privacy, and trust concerns might also play a role (Giaglis, 2005; Lin, 2004). To be viable, an m-commerce business model needs to:

1. Take full advantage of user mobility.
2. Offer services which would be either unavailable or prohibitively expensive if offered by means of e-commerce or brick-and-mortar commerce.
3. Offer services overcoming drawbacks caused by security and privacy related issues.

The degree to which the requirements above are met will influence the adoption of a particular m-commerce application and will act as a viability determinant of the associated business model. The investigation of the process of value creation and subsequent adoption needs to consider both technological and social factors (Carlsson et al., 2005; Pedersen, Methlie, & Thorbjornsen, 2002) and needs to include the different players involved: network providers and operators, content contributors and aggregators, portal hosts and application developers. One of the approaches is to consider the interactions among the players and their roles in the value chain model of m-commerce (Barnes, 2002, 2003).

A REFERENCE MODEL FOR M-COMMERCE

The value chain approach breaks down m-commerce into a structured chain of entities with associated "actors" and allows the researcher to identify easily and conveniently the companies and organizations involved in creating mobility-related value (Barnes, 2002; Buellingen & Woerter, 2004; Olsson & Nilsson, 2002; Siau et al., 2001).

The reference model (Figure 1) places together the players involved in the value chain, and captures the features of technologies, applications and services related to m-commerce. It incorporates three basic layers: an infrastructure layer (devices and networks), an interface layer (mobile middleware and platforms), and a business layer (services, content, application-based business models). Direct interactions with subscribers/customers occur mostly at the infrastructure and business layers where the value chain players act as enablers and direct providers, respectively. At the interface layer, the actors perform the role of intermediaries. The layered structure complies with the m-commerce definition in the previous section and enables the systematic investigation of the processes of value-creation across the m-commerce value chain. The model can be used to develop evaluation criteria and study m-commerce applications and their adoption within an industry segment, at national or at a regional level.

Other proposed approaches towards conceptual modelling of m-commerce include the bundled value proposition (Anckar & D'Incau, 2002), the open-plane framework (Varshney & Vetter, 2002), the reference model for m-commerce applications (Stanoevska-Slabeva, 2003), and extended three-dimensional models (Chen, Lee, & Cheung, 2001; Tarasewich, Nickerson, & Varkentin, 2002). The reference model introduced above is somewhat similar to Stanoevska-Slabeva's and Varshney and Vetter's models but is more comprehensive.

Figure 1. A reference model for m-commerce

Business layers	Companies and organizations interact indirectly with customers (consumers of mobile services and end-users of mobile applications)	
7	Business Model	Companies/organizations offering an mCommerce application to customers (direct providers)
6	Mobile Content	Companies/organizations providing or developing content for the application (intermediaries)
5	Mobile Service	Companies/organizations offering the application to the customer, or providing a related service (intermediaries)
Interface layers	Companies and organizations mostly interact indirectly with users (consumers of mobile services and applications)	
4	Application Platform	Developers of portals, integrators, and/or network providers (enablers)
3	Mobile Middleware	Developers of general purpose middleware or specialized consortia (include network providers and device manufacturers).
Infrastructure layers	Companies and organizations interact directly or indirectly with subscribers	
2	Mobile Device	Manufacturers and vendors
1	Mobile Network	Providers and vendors (enablers)
	Layers	Players in the value chain (enablers, direct providers, intermediaries)

M-COMMERCE ADOPTION STUDIES

Research in the area has been mostly based on prior work in the areas of adoption and diffusion and the technology acceptance model (Pedersen & Ling, 2003; Pedersen, Methlie, & Thorbjornsen, 2002). Though based on different background concepts, the research directions in adoption studies have much in common as they focus on end users and customers in different contexts.

The m-commerce reference model (Figure 1) includes two customer contexts where customers interact directly with the model constructs: "infrastructure" (the customer as a subscriber) and "business" (the customer as user of mobile application). The two interaction types correspond to the "technology user" and "consumer" perspectives defined by Pedersen et al. (2002). Factors influencing adoption related to the two perspectives have been identified as: (1) interoperability of devices and protocols, bandwidth availability, device features and functions, connectivity (technology); and (2) content personalization and localization, service ubiquity, timeliness, convenience, cost, privacy issues (consumer) (Chen, Lee, & Cheung, 2001, Petrova, 2004a, Turban et al., 2004, p. 423).

To improve the understanding of the adoption process and "move from description of the process into explaining it" (Pedersen & Ling, 2003), and to include the value chain perspective, the broader research questions can be formulated as:

1. Which of the factors contributing to the creation of mobility-related value are critical success factors for the viability of an m-commerce business model?
2. What other specific factors contribute to (or inhibit) business model viability, for example environmental factors (e.g., legislation) and demographic factors (e.g., age, gender)?
3. How might m-commerce actors such as "intermediaries" and "enablers" encourage or inhibit adoption processes?
4. What is the role of m-commerce payment mechanisms in the adoption processes?

Obtaining the answers to those questions might help develop appropriate applications and business models, taking into account not only customer perceptions but the roles played by all actors in the value chain (Heikkilä, Heikkilä, & Lehmonen, 2004). An example of such an innovative application is "interactive mobile TV" (Kihlström, 2005) which is driven by a partnership between the vendor (Ericsson) and content providers (media companies). Interactive mobile TV uses the handset screen to show images or information, to download multimedia content, to enable voting for TV shows, and to display advertising messages. Another developing area is mobile education (Kurbel & Hilker, 2003). Examples of mobile learning scenarios include the use of text messaging for interactive revision (Petrova, 2004b), and mobile Internet access to online seminars (Hino, Terashima, & Bunno, 2002).

FUTURE TRENDS

Using the reference model in Figure 1 as a framework, some of the current trends in m-commerce can be summarized as follows:

- **Layers 1 and 2 (Infrastructure):** To take advantage of new technology developments such as 3G networks and smart phones, developers focus on improving browsing capabilities (Lai et al., 2004) and improving the functionality of handheld devices (personal digital assistants—PDAs, smart phones).
- **Layers 3 and 4 (Interface):** Both general purpose mobile middleware and specific platforms are developed. Raatikainen, Baerbak and Nakajima (2002) state that future systems research will focus on software systems able to provide a seamless service in environments which are both dynamic and heterogeneous, specifically aiming to support large scale applications such as home entertainment. Tarumi, Matsubara and Yano (2004) envisage developing platforms such as the "virtual city", which will serve as a common infrastructure for location based services, including entertainment and advertising. The Japanese mobile portal and services provider NTT DoCoMo continues to expand its i-mode services, including multimedia and payment (NTTDoCoMo, n.d.).
- **Layers 5, 6, and 7 (Business):** Developments in the m-commerce landscape occur in different industry sectors, two of which provide interesting and innovative examples: entertainment, and tourism and travel.

Entertainment applications include streamed music, downloadable or interactive games, streamed movie shows, and chat rooms. Data indicate that the market for mobile entertainment services might be significantly fragmented based on professional background, age and culture, therefore customer preferences and requirements need to be better understood (Leavitt, 2003; Moore & Rutter, 2004; Vlachos & Vrechopoulos, 2004).

In tourism and travel, applications include providing maps or textual guides for tourists and visitors, including vehicle drivers. Such services are location based. The geographical location of the customer determines the content of the application (e.g., directions to the nearest hardware store, or instructions for reaching a particular destination). A possible impediment to the spread of these applications is the relative lack of compatibility across devices and provider networks (Brown & Chalmers, 2003; Köhne et al., 2005; Pavón, Corchado, Gómez-Sanz, & Ossa, 2004; Tarumi et al., 2004).

Other industries with potential to develop successful applications include mobile learning (Leung & Chan, 2003) and event management (Olsson & Nilsson, 2002).

Current research focuses on theory building and analysis and classification of the m-commerce landscape (Camponovo, Debetaz, & Pigneur, 2004), on general adoption models and patterns (Vrechopoulos, Constantiou, Mylonopoulos, Sideris, & Doukidis, 2002), and on services adoption in a specific industry-country context (for example, banking in Finland—Suoranta, Mattila, & Munnukka, 2005).

CONCLUSION

This article defines m-commerce and compares it to e-commerce. It identifies the important characteristics of m-commerce applications and the main research perspectives in application adoption studies. While it is recognized that technology is the primary driver behind m-commerce development, it has also become clear that the adoption processes are aligned with socioeconomic factors. The proposed layered reference model for m-commerce accommodates all actors in the m-commerce value chain and includes the m-commerce adopter as a mobile technology user and as a mobile services consumer. It can be used to derive research questions related to the adoption of emerging applications. The future trends in infrastructure development–such as improved device functionality and greater network capacity—will be able to support innovative and consumer-attractive applications across industry sectors including entertainment, travel, education and financial services.

KEY TERMS

3G: Stands for "third generation" mobile telephony—a wireless communication technology which supports multimedia, video streaming, and video-conferencing.

i-mode: A packet-switching wireless technology, used by NTT DoCoMo (Japan). A range of commercial and financial services are offered, including browsing the Web from a mobile phone.

LBS: Stands for "Location Based Services"—applications which can obtain information about the customer location and use it to customize the service offered.

Microbrowser: Client software (Web browser), designed to operate within the constraints of a handheld mobile device: low memory, small screen, relatively low bandwidth.

MMS: Stands for multimedia message service; similar to text messaging (SMS) but allows the transmission of graphics, sound files, video clips and text. It is based on WAP and can be used to send e-mail.

Mobile Applications: A broad range of applications and services accessible through a mobile handheld device. Examples include banking, news, betting, games, travel directions.

Mobile Commerce: Broadly refers to any value-added service providing access to a mobile application.

Smart Phone: An enhanced handheld device which combines the functions of a mobile phone and a handheld computer.

SMS: Stands for short message service (also known as text messaging, or "texting").

WAP: Stands for wireless application protocol. A set of standards which enable data display for handheld devices and support Web and e-mail access.

Mobile Commerce in South Africa

Anesh Maniraj Singh
University of KwaZulu-Natal, South Africa

INTRODUCTION

The last decade has seen a rush among businesses to get onto the Internet. Since its introduction, e-commerce has grown in leaps and bounds. The frenzy to get online and be a part of the "new economy" was spurred on by media hype describing the Internet as the greatest technology this century. Organisations embarked on initiatives to change their business models, looking for e-strategies as a means of revolutionising their business. By mid 2000, many of the dot.coms were "dot.gones." The primary reason for this sudden death was that businesses forgot the basic rule of business: creating economic value. Economic value as defined by Porter (1985) is the gap between price and cost—the larger the gap, the greater the economic value. According to Porter (2001), gaining a competitive advantage does not require a radical approach to business; it requires building on the principles of effective strategy. Businesses that went online should not have looked for e-strategies, but should have improved on their existing strategy to include an e-strategy.

GPRS, wireless Web, handhelds, m-commerce, 2nd coming of the Internet, m-management, killer apps, 2G or 3G, always-on, have been the buzzwords in the media. Is this new hype really worth the fuss? M-commerce has failed in the United States and has made a brief appearance in South Africa. Therefore, this article asks the question "Is there potential to revive m-commerce in South Africa?" In attempting to answer this question, this article will examine issues such as uses of m-commerce, the benefits and challenges of m-commerce, trends in the wireless industry, and the technology underlying m-commerce. This article will also attempt to provide suggestions for harnessing the power of the wireless Web. Most of the discussions are based on universal experience supported with what the current situation is in South Africa; therefore, this article will not be separated into a universal section with a smaller subset focussing on South Africa.

BACKGROUND

What is Mobile Commerce?

Organisations have just begun to get comfortable with e-commerce in terms of what it can do for them and what are its limitations. Some are still coming to grips with e-commerce and have now been hit with the new wave of m-commerce. According to Rainer (2000), m-commerce refers to the use of wireless communications technology to access network-based information and applications using mobile devices. Laudon and Laudon (2004) described m-commerce as the use of wireless technologies for conducting business-to-business and business-to-consumer transactions over the Internet, hence, m-commerce can be described as the mobile Internet (Herron, 2000). Cleenwerck (2002) describes m-commerce as the wireless Web. It is evident from these definitions that the main characteristics of m-commerce are mobility, wireless, mobile devices, and the Internet.

It is evident that m-commerce is merely an extension of the Internet to wireless handheld devices, thus bringing e-commerce into the palms of users beyond the physical boundaries of bricks and mortar. If m-commerce is e-commerce on the move, why all the hype?

Uses of Mobile Commerce

The proposed uses of wireless technology seem like something out of a James Bond movie. However, users should clear the image of driving a BMW with a Nokia cell phone from their minds. Improved communication is probably the most important use of the wireless Web. People have access to text-based data such as short message services (SMS), e-mails, news broadcasts, and file transfers. Advanced functions include booking of tickets for movies and shows and making restaurant reservations. Very advanced features would involve transactions such as purchasing airtime, ordering products online, and secure banking. Some of the other uses include the following:

- **Navigation Systems:** Global Positioning Satellite (GPS) services integrates the wireless Web with satellite and Geographic Information Systems (GIS) to locate people in space. These systems will be able to assist people who are lost to find their way. GPS will also be able to calculate the shortest route between two points, saving time and money.
- **Electronic Wallets:** According to Posthumus (2001), wallets built into cell-phone technology is highly appealing and could herald a new era in business

and financial systems whereby users could make payments to vending machines for the purchase of items and effect funds transfers at in-store point-of-sales (POS) systems.

- **Multipurpose Remote Controls:** Handheld devices will soon be linked to all the electronic devices in a home, allowing one to control gates, burglar alarms, televisions, sound systems, and just about anything that is electronic. Currently, some models of the Ipaq® have a multidevice interface. The use of these devices as remote controls is limited by appliance manufacturers' developing devices compatible with PDAs. Other uses of m-commerce include stock trading, weather forecasts, vehicle tracking, and instant messaging, among others.

The uses of m-commerce are limited only to the extent of one's imagination. However, Reedy, Schullo, and Zimmerman (2000) warned that certain products such as perishables and small items were not suited for sale on the Internet. Similarly, La Fontaine (cited in Brewin, 2000) noted that not all business opportunities can be translated onto the wireless Web. The uses of m-commerce are many, but do they bring with them any benefits?

M-COMMERCE IN SOUTH AFRICA

Benefits of Mobile Commerce

According to Navision (2002), the benefits of m-commerce are threefold (i.e., it provides immediate access to information where it is needed, it helps employees respond immediately to business needs, and it allows organisations to provide better field service). Wireless makes communication possible in areas of uneven terrain, such as mountains, where it is difficult to install cable. According to Haag, Cummings, and Dawkins (2000), serving customers goes beyond the provision of products and services. Businesses need to provide perfect service at the customer's moment of value; one of the dimensions of which is *place*. M-commerce makes it possible to deliver service where the customer wants it, such as at his or her work place, at home, and even at the beach. Armed with a cell phone or a PDA, a sales consultant can provide near-perfect information to assist the customer in his or her buying decision, immaterial of the customer's location.

M-management, an offshoot of mobile commerce, makes it possible to keep managers apprised of all events at the workplace, wherever in the world the manager may be. M-productivity, also an offshoot of mobile commerce, makes it possible to improve worker productivity. Employees can access their contact information, review their calendars, and respond to e-mail, which ordinarily would have to be done at a desk. Other benefits of m-commerce include the following:

- **Immediate Access:** Due to the nature of the technology, cell phones and PDAs are instantly on, which reduces overhead time, which is the time taken to get started. PCs take an extremely long time to get started, initialise all the peripherals, and then to establish a dial-up connection with the service provider.
- **Use of Niche Time:** Time that is unavailable or wasted whilst waiting for services or sitting idle in public transport can be leveraged for work (Rainer, 2000). GNER, a United Kingdom train operator, has installed WiFi on its trains. In first class, access is free, and as a result, standard-class commuters are upgrading to first class (WiFi Growth on UK Trains, 2004). WiFi hotspots are making it possible to access the Internet in airports, restaurants, and other public places in South Africa.
- **Generate New Income:** In order to generate new income, firms need to advertise extensively in traditional media such as television, radios, and billboards to stimulate impulse buying. The advertising must contain the message that these products can be ordered from ones handheld device.
- **Reduce Costs:** Cell phones, pagers, and PDAs are much cheaper than computers and laptops; this reduces organisational cost and makes m-commerce accessible to larger markets.
- **New Marketing Medium:** Short-range broadcast systems can be used within small areas or buildings such as malls, where advertisements and special offers could be sent to their mobile devices (Gaede, as cited in Mobile Services: Less Talk, More Profit, 2005).

It is evident that the benefits of m-commerce are immense. But how does one get around those tiny keypads?

Challenges Facing Mobile Commerce

Mobile phones have extremely small screens that are capable of delivering, at maximum, approximately eight lines of text (Herron, 2000). Furthermore, the absence of a QWERTY keyboard makes typing a painful experience. According to Ewalt (2000b), even when one gets the technology working, purchasing online using a cell phone or PDA is extremely difficult due to the low resolution of the screens, unreliable network support (dropped calls), and poor security.

In order for m-commerce to work properly, it will have to run seamlessly among different carriers, networks and handheld devices. In short, there must be interoperability (Mc Guire, cited in Ewalt, 2000b). Just like HTML offered a one-size-fits-all platform for the Internet, similarly, a common platform has to be developed for the wireless Web.

According to King (cited in Ewalt, 2000a), consumers are reluctant to use their phones for anything other than SMS and voice transmissions. However, user reluctance is not all. The number of users with data-enabled phones is low in the United States, which has only 1 million data-enabled phones (Brewin, 2000). Similarly in South Africa, only 3% of Vodacom subscribers had GPRS phones, and less than 0.5% of users had multimedia phones (Vodacom SA Launches GPRS, 2002).

The biggest challenge for m-commerce is developing and providing the technology infrastructure that underlies m-commerce.

Technology Required to Enable Mobile Commerce

Network Infrastructure

Current cell phone/wireless technology was not intended for m-commerce, which requires the transmission of data. Current networks were intended for transmission of voice and simple text messages. The evolution of cellular technology makes it easier to understand the technology underlying m-commerce. South Africa, a known follower in terms of technology development and technology implementation, has a more advanced cellular platform as a result of technology leapfrogging. Instead of investing in outdated technology and then upgrading systems, cellular providers in South Africa adopted the latest technology.

Debate still rages whether or not to implement 3G networks. However, the return on investment does not justify the cost of the infrastructure, especially because there are very few applications and services available that require the infrastructure.

South Africa has recently seen the emergence of GPRS with both Vodacom and MTN, making the service available on their networks. The business benefits of GPRS are immense. There is no need for dial-up modems, and users are always on. For private users, however, GPRS costs more than land-line downloads. MTN SA charges U.S.$ 8.33 for downloading one megabyte of data. The same amount of data downloaded on landlines take approximately 15 minutes, which at U.S. 1 cent per minute costs a mere U.S. 15 cents. Private users who opt for GPRS will have to pay the premium price for the convenience offered by the service. According to Socikwa (2004), broadband would enable a connection to each customer allowing for simultaneous combined voice and data services, this would reduce online time, which in turn will reduce cost. In a bid to increase broadband usage, South African mobile networks have discounted the price to a mere U.S. 33 cents (Masango, 2005). It is evident that that the enabling technology has to be in place to conduct m-commerce. However, focussing on technology and price will not drive the market; it is applications and services that will (Treguertha, 2005).

Applications

Users are beginning to realise that their phones are minicomputers and they are not satisfied with the limited choices of content available on their cell phones (King, 2005). Wireless Application Portal (WAP) was supposed to be the forerunner of bringing the Web into the hands of the user. However, according to Nadler-Nir (cited in Herron, 2000) and Gani (2002), WAP in South Africa has been a dismal failure. The failure of WAP has been attributed first to the boring services offered, and second to the wrong assumption that users want to browse the Web on their phones (Herron, 2000). Two of South Africa's leading banks, ABSA and Standard, have developed phone banking that allows users to check balances, pay accounts, and transfer funds. First National Bank has developed an alert system that alerts customers of the amount of money withdrawn when they use their debit or credit cards. If the card is used fraudulently, the customer can put an immediate stop on further purchases.

Handheld Devices

In order to get the full benefit of m-commerce, one requires a PDA, or a cell phone that has data-handling capabilities. GPRS phones were introduced in South Africa in mid 2002. These phones were only available on business contracts that cost more than an average contract, however, making the technology inaccessible to nonbusiness and prepaid users. The high cost of PDAs has made this technology equally inaccessible to non-business users. Furthermore, using PDAs is cumbersome due to the absence of a mouse and keyboard. It is evident that the network technology and hardware for m-commerce are readily available, but is this any indicator of the future of m-commerce?

Trends in M-Commerce

In the United States, several large companies are shutting down their wireless services mainly due to the fact that people use their cell phones for voice calls rather than SMS and transacting unlike elsewhere in the World, Americans use personal computers to shop online (Wolverton 2002). The hype surrounding m-commerce promised the consumer the wireless Web. However, what was delivered did not meet these expectations (Rainer 2000). For business, the promise of increased sales and exposure to new customers never materialised. According to Stahl (2002), m-commerce is still more myth than reality. M-commerce has suffered failure every bit as dramatic as the dot.gones (Ewalt, 2002b). In a survey conducted by *Information Week,* 75% of small companies and 58% of large companies were sceptical of the revenue generation potential of m-commerce (Ewalt 2002b). Is mobile commerce truly dead?

Growth Potential of Mobile Commerce

In South Africa, there are 18.7 million active cell-phone users, which increases by more than 9,000 users per day and has the potential to reach 21 million users in 2006 (Statistics of Cellular in South Africa, 2004). Between MTN and Vodacom, 71% of the geographic area is covered by cellular masts, which means that people almost anywhere in South Africa can engage in m-commerce. According to Tregurtha (2005), South Africa has the highest teledensity of mobile to fixed phones in the world. Based on the sheer numbers of cell phone users, it suggests that there is growth potential for m-commerce. However, it must be noted that South Africa has an illiteracy level of 33% (Aitchison 1998). M-Commerce which is text based, would require that users are literate in order to use the service effectively. There are no statistics to prove what numbers of users are illiterate or semi-literate. However, it will impact on the m-commerce market size. Furthermore, as mentioned previously, GPRS phones are inaccessible to a large number of cell phone users, which further diminishes the potential m-commerce market. It is evident as one dissects the statistics that the potential m-commerce market is not as large as one would expect. Does this then sound the death knell of business-to-consumer (B2C) mobile commerce?

Evidently not. Cointel, a trailblazer in m-commerce in South Africa, has reported revenues of up to R50 million per month. Rather than being distracted by new technologies such as GPRS, Cointel uses existing GSM standards to connect cell-phone users with their banks to purchase airtime. Users no longer have to go to a shop to purchase a recharge voucher—recharging can be done anywhere, 24 hours day, 7 days a week. Cointel is developing the technology to include the purchase of flowers, tickets, and limited shopping (*Comparex News,* 2001). Although m-commerce does not look very healthy, it is not entirely dead. M-Commerce needs to be given an injection in order to revive it.

What Needs to be Done to Revive Mobile Commerce?

All the stakeholders need to make an effort to revive m-commerce. Handset manufacturers, network service providers, businesses, and consumers need to work together to arrive at a solution that will harness the latent power underlying mobile commerce. Some of the issues that need to be addressed include the following:

- **Role of Network Service Providers:** Increase bandwidth to handle voice and data traffic at faster speeds. Increase capacity to hold extra traffic. Improve Security standards. Keep pricing low.
- **Role of Handset Manufacturers:** Handset manufacturers, in conjunction with networks, need to develop a transmission standard that is safe, cheap, fast, and convenient to use. Manufacture cheaper, user friendly handsets with built-in firewalls.
- **Businesses:** Businesses need to use traditional media such as newspapers, radio, television, and billboards to encourage consumers to transact through their phones. Businesses need to train their customers in the use of their m-commerce sites. Furthermore, businesses should not wait for B2C to take off; instead, they should use mobile commerce extensively to benefit from business to business transactions. Ferguson and Pike (2001) suggested that organisations choose one application and use it extensively to determine how it is adopted and how its works rather than trying to make a profit from it from the time it is implemented.
- **Content Providers:** The role of content providers is growing in stature in the revival of m-commerce. Customers are still looking for the “killer app” that will justify the move to transacting by phone. According to Cowper (cited in Mobile Services: Less Talk, More Profit, 2005), the killer app is always going to be personalisation. He stated further that Telecoms need to target the right content and services to the right customers.

It is evident that m-commerce requires a joint effort to become the new wave of electronic commerce. Stakeholders including competitors should collaborate initially to develop a set of standards. Thereafter, they can work independently at perfecting what they do best.

FUTURE TRENDS

Mobile commerce in South Africa saw a resurgence in 2004. The three networks—Vodacom, MTN, and Cell-C—

are focusing on their core business that is to provide efficient connectivity. As a result, they are not engaging in the development of mobile applications. Instead, they have invited independent content providers to develop applications for the mobile Web. WAP and SMS (short message service) have come to the fore. Companies such as Xactmobile have emerged. Users can purchase ringtones, backgrounds, games, and screensavers by simply sending an SMS request to Xactmobile. The cost of the item being purchased is debited to the users cellphone bill, which the networks then pay to the vendor. Like its predecessor e-commerce, mobile commerce has been increasingly used to download sex and pornography. For a fee, users can purchase sex stories and pornographic pictures, which are sent by WAP onto their cell phones.

After the December 2004 Tsunami disaster in Indonesia, local television stations advertised SMS numbers that users could contact to make financial contributions to the disaster relief fund. If they sent the SMS to number *x*, their cell phone account would be debited for US$ 2.50, and if they sent it to number *y*, their account would be debited for US$ 5.00.

Motor-vehicle dealerships could send courtesy SMSs to customers after they have had their vehicles serviced or repaired in order to gain valuable feedback regarding customer satisfaction. The University of Cape Town developed a content delivery system at the end of 2004, wherein lecture halls are wireless enabled, allowing for students to link their PDAs to the lecturers system. They can download lecture slides, make notes on the slides, and even answer simple multiple-choice questions. This system has great potential for e-learning. However, until the prices of PDAs drop, this will just be another great innovation that goes nowhere.

According to Ankeney (2001), research indicates that a 6-second increase in transaction speed can boost a fast-food franchise's revenues by 1%; the ability to order fast foods by phone before reaching the outlet could benefit both the consumer and the supplier. Other uses could include short-range broadcast systems where restaurants, cinemas, and other stores could detect all the cell phone users within a particular radius and broadcast messages inviting them to place their orders or make a booking in advance of arrival, thereby saving time. The biggest challenge for the mobile industry in South Africa is disposable income. Eighty-four percent of South African users are prepaid users (Statistics of Cellular in South Africa, 2004), many of whom are willing to forgo other luxuries to enjoy the status attached to owning a cell phone (Posthumus, 2001). If disposable incomes are limited, affordability of connectivity and purchasing online services will be limited as well.

Privacy and even security may be threatened due to eminent legislation. According to Perlman (2004), a draft proposal is being finalised that will oblige all mobile and fixed operators to provide real-time monitoring of all voice and data communications services including SMS, WAP, MMS, and GPRS messages. As a result, encryption techniques need to be disabled, which would expose communication and transactions to cyber-criminals on a relatively unsecure platform. This has the potential to threaten M-commerce even further.

CONCLUSION

This article has provided a balanced perspective on mobile commerce by answering the question, "Is there potential to revive m-commerce in South Africa?" Based on recent historic performance, it would seem that m-commerce was dying in South Africa. However, there are a number of issues that were outlined that need to be addressed that could see the turnaround of mobile commerce. Furthermore, current practice has shown that creative vendors are developing applications and products that cell phone and other mobile device users are willing to purchase using their mobile devices. With the large number of cell phone users in South Africa m-commerce has the potential to be the future, perhaps all it needs to rebound, is an affordable killer app and time.

KEY TERMS

Bandwidth: Determines the rate at which information can be sent through a channel.

Broadband: A transmission facility having a bandwidth sufficient to carry multiple voice, video, or data channels simultaneously.

Internet: The Internet is a global connection of individual and networked computers to other individuals and networks.

Killer App: Technical jargon for the eternal search for the next big idea.

Mobile Commerce: Refers to the use of wireless communications technology to access the Internet to conduct purchases and sales.

Network Service Provider (NSP): Also known as network carriers, NSPs provide the infrastructure that enables mobile communication. Cell phone users pay for using the infrastructure.

Teledensity: The number of telephones per 100 people in a region.

Mobile Commerce Multimedia Messaging Peer

INTRODUCTION

In a mobile-commerce world, shops could provide product brochures, cards, sounds, songs and so forth in the form of multimedia messaging presentations, which could be used by a customer to send to friends. Shopping malls will have information kiosks equipped with wireless access capabilities, and could perform searches across the mall's network to update its multimedia message repository. Customers can download and distribute to their friends such multimedia content via mobile messaging, leading to increased revenue for the shops.

Over the years, mobile messaging has become an essential means of communication, and it is going to be even more so with the merging of the Internet and Mobile Networks. The ability to message from a phone to a computer on the Internet and vice versa is making messaging a powerful means of communication (Yeo, Hui, Soon, & Lau, 2001).

This article discusses the development of a multimedia messaging client for a personal digital assistant (PDA) and a Kiosk providing multimedia messages composition, search, share and send capabilities. Various messaging technologies, enabling wireless technologies and the peer-to-peer model, are also discussed and evaluated in this article. We substantiate the ideas discussed in this article with a description of an MMS PDA client application using JXTA with specific references to a shopping mall scenario.

BACKGROUND

Short Messaging Service

Text messaging uses the short messaging service (SMS, 100-200 characters in length), and involves sending text messages between phones. Examples include "C U L8ER" and "OK. AT FLAT OR OFFICE." It is quick and dirty, hard to use the keypad, abrupt, punctuation challenged and incredibly useful and popular. Text messaging also has a lot of advantages, such as its convenience, availability on all phones and discreteness.

Text messaging is most prevalent in the youth market (Tan, Hui, & Lau, 2001), and especially teenagers, who are able to manipulate the difficulty of entering text with the mobile phone keypad. In fact, it is suspected that this steep learning curve and the necessary insider knowledge are two of the things that appeal to the youngsters (Bennett & Weill, 1997).

Multimedia Messaging Service

The multimedia messaging service (MMS), as its name suggests, is the ability to send and receive messages comprising of a combination of text, sounds, images and video to MMS-capable handsets (MMS Architecture, 2002). The trends for the growth in MMS are taking place at all levels within GSM (Patel & Gaffney, 1997), enabling technologies such as GPRS, EDGE, 3G, Bluetooth and Wireless Access Protocol (WAP).

MMS, according to the 3GPP standards, is "a new service, which has no direct equivalent in the previous ETSI/GSM world or in the fixed network world." Here is an introduction to the features of this innovative new service:

- MMS is a service environment that allows different kinds of services to be offered, especially those that can exploit different media, multimedia and multiple media.
- MMS will enable messages to be sent and received using lots of different media, including text, images, audio and video.
- As more advanced media become available, more content-rich applications and services can be offered using the MMS service environment without any changes.
- The MMS introduces new messaging platforms to mobile networks in order to enable MMS. These platforms are the MMS Relay, MMS Server, MMS User Databases and new WAP Gateways.

Table 1. SMS vs. MMS

Feature	SMS	MMS
Store and Forward (non real time)	Yes	Yes
Confirmation of Message Delivery	Yes	Yes
Communications Type	Person to person	Person to person
Media Supported	Text plus binary	Multiple-text, voice, video
Delivery Mechanism	Signalling channel	Data traffic channel
Protocols	SMS specific, e.g. SMPP	General Internet, e.g. MIME SMTP
Platforms	SMS Center	MMS Relay plus others
Applications	Simple person to person	Still images

- MMS will require not only new network infrastructure but also new MMS-compliant terminals. MMS will not be compatible with old terminals, which means that before it can be widely used, MMS terminals must reach a certain penetration.

Implications of SMS on MMS

The current SMS has some unique advantages that other non-voice services do not have, such as store and forward and confirmation of message delivery. However, SMS also has some disadvantages, such as limited message length, inflexible message addressing structures and signalling channel slowness.

Person-to-Person (P2P) Model

Today, the most common distributed computing model is the client-server model (Chambers, Duce, & Jones, 1984). In the client-server architecture, clients request services and servers provide those services. A variety of servers exist in today's Internet: Web servers, mail servers, FTP servers and so forth. The client-server architecture is an example of a centralized architecture, where the whole network depends on central points to provide services. Regardless of the number of clients, the network can exist only if a server exists (Berson, 1992).

Like the client-server architecture, P2P is also a distributed computing model (Yemini, 1987). However, the P2P architecture is a decentralized architecture where neither client nor server status exists in a network (Madron, 1993). Every entity in the network, referred to as a peer, has equal status, meaning that an entity can either request a service (a client trait) or provide a service (a server trait). Figure 1 illustrates a P2P network.

Though peers all have equal status in the network, they do not all necessarily have equal physical capabilities. A P2P network might consist of peers with varying capabilities, from mobile devices to mainframes (Budiarto & Masahiko, 2002). A mobile peer might not be able to act as a server due to its intrinsic limitations, even though the network does not restrict it in any way.

JXTA

Jxta strives to provide a base P2P infrastructure over which other P2P applications can be built (Project Jxta, 2002). This base consists of a set of protocols that are language independent, platform independent and network agnostic. These protocols address the bare necessities for building generic P2P applications (Jxta Technology Overview, 2002). Designed to be simple with low overheads, the protocol's target is to build, to quote the Jxta vision statement, "every device with a digital heartbeat."

JXTA vs. .NET and JINI

Jxta's XML-based messaging is similar to Microsoft's .Net and SOAP technologies. But that is a very thin foundation for comparison. As more and more third-party protocols make use of XML, it will become obvious that

Figure 1. P2P model

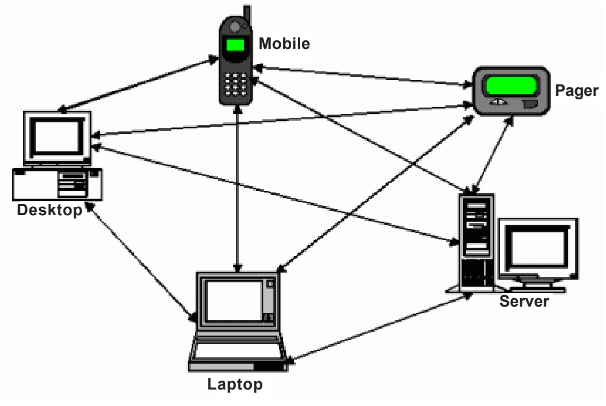

Figure 2. MMS Peers and kiosk architecture

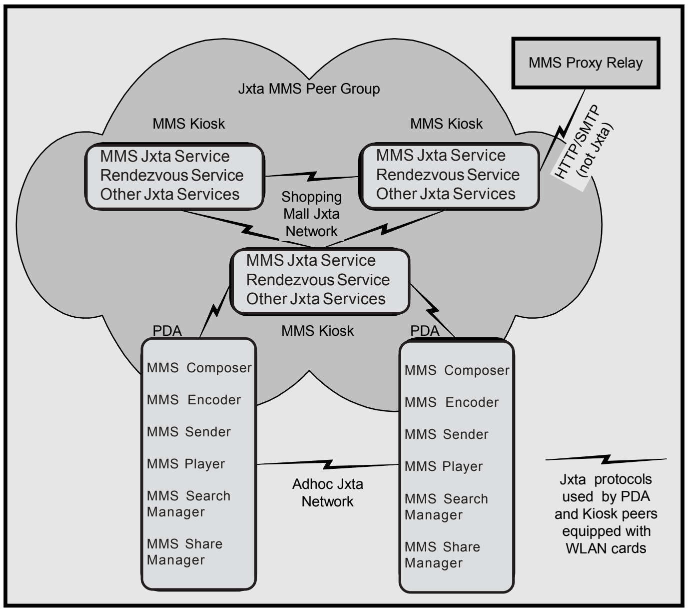


just using XML as a message format says nothing at all about an actual networking technology. Comparing the high-level, policy-rich, Web-services-based infrastructure that is .Net to the low-level, fundamental, policy-neutral nature of Jxta is a futile exercise.

Project Jxta and the Jini project are also fundamentally different. Both of them have some similarity in higher-level interaction, enabling true distributed computing over a network. However, the similarity abruptly ends there. Strategic differences between the two are: Jxta started life as a completely interoperable technology (any platform, any programming language, any vendor). Sun is a mere contributor in the community. Jini is a Java-centered technology that Sun will integrate and deploy strategically in future product offerings. Sun will maintain a degree of control over Jini's evolution.

MULTIMEDIA MESSAGING PEER FOR MOBILE COMMERCE

Most shopping malls have information kiosks, which could be equipped with a network point and wireless service access capabilities using technologies like Bluetooth and WiFi. These kiosks could perform searches across the mall's network to update its multimedia content repository and provide a common contact point for all the shops in the mall.

The kiosks could provide product brochures, cards, postcards, pictures, comic strips, sounds, songs and so forth in the form of MMS presentations, which could be used by a customer to send to another person. The customer need not visit all the shops and need not verbally describe a product to another person before making a decision to buy something. This leads to increased revenue for the shops. These kiosks could also provide multimedia messages intended for fun and entertainment purposes and charge for them.

MMS Peer and Kiosk Architecture

An MMS Peer would not only be a multimedia messaging client like the one on a mobile phone today but also would provide the capabilities to search for content and share content with other mobile devices in the vicinity. It would also not require a WAP stack, as it would send the messages directly to the MMS Proxy using either its HTTP or SMTP interface, which are expected to be accessible through the Jxta-based MMS service provided by a peer like the kiosk or another more powerful mobile device like a laptop, which is connected to the Internet and in the vicinity.

MMS Kiosk and Jxta

In a P2P environment like Jxta, commonly accessed information gets replicated (the peers have a choice to keep a copy of content passing through them) and becomes available at peers fewer hops away. This avoids "hotspots" and is ideal for content sharing, where the content can be of any type. For an MMS Kiosk searching for multimedia messages, the situation is no different and it would thus be ideal to use a P2P framework to advertise and search for multimedia messages and media content.

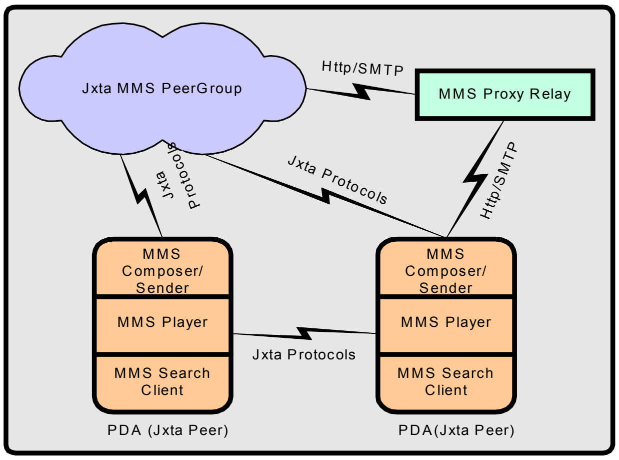
Design and Implementation of MMS Peers

Figure 3 shows the architecture due to the availability of the Jxta platform for a PDA (Jxta Platform, 2002). This architecture is almost fully P2P except the interaction between the Jxta Peer and the MMS Proxy-Relay. This offers the advantage that a customer can become part of a Peer Group due to other customers around him. This opens opportunities for customers to exchange MMS messages they have on their devices.

The PDA has been shown to have only an MMS Composer, MMS Player and MMS Sender. The MMS Composer composes a message by aggregating all the media and presentation information provided by the user. The MMS Sender performs an HTTP Post to the MMS Proxy-Relay to send the message to its destination. An MMS Player is also provided to the PDA client to view an MMS message before sending. The Kiosk/Shop is what provides the service to allow a customer to search for MMS messages and send them. The kiosk and the shops are part of a Jxta MMS Peer Group.

The protocols that the PDA can use to directly send to the MMS Proxy are either HTTP or SMTP (if the MMS Proxy-Relay provides an SMTP interface). The communication between the kiosk/shop and the PDA can be over Bluetooth, IEEE 802.11b or Infrared. Infrared is not a good choice due to its very limited range.

Figure 3. MMS kiosk environment architecture



PDA MMS Peer Design

The MMS Peer on the PDA consists of four modules:

- MMS Composer
- MMS Encoder and Sender
- MMS Player
- MMS Jxta Search and Share

MMS Composer

This module allows a user to compose an MMS on the move. It allows the user to select the media content and provide layout details and timing information for the slides of the MMS presentation. The process results in the generation of an SMIL file, which contains the presentation details of the media. Subsequently, a Jar file (JAR Documentation, 2002) is created with all the media files and the SMIL file. The MMS Sender (in the next section) takes the Jar as its input, encodes it into an MMS and sends it.

MMS Encoder and Sender

MMS can be sent either using HTTP Post or SMTP if the MMS Proxy-Relay provides both interfaces. The two modes of sending the message could be chosen based on the priority of the message. Using SMTP takes longer to send, as the message has to be ultimately encoded according to MMS standards (MMS Encapsulation Specification, 2002). Hence, SMTP could be used to send low-priority messages.

MMS Player

The MMS Player uses takes a Jar as input, extracts all the media and SMIL parts, and uses a SMIL parser to parse the SMIL and play it. The slides in the SMIL presentation are rendered using *double buffering*. The AMR audio is first converted to the WAV format and then played. Imelody (.imy files) files cannot be played by the application at this stage.

MMS Jxta Search and Share

The MMS application, once started, represents a Jxta peer. The peer becomes a member of a universal group called the NetPeerGroup. The peer then starts to discover its peers and available peer groups. The Search and Share module relies on two main modules called the Peer Group Manager and the Search Manager. The Search and Share use the Content Management Service.

Graphical User Interface (GUI) Design

The GUI was designed keeping the PDA in mind. The GUI uses as many components that can be either easily clicked or tapped with a stylus. The following things were taken into consideration for the GUI design:

- A user would always want to have the list of peers and peer groups in front of him or her because of constant interaction with these entities.
- The limited screen size of the PDA requires that every function be provided without cluttering the screen. Thus, every function is provided on a new screen.
- This sort of layout would be ideal if service clients are to be loaded dynamically upon discovery of a service.

Figure 4 shows the MMS player and sender GUI. It also shows the list of peer groups and peers currently visible. The peer groups and peers list keeps getting updated automatically. Figure 5 shows the MMS Search GUI. A user can enter the keywords and press enter to search. A button will be added also to allow easy use on the PDA.

Comparison with Other MMS Solutions

There are some other MMS clients for the PDA that exist now. The one from Anny Way (MMS—Opportunities, migration and profits, 2003) is specifically for Pocket PC. EasyMessenger (EasyMessenger, 2003) from Oksijen Technologies is the only other Personal Java-based MMS client but without the additional P2P features provided by us. Electric Pocket's Pixer (Pixer MMS, 2003) is another MMS Client that only supports Pocket PC and Palm OS and can be used to send images only. There seems to be no work done on using MMS and Jxta together or, for that matter, not even EMS or SMS and Jxta.

All the solutions above are MMS clients with a view to sending multimedia messages, a progress from SMS or EMS. The MMS Peer was developed with a view to making not only messaging a more pleasant and easier experience but also to provide features that would facilitate access to a variety of content. The searching and sharing of content from peers in the vicinity (shoppers) as well as content stores (kiosks) make it a compelling multimedia messaging solution.

FUTURE TRENDS

MMS Message Receiver Module for the PDA

The next step is to implement a receive module for the PDA so the MMS Peer is able to achieve two-way messaging. When a message is retrieved directly from the MMS Proxy-Relay using the HTTP GET method, the MMS Proxy-Relay will return with a message along with the HTTP headers. The HTTP headers can be easily skipped by looking for two consecutive carriage returns and line feed pairs. After this, the encoded MMS header are read byte by byte until the byte of number of body parts is reached. In this way, the MMS Peer will be able to both send and receive messages with other peers.

Service Client Plug-In Feature

The Service Client Plug-In feature refers to the client download option. The current implementation assumes the client for a service to be there on the peer. As the peer already has core Jxta functionalities, it is a good idea to

Figure 4. MMS Player and Sender

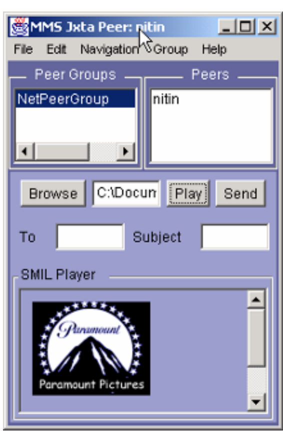


Figure 5. MMS Search

use them to provide this feature. The advertisements of a service could specify the location of a client, which could be transferred over to the peer and dynamically loaded. This is possible in Java using the API for loading classes. To enable this feature, one could create a Jxta Service that has clients registered with it.

PDA to PDA Messaging

With the existing application framework, PDA to PDA MMS messaging can be easily enabled using the Jxta messaging layer. As PDAs are more capable than mobile phones, even video could be enabled for PDA to PDA messaging. All it would mean is using another media type in the SMIL or encoded message.

To account for different PDAs communicating, the User Agent Profile Specification (UAProf) could be used for capability negotiation. The UAProf schema for MMS characteristics (client transactions) could be adapted to the PDA situation. The XML messaging layer for Jxta would enable the use of this XML scheme effectively.

CONCLUSION

The Jxta platform Personal Java port came out very recently and the application was designed and implemented with it in mind. If the basic platform functionalities have been ported correctly, then it should not take long to port this whole application to the PDA. The application conforms to the Personal Java standard when checked with the compliance tool. This implies it should work on the PDA without requiring any changes.

Currently, the MMS client by itself works on the PDA. An MMS Player and sharing of content were developed. The former was implemented while searching for a reasonably priced Bluetooth SDK for WinCE and trying various Bluetooth PCMCIA cards with the freely available Bluetooth stack called CStack. This project will have a commercial value when shopping malls in Singapore install wireless networks or have wireless kiosks.

In conclusion, with the increase in memory and processing power of a plethora of mobile devices found in the market, and the ongoing improvements in available bandwidth to the user, MMS is a service to look forward to, and more so with peer-to-peer technologies like Jxta, which will make it truly ubiquitous.

KEY TERMS

Application Programming Interfaces (APIs): Programming tools that provide developers with a simple, consistent mechanism for extending the functionality of an application and for accessing existing computing systems.

Distributed System: A system made up of components that may be obtained from a number of different sources that together work as a single distributed system, providing the run-time infrastructure supporting today's networked computer applications.

Multimedia: Involving or encompassing more than one concurrent presentation medium, such as text, sound and/or motion video.

Peer-to-Peer: A communications model in which each party has the same capabilities and either party can initiate a communication session.

Plug-In: Programs that can easily be installed and used as part of a Web browser. A plug-in application is recognized automatically by the browser and its function is integrated into the main HTML file that is being presented.

Protocol: A special set of rules that end points in a telecommunication connection use when they communicate with each other.

WAP Stack: A set of protocols that covers the whole process of wireless content delivery, from the definition of WML and WMLScript for creating and layout of the actual content and the specification of security measures in the WTLS to the lowest parts of the stack dealing with the actual transport of content.

Mobile Electronic Commerce

Samuel Pierre
École Polytechnique de Montréal, Canada

INTRODUCTION

Mobile electronic commerce (or m-commerce) is generally defined as the set of financial transactions that can be carried out over a wireless mobile network (Pierre, 2003; Varshney, 2001; Varshney, Vetter, & Kalakota, 2000). According to this definition, m-commerce constitutes a subset of all electronic commercial transactions (electronic commerce or e-commerce) from business-to-consumer (B2C) or business-to-business (B2B). Thus, short personal messages such as those from short messaging system (SMS) sent between two individuals do not fall within the category of m-commerce, whereas messages from a service provider to a salesperson or a consumer, or vice versa, do fit this very definition. M-commerce appears an emerging manifestation of Internet electronic commerce which meshes together concepts such as the Internet, mobile computing, and wireless telecommunications in order to provide an array of sophisticated services (m-services) to mobile users (Paurobally, Turner, & Jennings, 2003).

Before purchasing a product, clients need services such as those used to search for a product and a merchant who offer the lowest price for this product. Consumers also like to participate in auctions and analyze the quality/price ratio of a product for a certain number of suppliers (Jukic, Sharma, Jukic, & Parameswaran, 2002). Online shopping for a given product is becoming increasingly popular, and electronic purchasing and bargaining consist of looking up and deciphering the contents of electronic catalogues prior to making a decision. To automate this process and to ensure that these documents are comprehensible to computers, they must have a standard format. Such services exist in standard commerce; however, in e-commerce, they require further consideration such as those related to the market dynamics, the variety of platforms, and the languages used by various merchant sites (Itani, & Kayssi, 2003; Lenou, Glitho, & Pierre, 2003).

Just as in standard commerce, e-commerce includes an initial step wherein consumers search for products they wish to purchase by virtually visiting several merchants. Once the product is found, negotiation for this possible transaction can take place between the customer and the merchant. If an agreement is reached, the next step is the payment phase. At each step of the process, a number of problems arise, such as transaction security, confidence in the payment protocol, bandwidth limitations, quality of service, shipping delays, and so forth (Paurobally et al., 2003). The peak withdrawal periods have always presented a major challenge for certain types of distributed applications. The advent of m-commerce further highlights this problem. Indeed, in spite of rather optimistic predictions, m-commerce iss plagued by several handicaps which hinder its commercial development.

This article exposes some basic concepts, technology and applications related to mobile electronic commerce. The background and key technological requirements needed to deploy m-commerce services and applications are discussed, some prominent applications of m-commerce are summarized, future and emerging trends in m-commerce are outlined, and a conclusion of these topics are presented.

BACKGROUND AND RELATED WORK

E-commerce relies upon users' interventions to initiate a transaction and select the main steps of the process. Users' actions are based upon a succession of virtual decisions. Indeed, when shopping with a virtual catalogue, customers can select products that meet their needs, tastes, and respect their price range. Such decisions consistently require the users' input, thus costing them both time and money. These costs are even more exorbitant when a search is launched for an order that includes a variety of products from different providers that have different characteristics (price range, delivery dates, etc.).

Mobile commerce refers to an ability to carry out wireless commercial transactions using mobile applications in mobile devices. M-commerce applications can be as simple as an address-book synchronization or as complex as credit card transactions.

In standard commerce, negotiating a contract or a commercial transaction is a standard practice in purchasing or sales. An agreement between a customer and a merchant can involve various components (price, delivery, warranty, etc.). For example, a volume price can be negotiated (e.g., 20% off the purchase of 100 items or more), price can fluctuate according to the demand (flight and hotel room prices vary according to seasons), and so forth. Once the client has obtained the best offer possible for the product of interest, the negotiation comes to a close. Obviously, the result of such negotiation can vary from one merchant to another. By providing a machine with the appropriate strategies and algorithms, negotiation can be automated and taken over by a computer, hence the concept of electronic negotiation, or e-negotiation.

Significant growth of m-commerce cannot be expected until the required technology (such as SMS services, Bluetooth, WAP, or i-mode) is developed and deployed. Indeed, due to the widely available GSM wireless networks, the SMS service allows GSM users to send short messages of up to 160 characters. These messages are saved and sent within a few seconds, which makes them unsuitable for real-time applications. SMS can become increasingly more important with future improvements once they allow users to send longer messages, multiple messages at once and when they allow users to create mailing lists. Such features will make m-commerce much more accessible.

Bluetooth is a low-powered wireless standard that allows a certain level of communication between many devices. Currently, it is a global specification for close proximity wireless connections. Given the wide flexibility associated with the variety of terminals it supports, it is expected to play a significant role in m-commerce. It can be deployed on a large scale for short-range m-commerce where terminal proximity is minimal. However, its nonlicensed 2.4 GHz frequency is problematic as it can be encumbered by interference from other devices which use the same frequency.

The design of such applications requires a number of functional components. One of the major components is a mobile terminal that is equipped with sufficient power for its memory, display and communication functionalities. Many of these terminals are currently emerging, such as the Palm Pilot (a PDA with a wireless modem) or the Nokia Communicator (a mobile phone with computer functionalities). These devices offer various capacities involving communication, processor, battery, memory and display. Many of them are actually mobile phones enhanced with laptop features.

Given the enhanced functionalities of the mobile terminal and its improved processing and storage capacities, an operating system to manage the internal resources of the various applications and processes will become an essential requirement. However, operating systems require large storage capacities and they are not adapted to mobile terminals constrained by real-time requirements, limited processing capabilities, mini screen and small memory sizes. Mobile middleware can be defined as a functional layer of software provided by application developers to link their e-commerce applications to an OS and various mobile networks to allow their applications to bypass certain mobility issues.

With the emergence of mobile application environments in the recent years, Europe has focused on WAP technologies, whereas Japan has successfully developed with the i-mode. North American countries use other systems, which can include either of the previous two technologies. Indeed, in order to adapt Web contents to mobile users, Europeans use the Wireless Application Protocol (WAP). The WAP was designed to ensure interoperability amongst various wireless networks, mobile terminals, and applications which use the same type of protocols. It thus allows developers to design e-commerce applications from existing technology, which can function on a large number of mobile terminals.

The i-mode, a proprietary system developed by NTT DoCoMo, has been available in Japan since February 1999. It is a device that allows users to access the Internet from a cellular phone with a color display. It uses the packet switching technique with a bandwidth of 9.6 kbps (CDMA). The i-mode pages must be defined by a tag language called compact HTML (cHTML), which is, actually, a subset of HTML with additional adapted tags. Moreover, instead of paying for the amount of connection time, users pay for the quantity of data transmitted (0.3 penny/packet of 128 bytes).

Java i-mode phones have been available on the Japanese market since the beginning of 2001. These telephones allow users to download Java server applets (called i-appli) for games, agent-type services and other applications. There were nearly 19 million subscribers to the i-mode systems at the beginning of February 2001, and the number is increasing by 1 million every month. This system, which supports 11,000 Web sites and 30 search engines, is completely adapted to m-commerce.

One of the key aspects of m-commerce remains transaction security (Cai et al., 2004; He, & Zhang, 2003; Katsaros, & Honary, 2003; Kim & Chung, 2003). A new protocol for m-commerce was proposed by (Katsaros, & Honary, 2003). Fully applicable to third generation mobile networks, this protocol is characterized by three novel properties, as opposed to the existing methods of m-commerce. In fact, it provides a simplified and secure transaction method, minimizes the number of entities involved in the transaction, and reduces the source of security threats, thus reducing the risk of fraud.

MOBILE COMMERCE APPLICATIONS

There are a great number of m-commerce applications (see Table 1). According to reliable estimates, in the next few years, over half of European m-commerce will consist of

Table 1. Applications classes of m-commerce

Application Classes	Type	Examples
Mobile financial applications	B2C, B2B	Banks, brokerage firms, mobile-user fees
Mobile advertising	B2C	Sending custom made advertisements according to user's physical location
Mobile inventory management	B2C, B2B	Finding products and people
Proactive service management	B2C, B2B	Sending information to salespeople regarding age of components (car industry)
Finding products and shopping	B2C, B2B	Locate/order certain products from a mobile terminal
Mobile reengineering	B2C, B2B	Improve quality of service
Mobile auctions	B2C	Customer service to buy or sell certain products
Mobile entertainment services	B2C	Video on demand; other mobile services
Mobile office	B2C	Work from the car, from airports, at conferences
Wireless database	B2C, B2B	Information is downloaded by mobile salespeople or users
Mobile music on demand	B2C	Music is downloaded and listened to while using a mobile service

financial services, advertising, and purchasing. Various classes of applications along with their requirements in terms of services, platforms, and networks, are presented here, and four of those classes will be addressed in more detail.

Mobile Financial Applications

Mobile financial applications are likely to become a fertile niche for m-commerce. They include a wide variety of applications, from the banking environment, brokerage firms, mobile money transfers and mobile micro-payments. These mobile financial services can transform a mobile terminal into a business tool that replaces the bank, the ATM and credit cards and allows users to carry out financial transactions with mobile currency. However, to develop these applications, it is necessary to provide the users of these services with better applications and better network infrastructure. Moreover, security issues must be addressed prior to deploying such applications on a large scale.

An interesting mobile financial application is the micropayment, which consists of little purchases involving small transactions. A mobile terminal user can communicate with a sales machine via a wireless local area network (WLAN) to purchase these products.

The micropayment system can be implemented in several different ways (Kim, Lee, Kim, Lee, & Kang, 2002; Renaudin et al., 2004). For example, a user dials a number, and the cost for this call equals the price of the product. Sonera (http//www.sonera.net/asiakaspolvelu/wop.asetukset.html), a wireless service supplier, has tested this approach with a soft drink machine; the soda machine debits a certain amount of money from the user before crediting the same amount to the cola company.

Another way of carrying out these micropayments would consist of using prepaid amounts, bought from, for example, service suppliers, banks, or credit card companies. In order to support the financial transactions, including the micropayments, a mobile-service supplier must play the role of the banker.

Mobile Advertising

Mobile advertising can also constitute a significant part of m-commerce applications. Indeed, using demographic information compiled by mobile-service suppliers and information about the physical location of the user, a highly targeted advertisement can be launched. Advertisements can be tailored to target a given user, according to the information previously provided, during a preliminary stage, or a past shopping expedition. Advertisement can also take advantage of the user's physical location. For example, users could be alerted to sales and feature events occurring in their neighborhood stores and restaurants. This type of advertising functions with a short message service or a pager.

When more wireless bandwidth becomes available, advertisements will become contain more audio, photo, and video content to fit users' specific needs, interests, and habits. Moreover, the network service suppliers will be able to use push-pull methods to make mobile advertising best suited to the user's profile.

The number of advertisements and the level and type of content they include are interesting elements. The number of advertisements must be limited in order to avoid user frustration and network congestion. Wireless networks could consider this type of service as low priority when solving congestion problems that affect the quality of service of the entire network. Because these services require information about the user's physical position, a third module could be used in order to provide localization services. However, this would result in profit sharing among the network service and the position information provider.

Mobile Inventory Management

The mobile inventory management application is used to locate products and, possibly, people. Locating products can help service suppliers specify delivery time to customers, thus improving customer service, a competitive advantage. A very interesting application is the mobile inventory, which could allow a fleet of trucks to transport a significant inventory. As soon as a store requires a certain article or product, the application would locate a truck, preferably one in the area, and obtain just in time delivery of the product. The mobile inventory and delivery applications could significantly reduce inventory cost and space for the store. Moreover, it would also decrease the time span between the moment the merchant sends and receives an order.

The mobile inventory is a B2B type of application, whereas the localization of the products can be considered a B2C application. A wireless network can locate products and services by using a radio/microwave. Since the satellite signal can be disrupted inside a truck, a separate local area network can be deployed for internal communication and to locate products. Determining an appropriate correspondence between the inventory transported in the trucks within a certain geographical area and the requests which vary dynamically remains an interesting challenge to be addressed. Note that road conditions, traffic, and construction in one area can affect just in time delivery to nearby zones.

Prospective customers for mobile inventory management could include shipping companies (UPS, USPS, FedEx, etc.), factories (e.g., automobile, construction), airline companies, the transport industry, and supermarkets. In this context, one of the problems is the integration of the localization information into a geographical information system (GIS). Progress has been made in this field, which led to the development of products which can find the position of a vehicle and relay this information to a SIG.

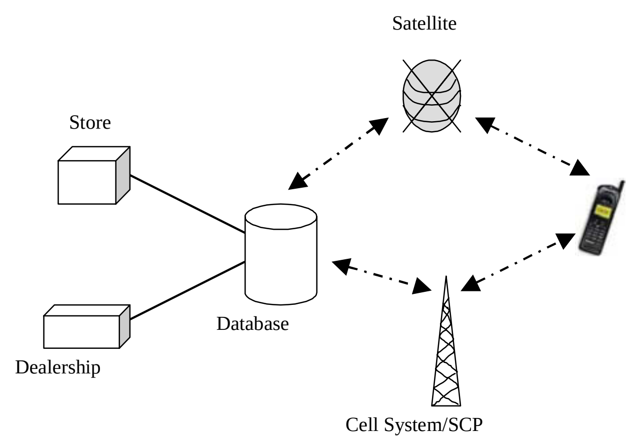
Finding Products and Shopping

The finding-products-and-shopping type of application can locate an article within a certain zone or neighborhood. It differs from the previous class because it is focused on finding a specific article or a person who offers a given service within a restricted zone, which can be delimited by the user. A specific article or an equivalent one (if indicated by the user) can be available through many different stores. In standard shopping, for major purchases (such as a new television, a videotape recorder, a car), many people visit several stores to compare various merchants' offers. By using a mobile terminal (e.g., a Palm Pilot, a Nokia Communicator or a Net Phone) and a database that includes information on the products, a user should be able to find the exact address of a store that carries this article. A list of the places as well as the distance from a specific point could be displayed. Then, the user can order this article online using the browser on his mobile terminal. If several stores carry the desired article, they can compete to earn the client's business by offering remote rebates or enticing prices in real time. This type of application can also include other forms of mobile shopping such as retail mobile sales, mobile ticketing or mobile booking.

As shown in Figure 1, a user can send a request to a central location, which can be interfaced with several stores to monitor whether a certain article is available or not, and if so, at what price. Conversely, the stores can connect their inventory systems to this site. Because the inventory systems of various stores generally use different product codes, a uniform product labeling system will be necessary to allow intelligible Web communication. If a database is unused, the mobile user will have to query stores one by one. However, the quantity of wireless traffic can quickly become problematic if the total number of requests per article and person surpasses the capacity of the wireless network. In order to avoid bottlenecks, it is preferable to use codes rather than specific data to refer to the articles. Thus, two factors must be considered:

- How will the database invoice users?
- How can one verify the database or Web site reliability concerning the availability and pricing of the goods and services?

Figure 1. Locating products and shopping



The use of mobile agents can be very efficient for these types of applications (Lenou et al., 2003). Thus, many cooperating and negotiating agents can be deployed to carry out transactions in various places.

FUTURE TRENDS

Some important issues and concerns must be addressed and solved in order to embrace and deploy mobile commerce. Future and emerging trends include three main challenges: security (Cai et al., 2004; Itani, & Kayssi, 2003; Renaudin et al., 2004), service discovery and transaction management (Veijalainen, Terziyan, & Tirri, 2003; Younas, Chao, & Anane, 2003).

Mobile commerce offers an exciting new set of capabilities that service providers can leverage to increment their revenue base while attracting new services that enhance the end-user's experience. With these new opportunities, the risk of new security threats also arises (Cai et al., 2004). New mobile devices such as PDAs and GSM/UMTS terminals enable easy access to the Internet and strongly contribute to the development of e-commerce and m-commerce services, whereas Smartcard platforms will enable operators and service providers to design and deploy new m-commerce services. This development can only be achieved if a customer's information and transactions are guaranteed to be protected by a high level of security (Renaudin et al., 2004). Thus, establishing security mechanisms which allow diverse mobile devices to support a secure m-commerce environment in wireless Internet is critical (Kim et al., 2003).

Providing security provisions for the m-commerce community is also challenging due to the insecure air interface of wireless access networks, limited computational capability of mobile devices, and users' mobility (He & Zhang, 2003). The limited equipment resources in terms of equipment require the e-payment protocol in the wireless Internet environment to be designed in consideration of the efficiency of the computing functions and the storage device.

Until now, much of the research on m-commerce has focused on the problem of service discovery. However, once a service is discovered, it needs to be provisioned according to the goals and constraints of the service provider and consumer. In this context, automated negotiation protocols and strategies that are applicable in m-commerce environments must be proposed (Paurobally et al., 2003). Specifically, time-constrained bilateral negotiation algorithms that allow software agents to adapt to the quality of the network and/or their experience with similar interactions must be developed and evaluated.

Finally, transaction management is a major issue in m-commerce. It enables people to order goods and access information anywhere, anytime. Given the nature of mobile computing, there is a need for a generic approach that adapts to the needs of m-commerce applications (Younas et al., 2003).

CONCLUSION

This article exposed some basic concepts, technology, and applications related to mobile electronic commerce. After having presented the background and related work, it summarized some prominent applications of m-commerce and outlined future and emerging trends in m-commerce.

End-to-end security remains a fundamental priority for large-scale deployment of m-commerce applications. It is also important to provide mobile terminals with a generic cryptographic functionality in its own right, which is accessible from the application layer. Moreover, because m-commerce transactions imply sharing confidential information such as credit card numbers, it is important that mobile terminals be equipped with a safe storage unit for data as well as mechanisms for authentication and access control. In addition, an infrastructure equipped with a public key is essential to authenticate both actors and ensure secure transactions. Finally, m-commerce applications should provide a consistent user interface for easy and intuitive access to security functionalities.

Because people are becoming increasingly more nomadic, many interesting services can be offered through mobile terminals and mobile networks, such as buying and selling shares on demand or simply entertainment or information services. Such services could also include mobile games and mobile music.

Finally, remember that the user plays the key role in accepting and deploying m-commerce applications. According to studies and market analysis carried out in this field, this technology still remains somewhat immature and large-scale deployment cannot occur until security problems are solved. However, long-term projections offer a very promising future for m-commerce, which is currently gaining ground with the younger generation.

KEY TERMS

Business-To-Business Transaction (B2B): Electronic commercial transaction from business to business.

Business-To-Consumer Transaction (B2C): Electronic commercial transaction from business to consumer.

Electronic Commerce (E-Commerce): A set of financial transactions that can be carried out over a network. E-commerce relies upon users' interventions to initiate a transaction and select the main steps of the process.

Electronic Negotiation (E-Negotiation): Standard practice in purchasing or sales consisting of using a networked environment to negotiate in order to reach an agreement (price, delivery, warranty, etc.) between a customer and a merchant.

Mobile Commerce (M-Commerce): A set of financial transactions that can be carried out over a wireless mobile network.

Mobile Middleware: A functional layer of software provided by application developers to link their e-commerce applications to an OS and various mobile networks to allow their applications to bypass certain mobility issues.

INTRODUCTION

With the introduction of the World Wide Web, electronic commerce has revolutionized traditional commerce and boosted sales and exchanges of merchandise and information. Recently, the emergence of wireless and mobile networks has made possible the extension of electronic commerce to a new application and research area: mobile commerce (MC), which is defined as the exchange or buying and selling of commodities, services, or information on the Internet through the use of mobile handheld devices. In just a few years, mobile commerce has emerged from nowhere to become the hottest new trend in business transactions. Despite a weak economy, the future of mobile commerce is bright according to the latest predictions (Juniper Research Ltd., 2004). Internet-enabled mobile handheld devices are one of the core components of a mobile commerce system, making it possible for mobile users to directly interact with mobile commerce applications. Much of a mobile user's first impression of the application will be formed by his or her interaction with the device, therefore the success of mobile commerce applications is greatly dependent on how easy they are to use. This article first explains the role of handheld devices in mobile commerce systems and then discusses the devices in detail. A mobile handheld device includes six major components: (a) a mobile operating system (OS), (b) a mobile central processor unit (CPU), (c) a microbrowser, (d) input and output (I/O) devices, (e) memory, and (f) batteries. Each component is described, and technologies for the components are given.

BACKGROUND

Internet-enabled mobile handheld devices play a crucial role in mobile commerce as they are the devices with which mobile users interact directly with mobile commerce applications. This section first introduces a mobile commerce system and then illustrates how it is used to carry out a mobile transaction. A mobile commerce system is inherently interdisciplinary and could be implemented in various ways. Figure 1 shows the structure of a mobile commerce system and a typical example of such a system (Hu, Lee, & Yeh, 2004). The system structure includes six components: (a) mobile commerce applications, (b) mobile handheld devices, (c) mobile middleware, (d) wireless networks, (e) wired networks, and (f) host computers.

To explain how the mobile commerce components work together, Figure 2 shows a flowchart of how a user request is processed by the components in a mobile commerce system.

Figure 1. A mobile commerce system structure

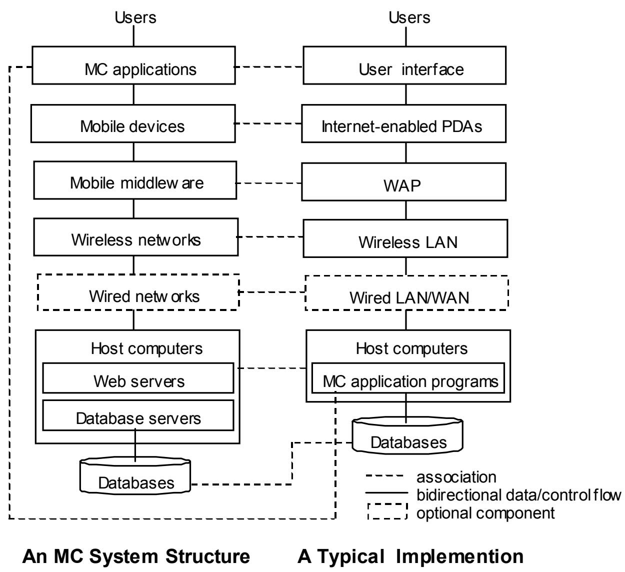

Figure 2. A flowchart of a user request processed in a mobile commerce system

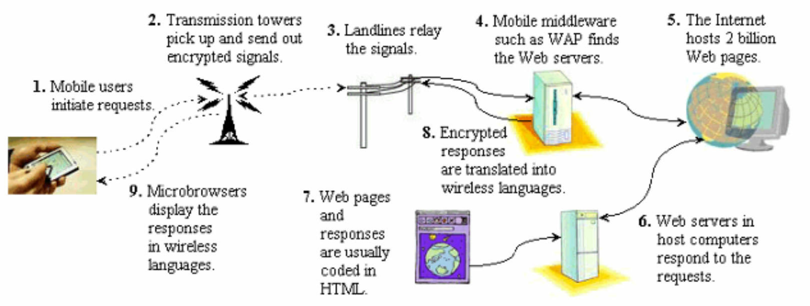

MOBILE HANDHELD DEVICES

Mobile users interact with mobile commerce applications by using small wireless Internet-enabled devices, which come with several aliases such as handhelds, palms, PDAs (personal digital assistants), pocket PCs (personal computers), and smart phones. To avoid any ambiguity, a general term, mobile handheld devices, is used in this article. Mobile handheld devices are small general-purpose, programmable, battery-powered computers, but they are different from desktop PCs or notebooks due to the following special features.

- Mobility
- Low communication bandwidth
- Limited computing power and resources such as memory and batteries

Figure 3 shows a typical system structure for handheld devices, which includes the following six major components: (a) a mobile operating system, (b) a mobile central processing unit, (c) a microbrowser, (d) input and output devices, (e) memory, and (f) batteries. Brief descriptions of all the components are given in the coming sections.

Mobile Operating Systems

Simply adapting desktop operating systems for mobile handheld devices has proved to be a futile endeavor; an example of this effort is Microsoft Windows CE. A mobile operating system needs a new architecture and different features in order to provide adequate services for handheld devices. Several mobile operating systems are already available and each employs a different architecture and implementation. Figure 4 shows a generalized mobile operating system structure, which can be visualized as a six-layer stack.

Although a wide range of mobile handheld devices are available in the market, the operating systems, the hubs of the devices, are dominated by just three major organizations. The following two lists show the operating systems used in the top three brands of smart cellular phones and PDAs in descending order of market share.

- **Smart Cellular Phones:** Microsoft Smartphone 2002, Palm OS 5, and Symbian OS 7 (Vaughan-Nichols, 2003)
- **PDAs:** Palm OS 5, Microsoft Pocket PC 2002, and Symbian OS 7 ("Mobile Computing," 2003)

Figure 3. System structure of mobile handheld devices

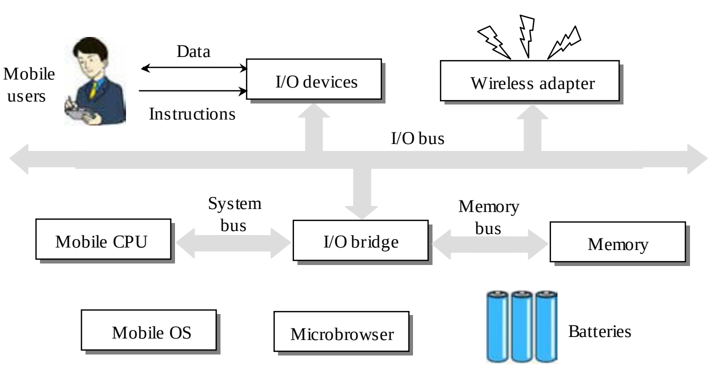

Figure 4. A generalized mobile operating system structure

1.	**Applications**
2.	**Graphical user interface (GUI)**
3.	**Application programming interface (API) framework**
4.	**Multimedia** **Communication infrastructure** **Security**
5.	**Computer kernel** **Power management** **Real-time kernel**
6.	**Hardware controller**

The market share is changing frequently, and claims concerning the share vary enormously. It is almost impossible to predict which will be the ultimate winner in the battle of mobile operating systems.

Mobile Central Processing Units

The core hardware in mobile handheld devices are the mobile processors, and the performance and functionality of the devices are largely dependent on the capabilities of the processors. There used to be several brands available, but recently mobile processors designed by ARM Ltd. have begun to dominate the market. Handheld devices are becoming more sophisticated and efficient everyday, and mobile users are demanding more functionality from the devices. For example, in 2002, *In-Stat/MDR* predicted that worldwide mobile Internet-access device unit shipments would increase from approximately 430 million that year to approximately 760 million in 2006 ("Demand Increasing," 2002). To achieve this advanced functionality, in addition to the obvious feature, low cost, today's mobile processors must have the following features.

- **High Performance:** The clock rate must be higher than the typical 30 MHz for Palm OS PDAs, 80 MHz for cellular phones, and 200 MHz for devices that run Microsoft's Pocket PC.
- **Low Power Consumption:** This prolongs battery life and prevents heat buildup in handheld devices that lack the space for fans or other cooling mechanisms.
- **Multimedia Capability:** Audio, image, and video applications are recurring themes in mobile commerce.
- **Real-time Capability:** This feature is particularly important for time-critical applications such as voice communication.

Microbrowsers

Microbrowsers are miniaturized versions of desktop browsers such as Netscape Navigator and Microsoft Internet Explorer. They provide graphical user interfaces that enable mobile users to interact with mobile commerce applications. Due to the limited resources of handheld devices, microbrowsers differ from traditional desktop browsers in the following ways.

- smaller windows
- smaller footprints
- fewer functions and multimedia features

Several microbrowsers, such as Microsoft Mobile Explorer and Wapaka Java Micro-Browser, are already available. America Online (AOL), Inc., the parent company of the Netscape Network, and Nokia are developing and marketing a Netscape-branded version of Nokia's WAP microbrowser, with AOL-enhanced features, for use across a wide variety of mobile handheld devices. Figure 5 shows a typical microbrowser, Mobile Browser version 7.0 from Openwave Systems, which includes the following features: compatibility with WAP (Open Mobile Alliance Ltd., n.d.) or i-mode (NTT DoCoMo, n.d.), multimedia support, color images and animation, and dual network-stack, HTTP (hypertext transfer protocol) and WSP, support (Openwave Systems Inc., n.d.).

Figure 5. Openwave® Mobile Browser version 7

Input and Output Devices

Various I/O devices have been adopted by mobile handheld devices. The only major output device is the screen, whereas there are several popular input devices, including the following:

- **Keyboards:** There are two kinds of keyboards: built-in keyboards and external, plug-in keyboards. The problem with the former is that they are too small for touch-typing, whereas the latter suffers from inconvenience. Fabric keyboards that can be rolled up or folded around the handheld devices are being developed to relieve the problem of external keyboards.
- **Touch Screens and Writing Areas with Styli:** A touch screen is a display that is sensitive to human touch, allowing a user to interact with the applications by touching pictures or words on the screen. A stylus is an input device used to write text or draw lines on a surface as input to a handheld device. A handheld device equipped with a writing area and a stylus needs a handwriting-recognition function, but existing systems do not yet have a satisfactory recognition rate. Graffiti, employed by many handheld devices, is the most popular writing software.

Some mobile handheld devices can also react to voice input by using voice-recognition technology.

Memory

Desktop PCs or notebooks usually have between 64 to 256 MB of memory available for users, whereas handheld devices typically have only 4 to 64 MB. PDAs normally have more storage space than smart cellular phones. The former commonly have 16 MB, and the latter may have a memory size as low as a few kilobytes. Three types of memory are usually employed by handheld devices.

- **Random Access Memory (RAM):** There are two basic types of RAM: dynamic RAM (DRAM) and static RAM (SRAM). Dynamic RAM, the more common type, needs to be refreshed thousands of times per second in order to hold data, whereas static RAM does not need to be refreshed, making it faster but also more expensive than dynamic RAM.
- **Read-Only Memory (ROM):** ROM is manufactured with fixed contents, and it is usually used to store the programs that boot the device and perform diagnostics. It is inherently nonvolatile storage, in contrast to RAM.
- **Flash Memory:** This is a kind of nonvolatile storage similar to EEPROM (electrically erasable, programmable read-only memory), but updating can only be done either in blocks or for the entire chip, making it easy to update. Flash memory is not as useful as random access memory because RAM can be addressable down to the byte (rather than the block) level.

It is expected that hard disks, which provide much more storage capacity, will be adopted by handheld devices in the near future. A comprehensive survey of storage options can be found in Scheible (2002).

Batteries

Rechargeable lithium ion batteries are the batteries most commonly used by handheld devices. The life of this kind of battery is short, generally only a few hours of operating time. Battery technology will not significantly improve unless and until manufacturers begin to switch to fuel cells, which is unlikely in the near future. A fuel cell operates like a battery, but unlike a battery, a fuel cell does not run down or require recharging and will continue to produce energy in the form of electricity and heat as long as fuel is supplied. Since the fuel cell relies on chemical energy rather than combustion, emissions would be much lower than emissions from the cleanest existing fuel-combustion processes.

Synchronization

Synchronization connects handheld devices to desktop computers, notebooks, and peripherals in order to transfer or synchronize data. The traditional method of synchronization uses serial cables to connect handheld devices and other computing equipment. Now, however, many handheld devices use either an infrared (IR) port or Bluetooth technology to send information to other devices without needing to use cables.

- IrDA Data, a standard formulated by the Infrared Data Association (n.d.) to ensure the quality and interoperability of infrared hardware, is designed for data transfer over distances of up to 1 meter, acting as a point-to-point cable replacement.
- Bluetooth wireless technology is a specification aiming at simplifying communications among handheld devices, printers, computers, and other devices based on short-range radio technology. The Bluetooth 1.1 specification (Bluetooth SIG, Inc., n.d.) consists of two documents: the core, which provides design specifications, and the profile, which provides interoperability guidelines.

FUTURE TRENDS

Mobile handheld devices are usually divided into two types: smart cellular phones and Internet-enabled PDAs. These two kinds of devices started out as very different products, but they have gradually blended into each other. In the near future, it will be difficult to tell the difference between these two types of devices. The newest products such as tablet PCs belong to the category of PDAs because both have similar functionality. There are numerous mobile devices available in the market today. Table 1 lists some major mobile-device specifications, although several table entries are incomplete as some of the information is classified as confidential due to business considerations.

From Table 1 and previous discussions, the future trends of mobile handheld device components are observed.

1. **Operating Systems:** There are several popular operating systems available; the big three are (a) Palm OS, (b) MS Pocket PC/Smartphone, and (c) Symbian OS. It is hard to tell the eventual winner at this moment.
2. **CPU:** The ARM processors (Cormie, 2002) have already dominated and will dominate the market.
3. **Microbrowsers:** Most HTML pages cannot be displayed on microbrowsers, which will be gradually improved to adopt more HTML pages.
4. **Input Methods:** The two major input methods are and will be touch screens and styli, and keyboards.
5. **Memory:** 64 MB or even 128 MB memory for a handheld device will be common.
6. **Batteries:** Fuel cells are likely the most promising method for extending battery life. However, they will not be available in the near future.

CONCLUSION

The emerging wireless and mobile networks have extended electronic commerce to another research and application area: mobile commerce. Internet-enabled mobile handheld devices are one of the core components of mobile commerce systems as they are needed for mobile users to directly interact with mobile commerce applications. Understanding the devices and knowing their functions and capabilities is vital for the success of mobile commerce applications. A handheld device relies on a wide range of disciplines and technologies for its suc-

Table 1. Specifications of some major mobile handheld devices

Vendor & Device	Operating System	Processor	Installed RAM/ROM	Input Methods	Key Features
Compaq iPAQ H3870	MS Pocket PC 2002	206 MHz Intel StrongARM 32-bit RISC	64 MB/32 MB	Touch screen	Wireless e-mail/Internet
Handspring Treo 300	Palm OS 3.5.2H	33 MHz Motorola Dragonball VZ	16 MB/8 MB	Keyboard/ stylus	CDMA network
Motorola Accompli 009	Wisdom OS 5.0	33 MHz Motorola Dragonball VZ	8 MB/4 MB	Keyboard	GPRS network
Nokia 9290 Communicator	Symbian OS	32-bit ARM9 RISC	16 MB/8 MB	Keyboard	WAP
Nokia 6800	Series 40			Keyboard	Innovative keyboard integration
Palm i705	Palm OS 4.1	33 MHz Motorola Dragonball VZ	8 MB/4 MB	Stylus	Wireless e-mail/Internet
Samsung SPH-i330	Palm OS 4.1	66 MHz Motorola Dragonball Super VZ	16 MB/8 MB	Touch screen/ stylus	Color screen
Sony Clie PEG-NR70V	Palm OS 4.1	66 MHz Motorola Dragonball Super VZ	16 MB/8 MB	Keyboard/ stylus/ touch screen	Multimedia

Toshiba E740	MS Pocket PC 2002	400 MHz Intel PXA250	64 MB/32 MB	Stylus/ touch screen	Wireless Internet

cess. To facilitate understanding, this article broke down the functions of a handheld device into six major components, which can be summarized as follows.

1. **Mobile Operating Systems:** Simply adapting desktop operating systems for handheld devices has proved to be futile. A mobile operating system needs a completely new architecture and different features to provide adequate services for handheld devices. A generalized mobile operating system structure can be visualized as a six-layer stack: (a) applications, (b) a GUI, (c) an API framework, (d) multimedia, a communication infrastructure, and security, (e) a computer kernel, power management, and a real-time kernel, and (f) a hardware controller.
2. **Mobile Central Processing Units:** Handheld devices are becoming more sophisticated and efficient everyday, and mobile users are demanding more functionality from their devices. To achieve this advanced functionality, in addition to the obvious feature, low cost, today's mobile processors must have the following features: (a) high performance, (b) low power consumption, (c) multimedia capability, and (d) real-time capability. The cores and architectures designed by Cambridge-based ARM Holdings Ltd. have begun to dominate the mobile CPU market.
3. **Microbrowsers:** Microbrowsers are miniaturized versions of desktop browsers such as Netscape Navigator and Microsoft Internet Explorer. They provide graphical user interfaces that allow mobile users to interact with mobile commerce applications. Microbrowsers usually use one of the following four approaches to return results to the mobile user: (a) wireless language direct access, (b) HTML direct access, (c) HTML to wireless-language conversion, and (d) error.
4. **Input and Output Devices:** Various I/O devices have been adopted by mobile handheld devices. The only major output device is the screen, but there are several popular input devices; among them are (a) keyboards and (b) touch screens and writing areas that need styli.
5. **Memory:** Three types of memory are usually employed by handheld devices: (a) RAM, (b) ROM, and (c) flash memory. Hard disks, which provide much more storage capacity, are likely to be adopted by handheld devices in the near future.
6. **Batteries:** At present, rechargeable lithium ion batteries are the most common batteries used by handheld devices. However, the life of this kind of battery is short, and the technology will not significantly improve unless and until manufacturers begin to switch to fuel cells, which may not happen for at least several years.

Synchronization connects handheld devices to desktop computers, notebooks, or peripherals to transfer or synchronize data. Without needing serial cables, many handheld devices now use either an infrared port or Bluetooth technology to send information to other devices.

KEY TERMS

Electronic Commerce: It is the exchange or buying and selling of commodities, services, or information, or the transfer of funds on the Internet through the use of desktop computers.

Flash Memory: This is a kind of nonvolatile storage similar to EEPROM, but updating can only be done either in blocks or for the entire chip, making it easy to update.

Microbrowsers: They are miniaturized versions of desktop browsers such as Netscape Navigator and Internet Explorer. Microbrowsers, due to the limited resources of handheld devices, are different from the traditional desktop browsers in the following features: (a) smaller windows, (b) smaller footprints, and (c) less functions and multimedia features.

Mobile Commerce: It is the exchange or buying and selling of commodities, services, or information, or the transfer of funds on the Internet (wired or wireless) through the use of Internet-enabled mobile handheld devices.

Mobile Handheld Device: It is a small general-purpose, programmable, battery-powered computer that can be held in one hand by a mobile user. It is different from a desktop or notebook computer due to the following features: (a) mobility, (b) low communication bandwidth, and (c) limited computing power and resources such as memory and batteries. There are two major kinds of handheld devices: (a) smart cellular phones and (b) PDAs.

Stylus: A stylus is an input device used to write text or draw lines on a surface as input to a handheld device.

Synchronization: Synchronization connects handheld devices to desktop computers, notebooks, and peripherals in order to transfer or synchronize data. Other than using serial cables to connect handheld devices and other computing equipment, many handheld devices use either an infrared port or Bluetooth technology to send information to other devices.

Mobile Information Filtering

INTRODUCTION

Information filtering techniques have been continuously developed to meet challenges arisen from new requirements of Information Society. These techniques gain even much more on importance in the facet of grater mobility of people. One of the most dynamic and compelling areas is the environment of wireless and mobile devices. Just recently, information filtering and retrieval have begun to take into consideration circumstances in which they are being used. As information needs of mobile users are highly dynamic, this points out the necessity of considering additional set of attributes describing user situation—context. This article presents an information filtering system for mobile users (mobileIF) being developed in the Department of Management Information Systems at The Poznań University of Economics. Architecture of the mobileIF is a result of research done in the field of contexts, their taxonomies and influence on information relevance in dynamic user's environment. The paper shows our approach to contexts, discusses time perspective on filtering systems and finally, describes mobileIF architecture and basic data flow within it. At last, we present our current research in fields related to the mobileIF system.

BACKGROUND

The process of providing a user with relevant information can be viewed in two different ways. On the one hand, it can be described as the process where single query is performed on a set of documents (information retrieval—IR). On the other hand, it can be understood as applying a set of queries to a single document (information filtering—IF). Although, the aim of both methods is serving users with relevant documents, the way of processing content in information retrieval and information filtering systems significantly differs from each other (Belkin & Croft, 1992). What is more, queries performed in IR represent short-term information needs, whereas profiles, representing information needs in filtering, stand for relatively constant interests in a particular subject (Baeza-Yates & Ribeiro-Neto, 1999). There are many different applications of IR and IF in various areas, however, majority of them utilizes similar techniques such as Boolean model, vector space, and probabilistic models, as well as some brand new ones, like neural network or Bayesian models. Baeza-Yates et al. (1999) provide exhaustive comparison of those techniques.

In the central point of our interests is information filtering domain, that could be divided itself into several additional subdomains according to methods used. The most important ones are content-based (cognitive) filtering and social (collaborative) filtering. The idea that stands for the content-based filtering is to select the right information (relevant to user) by comparing representations of information being searched to representations of user profiles' contents (Oard & Marchionini, 1996). This method of IF has turned out in many systems to be very effective, especially in dealing with textual objects. The latter one overcomes some limitations of content-based filtering (such as problems with filtering multimedia objects, difficult to use for novices, etc.). The collaborative filtering improves results of IF by taking advantage of judgements of multiple users who have similar interests on the read documents (Shardanand & Maes, 1995). Basis for this technique is the assumption that users who judged the same documents in the similar way to others in the group, will most probably proceed like that in future, while judging new documents.

Both of those methods have many specific advantages as well as some drawbacks. The natural way of evolution is combining these techniques in order to achieve better results of filtering. Claypool, Gokhale, Miranda, Murnikov, Netes, and Sartin (1999) and Li and Kim (2003) proposed some hybrid methods.

There are many definitions of context provided in literature. Among them, several deserve special attention as stimulus to our further considerations. In one of the earliest definitions Schilit (1995) distinguishes the following types of context: computing context (network capacity, connectivity, communication costs, and available devices), user context (user's profile, location, people nearby, and social situation), and physical context (lightning, noise level, temperature, and traffic conditions). According to Schmidt, context is divided into two categories, namely: human factors (information of the user, social environment, and user's tasks) and physical environment (location, infrastructure, and conditions) (Schmidt, Beigl & Gellersen, 1999). Both presented definitions try to identify context by simple division of some characteristics into several groups of potentially distinct attributes. However, neither of them is suitable for inferring more aggregated and complex information. This inconvenience is reduced in the definition by Chen and Kotz (2000) who distinguish low-level and high-level context. The former group contains raw contextual information such as location, temperature etc. (mainly acquired from physical sensors), whereas the latter one is specified on the basis of supplied low-level contexts. More formal definition is provided by Dey and Abowd (1999) who argue "context is any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves."

Systems that take into account context changes and adapt to them (to some degree) are defined as context-aware (Pascoe, 1999). Such adaptation may involve adjustment to user's device capabilities (e.g., screen resolution, memory, software attributes, network bandwidth, and user preferences). Context-aware information delivery system takes into account not only semantic information relevance, but also context of the user. Changes in context may suggest changes in user information needs. Information delivery systems that are based on these assumptions are often defined as context-aware retrieval (CAR) systems (Brown & Jones, 2001). Korkea-aho (2000) provides a wider spectrum of CAR application examples.

MOBILE INFORMATION FILTERING

Contextualization in MobileIF

A citizen of Information Society wants to be provided only with such information he or she requires. In case of filtering domain, user information needs are depicted by user profile that expresses rather long-term goals. On the contrary, active goals and current tasks can be supported by contextual information. It is obvious that the latter ones are more significant for mobile users as they can better adjust to their daily rapidly changing activities.

In order to fulfil this requirement, the system has to be able to process several types of user contexts. The notion of contextual information in mobileIF has to be examined from two different points of view.

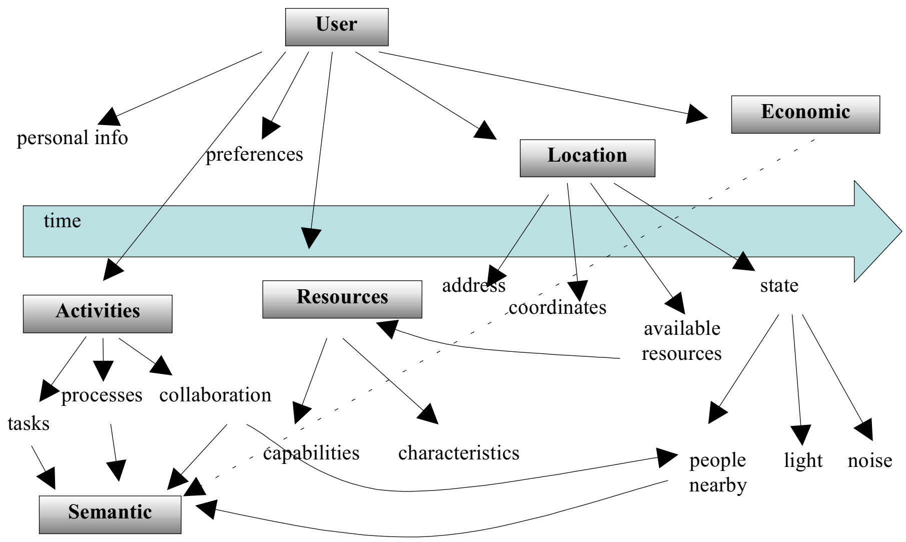
In the first one, we distinguish two new groups of contexts that influence:

- User information needs (named as semantic contexts). They are used to more precisely define queries to the system obtained out of the user's profile. The context can extend the query with some additional concepts as well as narrow it down (Wen, Lao, & Ma, 2004).
- The way the information is delivered to mobile users (named as distributive context). Such contexts allow an adaptation of the filtering results in order to provide the optimal presentation and delivery. This may be done according to the capabilities of devices or user preferences (Costa, 2003; W3C, 2005).

From the second point of view, both described groups may address several dimensions that are crucial for mobileIF system.

- **Time:** The time context is connected with the occurrence of other contexts.
- **Location:** The location context is intrinsically linked to the geographical context, given by the street-network and other infrastructure, points of interest, environmental and topological features etc.
- **Resources:** They correspond to characteristics and capabilities of utilized resources (e.g., user devices).
- **Social Context:** This interpersonal context gives information about relationships between user and other persons or organizations
- **User Activities:** Describing the user's current tasks, and in a broader sense, the existence of specific conditions or steps in a process.

Figure 1. Context dependencies



- **Economic Context:** That handles with relations among various dynamic economic metrics and constraints connected with acquisition of information.
- **Semantic (Cognitive) Context:** Represents current (or future) information needs acquired from user's current tasks, contacts, roles, and preferences. It may be directly derived from other contexts

Most of presented contexts influence each other and should not be treated separately (as shown in Figure 1). It is better to consider user context as a point in a multidimensional space with an unbounded number of dimensions. However, the most significant context in our model is time. The special treatment of this context is driven by the nature of mobileIF. As a dynamic system its main characteristic is changeability and continual adaptability to user's future situations.

Attention should be put to duality of time interpretation. On the one hand, it is linked to information and determines its actuality. On the other hand, it is the point of reference for other contextual dimensions. Another crucial assumption of our context model is ability of aggregation of basic contextual information to form more complex contexts. Therefore, it is essential to develop context representation that is interoperable and usable in many cases, independent from the context sources, and also flexible enough to accommodate future needs.

Time Perspective of Information Filtering

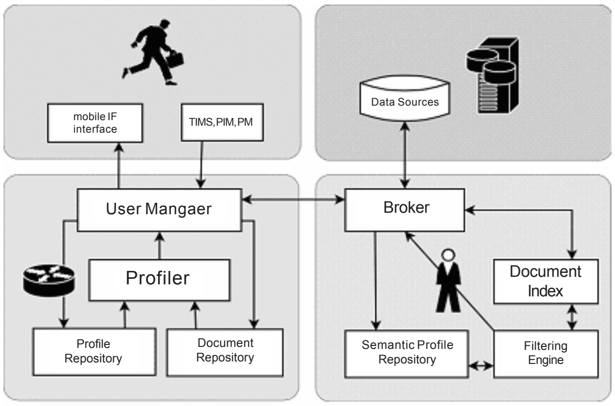
An information filtering process consists of several steps (Belkin & Croft, 1992). Although it is not explicitly stated, some of them start in distinct time moments. The most interesting are:

- Publishing texts
- Indexing texts
- Expressing user's information needs
- Comparison of profiles and indexed documents
- Dissemination of retrieved texts to users

Two of them are of a special importance: the time of specifying user needs and the time of delivery. They are related to the semantic context and to the distributive context respectively. A consequence of an existing time gap is that contextual information that influenced retrieval of a particular document is not the same when the document is delivered to the user (and should comply with his information needs). If we want to fully utilize contexts, both moments should be considered and each time moment ought to be treated differently.

Time management systems (TMS) allow the user to plan his future activities, record them in a computer manageable form, and finally trace their execution.

Figure 2. MobileIF architecture



Scheduled jobs enable distinguishing the time of filtering and the time of delivery. A planned task gives two important pieces of information: due time of the task and its description. That information is a source of distributive and semantic context, respectively. On one hand, a task description is an implicit expression of user needs, and on the other one, it instantiates a particular semantic context state in some point in future. When a task reaches its due time the semantic context becomes the current one (the semantic context changes along with time flow). Distributive contextual information can be obtained by analyzing user's resources and time-related properties of scheduled tasks. At each time moment we always have up-to-date state of both components of the context (semantic and distributive).

Architecture of the MobileIF System

In this article we describe prototype architecture of mobileIF system. One of the mobileIF's objectives is to provide the most relevant, quality-oriented information available from well-defined, specific web sources. Developing our system architecture, we assumed possible cooperation with a few predefined web portals. We concentrate on relevance and quality of information that will be presented on different mobile devices with diverse technical capabilities.

To improve information filtering we need to define user profile as precisely as possible. The system extracts the required information from the user's time or project management applications and sends it to proper mobileIF's modules. Raw data is processed and converted into specific parts of user profile. Semantics of an entry and related resources are stored in a form of semantic subprofile and are used later in the filtering process. Context tags determine a distributive profile that helps presenting filtered documents. All filtered documents are stored within an internal repository and are easily accessible within mobileIF system. With help of a GUI, documents are available anytime, anywhere. The mobileIF architecture is presented in Figure 2.

The whole system is divided into four parts:

- User-end module
- User manager module
- Broker module
- Data sources

The User-end module is an interface to mobileIF. We distinguished two main functions of this module: to present results and to extract data defining all parts of a user's profile. When a new entry within a user's TMS application appears for the first time, mobileIF creates a new profile. In this profile we put semantic content extracted from the entry (subject, description, related resources, etc.) as well as preferred time of presenting filtered documents, entry deadline, date of creation, mobile device currently in use.

The User Manager is a central part of the mobileIF system. That is the place, where information is being processed, organized into semantic and distributive profiles, and dispersed among different parts of the system. User data (user's profile) is stored within the Profile Repository. The Profile Repository is a dynamic module in the sense that all changes made by the user within an associated entry are always updated in the module. Furthermore, the Profile Repository is responsible for managing user's profiles linked to tasks marked by the user as done or expired. The next part of the User Manager is the Document Repository, a place where all downloaded documents are stored. The third part of the User Manager is the Profiler. This module is responsible for binding all the filtered documents with appropriate TMS entries and determining, which documents should be presented at a given time, according to distributive profiles.

The Broker module manages filtering processes and collaboration with external sources. The Semantic Profile Repository is a part where copies of all the semantic profiles are stored. The second part of the Broker is the Document Index that manages creation and updating of full-text documents' indices. The actual filtering process (comparisons) takes place within the Filtering Engine. The results are sent back to the User Manager.

An Exemplary Scenario

A new user starts his cooperation with the mobileIF system by creating a new task (entry) in his TMS application. He fills in a subject, an exact date of meeting, all necessary resources (e.g., people involved), a task category, its priority and marks the whole entry as information need. The user can also provide more details in the task's body.

MobileIF automatically extracts data from this particular task and sends it to the User Manager. There, a new profile connected to the initial task is created. This is the moment of determining all the crucial word entities that will be utilized during the process of information filtering.

Afterwards, the User Manager creates the semantic and distributive subprofiles. The first one is based on entities gathered from textual fields of task's description like subject, body and category. The latter one consists of data extracted from resource fields, mobile device currently in use, and task deadline.

Both the subprofiles are stored in the Profile Repository. The semantic part of the profile is transferred to the Semantic Profile Repository (within the Broker). The Broker keeps the semantic profile as long as an associated entry is valid within user's TMS application. When the entry is removed or its deadline expires, the associated profile is deleted from the Semantic Profile Repository.

In the meantime, the Broker downloads documents from an external web source on a regular basis and stores them in the Document Index. Each new semantic profile that appears in the Semantic Profile Repository is compared against the set of documents indices.

Relevant documents are sent back to the User Manager and are stored in the Document Repository. The User Manager binds them with an appropriate task in the user's TMS. When the user wants to see some relevant documents, Profiler determines the best set of relevant documents with respect to user's distributive subprofile.

FUTURE TRENDS

MobileIF is implemented only partially. There are many several areas that still require further research and testing. One of them is adjusting of graphical form of documents with respect to device capabilities. Many documents are considered relevant because only few parts of them really are interesting. We will try to extract only those relevant excerpts. We expect the task to have more in common with query answering.

Lack of precision in matching document content and user needs is another issue. The use of ontologies, shallow text processing, and automatic building of knowledge bases are approaches that may increase effectiveness of mobileIF system. At first they allow us to smartly expand our queries (from TMS entries) and to index documents.

Another issue we would like to investigate are index structures. Vector based information representation seems to be inappropriate as far as graph-based ontologies will be concerned.

CONCLUSION

Literature brings a great number of definitions of context, however, none of them have been adopted as a standard yet. They were usually developed for the purpose of specific use and for specific systems. They deal mainly with basic and easy detectable contexts like location, temperature, or devices. We present a novel approach to utilization of contextual data for information filtering purposes. There are seven basic contexts we take into account: time, location, resources, social, activities, economics and semantics. Those contexts can be used twofold. On one hand, they raise content's relevance (according to a semantic profile) and on the other hand they influence the process of a document delivery (according to a distributive profile). Such a partition allows us to use a planning or calendar application as a source of user's context. The architecture we have described addresses contextual issues related to the whole process of information filtering.

KEY TERMS

Context: All information about current user's situation.

Data Source: An external provider of information; the information is accessible either in passive or active way.

Distributive Profile: A part of a user's profile that defines which documents (from the relevant ones) and how should be presented to him/her in a particular time moment.

Information Filtering System: A system whose goal is to deliver to a user only this information that is relevant to her/his profile; system operates on large streams of unstructured data.

Mobile User: A user who needs an access to unstructured data anytime and anywhere.

Semantic Profile: A part of a user's profile that defines what kinds of information (topics) he/she is interested in.

Time Management System (TMS): Calendar based application that allows user to schedule her/his tasks, monitor they execution and provide various descriptions for them.

Mobile Public Relations Strategies

Chris Galloway
Monash University, Australia

INTRODUCTION

Public relations is about the "ethical and strategic management of communication and relationships" (Johnston & Zawawi, 2004, p. 6) with individuals and groups ("publics") important to an organization. At one time such publics could safely be thought of in relatively static terms such as geographic location. This is, of course, still possible—but such fixed categories are of diminishing importance when it comes to building relationships with modern publics and communicating organizational messages to them. Even the motor vehicles that facilitate physical movement are becoming "smarter" and converging with technologies such as mobile telephony, personal entertainment systems and handheld computing (Sherry & Urry, 2000, as cited in Sheller, 2002).

This article aims to explore the idea that mobile technologies mean PR practitioners must rethink both the notion of publics and also how to relate to them. A "mobile PR" will undermine taken-for-granted views about the nature of media, messages, and the kinds of relationships public relations people can expect to create on behalf of their clients. Many practitioners are still getting to grips with the online public relations they have known—through activities such as arranging the building of corporate Web sites, monitoring online discussions relevant to client interests and both disseminating company information online and responding to inquiries about it. The idea of an even more flexible communications environment enabled by mobile technologies may seem very daunting. No-one has so far worked out how to "do" PR in this new communications climate—there are no prescriptions or generally accepted approaches. Yet if practitioners do not confront the dilemma of how to reach mobile audiences they risk becoming irrelevant to many clients who must communicate in the mobile space or face unacceptable decay in their business.

BACKGROUND: WHY MOBILE IS DIFFERENT

The Internet and mobile marketplaces have important differences. As Lindgren, Jedbratt, and Svensson note, "The mobile marketplace has a much wider reach than anything before it. It becomes synonymous with everywhere" (2002, p. 5). Siau, Lim, and Shen agree that, "the emerging mobile commerce operates in an environment very different from e-commerce conducted over the wired Internet" (2003, p. 2). It is important that PR practitioners understand the differences and adjust their thinking and practice accordingly.

Siau et al. list mobile market features they consider are *not* characteristic of "traditional" e-commerce:

- **Ubiquity:** Users can get any information they want, whenever they want it, wherever they are (including, now, RSS feeds delivered via mobile internet services).
- **Reachability:** Businesses can reach customers anywhere, anytime—equally, a user can be in touch with and available for other people anywhere, anytime.
- **Localization:** Knowledge of a user's physical location allows locality-specific services to be provided.
- **Personalization:** Mobile commerce applications can be personalized to represent information or provide services in ways appropriate to a specific user.
- **Dissemination:** some wireless infrastructures support simultaneous delivery of data to all mobile users within a specific geographical region. (Siau et al., 2003, pp. 2-3)

As wireless technologies evolve, customer relations will experience dramatic change (Siau et al., 2003, p. 16). To what extent can these relations be called *public* relations and be the domain of PR practitioners rather than marketers? Lines of demarcation can be very blurry. But PR is foregrounded when the prime purpose is to use mobile technologies to create connections–relationships—where the end game is the nature of the relationship rather than an immediate output such as a purchase decision. Examples include:

- Viewer voting via SMS or mobile calls associated with television pop contests, where the goal is to create a broad community of fans who feel they are helping shape the outcome. Their sense of involvement and connection to the contestants—and to other contest followers—is something the promoters hope will morph into long-term enthusiasm for, and purchasing of, products associated with the winner.

- Free delivery of information to mobile devices where consumers have opted-in to receive it—such as notifications of airline or public transport schedule changes. Individuals who are thereby saved a fruitless trip to the train station will value such a convenience—and the organization which provides it, enhancing the organization's reputation for being accessible (if not always for making the trains run on time).
- Personalized, user-specified content delivery. This can range from downloading a daily prayer to getting top news points from the daily paper sent to a mobile device. The organization providing the service is extending its reach to consumers who may not otherwise stop to access their content, or in fact may not be able to access it by other means. This extended reach is valuable to the organizations concerned as a larger pool of customers creates more opportunities to piggyback paid services on free ones.
- Research conducted by SMS, where members of a group which may be dispersed through several countries both receive and respond to researchers' questions through their mobile devices. The group is connected to the research company solely through their mobile equipment but their relationship with the company is essentially no different in nature from that of a focus group meeting in the company's home office.

These examples draw on some of the characteristics of mobile commerce noted by Siau et al. (2003) such as ubiquity, reachability, and personalization to highlight the fact that mobile technologies are enabling new forms of connectivity between organizations and publics that differ from the previous concept of cyberspace as something entered through fixed, location-specific devices. In their difference, the examples also highlight the need for PR practitioners to rethink their approaches to electronic public relations, recognising they now need to do more than designing conventional public relations campaigns that may (or may not) incorporate some online activity. "Mobile PR" may constitute only one part of a public relations initiative—but it should be seen as one that cannot be ignored.

Public relations has developed a range of strategies and tactics to influence publics, most focused on using mass media. Audiences are assumed to be susceptible to media-based persuasion expressed in fact and logic-based statements that frame a particular advocacy position. When the Internet became widely available, public relations practitioners began using it as just a new tool for doing what they had long done, such as publishing media statements and other corporate information and disseminating advocacy material. E-mail meant that some interactivity could be introduced. A new field known variously as cyber-PR, online public relations, electronic PR or "E-PR" developed. Online press conferences were held and some companies began monitoring online chat groups where discussions could highlight an emerging issue that might affect their business. E-PR was used alongside traditional public relations approaches in campaign implementations. Discourse about it focused on translating questions of communication efficiency to the online environment, such as how organizations can integrate the Internet into their existing investor relations activities (Kuperman, 2000) and how they may identify issues that need to be managed (de Bussy, Watson, Pitt, & Ewing, 2000). Interest has focused on exploiting the technology to deliver communication efficiencies for the organization rather than on delivering experiences consumers may want, such as a sense of "connectedness", which Dholakia et al*.* (2000) describe as "the feeling of being linked to a world outside the specific site" (Gustafson & Tilley, 2003).

RECONCEPTUALIZING PR FOR A MOBILE WORLD

Existing E-PR tactics are not longer sufficient for mobile-driven markets. E-PR needs to encompass "M-PR" (mobile public relations). The fluid nature of mobile communications means some core, generally accepted notions of public relations planning need redefinition. PR campaign planning models vary (Bobbitt & Sullivan, 2005, p. 32). There are, however, common elements used in communication processes that aim to build a mutually beneficial relationship with a public – a best-practice goal of contemporary public relations. They include:

- The need to identify priority audiences ("target publics")
- Selecting appropriate media
- Designing effective messages

Mobile communication also reworks the idea of relationship.

Table 1 attempts to point to both similar and dissimilar aspects of the mobile and traditional electronic public relations environments, necessarily making generalizations as it does so.

Table 1.

Mobile PR	"Traditional" Electronic PR
Consumers access cyberspace from mobile devices	Consumers access cyberspace from fixed devices
Target publics form fluid communities linked by mobile communication	Target publics self-select by "pulling" information to themselves
Messages abbreviated, "burst-y", often in TXT and symbols—"emoticons"	Messages use symbols and plain text; facility for delivery of extensive content
Devices allow multimedia experience	Multimedia delivered via fixed devices
Demand to satisfy emotional needs such as sense of involvement is a strong driver for relationship formation	Greater opportunity to influence relationships with rationales for advocacy positions

Target Publics

The world of mobile commerce calls for a wider way of thinking about relating to publics, one that recognizes that mobile communicators—one description of them is "global knowledge-nomads" (Lindgren, Jedbratt, & Svensson, 2002, p. 10)—are consuming content and managing relationships, including with commercial organizations, every bit as much as those consumers who are working with fixed technologies. Mobile communicators cannot be unambiguously defined by familiar psychographic, demographic or even geographic characteristics. "Fleetingness" is the key characteristic, with audiences seeming to be always just beyond reach (Proctor & Kitchen, 2002).

This means the idea of "target publics" must be reconceptualized, taking into account that "in a global context mobile telephony is used by a far broader spectrum of the population than PCs and the Internet" (Lacohee, Wakeford, & Pearson, 2003, p. 206). To PR practitioners raised on linear, structured campaign planning models, elusiveness of audiences is as frustrating as it is demanding. Yet, as Proctor and Kitchen suggest, inconstancy of targets need not justify inactivity: a key may be to "adopt an open, untargeted, ill-defined approach which leaves scope for imaginative consumer participation" (2002, p. 154). Such an approach is ideal for the interactivity of mobile communication, acknowledging that "mobility does not only relate to our physical bodies. We are also mentally mobile and are adept at migrating between various mental states, various identities" (Lindgren et al., 2002, p. 24). Computer and mobile phone-supported social networks are enabling communities of shared interest to form in both physical and online spaces (Wellman, 2001, as cited in Sheller, 2002) and such communities may form the basis of new publics (Sheller, 2002, p. 46).

Media

Commonly used PR planning approaches based on a stage-by-stage implementation concept include a point where media are chosen to carry the messages intended to influence a target audience. Complementing traditional print and broadcast media, the internet has been used as a medium to reach online audiences. Mobile devices capable of supplying voice, video, and text (including RSS feeds) to a user constitute a new, rich and challenging medium for the E-PR practitioner. It is demanding because familiar tactics such as issuing press statements cannot be deployed as before: they require reconstitution for convergent mobile media use.

Messages

The "intensity, brevity, and the absence of narrative continuity" (Lash, 2002, p. 206) that characterize mobile-enabled communication are incompatible with delivering extended logic-based PR advocacy material. Post-modern audiences are likely to be influenced as much by emotion, experience and a desire to find meaningful connection with others as they are by logic (compare Caru & Cova, 2003; Ito & Daisuke, forthcoming, p. 3). Mobile communication's interactivity can offer this kind of intense connectivity.

On-the-move consumers not only seek to be accessible themselves most of the time—Ito and Daisuke's "persistent connectivity" (forthcoming, p. 19)—increasingly they also want to draw down needed information to their mobile devices. Many may remain consumers of traditional media such as newspapers, television and radio while relying largely on mobile devices to function in cyberspace. The condensed nature of much mobile communication means mobile communicators may be less exposed to the extended information and advocacy material available on organizational Web sites, thus obsoleting the press release in its traditional form. That in itself is a big challenge for E-PR practitioners, who must also take into account the mobile field's rapid technological change, which may lead to unexpected applications (Lacohee, Wakeford, & Pearson, 2003, p. 206).

PR people now face the task of designing and delivering content to mobile publics that meets their less tangible need for connection with others: according to Fox (2001) mobile telephones provide a "'social lifeline' in a fragmenting and isolating world" and even the gossip that comprises much mobile-based chat "restores our sense of connection and community" (2001, p. 1). They may need to consider an approach that has been dubbed "dynamic touch" (Galloway, 2005) because it relies on creating an *experience* of connectivity rather than on getting prose published or images broadcast. One example is the sense of connection with contestants that fans develop during the *American Idol* television contests through voting via SMS, e-mailing messages of support and discussing their favorite's progress on their telephones.

Public relations people may need to design more such virtual experiences as part of building and maintaining relationships with mutable, mobile publics, recognizing that "the mobile marketplace merges the virtual and physical marketplaces" (Lindgren et al., 2002, p. 6). This is not the stuff of PR "as we know it" but rather, largely uncharted territory for professional communicators who will need to learn how to imagine and deliver experiences that connect with people in ways that have a planned, overall consistency to them.

Relationships

Increasingly, today's markets are driven by many organizations' perceived need for a "continuous personalized dialog with customers" (Lindgren et al., 2002, p. 17). In the light of this pressure, any concept of E-PR as merely managing familiar tasks in an electronically-enabled environment falls far short. It does so for a number of reasons. One is simply the strong and sustained growth in mobile telephony and in wireless data usage. More than 20% of the world's population uses a mobile telephone and usage is increasing at more than 10% a year (Rerisi, 2003, as cited in Grant & Meadows, 2004). Such surging growth and the changes it is bringing in the way people connect with organizations and individuals that matter to them is simply too significant safely to ignore.

As Levy points out, "major technological inventions not only enable us to do 'the same things' more quickly, better or on a greater scale, but also allow us to do, feel or organize ourselves differently" (2001, p. 199). People now use mobile technologies to negotiate coordination of their activities, permitting "direct contact that in many ways is more interactive and flexible than time-based coordination" (Ling, 2004, p. 58), enabling users to "have a foot in both the here and now as well as the there and now" (2004, p. 190). According to Lacohee, Wakeford, and Pearson (2003), the linking of communication to mobility is central to contemporary social networks. As they point out, such communication need not be in a close social network: the BBC has found with text messages that "New technologies are giving us a level of interaction with out audiences that we have never seen before" (Chapman, quoted in Lacohee, Wakeford, & Pearson, p. 206).

Internet and mobile-linked consumers are primarily interested in building a sense of *connectedness* with others (individuals, groups, and organizations) rather than in consuming particular types of media content. As Proctor and Kitchen note, "Postmodern consumers seek to feel good in separate, different moments by acquiring self-images that make them marketable, likeable, and/or desirable in each situation or moment" (2002, p. 148). People choose to group themselves in shifting "neo-tribes" which share emotions and a "more spiritual sense of community" (compare Patterson, 1998, p. 70). While text messages are often low in informational value they are considered high in social grooming (Lacohee, Wakeford, & Pearson, 2003, p. 206).

FUTURE TRENDS

In the United States, the number of mobile device users exceeds the number of people who use personal computers (Lim & Siau, 2003). As more computing features become not only available on mobile devices but also easier and cheaper to use, this trend can be expected to continue. Wireless capabilities are being incorporated into more technologies and extended for others—and there is the prospect of "unheard of transmission rates" (Meadows, 2004, p. 356, as cited in Grant & Meadows). As more and more functions are offered on wireless devices, it is likely that those with one predominant use will give way to those with multiple capabilities (compare Banks & Fidoten, 2004, as cited in Grant & Meadows, 2004).

For public relations practitioners this means coming to terms with more than a need to understand these converging capabilities and how to deliver content in a way that is both technically and "culturally" compatible—culturally in the sense of being viewed by users as appropriate to the environment of the hybrid communication and computing devices. It also means learning to surf the fluid waves of the mobile market as "members of the communities in which they wish to communicate" (Nicovich & Cornwell, as cited in in Rettie, 2002, p. 261).

CONCLUSION

Public relations practitioners must learn to use mobile devices as new media for campaigns, not just as tools for managing their schedules or arranging the next client function. Doing so will demand a fundamental reworking of familiar concepts to adapt to the new mutable world of mobiles.

KEY TERMS

Cyberspace: The boundaryless virtual world accessed through computer networks, whether one's access device is fixed or mobile.

Dynamic Touch: An experience in cyberspace designed by a professional communicator to stimulate emotional responses that will help advance the interests of the communicator's client organization.

Media: In a public relations context, these are channels for delivery of organizational messages to target publics.

Message: Any content (audio/written/visual) an organization wishes to deliver to a public in order either to inform or to motivate them to a desired response.

Mobile-PR: The application of public relations strategies and tactics in cyberspace accessed through mobile devices.

Public: Any group of people an organization wishes to reach because their interest or influence is relevant to the organization in some way. People may belong to more than one public and shift between them quickly, depending on the issue in question. For example, an Internet user who is also an environmental activist who uses SMS to coordinate times and places of protests with other activists.

Public Relations: The planned and sustained effort to build mutually beneficial relationships between an organization and those individuals or groups whose interest or influence makes them relevant to the organization.

Multi-Agent System for Web-Based Customization

Thorsten Blecker
Hamburg University of Technology (TUHH), Germany

Nizar Abdelkafi
Hamburg University of Technology (TUHH), Germany

INTRODUCTION

Web-based customization refers to an e-commerce business model whereby customers can individualize their products via the electronic channel. The success of this business model to a great extent depends on the appropriateness of the information system, which supports online interaction between customer and supplier (Franke & Piller, 2003). For example, computer manufacturers offering their products online enable customers to select the type of components to be built in the final product (e.g., type of processor, motherboards, graphic and sound cards, etc.). This type of interaction is referred to as Web-based product configuration. In order to increase the chances that customers find suitable products, Web-based customization offers large variety. However, due to the limited information processing capacity of humans and lack of technical product knowledge, excessive product variety confuses customers (Piller, Koch, Moeslein, & Schubert, 2003). It triggers decision-making difficulties and uncertainty concerning the suitability of choices. In effect, customers are generally unaware of their needs and not capable of making optimal buying decisions. Furthermore, the support provided by common information systems is more consistency check than real assistance, since their main task is to verify the compatibility of components between each other.

On the other hand, the resulting variety brings about an increasing complexity of operations and manufacturing-related tasks on the supplier's side. The complexity that is perceived by customers during the interaction process is called "external complexity," whereas complexity that is experienced inside manufacturing and operations is referred to as "internal complexity." Therefore, a suitable information system that supports Web-based customization should simultaneously address both challenges. It should provide customers with appropriate assistance during the search for adequate products and support suppliers in managing variety. In the following, an information system that is capable of coping with both types of complexity will be developed.

BACKGROUND

In order to avoid customer confusion in Web-based customization, information systems should be capable of assisting customers through advisory (Blecker, Abdelkafi, Kreutler, & Friedrich, 2004a; Blecker, Friedrich, Kaluza, Abdelkafi, & Kreutler, 2005). They have to capture a customer's preferences and only display via the Internet the subset of product variants that would be interesting for customers. In this manner, external complexity can considerably be reduced because customers have to make decisions out of a few alternatives. In addition, since the product variants proposed to the customer have higher potential to contribute to the supplier's success, they should be retained in the product assortment. The product variants in which customers are not interested rather increase complexity and should be eliminated from the product assortment. Thus, the condition of success is to reach the final subset of product variants presented to the customers. The most successful product variants ensure long existence in the supplier's offer, while "losers," which cannot establish themselves over a period of time, should be discarded.

It can be imagined that the product variants compete against each other in order to be more successful. For the specification of the competition rules, a market mechanism supported by multi-agent technology (e.g., Jennings, 2000; Wooldrige, 2002) is a suitable solution approach. In fact, it is not practical to associate with each product variant an autonomous rational agent because the extent of product assortments can be very large (billions of possible variations). However, it is common in practice that suppliers providing Web-based customization use modular product design in order to manage high variety (e.g., Gilmore & Pine, 2000; Piller, 2003). Modularity enables one to mix and match product building blocks with standard interfaces in order to create many product variations. Thus, the problem can significantly be simplified if an autonomous rational agent is assigned to a module variation. Subsequently, the extent of the multi-agent population can be kept at a low level. Note that a module variation is an instance of a specific product module (e.g., an engine is a module, while 1.6 Diesel and 2.0 Diesel are two different engine variations). The corresponding agents are referred to as "module agents" and compete against each other for the sake of success, which means formation of product variants with high chances to be proposed to customers.

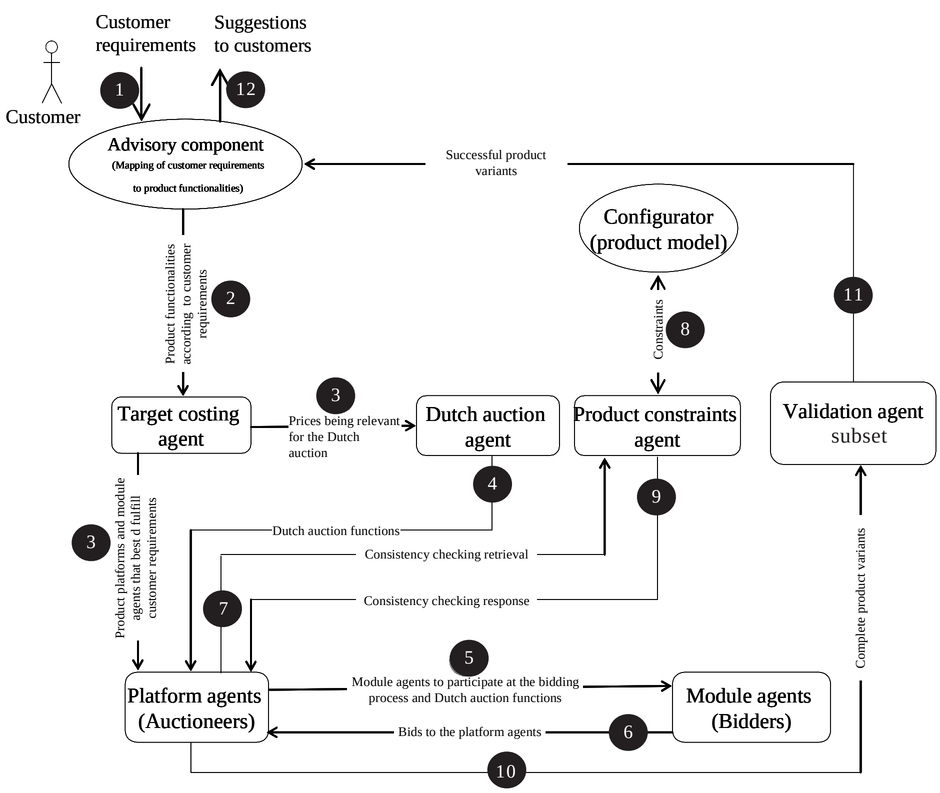
In industrial practice (e.g., automotive industry, computer industry, etc.), suppliers make use of an additional variety management concept called product platforms in order to alleviate the negative effects of variety on manufacturing performance (Nilles, 2002; Wildemann, 2003). A platform is a basic component (module) that is built into a large number of product variations (e.g., A-Platform of Volkswagen). The corresponding agents are called platform agents, which differ from the module agents in that their lifecycles are much longer. In effect, product platforms are cost intensive and developed to serve as the basic module of a product family for a long period of time. It follows that the platform agents should not compete with each other in order to survive, and the decision about their removal is left to managers.

The multi-agent-based system should dynamically assist users during interaction. It should generate and refine product variants that meet customer requirements. Variety formation refers to the process, by which module agents cooperate with each other in order to form customer-focused product variants. On the other hand, the module agents should provide useful information to support variety steering, which is the process of introducing or eliminating module variants so that variety offer can be optimized.

INFORMATION SYSTEM FRAMEWORK

The module and platform agents require some data that should be provided by other software systems. Therefore, the complete information system additionally includes four other agents (target costing agent, auction agent, product constraints' agent, and validation agent) and two components (an advisory component and a configuration system) as shown by Figure 1. The advisory component is a software system that initiates an interactive dialog (e.g., Meissner, 2002) with customers and captures their requirements in terms of product

Figure 1. Framework supporting the multi-agent system for Web-based customization (Blecker, Abdelkafi, Kreutler, & Kaluza, 2004b)



functionalities or other criteria such as emotions and feelings. It reacts on customers' inputs and adapts dialogs during the interaction process. The output of the advisory component consists of product functions and the product price range that the customer would accept. These functional requirements are mapped to technical product description in terms of modules by the target costing agent. This appellation is mainly due to a management tool called target costing that was used for the first time by Japanese companies in order to improve product design. The target costing method computes product target costs by subtracting the target profit that the supplier wants to achieve from the target prices, which are dictated by the market. Subsequently, the target costs of the components are estimated and compared to the actual costs so that specific design improvements can be generated (Seidenschwarz, 2001).

In our case, the target costing agent stores data concerning the contribution level of each module to the fulfillment of the product sub-functions. For instance, it can be set that the sub-function "entertainment" in a car is satisfied up to 60% by a hi-fi system. Using this data, the target costing agent determines the module variations with high chances to fulfill customer requirements. Due to the flexibility of modular product architectures, the combination of the proposed modules mostly results in many product variants. Consequently, a module variants' refinement process is necessary. This is ensured by the auction mechanism and validation agent that will be described later on. After translating the functional description to technical product specifications, the target costing agent has to carry out three main tasks:

- selection of the main platform agents that would best fulfill a customer's profile—the selected product platforms can be chosen more than once, so that many product variants can be formed on the basis of one platform;
- communication of the module agents that would suit customer's requirements to each selected platform agent, which initiates the auction process; and
- communication of the module variants' cost ranges to the auction agent.

On the basis of the module variants' costs, the auction agent derives the auction functions which specify the protocol that makes auctions run. The module agents are the bidders that strive to take part in successful product variants. The platform agents are the auctioneers and regulate the bidding process. When a module agent wins the bid, the platform agent asks the product constraints' agent to verify if the corresponding module variant violates product constraints. If there are no compatibility problems, the module agent is allowed to join. Otherwise, it is rejected and the auction will continue until a module agent with no compatibility problems wins the bid. Thus, in order to ensure the formation of consistent product variants, the product constraints' agent must have access to the configuration system logic which contains a representation of the different constraints between modules.

After the bidding processes terminate, it may result that some product variants are incomplete because some relevant modules are missing. These should be excluded, thereby only communicating the complete product variants to the validation agent. This agent selects the product variants' *subset,* which consists of the final products with the best specifications to suit customers' requirements. Finally, the advisory component displays the narrow range of selected product variants to the customer. In the following, the most important agents for the definition of the market mechanism are considered in more detail. These are the module agents, platform agents, and auction agent, which will be described according to their capabilities, tasks, and properties.

Module Agents

For the regulation of the bidding mechanism, it is necessary to introduce the module agent's account, in which a fictive amount of money is stored. In effect, each new module agent starts with a sum of money supposed to decrease in a linear fashion in the course of time. In addition, each time the module agent wins a bid; it has to pay the auction price. If the agent's account reaches zero, it risks "death" and the corresponding module variant should be considered for eventual elimination. However, module agents have the possibility to compensate their decreasing accounts by means of a reward mechanism. In effect, the number of product variants that come through the validation agent is inferior or equal to the number of all formed product variants. Thus, the collected sum of monetary units from all bidding agents can be distributed on the agents that participate in the successful product variants. The reward of a module agent is equal to the difference between the amount of money received and the auction price. Therefore, some agents make a profit, while others incur a loss. The successful agents more rapidly gain money and achieve better profits, which help them achieve longer survival.

Platform Agents

These are the auctioneers who initiate online auctions on the basis of the bidding functions received from the auction agent. Platform agents only handle product-specific information, but no customer requirements.

During auctions, the platform agents communicate with the product constraints' agent in order to check consistency between the module agents. Furthermore, they do not have to strive for their survival because their accounts are assumed to be infinite.

Auction Agent

The auction mechanism that suits our case has to satisfy the following characteristics:

- The formation of product variants should take place progressively, so that the platform agents can check compatibility between the module agents after each bid.
- Since the successful product variants should be displayed to the customer at once, it is necessary that all running auctions terminate at the same time.
- The auction should enable module agents to track product variants while forming. In this way, the module agents can evaluate their chances of success.
- The auction mechanism should drive the module agents to bid as early as possible. In effect, if a module agent bids early, say at the point in time when the auction starts, it avoids eventual restrictions, which could be imposed by other module agents.

Blecker et al. (2004b) demonstrate that the Dutch auction is the only mechanism that satisfies the proposed requirements. The corresponding agent is called "Dutch auction agent" and determines the functions on which basis platform agents initiate the bidding process. Two main parameters should be ascertained in order to completely define the auction: the opening price and the rate at which price decreases in time. It is noteworthy that the auction opening price is determined on the basis of the module agents' starting accounts, whereas the importance of the product functions depends on the fulfilment level of customer requirements.

Module Agents' Behavior

Because of the complexity of module agents, it is relevant to discuss their main properties. The bidding strategy of a module agent depends on its account and bidding behavior of other agents. The account is private information of the module agent as is usual in real-world auctions. A module agent has the capability of tracking its environment and pursues two types of strategies: a long-term and short-term strategy. The long-term strategy is the plan set by the module agent in order to ensure lengthy existence. To define the long-term strategy, two main inputs are required, namely *Acc (t=0)*, which is the starting account, and T_{∞}, the period of time the agent strives to survive. *Acc(t=0)* determines the period of time T_{∞} that the agent would survive even when it participates in no auctions. T_{∞} can be achieved if the module gains a sum of money called *Profits* during its lifecycle. Subsequently, the term $\frac{Profits}{T_{\infty}}$ indicates the amount of money that should be gained per unit of time in order to achieve T_{∞}. The higher $\frac{Profits}{T_{\infty}}$ is, the more aggressive is the agent. The aggressiveness level (Benameur, Chaib-draa, & Kropf, 2002) of a module agent characterizes its intention to bid early. It depends on the level of its account and the sum of money still to be gained in order to achieve T_{∞}.

The connection between the long- and short-term strategies of a module agent is achieved through the budget concept. It represents the sum of money allocated to the running auctions. An agent schedules its budgets in such a way that it can reach T_{∞}. Suppose that an agent recognizes *n* auctions to be good opportunities for achieving gains. It assigns accordingly a specific budget for these auctions. At the beginning of auctions, the module agent sets a plan and ranks the bidding times in an ascending way. After the auctions start, the module agent may lose, for example, the first bid it has planned. Therefore, it can reallocate the available budget differently, thus increasing its chances of winning the remaining auctions.

Description of the Market Mechanism

The process by which the market mechanism works can be described by four main steps:

1. The advisory component, target costing agent, and Dutch auction agent prepare relevant information for auctions. The number of module agents proposed by the target costing agent depends on the sharpness of information gained from customers. If this information is accurate (e.g., customer is a product expert and exactly knows what module variations are required for its customized product), then the target costing agent suggests a few modules. However, if the gained information is fuzzy, it is expected that the number of module variations is higher.
2. Then, the auction market mechanism determines consistent and complete product variants that would fulfill customers' requirements.
3. These product variants are submitted to the validation agent which…

4. selects the best variants to be displayed to customers.

Benefits of the Multi-Agent System for Variety Steering

The module agent's account level is the most relevant information used for variety steering. It documents the past successes and failures of the module agent, and provides interesting clues concerning its suitability to fulfill customer requirements. Variety steering depends on two parameters: *Acc (t=0)* and T_∞, which must be carefully ascertained. *Acc(t=0)* determines the time period that a module variant is allowed to exist in the supplier's offer even when it is not built into any product variant over time. On the other hand, T_∞ defines the longest period that the module variant can spend in the supplier's offer. It is determined by taking into account future technological innovations and changes in customers' preferences. Recall that the proposed information system suggests the elimination of the module variants whose accounts are equal or inferior to zero.

From a business administration point of view, this concept is a novelty. In the technical literature, it is frequently proposed to eliminate the product variants, which are not purchased by customers (e.g., Wildemann, 2000). However, this method is disadvantageous because the single truth after eliminating a product variant is that it no longer exists in the assortment and its turnover is dropped out. The introduction of the market mechanism enables one to avoid these shortcomings since variety steering is based on a market mechanism that only retains variants with high potential to fulfill customer requirements.

FUTURE TRENDS

There are two important trends that should be pointed out. The first trend is that the acceptance of the Internet as a transaction medium will continue to increase. The second trend concerns the increasing heterogeneity of customer requirements with respect to the buying experience and physical product. Subsequently, Web-based customization will become more and more important in order to survive in the competitive environment. Multi-agent technology provides a good support for industrial enterprises in order to cope with the problems encountered on the shop floor and during customer interaction. Furthermore, concepts such as "virtual reality" will find increasing popularity for the improvement of the buying experience in the digital world.

CONCLUSION

In Web-based customization, two main challenges should adequately be addressed: external and internal complexities. External complexity is faced by customers during the interaction process, while internal complexity is experienced inside operations and manufacturing-related tasks. Both problems should respectively be solved within variety formation and variety steering. An information system based on agent technology is proposed in order to mitigate both types of challenges. Due to the complexity of the problem, the developed system is also complex. Implementation difficulties concern the ascertainment of the parameters' initial values, which are necessary to make the system work. These difficulties are mitigated by simulating the market mechanism for the specific Web-based customization case.

KEY TERMS

Agent: An intelligent computer system that is capable of acting autonomously and proactively in some environment in order to achieve specific design objectives.

Configuration System: A software system in which the product components and the constraints existing between them are stored. A configuration system allows consistent and completely structured product variants that can be produced by the manufacturing system.

Customer Confusion: Refers to the difficulties and uncertainties encountered by customers when they have to make an optimal choice out a product assortment with large product variety.

Dutch Auction: A descending-bid auction, in which the price of an item is lowered until it gets the first bid, which is the highest price the customer is willing to pay.

Interaction Process: The process customers go through in order to find or configure the product variations that meet their requirements via the online channel.

Multi-Agent Systems: A population of autonomous intelligent agents, which coordinate their knowledge, goals, skills, and plans jointly to take action or solve problems.

Product Modularity: An attribute of the product that characterizes the ability to mix and match independent and interchangeable product building blocks with standardized interfaces in order to create product variants.

Web-Based Customization: An e-commerce business model that provides customers with the possibility to individualize their products via the electronic channel.

Multi-Channel Retailing in B2C E-Commerce

Maria Madlberger
Vienna University of Economics and Business Administration, Austria

INTRODUCTION

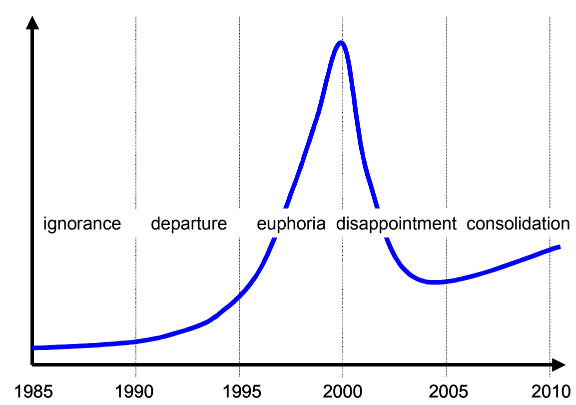
The Internet is not only a significant communication medium, it is also largely used as a channel of distribution. In the very beginning of the e-commerce era, most researchers and practitioners forecasted a sharp increase in Internet-based commercial applications, leading to a threat of existing business models. Already in 1980, Rosenberg and Hirschmann argued that in-home shopping could threaten store-based retailing, as consumers would tend to choose among a larger amount of competing retail formats. Early investigations by Moschis, Goldstucker, and Stanley (1985) revealed crucial conditions that can influence success of online marketing instruments. The conceptual work by Alba et al. (1997) provides basic implications of electronic shopping for consumers as well as for the supply chain and helps understanding key issues in Internet-based shopping. In contrast to the mainly positive discussions on the emerging e-commerce, George (1987) found significant obstacles to non-store retail formats and stated an uncertain future for Internet-based business.

The actual development of online shopping supported George's (1987) assumptions. In the late 1990s, the number of online shops as well as venture capital for them increased sharply. A few years later, many online shops broke down, mainly due to ignorance of business administration fundamentals. One of the most well-known examples is the U.S.-based online grocery retailer Webvan, which wanted to build a nationwide network of food distribution centers in order to replace supermarket shopping. Webvan's collapse was mainly caused by its misalignment between marketing and operations strategies (Delaney-Klinger, Boyer, & Frohlich, 2003). The large number of similar bankruptcies led to skepticism on e-commerce in general and a broad refusal of any e-commerce-related business activities. But with increasing particularity of e-commerce research and practice, this business area is supposed to recover and show growth again, although to a smaller extent than during the "hype." This development is depicted in Figure 1.

One important business area of e-commerce is the business-to-consumer (B2C) sector—that is, using the Internet as a channel of distribution towards consumers. Firms that run B2C online shops are regarded as retailers. In the e-commerce world, one type of retailer proved to be most successful: retailers that use the Internet as an additional channel of distribution, supplementing their network of physical stores. These so-called multi-channel retailers account for a large portion of e-commerce sales. In the U.S., they achieved 72% of online sales in 2002. They also show a higher profitability compared to retailers that operate solely on the Internet (dot-coms). Eighty percent of retailers that operate online shops and stores were profitable in 2002. In contrast, only 50% of the dot-coms were profitable (Haeberle, 2003).

This raises the question of which mechanisms enable a multi-channel retailer to achieve benefits that are not applicable to dot-coms. In order to understand the fundamentals of multi-channel retailing, a discussion on electronic retailing as a retail format and the main characteristics of multi-channel and dot-com retailing is provided. Starting from these considerations, this article presents benefits that arise from a multi-channel strategy and provides an overview for practitioners who want to assess their own as well as their competitors' opportunities and risks in electronic retailing. The conceptual findings are illustrated by examples of successful multi-channel retailers in practice. Finally, a short outlook on future developments is provided.

Figure 1. Expectations on e-commerce business models (Hansen & Neumann, 2005)



BACKGROUND

Any retailer acts as an intermediary and fulfills a number of different functions that are beneficial to consumers as well as to manufacturers. Their main contribution for consumers is bundling assortments of different suppliers and offering them in an appealing way to consumers. In practice, there exists a number of different, industry-specific retail formats (Levy & Weitz, 1992; Berman & Evans, 2001; Gilbert, 1999). On an aggregate level, retailers can be differentiated between store-based, mobile, and remote retail types, with a wide range of retail formats within these types. They show various assortment structures, price levels, and store- (or Web site) related particularities. Store-based and non-store-based retailers differ most from each other (Burton, 2000).

Internet-based retailing is referred to as electronic retailing or e-tailing (Yao & Liu, 2005; Lee, Katerattanakul, & Hong, 2005; Wilde, Kelly, & Scott, 2004; Carter & Sheehan, 2003) and is regarded as the part of B2C e-commerce dedicated to selling and buying goods (Madlberger, 2004). E-tailing fulfills the same functions as classical retailing, although performance and requirements of certain functions differ from store-based retailing (e.g., distribution, product presentation).

E-tailing can be operated as the sole channel of distribution. Such retailers are referred to as dot-coms (Razi & Tarn, 2004; Xing, Tang, & Yang, 2004) or, as expressed chiefly among practitioners, pure players (Janoff, 2001). If a retailer operates one or several other channels of distribution besides the e-tailing activity, it is denoted as a multi-channel retailer (Reynolds, 2002; Berman & Thelen, 2004; Webb, 2002; Schoenbachler & Gordon, 2002; Balabanis & Reynolds, 2001; Madlberger, 2004). A synonym is "bricks and clicks". In the following, synergies of multi-channel retailing are discussed.

SYNERGIES OF MULTI-CHANNEL RETAILING

Multi-channel retailing exists for several reasons. According to Moriarty and Moran (1990), retailers often run multiple channels because they add channels incrementally in order to expand their businesses. Academic literature has extensively investigated business models of multi-channel retailing (Webb, 2002; Schoenbachler & Gordon, 2002; Balabanis & Reynolds, 2001) and analyzed the chances and risks of this strategy. One key issue in multi-channel research is customer's channel choice. Early research in this field focused on channel choice between direct and retail store-based channels (Balasubramanian, 1998; Alba et al., 1997). With increasing relevance of e-commerce and Web-based distribution channels, more intensive research was performed on channel choice and attitudes toward a multi-channel retailer's Web site.

Empirical research has shown that consumers do not automatically switch from one channel to another. In fact, in many cases they would rather stick to existing stores and reject online presences, or use the Internet only as a source of information, but not for purchasing (Kaufman-Scarborough & Lindquist, 2002). A well-integrated multi-channel retail strategy is characterized by cross-channel promotions, consistent product assortments, an information system that supports both channels, and a high degree of channel integration in logistics (Berman & Thelen, 2004). Multiple channels are also an appropriate means of enhancing customer loyalty (Wallace, Giese, & Johnson, 2004). Attitude toward the existing distribution channels and time spent browsing the Web site are the most important influencing factors on attitude toward a multi-channel retailer's online shop (Balabanis & Reynolds, 2001). Multiple channels are associated with higher sales performance but lower channel profitability (Coelho, Easingwood, & Coelho, 2002). Conceptual work on antecedents of channel choice suggested to include perceived risk, past direct marketing experiences, motivation to buy from a channel, the product category, and Web site design into a causal model (Schoenbachler & Gordon, 2002).

Due to the recent emergence of e-commerce, there is one fundamental difference between multi-channel retailers and dot-coms. As dot-coms are directly resulting from the commercial use of the Internet, they are by nature recently established firms with little experience. In contrast, multi-channel retailers have gained knowledge on markets, products, and customers over time, which leads to a competitive advantage vis-à-vis the dot-coms.

In addition, there are several areas in which a multi-channel retailer can obtain synergies (Friedman & Furey, 1999). According to Steinfield, Bouwman, and Adelaar (2002), a multi-channel retailer can obtain four types of synergies: lower costs, differentiation through value-added services, improved trust, and product market extension.

Costs can be decreased in the areas of labor, inventory, and delivery costs (Steinfield et al., 2002), but also in marketing and advertising (Krishnamurthy, 2003). A multi-channel retailer has already established a store brand that is well known by the consumers. Labor costs can be reduced for routine and administrative processes like looking up product information, filling out forms, or online technical assistance. In distribution, a physical outlet can be used as a pick-up point for online orders and contribute to cost savings. Compared with dot-coms, the existing inventory infrastructure and vehicle fleet of a

Table 1. Summary of synergies in multi-channel retailing

Synergy potentials	Characteristics
Costs	Decrease of - labor, - inventory, - delivery, - marketing, - and advertising/branding costs
Differentiation through value-added services	- Complementary product information - Cross-channel promotional activities
Trust	- Confidence and experience by existing channel - Opportunity for customers to return products or give feedback
Market extension	- Entering new markets - Addressing new customer target groups - Offering new or larger assortments
Flexibility	- Financial complementarity of distribution channels (subsidization) - Use of customer-related information

store-based or mail-order retailer can be used for the e-tailing activities as well, and their costs can be spread over more distribution channels (Webb, 2002).

Differentiation through value-added services can be achieved by offering additional and complementary information in the different transaction phases (Otto & Chlung, 2000). Examples are product ratings in the pre-purchase phase, account information, or buying histories after purchase. A recent initiative of this kind has been launched by Sears that provides a virtual decoration feature for home furnishing at its online shop (Anonymous, 2005). Also cross-channel promotional activities can contribute to differentiation. A successful example was a campaign launched by the large Austrian retailer Spar. Consumers could participate in an online lottery. They received online coupons, printed them out, and redeemed them in the stores in order to get price reductions on selected products (Madlberger, 2004).

Trust can be improved through customers' confidence in the existing distribution channel that leverages their trust in the online shop (Balabanis & Reynolds, 2001). The presence of physical stores gives consumers an opportunity to return goods or register complaints (Steinfield et al., 2002). Also the retailer's brand is a source of confidence, as consumers are already familiar with it.

Geographic and product market extension denotes the opportunity for a multi-channel retailer to enter new markets and address new target groups. Especially when a retailer decides to position its online channel differently from the store-based channel, it does not only attract new consumer groups, but also relies on existing back-end infrastructure. This approach, however, is related to largely increased marketing costs and annuls the above-mentioned synergy of improved trust. The extension can also entail advantages for the assortment size. A retailer that has limited inventory space in the stores can extend its product range to slower moving items without need to increase store size. This leads to a benefit for the customer in the form of a larger product variety.

Beyond these synergies, there is also a strategic and financial perspective. A multi-channel retailer spreads its risks and can cross-subsidize less successful distribution channels by means of more successful ones. This allows a multi-channel retailer to be much more flexible than a dot-com that relies on one single distribution channel. As the Internet can provide a retailer with a large amount of customer-related information, multi-channel retailers can also use their additional knowledge about their customers for their store-based distribution channel (Otto & Chlung, 2000).

The higher the degree of channel integration, however, the higher is the risk of channel conflicts and cannibalization (Steinfield et al., 2002). This risk cannot be avoided reasonably by operating parallel channels without any interrelation, but only by careful customer segmentation and channel differentiation.

Table 1 summarizes the synergies and their main characteristics as described above.

Successful Multi-Channel Retailing in Practice

The most famous example of a successful multi-channel retailer is the British supermarket chain Tesco that claims to be the largest online grocer worldwide. Due to the comprehensive loyalty program that is strongly supported by the online shop, Tesco has a reputation for innovation concerning technology use and delivering customer value (Rowley, 2005). On the distribution side, Tesco uses its existing logistics infrastructure instead of building up new resources. Tesco communicates its delivery service as a value-adding process to the consumers thus allowing a charge for delivery fees (Delaney-Klinger et al., 2003). Off-line and online distribution channels are strongly integrated and complement one another (Madlberger, 2004).

Office Depot sells office products via 1,200 retail stores, catalog mailings, and several global online shops. It regards customer relationship as a key driver for e-tailing success. Cornerstones of its multi-channel strategy are loyalty programs and rewards, as well as a strong integration of all distribution channels. Office Depot's goal is to account for the consumer's wish to change between the channels without noticing any differences (Quinton, 2005).

The U.S.-based retailer Sears is another interesting case, as it acquired the online apparel retailer Lands' End and used its experience in e-tailing. This step allowed Sears to extend the online assortment and supplement its appliances and hardware assortment with a large number of apparel brands. Sears used Lands' End's technology for individualized product offerings and improved its online shop that way (Moin, 2004).

FUTURE TRENDS

In the e-tailing world, there seems to be a considerable separation of players in two directions. On the one hand, it will be the multi-channel retailers that dominate the scene and account for the mass business in the online retail sector. This trend will be fostered not only by the higher success rate among multi-channel retailers, but also by dot-coms that are establishing stores and therefore become multi-channel retailers coming "from the other side." Many of the above-mentioned synergies make multi-channel retailers more successful than their virtual competitors (Bertele, Balocco, Gandini, & Rangone, 2002), which is also reflected in market developments. A look at the top global retailers reveals that dot-coms still account for a very small proportion. Among the top 250 retailers of 2004, there are only two real dot-coms, namely Dell at the 65th rank and Amazon at the 116th rank. eBay lies beyond the 250 mark (Stores, 2005).

On the other hand, a consolidation process in e-tailing takes place. Among the large number of start-ups in the late 1990s, only a few dot-com e-tailers have survived. But they have become considerably stronger. Hence we can assume that the rules in the dot-com world are tougher and selection of players is stricter.

From a research perspective, we need deeper insights into consumers' perceptions of multi-channel retailing and relevant influencing factors like trust or experience with the retailer. Also, more knowledge on differences between product groups or industries is necessary.

CONCLUSION

The Internet has become a channel of distribution that allows a wide range of innovative business models and marketing opportunities. The obvious tendency that online retailers would threaten or even drive out traditional store-based retailers, however, did not become reality. Instead, multi-channel retailers are the players who dominate B2C e-commerce.

This article gives an overview of the fundamentals on online and off-line distribution channels and the characteristics of multi-channel retailing. The different synergies that are discussed can be used as a first orientation for practitioners who want to evaluate what opportunities can be achieved by running off-line and online distribution channels. The examples of success stories in multi-channel retailing strengthen these considerations and show that multi-channel retailing requires customer-orientation and a high degree of integration. As an e-tailer is mainly in competition with multi-channel retailers, it is vital to be familiar with the chances and risks that arise from multi-channel retailing.

KEY TERMS

Distribution Channel: The sum of all organizations or parts of an organization that are involved in making a product or service available to a customer. Distribution channels can also apply media (e.g., the Internet or TV) in order to address customers. Also called channel of distribution.

Dot-Com: An electronic retailer that operates exclusively through this one distribution channel. By nature, dot-coms are non-store-based retailers. Also known as pure player.

Electronic Commerce (E-Commerce): The usage of electronic networks, especially the Internet, as a channel of distribution and a support of inter-organizational business processes. E-commerce can be differentiated into the business-to-business (B2B) and business-to-consumer (B2C) sector. It includes selling and buying goods and services, exchanging business data, and providing information.

E-Commerce Business Model: A structured description of an organization's activities in order to operate a business based on electronic commerce. It consists of three main parts: the architecture for the flow of products, services, and information; the generation of value; and the source of revenue.

Electronic Retailing (E-Tailing): The application of electronic networks, especially the Internet, as channel of distribution, in order to address final consumers. Like traditional retailing, e-tailing is restricted to buying and selling physical or digital goods, but no services.

Multi-Channel Retailing: Also called bricks and clicks. It is the simultaneous application of more than one channel of distribution in retailing. A multi-channel retailer operates at least one electronic and one non-electronic (physical stores, catalog, etc.) channel of distribution.

Retail Format: The sum of different retail marketing instruments—such as assortment size, price level, service policy, and access points to the customer—that describe a type of retail policy. In practice, a wide range of different retail formats exists that are in many cases industry specific.

Multilingual Web Sites in Global Electronic Commerce

Shaoyi He
California State University, San Marcos, USA

INTRODUCTION

The World Wide Web (the Web), a distributed hypermedia information system that provides global access to the Internet, has been most widely used for exchanging information, providing services, and doing business across national boundaries. It is difficult to find out exactly when the first multilingual Web site was up and running on the Internet, but as early as January 1, 1993, EuroNews, the first multilingual Web site in Europe, was launched to simultaneously cover world news from a European perspective in seven languages: English, French, German, Italian, Portuguese, Russian, and Spanish. (EuroNews, 2005). In North America, Web site multilinguality has become an important aspect of electronic commerce (e-commerce) as more and more Fortune 500 companies rely on the Internet and the Web to reach out to millions of customers and clients. Having a successful multilingual Web site goes beyond just translating the original Web content into different languages for different locales. Besides the language issue, there are other important issues involved in Web site multilinguality: culture, technology, content, design, accessibility, usability, and management (Bingi, Mir, & Khamalah, 2000; Dempsey, 1999; Hillier, 2003; Lindenberg, 2003; MacLeod, 2000). This article will briefly address the issues related to: (1) language that is one of the many elements conforming culture, (2) culture that greatly affects the functionality and communication of multilingual Web sites, and (3) technology that enables the multilingual support of e-commerce Web sites, focusing on the challenges and strategies of Web site multilinguality in global e-commerce.

BACKGROUND

When the Internet was originally created as APARNET in 1969, it was only a small computer network interlinking four universities in the southwestern United States. Nowadays, the Internet has become a primary communication medium, with 820 million computers and one billion users all over the world (Computer Industry Almanac, 2004, 2005). Throughout the years, both the Internet and the World Wide Web have evolved with the monolinguality of English into the multilinguality of more than 1,000 languages (Crystal, 2001). In 1998, the majority (70%) of the Web content was in English (Nadeau, Lointier, Morin, & Descôteaux, 1998), but it dropped to 56.4% in 2002 (Netz-tipp.de, 2005). Also in 1998, the newly created non-English Web sites outnumbered the newly created English Web sites (Crystal, 2001). Global Reach, a marketing communications consultancy that specializes in global electronic commerce, has been tracking the evolution of the English and non-English Internet populations since 1995. In 1996, 80% of the Internet population spoke English while the other 20% were non-English speakers. The English dominance was gone when the non-English Internet population (52%) surpassed the English Internet population (48%) in 2000. In 2004, the non-English Internet population reached 71% while the English Internet population dropped to 29% (Global Reach, 2004). Furthermore, current Internet usage is growing strongly in non-English-speaking countries such as China, Japan, Germany, India, South Korea, Italy, France, Brazil, and Russia (Computer Industry Almanac, 2004). As the number of non-English-speaking Internet users around the world increases, Web site multilinguality has become an important aspect of the Internet and the Web, and is becoming indispensable for companies that want to meet the needs of this increasing non-English Internet population via global e-commerce (Hillier, 2003; Lebert, 1999; Schneider, 2005; Westland & Clark, 2002).

E-commerce refers to the commercial activities that take place over a computer network, usually the Internet and the Web. These activities generally involve the buying or selling of marketing products, providing or obtaining services, seeking or acquiring information, and requesting or transmitting funds (Wikipedia, 2005). E-commerce can be between or among entities in the private sector, government institutions, and/or members of the public, hence the categories of business-to-business (B2B), business-to-customer (B2C), business-to-government (B2G), government-to-government (G2G), government-to-consumer (G2C), and customer-to-customer (C2C). E-commerce makes the best use of any of the Internet applications, such as Web sites, e-mail, instant messaging, online auctions, online forums, Web services, and Weblogs (Fiore, 2001; Reynolds, 2004; Schneider, 2005). Because of the international nature of the Internet and the Web, the companies that engage in e-commerce would ultimately use the Web sites to conduct their commercial and noncommercial activities in a global e-commerce environment (Schneider, 2005; Westland & Clark, 2002). Furthermore, for any company that is serious about winning the competitive edge in global e-commerce, the better way to success is to build and maintain a multilingual Web site (Ott, 1999; Payne, 2005).

WEB SITE MULTILINGUALITY: CHALLENGES AND STRATEGIES

A multilingual Web site provides the same information in different languages. There have been different approaches to develop and implement a multilingual Web site, and two have been historically adopted for many of the e-commerce Web sites. One is Web site globalization and the other is Web site localization. The former globalizes the content for broadening a businesses appeal to a general international audience, and the latter localizes the content to appeal to customers of a particular nation or culture (Chen, 2002; Dempsey, 1999; Seilheimer, 2004). A typical mature corporate Web site uses both approaches and thus contains a mixture of global content and local content. The global content need be presented in many languages for customers all over the world, and usually covers product information, technical support documents, tutorials, corporate profiles, worldwide branding messages, and the design of the Web itself. The local content has to be written for each target language audience, and usually includes locally available products, local promotions, sales and advertising campaigns, and local points of purchase indices. While the global content is applicable everywhere and is relatively insensitive to national or cultural differences, the local content provides the most relevant information to convince the users that the Web site fits in their culture (Schneider, 2005; Yunker, 2003).

A properly designed multilingual Web site targets information to a given audience and adequately meets their information needs. For example, having a Chinese Web site will make it easier to promote information relevant to a Chinese audience. It would also help to overcome potential cultural barriers when users are able to navigate, understand, and interact on the Web site in the native language. Also, a properly designed multilingual Web site is one of the most cost-effective ways of marketing the company, giving its brand an international outlook, building relationships with clients, and showcasing the company across the globe. By having the Web site accessible to non-English-speaking users looking for products or services, it would be easier to capture their attention and they would be more likely to become new customers. In addition, a properly designed multilingual Web site has potential for an increase in sales. If an e-commerce Web site is translated into a few of the major world languages, such as Spanish, French, German, and Italian, there is potentially a 400% increase in sales (Payne, 2005).

One of the most visible challenges of Web site multilinguality includes overcoming the barriers of language, culture, and technology in global e-commerce, which have been observed and studied since the early days of the Web (Ott, 1999; Schneider, 2005; Vehovar, Batagelj, & Lozar, 1999). The language barriers not only refer to the historical dominance of the English language, but also refer to the present multilinguality of the Internet and the Web. Since 2000, there have been more non-English-speaking users than English-speaking users on the Internet (Global Reach, 2004). The culture barriers mean that cultural differences may cause misinterpretation in communication. Something that is appropriate and acceptable in one culture may not be appropriate and acceptable in another culture. The technology barrier mainly refers to the problems with character sets—there is no ASCII analogue for the non-Latin characters used by the Chinese, Japanese, Arabic, Hebrew, and other languages. Furthermore, on a multilingual Web site, the use of symbols, icons, images, colors, values, rituals, idioms, metaphors, and salutations needs be appropriately chosen according to cultural contexts, thus avoiding being misunderstood or offensive (Chen, 2002; Hillier, 2003; Singh & Matsuo, 2004; Schneider, 2005; Sun, 2001). When designing a multilingual Web site, the content and structure of the Web site should make sense for the eyes of people in that culture. If only the language was translated, the users in different cultures would experience difficulties of using and understanding the Web sites (Hillier, 2003).

Another major challenge of Web site multilinguality is related to the minority of non-English-speaking countries (Vehovar et al., 1999). Non-English-speaking countries face several language-related problems. In general, it is unrealistic to globally promote a company's Web site in a non-English language. If a non-English-speaking country were technologically undeveloped with a small number of Internet users, it would be very difficult to establish an audience large enough to justify the investment needed for elaborated applications on the Web. Such small non-English-speaking audiences can hardly enable the development of Web applications such as bookstores, travel agencies, search engines, portals, and news agencies in their own language (Ott, 1999).

Another major challenge of Web site multilinguality is the extremely high cost of designing and maintaining a multilingual Web site (P923-PF, 2000). Multinational companies such as IBM and Microsoft may find it a must to invest millions of dollars in developing multilingual Web sites to compete in international business. But, many small and mid-sized companies (SMEs) may find it very difficult to justify the high cost of multilingual Web sites because it would be very hard to generate enough online revenues from the Web-based applications to make a profit or keep balance. While the Web sites of large companies, usually Fortune 500 companies, can be in dozens of languages, these of the SMEs may be limited to much fewer languages due to the budget constraint. But, any company, whether large or mid-sized or small, cannot afford not to have a multilingual Web presence on the Internet if it wants to succeed in global electronic commerce (Vehovar et al., 1999; Schneider, 2005).

The other major challenge of Web site multilinguality is dealing with the common mistakes in the design of global e-commerce Web sites. In his book entitled, *Engineering Global E-Commerce Sites,* James Bean discussed in detail how to avoid some frequent mistakes in global e-commerce Web site design. Firstly, do not assume (1) a market is North American only, (2) an audience is exclusively English speaking, and (3) "globalization" simply means support for multiple languages. Secondly, do not ignore geography and time zones. Thirdly, do not neglect the importance of information and transaction data. Finally, do not transact business exclusively in U.S. dollars, and finally, be aware of regulatory acts (Bean, 2003).

As the combination of globalization and localization, "glocalization" is "a term that was invented in order to emphasize that the globalization of a product is more likely to succeed when the product or service is adapted specifically to each locality or culture it is marketed in" (Whatis.com, 2005). There are many examples of glocalization. For example, McDonalds' in China has changed the menu to serve rice to local Chinese customers, and McDonalds' in France has replaced the familiar Ronald McDonald mascot with Asterix the Gaul, a popular French cartoon character. When applied to global e-commerce, Web sites glocalization means thinking global and acting local. In a study on the Chinese Web sites of the 100 top global brands, Maynard and Tian (2004) found that a "glocal" strategy, as opposed to a standardized global strategy, was being practiced in cyberspace by many of the companies with top brands. These companies glocalized their Chinese Web pages by integrating local cultural characteristics into their brands' strategies, thus presenting themselves as being socially accommodating to the local market.

One of the emerging technologies associated with the creation and rendering of non-Latin alphabets is Unicode, which has been recognized and widely adopted as an international standard. As the alternative to ASCII coding scheme, Unicode allows more than 65,000 non-Latin characters and makes storing, displaying, and accessing non-Latin characters on the Web much easier. It enables a single software product or a single Web site to be targeted across multiple platforms, languages, and countries without re-engineering (Ott, 1999; Yunker, 2003).

JavaServer Pages (JSP) technology has been used to solve problems in the development of multilingual Web applications, for example, language, locale determination, and localization; character encoding; JSP source files encoding; number formatting and parsing; date and time formatting and parsing; and message formatting (Lindenberg, 2003).

Human language technology (HLT) enables multilingual support of global e-commerce Web sites that goes beyond Web site localization or text translation, improving Web site usability in terms of natural languages. Such a support implements cross-language information retrieval technologies that are able to handle searches made in the user's local language across knowledge bases coded in any number of other languages. The language technologies on HLT-enabled Web sites include applications of multilingual user interfaces and services, multilingual content management, multilingual trading, and multilingual customer relationship management, hence making multilingual Web sites more competitive in a global marketplace.

Machine translation systems connected by the Internet may allow cross-language communication with anyone, from anywhere, and at anytime. The Web-based translation makes it possible to instantly interpret regional dialects and idiomatic expressions in various languages. With the machine translation systems, the products and services can be obtained or provided in a local language, thus helping international businesses and markets to grow, and allowing local cultures and languages to thrive (Lehman-Wilzig, 2001).

In addition, there are various companies and organizations that specialize in providing software and service for multilingual Web site development and maintenance. The following are some of the more popular ones.

- **Lionbridge (http://www.lionbridge.com/):** A leading provider of globalization, testing, and development services. Enables Global 1000 organizations to develop, release, manage, and maintain technology applications and enterprise content worldwide.
- **TRADOS (http://www.trados.com):** Provides the world's leading localization and computer-assisted translation software to improve the consistency and quality of the clients' multilingual content.

Supports more than 72 languages, including English, all European languages, Arabic, Russian, Japanese, Chinese, Korean, and Hebrew.

- **GlobalSight (http://www.globalsight.com):** Enables companies to improve global business, manage multilingual information, and deliver time-critical content worldwide. Its flagship product, Ambassador, is the leading multilingual content management software solution and the only technology that allows for the development and reuse of all types of content throughout a global enterprise.
- **LISA (http://www.lisa.org/):** LISA (Localization Industry Standards Association) is the premier nonprofit organization for the GILT (Globalization, Internationalization, Localization, and Translation) business community. Membership includes 400 leading IT manufacturers and services providers. It has created the LISA's best practice guidelines and language-technology standards for enterprise globalization.
- **MultiLingual Computing (www.multilingual.com):** The information source for the localization, internationalization, translation, and language technology industry. The printed magazine *MultiLingual Computing & Technology* is the flagship product, and the Web site covers topics ranging from technical internationalization to project management to language histories.

FUTURE TRENDS

Every year in the next 10 years or longer, there will be more than 100 million non-English-speaking people going onto the Internet and the Web (Mosquera, 2001). To meet the needs of such a growing online population, the future of global e-commerce is dependent on the development and maintenance of quality multilingual Web sites, which is not easy at all. But, as pointed out by Crystal (2001)—"The future looks good for Web multilingualism"—there would be a great demand for multilingual Web sites. The triangular relationship among language, technology, and culture would continue to create new challenges for global e-commerce. Therefore, Web site multilinguality would remain as an important aspect of the Internet and the Web.

There are two immediate future research directions that are within the domain of Web site multilinguality. One future research opportunity is to include all of the other issues of Web site multilinguality in a further study of the challenges and strategies in developing and maintaining multilingual e-commerce Web sites. The other future research opportunity is to study the impact of glocalization on non-English e-commerce Web sites, such as the e-commerce Web sites in traditional and simplified Chinese, focusing on the correlation of global content and local content of the Web sites.

CONCLUSION

It has been shown in this article that Web site multilinguality plays a very important role in global e-commerce. As more and more non-English e-commerce Web sites are mushrooming on the Web, the issues of Web site multilinguality should be seriously taken into consideration, because they are closely related to language, culture, technology, content, design, accessibility, usability, and management. In this article, some important aspects of Web site multilinguality have been addressed with respect to: (1) language, which is one of the many elements conforming culture; and (2) technology, which is a useful and helpful tool enabling multilingual support of global e-commerce Web sites. The challenges and strategies involved in developing and maintaining successful multilingual e-commerce Web sites have been discussed in detail with examples, and the future trends have been provided, with future research opportunities for global e-commerce.

KEY TERMS

Global Electronic Commerce: Commercial activities that take place over a computer network, usually the Internet and the Web, across national borders.

Globalization: International exchange or sharing of labor force, production, ideas, knowledge, cultures, products, and services across national borders.

Glocalization: Creation of products or services intended for the global market, but customized to suit the local culture.

Human Language Technology: Branch of information science that deals with natural language information.

Localization: Process to create a product that looks as though it was created in the target country or market.

Multilingual Content Management: Processes of organizing, categorizing, and structuring information resources for multilingual storage, publishing, and reuse.

Web Site Multilinguality: Presence of Web sites in more than two languages on the Internet.

Web Site Translation: Process of transforming content of a Web site from one language into another language.

Multimedia Proxy Servers

Philip Kwok Chung Tse
The University of Hong Kong, Hong Kong SAR, China

INTRODUCTION

On the Internet, multimedia objects are stored in content servers. The clients behind some proxy servers are located over a wide area network (WAN) far from the content servers (Figure 1). When a client accesses multimedia objects from a content server, the content server must either allocate sufficient disk and network resources to multicast or unicast the objects to the client (Ma & Shin, 2002). Otherwise, it rejects the client. Thus, the popular content server becomes the bottleneck in delivering multimedia objects.

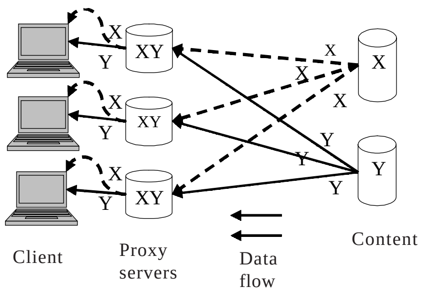
Proxy servers have the disk cache space, network bandwidth, and availability to cache parts of the multimedia objects for clients, making them good candidates to solve the bottleneck problem. However, large multimedia objects are not cached or only partially cached in current proxy servers. When fast optical networks are widely deployed, this problem is becoming more severe. Therefore, proxy caches must be enhanced to alleviate the bottleneck in popular content servers with multimedia objects.

Multimedia proxy servers perform several functions in accessing multimedia objects over the Internet. We first present the background in the next section. Next, the *cache replacement* policies being used in proxy servers are described. Then, the *object partitioning* methods are described. After that, the *transcoding* method that converts high-resolution objects into low-resolution objects is described. Afterward, we present the *cooperative caching* method that can be applied to cache objects on proxy servers. Lastly, we describe a method to distribute proxy-server load using a depot.

BACKGROUND

One of the main research issues in multimedia object delivery is the provision of *quality-of-service (QoS)* streaming. A multimedia stream is a group of periodic requests that are separated from each other at a fixed time interval. In order to support QoS streaming, the network bandwidth from the content server to each client needs to be able to support the variable data rate of the object stream. Otherwise, some blocks will be missed and jitters will occur. If many blocks are missed, the multimedia stream may even be discontinued.

Figure 1. Delivery of multimedia contents over the Internet using proxy servers

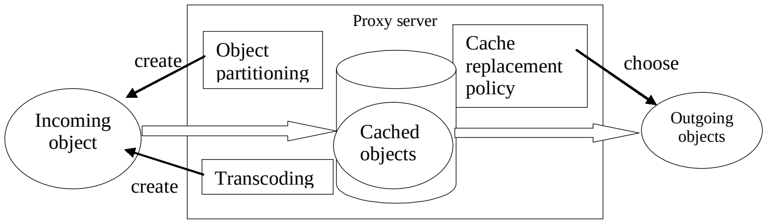


There was much research on enhancing individual proxy servers for multimedia streaming (Chang & Hock, 2000; Ham, Jung, Yang, Lee, & Chung, 1999; Nam & Lee, 1997; Xiang, Zhang, Zhu, & Zhong, 2001). The use of proxy servers, as virtual servers between the servers and the clients, was proposed to manage server-client connections, data delivery, and transcoding (Acharya, Korth, & Poosala, 1999; Chandra, Ellis, & Vahdat, 1999; Nam & Lee). The proxy server is becoming the centre of management to handle server bandwidth limitation and client bandwidth adaptation.

When a proxy server is placed between the content server and its clients, it may store some of the delivered objects in its local cache storage for repeated retrievals. When the cache storage is fully used, it deletes some cached objects to release space for new objects. The cache replacement policy will choose which object should be deleted. The cache content and the cache performance thus depend on the *cost function* of the cache replacement policy (Figure 2). In the literature, many cost functions have been proposed and studied for multimedia objects in a single proxy-cache environment (Acharya et al., 1999; Aggarwal, 1997; Bahn, Koh, Noh, & Min, 2002; Hosseini-Khayat, 1998; Paknikar, Kankanhalli, Ramakrishnan, Srinivasan, & Ngoh, 2000; Sohoni, Min, Xu, & Hu, 2001; Su et al., 2000; Wu, Yu, & Wolf, 2001; Xiang et al., 2001).

When a proxy server caches a large multimedia object, the cache space may not be able to store many objects.

Figure 2. Relationship among different functions in a single multimedia proxy server



Instead of storing the entire object, the proxy server may store only a part of it. The cached part can thus be directly retrieved from the local storage and only the missing part is accessed from the content server. The position and size of the cached part affect the network bandwidth requirement and the response time of new streams. In the literature, three object partitioning methods, namely, leader, *staging*, and hot spot, have been proposed for individual proxy servers (Fahmi, Latif, Sedigh-Ali, Ghafoor, Liu, & Hsu, 2001; State & Festor, 2001; Zhang, Wang, Du, & Su, 2000).

When multiple proxy servers are present in a regional network, they may exchange their cache contents to serve client requests more efficiently. The only found research works on the cooperative caching of multimedia objects are on the leader method (Park, Park, & Son, 2001) and the *multiple hot-spot* method (Tse, Leung, So, & Lau, 2003).

CACHE REPLACEMENT POLICIES

The main contribution or responsibility of proxy servers to the clients is their cache content. The cache content depends on the cost function in the cache replacement policy that determines the cache performance. Hence, the cache replacement policy must be optimized to achieve the lowest capacity miss rates on the cache.

Traditional cache replacement policies considered recency and frequency in the cost function of the cached objects to replace the oldest object in the cache. Xiang et al. (2001) added delays into the cost function. Acharya et al. (1999) added resolution size. Paknikar et al. (2000) added the object size and layer number. Aggarwal (1997) and Wu et al. (2001) increased the segment length when the position of a segment is far from the beginning of a video. This is advantageous when many users stop playing the media after only some initial blocks. Using these cost functions, either the cache hit rate or byte hit rate is optimized for each individual proxy server. In general, Bahn et al. (2002) described the cost function as

$$\text{Cache Value} = \frac{\left(d_i^{r1} * n_i^{r2}\right)}{\left(t_i^{r3} * s_i^{r4}\right)},$$

where d_i is the latency to fetch an object i, n_i is the number of references made to i since it has been brought into the cache, t_i is the last reference time, s_i is the size of object i, and $r1$, $r2$, $r3$, and $r4$ are constants with default values $r1 = 0.1$ and $r2 = r3 = r4 = 1$.

Web *prefetching* obtains the Web data that a client is expected to need on the basis of data about that client's past surfing activity. It reduces access latency by actively preloading data for clients. Bianchi and Mancuso (2003) minimize the connection outage probability by controlling the buffer size among connections. The prediction by the partial match model (PMM) makes prefetching decisions by reviewing the universal resource locators (URLs) that similar clients have visited (Chen & Zhang, 2003). The model forms a Markov predictor tree structure of these URLs. The standard PMM builds a tree for every visited URL. A fixed threshold is used to limit the length of each prediction branch. In order to achieve accurate prediction on future requests, the tree being built is very large and consumes too much space.

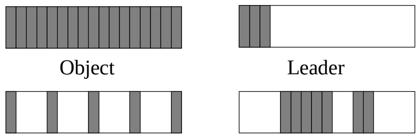
The longest repeating-sequence (LRS) PMM reduces the size of the prediction tree by storing only long branches with frequently accessed URL predictors. The tree size is reduced at the expense of lowered prediction accuracy.

The popularity-based (PB) PMM ranks a URL's relative popularity (RP) into four grades:

- Grade 3: 10% < RP <= 100%
- Grade 2: 1% < RP <= 10%
- Grade 1: 0.1% < RP <= 1%
- Grade 0: RP <= 0.1%

It assigns long branches to popular URLs and shorter branches to less popular URLs (Chen & Zhang, 2003). Thus, only frequently accessed paths are kept to reduce the storage requirement of the predictor tree.

Figure 3. Object partitioning methods



Web prefetching involves an overhead of extra traffic due to two reasons. First, the prediction of Web accesses is inaccurate. Second, the dynamic content may become stale and outdated after prefetching. Caching and Web prefetching at the proxy server reduce the number and latency of accesses for static contents at the Web server. Further investigations will be needed to improve prediction accuracy and cache performance on dynamic Web content.

OBJECT PARTITIONING

If the local proxy server caches only a part of a large multimedia object, the cached part can be directly retrieved from the local proxy and only the missing part will be accessed from the content server. The position and size of the cached part affects the response time of new streams and the minimum network bandwidth needed to deliver the object. In the literature, three object partitioning methods, namely, leader, staging, and hot spot, have been proposed (Figure 3) and studied for individual proxy servers (Fahmi et al., 2001; State & Festor, 2001; Zhang et al., 2000).

Some research has been done on delivering QoS multimedia streaming by caching the leader (or front part) of the objects (S. Park et al., 2001, Y. W. Park, Baek, & Chung, 2000; State & Festor, 2001). In this leader method, each object is divided into a front part and a rear part. The front part is placed in the proxy cache that is nearest to the client, and the rear part is placed in other LAN (local area network) proxy servers. This method allows more front parts to be cached close to clients and reduces startup latency. The rear part in other LAN proxy caches can reduce network traffic for repeated accesses from the same LAN.

The hot spot of an object can provide a preview of the object. The size of a hot spot is only a fraction of the object size. It is useful to provide previews of many objects from local proxy caches. Hot-spot caching thus improves the storage retrieval efficiency and scalability of a single proxy server (Fahmi et al., 2001). The proxy server's physical proximity to clients reduces the response time to a random seek when a video is being previewed.

In video staging, the portion of a video above a certain bandwidth to the proxy server is cached in advance to reduce the necessary WAN bandwidth for usage (Zhang et al., 2000). Zhang et al. proposed heuristic algorithms to choose the videos to be staged according to the temperature of the video or the highest reduction in WAN bandwidth.

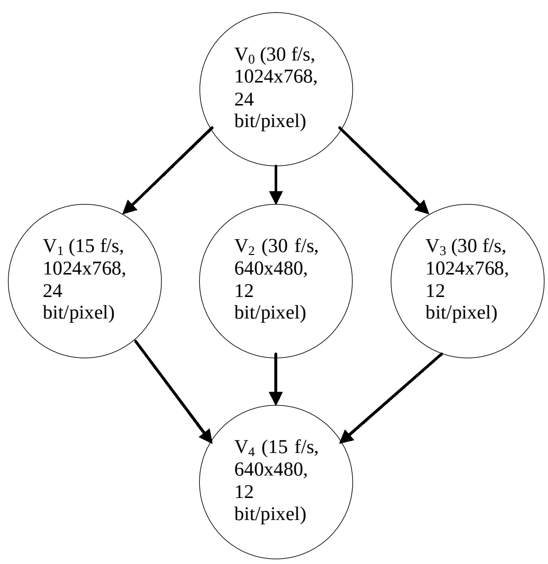
Each of the above object partitioning methods has its merits. The leader method reduces the start-up delay in viewing an object. The staging method minimizes the amount of WAN bandwidth. The hot-spot method provides a local preview prior to viewing the object.

Current object partitioning methods only cater the delivery of cached content to local clients. When multiple proxy servers are present within a region, it is helpful if each proxy server caches a different part of the object. The union of the cached contents in the regional proxy servers can thus form a bigger portion of the object. This can then reduce the size of the missing parts that must be accessed from the content server. Further investigations are thus needed to optimize the object partitioning method among cooperative proxy servers for the highest cache efficiency.

TRANSCODING FUNCTIONS

While proxy servers are continuously connected to the Internet at high bandwidth links, clients may be connected with a modem or a mobile device. The connection speed and storage capability of each client may be much lower than that of the proxy server. In this situation, the proxy server may reduce the resolution of the transmitted

Figure 4. Transcoding is an irreversible process to reduce the object resolution. An object is filtered in one or more of the resolutions.



objects so that the data rate will meet the capability of the client.

Transcoding is an irreversible process of adapting the spatial and temporal resolutions of objects (Figure 4) to that of the user specification, client limitations, and wireless-device characteristics (Cardellini, Yu, & Huang, 2000; Ham et al., 1999; Kassler, Neubeck, & Schulthess, 2000). Since a transcoded object cannot be converted into another object that is higher in any resolution, the transcoding process needs to be done carefully to avoid accessing the original object from the server again.

After transcoding, the proxy server should cache the transcoded objects only. Otherwise, repeated transcoding may erode the processing power of the proxy server. Since different clients at different network-link capacities may access from the same server, the proxy server may need to cache different transcoded objects for different clients.

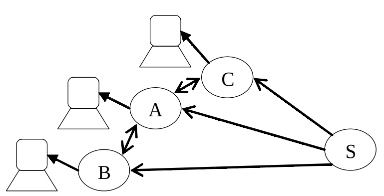
COOPERATIVE CACHING MECHANISMS

When multiple proxy servers have the capabilities to exchange their cached contents, they can cooperate to serve client requests (Figure 5). This cooperation mechanism may induce overhead that could erode its benefits. Thus, the cooperation mechanisms must be carefully designed to facilitate QoS retrievals from other proxy servers with minimal overhead.

The only found research works on the cooperative caching of multimedia objects include those on the leader method (S. Park et al., 2001) and the multiple hot-spot method (Tse et al., 2003). To be more comprehensive, we also consider research works on the cooperative caching of Web documents in this article. Three proxy cooperation mechanisms for Web documents, namely, the hierarchical, directory-based, and hash-based mechanisms, have been proposed and investigated (Cardellini et al., 2000; Dykes & Robbins, 2001; Law, Nandy, & Chapman, 1997; Lee, Amiri, Sahu, & Venkatramani, 2002; S. Park et al.; Y. W. Park et al., 2000; Wolman, Voelker, Sharma, Cardwell, Karlin, & Levy, 1999; Wu & Liao, 1997).

The hierarchical approach builds a proxy tree with one parent proxy server above a number of child proxy servers

Figure 5. Cooperative proxy servers B and C help content server S in delivering objects to proxy A



(Cardellini et al., 2000; S. Park et al., 2001; Y. W. Park et al., 2000). Each level of the parent proxy keeps some contents that are commonly accessed by the child proxies. A proxy server forwards its cache misses through its parents and finally to the content server. Large extra cache space is needed in the parent proxies to store the commonly accessed cache contents. When the proxy tree is deep, the miss penalty time (extra time in searching through the parent proxies) erodes the reduction in the miss rate.

The proxy servers in the directory-based approach exchange their directory contents with other cooperative proxy servers (Cardellini et al., 2000; S. Park et al., 2001; Y. W. Park et al., 2000). The proxy servers thus need extra space to store the directories of other proxy caches and extra bandwidth to exchange the directory contents.

In the hash-based approach, each document is assigned to one of the cooperative proxy servers (Lee et al., 2002; Wolman et al., 1999). If a document is fetched, it is either cached in the assigned proxy server or not cached at all. Thus, this approach minimizes the amount of cache space and the message overhead, but it involves many false-positive hits.

Cooperative proxy caching has been shown to be positive for Web document retrieval. The investigation on Web documents is, however, limited to the regional level. It is expected that cooperative proxy caching will become more appealing for streaming multimedia objects (Wolman et al., 1999).

An individual proxy cache may not be large enough to store several multimedia objects, but the aggregate size of multiple proxy servers can be large enough to store many popular objects. Thus, cooperative caching can be used to enhance the cache performance for multimedia objects (Tse et al., 2003).

The cooperative caching of multimedia objects will affect the local hit ratio and byte hit ratio of proxy caches. Each proxy server may decide the percentage of cache for its local clients and for the cooperative proxy servers. This percentage can be adjusted by tuning the cache replacement function.

DISTRIBUTED PROXY SERVERS

Another approach to use multiple proxy servers at a client is to add a depot between the client and the proxy servers. The depot distributes and balances the load by scheduling the Transport Control Protocol (TCP) sessions via proxy servers in a round-robin manner (Law et al., 1997). The performance of the depot proxy system falls in between two stand-alone proxy servers.

FUTURE TRENDS

Multimedia proxy servers may be enhanced in various ways. Some of the future research is described here. First, existing functions in proxy servers will be enhanced. In Web prefetching, prediction accuracy will be optimized to enhance cache performance. Object partitioning techniques will be optimized for the highest cache efficiency of cooperative proxy servers. Transcoded objects may be selectively cached among cooperative servers to improve the overall cache performance. Each cooperative proxy server may decide the percentage of cache size for its local clients and for other regional clients.

Second, new functions will be added to the proxy servers to handle multimedia objects more efficiently. The proxy servers may repair the missing data blocks in a transmission by caching some parity blocks. These parity blocks will be compared against the accessed blocks to recover the missing blocks. The methods to create these parity blocks will be investigated to repair the missing blocks efficiently. The placement of these parity blocks in cooperative proxy servers will also need to be investigated.

Third, the multimedia proxy servers will be placed in emerging networks, such as peer-to-peer networks, mobile ad hoc networks, and sensor networks. They may be placed in front of the servers to provide caching for content servers in order to share the workload of popular content servers. They may be placed among peers in peer-to-peer networks. The performance of multimedia proxy servers in these networks will be further investigated to provide their functions optimally in the new environments.

CONCLUSION

We have described the multimedia proxy server in this article. Multimedia proxy servers are virtual servers between clients and content servers to deliver multimedia objects on the Internet. They provide necessary functions to manage the QoS streaming of multimedia contents over the Internet.

Multimedia proxy servers store popular objects in local cache storage to reduce the access to content servers. When clients are connected with the proxy server using low-bandwidth links, the proxy server transcodes an object into lower resolutions to reduce the data rate of the object stream to the clients. Proxy servers cache only parts of large multimedia objects to optimize the response time for accessing the objects. When multiple multimedia proxy servers can cooperate, they may exchange their cached contents to minimize the load at the content servers and on the network.

Multimedia proxy servers will be enhanced with optimal performance in existing functions, new functions to improve stream quality, and better techniques in new network environments.

KEY TERMS

Access Latency: The delay time when a data item or object is accessed.

Cache Replacement Policy: The policy to choose a data item or object to be deleted from the cache when a new data item or object is stored to a full cache.

Depot: An intermediate server to choose a proxy server for a client request.

Hit Ratio: The number of times an item is found in the cache divided by the number of times an item is being matched.

Hot Spot: A collection of different portions of an object in which these portions are separated from each other at a fixed time interval.

Object Partitioning: The method to divide an object into smaller segments.

Object Resolution: The amount of details of a digital image or object. This is usually specified as the number of pixels and number of frames per second.

Proxy Server: A virtual server that serves the requests of a client. It usually stores copies of accessed data objects so that it may deliver the same objects immediately to repeated requests.

Transcoding: A process to change the resolution of a multimedia object.

INTRODUCTION

Information and knowledge are keys to development in the knowledge-based society. Information and communication technologies (ICT) are playing an increasingly important role in the daily lives of citizens, revolutionising work and leisure, and changing the rules of doing business. ICT encompass all technologies that facilitate the processing and transfer of information and communication services (United Nations, 2002). Mbigi (2000) indicated that interdependence and "networking are part of African cultural heritage" (p. 23). The African Networking Renaissance is about business organisations finding innovative ways of doing business by harnessing ICT, cultural strengths and inspiration to meet the challenges of its local delivery needs and global competition.

In the realm of government, ICT applications are promising to enhance the delivery of public goods and services to citizens not only by improving the process and management of government but also by redefining the traditional concepts of citizenship and democracy (Pascual, 2003). Van der Waldt (2004) noted that the South African government makes provision for the use of information technology (IT) to deliver certain services electronically (electronic governance). Because there is a need for municipalities in South Africa to realise "the strength and importance of a virtual infrastructure framework, which includes…technology and innovation" (eThekwini Municipality Integrated Development Plan 2003-2007, 2003, p. 24), the concept of a municipal information society (MIS) is proposed. An MIS conceptual framework to facilitate public service delivery is this article's objective. This article is challenging because it discusses a fundamental realignment of the manner in which information, knowledge, ICT, people, and business organisations need to network within a selected municipality in South Africa to meet the challenges of public service delivery.

The ideal attributes of successful public service delivery in a developing democratic society were formulated by an authoritative study of public service reform in South Africa (PRC, 1998). Public services are supposed to improve the lives of citizens in the policy areas for which a public service organisation (such as a municipality) is legally responsible. According to this approach to service delivery, local governments can utilise Internet technology to improve quality (better services), efficiency (cost effectiveness) and effectiveness (economic development). Electronic service delivery (ESD) is a method of delivering services and conducting business with customers, suppliers, and stakeholders to achieve local government developmental goals of improved customer service and business efficiency in a sustainable manner. The capacity to deliver services in a sustainable way refers to "the ability to perform appropriate tasks effectively, efficiently and sustainably" (Grindle & Hildebrand, 1995, p. 445).

There is no more important issue in South Africa than improving the delivery of public services (van der Waldt, 2004). eThekwini Municipality sees the e-government strategy (eThekwini Municipality Integrated Development Plan 2003-2007, 2003) and its Web site (http://www.durban.gov.za) as important management tools for improved citizen service delivery and communications to the business community in the eThekwini Municipality Area (EMA) in South Africa. The Web site is seen as "key to retaining constant communications" with its constituents (Corporate Policy Unit, 2004b, p. 64). Improving service delivery calls for a shift away from inward-looking bureaucratic systems and attitudes towards a search for new ways of working that puts the needs of the public first (van der Waldt, 2004). In African Networking Renaissance, there is thus a need for "how-to" knowledge and information on modernising existing service delivery in keeping with new, appropriate ways of serving the needs of South Africans. ICT represent a key enabler for improved service delivery to both its citizens and business organisations in the EMA. Cronjé, de Toit, Marais, and Motlatla (2004) noted that the crux of social responsibility is "the insistence of the community that business should in every respect be a 'good corporate citizen'" (p.106). The focus of this article is on ICT, eThekwini Municipality, and business organisations in the EMA. Good governance assumes that public service delivery (including ESD) is the implementation of public policies aimed at providing concrete services to business organisations.

BACKGROUND

The concept of governance developed out of the descriptive, positive public management school of thought, which originally sought to give new meaning to the traditional role of government in society by focusing on the effectiveness and efficiency of the outputs and outcomes of governmental decisions. Cloete (2000) indicated that as a result of the perceived inefficiencies of the traditional public management system that were highlighted by the public management approach, this descriptive approach was in turn expanded to the more prescriptive new public management (NPM) school of thought. This then coined the phrase *governance* to describe what was regarded as a new way of governing in order to be more effective (Toonen, 1998). There are major pressures for a renewed focus on the issue of "service delivery" in South Africa. An important consequence of public service transformation in South Africa has been the changing nature of state–society interaction and exchange (van der Waldt, 2004). E-government is about transformation that helps citizens and business organisations find new opportunities in the world's knowledge economy (Pacific Council on International Policy, 2002). Governments that define e-government as simply moving services online "miss larger opportunities which will determine competitive advantage in the long run" (Caldow, 2002, p. 17).

Since its creation, use of the term *governance* has started to change over time (Cloete, 2000). For example, increasingly in South Africa "there has been recognition of the value of demonstrating accessibility, transparency and accountability beyond the traditional domain of financial performance" (eThekwini Municipality Integrated Development Plan 2003-2007, 2003, p. 48). This change in focus led to the conceptualisation of self-organising networks providing services by the governmental, private, and voluntary sectors (Rhodes, 1997). As a result of the complex interactions between these sectors, NPM scholars no longer agree about the ideal boundaries between the public and private sectors in society.

Governance is defined as "the patterns that emerge from governing activities of social, political and administrative actors" (Kooiman, 1993, p. 2). According to Kooiman, these patterns form to the emerging outcomes that constitute a more abstract framework at a higher level for day-to-day governing activities (Cloete, 2000). Inherent in Kooiman's governance definition is the idea of public-private interactions within a network of relationships aimed at achieving desired objectives for society. With the advent of new ICT, there is a need to reengineer work processes and systems. Both cybernetic and network models of governance see the task of governments (including local governments) as the establishment of effective interactions between local government and central government, business organisations, and civil society in catering for social needs. In such interactions, ICT plays an important role. Rhodes (1997) noted that governance "is the result of interactive socio-political forms of governing" (p. 51). Good governance assumes that public service delivery (including ESD) is the implementation of public policies aimed at providing concrete services to citizens and business organisations.

Definitions of e-government range from "the use of information technology (IT) to free movement of information to overcome the physical bounds of traditional paper and physical based systems" to "the use of technology to enhance the access to and delivery of government services to benefit citizens, business partners and employees" (Deloitte and Touche, 2003, p.1). However, it is not a simple matter. Ultimately, e-government aims to enhance access to and delivery of government services to benefit citizens (Pascual, 2003). This effectively means the business community's use of innovative ICT (e.g., Internet and associated technologies) to deliver to all business organisations improved services, reliable information and greater knowledge in order to facilitate access to the governing process thereby improving customer satisfaction, improving cost effectiveness and efficiency, and promoting economic development in the EMA. E-government needs to find a positive developmental role. Heeks (2003) suggested that without this, "e-Government runs the risk of being a 21st century 'rusting tractor,' cast aside as it fails to fulfil its promise" (p. 1). E-government services focus on four main customers: citizens, the business community, government employees, and government agencies. The focus of this article is on the business community in the EMA.

eTHEKWINI MUNICIPALITY AREA IN SOUTH AFRICA

The population of eThekwini Municipality is 3.09 million citizens (Statistics South Africa, 2001). The population is an amalgamation of racial and cultural diversity. The eThekwini Municipality has a capital budget of US$337,760,000 (approximately ZAR2,29 billion) and an operating budget of US$1,262,537,000 (approximately ZAR8, 56 billion) for the 2004-2005 financial year (see http://www.durban.gov.za). The EMA's gross geographic product income is US$3,770 (approximately ZAR25,529) per person per annum, which is higher than the South African average of US$2,620 (approximately ZAR17,756) per person per annum. Thirty-eight percent (38%) of citizens in EMA are employed (URBAN-ECON, 2003). During 2004, eThekwini Municipality was voted the best metropolitan municipality in South Africa. It is the local authority governing the City of Durban, South Africa's major port and the second largest industrial hub after Johannesburg. Durban is becoming recognised for its ability to contribute towards building a knowledge and learning network not on on the African continent but also on an international scale (Corporate Policy Unit, 2004b).

ICT is seen as an effective mechanism to access municipal information and development information in general. ICT can be defined as the electronic means of capturing, processing, storing, and communicating information (Heeks, 1999). E-readiness can be defined in terms of availability of ICT infrastructure, the accessibility of ICT to the general citizen population, and the effect of the legal and regulatory framework on ICT use (Manyanga, 2002). In building a model of ICT, two separate elements exist: IT and information on which it operates. Heeks (1999) suggested that in order to make this model useful, two further processes should be added: processes of purposeful activity and the people to undertake those processes. Together these constitute an "information system," such as a support system that helps business organisations interact with their local municipality. The eThekwini Municipality plays a vital role in the cultural life of Durban (Corporate Policy Unit, 2004a). The spawning of a MIS is only possible if the availability of multilingual and multicultural information is encouraged, thereby espousing African Networking Renaissance.

Erwin and Averweg (2003) indicated that there is a need for organisations to adapt to constantly changing business conditions. During this adaptation and, in particular, during the African Networking Renaissance, transformation occurs that consists of rapid change in all the facets of an organisation. These changes may be so significant that they may result in a new identity. Van der Waldt (2004) suggested that transformation is thus "a process of becoming" that reorganises organisational knowledge and operations (p. 85). It creates new collaborative relationships between an organisation (such as eThekwini Municipality) within its environment (such as EMA). These new relationships in turn alter both the organisation and its environment in a knowledge-based society. Transformation comes not from moving services online but from redesigning the organisation and processes to place both its citizens and business organisations at the centre, integrating across agencies to simplify interaction, reducing costs, and improving service delivery. This redefines existing supply chain mechanisms into collaborative networks and the promotion of e-collaboration.

The eThekwini Municipality embarked on an initiative to understand the needs of business organisations in utilising ICT as a tool to improve service delivery and establishing effective communication between itself and its business organisation constituency. Public participation is a powerful tool; it informs and educates citizens and therefore enhances the democratisation processes in South Africa (van der Waldt, 2004). Public participation balances the tension between democracy and bureaucracy (Brynard, 1998). A requirement for effective e-governance requires an understanding of the e-readiness of business organisations. A survey of the e-readiness of business organisations in the EMA was conducted. The results of this survey provide some insights towards a proposed MIS conceptual framework.

A survey instrument was developed to gauge business organisations' information needs in the EMA. This survey tool represents an attempt to ascertain the current interaction (if any) with the eThekwini Municipality Web site, the manner in which business organisations receive information from eThekwini Municipality and the manner in which they will like to receive information. The survey instrument comprised two sections:

- **Section 1 (General Information):** Section 1 contains three subsections: (a) business organisation's information; (b) access and usage of Internet for business purposes; and (c) focus on the eThekwini Municipality Web site.
- **Section 2 (Business Organisation's Information Needs):** Section 2 contains three subsections: (a) how business organisations currently receive and will like to receive information about eThekwini Municipality; (b) how business organisations currently interact and will like to interact with eThekwini Municipality; and (c) business organisations' perceptions regarding eThekwini Municipality.

During May 2003, the questionnaire was telephonically administered to 100 business people in 100 different business organisations in the EMA. Fifty small and 50 large organisations were selected. Selection of organisations surveyed was undertaken on a random basis.

From Section 1 of the survey instrument, 30% of respondents surveyed were from the Upper Management organisational level, 22% from Middle Management level, 21% from Supervisor level, 11% from Secretarial level and 16% were Employees. The 100 respondents surveyed were spread across 43 different core businesses. Eighty-six respondents (86%) reported that their organisations have Internet access. The Internet access for the four highest reported core businesses is as follows: manufacturing 19 (86.4%), retail 11 (91.7%), accounting 6 (85.7%) and repair 3 (50%). An analysis of the number of employees in a business organisation requiring Internet access to accomplish their daily tasks was the "1-10" employee range that constitutes more than half (52.5%) of the employee number ranges. However, the success of the Internet should be measured in terms of accessibility and contribution to social progress, rather than in terms of numbers of connected individuals (Kamel & Hussein, 2000).

An analysis of the primary purpose for which the surveyed business organisations use Internet access is as follows: searching for information (39.1%), marketing (26.1%), e-administration (20.3%) and purchasing (14.5%). More than half (55.2%) of respondents surveyed reported that their business organisations had a Web site. However, only 23.0% of respondents surveyed were aware of the eThekwini Municipality Web site (http://www.durban.gov.za).

From Section 2 of the survey instrument, the predominant method in which business organisations receive information about eThekwini Municipality is via the South African Post Office (89%). This method is followed by municipal publications (7%). Other methods include information received via the telephone and at municipal offices. Respondents surveyed were satisfied (48%) or on average satisfied (30%) with the manner in which they receive information from eThekwini Municipality. Only 18% of respondents surveyed were not satisfied with the manner in which they receive information from eThekwini Municipality. When respondents surveyed were asked how their business organisations will like to receive information from eThekwini Municipality, more than half (54%) reported that they will like to receive information via the South African Post Office, followed by e-mail (34%) and then the Internet (9%). The aim is not simply to deliver services electronically in the EMA but to encourage business organisations to make use of the Internet for catalysing a MIS in the EMA.

When respondents surveyed were asked whether their business organisations will be interested in interacting with eThekwini Municipality using the Internet as a communication medium, 59% reported positively. This tends to suggest a need for effective ICT infrastructures and interaction mechanisms that will facilitate business organisations accessing and interacting with eThekwini Municipality using the Internet (i.e., better use of ICT for the delivery of services). It is argued that this will lead to virtual communities and spawn an MIS in the EMA. Similar societies could be propagated in other municipal regions in South Africa and southern Africa

FUTURE MUNICIPAL INFORMATION SOCIETY TRENDS

Effective use of ICT will facilitate the establishment of a MIS in the EMA. With this proposed MIS concept, it is argued that changes will arise in the way business organisations relate to each other and with the eThekwini Municipality. Some future trends for a MIS in the EMA are suggested as follows:

- Being dedicated to change, virtual communities will become efficient for new social tasks
- Existing supply chains between eThekwini Municipality and business organisations will be redefined into collaborative networks
- Developing an ICT footprint in the geographical region
- Facilitating learning and knowledge creation, sharing, and use with the goal to achieve self-sufficiency and sustainable development in the EMA
- In catalysing communication between eThekwini Municipality and business organisations, allocated capital and operational funding will be utilised with more flexibility and efficiency
- A wilting of excess municipal regulations allowing eThekwini Municipality to focus on “steering” and leaving the “rowing” to others
- Making better use of ICT in the delivery of services, products and communication to business organisations
- Accelerating the ability to change processes and/or policies when problems are detected by either eThekwini Municipality and/or business organisations
- Creating more choice for business organisations, thereby promoting economic development and output growth
- Making eThekwini Municipality more responsive to the needs of business organisations
- Capacitating business organisations by improving access to services and products to them individually and core business-related collectively
- Establishing “digital democracy” (e.g., informing citizens by improving access to information)
- Promoting virtual collaboration (or e-collaboration), whereby business organisations use ICT to collaboratively plan, design, develop, manage and research products and services, and innovative ICT and e-Commerce applications in partnership with eThekwini Municipality
- Catalysing African Networking Renaissance

van der Waldt (2004) indicated that there needs to be better use of technology in the delivery of services. It is important that innovative ICT be adopted to deliver to all business organisations in the EMA-improved services, reliable information and greater knowledge in order to facilitate the e-governance process by encouraging their participation. If this approach is not adopted, it may result in the envisaged ESD image being a few pixels short. Although this is no panacea for “perfect” ESD, the importance of spawning a MIS is a step in the right direction. This will facilitate the establishment of a digital democracy, thereby leading to improved customer satisfaction with eThekwini Municipality to achieve local government developmental goals.

CONCLUSION

South Africa's national government wants to see strong, vibrant, innovative, and responsive local municipalities delivering the quality of local leadership and public services that their communities and business organisations need. E-government is not just about municipal Web sites, e-mail, and SMS. It is not about service delivery using ICT via the Internet. It is not about digital access to eThekwini Municipality information. It is about how business organisations in the EMA change in relating to their eThekwini Municipality and the degree to which e-governance changes business organisations relating to each other in a MIS virtual infrastructure framework. Municipalities in South Africa need to accept both the challenges and opportunities presented by innovation, collaboration, and service delivery by adopting appropriate ICT infrastructures. This will lead to improved ESD and communication, satisfying business organisation needs, enabling African Networking Renaissance, and thereby propagating MISs in South Africa and southern Africa.

KEY TERMS

African Networking Renaissance: African Networking Renaissance is about business organisations finding innovative ways of doing business by harnessing information and communication technologies (ICT), cultural strengths and inspiration to meet the challenges of its local needs and global competition.

E-Collaboration: E-collaboration (or virtual collaboration) refers to the use of ICT by citizens and business organisations to collaboratively plan, design, develop, manage, and research products and services and innovative ICT and e-commerce applications.

E-Governance: E-governance refers to a local government's inventiveness to electronically govern areas under its jurisdiction.

E-Government: E-government refers to the use of technology to enhance the access to and delivery of government services to benefit citizens, business partners, and employees.

Electronic Service Delivery: Electronic service delivery (ESD) is a method of delivering services and conducting business with customers, suppliers, and stakeholders to achieve local government developmental goals of improved customer service and business efficiency.

E-Readiness: E-readiness may be defined in terms of availability of ICT infrastructure, the accessibility of information and communication technologies (ICT) to the general citizen and business organisation population and the effect of the legal and regulatory framework on ICT use.

Municipal Information Society: *Municipal information society* (MIS) is a term used to describe a society and an economy that makes best possible use of information and communication technologies (ICT). Citizens and business organisations in a municipality receive the full benefits of ICT in all aspects of their lives.

Virtual Communities: Groups of people with similar (business) interests who interact, collaborate, and communicate via the Internet.

Negative Effects of Advertising Techniques in Electronic Commerce

INTRODUCTION

Companies who engage in online commerce find themselves dwelling at the intersection of the real and the virtual, and facing a task that is more complex than delivering an attractive Web site (Mitra, 2003). Practitioners and scholars have paid attention to techniques used in site and product promotion, which include the overall structure of the online retailing interface and individual features like banners, animation, sound, video, interstitials, and pop-up ads (Rodgers & Thorson, 2000; Westland & Au, 1998). Banner size, image maps, audio, and Web site interactivity have been found to enhance site appeal (Coyle & Thorson, 2001; Li & Bukovac, 1999;). Banner ads effectiveness was also found to be affected by incentive offerings contained in the ads, as well as the emotional appeal imbedded in the ad (Xie, Donthu, Lohtia, & Osmonbekow, 2004). Nonetheless, the use of such promotional techniques also comes with its negative effects that could influence consumers' perceptions of and attitude toward a site.

BACKGROUND

A hierarchical chain of media effects in traditional advertising research spans the spectrum of ad content to cognition, attitude, and behavior (Olney, Holbrook, & Batra, 1991). Both content and form variables were considered predictors of attention, memory, recall, click-through, informativeness, attractiveness, and attitude (Rodgers & Thorson, 2000). The study of the effects of executional factors extended to the Web involves new techniques such as banners, sponsorships, interstitials, pop-up windows, and hyperlinks that need to be considered and require a higher level of comprehensiveness than print or TV ads. They may potentially contribute to the delivery of Web content and the enhancement of Web site appeal. Consumer behavior related to online shopping experience has also been continuously explored in the information systems literature (Jarvenpaa & Todd, 1997; Koufaris, 2002; Koufaris, Kambil, & Labarbera, 2001; Van den Poel & Buckinx, 2005; Vijayasarathy, 2003). Researchers have examined Web site design from the perspective of building a cognitive framework, emphasizing enhanced usability through coherent choice of design elements and composition of the layout (Rosen, Purinton, & Lloyd, 2004).

CONSUMER ATTITUDE TOWARD WEB SITES

Attitude toward the ad (Aad) is an important traditional measure for developing marketing and advertising strategies. Aad mediates advertising responses to influence brand attitudes and purchase intentions (Brown & Stayman, 1992). Attitude toward the site (Ast) is a measure parallel to Aad and was developed in response to a need to evaluate site effectiveness, measuring a Web user's predisposition to respond either favorably or unfavorably to the content of a Web site in a natural exposure situation (Chen & Wells, 1999).

The similarity between Aad and Ast arises from the fact that a commercial Web site contains information similar to that contained in traditional advertising. An informative site appealingly organized in an entertaining form is likely to be appreciated by the visitors and hence is likely to receive a favorable attitude toward the site. Ast is a direct result of a visitor's perceptual dimensions such as perceived entertainment and perceived irritation (Ducoffe, 1996; Gao, 2003).

Online consumers place great value on the Web as a source of information. In the meantime, consumers also seek entertainment and appreciate information in an enjoyable context. Studies have also shown that product representation, the quality of the shopping experience, perceived usefulness and perceived ease of use of the Web site have a significant effect on attitude toward online shopping, intention to buy, and actual shopping behavior (Del Giudice, 2004; Gefen, Karahanna, & Straub, 2003; Koufaris, 2002; Mummalaneni, 2005).

PERCEIVED IRRITATION

The experience and perception of a visitor are individual specific. A Web site intended to be entertaining and informative may produce an unintended outcome of a user's feeling of irritation. In traditional advertising research, irritation is believed to be caused by tactics perceived to be annoying, offensive, or insulting, as well as ad features that are overly manipulative (Ducoffe, 1996). An irritating commercial is one that provokes and causes displeasure and momentary impatience (Aaker & Bruzzone, 1985). In the Web context, irritation can indicate a user's confusion and distraction or the messiness of the site.

Web-based features that may have negative effects on visitor perceptions and attitude include scrolling text across the screen or the status bar, continuously running animation, nonstandard link colors, outdated information, complex URLs, broken links or anchors, error messages, and pop-up ads, among others (Nielsen, 2003). In traditional media, annoyance and irritation are the main reasons why people criticize advertising (Bauer & Greyser, 1968). Irritation leads to reduction in advertising effectiveness (Aaker & Bruzzone, 1985). Ducoffe (1996) found a negative and significant correlation of – 0.52 between irritation and the perceived value of advertising. Irritation is also a cause for visitors to leave a site (Nielsen, 2004).

Continuous Animation

A Web advertising technique that has been widely adopted is animation. It has been typically intended to facilitate the communication of product information between the Web site and its visitors. One such example is the online virtual showrooms of automakers. At sites featuring computer games and outdoor activities, animation may also increase the perceived realism of information presented. In a study of the effects of interactivity and vividness on consumer attitude, Coyle and Thorson (2001) find that a more vivid site, through the use of audio and moderate animation, was related to a more positive visitor attitude.

Animation can also be used to draw a visitor's attention. The use of continuous animation on many Web sites is for the purpose of alerting the visitor of a particular product or event, or an attempt to entertain the visitor while she or he is at the site. Nielsen (1999) suggested that animation should be done on a one-time-only basis and then the animated object should become a still image. Nielsen (1995) argued that Web users should not be constantly bombarded with the same intensity in impression an movement by the equivalent of the billboards of Times Square in New York City.

Due to the overpowering effect of moving images on the human peripheral vision, the presence of continuous animation on a page makes it very hard to read the text in the middle of a page (Nielsen, 1995). We argue that the continuousness poses a problem that is similar to TV advertising in terms of intrusiveness. Greyser (1973) found that people felt more irritated by TV commercials than by other media due to the intrusiveness of TV commercials. Continuous animation is much like scrolling text at the bottom of a television screen that cries for attention. It is a form of intrusive presentation of information to Web site visitors. Such intrusiveness demands attention like TV commercials, and will similarly cause irritation like any other intrusive means of advertising.

Pop-Up Ads

Another frequently adopted web-based promotional technique is the pop-up ad. We observe that pop-up ads, like animated banners, can be used for both cross-site and in-house advertising. Nielsen (2003) maintains that users at search sites are more receptive to targeted ads than in other contexts, because these ads often relate to what the users are after, and subsequently the users are more likely to follow the ads. Although some people often find them annoying, many others find them informative and related to their search goal and thus consider them less irritating than in other circumstances.

On the other hand we observe that, though less inclined to deploy cross-site ads, many firms use pop-up ads, along with animated banners, to inform visitors of certain promotions and events. Does the use of such techniques for in-house advertising cause a higher level of irritation than in the absence of them? Both animated site banner and pop-up ads are ways to reach the consumer within the site, but are they good delivery mechanisms for the store?

Unexpected pop-up ads could have similar negative effects. In traditional advertising, Greyser (1973) found that interruptiveness was a predominant reason why the British public considered TV advertisements more irritating than the print media. The Internet is a hybrid of the print and broadcast media. The use of unexpected pop-up ads closely mirrors the TV commercials' interruptiveness. In addition, the visitor has to find a way to get rid of the popped-up window, the process of which increases the level of irritation.

A FIELD STUDY

To test the effects of the above discussed advertising techniques, we conducted a field study with students from a northeastern college in the United States. A commercial Web site selling a variety of cameras was chosen as the stimuli. The Web site makes use of a frames page which contains a navigational header—the site banner, and a main frame underneath it.

This Web site was peripherally modified to operationalize the constructs in the study through a two by two (2×2) factorial design. Four versions were created based on the site, through the presence or absence of continuously running animation in the site banner, and the presence or absence of pop-up ads during a user's visit. The animated version included an animated logo, an animated neon sign, animated images of phone and e-mail icons, and an animated text banner linking to a prize contest. Still pictures were used in the nonanimated version. The pop-up ads included a message of quantity discount (save 5% on $200 purchase) offered by the site and a picture linking to a sweepstakes entry form then running at the site. Both were created with the theme of the Web site and used existing images of the site. Hence, the four treatment conditions were (a) animation without pop-up, (b) pop-up without animation, (c) animation *and* pop-up, and (d) *neither* animation *nor* pop-up. This experimental design maintained internal validity through the factor manipulations and external validity through the use of a slightly modified real commercial Web site.

Participants were drawn through a gift incentive (a disposable camera) and entry into a lottery of four cash prizes (one $100 and three $50 prizes). Each participant was randomly assigned to one of the four treatment conditions and was instructed to explore the site for product information and find a model of digital camera of interest.

Opinions about or attitudes toward the site formed from this initial exchange would be a key indicator of the effectiveness of the site in retaining site visitors and thus attracting return customers. Among surveys returned, 128 were substantially complete and used in data analysis of this study. These scale items have been developed, tested, and used in measuring perceived irritation of TV advertising and Web advertising, and have yielded fairly high Cronbach's alpha values (> 0.8; Coyle & Thorson, 2001; Ducoffe, 1996). Participants were asked to indicate their agreement or disagreement with each statement on the survey on a 7-point Likert scale. In particular, perceived irritation was measured through statements of a visitor's feelings of the Web site being annoying, irritating, and frustrating. Ast was measured through pairs of adjectives of "like-disklike," "favorable-unfavorable," and "good-bad."

More than 32% of the participants spent more than 10 hours per week online. With respect to the site, the participants seem to have a generally favorable attitude toward the site, with a mean Ast score of 5.47 on a 7-point scale.

Cronbach's alphas on multi-item scales adopted in this study indicate strong scale reliability.

The results of a principle component analysis with direct oblimin rotation indicate that items within each scale load on the same factor, and thus are all unidimensional. Items belonging to different scales load on their own separate factors, showing evidence of discriminant validity.

Manipulation checks were performed via one-way ANOVAs, with each fixed factor (animation or pop-up) as independent variables and a participant's acknowledgment of perceiving (or noticing) the features as the dependent variables. Those who were exposed to the animated sites were significantly more likely to agree that the site had continuous animation ($M = .8281$) than those who were exposed to the non-animated versions ($M = .1406$) ($F[1, 126] = 113.14$, $p < .001$). Those who were exposed to the sites with pop-up ads were significantly more likely to agree that they saw pop-up ads ($M = .8438$) than those that were not exposed to versions with pop-up ads ($M = .2500$) ($F[1, 126] = 69.55$, $p < .001$). Thus, the manipulations were successful. Age, gender, and weekly Web usage were not significantly correlated with either irritation or attitude and thus were dropped from further analyses.

Sample probability plots showed patterns of a normal distribution. A two-way ANOVA was performed treating perceived irritation as the dependent variable and manipulation of the presence of continuous animation and unexpected pop-up ads as fixed factors in a 2×2 design. Both continuous animation ($F[1, 124] = 9.78$, $p = .002$) and pop-up ads ($F[1, 124] = 7.87$, $p = .006$) had a significant effect on perceived irritation, at $p < .01$. No interaction effect emerged ($F[1, 124] = .026$, $p = .872$). Pearson correlation analysis also confirmed that irritation was significantly ($p < 0.001$) and negatively correlated with Ast with a correlation coefficient of - 0.613.

The direct impact of continuous animation and pop-up ads on Ast was also examined via an ANOVA model where Ast was treated as the dependent variable. Once again, no interaction effect emerged ($p = .322$). Both factors had a negative effect on Ast. Those who were exposed to animation had a less favorable attitude toward the site ($M = 5.1913$) than those who were not ($M = 5.7541$). Those who were exposed to pop-up ads also had a less favorable attitude toward the site ($M = 5.2063$) than those who were not ($M = 5.7571$). Both relationships were statistically significant, at $p = .009$ and $p = .011$ respectively, for animation and pop-up ads. With eta-squared (η^2) values at .073 and .06 for continuous animation and pop-up ads, respectively, the two techniques examined in this study had a medium to strong effect on perceived irritation, according to Cohen (1988).

FUTURE RESEARCH

Experimental research, though limited in scope, goes beyond the predictive power of observational research. It offers the advantage of being able to validate causal relationships between the treatment effects and the dependent variables.

Students are deemed appropriate subjects in that they make a significant portion of the Internet population (GVU's 10th Survey, 1998). One of the arguments for using a homogenous sample such as undergraduate college students is that it makes it easier to achieve internal validity (Greenberg, 1987). Although the use of students may threaten external validity, that threat is mitigated by the fact that our student population was from a college in a densely populated suburban area. Such students may be more representative of the general population and may be appropriate for consumer behavioral studies than more traditional college students that attend universities in remote rural areas (James & Sonner, 2001).

The findings we present in this article were based on a scenario of a visitor's initial exchange with a Web site. We believe that such an initial exchange plays a significant role in an e-store's ability to attract users and convert them to buyers. For ready-to-buy visitors, the effect of online advertising may vary. Whether similar results will be seen in the population of ready-to-buy shoppers remain to be studied in future research.

Despite the limitations addressed above, we were encouraged by the findings of this study. Future research should explore the effects of the use of such promotional techniques in combination with influences of situational factors such as portal sites vs. e-store sites, surfers vs. buyers, on visitor perceptions and attitude. Future research should also examine the impact of other media presentation factors in e-business.

Our results cast doubts on whether certain Internet advertising mechanisms are truly effective. Nevertheless, we recognize the use of cross-site ads, which are most likely used by portals and online publishing sites to generate revenue (as part of their business model). A recent study by Yoo, Kim, and Stout (2004) focused on just this type of cross-site animated banner ads and found that animated banners prompted better attention-grabbing capabilities and higher recalls as well as more favorable attitude toward the ad than static banner ads. In the meantime, Yoo et al. (2004) recognize that too much animation, though eye-catching, may reduce advertising effectiveness due to the potential negative affective responses such as irritation or annoyance. We also suspect that results could be very different from our current study in search engine sites due to the fact that users visiting those sites have an explicit intention to leave them once they find a link of interest, be it a text link or picture ad. What effects such cross-site ads may have remains to be examined in further studies.

CONCLUSION

This article discusses some common uses of Web advertising techniques and focuses its attention on the negative effects of some online techniques on user irritation and attitude. It reports findings from an experimental study examining the use of pop-up ads and continuous animation for in-house presentation of information on discounts, special offers, and announcements. Both factors were found to significantly influence perceived irritation. In turn, irritation is a significant predictor of attitude toward the site. Even though irritation is not the only factor in determining attitude toward the Web site, our results showed that it had a significant negative correlation with attitude. To Web marketers and site designers, it means that they should never overlook factors contributing to perceived irritation while exploring factors that may contribute to consumer perceptions in the positive direction. A recent study found that consumers have a generally negative attitude toward advertising through intrusive means of short messages delivered to their mobile phones without their prior consent (Tsang, Hi, & Ling, 2004).

The implication of the findings from this study is that practitioners need to exercise caution in deploying certain web advertising techniques. Nielsen (2004) advised that users have learned to stop paying attention to anything that looks like an advertisement, through what he calls banner blindness, animation avoidance and pop-up purges. This presents a new challenge to Web marketers and site designers. Thus, for researchers, it is necessary to take a rigorous and scientific look at the various components that go into doing business online, in order to help electronic business develop in a structured, efficient, and effective way.

KEY TERMS

Attitude toward the Ad (Aad): A mediator of advertising response that influences brand attitude and purchase intentions

Attitude toward the Site (Ast): A Web user's affectionate response either favorably or unfavorably to the content of a Web site

Electronic Commerce (eCommerce): the use of computer networks for business communications and commercial transactions

Continuous Animation: Animated objects deployed at a website to catch a visitor's attention to an advertising message or to attempt to entertain visitors

Irritation: an unwanted user feeling caused by tactics perceived to be annoying, offensive, insulting, or overly manipulative

Pop-up Ad: A Web-based promotional technique that places a new window of advertising message or image over an Internet user's current active window

Web Advertising: advertising through banners, sponsorships, interstitials, hyperlinks, and pop-up and pop-under windows in the Internet media

Web Marketing: the dissemination of information, promotion of products and services, execution of sales transactions, and provision of customer support via a company's Web site

Category: Applications of E-Technologies

Negotiating Online Privacy Rights

Călin Gurău
Groupe Sup. de Co. Montpellier, France

INTRODUCTION

The *Privacy Journal* (2003), a print newsletter and Web site devoted to privacy matters, defines the present-day use of the word privacy as "the right of individuals to control the collection and use of personal information about themselves." Similar definitions are provided by law specialists (Gavison, 1980; Warren & Brandies, 1890).

The *networked society* changes the way in which *privacy rights* are defined, used and interpreted, because:

a. The IT-enabled channels of communication change the rules of personal and commercial interaction;
b. The participation in the networked society implies a diminishing of individual privacy rights.

The fundamental principle of the networked society is information sharing and processing (Kling & Allen, 1996). Advances in computing technology—that represents the infrastructure of the networked society—make possible to collect, store, analyze, and retrieve personal information created in the process of participation.

The manifestation and the protection of individual privacy rights represent the field of conflict between various disciplines and social events. The heterogeneous nature of this phenomenon is mirrored in this paper, which aims to present the complex nature of privacy rights in the context of the networked society. The study proposes a negotiating model of online privacy rights, and analyses the necessary conditions for the implementation of this model on the *Internet*.

The new economy is redefined on the basis of information entrepreneurism (Kling & Allen, 1996; Zwick & Dholakia, 1999). This cultural paradigm emphasizes the use of data-intensive analysis techniques for designing and implementing effective marketing and management strategies. This has as a direct consequence the use of an information superpanopticon–a concept derived from Foucault's panopticon, a system of perfect surveillance and control.

Online *privacy* is a major concern for Internet users (Ackerman, Cranor, & Reagle, 1999). For the individual Internet user, the privacy threats fall into two main categories:

a. Web tracking devices that collect information about the online behavior of the user (e.g., *cookies*);
b. The misuse of the personal information provided by the online user in exchange of specific benefits: increased personalization, Web group membership, etc.

The databases, intelligent agents and tracking devices are surrounding the Internet users with a Web of surveillance, which is often hidden and unknown to the users. The surveillance is initiated by the simple act of presence on the Internet. Specialized software applications, such as cookies are tracking the online behavior of Internet users, feeding the data into databases, which create and permanently update a profile of online consumers. These profiles are then used for segmenting the market and targeting the most profitable consumers.

A company can use cookies for various valid reasons: security, personalization, marketing, customer service, etc., however, there is an important distinction between cookies, which are active only within a specific Web site, and the ones that can track the user's activity across unrelated Web sites. Recently, some aggregator networks have deployed hidden 'pixel beacon' technology that allows ad-serving companies to connect unrelated sites and overcome the site-specific nature of traditional cookies (Mabley, 2000). Additionally, some companies are now connecting this aggregated data with offline demographic and credit card data. Eventually, these resulting databases can be used or sold as powerful marketing tools.

Exercising control of information, after it was voluntarily released, presents another critical problem. The misuse of personal information covers many possible aspects, which can be defined as any use which is not explicitly defined in the company's privacy disclaimer, or which is not approved by the informed customer. For example, in 2000, Toysurus.com was subject to intense debate and controversy, when it was discovered that shoppers' personal information was transferred through an unmarked Internet channel to a data processing firm, for analysis and aggregation. This operation was not disclosed in the company's privacy disclaimer, and therefore, online customers were not aware of it.

Regulators and legislators have addressed the controversial privacy issue quite differently across the world (Nakra, 2001). The USA, the largest world's financial and Internet market, has not yet adopted a national, standard-setting privacy law (Jarvis, 2001). U.S. privacy statutes have primarily focused so far on protecting consumers' financial data, health information, and children's personal information (Desai, Richards, & Desai, 2003; Frye, 2001). In comparison with the American official opinion that online privacy protection is a matter of voluntary self-regulation by market-driven companies, the Europeans consider that it is more effective to enforce specific legislation regarding this issue.

The current European approach is based on three basic tenets:

1. Individuals have the right to access any data relating to them and have it kept accurate and up-to-date;
2. Data cannot be retained for longer than the purpose for which it was obtained, nor used or disclosed "in a matter incompatible with that purpose", and must be kept only for "lawful purposes";
3. Those who control data have "a special duty of care" in relation to the individuals whose data they keep. Data commissioners oversee these rights in each European country and require most "data controllers"—people who handle data—to register with them to track what information is being collected and where. They are charged also with investigating all complaints from citizens.

These principles have been incorporated in the European Data Directive, which came into effect in 1998, and more recently, in the European Directive on Privacy and Electronic Communications, adopted in 2002. Despite these legislative efforts, it is not yet clear how effective are the measures implemented by EU States. The direct involvement of governmental institutions can be considered as a form of censorship that can undermine the freedom and the flexibility of the Internet domain.

THE DESCRIPTION OF A NEGOTIATION MODEL FOR ONLINE PRIVACY RIGHTS

The relativism of personal rights in the networked society and the increased commodification of the digital self, indicate a *negotiation model* based on contractual rules as the most appropriate for defining and enforcing personal privacy.

A classical negotiation situation comprises a number of essential elements (Zlatev & van Eck, 2003): parties, rules (a negotiation protocol), a system of law enforcement (established and maintain by regulators), and specific benefits to be negotiated by the parties (negotiation objects).

In an online situation, the parties negotiating privacy rights are often in a position of inequality. Most privacy statements and disclaimers act as a standardized contractual clause that has to be entirely accepted by the Internet users. There is no room for negotiation, and the only alternative is non-participation in that particular transaction. On the other hand, after the Internet user discloses his or her personal information, as part of the online deal, he or she has no direct possibility to control the way in which the organization uses this information. The storage, retrieving and processing of information are fully covert, and the only hope of the Internet user is that the company will respect its promises.

Laudon (1996) proposes the implementation of National Information Accounts, a market-based negotiation system, in which information about individuals is bought and sold at a market-clearing price, to the level where supply equals demand. Within this system, individuals would create information accounts at specialised institutions, where they would deposit their personal information. Depositors would then grant to potential information users the right to use the information after paying the market price for it. The use of information would be limited to a specific period of time, and maybe, for specific purposes. The specialised information banks would have the role to aggregate the personal information deposited by their clients, retaining a part of the payment for covering the costs of their current operations.

This system implies a strict control of the information transfer in the society, possibly enforced and maintained by the government. This model, although interesting and ingenious, neglects the multiple possibilities to collect, store and process information in a networked society, centered around the Internet, as a global, unregulated communication channel.

A possible online alternative would be the use of specialised *cybermediaries* that can negotiate on behalf of their clients with online commercial organizations, in order to get a better deal and protect the use of personal information. However, the main problem remains: the negotiation would take place in the present online environment, which does not offer an appropriate protocol for a conflictual dialogue between users (or cybermediaries) and organizations. The negotiating aspects of personal privacy should be embedded into the technological tools of online interaction.

THE IMPACT OF THE NEGOTIATING MODEL OF ONLINE PRIVACY RIGHTS: THE PLATFORM FOR PRIVACY PREFERENCES

In May 1998, the Web Standards Organisation has released the first public draft of the Platform for Privacy Preferences, or P3P—a protocol meant to provide an automatic common Web language for the acceptable use of personal information (Cranor, 1998).

The *Platform for Privacy Preferences (P3P)* provides a standard way of communicating and negotiating Web site data practices. The Platform was developed by the World Wide Web Consortium, an international organization dedicated to the evolution and development of the Web, whose operations are administered by the MIT Computer Science and Artificial Intelligence Laboratory (CSAIL) in the USA, the European Research Consortium for Informatics and Mathematics (ERCIM) headquartered in France, and Keio University in Japan, following an initiative of the Center for Democracy and Technology (Cranor, 2002).

The P3P specification includes a standard vocabulary for describing the data practices used by Web sites, a set of data elements that Web sites can refer to in their P3P privacy policies, and a protocol for requesting and transmitting Web site privacy policies.

The P3P 1.0 Specification allows Web sites to transform their current plain language privacy policy into a machine readable P3P Policy, by encoding it in XML format. Several policy-writing software programs perform this translation automatically, such as IBM's P3P Policy Editor.

During the Web interaction, a P3P-compatible browser automatically detects the Web site's privacy policy, and depending on the level of promised protection, releases or not the customer's personal information. The browser also allows users to do selective cookie blocking based on the extent of the Web site privacy policy, and provides a report of the Web site data practices. As a support to this function, Microsoft has implemented an advanced cookie-filtering mechanism in the software package of *Internet Explorer 6 (IE6)*, based upon the P3P 1.0 Specification. The software presents various levels of cookie-filtering sensitivity, which users can adjust manually using a slider contained on the "Privacy" tab, under "Internet Options". When the user has not adjusted his or her preferences, the interaction between the site and the user's browser is based on default preference settings implemented in the program.

When IE6 interacts for the first time with a cookie, a dialog window entitled "Privacy" is presented to the user, informing him/her that the browser will show a privacy icon in the status bar each time a cookie is blocked or restricted. Users can then double-click on the icon, in order to obtain a short privacy report, which contains a message about the cookies and a list of the URLs of these cookies. From this dialog window, users can choose to see the full P3P policy, and grant or block cookie privileges to specific Web sites.

The P3P protocol is still in a developing stage, and has evolved rapidly during the project (Cranor, 2002). Originally the platform was design to permit a multi-stage negotiation process between the user's browser and the Web site, based on a series of offers and counter-offers. This system was later replaced with a single-round negotiation, in which the Web site has to present all the information about its data practices, which the user can then decide to accept or to reject. The public release of the P3P 1.0 Specification allowed the developers of this project to better evaluate its effectiveness and to define the existing problems that still have to be solved.

The P3P has many critics that emphasize various problems related with the implementation and use of the platform (Clarke, 1998; Harvey & Sanzaro, 2002; Thibadeau, 2000):

- **Implementation and Maintenance:** The translation of a written privacy policy into a P3P privacy statement requires additional effort from companies. The firms have to evaluate and define clearly their data practices, for each part of their site, and to adequately describe them into a P3P compatible privacy policy; the cost and time required for these tasks might prevent some firms to implement the P3P protocol;
- **Lack of Privacy Framework and Legal Enforcement:** The platform does not operate within an existing privacy framework, does not promote a minimum set of privacy or security standards that Web sites should follow, and does not provide an privacy enforcement mechanism;
- **Unclear Legal Consequences:** Some companies might be concerned with being held accountable for statements made in a P3P privacy policy, especially when there is a discrepancy among their non-P3P policies, the P3P statement, and their actual practices. Some firms have suggested the introduction of legal disclaimers in the P3P policy, but the effectiveness of such disclaimers is still untested;
- **Internet User Confusion:** In many cases, Internet users might not be willing to learn about the P3P platform and set their privacy preferences regarding to cookies. In this case, the dialog window

offered by IE6 might increase the confusion of Internet users, since they might not understand the purpose of a cookie and the reason for which it was blocked. Finally, P3P does not guarantee the security of the accessed Web sites.

These problems are certainly real, but the advocates of P3P consider them rather as limitations, and not as valid grounds for eliminating the entire concept (Cranor & Wenning, 2002). They emphasise that the implementation and use of the P3P platform is only a first step towards the standardization of privacy policies, and facilitates the users' choice of a desired privacy level, including anonymity and pseudonymity. On the other hand, the implementation of the P3P platform should be complemented with an appropriate level of legal protection and enforcement. Some critics have outlined that the widespread implementation of the P3P platform might discourage the enforcement of specific online privacy legislation, especially in the United States, where the accent is put on a voluntary regulation of data practices. However, this might not necessarily be the case: in 1998, European Union has issued a statement declaring that a technical platform by itself is not sufficient to guarantee online privacy protection and that any technical measures should be supported and complemented with an appropriate legal framework (Cranor & Wenning, 2002).

One major issue is the necessity to improve the control over the use of personal information accounts and to track down any possible infringement of the data practices policy. This would imply an increase in the governmental and intergovernmental control over the use of online information, which is considered unacceptable by the militants against Internet censorship.

Another possible solution would be the introduction of a voluntary auditing system, in which online organizations will be monitored by independent assessors (possible specialised cybermediaries). The organizations infringing the protocol will be denied the "seal of approval", that can become a differentiating sign between ethically correct and "rogue" companies.

CONCLUSION

Privacy rights and policies represent a subject of intense concern, debate and research world-wide (Cranor, 1998). The explosive development of the Internet has only highlighted this problem of the modern-day society.

Various research approaches can be used to further study this phenomenon:

- Surveys and analyses of the level of privacy described in companies' disclaimers, as well as the real versus the perceived protection provided by these statements;
- Surveys of the public opinion regarding online privacy, and analyses of the relation between privacy standards and consumer trust;
- Studies regarding the use by individuals of specific tools of privacy protection, such as encryption programs or anonymazer applications, and their effectiveness.

Online privacy will continue to provoke debate until a dynamic, adaptable solution will be found and implemented. This solution should balance the interests of individual customers with those of commercial organizations, and with the values of the present-day society. The definition and enforcement of privacy rights should represent a compromise between responsible individuals and ethical organizations, depending on the particular circumstances of every interaction.

Online Advertising Fraud

Robert S. Owen
Texas A&M University — Texarkana, USA

INTRODUCTION

This article discusses illegitimate activities associated with online promotion activities, specifically those related to *click-through fraud*. Whether one is starting a new brick-and-mortar restaurant, managing a charity organization, or building an online information portal, prospective customers, donors, or users must be informed, persuaded, and reminded of the features and benefits that are offered by the business. Online promotion has some unique and advantageous characteristics over traditional promotion media, but those characteristics create a potential for abuse. Click-through fraud, more commonly termed *click fraud*, is a relatively recent and evolving problem that currently has few deterrents. This article outlines why and how click fraud is done, and suggests some measures that can be taken to at least recognize the potential for click fraud.

The interactive nature of the Web would seem to make it an ideal advertising medium with a potential to completely eliminate advertising *waste*. Newspaper ads for, say, a pet store reach many people who do not have pets: the number of people in this category is termed as *waste*. With online advertising, it is possible—in an ideal world—to place an ad and to pay for the ad space only when a prospective customer shows interest by clicking on a linked advertisement that transports him/her to the advertiser's online place of business. This *pay-per-click* (PPC) pricing model would seem to completely eliminate advertising waste.

Unfortunately, advertisers, ad hosts, and fraudsters are discovering that the PPC model is open to abuse. Those who click on an online advertisement could include:

- Prospective customers who actually have an interest in the product
- Competitors who want to generate high advertising costs for the advertiser
- Ad hosts who earn a commission from displaying pay-per-click advertising

The latter two categories consist of entities that have absolutely no interest in the advertiser's offerings and absolutely no intention of ever performing any *target actions* such as purchasing a product. These fraudulent *click-throughs* or *debiting clicks* could turn an ad campaign from one that has almost no waste into one that has almost 100% waste. In a survey of advertisers, the Search Engine Marketing Professional Organization found that a quarter of respondents have tracked fraud as a problem (SEMPO, 2004).

BACKGROUND

Contextual advertising is one way of increasing the likelihood that an ad is reaching people in its target audience. In Web-based advertising, contextual advertising would include banner ads or search engine links that are displayed on a page that has a context that is related to the ad; people on that page are already searching for or browsing through ad-related content. Better reaching the target audience in this way should result in less waste and, in the case of online advertising, in a higher *click-through rate* (cf. Newcomb, 2003; Smith, 2004; Sullivan, 2004).

Search engines engage in contextual advertising through the *pay-per-click* (PPC) or *cost-per-click* (CPC) pricing model. When someone does a search, many search engines not only return links to pages that have been indexed on the search terms, but also return *sponsored links* to pages that the advertiser has paid to have listed at high ranking (cf., Brendler, 2005). When someone clicks on a sponsored link in the PPC model, this *click-through* is a *debiting click* that subtracts from the advertiser's prepaid advertising click budget. The price per click is set by a bidding process, whereby the advertiser who bids to pay the most for particular keywords will be ranked the highest in the list of *sponsored links* returned by the search engine (cf., Alchemist Media, n.d.). The Fathom Online Keyword Price Index shows that in March 2005, advertisers in the consumer retail industry were paying an average of $0.51 per click, while advertisers in the mortgage industry were paying an average of $5.39 per click (Fathom, 2005). Bids on some keywords can reach into the fifty-dollar range (cf., Associated Press, 2005a; Bruce Clay, n.d.).

Both advertisers and ad hosts have experienced fraud under the PPC advertising model, but legal action is relatively new at the time of this writing. In February 2005, the gift shop Lane's Gifts and Collectables filed suit against Google, Yahoo, and others for allegedly billing for inflated click-throughs for PPC advertising, charging that many click-throughs were not generated by *bone fide* potential customers (Associated Press, 2005b). But just a few months earlier, Google had itself filed one of the first click fraud lawsuits against one of its advertising affiliates who displayed Google-generated sponsored links on its own Web site. The affiliate, Auctions Expert, contracted with Google to display PPC links, but then allegedly clicked on those links itself in order to generate a commission (Olsen, 2004). In March 2004, Michael Bradley was arrested by the U.S. Secret Service in association with his Google Clique software that he claimed could be used to generate false clicks for Google affiliates (Nariane, 2004).

ADVERTISING CLICK FRAUD

Before looking at why and how click fraud is done, we need an understanding of some basic cost or pricing methods used in online advertising.

Pricing Models

Traditional Model: CPM and Pay-Per-Impression Advertising

A traditional measure of advertising cost for print and broadcast media has been *CPM*, or "cost-per-thousand." In traditional media, this is the cost of reaching 1,000 individuals or households with the advertising message in a given medium. With online advertising, CPM tends to be associated with the cost of 1,000 *impressions*, or actual exposures to a particular advertisement. In *pay-per-impression* advertising, the advertiser pays for some predetermined number of ad impressions. When this impression budget is exhausted, the ad is removed from the display list (cf., Internet Retailer, 2005).

Performance Model: Cost-Per-Transaction or Cost-Per-Action (CPT, CPA)

Although not often discussed and apparently not often used in online promotion, pricing that is based on the ultimate visitor's *target action* (e.g., making a purchase) could be done. The terms *cost-per-action* and *cost-per-acquisition* (CPA) are sometimes used to describe this idea (cf., Gold, 2005; Stevens, 2001; Think Metrics, n.d.). Mand (1998) discussed a model that has been called *cost-per-sale*, *cost-per-trade*, and *cost-per-transaction* advertising (CPT). This equates to a sales commission in traditional media.

Bid-for-Placement Model: Pay-Per-Click or Cost-Per-Click Advertising (PPC, CPC)

In *pay-per-click* (PPC) advertising, also known as *cost-per-click* (CPC) advertising, the advertiser pays a fee for each time someone clicks an advertisement that links to the advertiser's Web site. The advertiser pays for a predetermined number of clicks at a price that is often set by being the highest bidder in an auction. The advertisement host (e.g., a search engine) removes the ad from the display list when this click budget is exhausted. The advertisement host might also remove the ad from the display if the *clicks-to-impressions* (CTI) ratio or *click-through rate* (CTR) falls below some predetermined limit (because it is failing to generate sufficient revenues.)

Click Fraud Classification

Fraud can exist in all three types of pricing models, but click fraud is probably the most problematic at this time because the PPC model has become so widely used in online advertising. Many types of online advertising fraud are motivated by two basic objectives. One is associated with an attempt to either hurt a competitor or to force the competitor to decrease its advertising. Another is to profit from hosting advertising messages. The first type could be classified as *competitive fraud* and the second as *affiliate fraud* or *network fraud* (cf., Claburn, 2005; Lee 2005; Stricchiola, 2004).

Competitive Fraud

The objective of competitive fraud is often to hurt a competitor or to get a competitor to quit advertising. For example, one competitor can repeatedly click on another competitor's PPC ad with the intent to inflate the competitor's advertising cost rather than to obtain information about the advertised product. The objective of deliberately imposing this cost on the competitor could be to:

- drain the competitor's advertising budget in an effort to decrease the competitor's profitability.
- cause the competitor to see less value in bidding up the price to be at the top of the search engine list. This thereby lowers the prices for other competitors to bid for top listing.
- cause the competitor to quit advertising or to quit doing as much advertising because it either cannot budget for the volume of clicks or sees PPC advertising as providing a poor return on investment. If the competitor bows out of the top spot, it is now open for the remaining competitors at lower prices.

Click Monkey, for example, advertises that it can be hired to "Google bomb your competition" for pennies on an advertisement's bid price as a cost-effective way to lower high-bid PPC rates (Click Monkey, n.d.).

An interesting example of apparent competitor fraud is the alleged actions both by and against Blue Star Jets. Charter Auction, a charter jet broker, at one time spent $20,000 per month on search ads and $20 per click for some search terms. Charter Auction and another charter-jet broker, Air Royale International, believed that they were the victims of click fraud and identified an IP address (Internet address) assigned to Blue Star Jets that had repeatedly clicked on ads thousands of times. But Blue Star Jets itself was hit with click-through theft by a competitor who presumably believed that it was justified in retaliating against Blue Star Jets. Tag Aviation found that competitor Blue Star Jets had purchased clicks based on the search phrase for its own name, "Tag Aviation," thereby stealing customers who might have intended to go to Tag Aviation. Tag Aviation staff were told to retaliate by clicking on these Blue Star ads in order to deplete Blue Star's click budget for these ad keywords (McKelvey, 2005).

Note that we do not necessarily have to click on the competitor's ads to drive up its costs. We could also quit using particular keywords ourselves, causing the competitor to get all the hits (non-fraudulent, legitimate ones). If the competitor has a high bid price on these keywords, its advertising costs might increase if it is getting all of the hits. If it cannot temporarily afford this increase, it might be coerced into decreasing its advertising, leaving the market open for the rest of us (cf., Crowell, 2005).

It is also possible to hurt a competitor through a *click restraint* action rather than doing a click-through. When the clicks-to-impressions ratio falls below a certain threshold, the search engine or other advertising host might automatically drop the ad from the display list to be replaced by an ad that gets a higher click response (which therefore generates higher revenues). A click-through is a *debiting click* when it is used to consume a click from the PPC prepaid budget of clicks (cf. Stricchiola, 2004). But in this case, the fraudster opens a Web page that causes an ad to be displayed, but then refrains from clicking on it; this decreases the click-to-impression ratio and therefore could cause the ad to be dropped or lowered on the list (cf., McKelvey, 2005).

Affiliate/Network Fraud

The objective in affiliate or network fraud is to obtain a financial commission on PPC advertising that is being hosted. Mentioned earlier, Auctions Expert allegedly recruited as many as 50 people to click on ads that it hosted (Vise, 2005). Vidyasagar (2004) suggests that a small industry is developing in India in which housewives can earn up to $0.25 per click to browse online advertising. With *paid-to-read* (PTR) programs, list subscribers are paid to click on links that are e-mailed to them (e.g., StopClickFraud, n.d.); the unscrupulous affiliate thereby lowers the risk of detection by generating clicks that appear to be legitimate in originating with real people at real computers in a wide geography. Click Monkey (n.d.) outright advertises its *click farm* services, advertising rates for as little as one dollar per thousand clicks. The higher rates, however, would have to be paid to those who would spend 60 or 90 seconds on an ad—long enough to give the appearance of a legitimately interested party. It is also possible to automate hits with spoofs of varying IP addresses (i.e., the software pretends to be making clicks from a variety of geographic locations instead of from a single computer), as when Michael Bradley claimed that his Google Clique software could be used to generate false clicks for Google affiliates (Nariane, 2004).

An advertising affiliate can also commit *impression fraud* and *content fraud*. In impression fraud, the advertisers pays for visitors who merely arrive at a page with an ad (an ad impression), not for a click-through of that ad. Impression fraud can be committed by the same methods used in click-through fraud (cf., Feldblum, 2005; Internet Retailer, 2005; Lee, 2005). In committing content fraud, the PPC advertising affiliate (host) indexes pages using keywords that are unrelated to the actual content of the page and the advertisement. In this way, the fraudster can increase the number of hits to that page (impressions), but the visitors who reach that page arrived with the expectation of different content; the impressions are wasted on an audience that has no interest and had expected something different (cf., Feldblum, 2005).

Click Fraud Detection Hints

An advertiser should normally look at measures and ratios in order to evaluate the cost effectiveness of an advertising campaign. Importantly, some of these could be useful in tracking the onset of fraud activities.

Click-Through Rate

The click-through rate (CTR) of an ad or sponsored link is the number of visitors who clicked on the link vs. the number of visitors who were exposed to the ad, or click-throughs vs. impressions, expressed as a percentage. A higher CTR could suggest that the ad or link is effectively placed in the context of the page that displays it. A sudden increase in CTR, however, could also suggest the onset of click fraud activities.

Bounce Rate

Some Web site visitors will enter and then back out (leave) without viewing any other pages on the site. The *bounce rate* or *ratio* is the number of visitors who leave without linking from anything on the page vs. the total number of visitors (or *pageviews*), expressed as a percentage (cf., IndexTools.com, n.d.; Think Metrics, n.d.). A sudden increase in bounce rate could suggest the onset of click fraud activities.

Customer Conversion Rate

C*onversion* has to do with visitors who become revenue-generating customers. The customer conversion rate (CCR) is the percentage of Web site visitors who engage in an ultimate *target action*, such as making a purchase (cf., Gold, 2005; Pelland, 2005; ThinkMetrics, n.d.). A sudden decrease in conversion rate, or an increase in *non-converting traffic*, could suggest the onset of click fraud activities.

FUTURE TRENDS

If the value of online advertising decreases due to fraudulent activity, providers of online advertising services will ultimately have a financial motivation to take action to protect the interests of advertisers. As customers of these services, advertisers will gravitate to competing service providers who provide the best assurance that they are providing good value for the investment in advertising. How these services might best protect advertisers is beyond the scope of this article; this emerging issue currently does not appear to have any easy answers either in practice or in the courts.

CONCLUSION

While this article has not provided any answers regarding how advertising hosts can protect against fraud, it has hopefully helped to make advertisers aware of important emerging issues associated with online advertising. Although fraud is currently a cost of business that cannot be easily stopped, the advertiser can be wary of signs that suggest fraud and can take measures that compare different media or service providers to track the cost effectiveness of an advertising campaign. Advertising waste exists and is accepted as a cost factor in traditional advertising media; that fraud cannot easily be controlled in online advertising might ultimately (and unfortunately) force us to accept it as a mere nuisance factor of waste in contrasting the cost efficiency of various media.

KEY TERMS

Advertising Waste: Advertising that reaches an audience that is outside of its target market or intended audience.

Bounce Rate: A ratio of the number of Web page visitors who enter and then back out (leave) without linking from anything on the page (e.g., viewing other pages on the site) vs. the total number of visitors (total *pageviews*), expressed as a percentage.

Click Fraud: Clicking on an online advertisement link for the premeditated purpose of causing a PPC advertiser to pay for the click without the intent to take any other actions (such as buy a product).

Click-Through: When a Web page visitor clicks on a link, such as an advertisement, for more information.

Click-through Rate (CTR): A ratio of the number of Web page visitors who clicked on an ad link vs. the number of visitors who were exposed to the ad, expressed as a percentage.

Customer Conversion Rate (CCR): The percentage of Web site visitors who engage in an ultimate target action such as making a purchase.

Pay-Per-Click Advertising (PPC): A pricing model in which the advertiser pays for each click-through made on an advertising link. Also known as cost-per-click (CPC).

Sponsored Link: A link that is returned on a search engine search for which an advertiser has paid a fee in exchange for prominent ranking.

Ontology Development Tools for Ontology-Based Knowledge Management

Seongwook Youn
University of Southern California, Los Angeles, USA

Dennis McLeod
University of Southern California, Los Angeles, USA

INTRODUCTION

Ontologies play a key role in realizing the full power of e-technology. Ontologies allow for machine-understandable semantics of data, and facilitate the search, exchange, and integration of knowledge for B2B (business-to-business) and B2C (business-to-consumer) e-commerce. Ontology is defined as the specification of shared knowledge (Waterson & Preece, 1999). By using semantic data, the usability of e-technology can be facilitated. There are several languages like XML (extensible markup language), RDF (resource description framework), RDFS (RDF schema), DAML+OIL (DARPA Markup Language+Web Ontology Language), and OWL. Many tools have been developed for implementing metadata of ontologies using these languages. However, current tools have problems with interoperation and collaboration. The primary goal of this survey is to introduce and understand several tools through their use. Therefore, we can develop a new generation of tools that not only support more capabilities, but also solve the problems of current tools.

BACKGROUND

Ontology tools can be applied to all stages of the ontology life cycle including the creation, population, implementation, and maintenance of ontologies (Polikoff, 2003). An ontology can be used to support various types of knowledge management including knowledge retrieval, storage, and sharing (Pundt & Bishr, 1999). In one of the most popular definitions, an ontology is the specification of shared knowledge (Waterson & Preece, 1999). For a knowledge-management system, an ontology can be regarded as the classification of knowledge. Ontologies are different from traditional keyword-based search engines in that they are metadata, able to provide the search engine with the functionality of semantic matching. Ontologies are able to search more efficiently than traditional methods. Typically, an ontology consists of hierarchical descriptions of important concepts in a domain and the descriptions of the properties of each concept.

Traditionally, ontologies are built by both highly trained knowledge engineers and domain specialists who may not be familiar with computer software. Ontology construction is a time-consuming and laborious task. Ontology tools also require users to be trained in knowledge representation and predicate logic.

XML is not suited to describe machine-understandable documents and interrelationships of resources in an ontology (Gunther, 1998). Therefore, the World Wide Web Consortium (W3C) has recommended the use of RDF, RDFS, DAML+OIL, and OWL. Since then, many tools have been developed for implementing the metadata of ontologies by using these languages.

MAIN THRUST OF THE ARTICLE

There are several ontology languages like XML, RDF(S), DAML+OIL, and OWL that are used to implement tools for implementing the metadata of ontologies.

Protégé 2000

Protégé (Noy, Sintek, Decker, Crubezy, Fergerson, & Musen, 2001) is developed by Stanford Medical Informatics. With Protégé, a user can construct domain ontologies, customize data entry forms, and enter data. Protégé has an extensible plug-in architecture, allowing users to add functionality by using plug-ins. Hence, Protégé can be easily extended to use knowledge-based embedded applications. Tables and diagrams are constructed using graphical widgets. However, new basic types cannot be added in Protégé.

Protégé 2000 assumes that knowledge-based systems are usually very expensive to build and maintain because knowledge-based system development is done by a team including both developers and domain experts who may be less familiar with computer software. Protégé 2000 guides developers and domain experts through the process of system development. Developers can reuse domain ontologies and problem-solving methods with Protégé 2000, shortening the time for development and program maintenance. One domain ontology that solves different problems can be used in several applications, and different ontologies can use the same problem-solving methods.

OilEd

OilEd (Bechhofer, Horrocks, Goble, & Stevens, 2001) is developed by the Information Management Group of the CS Department at the University of Manchester, United Kingdom. OilEd is an OIL editor that allows a user to create and edit OIL ontologies. OilEd is primarily intended to demonstrate the use of DAML+OIL, but it does not support a full ontology-development environment. OilEd does not support many activities such as the creation of large-scale ontologies, versioning, augmentation, and the migration and integration of ontologies that are involved in ontology construction. OilEd has no extensibility, but arbitrary class expressions, primitive and defined classes, and concrete-type expressions can be used.

Apollo

Apollo (Koss, 2002) is developed by the Knowledge Media Institute of Open University, United Kingdom. Apollo allows a user to model an ontology with basic primitives such as classes, instances, functions, relations, and so forth. The internal model is a frame system based on the Open Knowledge Base Connectivity (OKBC) protocol. The knowledge base of Apollo consists of hierarchically organized ontologies. Ontologies can be inherited from other ontologies and can be used as if they were their own ontologies. Every ontology has a default ontology, which includes all primitive classes. Each class can create a number of instances, and an instance inherits all slots of the class. Each slot consists of a set of facets. Apollo can be extended with plug-ins, but it does not support collaborative working.

RDFedt

RDFedt is developed by Jan Winkler of Germany. RDFedt allows a user to build complex and structured RDF and RSS (RDF site summary) documents. It provides an overview of complex data structures with element trees. Also, it allows a user to test data and to give comments and error messages with the help of additional functions.

RDFedt supports RDF, RDFS, and Dublin core elements. RSS 1.0 provides modules like aggregation, notation, content, cut, organization, change of page, threading, and so forth. RSS 0.91 supports declaration and levels of styles in XML, sets of imported elements, and the automatic generation of an RDF-based linked list from an HTML (hypertext markup language) document.

RDFedt is a textual language editor. It is not a Java program, is not platform independent, and works only on Windows.

OntoLingua

OntoLingua (Fikes, Farquhar, & Rice, 1997) is developed by the Knowledge Systems Lab of Stanford University. It provides a user-distributed collaborative environment, a suite of ontology-authoring tools, and a library of modular, reusable ontologies. It also supports a World Wide Web (WWW) interface and translation into different formats. OntoLingua is an ontology library and server that can be accessed with a traditional Web browser. By assembling and extending the ontologies obtained from the library and tools in OntoLingua, authorization can be provided. Using Chimaera, the taxonomy is reorganized and name conflicts in the knowledge base are resolved. Multiple users can use OntoLingua via write-only locking and user access-level assignment.

OntoEdit

OntoEdit (Sure, Angele, & Staab, 2003) is developed by Ontoprise of Germany. There are freeware and professional versions. Our survey focused on freeware. OntoEdit offers export interfaces to all major ontology-representation languages and has a flexible plug-in framework. This feature allows a user to customize the tool in a user-friendly fashion. Several functions are modularized, so it can be easily extended.

An ontology requirements-specification document describing what an ontology should support is needed for ontology development. According to the ontology requirements-specification document, an ontology engineer determines relevant concepts and their hierarchical structure in the ontology. OntoEdit can be used in this phase using two plug-ins, OntoKick and Mind2Onto5, for metaontology description with the automatic calculation of statistic information.

WebODE

WebODE (Arpirez, Corcho, Fernandez-Lopez, & Gomez-Perez, 2001; Corcho, Fernandez-Lopez, Gomez-Perez, & Vicente, 2002) is developed by the Technical School of Computer Science in Madrid, Spain. It was made to use and test the methontology methodology. The motivation of WebODE is to support an integrated ontological engineering workbench, which has three activity groups: ontology-development, -management, and -population activities; ontology middleware services; and ontology-based application development. WebODE supports varied ontology-related services and most of the activities involved in the ontology-development process. It is not an isolation tool for ontology development. The WebODE architecture consists of three tiers. The first tier provides the user interface, the second tier provides the business logic, and the third tier consists of the data.

KAON

KAON (KArlsruhe ONtology) (Volz, Oberle, Staab, & Motik, 2003) is developed by the FZI Research Center and the AIFB Institute of the University of Karlsruhe, Germany. KAON is designed to manage business applications. KAON has two user-level applications: OiModeler and KAON PORTAL. All other modules except for these two applications are for software development. OiModeler is an ontology editor for ontology creation and maintenance. We can navigate and search ontologies with a Web browser using KAON PORTAL. KAON supports scalable and efficient reasoning with ontologies; RDFS extension with symmetric, transitive, and inverse relations; and metamodeling using axiom patterns.

ICOM

ICOM is developed by Free University of Bozen-Bolzano, Italy. The purpose of the development of ICOM is to provide a freeware conceptual modeling tool that can be used for knowledge representation in database and ontology design. It is useful in the conceptual modeling of databases and the design of various ontologies. It supports interontology mapping with the GUI (graphical user interface). ICOM is created with Java 1.2 and can be run on Linux and Windows machines. The CORBA (Commoon Object Request Broker Architecture) protocol with the FaCT (Fast Classification of Terminologies) description logic server is used for ICOM communication.

DOE

DOE (Differential Ontology Editor; Isaac, Troncy, & Malais, 2003) is developed by the National Audiovisual Institute in France. It follows a methodology proposed by Bruno Bachimont. DOE is not developed for full ontology development, so many activities in traditional ontology construction are not supported. DOE allows a user to attach a lexical definition to concepts and relations and justify their hierarchy.

DOE has problems importing Dublin core metadata. In DOE, interoperability can be applied using both RDFS and OWL, and concepts cannot be defined intentionally with constraints. Individuals cannot be imported during the running of WebODE.

WebOnto

WebOnto (Domingue, Motta, & Corcho Garcia, 1999), developed by the Knowledge Media Institute of the Open University in England, supports the collaborative browsing, creation, and editing of ontologies, represented in the knowledge-modeling language OCML (Operational Conceptual Modelling Language) without suffering from the interface problems. WebOnto attempts to be easy to use and yet scalable to large ontologies. The main features of WebOnto are the management of ontologies using a graphical interface, the automatic generation of instance-editing forms from class definitions, the inspection of elements taking into account the inheritance of properties, and consistency checking and support for collaborative work using broadcasting and receiving and making annotations. WebOnto consists of a Java-based central server and clients.

Medius Visual Ontology Modeler

Medius Visual Ontology Modeler (VOM) is a UML-based ontology-modeling tool that enables ontology development and management for use in collaborative applications and interoperability, and is available as an add-on to the Rational Rose Enterprise Edition. It is developed by Sandpiper Software. It has a set of ontology-authoring wizards that create and maintain the required UML model elements for the user, substantially reducing construction errors and inconsistencies. That is to say, it supports limited consistency checking.

LinKFactory Workbench

LinKFactory Workbench (Deray & Verheyden, 2003) is designed for very large medical ontologies. The LinKFactory client-server structure is an information system constructed using a three-tier architecture. First, LinKFactory Workbench is a client application on the user side to manage the LinKBase ontology database. Second, LinKFactory is the server interface that receives and answers user requests, holds the business logic, and requests data using the application-server tier. Third, the data layer accesses the underlying database. This database contains all information (user information, ontology contents, and maintenance information).

Table 1. Comparison table

	Import format	Export format	GUI	Consistency check	Multi-user	Web support	Merging
Protégé 2000	XML, RDF(S), XML schema	XML, RDF(S), XML schema, FLogic, CLIPS, Java, HTML	Via plug-ins like GraphViz and Jambalaya	Via plug-ins like PAL and FaCT	Limited (multi-user capability added to it in 2.0 version)	Via Protégé-OWL plug-in	Via Anchor-PROMPT plug-in
OilEd	RDF(S), OIL, DAML+OIL	RDF(S), OIL, DAML+OIL, SHIQ, dotty, HTML	No	Via FaCT	No	Very limited name spaces	No
Apollo	OCML, CLOS	OCML, CLOS	No	Yes	No	No	No
RDFedt	RDF(S), OIL, DAML, SHOE	RDF(S), OIL, DAML, SHOE	No	Only checks writing mistakes	No	Via RSS	N/A
OntoLingua	IDL, KIF	KIF, CLIPS, IDL, OKBC syntax, Prolog syntax	No	Via Chimaera	Via write-only locking, user access levels	Yes	N/A
OntoEdit (free version)	XML, RDF(S), Flogic, DAML+OIL	XML, RDF(S), Flogic, DAML+OIL	Yes	Yes	No	Yes	N/A
WebODE	RDF(S), UML, DAML+OIL, OWL	RDF(S), UML, DAML+OIL, OWL, Prolog, X-CARIN, Java/Jess	Form-based graphical user interface	Yes	By synchronization, authentication, and access restriction	Yes	Via ODEmerge
KAON	RDF(S)	RDF(S)	No	Yes	By concurrent access control	Via KAON PORTAL	No
ICOM	XML , UML	XML, UML	Yes	Via FaCT	No	No	With inter-ontology mapping
DOE	XSLT, RDF(S), OIL, DAML+OIL, OWL, CGXML	XSLT, RDF(S), OIL, DAML+OIL, OWL, CGXML	No	Via type inheritance and detection of cycles in hierarchies	No	Load ontology via URL	No
WebOnto	OCML	OCML, GXL, RDF(S), OIL	Yes	Yes	With global write-only locking	Web based	N/A
Medius VOM	XML schema, RDF, DAML+OIL	XML schema, RDF, DAML+OIL	UML diagrams via Rose	With a set of ontology-authoring wizards	Network based	Via read-only browser support from Rose	Limited (only native Rose model)
LinKFactory	XML, RDF(S), DAML+OIL, OWL	XML, RDF(S), DAML+OIL, OWL, HTML	No	Yes	Yes	Yes	Yes
K-Infinity	RDF	RDF	With graph editor	Yes	Network based	No	N/A

K-Infinity

K-Infinity is a tool developed by Intelligent Views, a German company, for the creation, maintenance, and use of a knowledge network. It is a knowledge editor with broad support for object-oriented knowledge modeling. Knowledge Builder is K-Infinity's main component. Using Knowledge Builder, knowledge engineers and lexicographers can create, delete, rename, and edit both objects and relations, as well as relate objects to each other according to defined relations. This can be done in two different workspaces: (a) the graph editor that enables the user to see a graphical view of the network of objects and the relations of them, and (b) the concept editor that is a supplemental data viewer to the graph editor.

In addition to tools for editing the knowledge, K-Infinity provides the K-Organizer, which provides administration, navigation, search, and query formulation.

Table 1. Comparison table (continued)

	Collaborative working	Ontology library	Inference engine	Exception handling	Ontology storage	Extensibility	Availability
Protégé 2000	No	Yes	With PAL	No	File & DBMS (JDBC)	Via plug-ins	Free
OilEd	No	Yes	With FaCT	No	File	No	Free
Apollo	No	Yes	No	No	Files	Via plug-ins	Free
RDFedt	No	No	No	Yes	Files	No	Free
OntoLingua	Yes	Yes	No	No	Files	No	Free
OntoEdit	No	No	No	No	File	Via plug-ins	Free
WebODE	Yes	No	Prolog	No	DBMS (JDBC)	Via plug-ins	Free

FUTURE TRENDS

There are still some research challenges. Ontology tools have to support more expressive power and scalability with a large knowledge base, and reasoning in querying and matching. Also, they need to support the use of high-level language, modularity, visualization, and so forth.

There are also research and applications about dynamic Web pages consisting of database reports. Database reports are indispensable for every e-commerce transaction (Tarassenko & Bukharova, 2001).

Research on ontology-integration tasks in B2B e-commerce is also undergoing. The infrastructure of business documentation from the integration perspective and the identification of the integration subtasks were suggested (Monostori, Váncza, & Ali, 2003)

There is research on a generic e-business model ontology for the development of tools for e-business management and IS requirements engineering. Based on an extensive literature review, the e-business model Ontology describes the logic for a business system (Osterwalder, Parent, & Pigneur, 2004).

CONCLUSION

So far, we have described 14 ontology tools. All of these tools are ontology-development tools. To compare each tool's features, we have chosen the tools with similar purpose. Of course, there are many other tools that have different purposes. For example, Chimaera, FCA-merge, and PROMPT are ontology-merge and -integration tools. AeroDAML, COHSE, MnM, and OntoAnnotate are ontology-annotation tools. Sesame, Inkling, rdfDB, Redland, jena, and cerebra are ontology-storing and -querying tools.

Several important aspects when we analyze tools exist. Most of the tools are moving toward Java platforms and extensible architectures as well. Interoperability and storage in databases are still weak points of ontology tools.

Polikoff (2003) used Protégé 2000, OilEd, and OntoEdit to test the interoperability of ontology tools. For example, plain RDFS from OilEd could be used in OilEd and Protégé 2000, but it was not working well in OntoEdit. Plain RDFS from Protégé 2000 could be used in Protégé 2000 and OilEd version 19990303, but it could not be used in OntoEdit. Also, standard Oil RDFS from Protégé 2000 and OWL from OilEd could not be used in all tools (OilEd, Protégé 2000, and OntoEdit). DAML+OIL from OilEd could be used in OilEd and OntoEdit with minor problems, but it could not be used in Protégé 2000. Interoperability with other ontology-development tools, -merging tools, and databases, as well as translations to and from some ontology languages, is an important factor in order to integrate ontologies in applications. However, there are few comparative studies about the quality of all translators, the possibility of exchanging ontologies between different tools, and the loss of knowledge in the translation processes.

In case of storage, only a few of the surveyed tools use databases for storing ontologies: LinKFactory, OntoEdit Professional Version, Protégé 2000, and WebODE. Also, only a few have backup-management functionality.

Although a lot of similar ontology tools exist for ontology creation, they do not interoperate well and do not cover all the activities of the ontology life cycle. The lack of interoperability between all these tools creates important problems, for example, when we integrate an ontology into the ontology library of a different tool, or when two ontologies built using different tools or languages are integrated using merging tools.

KEY TERMS

B2B (Business-to-Business): Business that provides some kind of services or sells some product to other businesses.

E-Technology: Technology including hardware and software, and their development using Internet, multimedia, mobile, wireless, and security technologies, and so forth.

Knowledge Management: Systematic process of finding, organizing, and presenting information according to a specific area of interest.

Metadata: Data about data, or machine-understandable information for the Web that describes other data.

Ontology: The specification of shared knowledge (Waterson & Preece, 1999) and the relationships of the collected concepts.

Ontology-Management System: System for querying, storing, creating, modifying, loading, accessing, and manipulating ontologies.

Semantic Web: Extension of the current Web with well-defined meaning, facilitating machines and people to work in cooperation.

Ontology for E-Government Public Services

Costas Vassilakis
University of Peloponnese, Greece

George Lepouras
University of Peloponnese, Greece

INTRODUCTION

In the past few years, information and communication technologies are increasingly used for provision of public services, improvement of managerial effectiveness and promotion of democracy, a development that is commonly termed as e-government (Gil-Garcia, 2004). Transactional services are an indispensable tool for delivering public services and can additionally be used for democracy promotion (e.g., via questionnaires and polls), thus, playing a central role in e-government. Transactional services development and promotion has also been in the focus of specific projects and initiatives (e.g., European Commission, 2004) or supporting frameworks (e.g., UK online, http://www.govtalk.gov.uk/schemasstandards/egif.asp).

E-government services have now been developed to cover the basic services that should be delivered to citizens and enterprises (Cap Gemini Ernst & Young, 2004). Administrations realise however, that besides making new e-services available or enhancing existing ones, a number of issues regarding e-services has to be addressed, including:

1. **E-Service Composition:** In many cases, different public services need to be combined to fully service the needs of a service consumer (citizen or enterprise) in a particular point in time. This issue is often termed "handling of life events" (Wimmer & Tambouris, 2002).
2. **E-Service Cataloguing:** Mechanisms enabling service consumers to locate the available e-services should be provided (Gant & Gant, 2002). These mechanisms should cater for the needs of all service consumers, such as incorporation of multiple taxonomies for e-services (e.g., by delivering organisation, life events, by service category, etc.), provision of search facilities, retrieval of relevant legislative information, etc.
3. **Change Management:** Legislation regarding governmental services is often revised, necessitating changes to the content or procedures of services (Vassilakis, 2003). E-services are more prone to changes since the regulatory framework of e-service provision can also be subject to modifications (e.g., stronger encryption or stricter authentication requirements). Whenever changes occur, the affected services (or service portions) must be located and undergo maintenance activities. *Cascading effects* may also appear, (e.g., if service A depends on service B and service B is modified, harmonisation actions may be needed for service A).
4. **Administrative Responsibility:** The administrative responsibility must be clearly reflected in all phases of e-services lifecycle (Cassese & Savino, 2005), since it determines both the authoritative source to define (or revise) requirements and procedures and the canonical bureau for operating the e-service, resolving issues, etc. In some cases, operation of services can be delegated by the administratively responsible authority to other agencies, (e.g., the ministry of internal affairs is administratively responsible for the service "issuance of birth certificates", but municipalities or citizen service centres can be endorsed to also deliver this service.

The issues previously identified reveal the need for *semantically rich* means for representing the various aspects of e-services. Indeed, through these descriptions a number of *concepts* (i.e., types of entities such as service, document, service consumer, legislation, etc.) are identified, which are connected through various *relationships* (e.g., a service "issues" a document, a regulation "governs" a service and so forth). Such a representation, together with the appropriate tools, would facilitate the task of locating specific concepts, and then exploit the relationships to trace other concepts linked to them. For instance, if a piece of legislation is linked to a number of e-services through links of type "governs", these links can be used to pinpoint the services that should undergo maintenance activities when this piece of legislation is modified.

In this article, the usage of ontologies for meeting the requirements previously listed is examined. An ontology for e-government services is presented, covering various aspects of services, including administrative responsibility, meta-data, involved documents, and legislation. Both the development and usage phase of the ontology are covered and directions for further exploitation of the potential offered by the ontological representation are given.

BACKGROUND

According to W3C, "an ontology defines the terms used to describe and represent an area of knowledge" (W3C, 2004), defining *classes* (or *concepts*), which are general things in the domain of interest, *relationships* that may exist among things and *properties* (or *attributes*) those things may have. Ontologies can also be viewed as descriptions (like a formal specification of a program) of the concepts and relationships that can exist for an agent or a community of agents (Gruber, 1993).

The representational capabilities of ontologies can be complemented with reasoning capabilities through specific rule languages and rule evaluation engines, (e.g., SWRL [Horrocks, et al. 2004], the KAON2 reasoning engine [Motik, Sattler, & Studer, 2004]), providing thus a framework that completely supports the requirements presented above. Reasoning aims at extracting information not directly represented, mainly through the application of rules on the given facts. For example, the organisations through which a document is issued can be determined by first identifying the services that produce the specific document and then retrieving the organisations that offer these services. This can be represented as a rule of the form "if (offers (Organisation, Service) AND issues (Service, Document) THEN issues (Organisation, Document))". Such a rule is evaluated by a reasoning engine against the existing ontology to produce the list of organisations issuing a specific document. Finally, the use of ontologies enables direct integration of public services into the semantic Web (Berners-Lee, Hendler, & Lassila, 2001), multiplying the benefits of this approach. For this purpose, special languages have been designed, including DAML and OIL, whereas RDF can be also used for defining assertions (Davies, Fensel, & Harmelen, 2003).

The issue of service composition is typically tackled using pre-determined execution scenarios, where human experts model the execution order, flow control, and data dependencies of constituent services (Bunting, et al., 2003; Wimmer & Tambouris, 2002). More flexible frameworks allow the dynamic modification of certain model elements (Casati, et al., 2000), while commercial systems enable the graphical modelling of composite services and provide engines for their execution (Iona, 2005; Oracle, 2004).

In the area of e-service cataloguing, the predominant approach is the use of portals, (e.g., FirstGov of US (http://www.firstgov.gov) and DirectGov of UK (http://www.direct.gov.uk/). Portal maintenance is however a costly task, since the need for flexibility and support of multiple views in a change-prone environment, necessitates frequent updates and extensive consistency checks.

The relationship between e-services and legal documents or administrative information is usually handled in an ad-hoc manner. In the best case, legislation databases will be used for maintaining the "point-in-time" versions of the legislation (Teratext Solutions, 2004), but no direct linkage to relevant e-services is established. Similarly, administrative information for e-services is stored in an unstructured form within the legislation and/or the public authorities' regulatory framework.

Recently, the usage of ontologies for modelling e-services has been examined. In Bougouettaya, et al., (2001) ontologies are used as a basic model for organising and discovering e-services. An important aspect of this work is the *ontology distribution*, which facilitates a semi-autonomous maintenance of the ontology data, with each administration maintaining a specific ontology portion. In (Tambouris et al., 2004), the usage of ontologies in application development is examined. Finally, in Adams et al., (2002) an ontology is formulated to promote knowledge management in the context of e-service development.

PUBLIC SERVICE ONTOLOGY: KEY REQUIREMENTS, MODELLING, AND USE

For a public services ontology to be useful, a number of requirements have to be met. Firstly, the ontology should be *complete*, (i.e., it should cover all relevant aspects of services). Secondly, it should facilitate *incremental development* by incorporating certain concepts and relationships at an initial phase and then defining new ones, or creating instances as needed. Due to the decentralised responsibility scheme for public services, it is desirable to build an ontology scheme that can be jointly developed by multiple authoritative sources. Each source would maintain its own portion of the ontology, and the combination of all portions would form the global perspective. The ontology should allow the extraction of different *views* or *taxonomies* (Adams et al., 2002) enabling public service stakeholders to navigate within the ontology concepts as best suited to their interests, or the task at hand. The *semantics* of the concepts and relationships within the ontology should be clearly defined; semantic ambiguity and ad-hoc concept and relationship types would encumber user navigation within the ontology and hinder reasoning through rules.

The Ontology Template

In order to guarantee that the ontology only contains approved concept and relationship types, the editing process is supported by an *ontology template*, which defines all the allowable concepts and relationships that can be used by the ontology editor. For relationship types, the ontology template also designates which concept types can be linked using any particular relationship. For example, the "offers" relationship type can link concepts of types "service" and "organisation" but cannot two concepts of types "service" and "legislation". Table 1 lists some of the main ontology template concepts, while Figure 1 illustrates these concepts, along with associated selected specialisations (sub-concepts), as modelled using the KAON tool (http://kaon.semanticweb.org/).

In Figure 1, only *isa*-type relationships (specialisations) are displayed, for clarity purposes. The input for this ontology was gathered from e-government public service stakeholders (including managers, domain experts, help desk workers and IT staff) in three European countries (UK, Greece, and Spain). Cognitive maps (Axelrod, 1976) were the basic tool for guiding the input collection process.

Ontology Population

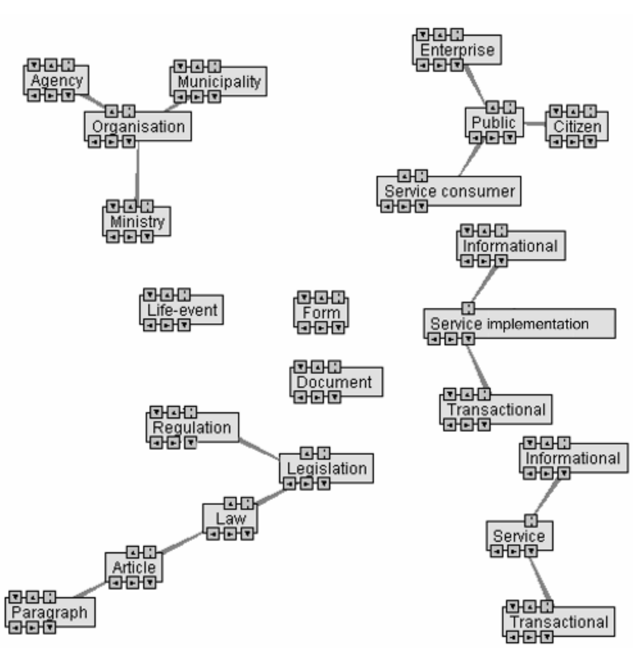
The ontology template is the basis for enabling the ontology development process, since it defines the semantics available to ontology editors. A second necessary step is the definition of *administrative responsibilities*, associating editing rights on portions of the ontology to different public authorities. Under this scheme, first-level administration entities (such as ministries) are created as *instances* of the relevant "organisation" sub-concept and are granted the privilege to create sub-concepts or instances of concepts in the ontology. For example, the Ministry of Finance may create the "Taxation Office" concept as a sub-concept of "Agency" and instantiate it multiple times to populate the ontology with information about tax offices. Additionally, the Ministry of Finance can directly instantiate a concept of the ontology template (e.g., "regulation") to provide data for a new piece of legislation. The organisation creating a specific sub-concept or instance is its *owner* and automatically assumes full permissions on it. Other organisations may view all sub-concepts and relationships between them in the "global" view, however they cannot modify them. Establishment of relationships between concepts may be subject to restrictions, depending on the relationship semantics. For example, the "offers" relationship linking an organisation to a service can only be established by the organisation that is administratively responsible for the service. Such a linkage states that the organisation has the right to offer this service and enables it to create an instance of the "service implementation" concept, which describes the characteristics of the specific service offering. Conversely, no restrictions are placed for the establishment of the "involves" relationship between a life-event and a service, since life-events may include services offered by any organisation, regardless of the organisation defining the life-event.

Both concept and relationship instances host various data items describing the information items they represent, constituting thus *meta-data*. The allowable data items per concept and relationship type are recorded

Table 1. Concepts in the ontology template

Concept	*Description*
Service	A means offered to the public for conducting business with the government.
Service consumer	A citizen or enterprise that is a potential user of a service.
Organisation	A governmental division that is responsible for defining and/or offering services to service consumers.
Service implementation	A concrete form of a service offered by an organisation and made available to service consumers.
Legislation	Any type of official document or practice that regulates the operation of services.
Form	An instrument through which a service consumer requests a service, typically by provision of field values and submission.
Document	An official certificate issued by services.
Life-event	An incident for a service consumer that necessitates the use of a number of services.

Figure 1.Part of the e-services ontology



within the ontology template. For example, a "service implementation" concept instance contains data slots regarding the method for invoking the service (Web form, Web service, RMI, etc), the address at which the service is accessible (e.g., URI for Web form, WSDL file location for Web services and so forth), the expected turnaround time for an invocation etc.

Service Composition Using the Ontology

Two of the relationship types defined in the ontology template, namely the "issues" and "uses", are of particular interest for the purposes of service composition. A relationship of type "issues" between an instance of the "service" concept and an instance of the "document" concept, asserts that the specific service may be used to obtain the designated document. A relationship of type "requires" between an instance of the "document" concept and an instance of the "service" concept declares that the service uses as input a document of the indicated category. For example, a "requires" link pointing from the "Marriage License Issuance" service to the "Birth Certificate" document illustrates that service consumers must present a "Birth Certificate" document as input to the "Marriage License Issuance" service. These relationship types can be exploited by *dynamic service composition engines* to formulate on-the-fly *service composition paths*. When a service S is requested, the service composition engine extracts all relationships of type "requires" emanating from it to identify the required input documents and, by subsequently following the "issues" relationships, the services producing these documents are pinpointed. This procedure is iteratively executed until no further dependencies exist. Note that if multiple services can issue the same document, or if multiple implementations for a single service exist, the service composition path will contain alternative routes leading to the desired result. The service composition path enactment mechanism may select the most prominent routes, employing optimisation criteria (e.g., current system load or expected turnaround time of services, as indicated by the metadata in the ontology).

Service Cataloguing through the Ontology and Ruels

The ontology can be exploited by service cataloguing mechanisms (e.g., portals), to present service consumers with flexible means for locating services. Since service catalogues are generally organised as taxonomies, the first step towards building a catalogue is to locate the taxonomy root entry. This can be any top-level concept (e.g., "Organisation", "Life-event" or "Document"). Afterwards, sub-concepts and instances are extracted to formulate lower-level taxonomy branches, and relationships are used to identify services that will become the taxonomy intermediate-level or leaf nodes. For example, if the "Life-event" node is used as root entry, its instances ("Birth of a child", "Building a house" etc.) are extracted and afterwards the "involves" relationships between the life-event instances and the respective service instances are traversed to populate taxonomy branches with pertinent services. Through this approach, the ontology may be used to create multiple service classification schemes, by selecting alternate root entry concepts and/or traversing different relationship types. The rules for service catalogue creation (i.e., the definition of concept and relationship types that will be used, the order of processing etc.) can be stored alongside the ontology, or be incorporated within each service cataloguing mechanism. Finally, querying mechanisms may be provided to enable service consumers to locate elements of the ontology whose contents match a set of criteria (e.g., the name of a service or a document), as an alternative to browsing.

FUTURE TRENDS

Ontologies are considered nowadays a key element for semantic interoperability, and information exchange between computers and humans in high complexity environments, providing an effective means for representing information in high levels of abstraction. For a more efficient use of ontologies, it would be beneficial if the immediate possessors of the knowledge could directly maintain the relevant ontology portions, without ontology experts' intermediation. To this end, ontology elucidation frameworks should be designed and appropriate tools must be developed and made available to domain experts.

Temporal characteristics are also of particular importance, especially in highly volatile environments such as the one of public services. The ontology framework must be thus extended to cater for the creation and querying of concept and relationship versions, maintaining simultaneously temporal consistency rules for concepts, relationships and instances (e.g., only one version should be active at any point in time).

CONCLUSION

In this article we have presented an ontology for e-government public services. The ontology covers multiple aspects of services, including administrative responsibility, involved documents, legislation, and metadata, formulating a semantically rich network of interrelated concepts. This network can be jointly developed by public administrations, subject to administrative authorisation, and directly supports essential tasks of service provision, such as service composition, change management and service cataloguing. This ontology may be complemented with active mechanisms, including rule processing engines, workflow enactment modules, etc., to deliver value-added services (e.g., invocation, coordination, and data exchange between the constituent services within a service composition path). Future work will focus on the definition and management of temporal characteristics, the creation of an integrated platform that will fully manage the ontology and encompass mechanisms for provision of value added services. Integration with third-party information systems, such as legal databases for extracting legislation information, will be also considered.

KEY TERMS

Change Management: The procedure that controls the evolution of public services to keep them consistent with their governing legislation, user needs, technological developments etc.

E-Service Catalogues: Mechanisms enabling service consumers to locate the available e-services. Most often, these mechanisms are hierarchical classifications of the services under some categorisation axis (offering organisation, target group, etc).

Life-Event: An incident for a service consumer that necessitates the use of a number of services.

Ontology: An ontology defines the terms used to describe and represent an area of knowledge, defining classes (or concepts—general things in the domain of interest), the relationships that may exist among things and the properties (or attributes) those things may have. A set of concepts interrelated by binary typed roles. The concepts may be organised in specialisation/generalisation hierarchies. Ontologies may be used for information exchange between computers and humans in environments of high complexity.

Ontology Distribution: A mode of semi-autonomous maintenance of ontology data, according to with each public authority maintains specific portions of an ontology.

Public Service: A means offered to the public for conducting business with the government. The service may be directly targeted to be used by humans (e.g., Web forms and the associated back-end programs) or be oriented towards invocation by information systems (e.g., a Web service).

Reasoning: The extraction of information not directly available, mainly through the application of rules on the given facts. This procedure is driven by the reasoning engine.

Service Composition: The combination of simple services to achieve a value-added result and fully service the needs of a service consumer (citizen or enterprise) in a particular point in time

Ontology-Based Query Formation and Information Retrieval

Sheng-Uei Guan
National University of Singapore, Singapore

BACKGROUND

M-commerce is largely unrealized to date because there still does not exist a single killer application that can attract wireless users to use wireless services. According to a recent survey by the Gartner, Inc. (Wong, 2005), besides the importance of coverage of wireless network and pricing issues, the wireless Internet and data services is the next crucial factor that attracts users to wireless service. As such, there is a need to improve the data services over the wireless network. One of these services is the information retrieval service.

This article discusses the usage of ontology to create an efficient environment for m-commerce users to form queries. The establishment of a method that combines keyword searches with using ontology to perform query formation tasks further allows a more flexible m-commerce environment for users. Also, with the use of genetic algorithm, it is hoped that query effectiveness can be achieved, at the same time saving computational time.

Definition of Ontology

In artificial intelligence, ontology is defined as a design of a conceptualization to be reused across multiple applications (Bailin, 2004; Braga, Werner, & Mattosso, 2000; Fensel, 2000; Hendler, 2001; Riza & Oguz, 2002). A conceptualization is a set of concepts, relations, objects and constraints that define a semantic model of some domain of interest. In other words, ontology is like the structure that describes or encodes the conceptualization in any relational aspect (Ambrosio, De Santos, De Lucena, & De Silva, 2004; Karp, 2000; McGuinness, 1998; Sugumaran & Storey, 2003).

Chandrashekaran and Josephson (1999) described ontologies as the conceptualization that underlies knowledge, without which there will not be a vocabulary for representing knowledge. Besides modeling knowledge, the ontology is also a structure that can be made publicly available, thereby enabling knowledge sharing.

According to Howarth (2004), in agent technology, ontology is especially useful, as agents are able to learn the behavioral patterns of constraints and resources of business networks. These intelligent agents are then able to store their knowledge into an ontological structure which, besides storage, enables the observation of the interaction of the resources. Ontology, therefore integrates intelligence into the nodes of the network, providing a context in which intelligent decisions are made.

Literature Review

Unlike in e-commerce, query information using keywords alone in m-commerce is unrealistic, as mobile devices are too small and keypads are not suitable for typing. Moreover, it may be difficult for the user when vocabulary of subject is unfamiliar. Thus, relevance feedback is still the main technique for query modification.

Relevance feedback technique has been investigated for more than 20 years in various information retrieval models, such as the probabilistic model and vector space model (Boughanem, Chrisment, & Tamine, 1999; Salton, 1989). It is based on randomly changing the set of query terms as well as the weights associated with these terms according to the document retrieved and judged during the initial search.

In genetic algorithm, much research (Boughanem et al., 1999; Guan & Zhu, 2004; Kraft, Petry, Buckles, & Sadasivan, 1994; Kouichi, Taketa, & Nunokawa, 1999; Yang & Korfhage, 1994) has been done on how it (GA) can be used in information retrieval. One popular approach is query restructuring, which is used to improve the efficiency and effectiveness of the queries formed. GA actually extends the concepts of relevance feedback. The difference is that genetic algorithm uses more than one query and compares the fitness among these queries. The fittest query will survive in the end. Thus, this article focuses on extending the concepts of using genetic algorithms in query restructuring.

Fitness Functions

There are a number of measures of query fitness used in previous works, namely precision and recall retrieved (Kraft et al., 1994; Salton & McGill, 1983), average search length (Losee, 1991), and average maximum parse length (Losee, 1991).

Precision is the percentage of documents retrieved that are relevant, whereas *recall* measures the percentage of the relevant documents retrieved (Kraft et al., 1994; Salton & McGill, 1983). These two terms tend to be inversely proportional so that one is traded for one another in most situations. *Average search length* is the average number of documents or text fragments examined in moving down a ranked list of documents until arriving at the average position of a relevant document (Losee, 1988, 1996). Evaluating the performance of a filtering or retrieval process with average search length provides a single number measure of performance. *Average maximum parse length* is the average (over a set of sentences) of the largest number of terms in a parse for each sentence. There are also measures that combine both average search length and average maximum parse length.

Typically, present methods had only dealt with the relevance of the document retrieved. This is reasonable but inefficient because it is rather difficult to indicate the relevance of a document when the number of documents could be very large. This chapter measures the relevance of queries instead of documents retrieved. Based on this, efficiency will be improved significantly as the number of queries will be much smaller than the number of documents retrieved, which is ideal for mobile devices. The objective of this article is threefold: (a) to research the use of ontology to assist the users in shaping up their product enquiries; (b) to study the use of genetic algorithms and agents in query optimization, and (c) to develop information retrieval services for the m-commerce arena. This article proposes a methodology for efficient query formation for product databases and for effective information retrieval systems, which includes the evaluation of retrieved documents to enhance the quality of results that are obtained from product searches.

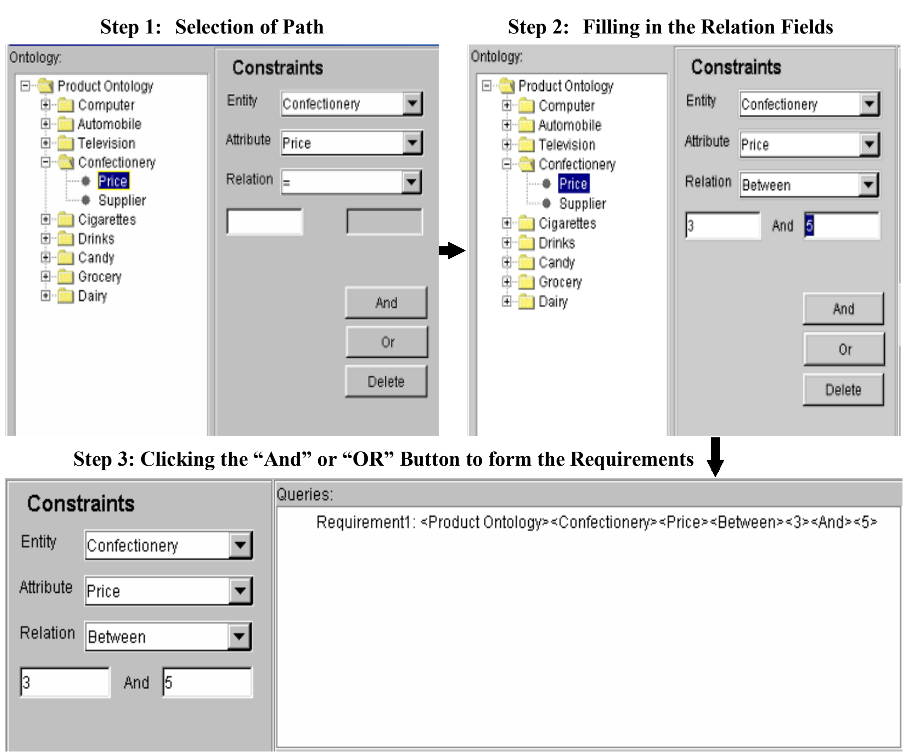
DESCRIPTION OF ONTOLOGY-BASED QUERY REFINEMENT APPROACH

Prototype Design and Implementation

Query Formation Using Ontology

Query formation will be done with the aid of tree ontology. Following the tree path will help form the requirements of a query and thus allow easy forming of a query. An illustration of the query formation process is shown in Figure 1. As can be seen from this illustration, using ontology helps the user to save several steps by forming a query using the ontology path that is selected. Thus, it can be claimed that forming queries using ontology are actually more efficient than using keywords.

Figure 1. Illustration of using ontology to form queries



Combining Keywords and Ontology

The design of parallel combination is rather straightforward. Ontology does not cover everything. Thus, besides having ontology for the user to click on when forming a query, there should be some fields present for the user to fill in. When these fields are being filled in, they can either replace the use of ontology either partially or completely. For a serial combination, keywords are used to look for ontology terms in the ontology. This is necessary because when the ontology is too large, search for an ontology term by manual clicking becomes difficult. Thus, there would be a field that allows the user to highlight the terms in the ontology itself as shown in Figure 2. From this illustration, it can be seen that using keywords to search ontology terms in the ontology creates an efficient environment and context for the user.

Information Retrieval

Using the query formed by the query formation application, an application searches the databases to retrieve information. Intuitively, this application would first do a normal search before allowing the user to proceed with a genetic algorithm search. This is because a genetic algorithm search would definitely take a much longer time than a normal search because of its expensive iterations. The retrieval results are presented to the user and if he is not satisfied, he can then choose to proceed with a genetic algorithm search.

Genetic Algorithm

If the user requests for the use of a genetic algorithm, the system will request for some input from the user to perform genetic algorithm computation. The system then creates a population of queries from the original query. Basically, genetic algorithm will mutate the queries according to the synonyms of the terms in the ontology.

The Fitness Function

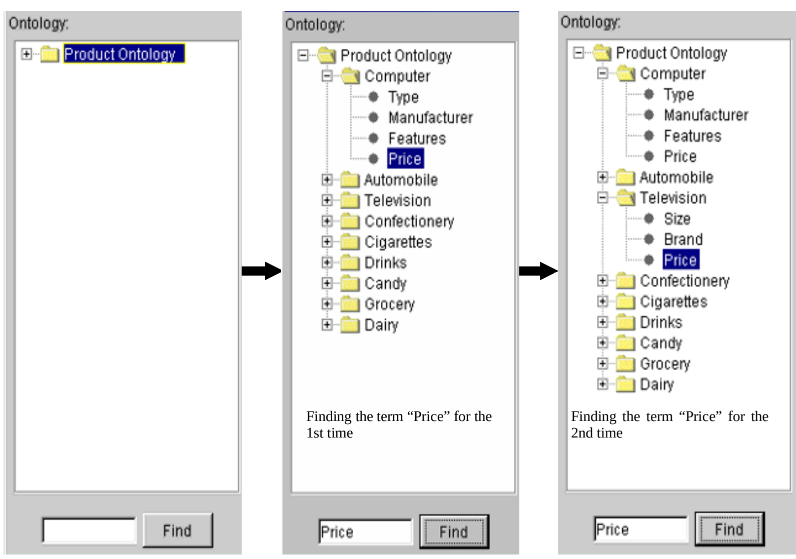
The main concern of using genetic algorithm is the design of the fitness function. In this application, three major elements are used to define the fitness function, namely, the fitness of the number of documents retrieved (f_d), the fitness of the average quality of the query results (f_q) and the overall correlation for the query (f_r). The fitness of each chromosome is calculated as follows:

$$\textit{Fitness} = |f_r \cdot (f_d + f_q)|$$

| . | indicates that the fitness function is normalized to form a population distribution function.

The calculation of the value of f_d is not straightforward. Let i be the ideal number of documents specified by the user. If the user does not know the value of i, the default value will be 20. Using the value of i as the mean value, two "band pass filters"-like functions, namely the triangular and Gaussian functions, are used to create a more flexible mapping from number of documents retrieved (d) to f_d. The triangular function gives a constant

Figure 2. Illustration of the sequence of events for finding ontology terms



drop in "gain" (decrease in fitness) from the "center frequency" (the mean). This function is good when the user wants to give an equal amount of demerits for every document that is away from his expected or ideal number. The Gaussian function is a more robust or high-ordered "band pass" such that its" bandwidth" could be specified by the value of the standard deviation. Thus, this function is useful when the user wants to give heavy demerits to queries that do not fall near his expected or ideal number.

Only requirements that are specified by numerical constraints will have the value f_q. Here, it is required that the numerical values are summed up and averaged. Then, they are normalized. The signs "<" and ">" formed during the query indicate the direction towards which the quality is favored.

Another interesting portion that contributes to the fitness function is the correlation of the synonyms (f_r) with the ontology terms. A value from 0 to 1 is assigned to each relation between the ontology terms and their synonyms. When a requirement is <Television> <Price><<><2000>, the value or f_r will be the product of all the discrete correlations. Also, the user should be able to edit the correlation values to his preference. When there are many requirements in the query, these requirements will be linked with an "OR" or "AND" term.

Mutation and Crossover

The concept of mutation is to replace some terms with synonyms when parsing the results. Basically, the mutants are the terms that are included in each query. These terms are mutated randomly according to the synonyms so that new populations will be formed. Crossover will only be just interchanging the different genes between two different chromosomes. A 1-point crossover will be performed. This is also done randomly.

Feedback and Selection of Survival

The survivors are selected according to their overall fitness in the roulette-wheel selection manner. However, before this is done, the system will prompt for feedback from the user. The feedback will show the user some quality of each query. From this quality metric, the user may choose to kill queries that do not meet his requirements. Figure 3 shows a screenshot of a feedback presented to the user. If the user is satisfied with the results, he can choose to end the genetic algorithm by clicking on the "Stop" button. In this way, he can look at the retrieved results immediately.

Prototype Testing and Evaluation of Genetic Algorithm

Effectiveness of the Genetic Algorithm

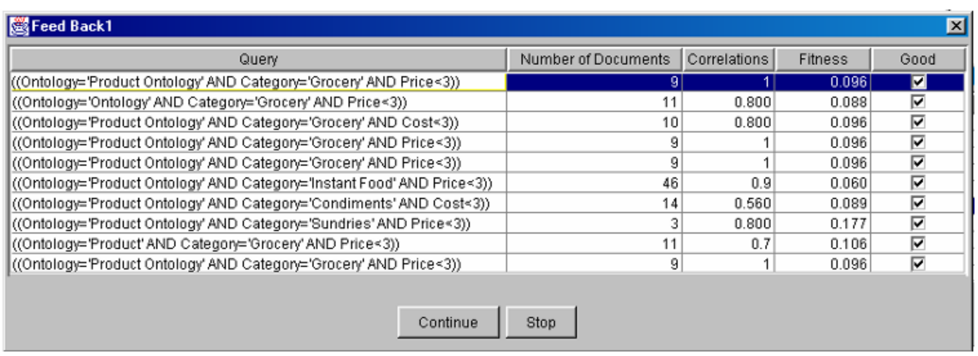
It is believed that the effectiveness of the chosen genetic algorithm is mainly determined by its supremacy in query effectiveness amplification. This is because its evolution power allows more retrieval results. The system was tested with a product list database. The effectiveness was measured by testing a series of queries with and without using genetic algorithm. For example, a query, "<Product Ontology><Grocery><Price><<> <3>", can retrieve only 9 items when a normal search was performed but can retrieve 98 items when genetic algorithm was performed. Table 1 shows the other results obtained by other queries.

By comparing the results shown in Table 1, it is obvious that using genetic algorithm does, in fact, retrieve more items than using a normal search.

Effect of the Fitness Function

The fitness function in a genetic algorithm determines how well it can optimize a query. The OntoQuery system tested out various fitness functions to improve the power of the genetic algorithm. The usage of triangle or Gaussian functions to evaluate the fitness for the number of documents retrieved suggested some ways to counter the "too

Figure 3. Screenshot of a feedback frame



Query	Number of Documents	Correlations	Fitness	Good

<Product Ontology><Confectionery><Supplier> <Contains><Ho>	1	52

many or too few retrieved documents" dilemma in typical search engines.

Efficiency of the Genetic Algorithm

Although using genetic algorithm allows a more flexible and effective platform in retrieving information, there is no doubt that it trades off efficiency due to its expensive iterations. Thus, the only study that can be made here is about its improvement over relevance feedback. In relevance feedback, query expansion is achieved by modifying a query. Similarly, genetic algorithm extends the relevance feedback techniques with an additional rule, the survival of the fittest.

In this research, the efficiency of the system is measured as follows:

$$\varepsilon\,(\text{Efficiency}) \approx \frac{E}{t} \approx \frac{D}{I}$$

where E denotes the effectiveness of the system,
t denotes the time taken for the system,
D denotes the number of relevant documents retrieved, and
I denotes the number of iterations.

Efficiency is formulated as above because it is believed that the number of documents retrieved is linearly proportional to the effectiveness of the system. Also, the number of iterations is directly related to the time taken to retrieve the results.

IMPACT OF ONTOLOGY-BASED QUERY REFINEMENT APPROACH

Both keyword-based and ontology-based approaches have their advantages and disadvantages. Ontology provides the structure, context and visual aid while keyword provides a direct search mechanism. Both approaches are relevant for mobile commerce because they save time in browsing and searching, which is very much required by mobile users who are always on the move. Thus, by combining keyword queries with ontology, it is possible to achieve a better and more effective query formation. Before ontology terms are accessed to form the queries, there will be a keyword search to find the required ontology term. For example, ps2 can be hidden in the node "mouse" when presented in the ontology. The user will not be able to know where ps2 can be found intuitively without eyeballing the ontology. With the help of keyword search, the term *ps2* can be found easily.

In forming queries, there can be a high chance that the vocabulary used by the user to describe a query does not exactly match the vocabulary used by a query system (Preece et al., 1999). This will result in getting insufficient information. Therefore, restructuring dealing with domain ontology relationships might be useful. These relationships involve semantic links such as hyponyms and synonyms (Braga et al., 2000). Using synonyms is an adequate option to restructure queries because it correctly broadens the scope of search, even to the extent of different languages.

When too little information is retrieved, the use of synonym or hyponym might be necessary in order to relax the constraints of the query. This approach, however, has a major disadvantage. By relaxing the constraints of a query using synonym or hyponym to increase the number of documents retrieved, one could actually deface the meaning of the original query such that it could drift away from the user's intention. This concern can be alleviated by having user feedback along the process. Also, we have considered to relax constraints step-by-step. This option can better eliminate the chances of constructing far-fetched queries from the use of genetic algorithm.

CONCLUSION AND FUTURE WORK

This article investigated the OntoQuery system within an m-commerce agent framework against current query formation and information retrieval systems from extant work that were not intended for m-commerce. The prototype implementation results showed that querying formation using an ontology approach is efficient as it provides a friendly environment to the user using mobile devices. In addition, by combining the keyword and ontology approaches, a more efficient and effective way of forming queries could be achieved. Thus, the objective to propose efficient query formation for product databases is successful.

It was found that genetic algorithm is able to optimize queries effectively. Also, using genetic approaches, we have proposed and tested out various fitness functions for searching product databases. Moreover, adding feedback to the system helps it to cater to the needs of the user more closely.

Considering typical e-commerce or m-commerce users using mobile devices for product enquiry tend to have some time constraints and they need quick response before making decisions, our work suggests a feasible approach. With the use of ontology, product enquiry can be formed easily and quickly. With the help from genetic algorithms and agents and the technique of query optimization such as query restructuring, futile enquiries can be turned into productive. And finally, the use of genetic algorithms help improve the quality of product information retrieved.

We consider the following for future work. With the usage of synonyms, it is rather tedious for the user to add synonyms to his ontology terms. There is a need to automate the learning of synonyms from other agents. The synonym table of each agent may start off as one with only a few synonyms. Because the synonym table is also an ontology, learning synonyms can be achieved by ontology exchange. During the interaction among agents, the agents will exchange their synonyms for a particular query or even during product ontology exchange.

KEY TERMS

Agent: A software agent is a piece of autonomous, or semi-autonomous proactive and reactive, computer software. Many individual communicative software agents may form a multiagent system.

Genetic Algorithm: A genetic algorithm (GA) is a heuristic used to find approximate solutions to difficult-to-solve problems through application of the principles of evolutionary biology to computer science.

Information Retrieval: Information retrieval (IR) is the art and science of searching for information in documents, searching for documents themselves, searching for metadata which describes documents, or searching within databases, whether relational stand alone databases or hypertext networked databases such as the Internet or intranets, for text, sound, images or data.

M-Commerce: M-commerce or mobile commerce stands for electronic commerce made through mobile devices.

Ontology: In computer science, ontology is the product of an attempt to formulate an exhaustive and rigorous conceptual schema about a domain.

Relevance Feedback: Relevance is a score assigned to a search result, representing how well the result matches the search query. In many cases, a result's relevance determines the order in which the result is presented to the user.

Open Content Distribution Management in Virtual Organizations

Amir Hassan
Lappeenranta University of Technology, Finland

Herkko Hietanen
Lappeenranta University of Technology, Finland

INTRODUCTION

Future scenarios of **organization**s envision companies that are organized around a central **knowledge** base in the form of a **network**. It is assumed that each company contributes its own expertise and intellectual capital to the network's knowledge base. This article discusses the use of **open content** distribution management systems (OCDMSs) in knowledge-intensive fields, such as content production and software development, in order to ensure seamless and open collaboration between the firms in the organization.

OCDMSs offer participants several advantages. For instance, such systems can be seen as a way of enhancing the competitiveness of small and micro-sized knowledge-based firms by ensuring that each firm receives fair compensation for the content it develops. OCDMSs are revolutionary in the sense that they allow participants to contribute content to a common resource pool and add all the required **metadata** to the content. A common information pool where information is shared with well-defined rules lowers transaction costs between participating organizations. This article looks at one open content distribution management system that was developed in a university-industry research project and is being further developed by a company that is a spin-off company from the project.

BACKGROUND

Virtual Organizations

Developments in information technology as well as new organizational concepts have led to the emergence of new types of organizations. Miles, Miles, and Snow (2004), Miles and Snow (1995), and Miles, Snow, and Miles (2000) have discussed network organizations that rely on collaboration between independent units. The term virtual organization has become ever more commonplace in organizational literature. Walters (2004) discusses the business model of the virtual or holonic organization and refers to McHugh, Merli, and Wheeler (1995) in listing the following properties of a virtual organization.

- The organization consists of businesses of equal standing; that is, there is no hierarchy between the individual businesses in a virtual organization.
- Information can be accessed and exchanged freely throughout the organization and across its boundaries; that is, the organization is open.
- The organization is evolutionary and is involved in constant interaction with its environment.

One interesting form of virtual organizing is the virtual web, defined by Franke (1999) as "the base of virtual corporations" (p. 211). According to Franke, a virtual web belongs to the typology of dynamic networks, as defined by Miles and Snow (1986), which has the following characteristics.

1. **Vertical Disaggregation:** Different organizations in the network perform separate functions that have been performed by functional units in a traditional organization.
2. **Brokers:** Brokers bring together the necessary functions available in the organization and play a leading role in building business units and subcontracting for needed services. Brokers can operate at different levels of a dynamic network and, thereby, have varying degrees of responsibility.
3. **Market Mechanisms:** These hold the network together and regulate its functioning. Competition is promoted amongst the members of the network and also with external companies, and this regulates the internal prices of the services available in the network.
4. **Full-Disclosure Information Systems:** Companies wishing to become a part of the network, even for a fixed-term project, are expected to connect their information systems to the network's continuously updated information system via broadband access in return for a general payment structure for the value they add to the network. The purpose of this,

according to Miles and Snow (1986), is to facilitate the rapid and mutual assessment of contributions and to speed up the trust-building process.

According to Franke (1999), virtual corporations are involved in temporary partnerships established by brokers in a virtual web in order to bring together the necessary combination of skills and resources. In order for a virtual web to successfully generate virtual corporations, the web must offer an environment that encourages the member companies to participate in virtual corporations without compromising confidentiality and intellectual property rights, while, at the same time, preserving the dynamic and flexible properties of the virtual corporation.

Virtual Communities

Lee, Vodel, and Limayem (2003) have analysed various definitions of virtual communities and have identified four elements that they found common to most definitions. First, a virtual community should exist in cyberspace; that is, the members of a virtual community use computer-mediated spaces in order to interact. Second, the activities of a virtual community are supported by computer-based technologies, such as e-mail, message boards, and chat. Third, the main focus and content of virtual communities are participant driven, and the content of such communities is formed through the communication between the members of the community. The fourth and final element that Lee et al. found to be common to all virtual community definitions was the formation of a sustained relationship as a result of the interaction between the members of the community. Koh and Kim (2003-2004, 2004) have also observed cyberspace to be a usual feature for identifying virtual communities. However, they also found the interaction of many virtual communities to take place off line as well as online, especially in the case of communities that have originated off line. Koh and Kim's definition of a virtual community is "a group of people with common interests or goals, interacting for knowledge (or information) sharing predominantly in cyberspace" (p. 157). Etzioni and Etzioni (1999) point out the discrepancies in the definitions given for computer-mediated communities (CMCs) by different authors; some authors may refer to tightly knit communities while others to groups of acquaintances. The authors have found communities to have two common features: networks of relationships that may overlap rather than single links between the members, and a common set of values and norms to which the members of the community adhere and are committed and a common shared history.

One of the most productive virtual organization models is the free and **open source** software (later FOSS) movement (see DiBona, Ockman, & Stone, 1999). It uses licenses that allow the use and modification of FOSS program components. Open-source licenses grant rights that are otherwise exclusive to the copyright holder. FOSS licensing enables the flexible but controlled use of software resources. FOSS is a multibillion-dollar business that has shown how less restrictive content sharing can lead to considerable benefits for the whole software industry and society at large.

The uncontrolled sharing of information goods leads to exploitation that does not benefit content providers or society in the long run. According to Kwok, Yang, Tam, and Wong (2004), digital and peer-to-peer (P2P) technologies have made it easier to produce and distribute illegal copies of copyrighted material. Thus, a virtual web that is supported by a common broadband information system, to which all the participants are linked, poses risks in terms of content and copyright management. Digital rights management (DRM) is one of the concepts for managing the rights of information products. Benkler (2002) points out how computers have changed copyrights into "privately created and enforced exclusion—created by contracts and enforced by technology" (p. 81). In most cases, DRM systems limit access to information through the use of technical protection measures. This does not serve the purposes of virtual organizations. While DRM might be an overly restrictive tool, some control is needed. This can be obtained by using digital rights expression (DRE).

DIGITAL RIGHTS EXPRESSION

In the digital environment, it is possible to attach a license to a work. Most new music, image, and text formats have a field reserved for metadata. The attaching of metadata that describes the copyright status of a work is called digital rights expression. DRE uses semantic web methods to let users know of the permission that they have. Unlike DRM systems, DRE does not use technical means to restrict users from violating these terms.

One of the most commonly used ways of expressing digital rights is W3C's (World Wide Web Consortium's) resource description framework (RDF). It provides a foundation for the processing and exchange of machine-understandable information on the Web. RDF can be used for cataloguing (to describe content that is in a digital format on a Web page, in a digital library, or on a P2P network), for resource discovery (for example, to let a search engine search for works that have certain licenses), and by intelligent software agents (to facilitate knowledge sharing and exchange) in content rating. The W3C glossary (http://www.w3.org/2003/glossary/) defines metadata as "Data about data on the Web, including but not limited to authorship, classification, endorsement, policy, distribution terms, IPR, and so on." Most file formats support metadata. Metadata can be easily attached and read from Mp3, PDF (portable document format), mpeg4, and HTML (hypertext markup language) formats. Machine-understandable metadata can be used to efficiently define rights in the information management system of a virtual organization. Metadata can hold pricing and author information as well as licensing terms.

Open content can be briefly defined as being creative works that are in a format that explicitly allows their copying and distribution. Open content must also have a license that allows copying and distribution, or must belong to the public domain. By automating the licensing procedure, transaction costs can be further lowered. While the licenses are expensive to write, they can be used over and over again with minor modifications. These modifications can be made automatically through the use of a licensing engine. In this way, licensing can be fixed to an organization's work flow. Creative Commons (http://www.creativecommons.org), a nonprofit organization, has produced a set of open content licenses and a Web interface that allow content producers to tailor copyright licenses that suit their needs. They also provide licenses in RDF format. More than 4 million works have been licensed with Creative Commons licenses.

Open content files carrying legal metadata serve virtual organizations by lowering transaction costs. Members of an organization do not have to search for the holders of the rights and negotiate license agreements, and they have the content at their disposal. Open but controlled sharing also has a positive impact on marketing (Nadel, 2004). Benkler (2002) notes how organizations should adapt different information policies and levels of exclusivity depending on their business models. Open content systems benefit creative networks that depend on cooperation.

For the rights holder, the system enables easy licensing, a distribution channel, and the possibility for price discrimination. The price can be set dynamically for different projects. For example, the Magnatune record company (http://www.magnatune.com) uses dynamic pricing for their records that are available online. Magnatune music is available for free for noncommercial use, but commercial licenses must be bought from the Magnatune Web site. The price is preset and is fixed by the licensee, who has to enter the details of the commercial activity. Magnatune's system calculates the prices of licenses, which depend on the size of the budget and the rights to be licensed. The system also generates a license that is valid after the license payment has been made.

AN EXAMPLE OF AN OPEN CONTENT INFORMATION SYSTEM

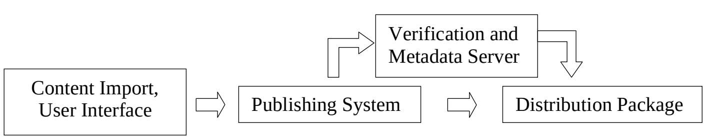
Virtual organizations and communities that have grown on the Internet and out of networks of content-production companies need systems for managing content contributed by their members for common use. This article discusses one such system, the Digital Content Distribution Management System (DiMaS). DiMaS is a prototype of a system designed for use within a community of content producers and was developed in cooperation with the Digital Economy Core (DE Core) and Mobile Content Communities (MC^2) research projects at the Helsinki Institute of Information Technology (HIIT).3 The following description is based on two papers by Reti and Sarvas (2004a, 2004b) that outline the functions of the system.

DiMaS enables multimedia producers to publish their works along with content metadata. The content-import user interface is the front end of the system and contains the user registration, user-information database, log-in, user manual, and content-import functionalities. At the point of registration, the user must accept the system's rules of conduct. After registration, the content provider can upload content to a server. Users enter content-related metadata using a chain of Web forms that appear in a particular succession and between which the user can move freely backward and forward. During the upload procedure, the content provider can add metadata, preview files, and feedback questions for the primary content payload. Once entered, the content file, metadata, and preview image are stored in the system until the user publishes them using a specific control button in the user interface.

The structure of the DiMaS system is shown in Figure 1.

After being uploaded, the content is forwarded to the publishing system. The publishing system forms a distribution package using the inserted content file, pre-

Figure 1. The structure of DiMaS



view file, user interface, and metadata. The publishing system can be in a closed or open environment. Publishing can be performed in uncontrolled peer-to-peer networks, such as Gnutella or KaZaa. DiMaS also enables content encryption. In this way, the content can be distributed on public P2P networks and stored on uncontrolled servers. If the content is access controlled, it is not open content.

When consumers, or other end users, find content that they want, they can download and open it, for instance, on their PDAs (personal digital assistants). When opening the content, a user application that resembles a DVD (digital videodisc) menu appears and the system can update the content metadata, for example, the description of the content stored on the metadata server. This makes it possible for the content provider to change the pricing or licensing terms after the content has been uploaded and even after it has been distributed to end users. This feature can be used to set the price of the product according to the product's life cycle. Novel works may carry a higher price tag than vintage material. The system can also notify the user when a new version of a work is available. Users can browse through the copyright license or contract in the price section of the application. The only technology required by the end user in order to run the distribution package is the Java Standard Edition Runtime Environment (http://java.sun.com).

In open content mode, an entire virtual organization can browse the content freely. The metadata inform users on how the content can be modified or exported out of the virtual organization for commercial use. DiMaS also has a feedback option. The system can collect user feedback after content browsing and store this information along with the metadata. Feedback enables content rating, which helps to distinguish premium content from large information masses.

DiMaS is an MIT-licensed open-source product and can be customised to meet the needs of specific content-production communities. The goal of DiMaS is to be executable without specific client software and independent of the type of content to be distributed. The DiMaS prototype supports Windows Media Player files and, as mentioned above, requires that the user have the Java Standard Edition Runtime Environment installed on his or her system. As yet, DiMaS has not been used in any real-life organizations since it is still in the prototype stage.

CONCLUSION AND FUTURE TRENDS

This article has discussed the problems related to the management of digital rights in virtual communities and the meaning of open content systems. It also presents the prototype of one system for content distribution: DiMaS. DiMaS allows content producers to attach metadata to their works, share works on a publishing platform, and modify the metadata attached to content after the content has been published. DiMaS enables version handling as well as the dynamic pricing of copyright licenses. Because the system packs the metadata into a distribution package, it does not have to rely on any proprietary file format. This also means that the system can be used to distribute all kinds of content without introducing new file formats or players.

Semantic webs and metadata will be a part of knowledge management in future organizations. The management of the vast knowledge bases of networks will require systems that can handle different types of files and can hold all various types of information. Already, file sharing and P2P technologies have made it important for organizations to have in place tools for the management of content with different rights, and there is a clear market for technologies that allow different users different levels of access to common content pools.

KEY TERMS

Digital Rights Expression (DRE): The attachment of metadata to a work in order to describe the copyright status of that work

Digital Rights Management (DRM): The limitation of the access of users to information in a repository through the use of technical protection measures.

Metadata: Metadata are data about data. In information repositories, metadata are used for labeling the content of such repositories with appropriate descriptions.

Resource Description Framework (RDF): RDF provides the foundation for the processing and exchange of machine-understandable information on the Web. RDF can be used for cataloguing, for resource discovery, and by intelligent software agents in content rating.

Virtual Community: Virtual communities are communities of users that have the following characteristics.

1. They exist in cyberspace and the communication between the members of the community is computer mediated.
2. They use communication technologies, such as e-mail, message boards, blogging, and online chatting, for communication.
3. They develop largely through the activeness and interests of their participants. The content of virtual communities is formed through the communication between the members of such communities.
4. They lead their members to form sustained relationships as a result of their interaction.

Virtual Organization: An organization in which business partners and teams work together across geographical or organizational boundaries through the use of information technology. It is also a strategy for revolutionizing customer interaction, asset configuration, and knowledge leveraging.

Virtual Web: A form of virtual organization that belongs to the typology of dynamic networks and has the following properties.

1. The member organizations of the network perform separate functions that are performed by functional units in traditional organizations.
2. Brokers in a virtual web combine resources to build business units and subcontract to bring together the necessary functions available in the organization. They play a leading role in building business units and subcontracting for needed services.
3. Internal and external market mechanisms hold the network together and regulate its performance.
4. The information system is open, and there is free access to the web's joint knowledge base. Companies belonging to the network have integrated their information systems into the network's continuously updated information system via broadband access in return for a general payment structure for the value they add to the network.

Open Source Community Portals for E-Government

Kwasi Boateng
Ohio University, USA

Beatrice A. Boateng
Ohio University, USA

BACKGROUND

The value of the Internet as a flexible tool for the posting and exchange of information is expressed in the potential it has for governance, commerce, and social interaction. The Internet is symbolic of the *digital revolution* of the 20th century that changed the packaging and dissemination of electronic information. In politics, the potential of the Internet is perceived to be in *e-government.* In the book *The Internet Galaxy,* Castells (2001) indicates how the Internet is expected to be an instrument to further democracy. The Internet has a significant role to play in government or politics; it provides a two-way medium of communication between government and society in flexible personalized and mass forms of communication.

Through the Internet, information can be easily accessed by both citizens and their leaders as a means of effective communication. All kinds of information, public records, service forms and requests, and a wide range of non-classified information can be disseminated on the Web. The interactive nature of the Internet technology allows for on-demand accessing of information in the form of citizen request, the voicing of opinion, and in some cases, asking government representatives for information or answers to issues of concern. The typical use of Internet portals by governments has been in the form of information access points where governments post information without a concerted attempt at interacting with the potential users of the resource. Such approach to e-governance is cast in the traditional mode of top-bottom political activity that focuses on what government leaders or their administrative systems want to give to their constituents, with little concern or regard to issues of interest to their constituents.

Chadwick (2003) makes a distinction between what he calls e-government and *e-democracy.* According to him:

Public administration scholars, public policy analysts, and public management specialists focus on e-government, whereas political communication specialists, social movement scholars, and democratic theorists sharpen their analytical tools on e-democracy. (p. 444)

Chadwick points to the need to have e-democracy, which is found with civil society, and e-government that operates at the local and national levels of political administrations to converge. The discourse of how these two aspects of *electronic politicking* can converge using *open source content management systems* (CMSs) is the focus in this discussion. E-democracy and e-government allude to the fact that electronic politicking has two distinct aspects:

1. **Managerial:** This feature is typical of e-government because it involves government bringing people closer to government by providing an information system that is convenient and prompt in the dissemination and retrieval of information.
2. **Policy Making:** This element is characteristic of the e-democracy in the sense that it entails deliberation of public policy and in some cases advocacy.

Musgrave (2005) identifies these two aspects of e-government as community and civic portals. Castells (2001) indicates that e-government has its origin in the convergence of three different components of online political activities:

…the pre-Internet grassroots movements in search of new opportunities for self-organizing and consciousness-raising; the hacker movement in its most politically oriented expressions; and municipal governments trying to strengthen their legitimacy by creating new channels of citizen participation. (p. 144)

Drupal, Xoops, and *Mambo* are open source CMSs that facilitate the convergence of all the elements of online political activities, and the dissemination of information that usually gets lumped together as e-government. We compare Drupal, Xoops, and Mambo and outline how they can be used as integrated e-government portals. The three CMSs are among the most popular open source CMSs used for creating online communities and systems for the discussion of issues and dissemination of information.

DESCRIPTION OF E-GOVERNMENT APPLICATIONS/SYSTEMS

Open source is software that is developed by software engineers who give users the right to alter the software code in order to develop and improve the software for use and distribution. This approach to software development and distribution has created unprecedented opportunities for the exchange of information between businesses, society, and government. The open source movement is a deliberate attempt to keep access to software code and information open. The movement originated from an initiative by Richard Stallman of the Massachusetts Institute of Technology's Artificial Intelligence Laboratory in 1984. It was an attempt to counter the decision by American Telephone and Telegraph (AT&T) to claim proprietary rights to the UNIX operating system. His efforts were supplemented in 1991 by Linus Torvalds, a student at the University of Helsinki, who developed the Linux system and posted it on the Web for distribution and further development. By 2001, "over 60 percent of World Wide Web servers in the world were running on Apache, which is an open source server program developed by a cooperative network of UNIX programmers" (Castells, 2001, p. 14).

All open source software and applications are developed through cooperative networks of programmers. Drupal, Xoops, and Mambo open source content management systems are also developed by programmer networks that have fashioned them to be useful for the launching of online portals. Open source portals have the ability to be customized and localized in every language. Donnelly and Merrick (2003) identified this type of customization as *communitization*, of which there are two types—protected and public. *Protected communitization* enables "a design to be customized by an acknowledged community representative who adapts a design for a group of people based on their own expert knowledge of the characteristics, abilities and environment of the community they represent." *Public communitization* is the "active adaptation by anyone allowed within the community, in the same way that communities allow participation in forums and chat rooms" (p. 10).

A 2001 Pew Internet study on online communities in the United States indicated that people used the Internet "to intensify their connection to their local community … arrange neighborhood gatherings, and petition local politicians" (p. 2). According to the Pew Internet Research Study, people who joined online communities reported that online communities lowered the barriers that prevented them from democratic participation. Flew (2002) also determined that community portals "reinvigorated [a] sense of community-building and citizen participation in public life" (p. 77).

Interactive online technology has redefined and changed the way society communicates: "The Internet provides virtual third places (different from home and work) that allow people to hang out and engage in activities with others" (Preece, Maloney-Krichmar, & Abras, 2003, p. 5). Preece et al. (2003) described how technologies such as *e-mail, chat rooms, blogs,* and *wikis* have changed the nature of online interactions and facilitated the exchange of ideas and dissemination of information. Such activities have empowered people and promoted development. The type of software used for these online communities is very crucial in the usability of the portal. Drupal, Xoops, and Mambo are CMSs that have the potential to integrate different online interactive features into a portal through the configuration of modules that are developed by programmer cooperatives and are posted online for use.

Drupal, Xoops, and Mambo

The *scalability* of open source CMSs makes them suitable for customization and use in launching sustainable e-government systems. We examined the features of Drupal, Xoops, and Mambo by downloading and installing these software on a Sony VAIO PCV-RS620G desktop computer with a Windows XP operating system.

To be functional, most CMSs use a combination of a Web server, database, programming language, and operating system. Apache Web server is the most widely used Web server. Open source CMSs use either MySQL or PostgreSQL database systems. The programming languages that are often used are PHP, Perl, or Python, and the operating systems used are either GNU or LINUX. The combination of these components is sometimes called a LAMP platform. This enables open source CMSs to run on other operating systems (OSs) such as Windows, Mac OS, and Solaris.

In studying Drupal, Xoops, and Mambo, we documented the following steps that are worth noting for the deployment of an open source CMS portal. We did not do an online installation, but rather installed it on a standalone desktop computer. Since the computer used was not a server, we downloaded Easy PHP 1.7, which consisted of Apache Web server and MySQL open source database with a Web interface. EasyPHP provides a Web interface for MySQL called PHPMyAdmin, which means there is no need to know MySQL coding or programming in order to populate the database you create for the portal. We unzipped the downloaded CMS files and used the Web interface of EasyPHP to install the CMSs onto the computer. The Web interface walks you through the various installation steps, including the creation of the database. After the installations, the rest of the development of the portal depends on identifying modules or components as add-ons for the customization of the portal.

The approach to attaching modules or components on Drupal, Xoops, and Mambo are similar with minor variations. Module attachment in Xoops requires unzipping the files and saving them into a specific modules folder. Mambo eliminates unzipping files, because it has an inbuilt function that unzips the module or component, and installs it in the appropriate places. Drupal requires that modules and module tables be installed through the Web interface of the database, PHPMyAdmin. These processes, although different, are user friendly and make it possible to install modules and components without knowledge of MySQL. The installation and customization of a portal using any of these three open source CMSs can be completed without knowledge of any programming language.

Drupal, Mambo, and Xoops have localization and multi-language support. In order to monitor content posted on sites, Drupal has a review and approval process. With Xoops and Mambo this process is optional depending on the module installed.

Table 1 is a comprehensive comparison of the three products. The aim of this comparison is to show these products can be used for e-government depending on the rationale for setting up the CMS and the needs of the users.

Table 1. A comparison of Drupal, Mambo, and Xoops

Content Management System	**Drupal 4.6.0**	**Mambo 4.5.2**	**Xoops 2.0.9.2**
System Requirements			
License	GNU GPL	GNU GPL	GNU GPL
Server	Apache	Apache	Apache

IMPACT OF E-GOVERNMENT APPLICATIONS

Many e-government initiatives are driven by open source technology. Governments in countries like Brazil, India, and the United Kingdom have recognized the importance of open source applications in creating online spaces where people can interact with their government.

A United Nations press release illustrated how open source software applications are being used to create e-municipalities in Bulgaria, Bosnia and Herzegovina, Croatia, Macedonia, Romania, Serbia, and Montenegro (United Nations Development Program, 2004). Other e-government portals are The Knowledge Village Portal developed by Karakulam Panchayat in India, the E-shringla project (Kumar, 2002), and the Maleny community portal in Australia (MENA, 2004).

The effectiveness and success of e-government platforms requires enthusiasm and expertise in the delivery of information online. The challenge is not with the technology, but politics and how e-government sites are set up. Most e-government platforms are not given the necessary design detail and attention. Many of them are poorly designed and maintained. They are usually set up by content managers who have limited skills in the design and maintenance of online portals.

In some cases, e-government portals are experimental projects that are left to dysfunction after an initial enthusiasm and elaborate work on the site. Over time they are not given the attention, detailed preparation, and delivery of service. Some sites end up becoming passive or less active compared to when they were established. What appears to be affecting most e-government initiatives are the issues of continuity and longevity. Tied in with these issues is the fact that political or administrative personalities that are really interested in e-government portals are usually not tech savvy. Even though, they may posses the drive and the material resources to run an e-government portal, and politicians and administrators may lack the barest minimum of technical skills to do so. Table 2 catalogs the strengths and challenges of e-government.

Increasingly, open source CMSs have emerged to address the issue of skill as a determinant for the running and maintenance of e-government portals. They offer a cost-effective technology package for the setting up and running of portals. Drupal, Xoops, and Mambo offer an opportunity to the content manager with little or no knowledge of Web authoring to process and publish materials after a portal has been configured and launched. They use the WYSIWYG authoring interface to allow portal administrators and users to process and post materials on a portal.

Despite these opportunities, there are still issues related to government and politics that are beyond the digital technology of open source software and CMSs. Technology cannot redeem political and government difficulties. And as Castells (2001) rightly points out:

> *In the world of widespread crisis of political legitimacy, and citizens' disaffection vis-à-vis their representatives, the interactive, multi-directional channel of communication provided by the Internet, finds few active takers on both sides of the link.* (p. 156)

Table 2. Issues related to e-government

Strengths	Challenges
Promotes participation of citizens in political decision making. Helps create a dynamic network of citizens who are well informed Facilitates bottom-up approach to decision making Helps create transparency in government Twenty-four-hour on-demand source of information Helps improve government performance	Involves a lot of planning and design work greater than e-government advocates are aware Investment needs for an efficient e-government portal could be expensive Could become static, one-way government hand-down of information and instruction, instead of a two-way free flow of information The focus could easily be on the technology development instead of provision of service

Nevertheless, the flexibility in online communication that Drupal, Xoops, and Mambo offer provides a lateral system of communication that is relatively inexpensive, but possesses the potential to facilitate the management and legislative functions of government. With a team of highly motivated public managers schooled in the ideas of creative public entrepreneurship of new public management as espoused by Osborne and Gaebler (1992), Drupal, Xoops, and Mambo can be used to deploy e-government systems that will make any government a learning government. Governments become responsive and effective through a system that allows government "to respond to the needs of its citizens, who are in turn able to influence public policies by rapid, aggregative feedback mechanisms such as e-mail and interactive Web site" (Chadwick, 2003, p. 447).

Web portals offer extraordinary potential for the expression of citizen rights, as well as for public management, because they are capable of broadening the sources of communication between citizens, public managers, and politicians.

Given that Drupal, Xoops, and Mambo are not the only open source CMSs available, and given that many public managers who would like to launch a portal get overwhelmed by what technology to use, THE Open source movement has a Web site, Open Source CMS (http://www.opensourcecms.com), which allows potential users to explore various CMSs. This site provides administrator access to anyone willing to evaluate a CMS without having to download and install it.

CONCLUSION

Increasingly, open source CMSs used for community portals have great potential for e-government. They are easy to install and relatively inexpensive compared to their proprietary alternatives. They offer a great opportunity for governments that want to encourage citizen participation in government affairs, but do not posses technology expertise in online publishing. The add-on modules and components enable public mangers in government to promote transparency and increase accessibility to government services.

KEY TERMS

Blog: Short for Weblog. Usually a personal journal on the Web, it could be of opinions, social issues, or reflections. People that blog are often identified as bloggers.

Chat Rooms: Online spaces where virtual users can "converse" in real time about issues of specific interest. Users can engage in both public and private chats with other users.

Community Portal: A Web site tailored for the needs of a community.

E-Democracy: The use of electronic media such as the Internet to enhance democracy.

E-Governance: The delivery of government services in an electronic medium. It also includes the online interactions between government and citizens.

E-Mail: A form of communication in which electronic mail is transmitted via communication networks.

Open Source: Software that is developed by software engineers who give users the right to alter the software code in order to develop and improve the software for use and distribution.

Wiki: Web pages that are editable by users of a site. A form of online collaboration or community development project.

Open Source LMS for Management and E-Business Applications

Beatrice A. Boateng
Ohio University, USA

Kwasi Boateng
Ohio University, USA

BACKGROUND

Advances in computer technology have led to the increase in the use of information technology in business (Barron, 2002). Computer-mediated communication in the form of the Internet offers unprecedented avenues for the exchange of information and the delivery of instructional materials globally and locally (NHDP, 2003; Robey, Boudreau, & Rose, 2000). Through the Internet and related technologies, people are able to acquire skills and knowledge, adapt learning experiences to their own needs, and assimilate information faster (Azad, Erdem, & Saleem, 1999; NHDP).

An organization that is making use of such e-technologies for the advancement of e-business is the Advance Information Technology Institute's Kofi Annan Center of Excellence for Communications and Information Technology (AITI-KACE), established in 2003 in Ghana. The center is a collaborative initiative between Ghana and India, and is aimed at bridging the gap between education and industry. This initiative was in response to Ghana's recognition of the social and economic benefits of information and communications technologies. The center is considered part of a national initiative to educate Ghanaians and unleash their creative potential in the use of digital communication technologies for business and education. It is a major skills-development and training institution whose graduates can transition into industry immediately as employees or employers. Ghana's main challenge is that computer education at all levels is inadequate, and businesses are struggling to incorporate computer applications in their operations. Despite the relative advances made in the adoption of e-technologies in businesses and education, the greatest challenge lies in the fact that a greater part of the adult population does not have adequate knowledge and skills in computer software applications or hardware in order to explore their use in everyday activities or at their workplaces. It is therefore expected that by enrolling in the programs at AITI -KACE, a participant[1] can either be employable or have skills to venture out into self-employment. AITI - KACE targets adults—at least those who have completed high school.

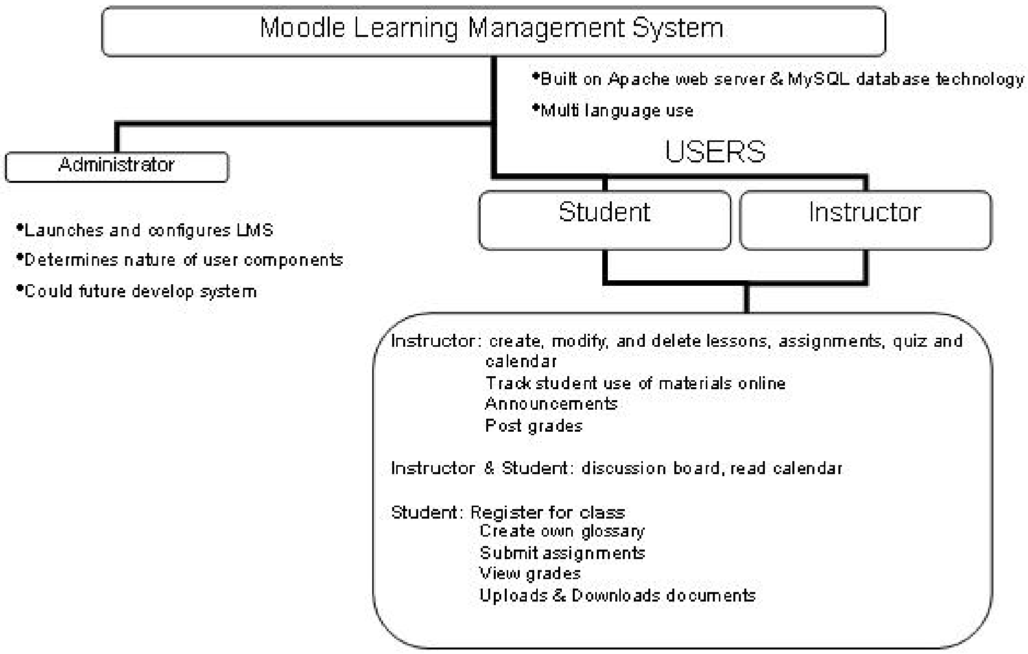
DESCRIPTION OF E-BUSINESS APPLICATIONS

The main technology used by AITI-KACE to deliver instruction and learning materials, and promote e-business solutions is an open-source learning-management systems (LMS). Free and open-source software (F/OSS) is software with an unrestrictive license whose source code is made available for modification, customization, and distribution by others. Martin Dougiamas (n.d.) began the development of the Moodle LMS in the 1990s. However, it was not until August 20, 2002, that version 1.0 was released. Moodle assists in the planning, delivery, and management of e-learning, and is aimed at remedying the fragmented nature of e-learning by creating an integrative system.

LMSs were developed to enable instructors not only to deliver materials in an online environment, but also to track user activities and progress across various learning activities (Barron, 2002). LMSs are characterized by the following customizable elements: a course-development component that enables an instructor to develop a course, a roster component that enables the instructor to enroll users in a course, the assignment-management component that enables the instructor to assign lessons and activities for the users, the courseware-launching component that provides the interface for users to have access to course content and activities, and the data-collection component that enables the instructor to collect and manage information, as shown in Figure 1.

The F/OSS that have been operational at AITI-KACE are Open USS, Eledge, and Moodle. Open USS is an open-source administration system aimed at institutes of higher learning. Eledge is a learning- and course-management system developed by the University of Utah. AITI-KACE

Figure 1. The basic setup of the Moodle LMS



has since discontinued the use of Eledge, but has combined the examination section of Open USS with Moodle as the main system for delivering and managing its online program. The AITI-KACE e-learning-management system is a virtual campus with instructional material on e-technology applications in business such as those required for diplomas in advanced computing (DACs), business computing, Web technologies, and Microsoft .Net technologies; and certificates in C programming, Web programming, and database technologies.

The installation of Moodle requires three other open-source software: Easy PHP, Apache, and MySQL. Easy PHP is a software application written in the dynamic PHP language that combines an Apache Web server and a MySQL database to create flexible Web development tools. Apache is an open-source Web server. Web servers use the hypertext transfer protocol (http) to enable a computer user to connect to the Internet. MySQL is an open-source database that organizes information through tables, and enables interactions between the user and the Web through the creation of dynamic Web pages. The system was implemented by the AITI-KACE management to ensure efficiency and the effective delivery of the services at the center. It was aimed at providing an alternative and flexible approach to the development of ICT skills of the participants enrolled at the center. It also serves as a practical demonstration of the use of ICT in the management and delivery of services in business.

Moodle is a learner-centered application grounded in the social constructionist pedagogy (Dougiamas, n.d.). Social constructionists assume that knowledge is acquired through interaction with an environment. Learners acquire knowledge through active construction and discovery, and by explaining their understanding of concepts to others. Learner-oriented LMSs such as Moodle are suitable for the adult learner because it facilitates the design and delivery of custom-fit materials. Adult learners are considered to be motivated by their perceived benefit of a learning exercise, especially if it may have a positive impact on their profession (Holton & Swanson, 1998). In this regard, the use of Moodle offers AITI-KACE an opportunity for self-directed learning, consistent with Campbell's (2000) notion of an education environment where learners take responsibility for their own learning in a flexible instructional environment that allows for the designing and use of nonlinear instructional material suitable for adults. Such an environment provides the opportunity for adult learners to apply previously gained knowledge and experience, and to also relate their future goals to the learning process.

IMPACT OF E-TECHNOLOGY APPLICATIONS

AITI-KACE is a novelty and is in principle an initiative long over due. It has created more awareness about the value of e-technologies in the development of the economy of a nation like Ghana. The center is involved in the development of expertise in the field of ICT. The use of Moodle in the facilitation and promotion of ICT applications in business at AITI-KACE is a pioneering effort in the teaching of ICT in Ghana that combines traditional teaching and learning methods with the online delivery of teaching and learning materials.

The Moodle LMS is used to provide an online version of all instructional and learning material used at AITI-KACE. It provides an online teaching and learning environment alternative to the daily on-site teaching activities at the center. It provides students access to learning and instructional materials on demand and at their convenience. According to the Moodle administrator at AITI-KACE, it is a more flexible approach to the delivery of services compared to on-site delivery. From the perspective of the system administrator, the on-site delivery of services has spatial limitation in terms of where, when, and how students can access, use, and submit materials.

The center's e-applications administrator has configured Moodle such that all of AITI-KACE's 12 lecturers have automatic accounts based on the courses they teach. Each course has a maximum class size of 25 participants. At the moment, the center, which started in 2003, has 145 students (F. Ankamah, personal communication, February 4, 2005) and has turned out 635 graduates (Ghana News Agency, 2005).

Administratively, the use of Moodle is considered a success because it is cost effective (the Moodle LMS software is free, and all the setup and content management are done at the center) and works well for the center. The greatest challenge in running the Moodle application at the center lies with its use by the lecturers and participants of the center. Currently, 21% of participants and 8% of lecturers use the Moodle LMS. According to the system administrator, the percentage of usage is attributable to the Ghanaian learning culture, to which the Internet-based delivery of educational instructions and the performance of learning activities are new. The participants, especially, are not familiar with online virtual campuses, and would rather prefer traditional on-site teaching and learning activities, and hard-copy delivery and submission of learning materials.

To ensure that the Moodle LMS e-application does not fail, the AITI-KACE administration adopted and implemented an e-documentation policy by declaring the center's learning environment paperless. However, there are drawbacks in the implementation of the paperless e-documentation policy for the following reasons. First, it has been observed that even though participants appreciate the online delivery and submission of instruction and learning material, most of them do not have access to the Internet at home. Second, not all of the lecturers have used the Moodle LMS as an alternative to the delivery of instructional and learning materials to the center's participants, and that is a major concern. Finally, building up a team to manage the Moodle LMS has been a challenge.

The center had a system administration team of three, which has now been reduced to one because the other two who trained on the job quit their positions. The current team of one is fully stretched with regard to the maintenance and further development of the system; this is quite a challenge. The Moodle LMS is a stand-alone Web application at the center, and the administrator is working toward integrating it with its post-nuke-based Web site. The other challenges are how to improve participant access and lecturers' usage of Moodle as an alternative medium for delivering their work (E. Ofori, personal communication, February 4, 2005).

The center estimates that about 80% of its graduates are able to apply their acquired skills at their jobs or start-up businesses. The majority of the center's participants enroll with sponsorships from their employers. The center does not know what the remaining 20% do with the skills they acquired after their respective programs. Tracking and knowing what this significant minority does with its skills is another challenge.

CONCLUSION

The establishment of the Moodle LMS at AITI-KACE offers alternative, electronic means for delivering learning and instructional material at an information and communications technology innovation center. The use of the Moodle LMS is considered successful because it allowed the administrators of the center to adopt and implement a paperless learning environment while promoting e-business application in Ghana. The center's activities for which the Moodle LMS was used to implement support the principles of social constructionist pedagogy, which is favorable to adult learning.

The use of the Moodle LMS at AITI-KACE indicates, first, that F/OSS have the potential to support the integration of e-technologies in institutions and in regions like Africa as suggested by Castells and Ince (2003). Particularly, the use of business models based on open-source software has been very successful in developing countries (Weerawarana & Weenatunga, 2004), and AITI-KACE is on the right track. Second, the use of the Moodle

LMS by the lecturers and participants illustrates that the deployment of e-applications for the delivery of services in an institution requires taking into consideration the cultural influences on the users. Third, the delivery of e-business services requires that end-user access to the Internet in their homes or off campus is essential, especially when the service is Web based.

Twenty percent of the graduates of AITI-KACE are not known to have either taken up employment or set up new businesses. This calls for a tracking system and an evaluation of the mechanism used in accessing the needs of participants when they enroll at the center. The center should seek ways to improve its mechanism for identifying and tracking the needs of participants after they have completed. This will enable it to cater to those needs that are not easily discernable, and assess the full impact of the activities of the center. Perhaps an approach to supplement existing procedures is to expose participants to developed prototypes of information and communications technology applications as a first step toward developing their own models for implementation.

The center should consider having an office or setup for innovations in teaching and learning that will explore other electronic means of packaging their electronic materials. For instance, the center could package their materials into portable files on compact discs or other downloadable forms to be used by participants who do not have personal Internet access in their homes. Finally, the center should consider making its business incubation component more prominent.

KEY TERMS

Apache: An open-source Web server. Web servers use http to enable a computer user to connect to the Internet.

Easy PHP: Software application written in the dynamic PHP language that combines an Apache Web server and a MySQL database to create flexible Web development tools.

E-Business Models: Strategies that enable businesses to take advantage of the latest technologies to generate profits and customer satisfaction.

E-Innovations: Innovations encouraging users of new communications technologies to develop dependable and viable business plans or systems that can be used for an economic (business) or social (health care, education, etc.) enterprise.

E-Learning: Effective and continuous learning process that occurs through the delivery of interactive multimedia educational materials that have no spatial limitation.

E-Models: The designing of prototypes of electronic businesses or systems that illustrate how digital technology can be used in any enterprise.

F/OSS: Software with an unrestrictive license whose source code is made available for modification, customization, and distribution by others.

MySQL: Open-source database that organizes information through tables and enables interactions between the user and the Web through the creation of dynamic Web pages.

Virtual Campus or Learning-Management System: Web-based, customizable e-learning environment that integrates a variety of educational tools with interfaces to accommodate the technology competencies of the user and his or her learning needs.

ENDNOTE

[1] The center refers to those enrolled in its programs as participants and not students.

Overall Satisfaction Prediction

INTRODUCTION

Strides in information technology and improvements in networking technology have set the pace for rapid growth in new applications of electronic commerce in a variety of settings. Business to business (B2B), business to customer (B2C), customer to business (C2B), and customer to customer (C2C) have become prevalent business channels and have reshaped the ways that business transactions are conducted in the marketplace. According to Internet Data Corporation (IDC), the number of Internet users worldwide will exeed 1 billion Internet users by 2007 (IDC, 2004). Given recent trends and forecasting, it is clear that no business enterprise can afford to ignore the tremendous potential of these emerging technologies in terms of the rate of creating, processing, and distributing the volume of business.

The proliferation of the Web potential for business, together with its profuse customer information, have offered an alternative sales channel for a growing number of firms and have prompted extensive research on the effect of negative critical incidents on customer satisfaction with Internet shopping. The increase in business-to-customer (B2C) channels has made several firms look for new strategies to understand online shopping behavior in order to attract, retain and satisfy customers' needs (Ranganathan & Ganapathy, 2002). In fact, many researchers have considered that customer satisfaction leading to higher levels of customer retention would depend on the success of critical factors, such as quality design (Huizingh, 2000; Liu & Arnett, 2000; Stefani & Xenos, 2001), security concerns (Belanger, Hiller, & Smith, 2002; La & Kandampully, 2002), and other factors for electronic commerce (Loiacono, Watson, & Goodhue, 2002; Yang, Cai, Zhou, & Zhou, 2005). However, Waterhouse and Morgan (1994) reported an interesting finding that just one factor of dissatisfaction and defection would be enough to cause customers to become disenchanted with Internet shopping. Thus, the call for the managers to find and discriminate the dissatisfaction or defection in the velocity and dynamic nature of the Internet environment becomes loud.

According to Fang, Shih, and Liu (2004), the slow response affected overall satisfaction indirectly by quality attributes satisfaction (QASAT) seems to be more important to customers who have less purchase frequency or purchase amount than high one. Furthermore, online bookstores with incomplete content and have untrustworthy transaction would affect overall satisfaction indirectly to customers with high loyalty by QASAT. The main purpose of this study was threefold. First, it designed a set of quality attributes satisfaction, in term of the negative critical incidents concept, to measure individual satisfaction, an online shopping bookstore served as empirical cases. Second, from predictive model standpoint, a method, call multiple discriminant analysis (MDS), was used to analyze customers' satisfaction based on QASAT and estimated data. Finally, it adopted holdout samples to confirm the ability of generalization with a predictive model.

BACKGROUND

In the past decade, perhaps, the most dramatic evolution, a new agenda, in business is the dawn of the Internet. A hallmark of the new economy is the ability of company to increasingly recognize that in the postindustrial era, a company success is determined mainly by economic value from its new application of electronic commerce in a variety of settings.

Based on the book chapter in e-commerce and m-commerce technologies (Fang et al., 2004), research on web quality attributes for measuring Internet shopping falls into four broad categories: quality e-store, information content, security concerns, and consumers' experience. These four categories were specified to construct a set of critical incidents for encounter satisfaction. The four factors consisted of 34 items from previous literature described as follows:

1. **Quality E-Store (10 items):** Fast Web-page download, store size, promotions, ease of use and so on (Huizingh, 2000; Liu & Arnett, 2000).

2. **Information Content (8 items):** Availability of information to compare across alternatives, completeness of information provided about a firm, product, and service, and so on (Huizingh, 2000; La & Kandampully, 2002; Ranganathan & Ganapathy, 2002).
3. **Security Concerns (5 items):** Availability of secure modes for transmitting information, provisions made for alternatives, overall concern about security of transactions over the Internet, gathering of personal information, and so on (Belanger et al., 2002; La & Kandampully, 2002; Ranganathan & Ganapathy, 2002).
4. **Consumer Experience (11 items):** Increased customization, convenience in purchasing, responsiveness in product delivery, and so on (Elliot & Fowell, 2000; Iwaarden, van der Wiele, Ball, & Millen, 2004).

There are a number of custom satisfaction measurements currently in place. However, the assessment from negative critical incidents is spare. For the content validity purpose, these items were initially assessed using a Delphi method (Green, 2000). Furthermore, three e-commerce scholars were asked to evaluate the items and make changes to eliminate repetitive items. After two evaluation rounds, there remained 22 critical incidents of Web quality attributes for further study.

Two questions were used to measure overall satisfaction. One question is, "What is the degree of satisfaction for online bookstores?" The other question is, "Will you recommend using online bookstores to a friend?"

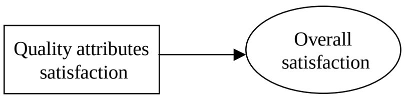
To detect customer's satisfaction in online shopping, a model was proposed and applied to the empirical case—online bookstores (shown in Figure 1). This model used dimension of quality attributes satisfaction to discriminate and forecast overall satisfaction by multiple discriminant analysis.

METHODOLOGY OF THE MANUSCRIPT

Research Procedure

First, to produce more precise and interpretable factors for the dimension of quality attributes satisfaction, the principal component analysis (PCA) was used to examine related items. Moreover, to provide meaningful interpretation of the relative importance among the various factors, a multivariate analysis-discriminant analysis was chosen as the appropriate statistical technique. This technique derives a profile based on a linear combination of variables that will best discriminate between the a priori defined groups. In this study, a degree of overall satisfaction was divided into two groups, based on the cutting

Figure 1. Proposed model



score (a score of more than 4 indicates customer who has higher overall satisfaction; a score of less than 3 represents customer has lower overall satisfaction).

Finally, for the cross validity purpose, a holdout sample was used for validation of the discriminant function. In this study, 70% of the cases were assigned to the analysis sample for purposes of training the discriminant function first; then, it was validated by assessing its performance on the remaining cases in the holdout sample.

Measurement

A questionnaire was designed to measure satisfaction of service quality, overall satisfaction, demographic variables, and experience of online purchasing. The questionnaire was based on the previous studies (Fang et al., 2004). A measurement of quality attributes satisfaction and overall satisfaction, such as "What is the degree of satisfaction for online bookstores?" included a 5-point Likert scale from 5 (*strongly agree*) to 1 (*strongly disagree*). A measurement of the second question of overall satisfaction, "Will you recommend using online bookstores to a friend?" included a 5-point Likert scale from 5 (*strongly willing*) to 1 (*strongly unwilling*). In addition, two demographic variables (gender and income) and three variables with experience of online purchasing (number of online bookstore visits per month, frequency of purchasing per month, average amount of money spent in online bookstores per month) are all measured by a nominal scale from respondents to obtain more information for explaining the analytical results.

Data Collection

According to Fang et al. (2004), 15 critical incidents were for measuring the constructs of QASAT. An online survey was performed for collecting the data. Participation in this study was completely voluntary, but respondents of at least one online purchase were considered qualified for analysis. In this online survey, our system would check incomplete data and ask the respondents to fill out the questionnaire on time.

This paper used 210 respondents to predict their overall satisfaction based on quality attributes. Table 1 presents the characteristics of respondents. The sample included 88 (42%) males and 122 (58%) females, all of whom had made purchases online, with 75% having had

Table 1. Profile of respondents (N = 210)

	Frequency	(%)		Frequency	(%)
Gender			No. of books purchasing a month		
Male	88	42	1-2	158	75.2
Female	122	58	3-4	43	20.5
Income			5-6	6	2.9
<=20,000	134	61.9	7-8	2	1.0
20,001~40,000	45	21.4	>8	1	0.4
40,001~60,000	27	12.9	Average spending a month		
60,001~80,000	4	1.9	<=500	88	41.9
80,001~100,000	4	1.9	501-1,000	85	40.5
No. of bookstores a month			1,001-	16	7.6
1-2	75	35.7	1,501-	13	6.2
3-4	48	22.9	>2,000	8	3.8
5-6	31	14.8			
7-8	17	8.1			
>8	39	18.6

at least one or two experiences in online book purchasing per month, spending varying amounts.

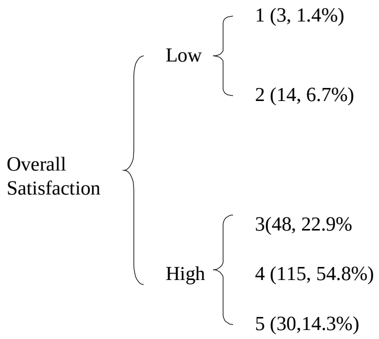
Analytical Results

Factor Analysis—Quality Attributes Satisfaction (QASAT)

Hair, Anderson, Tatham, and Black (1992) suggested that item loadings > 0.3 are considered significant, > 0.4 are more import, and > 0.5 are considered very significant. There are no accepted "absolute" standards for the cut-offs; the choice is based on judgment, purpose of the study, and prior studies. Because our goal is to examine a set of the most significant criteria incidents to assess overall satisfaction, a cut-off point of 0.7 for item loadings and eigenvalue ≥ 1 was used, factor analysis revealed five factors were obtained from quality attributes satisfaction (see Table 2).

Because three item scales (sat8, sat9 and sat13) did not load on any factors, they were removed. Sat4 and sat20 factor loading less than 0.7 were removed, respective. Finally, 10 measured variables onto the four latent factors of positive emotions were constructed. Furthermore, quality e-store, customer experience, and information content were renamed into ease of use, quick response, complete information, and trustworthy.

It was found that ease of use consisted of three items and dealt with such attributes as diversity shipping, *Figure. 2. Two groups among overall satisfaction*



diversity ordering, and diversity receiving. "Quick response" reflects concerns related to finding specific details about supporting multiple channels of communication with organizations and response quickly. "Complete information" consisted of two items: support of infrequent books and complete introduction of books. "Trustworthy" contains two items: security of transactions and privacy of personal details. The standardized Cronbach's alpha coefficients with 0.81, 0.79, 0.7, and 0.78 for ease of use, quick response, complete information and trustworthy were all exceeding the generally accepted guideline 0.7 and above (Hair, Anderson, Tatham, & Black, 1995).

Results of Multiple Discriminant Analysis

As mentioned previously, two groups based on cutting score of customers' overall satisfaction are listed in Figure 2. Overall satisfaction was measured using a 5-point Likert scale ranging from 1 (*lowest overall satisfaction*) to 5 (*highest overall satisfaction*). Because nearly half of samples are below scale 3 (37.2%), a cutting score of 3 was used in this article. The high group (individuals with scores over 3) indicated customers with high overall satisfaction, and a low group (individuals with scores under 3) represents low overall satisfaction.

The result of the discriminant analysis (see Table 3) indicated the overall model for overall satisfaction (Wilks' Lambda = 0.583, F = 10, $p < 0.01$) was significant. The canonical correlation was found to be 0.645, indicating that these dimensions explain 41.7% of the variance (by squaring it) in overall satisfaction. The subsequent analysis of variance (ANOVA) procedures revealed groups are significant different all variables (acceptable level equals 0.001), except sat12 (Convenience to exchange product) and sat18 (Infrequent books).

Furthermore, in case of multicollinearity, discriminant loadings is a better parameter for evaluation of variables (Hair, Anderson, Tatham, & Grablowsky, 1979). The discriminant loadings reflected the variance shared by the QASAT to demonstrating the contribution of each variable to the discriminant function. Generally, discriminant loadings of absolute value was greater than 0.3 to be considered significant (Hair, Anderson, Tatham, and Grablowsky, 1979).

The results indicate that not all the factors were significantly discriminate overall satisfaction, such as convenience to change products and has infrequent books. The quality attribute of diversity receiving (sat7) was the most significant variable to discriminant between two groups of overall satisfaction. Moreover, discriminant function for overall satisfaction is very good at 86% compared with a chance accuracy of 57.2% (calculated as $p^2 + (1 - p)^2$), where p is the proportion of sample in the low overall satisfaction group.

To validate predictive accuracy of the discriminant function, holdout sample was used to address the valid-

Table 3. Summary of two-groups discriminant analysis results

Factors (predictors)	Discriminant Loadings	F-value	Significance	Mean (overall satisfaction) High	Low
Sat5	0.39	15.48	0.0001*	4.08	3.46
Sat6	0.47	23.41	0.0001*	4.11	3.32
Sat7	0.64	41.92	0.0001*	4.51	3.46

Sat21	0.58	34.99	0.0001*	3.80	2.94
Sat22	0.34	11.86	0.0008*	3.59	3.06
Wilk's Lambda = 0.583 F = 9.72 (df = 10), $p < 0.0001$					

*: Significant level = 0.001

Table 4. Classification matrix

	Analysis sample				Holdout sample		
	Low	High	Total		Low	High	Total
Low	38	12	50	Low	12	3	15
High	12	85	97	High	4	44	48
Accuracy = 84%				Accuracy = 89%			

ity. We split roughly 70% (147 cases) of total sample for training the discriminant function, then validated by assessing performance on the remaining 63 cases in the holdout sample. Hair, Anderson, Tatham, and Grablowsky (1979) suggest that the classification accuracy reflected in the overall hit ratio should be at least 25% higher than the proportional chance criterion (e.g., should be 71.5% or more) before one can have confidence in the predictive validity of the discriminant function. Because the overall hit ratio of holdout sample (89%) exceeds 71.5%, the discriminant model is valid. The classification accuracy for analysis sample and holdout sample, respectively, was summarized in Table 4.

FUTURE TRENDS

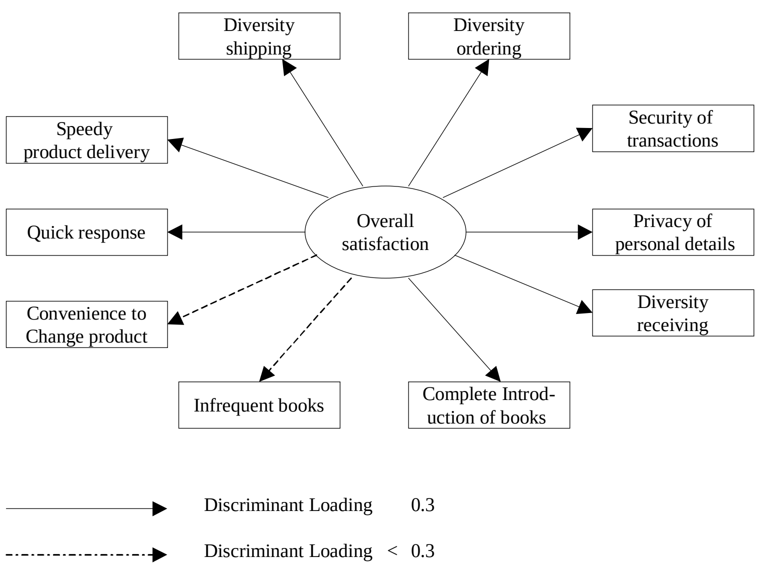
Like all research, this study has its limitations. One such limitation is that the predictive model was designed for applying to online bookstores. Accordingly, whether the predictive model is appropriate to other range of sites needs to be verified in future study. Furthermore, that we only use quality attributes to predict customers' overall satisfaction. Therefore, more dimensions or factors will be involved in the future to enhance the power of model explanation.

CONCLUSION

At the end of the 20th century and the beginning of the 21st, Internet has emerged as an important and increasing interest research area in a variety of academic setting. This phenomena stem from both its proliferation of the Web potential for business, together with its profuse customer information.

Armed with the aforementioned points, 10 measured variables onto the four factors of positive emotions were constructed in this study. Two-hundred ten online users from a Web-based survey who have made at least one online shopping experience was included the following analysis. Using the discriminant analysis, a good predictive accuracy (86%) was achieved and a good validity results (86%) was produced adopted on predictive model. Finally, based on Hair et al., (1995), discriminant loadings suggestion (values greater than 0.3), the proposed model was revised into Figure 3. Therefore, once customers have a feeling with the slow response, slow product delivery, cannot offer diversity shipping, or diversity ordering, diversity receiving, security problems, privacy concerns, or incomplete content, will be influenced by these nega-

Figure 3. Revised model



tive emotions, and affect overall satisfaction indirectly. Therefore, that we also verified that if customers are first time to visit online bookstores, these factors are not effect on overall satisfaction in this study.

KEY TERMS

Electronic Commerce: A way of doing business transactions over the Internet. Electronic commerce has three different categories: those are business to business or B2B, business to consumer, or B2C, and consumer to consumer, or C2C.

Business-to-Business (B2B): It takes the form of automated processes between trading partners.

Business-to-Consumer (B2C): In this method, products or services are sold from a firm to a consumer.

Consumer Experience: Such as increased customization, convenience in purchasing, responsiveness in product delivery, and so on.

Customer-to-Customer (C2C): In this method that participants bid for products and services over the Internet, such as online auction.

Delphi Method: The objective of most Delphi applications is the reliable and creative exploration of ideas or the production of suitable information for decision making.

Information Content: Such as availability of information to compare across alternatives, completeness of information provided about a firm, product and service, and so on.

Multiple Discriminant Analysis: Discriminant analysis is one of the available technologies for identifying the variables that discriminant "best" between groups. Furthermore, that we can use the identified variables to develop a rule to classify future observations into one of the groups.

Quality E-Store: Such as fast Web page download, store size, promotions, ease of use, and so on.

Security Concerns: Such as availability of secure modes for transmitting information, provisions made for alternatives, overall concern about security of transactions over the Internet, gathering of personal information, and so on.

Password Security Issues on an E-Commerce Site

INTRODUCTION

With the exponential growth of the Internet and e-commerce, the need for secure transactions has become a necessity for both consumer and business. Even though there have been advances in security technology, one aspect remains constant: passwords still play a central role in system security. The difficulty with passwords is that all too often they are the easiest security mechanism to defeat.

Kevin Mitnick, notably the most recognized computer hacker, made the following statement concerning humans and their passwords:

…the human side of computer security is easily exploited and constantly overlooked. Companies spend millions of dollars on firewalls, encryption and secure access devices, and it's money wasted, because none of these measures addresses the weakest link in the security chain. (Poulsen, 2000)

Without secure passwords, e-commerce sites invite online criminals to attempt fraudulent schemes that mimic the goods and services that legitimate e-commerce merchants offer. With increasing numbers of users on an increasing array of e-commerce sites, often requiring the use of passwords, users often choose to reuse the same simplistic password, and do so on multiple sites (Campbell, Calvert, & Boswell, 2003).

For most computerized systems, passwords are the first line of defense against hackers or intruders (Horowitz, 2001). There have been numerous published articles that have created guidelines on how to create better or safer passwords with the following recommendations:

1. passwords should be memorized and not written down;
2. passwords should be an eight- or nine-character word or phrase, and end users should randomly add
3. passwords should contain a mixture of letters (both upper- and lowercase), numbers, and punctuation characters; and
4. passwords should never be words that can be commonly found in a dictionary.

But if an individual adheres to security experts' suggestions about password authentication, it usually involves a trade-off. If a password is easy to create and remember, it is most likely that it is easy for others to guess or a hacker to crack.

Eventually, any password can be cracked. Password crackers use a variety of methods and tools that can include guessing, dictionary lists, or brute force attacks. Dictionary lists are created by using an automated program that includes a text file of words that are common in a dictionary. The program repeatedly attempts to log on to the target system, using a different word from the text file on each attempt. A brute force attack is a variation of the dictionary attacks, but it is designed to determine passwords that may not be included in the text file. In a brute force attack, the attacker uses an automated program that generates hashes or encrypted values for all possible passwords and compares them to the values in the password file (Conklin, White, Cothren, Williams, & Davis, 2004).

Unfortunately, many of the deficiencies of password authentication systems arise from the limitations of human cognitive ability (Pond, Podd, Bunnell, & Henderson, 2000). The requirements to remember long and complicated passwords are contrary to a well-known property of human memory. First, the capacity of human memory in its capacity to remember a sequence of items is temporally limited, with a short-term capacity of around seven items plus or minus two (Kanaley, 2001). Second, when humans remember a sequence of items, those items cannot be drawn from an arbitrary and unfamiliar range, but must be familiar "chunks" such as words or familiar symbols. Third, the human memory thrives on redundancy. In fact, studies have shown that individuals' short-term memory will retain a password for approximately 30 seconds, thereby requiring individuals to attempt to memorize their passwords immediately (Atkinson & Shiffrin, 1968).

BACKGROUND

Password security research has dramatically increased over the past 20 years (Ives & Walsh, 2004). Even though there has been an increased awareness surrounding the topic of password protection, password vulnerabilities remain significant. Most of today's e-commerce sites allow access to both data and the networked system by granting permissions based on password approval. The increased usage of passwords and logins has revealed several interesting issues associated with users' difficulty in developing and remembering passwords (Jones, 2002).

In order to combat the issue of having to remember so many different passwords, some users have resorted to selecting familiar terms such as a pet or family name, their own name, their phone number, or other common terms that could be found in a dictionary. British psychologist Helen Petrie, PhD, a professor of human/computer interaction at City University in London, analyzed the passwords of 1,200 British office workers who participated in a survey funded by CentralNic, an Internet domain-name company in 2001. She found that most individuals' choices of passwords fell into one of four distinct password "genres" or categories (see Table 1).

The first group, which she labeled as "family," comprised nearly half of the respondents. These individuals selected their own name or nickname; the name of a child, partner, or pet; birth date; or a significant number such as a phone or social security number. Further, Petrie found that these individuals chose passwords that symbolized people or events with emotional value or ties.

One-third of the respondents were "fans," using the names of athletes, singers, movie stars, fictional characters, or sports teams. Petrie also found that these individuals were generally young and wanted to align themselves with the lifestyle represented by or surrounded around a celebrity status such as Madonna and Homer Simpson.

Eleven percent of responses were "fantasists." Petrie found that their passwords comprised sexual terms or topics. Some of the examples included in this category were terms such as "sexy," "stud," and "goddess." The final 10% of participants were identified as "cryptics." These users were seemingly the most security-conscious, but it should also be noted that they were also the smallest of all of the four categories. These individuals selected unintelligible passwords that included a random string of letters, numbers, and symbols.

IMPACT

To assess the security level of the passwords selected by consumers at the online bookstore, the researchers reviewed current best practices for online password security (Ohio State, 2004; University of New Mexico, 2004; Department of Defense, 1985; Security Stats, 2004) and aggregated the guidelines into an instrument that was used to rate the security level of each password. The data set contained 520 customer profiles collected from an e-business site from the summer of 2003 until the summer of 2004, with the majority of the respondents being from the western United States. Also, it should be noted that the e-commerce site did not require a signed consent from the user, as the information was obtained via the owner of the site, nor was a password recommended or created by the system.

Using the five-point human rating system gathered from a review of the literature, a panel of three individuals familiar with the current literature related to password security developed the categories presented in Appendix A. To provide a greater degree of granularity for analysis, a series of dichotomous yes or no questions was developed that was both positive and negative. From these questions, a standardized scoring system was developed (see Appendix B). The scoring system included eight

Table 1. Petrie's category definition

Category #	***Name***	***Definition***
1	Family	Name or nickname; name of a child, partner, or pet; birthday
2	Fan	Names of athletes, singers, movie stars, fictional characters, or sports teams
3	Fantasists	Interest in sex is evident in passwords such as "sexy," "stud," and "goddess"
4	Cryptic	Unintelligible passwords or a random string of letters, numbers, and symbols, such as Jxa+157

Table 2. Descriptive statistics

Category	N	%
1—Family	101	19.3%
2—Fan	11	2.1%
3—Fantasists	2	.4%
4—Cryptic	201	38.5%
5—Faith	30	5.7%
6—Place	7	1.3%
7—Other	143	27.4%
8—Numbers	25	4.8%
Total	520	100%

questions concerning positive recommendations of what people should be doing according to best practices, and an additional eight concerning negative "what not to do" practices. Next, the researchers developed an aggregate score for the positive and negative section by assigning a 1 or a 0 to the password for each question and then summing the scores. An overall score was assigned by subtracting the overall negative score from the overall positive score.

The review of Table 2 suggests that users are using good password practices that include numbers, symbols, and upper- and lower-case letters. This result differs from the study conducted by Petrie (2001), in that Cryptics were the smallest group of users in her study, but the largest in this study. The second largest group in this study was "Other," where consumers selected common English words such as "checkers," "onions," "cake," and so forth.

As noted earlier, Petrie's study identified four distinct categories in the order of family, fan, fantasists, and cryptics, while this study identified eight separate categories. It should be noted that in this study the classification of groups became more refined. Our additional categories are Other, Faith, Place, and Numbers, which appear to be more descriptive of consumers' passwords (see Table 3). It could be argued that the categories of "other," "faith," "place," and "numbers" should be included in, for instance, the "family" category in that it may represent words that relate to individuals' choices of favorite food, religious choices, favorite places, or places that have emotional ties and numbers that are meaningful to them personally. It appears that individuals, and males in particular, are becoming more careful in their password selection.

The results in Table 4 are an indicator of password strength and present the results of an ANOVA procedure with comparison of means. The procedure identified significant differences in the means of the rating for password categories. Additionally, the analysis identified groups that have statistical homogenous means.

For the dichotomous scale, the mean rating for cryptics is statistically higher than the mean rating of the categories of numbers, faith, other, and fan. For the five-point human categorization scale, the procedure identified three different groups: Group 1 comprises the cryptic category, Group 2 comprises the numbers category, and Group 3 comprises the fan, faith, and other categories. For both scales, Cryptics are more secure in creating their passwords, followed by the Numbers category.

Table 3. Current study category definition

Category #	Name	Definition
5	Other	Common English dictionary terms that did not include religious terms or places
6	Faith	Terms associated with religion or religious activities
7	Place	Names associated with towns or cities
8	Numbers	A string of all numbers

Table 4. Results of linear model procedure for the comparison of means

Variable	F-Statistics (p-value)	Category 1 Fan	Category 4 Cryptic	Category 5 Faith	Category 7 Other	Category 8 Numbers
Dichotomous positive/negative scale (-8 to 8)	111.51* (0.0001)	0.44 ^{A}	2.78 ^{C}	1.00 ^{B}	0.91 ^{B}	1.88 ^{D}
Five-point human categorization	78.68* (0.0001)	2.34 ^{E}	3.36 ^{G}	2.37 ^{E}	2.52 ^{E}	2.92 ^{H}
Sample size (n)	--	101	201	30	143	25

Means with the same letter indicate that they are not significantly different in each row
*H_o: $\mu_1 = \mu_4 = \mu_5 = \mu_7 = \mu_8$ vs. H_1: At least one of them is not equal

In the scoring system we had eight questions concerning the positive recommendation of what people should be doing according to best practices, and an additional eight concerning negative "what not to do" guidelines. The researchers then developed an aggregate score for the positive and negative section by assigning a 1 or a 0 to the password for each question and summing the scores for each section. An overall score was assigned by subtracting the overall negative score from the overall positive score. Since we have eight positive questions and eight negative questions, this gives us a theoretical range of between -8 and +8 for the overall score.

FUTURE TRENDS

Certainly, the future of passwords is debatable as more and more identify thefts are occurring. Both individuals as well as e-commerce sites are feeling the wrath of hackers who have broken into their systems and stolen millions of dollars worth of information. In response to the increase of online fraud, many organizations are beginning to use other forms of verification in addition to passwords, such as two-factor authentication where the consumer uses his or her password in conjunction with an additional piece of information. Another level of security is the use of personal Web certificates, where an e-commerce site relies on these personal Web certificates and the authentication process of the corresponding public/private keys to verify that you are who you claim to be.

Authenticating consumers in the future on an e-commerce site may be based upon what someone has (a smart card, token, or ID card), what he or she knows (a password or PIN), what he or she is (a biometric like a fingerprint or voiceprint), or any combination of these (Ciampa, 2005). Normally, the more authentication factors in use, the more secure the authentication. Some methods of authentication, such as a simple user ID and password, are not considered particularly strong since they are susceptible to hacking with freely available tools. Therefore, it would seem evident that other methods of security would be adopted.

Advanced authentication measures such as smartcards, authentication tokens, biometrics, and software-based mechanisms are designed to counter the weaknesses of traditional passwords. While the authentication techniques vary, they are similar in that the passwords generated by advanced authentication devices cannot be reused by an attacker who has monitored a connection. Given the inherent problems with passwords on the Internet, it appears that the use of advanced authentication measures will be necessary.

CONCLUSION

Although humans may be creative, it appears that we are still very predictable in our choices. It is evident through our research that individuals are becoming more aware of the need to create passwords that are relatively secure. Our research subjects, though different from the prior study (Petrie, 2001), have apparently learned the necessity of secure password selection. Overall, this study indicates that there are some statistical differences between the categories, and that the category's password may give some clues about its security level. It is not known whether the knowledge gained concerning good password selection has been gained through education, direction from administrators, information regarding ID theft, nature of the demographic population, or possibly a post 9-11 paradigm shift, but individuals have apparently seen the need for more secure passwords that involve both length and complexity.

Extensions of this study are also needed. Currently, further research into the areas of gender and categories may lead system administrators and e-commerce sites to make specific recommendations and/or policies related to password creation based upon gender, and in the future, it could be studied as to how effective the aforementioned devices have been in securing computerized systems.

KEY TERMS

Advanced Authentication Measures: Techniques beyond passwords that can be used to identify the end user to determine if they are who they say they are.

Authentication: Determines a user's identity, as well as determining what a user is authorized to access.

Categories: Levels of observed actions or choices made by an individual.

Password: A word or string of characters which serves as authentication of a person's identity (personal password), or which may be used to grant or deny access to private or shared data (access password).

Password Best Practices: Guidelines to create a safe password that is hard for someone else to guess.

Password Cracking Software: A purpose of password cracking software might be to gain unauthorized access to a system, or as a preventive measure by the system administrator to check for easily crackable passwords.

Password Security: Methods or ways to protect a person's password.

APPENDIX A: ORIGINAL FIVE-POINT HUMAN PASSWORD RATING SYSTEM

Level	Description	Criteria
1	Obvious name or number	1. Password contains all or part of a username, e-mail, name, etc. 2. Or is somehow related to known information, such as a spouse or a child's name. We may not have enough information to always assess this. 3. It is easily guessable by someone that knows a little about the individual, based on publicly available knowledge.
2	Common word or number	1. Password is a repeating number (i.e., 99999). 2. Or it is a common word recognizable as either a name or word likely to be found in a dictionary.
3	Words with number at start or end or non-repeating numbers	1. Example: John52 or 73horses, combining recognizable words or phrases with a number. 2. Or having a non-repeating number, such as 345820, that does not appear to be a social security number, phone number, or street address. 3. Or adding a compound word, such as lovejohn or tomuchfun. 4. Or unrecognizable alpha characters that did not form a common word or name (i.e., mtlyfll).
4	Unrecognizable alpha and number combinations	1. Has a mixture of unrecognizable alpha characters with numbers thrown in (i.e., jds932). 2. May include compound words with numbers lovejohn99.
5	Special characters	1. Numbers and letters mixed with the inclusion of special characters like #, %, and @, etc. 2. Spaces and dashes are included in this category.

APPENDIX B: DICHOTOMOUS PASSWORD SCORING SHEET

Question	**Yes**	**No**
Positive Questions		
1. Does the password have both upper- and lower-case letters?	1	0
2. Does the password have both upper- and lower-case letters throughout the password, not just the beginning?	1	0
3. Does the password have both letters and numbers?	1	0
4. Does the password have both letters and numbers throughout, not just at the beginning or end?	1	0
5. Does the password have any special characters?	1	0
6. Does the password have at least six characters?	1	0
7. Does the password have eight or more characters?	1	0
8. Does the password appear to be random?	1	0
Negative Questions		
9. Is the password the same as the username, e-mail, or name?	1	0
10. Does the password resemble the username, e-mail, or name?	1	0
11. Does the password appear to be the name of a person (real or in book)?	1	0
12. Does the password appear to be the name of a place (real or in book)?	1	0
13. Does the password appear to be a word that could be found in an English dictionary?	1	0
14. Does the password appear to be a word in a foreign dictionary?	1	0
15. Does the password appear to have a discernible pattern to it (i.e., 123321, 8888888, or aabbccbbaa)?	1	0
16. Does the password appear to be a date?	1	0

Payment Mechanism of Mobile Agent-Based Restaurant Ordering System

Jon T. S. Quah
Nanyang Technological University, Singapore

Winnie C. H. Leow
Singapore Polytechnic, Singapore

Chee Chye Ong
Nanyang Technological University, Singapore

INTRODUCTION

The Internet, especially the World Wide Web, is moving from a free, academic domain to a profitable commercial world. This underscores the importance of a digitally secure means of electronic payment for an electronic commerce application. The payment is usually an important part of an electronic commerce transaction, and it deals with the transfer of trust, either as cryptographically signed promises, or as digital cash, between the customer, the merchant, and the payment service provider.

Due to the explosive growth of e-commerce transactions, many electronic modes of payment are devised to address a diverse set of Internet user requirements (Guida, Stahl, Bunt et al., 2004; Tsiakis & Sthephanides, 2005; Garfinkel, 2003; Usher, 2003; Polk, Hastings, & Malpani, 2003; Evans & Yen, 2005; Marchesini, Smith, & Zhao, 2005; Lancaster, Yen, & Huang, 2003; Lekkas, 2003; Medvinsky & Neuman, 1995; Schoenmakers, 1997; Levi & Koc, 2001; Mahony, Peirce, & Tewari, 2001; DigiCash Press, 1994; Neuman & Tso, 1994; Vivtek, 2000).

The background of this article is that we have developed a mobile agent-based restaurant reservation and ordering system whereby users are able to search for restaurants that fulfill a list of user-entered parameters (e.g., type of cuisines, ambiance, specialties such as steaks, etc.) (Quah & Leow, 2003). The system is built on the IBM Aglet mobile agent platform. (A mobile agent is a small executable code/program that can migrate itself to remote hosts and execute predefined instructions—e.g., information retrieval, and return the processed information to its originating host system) (Lanage & Oshima, 1998). Due to the uniqueness of our system, we find the existing e-commerce payment methods inadequate to fit our system's need. As such, we studied several existing methods and adapted one into our system operation structure. The use of mobile agent to implement the payment system adds robustness and scalability to the system.

DESCRIPTION OF THE ELECTRONIC PAYMENT SYSTEM

To support electronic commerce, various Internet payment protocols have been proposed and adopted by a variety of organizations. In fact, the existence of different payment mechanisms are justified because there are different needs to be satisfied in terms of:

- Cryptographic needs (strong, symmetric, exportable, importable, etc.)
- Latency of the transaction (micropayment must be very fast)
- Minimal and maximal amount for the transaction itself
- Minimal and maximal amount for the cost of the transaction
- Repudiation, notarization needs
- Involvement of financial institution (i.e., online vs. off-line)

Some of the above requirements may call for contradictory system requirements, and as such, trade-offs have to be made. In a nutshell, an electronic payment system should meet the following requirements:

1. Sufficient security means based on the amount of money transferred in a transaction.
2. Similar running scenario as the traditional business whenever possible to ease the doubts of the public and encourage them to participate.
3. Minimum changes on the current financial system to avoid tremendous costs when electronic commerce is introduced.

The participants of an electronic commerce transaction must be able to exchange trade and payment information over a network. The implementation addresses the problem of online payment by credit card in which anyone with knowledge of the customer's credit card number can create an order for payment. It also tries to eliminate the requirement of a Certificate Authority (CA), and consequently a CA-based Public Key Infrastructure (PKI), in order to verify a public key-based digital signature.

Characteristics of the Mobile Agent-Based Restaurant Order Payment System

Secure Socket Layer- (SSL) (Rainbow Technologies, 2001; Freier, Karlton, & Kocher, 1996; Albrecht, 1998) based protocols used in credit card payment are convenient but have some authentication and non-repudiation problems. Secure Electronic Transaction standard (SET) (MasterCard, 1997) and other payment-card-based protocols, which require either intermediary agents or CA-based PKI, are secure, but not so convenient, particularly for financial institutions (FIs). The mechanism of our implementation tries to find a middle ground in the "security vs. convenience" trade-off.

In our payment mechanism implementation, both the customer and the merchant need to be registered off-line with a network payment service (or trusted party) with their credit card data and given a unique persona. This persona acts as a mapping between an identified user and that user's public key and credit card information stored in the trusted third-party system. The trusted third party then acts as an intermediary in collaborating with the customer's issuing bank and the merchant's acquiring bank in the settlement of the credit card bill.

The basic idea behind the mobile agent-based restaurant order payment system is to avoid the necessity of consumer certificates. It also provides a remedy to the inability of the traditional credit card payment system in authenticating the customer's identity. The trusted third party makes use of the stored public key to authenticate the identity of the customer and merchant. Only signed payment request from the customer and an order endorsed by the merchant can effect the payment. The merchant verifies the digital signature of the consumer in most of the electronic payment protocols. In our payment scheme, the trusted third party is the authority who verifies the consumer's digital signature.

The payment system serves like a credit card system without the online authorization with the issuing bank. This payment method does not require changing the existing credit card settlement infrastructure tremendously to adopt this scheme. Another important characteristic of the system is that messages transmitted among the consumer, merchant, and trusted third party are not encrypted. Justifications for this challenging characteristic are as follows:

1. The persona is not valid unless there is an accompanying digital signature issued by its owner. Any third party cannot take advantage of knowing the persona, since it cannot produce a digital signature. Thus, personas need not be encrypted.
2. The strong public private key authentication is sufficient to prevent the majority of consumer and merchant frauds. Using the persona concept and strong authentication make encryption a luxury in this payment system.

Mobile Agent-Based Payment Protocol

A payment protocol based on mobile agents is devised to structure the interactions and information exchange among agents to complete a payment transaction. The payment structure integrates the use of public key cryptography into the mobile agent framework for enhancing security in electronic payment.

The payment protocol consists of the following steps, as shown in Figure 1:

- CC—Consumer
- TTP—Trusted third party
- Mer—Merchant
- SigCC—Consumer's signature of payment data and order information
- SigMer—Merchant's signature of order information

1. Having decided the food to order, the consumer clicks on the "Pay" button at the Aglet Service center. The ASC launches the consumer aglet that carries the payment request which most importantly contains the merchant's persona and the payment amount.
2. At the merchant site, the consumer aglet passes the payment request to the merchant aglet. The merchant aglet carries the consumer's payment request with its own signature of the order and dispatches to the TTP site.

   Consumer payment request:
   > Consumer persona, [payment data, H(Order)], SigCC

   Merchant signature of the order:
   > Merchant persona, [H(Order)], SigMer

3. At the TTP site, the merchant aglet passes the consumer's payment request and merchant's signature of the order to the TTP aglet. The TTP aglet verifies the consumer's signature on the payment request and the merchant's signature on the order.

Figure 1. Payment protocol

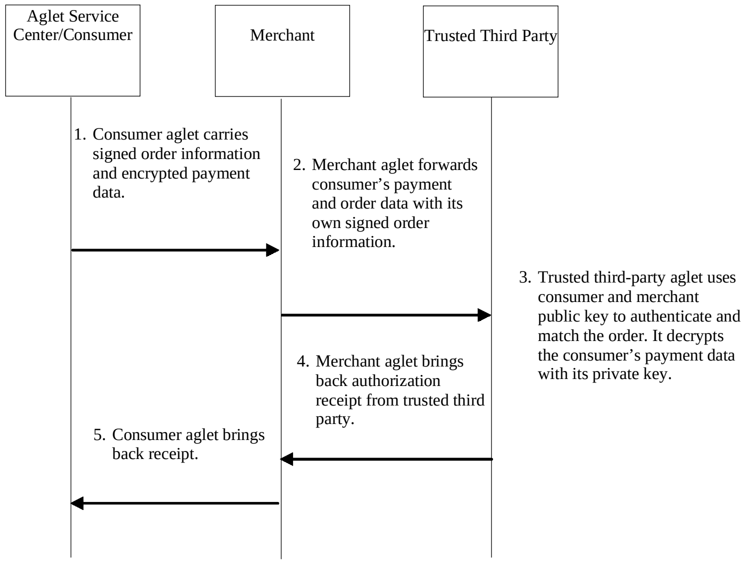

Figure 2. System setup

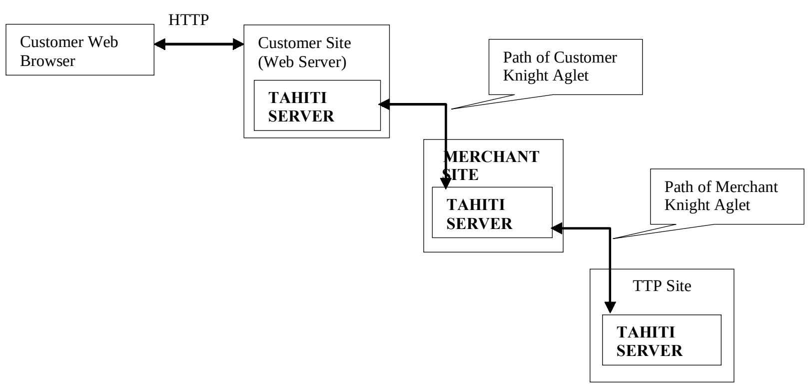


The TTP aglet verifies that both the customer and merchant agree on the order and authorizes the payment. The TTP aglet returns a receipt to the merchant aglet.

4. The merchant aglet returns to the merchant site with the receipt.
5. The merchant aglet forwards the receipt to the consumer aglet waiting at the merchant site. The consumer aglet returns to the consumer site with the receipt.

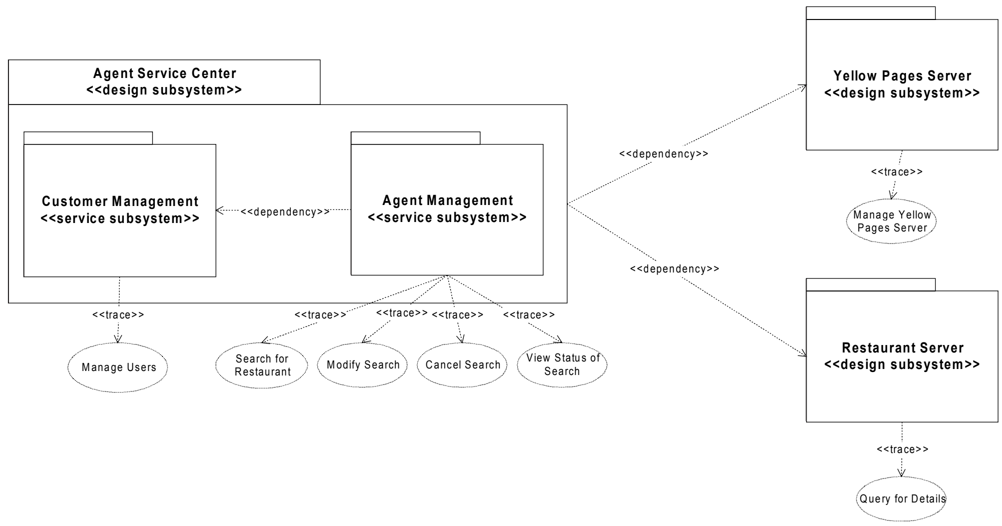
Figure 2 shows the setup of the payment system prototype in the aglet environment. Our system implements a master-slave mechanism of agents. The master agent is a stationary agent residing in the Tahiti Server. It spawns off one or more slave agents to accomplish a task. The slave agents are mobile agents, as they need to execute on a remote host. The mobile slave agent keeps information about its origin, the destination site on which it is going to run on, and the aglet information of the master who created it, as they need to inform their master on their return.

IMPACT AND USEFULNESS OF THE PAYMENT MECHANISM

Features of the payment system that is used in our mobile agent-based restaurant system include:

1. Anonymity, meaning the merchant would not know the customer's identity. Only the trusted third

Figure 3. Architecture framework for online restaurant system



party knows the identities to process the payment. But the trusted third party would not know the order detail. He can only verify that both the merchant and customer agreed with the order.

2. No credit card number is required to be sent over the network by using the trusted third-party approach. Instead, the customer's persona, sent with the signed payment request, acts as an identifier that is only recognized by the specific trusted third party. This unique persona will map to the credit card information preregistered by the customer with the trusted third party.
3. Non-repudiation using public private key authentication. In the proposed payment system, it can be later proven that the customer had agreed to pay for the food and the merchant had endorsed the order, as the trusted third party kept record of the signed payment request from the customer and signature of the order from the merchant. This addresses the problem of the credit card and token-based payment system where there is no proof that the cus4. Offline settlement via third-party avoid transaction latency resulted from online authorization via the banking infrastructure as in a typical credit card transaction. The transaction and its associated authorization are stored in a "batch," along with the rest of the transactions for the day. The trusted third party will submit the batch request to the processing network to process the transactions for which authorizations have been recorded.
5. Auditability, meaning the trusted third party has records of transaction signed by the customer and the merchant.
6. Widespread use and acceptance of credit card payment is a proposed scheme which can leverage on the existing credit card payment infrastructure. The credit card billing procedure that current customers are accustomed to can be utilized. As for merchants, there is no overhead since the trusted third party acts as a bridge for payment between the acquirers and merchants.
7. Achieve interoperability and reduce message exchange across network using Java mobile agent technology.

A potential weakness of the payment mechanism is the bottleneck at the trusted third party during peak traffic volume because all payment requests are sent to the trusted third party for signature verification. This, however, is a common problem for most online payment systems. One possible solution is to have a cluster of high-power servers at the verification site.

RESULTS

The mobile agent framework consists predominantly of Client, Agent Service Center (ASC), and the Restaurant Server Platform (see Figure 3).

The hotel guest will be able to access the online restaurant recommendation system through a Web browser in his hotel room. The search request(s) made by the guest will be registered with the ASC, which will then process each request and generate a list of online restaurants sites that will likely provide the pertinent information (i.e., food dishes) requested by the guest. The Yellow Page (YP) server that provides a database of such online sites helps to facilitate the compilation and generation of a list of such relevant online sites. This list of online sites will constitute the itinerary list that the mobile agent (MA) will have to visit. As mentioned, another main functionality of the ASC server would also be to generate a mobile agent that will begin traveling to the online restaurant sites to gather data on behalf of the user.

The mobile agent will abide by the generated itinerary list as it travels from one online restaurant server to another in order to complete its search for food and restaurant information. Upon arrival at each online site, the mobile agent will enquire the restaurant server to search for the food based on the user's search requirements. In addition, the restaurant server can retrieve its promotional information and push it to the ASC server, which in turn displays the promotional information to the users.

When the returned information is consolidated, the user (the customer) will be able to browse through the information and decide on his purchases.

CONCLUSION

A mobile agent system has been developed to perform restaurant food searches for customers from restaurants with Web presence. Details on promotional offers are also 'pushed' to the user. The security aspect of the system and integrity of the data are ensured by means of cryptography and digital signature schemes. The system provides a user-friendly environment for easy usage.

There are areas that we are currently exploring to further improve the system. Firstly, we are extending the aglets server functions to handle advance reservation requests from the user; this will require further mobile agent activity such that the mobile agent will interact with the restaurant reservation system to place a booking. This will also involve expanding payment options that must be provided for the user to pay for his meals. To push the technology further, we are exploring the possibility of allowing autonomous negotiation by the mobile agent. Basically, mobile agents representing the users and the restaurant servers will meet at some cyberspace negotiation room to transact their requests for their respective hosts that they are representing.

KEY TERMS

Aglets: Platforms for mobile agents to operate on and on which to perform transactions.

Electronic Commerce: Business transactions over the Internet.

Encryption: Data coding schemes to protect information privacy.

Mobile Agent: Software code that can migrate host to host autonomously to perform operations.

Payment System: A mechanism for enabling payment for Internet transactions.

Trusted Third Party: A trust center that serves as an intermediary for Internet transactions.

Personalization and Customer Satisfaction in Mobile Commerce

HY Sonya Hsu
Southern Illinois University, USA

Songpol Kulviwat
Hofstra University, USA

INTRODUCTION

The advancement of wireless technology facilitates both consumers' activities and business transactions. With the rapid proliferation and widespread use of mobile devices, including mobile phones, personal digital assistants (PDAs), and handheld computers, mobile commerce or m-commerce is widely considered to be a driving force for the next generation of electronic commerce (e-commerce). According to Jupiter Research, the m-commerce industry is expected to be US$22 billion globally by 2005. However, to date many promising technologies—especially m-commerce applications—have failed with the notable exceptions of i-Mode service and short messaging service (SMS).

Popular "i-Mode", produced by NTT DoCoMo of Japan, is a service that enables wireless Web browsing and e-mail from mobile phones. The "i-Mode service" has been the first successful commercial introduction of 3G (third-generation) mobile applications. It exceeded expectations and acquired over 30 million profitable users in a three-year period (Cohen, 2002).

One of the main goals of most operators might be building customer satisfaction and loyalty by providing one or more 'killer apps' to them. One way is to integrate customer relationship management (CRM) into the development of mobile services' applications. Some firms have tried to target these applications to their customers on an individualized basis. "Personalization" may be the way to achieve that. Specifically, personalization can be regarded as the use of technology and user/customer information to match multimedia content with individual needs with the goal of producing user satisfaction. Personalization can be presented by an IP services framework that allows operators and subscribers through self-service provisioning approaches to control the types of service and applications they want and are willing to buy.

The purpose of this article is to develop a deeper understanding of personalization, with an emphasis on those factors that lead to customer satisfaction and/or delight. Specifically, this article presents factors contributing to consequences derived from using personalized applications and services in m-commerce.

BACKGROUND

In their pilot study, Ho and Kwok (2003) applied the technology acceptance model (TAM) originated by Davis (1989) to their m-commerce study. They utilized four constructs to predict the service subscribers' intention to switch: number of generalized messages, perceived ease of use of general advertisements, perceived usefulness of personalized message, and privacy issues about personalized advertisements.

This article extends the thrust of Ho and Kwok's research to incorporate the effect of personalization on customers' satisfaction and delight that could contribute to CRM. Customers' satisfaction and delight are derived from expectancy theory, and they are discussed by Oliver (1981), Oliver, Rust, and Varki (1997), Spreng, Mackenzie, and Olshavsky (1996), and Verma (2003).

Expectancy: Satisfaction and Delight

Expectancy theory is used to frame the evaluation of mobile services users. Oliver (1981) defined expectation to include two components: the probability of occurrence (e.g., the likelihood that a personalized cell service will be available) and an evaluation of the occurrence (e.g., the degree to which the personalization level is desirable or undesirable). The disconfirmation/confirmation paradigm of satisfaction is based on expectancy theory. It can be an emotional response to the comparison of the performance received and the products' normative standards. When the performance and expectations are at variance with each other, there is a discrepancy. This discrepancy could be either *positive* (when performance exceeds the expectations), which often causes satisfied state, or it could be *negative,* when performance is worse off than expected (Oliver, 1981). In other words, the consumer would be satisfied if perceptions match expectations or if confirmations are reached. Consistent with Spreng et al. (1996), satisfaction arises when consumers compare their perceptions of the performance of a good and/or service to both their desires and expectations. As such, satisfaction is a subjective judgment and may imply mere fulfillment.

Delight is a positively valence state reflecting high levels of consumption-based affect. The feeling of delight is experienced when the customer is pleasantly surprised in response to an experienced disconfirmation. It is the feeling state containing high levels of joy and surprise (Westbrook & Oliver, 1991). Further, Oliver et al. (1997) proposed and confirmed that delight is a function of surprising consumption, arousal, and positive effect or a function of surprisingly unexpected pleasure. They empirically confirmed that delight is a "mixture" of positive effect and arousal or surprise. It is associated with the level of arousal intensity. Moreover, it is a reaction experienced by the customer when he or she receives a service and/or a good that does not simply evoke a feeling of satisfaction, but also provides an unexpected value or unanticipated additional pleasure. In other words, delight occurs when the outcome is unanticipated or surprising. It can be marked by pleasurable, unforgettable, and memorable feelings in a service encounter or a product purchase (Verma, 2003). It is thought to be the key to customer loyalty and loyalty-driven profit (Oliver et al., 1997) and is known as the highest level of expectation-disconfirmation paradigm.

Technology Acceptance Model (TAM)

From Davis' (1989) TAM model, ease of use (EOU), and perceived usefulness (PU) of a technology are factors that either directly or indirectly increase a person's intention to adopt an innovation. While *perceived usefulness* is the degree to which a person believes that using a particular technology/system would enhance the outcome performance, *perceived ease of use* is the extent to which a person believes that using a particular technology/system will be free of effort (Davis, 1989). TAM could be helpful in predicting the usage of personalized applications and services. Greer and Murtaza (2003) adapted the TAM model to study issues that impact the valuation of Web personalization as well as factors that determine customer use of Web personalization. Ho and Kwok (2003) adapted Davis' (1989) EOU and supported the effect of using a generalized message on changing a service provider. They also used "PU of personalized service" to test the importance of personalization in mobile commerce. They found support for both. Most importantly, the PU of personalized service was the most effective factor, together with ease of locating generalized message and the amount of generalized message that affected the decision to change to a new service (Ho & Kwok, 2003).

MAIN THRUST OF THE ARTICLE

Usually when there are too many generalized messages, customers lose their motivation to read, retrieve, or even locate a useful message. In addition, the amount of space available on the mobile screen limits the amount of options and information. Given this, personalization is considered to be the key factor for success/failure of mobile devices and services. Information and services must become increasingly tailored to individual user preferences and characteristics in order to accommodate limited space and scarce airtime. Personalization is viewed as including "recognition of a customer's uniqueness" (Surprenant & Solomon, 1987, p. 87), use of a customer's name, and response to customer needs (Goodwin & Smith, 1990).

Message Format

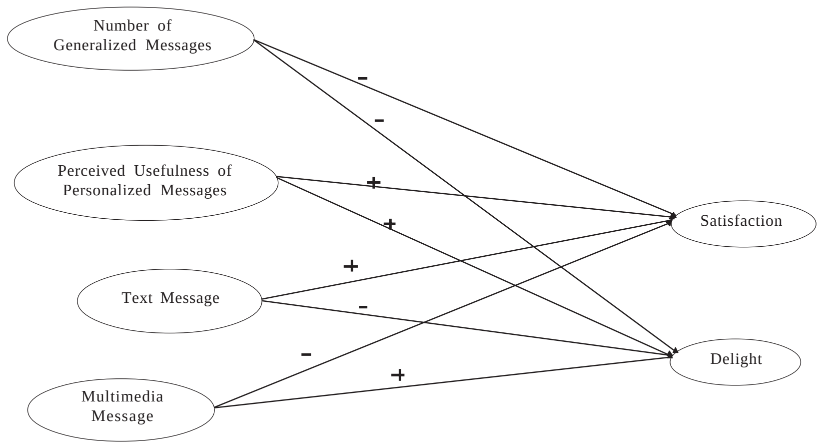
Carlson et al. (1998) characterized medium *richness* as the capacity to convey information. It is further defined as the ability to provide immediate feedback to customers' consumption of media. Rich information can be produced by giving immediate feedback, having a variety of available communication cues, understandable/common language, and foremost, personalization of the medium (Carlson et al., 1998).

Media richness theory postulates that media selection depends on the uncertainty of the task at hand (Kumar & Benbasat, 2002). Both media richness theory and the TAM model have illustrated their relationships with task orientation. Also, social presence theory postulates a particular communication task based on the degree of necessary social presence that links a selection of media (Kumar & Benbasat, 2002). Originally, it referred to the degree to which a medium allows a user to establish a personal connection with the other users. Social presence seems to be moving towards a task orientation at an individual level in the latter theoretical development, such as the para-social concept from Kumar and Benbasat (2002). Para-social is a combination product of social presence and media richness. This article focuses on the PU of personalized messages that employ a task orientation, while two different formats of messages (text and multimedia) were drawn from media richness theory.

Personalization

Personalization can be defined as the use of technology and user/customer information to customize multimedia

Figure 1. Research model



content so as to match with individual needs and ultimately produce user satisfaction (Zhang, 2003). Personalization is primarily regarded with sending the right message to the right person at the right time. The main goal behind personalization is to make any medium's usage easier and enhance any channel communication between customers and service providers.

Personalization translates individual profiles into unique presentations. The individual profiles can be built upon user preferences, the quality of his or her senses, user location/environment, contexts, users' network, and terminal capabilities. Morris-Lee's (2002) study on personalization of brochures indicated that personalization helped increase interest and involvement. The more personalized features are, the greater the possibility of increased costs (Greer & Murtaza, 2003). Hence, these increasing costs hopefully should produce greater customer satisfaction and retention, thus a greater return. This is a very important point because, for example, a 5% increase in customer retention costs can translate into a 25%-125% increase in company profitability (Reichheld et al., 2001). Also, personalization of service has been found to have a positive impact on customers' evaluations of service encounters (Surprenant & Solomon, 1987).

Figure 1 presents the research model of personalization in m-commerce. The model is developed based on the TAM (Davis, 1989) and expectancy theory (Oliver, 1981). Specifically, this research model extends Ho and Kwok's (2003) research framework. Further, our model integrates customer expectancy as an endogenous variable. The model includes six sets of variables: (1) number of generalized messages, (2) perceived usefulness, (3) text messages, (4) multimedia message, (5) satisfaction, and (6) delight.

FUTURE TRENDS

As predicted, text message predictor had a positive association with the dependent variable. Number of generalized messages was negatively related to satisfaction. Multimedia message was not a significant predictor of satisfaction and was deleted in the second model. On the other hand, the analyzes of "delight," "multimedia message" contributed the most importance to the equations and was positively related to delight. Text message and PU of personalized message had positive associations with delight, while the number of generalized messages had a negative contribution to the equation (Hsu, Bruner, & Kulviwat, 2005).

According to Santos et al. (2003), even though satisfaction and delight are two different constructs, each serves a dimension of confirmation (satisfaction) at one end and disconfirmation (delight) on the other end. Increasing literature has being drawn in the difference between consumer satisfaction and delight (Kumar & Olshavsky, 1997; Oliver et al., 1997). To compare satisfaction with delight, Oliver et al. (1997) see customer delight as being fundamentally different from customer satisfaction. Compared to satisfaction, delight seems more abstract and more extreme in terms of affection. While satisfaction may be induced by avoiding problems or may meet standard/minimum requirement, delight requires more than that. Oliver et al. (1997) empirically confirmed the distinction between the satisfaction and delight constructs, with delight being a higher level of satisfaction. In fact, customer delight is associated with a strong and positive emotional reaction to a product or service. Thus, both practitioners and scholars should manage customer delight as a separate goal from satisfaction.

Te'eni, Sagie, Schwartz, Zaidman, and Amichai-Hamburger (2001) used three dimensions to define media richness further; these are interactivity, adaptiveness, and channel capacity. Beyond just a different format from a text message, future researchers may look into a deeper understanding of multimedia messages that convey information for possible customers' delight in addition to satisfaction. Delightedness can be marked with pleasurable, unforgettable, and memorable where customer loyalty is rooted (Verma, 2003; Oliver et al., 1997). With the limitation of student population, future research may investigate some professional group that has reasons to use mobile commerce and/or some population that has more disposable income at hand. Another limitation that can also be addressed in the future is the sophistication of multimedia services and the maturity of users. In other words, future researchers may look into some markets that have rolled out the mMode of AT&T, Mobile Web of Verizon, and/or Sprint's PCS.

From mobile application point of view, "personalization" can be more sensitive to users' needs, for example, location-based application as in www.mobull.usf.edu. Local merchants ally to deliver a personalized text message—such as sales, promotion advertisement, coupons—from a Web site to a wireless device based on personal preferences that are set up by each individual. Location-based services utilize location information to provide specialized contents to mobile users (Varshney, 2003). Explicit user permissions should be obtained before "pushing" any advertising contents to particular users (Varshney, 2003). Push and pull advertisement, of course, relates to the issues of privacy and sharing of user information. Therefore, the "trust" matter may surface between a group of local merchants and individual consumers.

CONCLUSION

This article identifies the same situation as in Ho and Kwok (2003) that the amount of generalized message had a negative effect on customer satisfaction. Personalized message is more likely related to customer satisfaction and delight. The TAM model and expectancy theory were drawn as the foundation of this research model. Media richness explains the division between text message and multimedia message, whereas TAM contributes the perceived usefulness of personalized message.

Beyond personalization, this article attempts to merge the media richness theory with expectancy theory. Specifically, it explains the relationships between text/multimedia message and customer's satisfaction/delight. The article concludes that consumers would like to have a richer media to experience a "delightful" emotion. Consistent with the principle of media richness (Carlson et al., 1998): the more complex media format, the more information can be delivered in a message. If managers would like to increase effectiveness and/or efficiency of mobile services, text message alone would not be sufficient for market differentiation to gain competitive advantage. With personalization, multimedia formats can be a supplement tool to increase the interaction with consumers when launching advertising campaigns. The richer the media, the more effective it is in communication.

KEY TERMS

Customer Delight: The feeling of delight is experienced when the customer is pleasantly surprised in response to an experienced disconfirmation.

Customer Satisfaction: Based on the consumption, consumer would be satisfied if perceptions match expectations or if confirmations are reached.

Expectance Theory: Oliver defined expectation to include two components: the probability of occurrence and an evaluation of the occurrence. The discrepancy of confirmation could be either positive or negative.

Media Richness: Media richness theory postulates that media selection depends on the uncertainty of the task at hand. The more complex media format, the more information can be delivered in a message.

Mobile or M-Commerce: Both consumers' activities and business transactions are facilitated by the advancement of wireless technology including cellular phones, wireless PDAs, or any hand-held units.

Personalization: Can be regarded as services of the use of technology and user/customer information to customize multimedia content aiming to match with individual needs and ultimately deliver customers' or users' satisfaction.

Technology Acceptance Model (TAM): From Davis' TAM model, ease of use (EOU) and perceived usefulness (PU) of a technology are factors that either directly or indirectly increase a person's intention to adopt an innovation.

Personalization Techniques and Their Application

Juergen Anke
Dresden University of Technology, Germany

David Sundaram
University of Auckland, New Zealand

INTRODUCTION

Personalization is an approach to increase the usability of complex information systems and present the user with a comprehensible interface that is tailored to his or her needs and interests. In this article, we examine general techniques that are employed to achieve the personalization of Web sites. This is followed by a presentation of real-world examples. It will be shown how different levels of personalization can be achieved by employing the discussed techniques. This leads finally to a summary of the current state in personalization technologies and the issues connected with them. The article closes with some ideas on further research and development, and a conclusion.

In general, the concept of personalization refers to the ability of tailoring standardized items to the needs of individual people. It is originally derived from the ideas of Pine (1993) who proposed that companies should move from the paradigms of standardized products and homogeneous markets to customizable products that meet the requirements of many different customers. The principle of mass customization applies to a certain degree to most car manufacturers and some computer manufacturers, for example, Dell.

In the digital world of the World Wide Web, the degree of customization can be much higher than in the physical world. Currently, a number of online portals and e-commerce shops make use of personalization to provide a better user experience. Although Web sites may be the most popular examples of personalization, the concept is not limited to the Web. Every information system that deals with large amounts of data and/or has a heterogeneous group of users can benefit from it. Examples include e-learning environments, electronic books, computer-operated voice and telephony services, and tourist guides.

Personalization is also very useful for mobile devices like personal digital assistants (PDAs) or mobile phones (cf, Mulvenna, Anand, & Buchner, 2000). Technologies like mobile Internet access, WAP (Wireless Application Protocol), and future multimedia applications based on high-capacity wireless technologies require the designers of services for these devices to deal with limited input capabilities and small display sizes. For that reason, every method that assists the user in navigating and finding information easily adds real value to applications for such devices.

PERSONALIZATION TECHNIQUES

The core idea of personalization is to customize the presentation of information specifically to the user to make user interfaces more intuitive and easier to understand, and to reduce information overload.

The main areas of tailoring presentation to individual users are content and navigation. Content refers to the information being displayed, and navigation refers to the structure of the links that allow the user to move from one page to another. Personalized navigation can help the user to easily find what he or she is looking for or to discover new information. For example, a system discussed by Belkin (2000) assists users in refining search queries by giving recommendations on related or similar terms.

Adaptable vs. Adaptive

There are two approaches to achieve personalization: adaptable and adaptive methods. The former is a term for systems that can be customized by the user in an explicit manner; that is, the user can change the content, layout, appearance, and so forth to his or her needs. This data is called a user profile, and all personalized presentation is based on data the user provided for configuration purposes. It is important to note that the customized appearance does not change over time until the user decides to change his or her preferences.

In contrast, adaptive methods change the presentation implicitly by using secondary data. This data can be obtained from a variety of sources, for example, from the user's actions, from the behaviour of other users on that

Table 1. Application of adaptable and adaptive methods to content and navigation

	Content	Navigation
Adaptable	▪ explicit selection and ordering of content items by the user ▪ providing personal information to be listed in directories ▪ setting up stock portfolios	▪ building link lists (favourites, bookmarks) ▪ setting default links for generic navigational structures/menus to omit intermediate step(s)
Adaptive	▪ present the user new items which are related to the current items (recommendations) ▪ filter content based on current actions (remove items which are dissimilar)	▪ hiding unsuitable links based on the context ▪ annotate links to give meta-information about value of the linked content relating to the user's navigation history (e.g. "no new information", "insufficient previous knowledge" etc)

site, or based on the currently displayed content. Methods that use this data as input are discussed in detail below. The most distinctive characteristic of adaptive methods is that they are constantly monitoring the user's activities to adjust the arrangement and selection of relevant information.

Adaptive methods or machine-learning algorithms are huge steps toward automated customization. Current static interfaces suffer from the fact that the designer has to anticipate the needs, interests, and previous knowledge of the users in advance. As these preferences change over time, customization that requires human interaction for collecting and identifying preferences leads quickly to outdated user profiles.

Table 1 shows how adaptive and adaptable methods can be applied to customize content and navigation. The examples given are intended to be generic; more concrete examples are examined in the case studies below.

Degree of Personalization

Another important criterion for classification is the degree of personalization. Systems can have *transient* or *persistent personalization*, or be *nonpersonalized*. With transient personalization, the customization remains temporary and is largely based on a combination of the user's navigation and an item-to-item correlation. For example, if an item is selected, the system attaches similar items as recommendations to it whereby the content of the shopping cart is taken into consideration.

Persistent personalization systems maintain a permanent user account for every user to preserve his or her settings and preferences across separate sessions. Although this raises privacy issues and is the most difficult to implement, it offers the greatest benefit. These systems can make use of user-to-user correlation algorithms and thus provide higher accuracy.

Another technology that belongs to the broad area of personalization is *recommender systems* (Mulvenna et al., 2000). Whereas straight personalization tailors just the presentation of information, recommender systems support the user in discovering new information. As recommendation relies on user preferences and interests, it is often part of personalized systems. From another perspective, one can say that recommender systems provide a selection of the most suitable content for the user. The application of recommender systems to e-commerce is discussed by Schafer, Konstan, and Riedl (2001).

In the following sections, we look at two cases that highlight the adaptive and adaptable approaches to personalization.

APPLICATION AND IMPACT OF PERSONALIZATION: AMAZON.COM

Amazon.com is one of the pioneers of e-commerce. Originally set up as a bookstore, it has grown to a general retailer for a wide range of products. It also provides an auction platform and a marketplace where customers can sell used goods. The marketplace is seamlessly integrated into the main product catalogue, therefore customers can decide whether they want to buy a particular product as a new or a used one.

Goal

As the Amazon.com product catalogue contains more than 2 million products, users can easily get frustrated if they do not find what they are looking for. Thus, one of the main goals is to tailor the product catalogue as much as possible to the needs and interests of the user.

Aside from easy navigation, the site offers a seamlessly integrated recommendation system. It is intended to offer customers products that are either related to their interests or to the product that is currently displayed to exploit cross-selling potentials.

Personalization Techniques

Amazon.com is a highly developed online shopping site and incorporates a combination of numerous adaptive and adaptable methods. The generated user profile is stored in a database on the server; that is, the degree of personalization is persistent.

The prevalent recommendation method is based on the purchases of other customers. It appears as a list beginning with the phrase "Customers who bought this book also bought…" on each product detail page (Figure 1a). A second list contains up to five authors whose books were bought by customers who also bought the currently selected book. Both of these features are collaborative-filtering methods of implicit collected data. Another feature called purchase circles is also a collaborative-filtering mechanism that displays the top-10 products for a particular region, institution, or company.

Other recommendation methods are based on the activities of the customer. For example, there is always one product recommendation in a sidebar that is apparently directly derived from the list of recently viewed items (Figure 1c). Moreover, there is also a recommendation page for each of the main categories (books, software, etc.) that is completely based on the customer's purchase history.

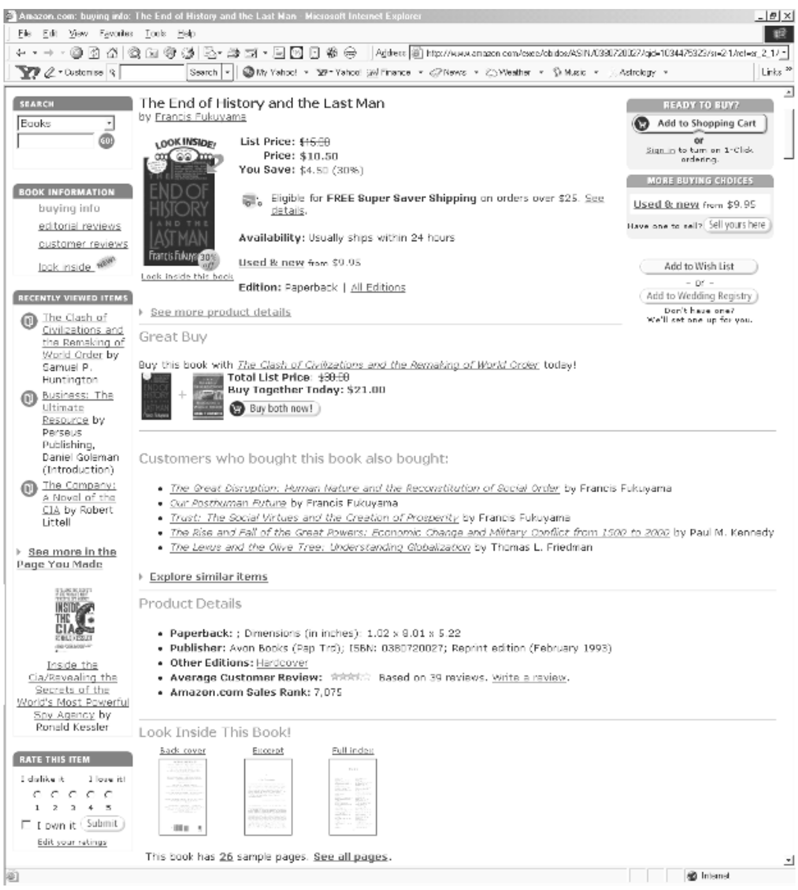
Amazon.com also encourages customers to rate their purchased products (Figure 1e). Ratings belong to the collaborative-filtering methods. However, in contrast to the list of products other customers bought, they require explicit interaction for the sake of personalization. The ratings can also be part of customer reviews and comments. Interestingly, it is even possible to rate the ratings; that is, customers can indicate whether they found the rating helpful or not (e.g., "3 of 5 people found the following review helpful"). This mechanism is used to display the most helpful comments first and let the least helpful comments move to secondary pages.

As mentioned before, one of the goals is to exploit cross-selling potentials. One of the recent additions to Amazon.com is the "Great Buy" feature. It offers the customer the current product together with another product in a bundle at a special price (Figure 1b). The two products must have a complementary relationship to be valuable to the customer.

Outcome and Lessons Learned

Amazon.com has clearly utilized a very broad range of different personalization methods. As this site has developed constantly in product variety, functionality, and comfort, it is nearly at the state of the art in this area. The

Figure 1. Amazon.com detail page for a book



goals stated above are nearly completely fulfilled. The site is easy to navigate, the products are easy to find, and the accuracy of the recommendations seems to be very high, which animates the customer to buy further products.

The "Great Buy" feature is certainly one of the best ways to take advantage of the cross-selling potential, whereas the list of products other customers bought is more useful for the discovery of new, interesting items and navigation. The latter seems to be less accurate compared to the earlier days of the site. This might have something to do with the enormous number of customer profiles that do not provide enough distinctive attributes to form useful clusters.

Ratings and reviews can be considered as a helpful feature; however, there are a number of relatively unqualified comments. To improve the situation, the rate-the-rating feature was introduced (far after the review function itself). While this highlights the more valuable reviews, there is still room for improvement.

APPLICATION AND IMPACT OF PERSONALIZATION: YAHOO!

Yahoo! was one of the first search portals on the Web and one of the first Web sites that applied personalization on a larger scale (Manber, Patel, & Robinson, 2000). In 1996, the My Yahoo! service was introduced. It allows setting up a personal version of Yahoo! for every user. Not only the content, but also the layout and the appearance of the page can be modified. Yahoo! is a completely adaptable system; therefore, all personalization is based on the data the user entered beforehand. The ZIP code is especially central as a lot of personalized features rely on it. The intelligence of the system lies in the ability to use this data in different situations to tailor the presentation specifically to the user.

Goal

The goal of Yahoo! is to bind its users by differentiating from other Web catalogues and search engines, and to provide a fully customizable and integrated portal. As the customer structure of Yahoo! is very heterogeneous, it is a good idea to offer personalization and let users construct an individual start page. Yahoo!'s service is free for its users; money is mainly earned with advertising and revenue provisions of shopping partners. Thus, the second goal is to make advertising as effective as possible. This can be achieved by selecting banner ads that are likely to be of interest for the user.

Personalization Techniques

Yahoo! offers an adaptable system that requires the user to explicitly provide information for personalization. The user profile is kept on a server between different visits, thus Yahoo! offers persistent personalization.

My Yahoo! enables registered users to build their own Yahoo! pages. The content is selected as so-called modules. Among the available modules are ones for weather, news, sports results, stock quotes, horoscopes, movie reviews, personal news filters, and many more. Further configuration can be done within these modules. In the example shown in Figure 2, the headline module (a) is set up to show world news from British news agencies and German Formula 1 news. The weather module (b) displays the current weather situation of selected cities only. Modules can be edited or deleted (c) directly on the page. Some of the modules offer an individual default setting that is based on the user profile. For example, when the sports-results module is added, it already contains the results of teams in the user's area.

Not only the content, but also the layout is customizable. The chosen modules can be distributed on multiple pages that in turn consist of two or three columns where modules can be ordered arbitrarily. There are also options like colour sets and themes to change the appearance of My Yahoo!.

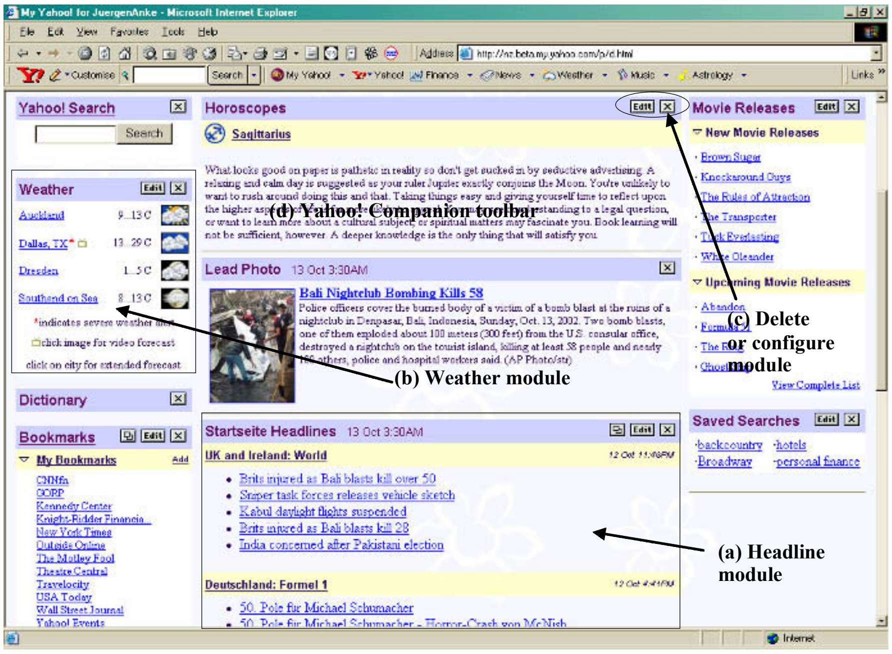
Outcome and Lessons Learned

The goal of flexible customization to provide an integrated portal can be considered to be fulfilled. Whether the effectiveness of advertising is increased by personalization cannot be decided with certainty since most of the literature does not mention it. However, as it is vital for Yahoo! to have effective advertising, it can be assumed that it incorporates a relatively advanced system for selecting banner advertisements on an adaptive basis.

Apart from these sophisticated personalization features, it is also essential to design high-quality default pages for people who do not want to customize at all. It turned out that only a small number of users actually customize Yahoo!; most of them take what is offered. The reasons for this may be either that the personalization tools are too complicated, or the users do not need complex personalization as the default page is satisfactory for them. Addressing all types of users also includes not requiring users to enter any personal data and not forcing them to use personalization features.

Yahoo! has decided not to use adaptive methods. They believe that these methods are still not good enough for such a complex site as a user's behaviour is not

Figure 2. A customized version of the My Yahoo! start page



sufficiently predictable. People must not be unsure of how the systems work; otherwise, it prevents them from experimenting as they fear breaking something. The people from Yahoo! reckon that any kind of personalization should encourage the users to experiment.

While it is beyond the scope of this article to look at the numerous other cases of personalization, it is worthwhile to mention the large-scale personalization project at ibm.com. Karat, Brodie, Karat, Vergo, and Alpert (2003) describe this in detail, and they provide an overview of the many different personalization techniques used and the reasons for selecting them for the project.

CONCLUSION

Current State of Development

A number of different approaches to personalization are currently used in various applications. Highly sophisticated e-commerce sites usually employ a combination of multiple methods and contain adaptive as well as adaptable elements in a coherent user interface. As the case study of Amazon.com has shown, organisations can add real value for the users by making it more convenient to tailor the presentation to individual needs.

Adaptive methods for personalization are very powerful means to manage information overload and simplify user interfaces. Despite their sophisticated algorithms, they can produce unpredictable and unwanted results. This is an area where further research is necessary as adaptable methods have the serious disadvantage of their configuration remaining static until the user changes it explicitly. This can be a tedious task for most users, which lowers the value even of the most flexible customization services. Hence, there are only a small number of users who actually want to customize their pages.

Directions for Future Research and Development

Improve Group-Based Personalization

The personalization based on a user's preferences is increasingly being extended by collaborative methods. Instead of recommending items based on the profile of a single user, the system should try to take advantage of other users' ratings and preferences as well. While this might in fact increase the accuracy of predictions, it raises the issue of proper user selection.

New Input Methods

Methods that allow formulating queries in a natural language rather than in special inhuman query syntax could make the interaction between the user and the system even more personalized and individualistic (Zadrozny, Budzikowska, Chai, Kambhatla, Levesque, & Nicolov, 2000).

Combination of Explicit and Implicit Data

Both adaptive and adaptable methods have their strengths and weaknesses, and may be more or less applicable for a particular situation. However, it seems to turn out that the combination of explicit and implicit user data provides the best results. On one hand, the effort of manual customization is minimized, and on the other hand, an adaptive method will not cause much unpredicted results when it is limited by explicit statements. Wells and Wolfers (2000) explain how customers who use online banking services need to make some basic statements about their financial goals and situations. After that, adaptive methods are used to offer financial products and services that are tailored to the customer and suitable for his or her particular needs. However, not all techniques applicable to a certain scenario will be successful in practice. Alpert, Karat, Karat, Brodie, and Vergo (2003) show in their study about users' attitudes toward adaptive systems that users have a strong desire to always be in full control of all interaction. It is therefore important to carefully analyze the potential acceptance barriers of a designed solution before finally deploying it.

Future Outlook

Personalization technologies have found their way out of experimental systems of researchers into commercial applications. They are a powerful means to handle information overload, to make complex information systems more usable for a heterogeneous group of people, and to help online businesses establish personal relations with their customers (one-to-one marketing). Although we have focused on applications of personalization to Web sites, they can be used in a wide range of human-computer interactions. Personalization techniques are the key to mass customization and provide people with a much more individual experience instead of standardized services.

KEY TERMS

Adaptable Personalization Systems: Systems that can be customized by the user in an explicit manner; that is, the user can change the content, layout, appearance, and so forth to his or her needs.

Adaptive Personalization Systems: These change the presentation implicitly by using secondary data. This data can be obtained from a variety of sources, for example, from the user's actions, from the behaviour of other users on that site, or based on the currently displayed content.

Decision-Support Systems and Tools: In a wider sense, it can be defined as systems and tools that affect the way people make decisions.

Mass Customization: The customization of products and services for individual customers, but at a mass-production price.

Personalization: An approach to increase the usability of complex information systems and present the user with a comprehensible interface that is tailored to his or her needs and interests.

Recommender Systems: A special type of decision-support system that gives recommendations for further actions or related items.

Tailoring: In the context of personalization, it can be with respect to content or navigation. Content refers to the information being displayed, and navigation refers to the structure of the links that allow the user to move from one page to another.

Process-Oriented Reorganization Projects in Electronic Government

Jörg Becker
University of Münster, Germany

Lars Algermissen
University of Münster, Germany

Björn Niehaves
University of Münster, Germany

INTRODUCTION

From the beginning of the 90s, public administration has been confronted by a series of new demands. Society has been transformed by the influence of new technologies. There is a strong trend towards growing individualization, whereby there are increasing demands by individuals on the state. Simultaneously, in the context of national and international competition, efficient and effective state activity and support for entrepreneurial activities in a region or country are becoming an increasingly decisive factor in location decisions. No one has yet succeeded in improving the performance capability of the state, in a manner and degree that is commensurate with the increasing number of responsibilities. According to Budäus and Schwiering (1999) a modernization and performance gap has arisen because of the difference between the volume of work and performance.

For some years, the term electronic government, coined from e-business, has been universally proposed as a way of closing this gap. The core of e-government as well as e-business is the execution of administrative processes (Langkabel, 2000, p. 6). In recent years, businesses have already initiated and successfully undertaken measures to strengthen the organization of business processes. At the same time, the academic disciplines of business management studies and business information technology have taken up this issue (Davenport, 1993; Earl, 1994; Hammer 1990; Hammer & Champy, 1993). Commensurately, fields such as process modeling, workflow management or process cost calculation demonstrate a deep understanding of theory and have consequently attained a high standard of development.

However, the practical application of this knowledge, acquired in the domain of public administrations, has only occurred to a limited degree. Alongside an insufficient translation of theoretical knowledge into practice, the urgent practical challenges of process management, for example, and the design of procedure models for specific domains, have not so far been adequately taken up by the relevant academic disciplines and conceptualized soundly.

The purpose of this article is to stimulate an improvement in the situation outlined above. The objective is the presentation of a systematic approach how to prepare process oriented e-government projects. As a rule, comprehensive preparation is essential for process modeling, because, on the one hand, the model design is characterized by a high degree of process complexity and on the other hand, the information model is characterized by a high degree of object complexity. When considering the aim of the modeling, it is necessary to determine both the object of modeling, and the modeling methods and tools.

As an introduction we first provide an overview of related work. In section one we briefly describe different modeling objectives and explain, why organizational design is one of the most important aims of process modeling in the context of e-government ("why" should be modeled). In section two we identify requirements for a modeling method based on the domain e-government and the modeling objective organizational design. The requirements lead to the selection of event-driven process chains (EPC) ("how" should be modeled).

In section three we show how the target environments for modeling projects can be identified. Based on a public service classification scheme we therefore introduce a two-phase procedure comprising the successive application of the portfolio analysis and the profile method ("what" should be modeled).

BACKGROUND

Business process modeling and business process reengineering are the dominating topics in the discussion of enterprise modernization (Davenport, 1993; Hammer, 1993; Hammer & Champy, 1993; Harrington, 1991; King, 1994).

Several methods, techniques and tools have been developed and implemented to support process oriented reorganization (Keen, 1991; Kettinger, Teng, & Guha, 1997). The Architecture of Integrated Information Systems (ARIS) presented by Scheer, is an approach for specifying organizations and information systems (Scheer, 2000). The four different perspectives data, functions, organization, and control, each consisting of the three layers of conceptual model, technical model, and implementation, can be used to model different aspects of a software system from a business perspective as well as an IT perspective.

Modernization efforts are also undertaken in the area of public administrations. The discussion of public administration modernization and e-government is often limited to the provision of online services and public administrations' Internet portals. Big steps towards an integrated European e-government were taken within the eGOV project, funded by the European Commission. Within this project, an integrated platform for online one-stop government was specified, developed, deployed and evaluated. Based on "life-events" the effectiveness, efficiency and quality of public administrations' services were improved (Krenner, 2002; Wimmer, 2002).

Much remains to be done, both optimization of services delivered via Internet (e.g., one-stop-government), and the optimization of public administrations' internal and inter-organizational processes (Traunmueller & Wimmer, 2001).

In order to reach the goals described we show one approach how the optimization of administration's processes can be prepared: the questions which will be answered are why, how and what should be modeled in order to generate benefits in public administrations through process oriented e-government projects.

PROCEDURAL MODEL FOR E-GOVERNMENT REORGANIZATION PROJECTS

Select the Modeling Objective

The main aims of process modeling according to Rosemann and Schwegmann (2002, p. 58) are organization and application system design.

Organization Design:

- Organization documentation
- Process-oriented reorganization
- Continuous process management
- Certification
- Benchmarking

Application System Design:

- Selection of ERP software
- Model-based customizing
- Software development
- Workflow management
- Simulation

Models for organizational design require a high degree of clarity, whereas models for application system design require a high degree of technical precision, because of their close relationship to the final implementation.

The above listed purposes of process modeling obviously force the process models to meet certain different requirements in terms of content and methodology. With respect to contents, the requirements differ in the related model components. The first step in order to improve public administration's processes and make them suitable for e-government applications should be organization design, in particular, the process-oriented reorganization. An examination of application system design is only considered worthwhile on the basis of organizational process improvements (Raymond, Pare, & Bergeron, 1995).

SELECT THE MODELING METHOD

Modeling Method: Requirements

There are various and diverse model types for modeling (business) processes. Petri-nets (Jensen, 1985), added-value chain diagrams (Porter, 1990) and event-driven process chains (EPC) (van der Aalst, 1999), are amongst the best known. The choice of a model type is influenced mainly by the purpose of the application and the requirements of the model users. Application aims, such as simulation and workflow management, require model types which produce detailed, precise, formally itemized models. Application objectives such as process-oriented reorganization require less formal models. In this case, *clarity* is especially important. For a modeling method to meet the requirements of administrative processes, their most salient characteristics need to be considered first (Scheer et al., 1996, p. 120):

- Information processing functions predominate. Even if actual products are being produced, information processing predominates as the main resource for the public administration is information.

- Business processes are regulated either by law or at least hinge on legal regulations. This frequently leads to inflexibility and long time horizons for change.
- The responsibility for business processes is divided among a number of people, who work only on a small portion of the process “bureaucratically”. There is an enormous flow of documents between the individual stages. Because of this decentralized structure it makes the integrated overview of a business process more difficult.
- Citizens must be treated equally, irrespective of origin and assets, because of legislation and its legal implications. A high degree of procedural soundness, stability and comparability must be ensured.

Based on the characteristics described, the most important requirements of a modeling method are summarized as follows:

- Simple principle, clear presentation
- Comparability between various models
- Presentation of information systems
- Presentation of organization units and places
- Presentation of information flow

Modeling Method: Selection

Based on these requirements, the event-driven process chain (EPC) is often selected as a method in several projects, because of its high degree of clarity, and its potential for integrated evaluation. The high level of clarity is especially important in the interview phases as the results are usually documented in process models and have to be verified by the employees. Moreover the final presentation of target processes has to be easily understandable for a range of individuals with heterogeneous backgrounds (e.g., mayor or information technology officer). The other advantage is that weaknesses in the processes could easily be identified by analyzing the models.

SELECT THE MODELING OBJECT

Before the first modeling process, relevant problem areas should be (1) identified, (2) classified and then (3) prioritized with respect to financial and personnel resource constraints.

1. Business process framework for identification of target environments

An analysis of the organizational structure of the public administration and its effects on the organizational structure should be summarized to serve as a guiding principle for the processes to follow. The most suitable way of doing so is to use a business process framework. A business process framework divides the structures of the administration on an abstract level by a selected organizational paradigm and clarifies the relationships between the individual parts of this framework. It is important to adapt the business process framework according to the gained recognition of required processes. Often, the final business process framework is not ready before the process modeling is completed. After the modeled processes are implemented or when presenting the organizational structure, the business process framework can then be ideally used as a communication means and as a navigator through a number of process models that were generated within the scope of a project.

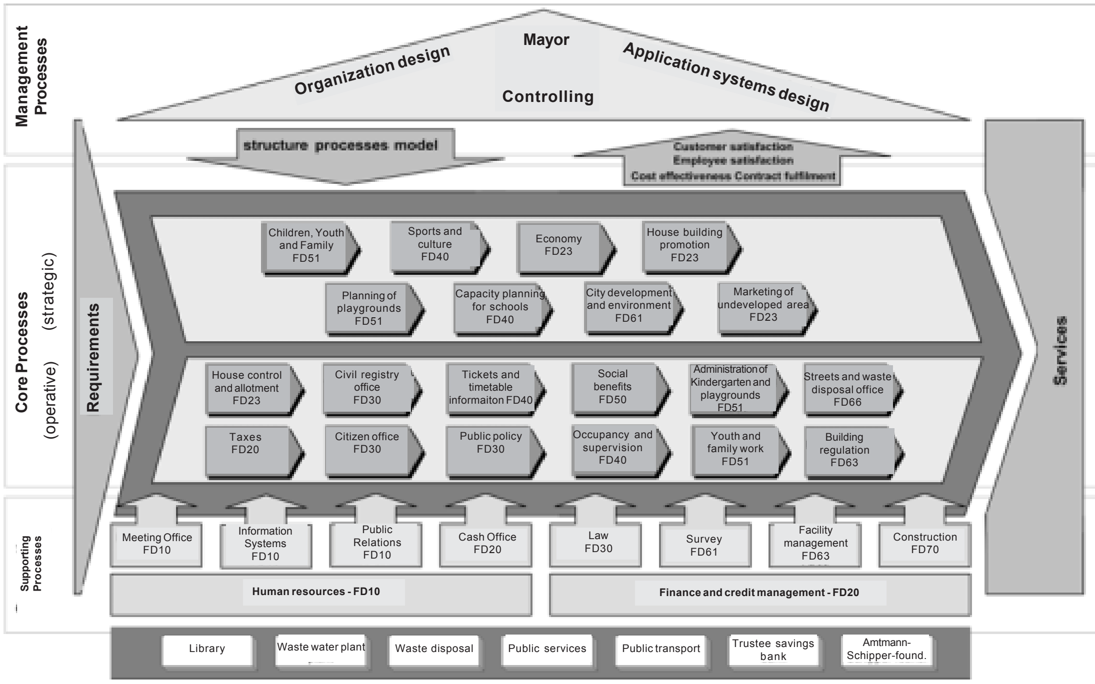
Figure 1 shows a framework for municipalities, which helps to identify potential target environments for organizational engineering. To support that, management processes, operative and strategic core processes and supporting processes are differentiated.

The most relevant processes for e-government projects are the core processes as they are directly connected to the environment consisting of citizens, companies and other administrations. After identifying the relevant target environments the next step is to classify the underlying processes, usually more than 1000 different ones in a common German municipality.

2. Classification of processes in target environments

A classification scheme is an appropriate way of structuring the identified services, taking into account different perspectives. In the context of the administration domain, the application of an internal and external perspective is provided, to show potential for improvements in administration (greater efficiency) and also for the citizens as customers (improved performance). The degree of interaction between citizens and local government can be a performance criterion. Three levels, information, communication and transaction have been widely used (Boller & Beuchat, 2002, p. 56; Budäus & Schwiering, 1999, p. 155). On the other hand, the degree of integration is used as a measure of the efficiency of a service and is part of the internal perspective. A hierarchy, for instance, can be structured according to whether a service is performed with media breaks, without media breaks, or completely automated. If the level of interaction and the degree of integration are combined, a matrix will be obtained, which can be of assis-

Figure 1. Framework for identification of processes



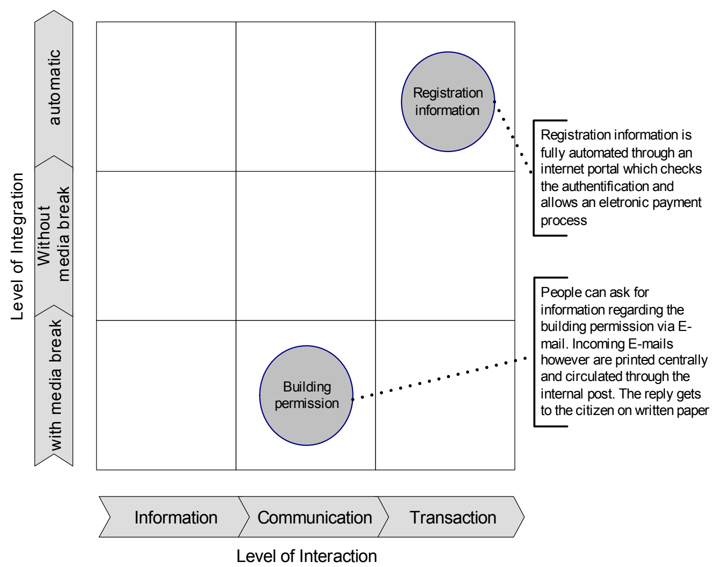
tance in categorizing and classifying existing services in a municipality (see Figure 2).

With the aid of a classification scheme, the extent of application of individual services can be visualized at a glance. In this manner, services, for example, can be identified, whose processing is already largely optimized and do not, therefore, need to be part of any reorganization project.

3. Prioritization of target environments

In order to select appropriate services on the basis of classification schemes, a two-phase procedure comprising the successive application of the portfolio method and the profile method is introduced. From phase to phase, the number of services considered and the level of

Figure 2. Classification scheme for administration services



precision of the investigation increase through using a rising number of decision-making criteria.

The *portfolio analysis* is a tool that, at minimal cost, can provide a basic overview of the most important qualitative features of a service and can convey its potential for a modeling project (Francis & Archer, 1971). It is then a question of which dimensions can provide the optimal prioritization of existing services.

- **Dimension 1:** The starting point is that all decisions have to be financially justifiable, because of the high pressure to contain or reduce costs. Hence local government should focus on services with a high number of cases as incremental costs decrease with an increased volume of users.
- **Dimension 2:** For every service performed on the part of local government, there is a user on the demand side. It is advisable first to aim for increased efficiency in areas of high usage through so called power users (e.g., businesses, associations and other external institutions), as the greatest results can be achieved there. Figure 3 shows the portfolio together with some selected services.

Recommendations for prioritization of implementation can be derived from the fields of the matrix (see Figure 3). The figures in the individual fields can be interpreted as *priority ratios*. The profile method, which is outlined in the following section, should therefore logically be used only for services that are found in field 1 of the portfolio.

Figure 3. Service performance portfolio

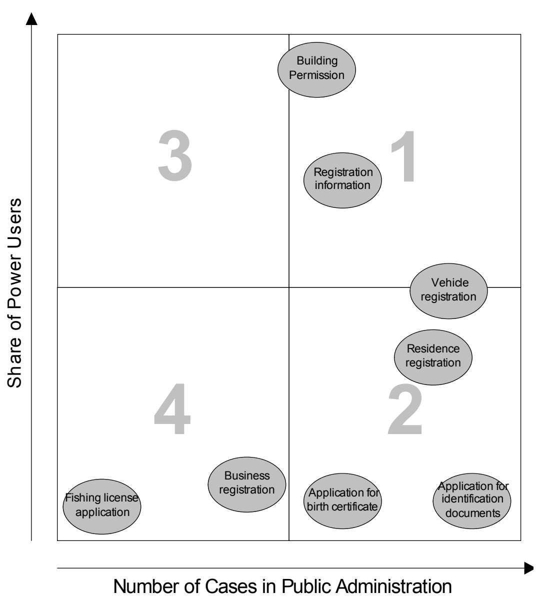


Figure 4. Service profile for registration information

Service:	Information from Citizen Register					
Evaluator:	Douglas Adams (City Adminstration)					
Date:	2003-02-24					
Evaluation Criterion	Assigned Value					
1. Transaction frequency Customer		1	2	3	4	5
2. Transaction frequency Administration		1	2	3	4	5
3. Organisational Complexity		1	2	3	4	5
4. Technical Complexity		1	2	3	4	5
5. Necessary Level of Security		1	2	3	4	5

The next step—the so-called *project profile method*—has the advantage of allowing the examination of the alternatives at one's disposal and with regard to several qualitative characteristics. Each aspect of an alternative is evaluated on a numerical scale of 1 to 5 and the total evaluation is depicted graphically. A distinctive positive feature is the explicit representation of evaluation criteria, which gives the decision-maker a more concrete picture of the individual services, than the portfolio presentation provides. A written definition of each numerical rating is given in the key.

The scale anchoring table provides a firm basis for evaluation and avoids any deviation in the results that could be caused by the subjective interpretations of different appraisers. The visualization of a service profile results in a matrix representation, which incorporates various evaluation criteria on one side and their possible ratings on the other. The relevant characteristics are marked by circles and connected with lines. This graphic presentation enables a fast visual estimation of a service. The choice of criteria for a service performance profile must be determined on a case-by-case basis. Figure 4 shows an example of a project profile with five features (in this case, for evaluation of the register information).

As with the portfolio method, in the case of service performance profiles, accurate results are less important in the context of prioritization, than the straightforwardness of the application.

After this phase—the organization possesses a prioritized list of processes which are suitable for process reorganization. The process modeling and reorganization itself will then commence with the phases:

- As-is modeling and process analysis
- To-be modeling and process optimization
- Process implementation and process roll-out
- Continuous process management

FUTURE TRENDS

It is clear that there are considerable structural analogies amongst various administrative processes within a civic authority, and to a greater extent with similar processes between authorities. In moving towards an extensive process oriented and IT-supported modernization of an administration, the development of a reference process model as a store of domain knowledge has the potential to significantly reduce the complexity of e-government projects and to simplify their implementation by means of an orientation around reference processes. Especially the use of business process performance metrics during the modeling process will allow the potential user of a reference model to assess its benefit by benchmarking the own process metrics against the reference model. With this approach the impact of reference models will become measurable.

CONCLUSION

The importance of the preparation of process modeling projects has been introduced. The three described steps have proven effective in achieving objectives and appropriate and correct for the several modeling projects in public administrations. Despite some remaining developmental barriers, process management in an e-government context, is a viable mechanism for advancing efforts to modernize an administration.

KEY TERMS

Electronic Government (E-Government): E-government entails the simplification and implementation of information, communication and transaction processes, in order to achieve, by means of information and communication technology, an administrative service, within and between authorities and, likewise, between authorities and private individuals or companies.

New Public Management: New public management is a stream of thoughts aiming at applying business management concept to public administrations.

Process Management: Process management aims at codesigning organizations and information systems.

Procedural Model: A procedural model seeks to analyze a certain process, business process reorganization in this context, in order to identify distinct stages and steps which require the application certain tools and methods.

Reorganization: Reorganization aims at changing the structure, the processes and the policy of an organization.

Process Simulation for E-Commerce Systems

INTRODUCTION

As a modern way to conduct business in the global economic environment, e-commerce is becoming an essential component integrated with traditional business processes in enterprises. To reduce risks and increase profits in e-commerce investments and to provide the best services to their customers, enterprises have to find appropriate ways to analyze their e-commerce strategies at the business planning stage. Strategic management tools are designed for enterprises to evaluate their business strategies, and can be used to evaluate an e-commerce business plan, as well. For example, the SWOT (strengths, weaknesses, opportunities and threats) analysis is regarded as a popular way to conduct an e-commerce business plan evaluation, with business environmental scanning based on internal environmental factors (strengths and weaknesses) and external environmental factors (opportunities and threats) (Turban, King, Lee, & Viehland, 2003). To facilitate the application of the strategic management tools, different forms of applications are adopted, such as checklist (OGC, 2004), rating system (UNMFS, 2004), expert system (PlanWare, 2004) and so forth. Among these, computer-driven business simulation tools enable participants to run with virtual business processes, experiment with different strategies and compete with other supposed companies or plans in a virtual business environment. As an example, the *Marketplace* (ILS, 2003; IDC, 2004) is a business simulator for integrative business courses that provides decision content, including marketing, product development, sales force management, financial analysis, accounting, manufacturing and quality management. Regarding the application of computer simulation in e-commerce, the *Marketplace* strategic e-commerce simulation is specifically designed, and it illustrates the business concepts of an e-commerce environment, as well (ILS, 2003). For an e-commerce system simulation, Griss and Letsinger (2000) studied agent-based flexible e-commerce systems with an experimental multi-player shopping game to experiment with alternative individual and group economic strategies, and to evaluate the effectiveness of agent-based systems for e-commerce. Both academic and professional practice have proved that using computer simulation is an effective, efficient and economical way for e-commerce business plan evaluation.

However, it is hard to conduct simulation based on the flowchart of business processes within the current e-commerce simulation environment as mentioned above. This actually provides a limitation for applying e-commerce simulation. In fact, computer simulation has tackled a range of business problems, leading to improving efficiency, reduced costs and increased profitability since the 1950s (Robinson, 1994). Simulation tools are on the increase in various application areas (Google, 2005) and process-oriented simulation has been increasing in popularity for business management (Swain, 2001). We believe that a process-oriented simulation for e-commerce system evaluation is more directly perceived through the human sense, and our interest is to conduct a quantitative approach to e-commerce system evaluation based on the theory of process simulation.

The e-commerce system simulation is an integrative procedure to run a business processes-oriented simulation program based on both internal and external business environmental factors to demonstrate the actual results of

Table 1. A statistic analysis of C&D waste disposal in Hong Kong (EPD, 1999/2002)

Year	Amount of Waste at landfills (ton)		Percentage of C&D waste (%)
	C&D waste	Total waste	
1998	7,030	16,738	42
1999	7,890	17,932	44
2000	7,470	17,786	42
2001	6,410	16,686	38

implementing an e-commerce business model by using computer-driven software toolkits. The e-commerce system simulation is an effective, efficient and economical approach, and can be used to experiment and evaluate different e-commerce business models or plans. The adoption of e-commerce system simulation can reduce potential risks in e-commerce system development, such as the huge amount of initial investments of time and money, and the long period from business planning to system development, then to system test and operation, and finally to exact return; in other words, the proposed process-oriented e-commerce system simulation can help currently used system analysis and development methods to tell investors in a very detailed way about some keen attentions, such as how good their e-commerce system could be, how many investment repayments they could have and in which area they should improve from initial business plans.

The definition of the proposed process-oriented e-commerce system simulation normalizes its procedure to apply a process simulation to experiment with an e-commerce model. In this regard, this article focuses on the adaptation of an e-commerce model into a process simulation environment by using an experimental case study. Results from this article include the conception of e-commerce system simulation, a comprehensive review of simulation methods adopted in e-commerce system evaluation and a real case study of applying simulation to e-commerce system evaluation. Furthermore, we hope that the adoption and implementation of process simulation approach can effectively support business decision-making, and improve the efficiency of e-commerce systems.

BACKGROUND

Generally speaking, construction and demolition (C&D) waste can be reduced by using innovative construction techniques and management methods. Although these approaches have proven to be effective to some extent, most of them are still in a stage of research, and contractors usually do not like to invest in high-cost techniques. For example, surveys show that local constructors in Hong Kong feel it is expensive to use new machinery and automation technology (Ho, 1997); most local constructors agree to adopt alternative low-waste but high-cost techniques only when they are demanded by the designers, the specifications or the clients (Poon & Ng, 1999). As a result, C&D wastes are normally not controlled effectively on sites in Hong Kong. According to statistical data, C&D debris frequently makes up 10%-30% of the waste received at many landfill sites around the world (Fishbein, 1998), but this figure has been more than 40% in recent years in Hong Kong. So there is an urgent need to deal with the problem and to find a practical solution for C&D waste reduction in Hong Kong.

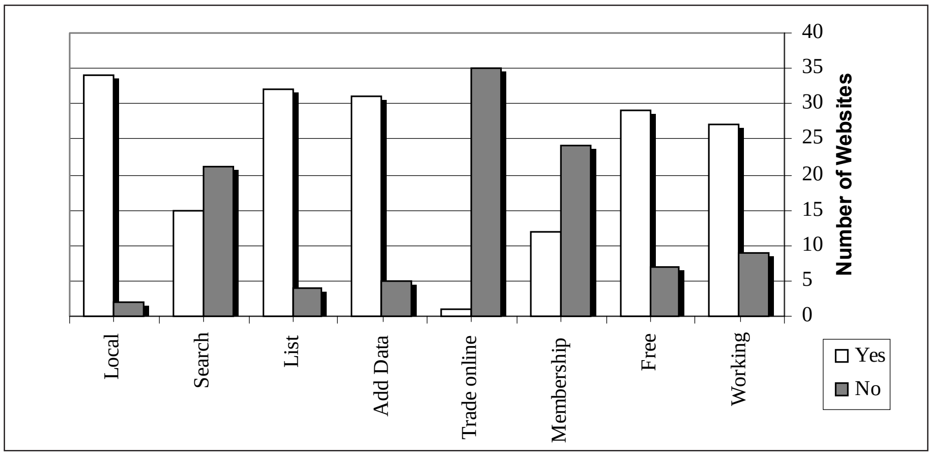
To deal with the serious problems in C&D waste management in Hong Kong, this article proposes an e-commerce model called Webfill for C&D waste exchange to enhance efficiency and effectiveness of the currently used charge system—that is, Trip-Ticket System (TTS) for C&D waste disposal—and accordingly, to reduce the total amount of C&D waste disposed to landfills in Hong Kong. To test whether the Webfill can provide an ideal result in e-commerce for C&D waste reduction, a simulation-based comparison between the existing TTS and enhanced TTS is conducted. With a full view of reducing C&D waste in Hong Kong, the Webfill as a waste exchange model can only work for reducing existing C&D waste; the control of waste generation cannot be expected. As a result, this article only focuses on the e-commerce model for C&D waste reduction at the post-construction stage and the process of e-commerce simulation.

E-COMMENCE SYSTEMS AND SIMULATION

Online Waste Exchange

The concept of waste exchange systems for exchanging industrial residues and information and for reducing the waste volume was introduced in the 1970s (Middleton & Stenburg, 1972; Mueller et al., 1975). In recent years, Web-based services for waste material and equipment trade and information exchange have been developed based on the

Figure 1. Feature comparison of C&D waste exchange Web sites



Internet, because it supports effective multimedia communication. Online search results shows that a number of Web sites are related to waste exchange, and some of them also provide in advance a special area for quality salvaged C&D waste at comfortable prices on their Web sites. However, it is apparent that no Web site has been found to be solely dedicated to e-commerce of C&D waste exchange. Appendices A and B summarize 36 online C&D waste exchange-related Web sites, and Figure 1 shows a statistic comparison of these Web sites.

According to the Web site review, we noticed that there exists a generic online C&D waste exchange model, which has been adopted by most of the observed Web sites (see Appendices A & B). The generic model can be developed based on common features existing in current waste exchange Web sites as summarized in Figure 1. Although there are some differences among their profile designs, the common features exist in data transfer and Web site functionalities.

In fact, e-commerce grows quickly in the construction industry as value-adding to business processes (Berning & Diveley-Coyne, 2000; DeMocker, 1999; NOIE, 2001; Waugh & Makar, 2001). According to the business model adopted, e-commerce systems can be categorized into three types: business-to-business (B2B) model (e.g., e-IDC.com), business-to-consumer (B2C) model (e.g., Build.com) and a combinatory model (e.g., Ei-Internets.com). Because the B2B model has proven sustainable and profitable in the e-market of the construction industry, it is most commonly used to develop e-commerce systems (Lais, 1999), and more than 90% of architects, designers and contractors expect to conduct more business over the Internet (Mark, 2000). We thus selected the B2B model to develop our online C&D waste exchange system that will be integrated with the TTS.

Webfill Model

Webfill is an e-commerce model for construction and demolition waste exchange in Hong Kong, and it has been further developed to an online C&D waste exchange portal for the Hong Kong construction industry. There are two basic models of business strategies for online exchange (Rappa, 2002): brokerage model and infomediary model. The brokerage model—for example, Marketplace Exchange—provides a full range of services covering the transaction process, from market assessment to negotiation and fulfilment, for a particular industry. The exchange can operate independently of the industry, or it can be backed by an industry consortium. The broker typically charges the seller a transaction

Figure 2. Webfill e-commerce model for C&D waste exchange

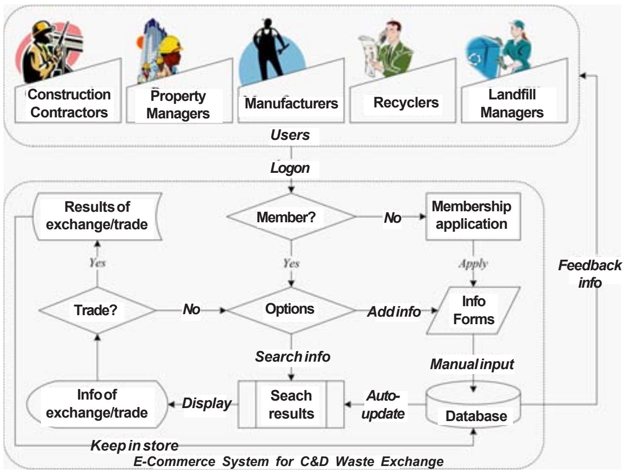


Table 2. Potential users and desires to and anticipated profits from Webfill

Users	***Roles***	***User requirements***		***Benefits***
		Sell	*Buy*	
Construction Contractors	Waste generation	Recyclable waste Residual materials	Recovered materials Residual materials	Reduce tipping fee Reduce wastage Save on buying materials
Property Managers	Waste generation	Recyclable waste Residual materials	Recovered materials Residual materials	Reduce tipping fee Reduce wastage Save on buying materials
Manufacturers	Waste recovery	Recovered materials	Recyclable waste; Residual materials	Save on buying raw materials Increase sell
Recyclers	Waste trade	Recyclable waste Residual materials Recovered materials	Recyclable waste Residual materials Recovered materials	Increase trade
Landfill Managers	Waste disposal	Recyclable waste	N/A	Decrease disposal of waste

Table 3. Parameters for the comparison simulation

Adjusted Items	*System Parameters*	*Real Characteristics*	*Simulation Settings*
Process Duration	40 hours	8 years (300 working-days/year)	1 min=1 day
Waste Quantity	1 unit	7,200 t/day (Mean value of the statistic data from 1998 to 2001)	2 unit=7,200 t waste rate is 3.6% 0.036×N(20,5)

fee based on the value of the sale. There also may be membership fees. On the other hand, the infomediary model—for example, Metamediary—facilitates transactions between buyer and sellers by providing comprehensive information and ancillary services, but does not get involved in the actual exchange of goods or services between the parties. The infomediary model is selected for the Webfill system. The information flowchart of Webfill is developed as described in Figure 2. This flowchart takes into account the common features of waste exchange systems summarized above as well as the functional requirements of e-commerce.

There are five kinds of potential users of the Webfill system, including construction contractors, property managers, manufacturers, recyclers and landfill managers. Table 2 describes these potential users regarding their roles and benefits in using the Webfill system. The Webfill system is able to attract those groups to work together, as the Webfill system creates a win-win situation for all of them.

Webfill Simulation

Although a demonstration Web site of Webfill was developed, it is still a question whether Webfill really can play an expected role in C&D waste reduction in Hong Kong. Besides research initiatives in a questionnaire survey regarding acceptance of the Webfill system, the Webfill model recalls a business process system, and we thus try to adopt the conception of an e-commerce system simulation for the experiment of the Webfill system based on process simulation with statistical parameters relating to the generation, reuse, recycling and disposal of C&D waste in Hong Kong. The simulation is conducted, which enables us to evaluate the performance of the Webfill system by comparing the results from two models, including simple TTS and Webfill-enhanced TTS. Considering the specific characters of the process flowcharts of the TTS and the Webfill system (refer to Figures 2-4), a commercial simulation software, that is, ProcessModel (processmodel.com), was selected as the tool to simulate the TTS and the Webfill-enhanced TTS.

Basic Parameters

Two basic steps are involved in developing a simulation model; one is to establish a process model for simulation, and the other is to set some basic parameters according to real conditions. A process model is a process flow diagram that uses associated data to describe a real-life process, where objects (graphic shapes) and connections (lines connecting the graphic shapes) are used to represent process elements and relationships, respectively. To compare the simulation results between the TTS and the Webfill-enhanced TTS, two process models are established (refer to Figures 3 and 4). Table 3 lists the parameters selected in the simulations. In addition to the parameters set in Table 3, we assume the quantity of C&D waste

Figure 3. Current simple TTS in Hong Kong

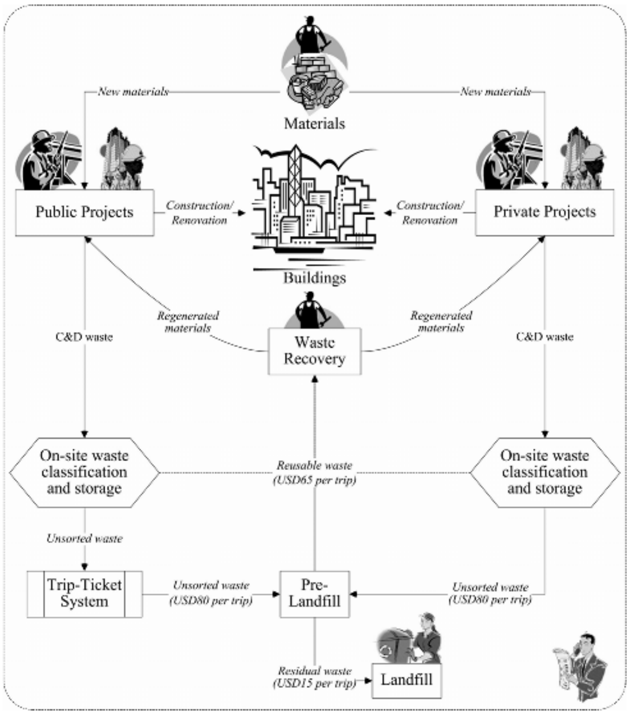

Figure 4. Proposed Webfill-enhanced TTS model

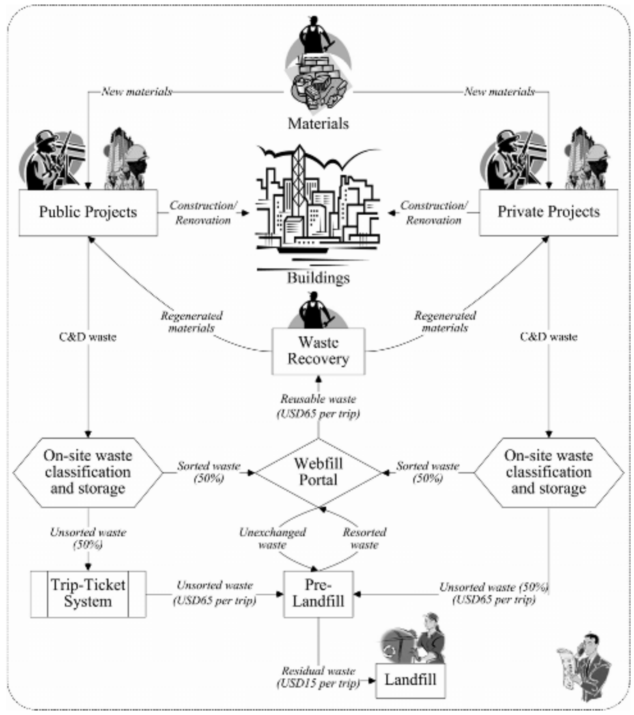

($G_{C\&Dwaste}$) generated by either the Public Projects or the Private Projects at the beginning of each of the two simulation models is set by Formula 1.

$$(G_{C\&Dwaste}) = 0.036 \times N(20,5) \qquad (1)$$

The amount of C&D waste is derived from the governmental statistic data of the C&D waste, and we assume a normal probability distribution for the ($G_{C\&Dwaste}$) estimates (EPD, 1999-2002).

Table 4. Simulation results and comparisons

Simulated Items	***TTS***	***Webfill enhanced TTS***	***Rates***
1. Landfill Utility (%)	**12.21**	**3.42**	**- 72%**
2. Waste Recovery Utility (%)	**1.75**	**16.33**	**+ 833%**
3. TTS Utility (%)	**6.08**	**3.92**	**- 46%**
4. Quantity of C&D waste (unit)			
Public project	**146**	**133**	**- 9%**
Private project	**147**	**140**	**- 5%**
Average	**146**	**137**	**- 7%**
5. Average waste cycle time (day)			
Public project	**6.4**	**9.4**	**+ 48%**
Private project	**4.3**	**7.9**	**+ 86%**
Average	**5.4**	**8.7**	**+ 67%**
6. Average value-added time (day)			
Public project	**2.2**	**3.8**	**+ 74%**
Private project	**1.1**	**3.1**	**+ 177%**
Average	**1.7**	**3.5**	**+ 126%**
7. Average waste transportation cost (USD)			
Public project	**91.55**	**138.85**	**+ 52%**
Private project	**87.11**	**130.83**	**+ 50%**
Average	**89.33**	**134.84**	**+ 51%**

Simulation Results

The simulation results and comparisons are presented in Table 4.

As shown in Table 4, after adopting the Webfill-enhanced TTS, the utility of landfill decreases by 72% and the utility of the TTS reduces by 46%, while the utility of waste recovery increases by 833%. Moreover, the total quantity of C&D waste reduces by 7%; the average waste cycle time increases by 67%; the average valued-added time of waste recovery lengthens by 126%; and the average waste transportation cost increases by 51%. These results indicate that the Webfill-enhanced TTS can reduce the amount of C&D waste at the landfill sites by increasing waste recovery and reuse.

Although it has been proven that the Webfill-enhanced TTS is more effective than simple TTS in C&D waste reduction, simulation results also indicate that the average waste transportation cost will increase, which means that the e-commerce system for C&D waste exchange will lead to more transportation from the construction industry, and more energy consumptions thereby. To reduce potential pollution due to the extra energy consumptions, simulation results also indicate necessary revisions to the Webfill model.

FUTURE TRENDS

The simulation reveals several unique results that other evaluation tools can hardly provide, and the successfully applied process simulation in e-commerce business plan evaluation reveals an emerging trend in e-commerce strategic management to support quantitative decision-making. Because process simulation is generally accepted in business management, it is an economical way to directly adopt a commercial process simulation package for e-commerce simulation. However, as there are currently some limitations in process simulation packages, such as no permission for users to modify internal and external business environmental factors based on their various experiments, it is essential to use business strategic management tools, such as the SWOT analysis, in e-commerce system evaluation as complements. In this regard, further research tasks are required to integrate current qualitative strategic management tools into the business process simulation environment.

CONCLUSION

This article introduces a quantitative approach to e-commerce system evaluation based on the theory of process simulation. The general concept of e-commerce system simulation is presented to reduce risks in e-commerce system development by simulating the initial e-commence business plan. To evaluate an e-commerce business plan, it is necessary to use a quantitative evaluation approach, and we believe that process simulation is an appropriate option. The overall objective of this article is to apply the theory of process simulation to e-commerce system evaluation, and we achieve this though an experimental study on a business plan for online C&D waste exchange. The methodologies adopted in this article include literature review, system analysis and development, simulation modeling and analysis, and case study. The results from this article include the concept of e-commerce system simulation, a comprehensive review of simulation methods adopted in e-commerce system evaluation and a real case study of applying simulation to e-commerce system evaluation. Furthermore, the Webfill simulation introduces a new area for e-commerce business plan evaluation, in which the concept of process simulation can be successfully implemented. We hope the adoption of process simulation can effectively support business decision-making and improve the efficiency of e-commerce systems.

KEY TERMS

E-Commerce System Simulation: An integrative procedure to run a business processes-oriented simulation program based on both internal and external business environmental factors to demonstrate the actual results of implementing an e-commerce business model by using computer-driven software toolkits. It is an effective, efficient and economical approach, and can be used to experiment and evaluate different e-commerce business models or plans.

Trip-Ticket System (TTS): A recording system for orderly disposal of construction and demolition waste to disposal facilities in Hong Kong. Under the TTS, construction or demolition contractors are required to fill in a standard trip-ticket form outlining the details of the transportation vehicle, type and approximate volume of waste and the designated disposal facility. The trip-ticket is used for verifying a contractor's compliance with the policy requirements, and contractors are then charged by trip-tickets as their receipts from the disposal facilities.

SWOT Analysis: A popular way conduct e-commerce business plan evaluation with business environmental scanning based on internal environmental factors (strengths and weaknesses) and external environmental factors (opportunities and threats).

Waste Exchange System: An e-commerce system for exchanging industrial residues in the form of waste-related information exchange among waste generators, waste recyclers, waste users and possibly landfill managers, which can benefit the society by reducing the total waste volume and facilitating waste reuse, recycle and disposal.

Webfill: An e-commerce business model for construction and demolition waste exchange in the Hong

Kong construction industry, in which construction contractors, property managers, manufacturers, recyclers and landfill managers are all involved to participant the waste exchange. And it is being further developed to an online C&D waste exchange portal for the Hong Kong construction industry.

Product Configuration Systems

Thorsten Blecker
Hamburg University of Technology (TUHH), Germany

INTRODUCTION

Product configuration systems are considered to be important enablers of the mass-customization strategy. They are the most successful applications of e-technologies and artificial intelligence in e-business, particularly in customer interaction. Product configuration systems support the acquisition of the customers' requirements while automating the order-taking process, and they allow customers to configure their products by specifying their technical requirements.

In this article, the state of the art is explained and the different product configuration systems are classified in a morphological box. The analysis of the criteria according to which configurators are designed thus far reveals a neglect of the front-end perspective. Therefore, necessary enhancements and development directions toward a comprehensive tool for customer interaction in mass customization are analyzed.

BACKGROUND

Product configuration systems or configurators are important enablers of the mass-customization (Pine, 1993) paradigm. Configurators are information tools that allow the automation of the order-taking process by automatically capturing customers' requirements without involving human intermediaries. Therefore, a configurator has additional relevance because it may be one of the few information systems with which the customer directly interacts in e-business (Bramham & MacCarthy, 2003).

Configurators can be implemented at the interface between a supplier and its customers over the Internet. Its principle task is to support customers in the self-configuration of their products according to individual requirements. For example, customers can be provided with the possibility to alter a basic product and also to graphically visualize the effects of these changes (e.g., http://www.customatix.com/).

Configurators support the configuration process that requires one to accurately understand the customer's needs and to create a complete description of a product variant that meets those needs. Given a set of customer requirements and a product family description, the task of configuration is to find a valid and completely specified product structure among the alternatives that the generic structure describes (Sabin & Weigel, 1998).

Product configurators have been employed in one form or another for many years. Freuder (1998) notes that Lucent Technologies has used product configurators for more than 20 years. Configurators support the configuration task, which is defined as the process of designing a product using a set of predefined components while taking into account a set of restrictions on how the components can be combined (Soininen, Tiihonen, Männistö, & Sulonen, 1998).

STATE OF THE ART AND TYPES OF PRODUCT CONFIGURATION SYSTEMS

Based on heterogeneous application scenarios and solution approaches, the technical literature discusses many types of product configurators. In the following, different classification criteria for product configurators are presented (Blecker, Friedrich, Kaluza, Abdelkafi, & Kreutler, 2005).

Knowledge Base

The representation of the domain knowledge may rely on different ontologies: (a) rule-based, (b) model-based, and (c) case-based approaches. Rule-based configurators work by executing rules with the following form: "if condition then consequence." The product solutions are derived in a forward-chaining manner. At each step, the system examines the entire set of rules and considers only the set of rules that can be executed next. The most important model-based representation types are logic-based, resource-based, and constraint-based approaches (Sabin & Weigel, 1998). Logic-based approaches are often based on description logic. Description logics are formalisms for representing and reasoning with knowledge. The inference mechanism is based on subsumption. However, resource-based systems are based upon a producer-consumer model of the configuration task. Each technical entity is characterized by the amount of resources it supplies, uses, and consumes. In constraint-based reasoning, components are defined by a set of properties and a set of connection ports. Constraints among components restrict the ways components can be combined (Tsang, 1993). The case-based approach relies on the assumption that similar problems have similar solutions. The knowledge necessary for reasoning consists of cases that record a set of product configurations sold to previous customers. The configuration problem is solved by finding and adapting a previous solution to a similar problem.

Strategy

From the point of view of mass customization, three main strategies with different requirements for configurators are distinguished, namely, assemble to order, fabricate to order, and engineer to order. The assemble-to-order concept enables customers to configure a product by combining a finite number of standard modules. However, the fabricate-to-order and engineer-to-order concepts may assume an infinite number of configuration possibilities. The technical realization of configurators for fabricate to order and engineer to order is more demanding than those for assemble to order because a parameterization of component dimensions should be made possible.

Organization

The organization of a configurator can be either central or distributed. A central configurator works locally and its configuration knowledge is completely stored in one unique system. All potential product instances that may represent a solution to the customer configuration problem are derived from these local data. However, the knowledge base of a distributed configurator is locally incomplete. It is integrated with other configurators (e.g., suppliers' configurators) in order to generate consistent product instances for specific customer requirements.

Internal vs. External

Internal configurators are only implemented for a company's internal use. For example, internal configurators support sales experts in capturing a customer's requirements and translating them into technical features without errors. External configurators are designed to provide customers with direct assistance during product configuration. They are equipped with front-end interfaces to facilitate the configuration task for customers.

Interaction Nature

The nature of interaction can be either off line or online. Off-line configurators work independently from networks. The necessary data for configuration are stored on a data carrier such as a floppy disk, CD-ROM, or DVD-ROM. After product configuration, customers can send the specifications via, for example, e-mail or fax. However, today, mainly online configurators are applied. They enable communication with customers over the Web. The configuration knowledge is stored on a central Web server. Online configurators can be further divided into two categories: online configurators with central data processing and online configurators with local data processing. Online configurators with local data processing require the loading of the configuration application (Java applets, full Java applications) onto the customer's local unit.

Update Execution

The update execution can be either push or pull based. A push mode is realized when the supplier's central unit containing the product configuration logic communicates product updates to the customer's local unit. In this mode, the central unit imposes the updates that have to be accepted by the local unit. In contrast, one speaks about a pull mode when the local unit retrieves the updates if required.

Scope of Use

Configurators can be categorized as single-purpose or general-purpose systems. A single-purpose system is developed to support the sales-delivery process of a product or a set of products of only one company or business field. Single-purpose configurators are called special-purpose configurators and may be designed for a particular industry such as, for example, the window and door industry. However, general-purpose systems are used to configure diverse product types in different companies (Tiihonen & Soininen, 1997).

Complexity

Tiihonen and Soininen (1997) distinguish between primitive, interactive, and automatic configurators. Primitive configurators are the simplest ones. They merely record the configuration decisions made by the user without checking the validity of the decisions. Interactive configurators are capable of checking as to whether the configuration decisions are valid. They also guide users in making all of the necessary decisions. In addition to the functionalities of interactive configurators, automatic ones are able to provide full support and to automatically generate parts of configurations or even entire configurations.

Integration Level

At the integration level, Blecker et al. (2005) distinguish between stand-alone, data-integrative, and application-integrative configurators. Stand-alone configurators cannot be integrated because they do not dispose of interfaces to other information systems. Data-integrative configurators enable one to avoid data redundancy. However, the application-integrative configurators enable the integration of whole applications. For example, when a configurator and Computer-Aided Design (CAD) system are integrated, drawings of new parts or components can be automatically generated for customers.

Solution-Searching Approach

Two main solution-searching approaches are discussed in the technical literature (e.g., Blecker et al., 2005): either by technical elements or by features. Searching by technical elements means that the configurator enables customers to start from a standard product and then to specify step-by-step product options. In contrast, a configurator working by features provides customers with the possibility to specify their requirements in terms of product functionalities. Based on the customers' specifications, the configurator searches for optimal product variants.

Product Life-Cycle Support

Product life-cycle support refers to the product reconfiguration that is necessary when the customer would like to upgrade the product by including new or better functionalities, or to replace nonfunctioning parts or modules for which identical replacements no longer exist (Sabin & Weigel, 1998). Different cases that can be encountered are (a) a configurator without a reconfigurator, (b) separate configurator and reconfigurator, and (c) integrated configurator and reconfigurator.

By presenting all of the results of the configurators' classifications in a morphological box (Figure 1), it is possible to provide software engineers and developers with the main dimensions to be considered when designing a configurator. The zigzag line shows the relevant characteristics of an example of a configurator software with respect to each dimension.

SHORTCOMINGS OF PRODUCT CONFIGURATION SYSTEMS

Compared to standard products, customers face a complex decision-making process when buying mass-customized products. They have difficulties in deciding on their preferences between different alternatives and in comparing performance and price ratios of distinct variants. This problem often arises because in practice the technological perspective generally dominates the user perspective when addressing configuration. In addition, in the technical literature, configuration tool kits are criticized more often. For example, Rogoll and Piller (2002) have shown through a market study on configurators that there is no standard software solution that is able to fulfill optimal requirements from the supplier's and customer's perspectives. Von Hippel (2001, p. 2) criticizes the implemented configurators in the automobile

Figure 1. Morphological box: Classification of configurators (Adapted from Blecker, Abdelkafi, Kreutler, & Friedrich, 2004)

Knowledge base	Rule based	Model based	Case based	
Strategy	Fabricators	Involvers	Modularizers	Assemblers
Organization	Central	Distributed		
Internal/external	Internal	External		
Interaction nature	Online central data processing	Online local data processing	Off line	
Update execution	Push	Pull		
Scope of use	Single purpose	General purpose		
Complexity	Primitive	Interactive	Automatic	
Integration level	Stand alone	Data integrative	Application integrative	
Solution-searching approach	Technical elements	Features		
Product life-cycle support	Configurator without reconfigurator	Separate configurator and reconfigurator	Integrated configurator and reconfigurator	

industry and points out that "automakers allow customers to select a range of options for their 'custom' cars—but they do not offer the customer a way to learn during the design process or before buying." Learning during the design process means that customers should be provided with the possibility to verify, before placing their buying orders, as to whether the configured product meets their expectations exactly or not.

Designers of configurators considerably concentrate on the back-end technical aspects and neglect the customer perspective. Especially in the business-to-consumer field, customers generally do not have sufficient product expertise. They cannot express their preferences in terms of technical specifications. Therefore, it is relevant to better assist customers during configuration in order to help them find satisfying product variants.

NECESSARY ENHANCEMENTS AND FUTURE DEVELOPMENT DIRECTIONS

From a customer-oriented point of view, it is necessary that configurators are extended with an additional component that aims at helping customers to better recognize their needs. This component is called an advisory system. Advisory systems for mass customization are software systems that guide customers according to their profiles and requirements through a customized advisory process, ending with the generation of product variants that better fulfill their needs. They are customer oriented and do not assume any specific technical knowledge of the product.

However, the classical advisory systems discussed in the technical literature often do not lead to a suitable advisory process during product customization. According to the customer-needs model (Blecker et al., 2005), there are three faults that may lead to problems in customer interaction. These faults arise when the following happen.

- The customers do not know their real needs.
- The customers cannot correctly express their real needs.
- The supplier wrongly interprets customer requirements.

In order to tackle these problems, two main levers are identified: (a) the dialogs with customers and (b) the mapping techniques that permit one to translate customer needs into product specifications and vice versa. Furthermore, these levers should be supported by adequate technologies and tools. Whereas the main identified technology is Web mining, which enables one to process Web data, the relevant tools to be implemented are customer-interest modeling and Web metrics. Both tools aggregate the data provided by Web mining in order to present them in an understandable goal-oriented form (Figure 2).

Dialogs with customers refer to the communication interface during interaction. Customers should not perceive complexity when specifying their requirements. Therefore, they should only be asked appropriate questions. When customers do not know their real needs, Kansei engineering and interaction-process simplification are suitable solutions, whereas when customers have difficulties in expressing their real needs, personalization and interaction-process simplification are especially relevant. However, the dialogs are unsuitable to solve the problem arising when the supplier wrongly interprets customer requirements. This is due to three main reasons.

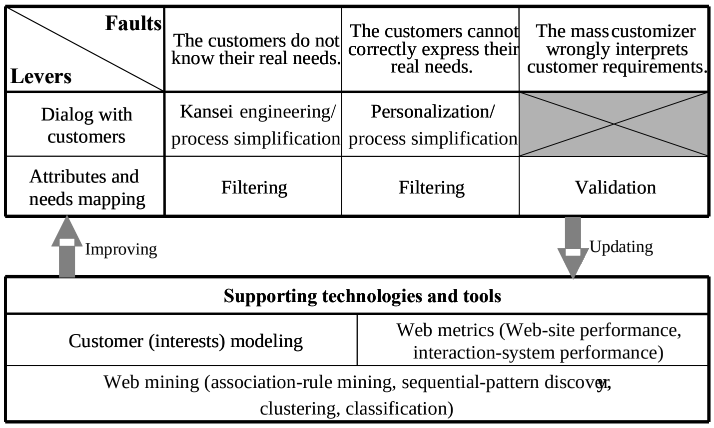
- Dialogs only deal with the front-end aspect between the customer and the interaction system.
- Dialogs do determine the communication process, but not the way information is interpreted.
- Only available information that is no longer the object of dialogs can be interpreted.

To make customers aware of their requirements, a potential solution is to conceive dialogs according to Kansei engineering, which uses verbal language that is near to the language customers are used to understanding. It is a "translating technology of consumer's feeling and image for a product into design elements" (Nagamachi, 1995, p. 2). For example, when buying a watch, customers are not asked to specify design components; they may be asked, for example, what social position they want to express.

Moreover, in order to not overstrain customers during the interaction process, it is relevant that the advisory system guides them to their optimal choices by following the shortest path. This refers to interaction-process simplification. For example, the advisory system appreciates the customer's knowledgeability and then accordingly estimates what technical parameters the user is able to specify. If some product parameters are too difficult, the advisory system can set default values without asking questions (Ardissono et al., 2003). A superfluous flexibility providing customers with the possibility to specify parameter values that are difficult will confuse rather than help them.

The gained customer data have to be used for personalization purposes. Personalization aims at recognizing special customer characteristics such as desires and preferences to individualize the interaction process. The advisory system should adapt the Web-site layout to customer requirements and also personalize the formulation of customer dialogs.

Figure 2. Levers and supporting technologies and tools for an advisory system (Adapted from Blecker et al., 2004)



The captured customer requirements during the interaction process have to be correctly translated into product specifications. This is ensured by mapping techniques that not only adequately transform customer preferences and requirements into product-specific characteristics (filtering), but also guarantee that product specifications are adequately mapped to customer needs (validation).

When customers do not know or cannot express their real needs, filtering methods are suitable solutions. For example, with content-based filtering, product configurations can be selected on the basis of correlations existing between product characteristics and the user's preferences that can be captured either implicitly or explicitly. This will considerably restrict the domain of the products' solution space that customers would be interested in.

As opposed to filtering, validation methods have to be implemented to ensure that the supplier did not wrongly interpret customer needs. Thus, the restricted solution space resulting from filtering can be further refined to ensure that the product specifications really correspond to customer requirements.

The described potential solutions have to be supported by Web mining. This technology aims at processing the raw data being stored in Web-server logs by applying data-mining techniques in order to extract statistical information, cluster users into groups, and discover correlations between Web pages and user groups (Eirinaki & Vazirgiannis, 2003). Web mining provides the information necessary to model customer interests in e-commerce and to compute relevant Web metrics.

Customer-interest modeling is a tool enabling one to better understand customer preferences and, thus, to correspondingly support the personalization of dialogs during the advisory process. Web metrics are necessary to measure the performance of the entire Web site and especially the performance of the interaction system. For example, it is relevant to appreciate how long one customer has spent on a certain Web page or what the average number of pages a customer browses is prior to their reaching the interaction system. From the Web-metrics analysis, proposals can be derived for process simplification that can be introduced either automatically online or off-line.

Recapitulating, with Kansei engineering and personalized dialogs, customers who have no technical knowledge about products are adequately assisted during interaction. Furthermore, process simplification permits customers to express their requirements in a fast-paced manner and with little effort. Due to filtering and validation methods, the advisory system generates optimal product alternatives. Moreover, the advisory system initiates a virtuous circle, which is ensured by a learning process consisting of the continuous improvement of the presented solutions and an updating of the data processed by Web-mining techniques. The more customers use the advisory system, the better they teach it what they would like, and the better the advisory system is at refining product suggestions leading to a better fulfillment of customer requirements.

CONCLUSION

Product configurators are the most important application of e-technologies in customer interaction. However, they are up to now mainly designed according to technical aspects, shown in the morphological box. It was exposed that the back-end perspective generally plays a more important role, whereas the front-end perspective is more or less neglected, especially in the business-to-consumer field. That is why it is relevant to extend configurators with a front-end component, which makes the task of searching product configurations among the solution space of the supplier easier for customers. Therefore, the notion of advisory systems is introduced. The advisory systems and configurators together form a comprehensive customer-oriented interaction system in mass customization.

KEY TERMS

Advisory System: Front-end software system that guides customers according to their profiles and preferences through a personalized consulting process resulting in the generation of product configurations that better fulfill customers' needs. In opposition to the commonly used product-oriented interfaces in configurators, advisory systems are customer oriented and do not assume any specific technical knowledge of the product.

Filtering: A collective term for techniques that automatically select product attributes that meet customer profiles and preferences by applying predefined rules, similarities, or clustering.

Interaction System: Comprehensive entity for optimal customer-supplier interaction in e-business consisting of two separate yet interconnected information systems: an advisory component and a product configurator.

Mass Customization: Business strategy, often applied in e-business, that aims at satisfying the customer's individual needs with near-mass-production efficiency. In essence, mass customization describes the ability of a firm that provides customized goods in high volume for mass markets by deriving a high number of variants from a single or a few core products.

Morphological Box: Efficient tool for creativity and the structuring of ideas first introduced by Zwicky (1966). The main advantage of it is being able to present in a straightforward manner all of the possible solution alternatives for a specific problem.

Personalization: Matching categorized content with special customer characteristics such as desires and preferences in order to individualize an interaction process.

Product Configurator: Information system that supports customers during (online) product customization and the order-taking process, especially in e-business. It has the logic capabilities to create, maintain, and apply electronic product models in order to define all of the possible variants of a product and to display them to the customer.

RFID in the Retail Supply Chain

Claudia Loebbecke
University of Cologne, Germany

INTRODUCTION

The use of RFID (radio-frequency identification) in the retail supply chain and at the point of sale (POS) holds much promise to revolutionize the process by which products pass from manufacturer to retailer to consumer. The basic idea of RFID is a tiny computer chip placed on pallets, cases, or items. The data on the chip can be read using a radio beam. RFID is a newer technology than bar codes, which are read using a laser beam. RFID is also more effective than bar codes at tracking moving objects in environments where bar code labels would be suboptimal or could not be used as no direct line of sight is available, or where information needs to be automatically updated. RFID is based on wireless (radio) systems, which allows for noncontact reading of data about products, places, times, or transactions, thereby giving retailers and manufacturers alike timely and accurate data about the flow of products through their factories, warehouses, and stores.

BACKGROUND

Management research and academic management literature on the use of RFID in the retail supply chain is still scarce. The technical aspects of RFID business applications have been highlighted in recent engineering and computer science publications (e.g., Glidden et al., 2004). Consulting-oriented papers have also offered in-depth technological overviews of state-of-the-art developments (e.g., among many others, Das, 2002; Harrop, 2004). Certainly, the technology has recently also been covered in management-related academic journals, which have focused on different aspects of electronic business and supply chain management (e.g., Angeles, 2005; Juels, Rivest, & Szydlo, 2003; McGinity, 2004; Loebbecke, 2004; Loebbecke & Wolfram, 2004; Singh, 2003).

However, as of late 2004, actual RFID applications in the real world, beyond lab studies or pilot projects, were still so new that academic research into their impact, lessons learned, and recommendations have not been possible. The main discussions of RFID applications currently appear in magazines, such as *Information Week*, *Infoworld.com*, and *RFID Journal*, in pamphlets written by technology consultants, and in the daily press. These publications focus mainly on case studies and discussions of business opportunities, but their life cycle time is too short to be included in this encyclopedia contribution.

TECHNOLOGICAL ISSUES

Using RFID, product data is automatically transmitted by radio signals. The key component of RFID technology is the RFID tag (called a transponder), which is a minute computer chip with an antenna. This tag is attached to transport packages (pallets or cases) or products (items). An RFID tag can carry an impressive array of data. Passive or semipassive tags identify themselves when they detect a signal from a compatible device, known as an RFID reader. As a tag passes through a radio-frequency field generated by a compatible reader, it transmits its stored data to the reader, thereby giving details about the object to which it is attached.

RFID systems operate in free air, that is, nonregulated frequencies of the wireless communications spectrum (called the radio-frequency spectrum). National regulations for radio communications vary and are established by different bodies. In the United States, regulations are less restrictive than in Europe, where the relevant spectrum is partially reserved for mobile telephone networks or medical services.

In retailing, a numeric, article-specific code (electronic product code, EPC) is stored on the RFID chip. The EPC is comparable to a conventional bar code. As soon as the chip comes within 39.37 inches (1 meter) of an RFID reader, it sends its numeric code to the reader. The reading device recognizes the EPC stored and matches it with other pieces of data, such as the price, size, weight, and expiration date of the product, stored in various databases.

Towards RFID Standardization

To achieve large-scale RFID usage in the retail supply chain, RIFD technology needs to be standardized. That process is currently under way. On the global front, two international bodies are involved: EPCglobal™ (http://www.epcglobalinc.org) and ISO, the International Organization for Standardization (http://www.iso.org).

EPCglobal was created in the fall of 2003 as a joint venture of EAN International (http://www.ean-int.org) and the Uniform Code Council (http://www.uc-council.org). The launch signaled the drive toward a worldwide, multiindustry adoption of the EPC, key identification aspects of RFID, and its network of links to Internet technologies. EPCglobal is leading the development of the industry-driven standards for the EPC Network (http://www.epcglobalinc.org) to support the use of RFID in information-rich trading networks. The association is working on the structure of the data stored in the transponder. It aims to define naming standards to foster the use of RFID technology between suppliers and retailers. Comparing EPC to the traditional EAN code, EPC stores only the serial number on the chip while EAN has extensive information on the chip. Hence, for the EPC, only the serial number needs to be coded and understood. The serial number then provides access to databases containing information about specific products.

The ISO standards for RFID, on the other hand, cover the physical characteristics of RFID labels and cards, the air protocols, the anticollision and transmission protocols, and commanded-set and security features.

As these two standardization bodies work on their separate issues, RFID choices made by players along the value chain can be both EPC and ISO compliant.

Technical Challenges on Data, Network, and Application Layers

Any RFID-enabled process begins with an RFID reader reading an RFID tag: The reader hits the tag with a radio beam and reads the data on the tag. Some readers are designed to simply pass the tag read along to an attached computer, relying on the computer to do validation (e.g., reading a check sum, elimination tag collisions, etc.). Other smart readers have the ability to validate data and even perform basic filtering.

With traditional bar code technology, the laser beams must have an unobstructed view of the bar codes to read them. Radio waves, however, do not require a line of sight; the signal can pass through materials, such as cardboard or plastic. With no line of sight required in RFID, multiple tags can be read simultaneously, even when hidden from sight. An RFID portal, for example, can read all the goods on a pallet with one pass. A bar code scanner would require each item to be scanned individually.

This RFID process presents challenges relating to the data, the network, and the application. An RFID reference architecture (RRA) addresses all three.

Data Layer

On the data layer, the RFID reference architecture determines what to do with the data gleaned from the tag. The following are examples of applications with increasing requirements for managing data.

1. **Querying Applications:** A conveyer belt that automatically routes cases to their destination needs to be able to simply pass the tag data on to the appropriate system, receive the response, and then purge the tag scan from its memory.
2. **Mixed-Goods Applications:** Assume a reader on a picking cart scans, say, every 5 seconds all tags within range (e.g., placed on the pallet). Such an application needs to be able to constantly evaluate each scan's results against expected results and alert the operator of exceptions.
3. **Smart-Shelf Applications:** Smart shelves keep track of the products placed on them. Scanning a 96-bit EPC-compliant RFID tag every 5 seconds in a distribution center that holds approximately 500,000 cases generates 32,958 gigabits of data every hour. The majority of this data should simply confirm the existence of the requisite number of cases on each shelf, and should therefore be disposable. The RRA needs to be able to filter and process such large amounts of data.

Applications built to track serialized data (such as EAN-128 numbers on pallets) should be able to accommodate the real-time stream of single-tag reads. Data requirements are much higher for systems that deal with the more granular serialized data that comes from RFID tagging at the case level rather than the pallet level. For example, take a distribution center that ships about 616,000 pallets to stores per year, each of which is duly recorded and serialized. Bringing that serialization down to the case level would require applications to handle approximately 46 million items—a 74-fold increase in data management and storage requirements over pre-RFID requirements (Metro Group, 2004). Systems that track at the item level generate orders of magnitude—more data than is currently common because each item is repeatedly scanned by the multiple readers, which report on everything within their range. The applications must be able to handle these voluminous, multiple real-time streams of data.

Network Layer

RFID-driven network requirements result mainly from the design of the data layer because the network must be capable of moving the quantity of data generated by the scans. For simple applications, 10-megabit Ethernet may suffice. For smart shelves to track individual items, though, the bandwidth requirements challenge even today's sophisticated gigabit Ethernet switches. Calculating-required network bandwidth, though, is straightforward.

For the physical location of readers and other hardware, RFID-based systems demand constant communication between each reader and the RRA, which in turn requires universal access to wireless networking throughout the physical facilities that use RFID.

Blurring the line between electronic security and physical security carries important network and security implications. With literally a computer on every pallet, case, or item, the distinction between data and product becomes less clear. Hence, while RFID reduces the accidental introduction of errors in the data, it increases the possibility of data corruption.

Item-level RFID creates additional networking and security challenges. While the traffic between readers and the store network can be secured through encryption, the standards-based data encoded on each EPC-RFID tag is, by definition, unencrypted. The contents of RFID tags can therefore be read by any reader tuned to the correct frequency. Thus, in an RFID-enabled environment, it is difficult to prevent a competitor's employee from walking through a store with a hand-held RFID reader and capturing the current inventory level. It is even more difficult preventing somebody from walking into the store with an RFID read-writer and, for example, flipping the privacy bit that deactivates each RFID tag in the store.

Application Layer

Enterprise applications that do not need to handle the raw RFID data are minimally affected. But, these same enterprise applications may need to handle messages from other applications in real time. RFID could affect these requirements. Furthermore, the data model used by enterprise applications must support serialization at the appropriate granularity. For example, a warehouse management system must be able to keep track of which specific cases have been removed from the building and which still remain.

RFID-BASED APPLICATIONS ALONG THE RETAIL SUPPLY CHAIN

In the retail supply chain, it is necessary to distinguish between RFID tag usage on pallets and cases on the one hand, and RFID item tags on the other.

Applications Using RFID Tags on Pallets and Cases

RFID tags on pallets and cases mainly require process innovations along the intercompany value chain. The following illustrates the potential use of RFID at the pallet and case levels throughout the value chain, from manufacturer to POS.

- **Product Transport:** The manufacturer or retailer affixes RFID tags to all product pallets and cases before they are shipped. The tags are electronically time-stamped and then entered into the central computer of the retailer's RFID goods tracking system. The tagged pallets and cases can thus be identified and located along the entire logistics chain, all the way to the sales floor.
- **Warehouse Dispatch:** Goods ready to be shipped to a store are taken from the central warehouse to the dispatch area. As they pass through the exit gate, an RFID transceiver reads the codes on the pallets and cases and passes this data on to the RFID goods flow system. The goods then have the status of being on route to their destinations.

Further RFID-driven processes follow in the store.

- **Goods Delivery to the Store Stockroom:** RFID helps match arriving goods to orders. When a truck arrives at a store, its pallets are once again identified by an RFID reader, which can handle as many as 35 pallet or case tags per second. The goods are then registered as being in the store stockroom.
- **Warehouse Management and Storage Processes:** Once received, the goods flow system registers the goods as being in the stockroom. Each storage location has an RFID tag, which is stored in the RFID goods flow system along with the RFID numbers of the pallets and cases stored at each location.
- **Transport of Goods into the Salesroom:** RFID readers, located at the store stockroom exit doors, identify every pallet and case that is moved into the store. These readers send the relevant RFID numbers to the RFID goods flow system, which identifies the products as having been transported into the store.

RFID tags attached to pallets and cases enable the tracking of the transport and whereabouts of goods throughout the supply chain. The fast and convenient data transfer enabled by RFID supports retailers in accelerating their work flows, increasing the transparency of their inventory, and improving the effectiveness of their processes.

- Warehouse and stockroom inventories can be monitored more accurately, and replenishment orders can be issued faster.

- Time lost from ordering incorrect supplies can be avoided.
- Store requirements can be uncovered earlier and deliveries received faster, thus improving the availability of the store's merchandise.
- Employees can recognize shelves about to run empty sooner; the chances of an item being out of stock can be reduced.
- Merchandise can be accurately located at all times.
- Inventories in warehouses, stockrooms, and shop shelves are more visible and easily tracked.
- An improved logging of sales indicates when and under which conditions goods are sold, improving management oversight.
- Quantities ordered can more accurately reflect demand.
- Manufacturers can better plan production.
- Less storage space is needed, reducing warehousing and handling costs.

Beyond the process improvements in stores, the use of RFID can further affect retailing and the retail value chain (Metro Group, 2004) by offering the following.

- Automation benefits from RFID providing savings in labor costs or time
- New process benefits from RFID enabling more efficient, faster, or less complex processes
- Collaborative benefits from data sharing among manufacturers and retailers

Furthermore, by gathering purchasing data at checkout, stores can use item-level RFID data to provide product information to consumers on the one hand, and gain customer information for itself on the other.

Applications Using RFID Tags on Items

RFID tagging at the item level, still in its early development, offers enormous opportunities but also additional challenges. The main opportunities are the following.

- New types of services in stores, such as personalized advertising displays and self-checkout (e.g., Loebbecke & Wolfram, 2004), aimed at increasing customer loyalty and promoting sales
- Electronic price labeling in stores, making price tags easier to understand and more current
- Improved theft protection in stores because products cannot be taken out of the store without payment (or notification of theft)

At the same time, with wider item-level tagging, deploying RFID-based solutions to a wider scale beyond company walls poses immense and complex challenges to all parties involved. Two main challenges are the business transformation needed to capitalize on the technology and the new technology infrastructure investments needed. So far, in spite of standardization and technological advancements, every retailer and manufacturer uses slightly, but importantly, different processes.

At this early stage of item-level RFID tags, three problem areas have become obvious.

- Tags on items that contain metal or liquids pose technical problems due to the product material itself.
- Data volume increases by orders of magnitude when each individual product is followed all the way through its product life cycle. Traditional information and data management technologies need revolutionary solutions.
- Privacy issues are delicate, both from legal and consumer views. Privacy violations have gained public attention, leading to increasing pressure on item-level tagging, which was intended to enhance customer convenience. Consumer and civil liberties advocates have viewed tagging as privacy invasion. They warn that authorities could be able to follow every move by each citizen through tags and dense networks of RFID readers, as well as through interlinked RFID profiles collected from a multitude of data readers.

While an overall rollout of item-level tagging is not expected to take place within the next 5 to 10 years, some applications at consumers' premises are already being pictured to increase customer demand for products and thus create a pull effect.

- An intelligent fridge could inform its owner when an RFID-tagged carton of milk is close to empty or the milk is approaching its expiration date. Such a refrigerator could conceivably send such messages directly to the retailer, thereby requesting replenishment.
- An intelligent washing machine could conceivably read the tags on the clothes and automatically initiate the correct washing program. It could even alert the owner when no appropriate washing program is possible, such as when the clothing in the machine should not be washed together.

CONCLUSION

The worldwide sales of RFID technologies in 2003 were estimated to be $1.3 billion. Current investments have concentrated on hardware, software, and related goods. There have been limited expenditures on integrating RFID into legacy IT and logistics infrastructures (OECD, 2004). But sales for integration services, estimated at almost $600 million in 2003, have been increasing, and they currently outpace the growth in product sales. Figures for the retail supply chain, however, are not available yet.

In the retail industry, RFID has shown the potential to significantly reduce the costs of getting products to consumers in stores. RFID can (a) increase accuracy, (b) gather information at new points in the supply chain, (c) make additional data available, (d) permit new kinds of collaborative sharing of data between retailers and manufacturers, and (e) provide interactivity between store and customer devices.

Customer satisfaction and customer loyalty have improved as a result of more reliable product availability, customized service, and more convenient shopping. These effects are likely to contribute to an overall increase in retail sales when databases are linked to customer devices, such as intelligent refrigerators, because they can automate stock deliveries and invoicing. Thus, with RFID technologies, retailers can better understand consumption patterns, manage their client relationships more individually, and tailor supply to demand.

So far, the main uses of RFID systems in logistics operations have been in the areas of production flow and supply chain and inventory management. Furthermore, RFID processes and databases can also be integrated with other back-office operations, such as accounting and personnel, with implications for the better management of cash flow and workers' schedules.

In conclusion, uses of RFID are still developing, and many firms investing in the technology do so under pilot programs. Much research on potential applications is under way. Overall, the main benefits will derive from more fully integrating RFID systems into broader business practices and interlinking organizations' RFID databases.

KEY TERMS

Active RFID Tags: Tags containing their own power source (batteries).

Electronic Product Code (EPC): Global coding scheme, administered by EPCglobal, identifying an item's manufacturer, product category, and unique serial number. The numerical code is stored on the RFID chip, which is comparable to a conventional bar code.

EPCglobal: A joint venture between EAN International in Europe (http://www.ean-int.org) and the Uniform Code Council in the United States (http://www.uc-council.org) to administer the numbering and data standards for EPC (http://www.epcglobalinc.org).

Passive RFID Tags: Passive or semipassive tags identifying themselves when they detect a signal from a compatible RFID reader. When passing through a radio-frequency field generated by such a reader, they transmit the data on their chips to the reader, thereby giving details on the objects to which they are attached.

RFID (Radio Frequency Identification): Automatic identification system transmitting product data automatically by radio signals (noncontact). RFID systems operate in the free air areas of the wireless communications spectrum (radio frequency spectrum) across the regulatory boundaries of countries.

RFID Item-Level Tags: RFID tags with unique EPCs on individual items; every jacket has its own EPC.

RFID Pallet-Level and Case-Level Tags: RFID tags with EPCs per pallet or case integrated into the packaging material or sometimes attached during the production or logistics process, for example, as part of a printed label.

RFID Reader (Interrogator): Device communicating with RFID tags and passing the tag data in digital form to a computer system.

RFID Tag (Transponder): Key component of RFID technology consisting of a minute computer chip with an antenna attached to transport or product packages. Tags can be updated and reprogrammed.

Smart Labels: RFID tags looking like printed labels.

Secure Agent Fabrication, Evolution, and Roaming

Sheng-Uei Guan
National University of Singapore, Singapore

BACKGROUND

Agent-based e-commerce is a promising novelty that performs tasks such as payment, mediation, interaction, and sales promotion in simple and intelligent manners. The agents can be endowed with attributes such as mobility, intelligence, and autonomy.

Constructing appropriate architecture for agent systems in e-commerce is a fundamental consideration in facilitating agent-based transactions (Lee, Kang, & Lee, 1997). A practical way is to provide sites with methods to fabricate various agents according to the requirements of the clients. Due to the nature of e-commerce and the Internet, agents should be able to adapt to a changing environment automatically. Agents should therefore be able to evolve in terms of intelligence and also be able to roam so as to utilize the power of network computing (Guan & Yang, 1999; Yang & Guan, 2000). In order to meet the requirements discussed and to provide an environment for an in-depth research in e-commerce, this chapter proposes secure agent fabrication, evolution and roaming (SAFER) for e-commerce.

DESCRIPTION OF SAFER

Secure Agent Fabrication Evolution and Roaming (SAFER) is an infrastructure to serve agents in e-commerce and establish the necessary mechanisms to manipulate them. The goal of SAFER is to construct open and evolutionary agent systems for e-commerce. The SAFER architecture comprises different communities, as are described in Figure 1. Each community consists of the following components: Owner, Butler, Agent, Agent Factory, Community Administration Center, Agent Charger, Agent Immigration, Clearing House and Bank, which are illustrated in Figure 2. Each component will be elaborated in the following subsections.

Community

As is shown in Figure 1, we divide agents into SAFER communities and non-SAFER communities. Each SAFER community possesses a set of facilities ad individuals as described in Figure 2. The local community administration center will approve an applicant as a SAFER community member and issue it a digital certificate.

Agents can also migrate within communities. Therefore, in addition to permanent residence in a community, an agent can carry out its tasks in a foreign community. Visiting agents can register with the foreign community administration center as guests and obey migration rules. Figure 2 illustrates the concept of SAFER agent community.

A community is therefore the basic unit in SAFER e-commerce. It offers factories and evolution vehicles to

Figure 1. SAFER architecture (1)

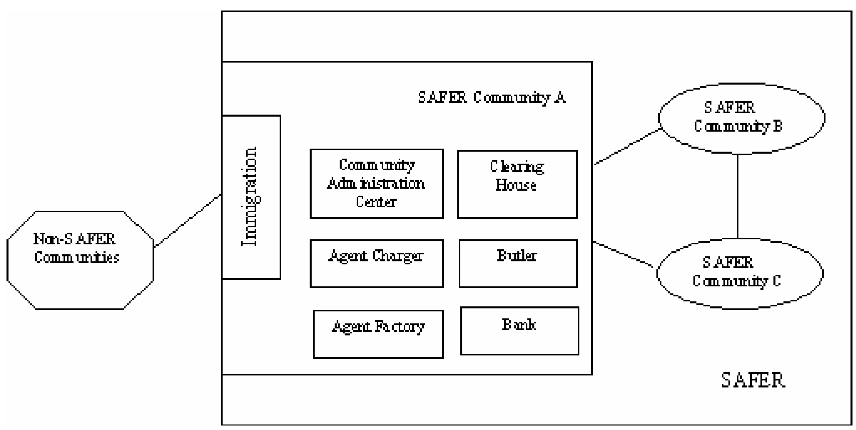

Figure 2. SAFER architecture (2)

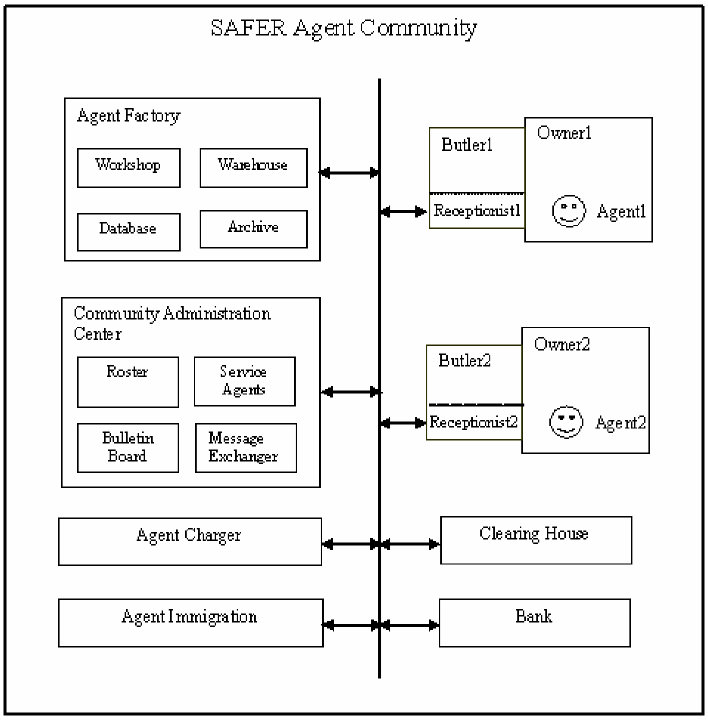

fabricate e-commerce agents. Agents can therefore be regulated in order to perform their tasks more efficiently and their security enhanced.

Owner

Agents act on behalf of their owners. The owner therefore has the priority and responsibility for all his agents. The owner therefore has the responsibility for all his agents and controls them from creation to termination. Owners should register in the community administration center before having the access to the facilities of the community. The owner can authorize a butler to handle most of his tasks and reduce his burden.

Butler

An agent butler will, in the absence of the owner, make decisions on his behalf. As agents are dispatched for certain missions, the agent owner will issue authorization to them. The agent butler takes on the role of enforcing these authorizations when necessary. The butler is also involved when making payments during transactions with external parties and in keeping track of the agent's activities and its location.

Butlers can also detect agent loss or abduction. In order to ensure that an agent is "alive," critical agents are required to send a "heartbeat" signal back to the agent butler at fixed intervals. If the butler does not receive heartbeats from an agent after the fixed interval, the butler will immediately alert the agent owner and appropriate actions can be taken to either recover the agent or issue new agents to continue the mission.

Butlers also act as receptionists in agent roaming (Yang & Guan, 2000), coordinating agent transport, and servicing incoming and outgoing agents.

Agent

The SAFER e-commerce is based on agents. Each agent has a unique identification (in the form of owner-issued digital certificates) and belongs to one specified owner. According to the tasks assigned by the owner, we can classify agents into categories such as negotiation agents, payment agents, mediation agents, and so forth. Agents can be resting in the owner's computer when they are idle, or roaming from one host to another, or executing a task in a foreign host.

As an agent acts on behalf of its owner, it should have certain degree of intelligence. For example, an agent should be able to learn the owner's preference, adjust its behavior according to the task assigned and the resources available, and so forth. Mobile agents can carry important information when they are roaming through the network to complete transactions and should be immune from attacks from hackers or malicious agents.

Agent Factory

An agent factory consists of four components, namely, workshop, warehouse, database and archive. Workshop is the site where an agent is fabricated, fixed, and checked. Coarse agents that are suspended in fabrication and those waiting for further fixing or checking are queued in the warehouse. Database includes various ontology structures and standard modules to assemble different agents in the workshop. Archive is the set of the factory logs and information of agents that have undergone certain processes in the agent factory. An agent factory therefore provides the interface for owners to customize agents with desirable functionality.

Community Administration Center

The community administration center is responsible for administrative matters in the community. The administration center has a periodically updated roster of the community, which includes data on the registered facilities, owners, agents, and guest agents from other communities. The administration center is also responsible for information exchange and communication with other communities. Moreover, it collects information (such as addresses of new auction Web sites) from the Internet to update the databases in the agent factory.

Agent Charger

The agent charger is part of the security mechanism to ensure agent integrity in SAFER. "Agent battery" is carried by each agent and specifies the number of "actions" it can perform. The agent battery decreases its energy level (i.e., number of actions) by one, each time before an action is executed. If the level reaches zero, the agent is not allowed to perform any more action. In order to restore its energy level, the agent approaches an agent charger to regain its energy. Before restoring an agent battery, the agent charger should inspect the agent for its fitness and integrity.

Clearing Houses and Banks

In order to facilitate financial transactions and clearance, clearing houses and banks are included as separate entities in each SAFER community. If a transaction takes place within a community that does not involve any party of other communities, it can make an appropriate request directly to a local bank for immediate settlement. However, if a transaction involves parties from other communities, a clearing house must be used as the medium for settlement with different banks. Different from banks, clearing houses do not contain account information, as banks do. It is merely a medium through which interbank settlement can be facilitated.

Agent Fabrication in SAFER

In SAFER, agents are fabricated by an agent factory in their community, for the following reasons:

- Although some users may design agents themselves, most users do not have the ability to do so. Also, there are many types of software agents in e-commerce. It will be more convenient if an agent can be customized according to its own specification by using the agent factory.
- Adopting this mode of agent fabrication will enhance the security of SAFER e-commerce. Because information of all fabricated agents is stored in agent factories, agents can be administered more efficiently and safely.

Under SAFER, the fabrication of agents obeys prescribed routine procedures. An owner customizes new agents through the interface provided by an agent factory. When an agent factory fabricates a new agent, it chooses the corresponding ontology structure from the database, according to the requests from the owners. The agent factory then assembles the agents according to both the ontology structure and the owner's specification. The procedures of agent fabrication are demonstrated in Figure 3 and Table 1.

SAFER adopts a tree structure to express the ontology and agent. Figure 3 lays out an ontology structure for negotiation agents, and the details of nodes in Figure 3 are shown in Table 1. Terminal nodes are the "leaves" of the tree. They correspond to data and variable arguments such as node D1 for agent ID and node D2 for a destination. They can be customized or set to default value. The function nodes are internal nodes, showing the categories of their child nodes. The ontology structure also specifies the attribute of every node. If the node is indispensable in the structure, its attribute number will be zero. For example, node D1 in Figure 3 stands for agent ID, which is mandatory for every agent, its attribute is specified as zero, and the node is represented as D1/0. Similarly, if the node is optional or can be replicated to a

S

Figure 3. Ontology structure

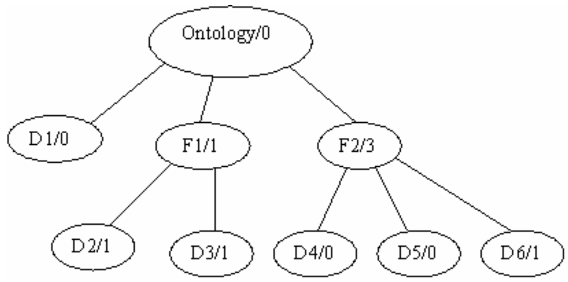

Table 1. Details of nodes in Figure 3

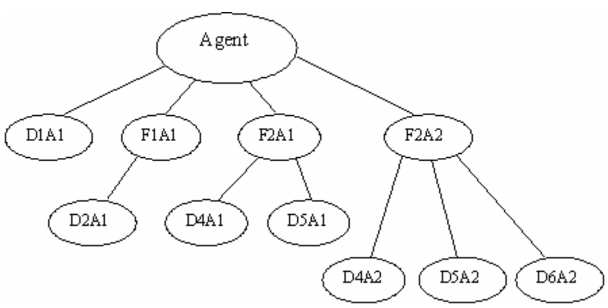
NODE	CONTENT	ATTRIBUTE
Ontology	Ontology Type	0
D1	Agent ID	0
F1	Destination site	1
D2	Destination 1	1
D3	Destination 2	1
F2	Negotiation Strategy	3
D4	Strategy Parameter 1	0
D5	Strategy Parameter 2	0
D6	Strategy Parameter 3	1

0 – Indispensable 1 - Optional
N – Maximum replication number (positive integer except1)

Figure 4. An agent fabricated using the ontology in Figure 3



maximum of *N* times, then the attribute for that node is represented with 1 or *N*, respectively. Examples are node D3/1 and node F2/3 in Figure 3.

When an agent factory fabricates a new agent, it arranges the data and functions according to the instructions from the ontology structure. Figure 4 demonstrates a negotiation agent fabricated according to the ontology structure illustrated in Figure 3, and the details of nodes in Figure 4 are specified in Table 2. The first two digits in the nodes of Figure 4 correspond to the nodes in the ontology structure in Figure 3. For example, node D1A1 corresponds to node D1, nodes D4A1 and D4A2 correspond to node D4. Note that node F1A1 in the agent has only one child node—D2A1—whereas node F1 in the ontology has two child nodes. This is because the attribute of node D3 in the ontology in Figure 3 is 1, which means that it is optional. So when the agent factory fabricates the agent, it can choose to assemble only one node under node F1A1, which means that node D3 has no counterpart in the new agent. The new nodes F2A1 and

Table 2. Details of nodes in Figure 4

NODE	CONTENT
Agent	Agent Name
D1A1	Agent ID
F1A1	Destination site
D2A1	Destination 1
F2A1	Negotiation Strategy 1
D4A1	Strategy Parameter 1
D5A1	Strategy Parameter 2
F2A2	Negotiation Strategy 2
D4A2	Strategy Parameter 1
D5A2	Strategy Parameter 2
D6A2	Strategy Parameter 3

Table 3. Details of nodes in Figure 5

NODE	CONTENT
Other Nodes	Same as in Table 2
F2A3	Negotiation Strategy 3
D4A3	Strategy Parameter 1
D5A3	Strategy Parameter 2

F2A2 are replications of node F2 in the ontology, because node F2 in the ontology has an attribute 3, which means that it can be replicated up to as many as three times. Node F2A1 has two child nodes and node F2A2 has three child nodes. Similarly, this can be seen from the attributes of the nodes D4, D5, and D6 in the ontology structure.

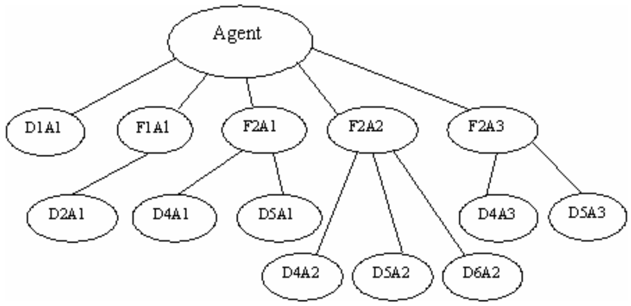
Agent Evolution

Agent evolution is one of the most prominent features of SAFER. Collaboration and competition exist among agents with similar goals. Agents can cooperate to adjust their strategies in order to negotiate with sellers and reach satisfactory deals. Competition between agents occurs when, for instance, a limited number of products are available. Agents that win the product will have an increased fitness, whereas agents that lose will also lose some fitness.

In this article, some evolution related attributes for agents are proposed, including the following:

1. **State of Agent:** Agent states include newborn, executing, suspended, communicating, and terminated. Evolution amongst these states can result in an agent migrating from one state to another.
2. **Agent Relationship:** Is two agents succeed in collaboration to embark on one task of if one agent gets useful information from another, their relationship becomes tighter. This relationship affects the track of their evolution.
3. **Agent Fitness:** This attribute indicates the ability of an agent to survive and adapt to the environment. The Agent fitness is evaluated based on the following factors
    a. the *integration of agents* and their susceptibility to attack and damage;
    b. The *history of agents,* including the number and quality of completed tasks; and
    c. the *agent evolution record*, which shows whether the agent's growth is healthy.

Figure 5. An agent after evolution



The evolution of agents and ontology structures are also implemented by tree structure. For example, if the negotiation agent in Figure 4 needs a new strategy to enhance its negotiation skill, its owner or butler will send the requests to the agent factory. The agent factory will add the requested modules to the agent. Figure 5 and Table 3 demonstrate the structure of the agent after evolution and details of nodes in the structure. The new node F2A3 and its child nodes D4A3 and D5A3 are built into the new agent as a new negotiation strategy. The same evolution procedures can be applied to the evolution of ontology structure.

A set of agent transport protocols has been designed for SAFER in (Yang & Guan, 2000) to allow intelligent agents to roam from host to host. The transport protocols designed provide a secure mechanism for agents in e-commerce to roam across different hosts and communities in SAFER.

IMPACT OF SAFER

We are implementing the SAFER architecture, which covers many facilities, such as butlers and agent factories, as well as routine procedures such as fabrication,

Figure 6. Supervised agent transport in SAFER

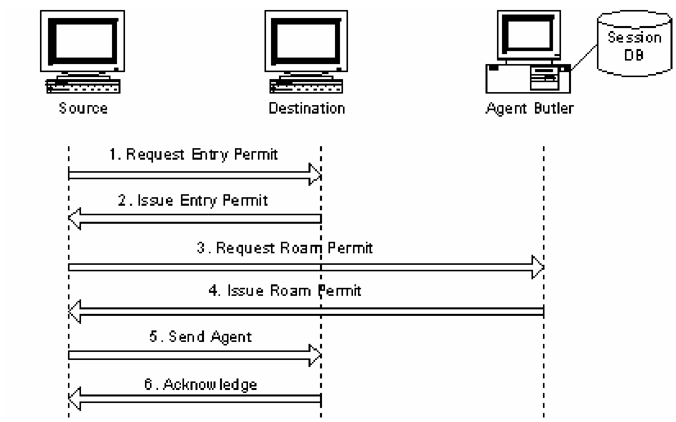


Figure 7. Prototype of agent butler

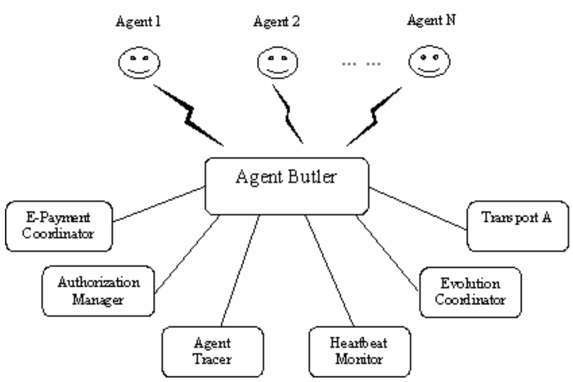

evolution, and roaming. Three transport protocols have been implemented: supervised agent transport, unsupervised agent transport, and bootstrap agent transport. We have successfully realized the transportation of an agent from one host to another in the above three different ways. A simplified implementation diagram of the supervised agent transport protocol in SAFER is shown in Figure 6 (Yang & Guan, 2000).

The prototype of an agent butler is being implemented. Functions designed for the agent butler include coordination of agent payment, management of authorization, keeping track of agent whereabouts, detection of agent abduction, coordination of agent evolution as well as assistance in agent roaming. Each function is implemented as a separate module in the agent butler, as shown in Figure 7.

Java is chosen as the implementation language, as it has a list of important features including robustness, security, and portability. The most important issue in e-commerce architecture is the security of the system. Java provides a three-layered security model and many mechanisms to enhance security protection.

CONCLUSION

In this article, the SAFER architecture for agent-based e-commerce was proposed. SAFER provides the facilities to serve agents in e-commerce and establishes the necessary mechanisms to manage and control their activities. We elaborated the functions of the components in SAFER and three aspects of SAFER: fabrication, evolution, and roaming.

SAFER provides an open and evolutionary agent architecture for e-commerce. With SAFER, conducting transactions in the Internet will be more secure and efficient. We have finished the design and implementation of the secure agent transport protocol in SAFER (Guan & Yang, 1999; Yang & Guan, 2000). We are trying to provide the basic modules and facilities, as we regard SAFER as our infrastructure for further research on e-commerce. As evolution is proposed in the SAFER architecture, its mechanism and theory presentation is also being constructed. Furthermore, we have developed the payment mechanism in SAFER, as it is essential in e-commerce.

KEY TERMS

Adaptability: The ease with which software satisfies differing system constraints and user needs.

Agents: A piece of software that acts to accomplish tasks on behalf of its user.

Anonymity: The degree to which a software system or component allows for or supports anonymous transactions.

Client: In this article, "client" refers to customers who pay for good and services.

Confidentiality: The nonoccurrence of the unauthorized disclosure of information.

Cryptography: The art of protecting information by transforming it (i.e., *encrypting* it) into an unreadable format, called "cipher text." Only those who possess a secret *key* can decipher (i.e., *decrypt*) the message into plain text.

Flexibility: The ease with which a system or component can be modified for use in applications or environments other than those for which it was specifically designed.

Secure Agent for E-Commerce Applications

Sheng-Uei Guan
National University of Singapore, Singapore

INTRODUCTION

One hindrance to the widespread adoption of mobile agent technology (Johansen et al., 2002) is the lack of security. SAFER, or Secure Agent Fabrication, Evolution and Roaming, is a mobile agent framework that is specially designed for the purpose of electronic commerce (Guan & Yang, 2002, 2004; Yang & Guan, 2000; Zhu, Guan, Yang, & Ko, 2000). By building strong and efficient security mechanisms, SAFER aims to provide a trustworthy framework for mobile agents. Although such an agent transport protocol provides for the secure roaming of agents, there are other areas related to security to be addressed.

Agent integrity is one such area crucial to the success of agent technology. The integrity protection for agent code is relatively straightforward. A more complex code integrity scheme to handle code-on-demand is also proposed in Wang, Guan, and Chan (2002). Agent data, however, is dynamic in nature and will change as the agent roams from host to host. Despite the various attempts in the literature (Chionh, Guan, & Yang, 2001), there is no satisfactory solution to the problem so far. Some of the common weaknesses of the current schemes are vulnerabilities to revisit attack and illegal modification (deletion/insertion) of agent data.

DESCRIPTION OF SADIS

SADIS has been designed based on the following assumptions:

1. Entities including agents, agent butlers, and hosts should have globally unique identification number (IDs).
2. Each agent butler and host should have a digital certificate that is issued by a trusted CA. These entities will be able to use the private key of its certificate to perform digital signatures and encryption.
3. Whereas the host may be malicious, the execution environment of mobile agents should be secure and the execution integrity of the agent can be maintained.
4. Entities involved are respecting and cooperating with the SADIS protocol.

Key Seed Negotiation Protocol

The proposed key seed negotiation protocol defines the process for key seed negotiation and session key and data encryption key derivation. When an agent first leaves the butler, the butler generates a random initial key seed, encrypts it with the destination host's public key, and deposits it into the agent before sending the agent to the destination host. It should be noted that agent transmission is protected by the agent transport protocol (Guan and Yang, 2002), thereby protecting the system from being compromised by malicious hosts.

The key seed negotiation process is based on the Diffie-Hellman (DH) key exchange protocol (Schneier, 1996), with a variation. The agent will first generate a private DH parameter a and its corresponding public parameter x. The value x, together with the ID of the destination host, will be encrypted using a communication session key and sent to the agent butler.

The agent butler will decrypt the message using the same communication session key (discussed later). It, too, will generate its own DH private parameter b and its corresponding public parameter y. With the private parameter b and the public parameter x from the agent, the butler can derive the new key seed and use it for communications with the agent in the new host. Instead of sending the public parameter y to the agent as in normal DH key exchange, the agent butler will encrypt the value y, host ID, agent ID and current timestamp with the destination host's public key to get message M. Message M will be sent to the agent after encrypting with the communication session key.

$$M = E(y + \text{host ID} + \text{agent ID} + \text{timestamp}, H_{pubKey})$$

At the same time, the agent butler updates the agent's itinerary and stores the information locally. This effectively protects the agent's actual itinerary against any hacking attempts related to itinerary, thereby protecting against the data deletion attack.

When the agent receives the double-encrypted DH public parameter y, it can decrypt with the communication session key. Since the decrypted result M is parameter y and some other information encrypted with the destination host's public key, the current host will not be able to find out the value of y and thus find out the new key seed to be used when the agent reaches the destination host. It should be noted that this does not prevent the host from replacing M with its own version M' with the same host ID, agent ID, timestamp but different y. The inclusion of host ID, agent ID inside M can render such attack useless against SADIS. A detailed discussion on this attack can be found in the security analysis section.

Subsequently, the agent will store M into its data segment and requests the current host to send itself to the destination host, using the agent transport protocol (Guan & Yang, 2002).

On arriving at the destination host, the agent will be activated. Before it resumes normal operation, the agent will request the new host to decrypt message M. If the host is the right destination host, it will be able to use the private key to decrypt message M, and thus obtain the DH public parameter y. As a result, the decryption of message M not only completes the key seed negotiation process but also serves as a means to authenticate the destination host. Once the message M is decrypted, the host will verify that the agent ID in the decrypted message matches the incoming agent, and the host ID in the decrypted message matches that of the current host. In this way, the host can ensure that it is decrypting for a legitimate agent instead of some bogus agent. If the IDs in the decrypted messages match, the decrypted value of y is returned to the agent.

With the plain value of y, the agent can derive the key seed by using its previously generated private parameter a. With the new key seed derived, the key seed negotiation process is completed. The agent can resume normal operation in the new host.

Whenever the agent or the butler needs to communicate with each other, the sender will first derive a communication session key using the key seed and use this communication session key to encrypt the message. The receiver can make use of the same formula to derive the communication session key from the same key seed to decrypt the message.

The communication session key K_{CSK} is derived using the following formula:

$$K_{CSK} = \text{Hash}(\text{key\_seed} + \text{host ID} + \text{seqNo}).$$

The sequence number is a running number that starts with 1 for each agent roaming session, and is reset to 1 whenever the agent reaches a new host. Each message communicated will therefore be encrypted using a different key. As this means that the butler and agent will not be able to communicate if messages are lost without detection, SADIS makes use of TCP/IP as a communication mechanism. Once the communication is reestablished after a send failure, the sender will resend the previous message (encrypted using the same communication session key). The agent and the butler can therefore synchronize on communication session key calculations.

The agent encrypts host information with a data encryption key K_{DEK}. The data encryption key is derived as follows:

$$K_{DEK} = \text{Hash}(\text{key\_seed} + \text{hostID})$$

The details on encryption will be discussed in the next section.

Data Integrity Protection Protocol

The key seed negotiation protocol lays the necessary foundation for integrity protection by establishing a session-based key seed between the agent and its butler. Digital certificates also help protect the agent data integrity.

Our data Integrity Protection protocol is comprised of two parts: chained signature generation and data integrity verification. Chained signature generation is performed before the agent leaves the current host. The agent gathers data provided by the current host d_i and construct D_i as follows:

$$D_i = E(d_i + ID_{host} + ID_{agent} + \text{timestamp}, k_{DEK})$$

or

$$D_i = d_i + ID_{host} + ID_{agent} + \text{timestamp}$$

The inclusion of host ID, agent ID and timestamp is to protect the data from possible replay attack, especially when the information is not encrypted with the data encryption key, thereby creating an unambiguous memorandum between the agent and the host. The construction of D_i also gives the flexibility to encrypt the data or keep it in plain. After constructing D_i, the agent will request the host to perform a signature on the following:

$$c_i = \text{Sig}(D_i + c_{i-1} + ID_{host} + ID_{agent} + \text{timestamp}, k_{priv}),$$

where c_0 is the digital signature on the agent code by its butler.

One design focus of SADIS is not only to detect data integrity compromise, but also, and what is more important, to identify malicious hosts. To achieve malicious host identification, it is an obligation for all hosts to verify the incoming agent's data integrity before activating the agent for execution. In the event of data integrity verification failure, the previous host will be identified as the malicious host.

Data integrity verification includes the verification of all the previous signatures. The verification of signature c_0 ensures agent code integrity, the verification of c_i ensures data provided by host h_i is intact. If any signature failed the verification, the agent is considered compromised.

While the process to verify all data integrity may seem to incur too much overhead and somewhat redundant (e.g., why need to verify the integrity of d_1 in h_3 while host h_2 already verifies that), it is necessary to ensure the robustness of the protocol and to support the function of malicious host identification. Although the agent butler can eventually detect such data integrity compromise (since agent butler has to verify all signatures), but there is no way to establish the identity of malicious host(s).

Security Analysis

To analyze the effectiveness and reliability of SADIS, a detailed security analysis is performed subjecting SADIS to a variety of attacks. Based on the attack targets, the various attacks to SADIS can be classified into data attack, key attack, signature attack, itinerary attack, and composite attack. Composite attack refers to attacks that are combinations of two or more of the afore-mentioned attacks. The security analysis will be organized according to the previously mentioned classifications.

Data Attack

Data attack refers to any attempt that aims to compromise the data carried by an agent. Compromise can be in the form of data modification, deletion, or insertion.

Considering the data modification scenario, let us assume that the data targeted is D_i provided by host i, because the agent itinerary is protected by the butler and cannot be changed, only host i can produce a valid signature if the data were to be modified. However, even if the malicious party (or even host i) can produce a valid signature c_i' corresponding to D_i', since c_i is chained to the signature of the next host c_{i+1}, signature verification for host $(i+1)$ will fail. Therefore, in order to perform a successful data modification attack, the malicious host must be able to forge the signatures for all hosts in the itinerary since host i. As the only way to achieve this is to obtain the private keys of all the following hosts, data modification attack is extremely difficult under SADIS.

A number of the existing data integrity protocols suffer from data deletion attack. After analyzing the root cause of the vulnerabilities, it is realized that it is extremely important to protect the agent's itinerary. If the agent's itinerary is closely guarded by the butler, any data deletion will result in modification to the agent's itinerary and thus be detected.

Key Attack

Besides direct attack on data integrity, a malicious host may attempt to attack the various keys in order to compromise data integrity. There are three different types of keys in SADIS. They are session-based key seed, communication session key, and data encryption key. In SADIS, the key seed is kept by the agent and the butler separately. Attacks to the key seed can only target at the key seed negotiation protocol. As all communication in key seed negotiation is protected by the communication session key, we can safely rule out the possibility of any third-party malicious attempts to break the protocol. We can focus on the scenario where the current host attempts to break the key exchange to obtain the key seed to be used in the subsequent host.

First, as the DH public parameter is encrypted using the destination host's public key, the current host will not, without manipulation, be able to complete DH key exchange to find out the new key seed. Without the private key from the destination host, no one can obtain y to complete the key exchange. Furthermore, as the encrypted message contains the agent ID and destination host ID, the current host won't be able to send a bogus agent carrying this encrypted y to the destination host for decryption.

If the current host attempts to manipulate any one or both of these parameters, it is able to manipulate the key seed derived when the agent reaches the destination host. However, the change in key seed will be immediately detected when the agent communicates with the butler or vice versa. In order to perform a successful attack, the current host must therefore be able to obtain the key seed in the butler so that it can intercept and replace message communicated between the butler and the agent. Unfortunately, as illustrated earlier, there is no way the current host can find out the value of DH public parameter from butler y. Thus, the key seed will not be compromised.

Besides key seed, SADIS makes use of communication session key and data encryption key in the protocol. These two keys are directly derived from the session-based key seed using a hash function. As far as any third-party host is concerned, attack to communication session key or data encryption key is equivalent to attacking the encryption key given only the cipher text. Even in the extreme case when such a key is compromised, the loss is limited to the message it encrypts.

Signature Attack

Usually a malicious host would need to forge digital signature when it attempts to compromise data integrity. If data integrity is not compromised, there is no need to attack the chained signature at all.

Itinerary Attack

If the agent itinerary is not carefully protected, it may lead to compromise to data integrity, especially in the case of data deletion as illustrated earlier in the section. In SADIS, as the agent updates the butler of its next destination host as part of the key seed negotiation protocol, there is no additional overhead related to the itinerary protection mechanism. Therefore, there is no way a malicious host can perform any attack on the itinerary (except, of course, if it breaks into the agent butler).

Composite Attack

At times, in order to perform a successful attack, more than one area is targeted simultaneously. In addition to attacks with specific targets, there are certain general hacking techniques such as man-in-the-middle attack and replay attack. The design of SADIS employs a mechanism to protect the protocol against these hacking techniques. Through the use of communication session key, man-in-the-middle attack can be avoided. On the other hand, the use of sequence number in communication session key generation effectively protects the protocol from replay attack by a third party host. In addition, the inclusion of host ID, agent ID, and timestamp during the key seed negotiation process prevents the current host from performing a replay attack with the next destination host.

The design of SADIS does not have dependency on any specific encryption/hashing algorithm. In an unlikely scenario when one algorithm is broken, SADIS can always switch to a stronger algorithm.

Implementation

In order to verify the design of SADIS and assess its applicability, a prototype of SADIS is developed. The prototyping language is chosen to be Java, because of its platform independent feature.

Just like any other security mechanism, there is certain overhead associated with SADIS. The overhead is incurred as additional time required for processing as well as additional data carried by the agent. To assess the efficiency of SADIS, a study is performed on the prototype.

The result of this experimental study on SADIS is broken down, based on functionality and is shown in Table 1 and Table 2. It can be seen that the bulk of the overhead is incurred during key seed negotiation where the key exchange protocol and the public key operation is performed. Despite the relatively high overhead, this will not impact the overall performance of SADIS significantly because the frequency of agent roaming is low compared to the frequency of some other agent operations (such as agent-to-butler communication). As a result, the overhead incurred at this stage is "one-time" in nature. Other

Table 1. SADIS time efficiency (time taken for operations in milliseconds)—Performance without SADIS

Key Seed Negotiation (butler timing)	40	50	50	40	40	44.0
Key Seed Negotiation (destination host)	41	41	40	40	40	40.4
Agent Butler Communication (agent timing – send)	40	40	50	40	40	42.0
Agent Butler Communication (butler timing – send)	30	30	31	40	30	32.2
Agent Butler Communication (agent timing – receive)	10	10	10	10	10	10.0
Agent Butler Communication (butler timing – receive)	10	30	10	10	20	16.0

Table 2. SADIS time efficiency (time taken for operations in milliseconds)—Performance comparison with SADIS

Operation	1 (ms)	2 (ms)	3 (ms)	4 (ms)	5 (ms)	Avg (ms)	Overhead (ms)
Key Seed Negotiation (butler timing)	250	260	250	220	260	248.0	204.0
Key Seed Negotiation (destination host)	290	281	260	280	290	280.2	239.8
Agent Butler Communication (agent timing – send)	60	60	70	50	60	60.0	18.0
Agent Butler Communication (butler timing – send)	41	50	40	40	40	42.2	10.0
Agent Butler Communication (agent timing – receive)	10	20	10	10	10	12.0	2.0
Agent Butler Communication (butler timing – receive)	30	30	30	20	20	26.0	10.0

Table 3. SADIS data overhead

	Original Data Size (bytes)	Maximum Overhead (bytes)	Overhead	OKGS Overhead
1	1800	96	5.33%	33.87%
2	2001	96	4.80%	37.73%
3	5000	96	1.92%	N/A
4	10000	96	0.96%	N/A
5	100000	96	0.10%	N/A

than in the key seed negotiation, the time overhead incurred elsewhere in the protocol is negligible.

Other than overhead in terms of processing time, there is certain overhead to the data size as well. SADIS is designed to produce almost fixed data overhead regardless of the data size. SADIS therefore tends to be more efficient when actual data size is higher. This ability to limit the size of overhead data regardless of actual data size is an improvement in efficiency over existing work. The last and most significant overhead is the digital signature created by the host. The overhead of digital signature is a fixed length of 64 bytes. Altogether, SADIS has a maximum data overhead of 96 bytes.

As the statistics show, SADIS is optimized to improve time efficiency and data efficiency compared with related work in the literature. The feasibility and practicality of SADIS is thus demonstrated through the prototype.

IMPACT OF SADIS

Various techniques have been developed to protect agent integrities (Borselius, 2002), based on trusted hardware, trusted host, and conventional contractual agreements. SADIS addresses the problem of data integrity protection via a combination of techniques such as execution tracing, encrypted payload, environmental key generation, and undetachable signature. The security of SADIS is completely based on its own merits without making any assumption about the integrity of external hosts. SADIS also makes use of a negotiated key seed to generate data encryption key. Therefore, no random value needs to be encrypted and stored with the agent. With SADIS, the data and the communication keys undergo one time encryption. Thus, even if some of the keys are compromised, the key seed will still remain secret.

CONCLUSION

In this article, SADIS—a new data integrity protection protocol—has been proposed. Besides being secure against a variety of attacks and robust against vulnerabilities of related work in the literature, the research of SADIS includes the objective of efficiency. Unlike some existing literature, the data integrity protection protocol aims not only to detect data integrity compromise, but more important, to identify the malicious host. With security, efficiency, and effectiveness as its main design focuses, SADIS works with other security mechanisms to provide mobile agents with a secure platform.

KEY TERMS

Agents: A piece of software, which acts to accomplish tasks on behalf of its user.

Cryptography: The art of protecting information by transforming it (*encrypting* it) into an unreadable format, called "cipher text." Only those who possess a secret *key* can decipher (or *decrypt*) the message into plain text.

Flexibility: The ease with which a system or component can be modified for use in applications or environments other than those for which it was specifically designed.

Protocol: A convention or standard that controls or enables the connection, communication, and data transfer between two computing endpoints. Protocols may be implemented by hardware, software, or a combination of the two. At the lowest level, a protocol defines a hardware connection.

Security: The effort to create a secure computing platform, designed so that agents (users or programs) can only perform actions that have been allowed.

Security Issues Concerning Mobile Commerce

Samuel Pierre
École Polytechnique de Montréal, Canada

INTRODUCTION

Electronic commerce or e-commerce can be briefly defined as a financial transaction or commercial information between two parties based on data transmitted over communication networks (Soriano & Ponce, 2002). It relies upon users' interventions to initiate a transaction and select the main steps of the process. Users' actions stem from a succession of virtual decisions. Indeed, when shopping with a virtual catalog, customers can select products which meet their needs, tastes, and respect their price range. Such decisions consistently require the users' input, thus costing them both time and money. These costs are even more exorbitant when a search is launched for an order that includes a variety of products from different sources which have different characteristics (price range, delivery dates, etc.). When transactions involve users who are moving or take place over mobile networks, this is referred to as *mobile electronic commerce*, a specific type of e-commerce.

Mobile electronic commerce (or m-commerce) refers to an ability to carry out wireless commercial transactions using mobile applications within mobile devices, such as mobile phones and personal digital assistants (PDAs). It is generally defined as the set of transactions or processes which can be carried out over a wireless mobile network. According to this definition, m-commerce constitutes a subset of all electronic commercial transactions (electronic commerce or e-commerce) from business to consumer (B2C) or business to business (B2B). Thus, short personal messages such as those from SMS (short messaging system) sent between two individuals do not fall into the category of m-commerce, whereas messages from a service provider to a salesperson or a consumer, or vice versa, do fit this very definition. M-commerce appears as an emerging manifestation of Internet electronic commerce which meshes together concepts such as the Internet, mobile computing, and wireless telecommunications in order to provide an array of sophisticated services (m-services) to mobile users (Varshney, Vetter, & Kalakota, 2000; Veijalainen, Terziyan, & Tirri, 2003).

E-commerce includes an initial step where consumers search for a product they wish to purchase by virtually visiting several merchants. Once the product is found, negotiations can take place between the customer and the merchant (electronic negotiation or e-negotiation) (Paurobally, Turner, & Jennings, 2003). If an agreement is reached, the next step is the payment phase. At each step of the process, some problems arise, such as transaction security, confidence in the payment protocol, bandwidth limitations, quality of service, shipping delays, and so forth (Younas, Chao, & Anane, 2003; Zhang, Yuan, & Archer, 2002). The peak withdrawal periods have always presented a major challenge for certain types of distributed applications. The advent of m-commerce further highlights this problem. Indeed, in spite of rather optimistic predictions, m-commerce is plagued by several handicaps which hinder its commercial development, security being the main one.

Many market research studies, like those carried out by Strategy Analytics and the Gartner Group, predicted that by 2004 there would be over one billion wireless device users, some 600 million wireless Internet subscribers, a $200 billion m-commerce market, and 40% of consumer-to-business e-commerce will take place over Web-enabled phones (Gosh & Swaminatha, 2004). However, these business opportunities could be compromised by new security risks specific to the wireless medium and devices. As a result, the potential boom in the number of new m-commerce applications and markets can be achieved if and only if security and privacy can be integrated into online m-commerce applications.

This article analyzes some major security issues concerning mobile commerce. The next section presents background and related work, followed by a summary of some security issues and challenges. Future and emerging trends in secure m-commerce are then outlined, and the article is concluded.

BACKGROUND

While e-commerce systems are designed for purchases conducted on the wired Internet, m-commerce is extended to handle the mobility aspects related to the user equipment such as a mobile phone or a PDA. One of the main characteristics of an m-commerce system is the use of the Internet as the backbone and e-commerce with mobile terminals as user equipment. M-commerce applications can be as simple as a system to synchronize an address book or as complex as the system used to enable credit card transactions. They are deployed using mobile middleware which can be defined as a functional layer of software provided by application developers to link their e-commerce applications to an operating system and various mobile networks to allow their applications to bypass certain mobility issues.

Any party engaging in business needs a certain level of security. Security relies on a set of basic concepts and requirements such as: confidentiality, authentication, integrity, non-repudiation, and authorization. Confidentiality assures that the exchange of messages between parties over wireless access networks or global networks is not being monitored by non-authorized parties. Authentication ensures that the parties engaging in business are who they claim to be. Integrity allows users to verify whether modifications have occurred; however, it does not guarantee that information has not been altered. Non-repudiation certifies that the business transactions the parties engage in are legally binding. Authorization refers to a set of access rights assigned to an entity by a certification authority (CA). It does not guarantee that messages received do really come from a given counterpart; that is the task of authentication.

In a wired network, the secure socket layer (SSL) protocol and the transport layer security (TLS) protocol, which are well-established security protocols, provide privacy and data integrity between two communicating applications. In fact, HTTP over TLS-SSL is used to secure transactions for security-sensitive applications like m-commerce. It is generally known that these protocols do not adapt well to wireless environments with reduced processing capability and low-bandwidth links. Indeed, wireless devices such as cellular phones and PDAs have limited storage and minimal computational capacity. As a result, security issues were not taken into account when they were designed.

The scheme devised during the wireless application protocol (WAP) forum, which has defined an entirely new suite of protocols, uses a WAP gateway or proxy between the wireless and wireline environments to ensure connection and security. The SSL and TLS ensure security within the Internet, while the wireless transport layer security (WTLS) protocol ensures secure channels between the client and the WAP gateway. Transactions between WTLS and TLS are executed by the WAP gateway. However, the use of the WAP proxy, which is also a point of failure, does not allow for end-to-end security. As a matter of fact, because there are storage and translation operations at the WAP proxy, it becomes a point of entry for attacks. A solution to strengthen this weakness was provided by Soriano and Ponce (2002). They suggested providing a secure end-to-end tunnel between an Internet server and a mobile user by implementing a TLS compatible security layer at the wireless application environment (WAE) layer on the client side, named WAE-Sec. WAE-Sec therefore prohibits translations by the WAP gateway and permits compatibility with the TLS protocol. Note, however, that this solution resembles the one proposed by Gupta et al. (2001).

On the other hand, Tang, Terziyan, and Veijalainen (2003) have defined other related security issues to m-commerce, namely hostility, information security, and vulnerability. Hostility means that dishonest customers who get fraudulent identities by stealing mobile devices can make illegal operations and, thus, should be quickly identifiable. Information is more vulnerable in wireless networks since other parties can easily intercept it. The solution is to encrypt data with adequate keys. Vulnerability arises from a malfunctioning of the mobile device itself or from the physical access of malicious persons to the terminals. To remedy these additional problems, Tang et al. (2003) suggested the use of a mixed personal identification number (PIN) storage scheme which let the PIN be partially stored on the mobile device while the remainder of the PIN is stored on the network. Researchers assume that the probability of discovering the PIN located at two different places does not depend on the length of the PIN nor on the fact that a single part was discovered. Thus, discovering the whole PIN will require digging and/or guessing for twice as long than if the PIN was located at a single place. The improvements brought about by this strategy have been shown using a probabilistic model, but its implementation has yet to be investigated.

A new protocol for m-commerce was proposed by Katsaros and Honary (2003). Fully applicable to third-generation mobile networks, this protocol is characterized by three novel properties, as opposed to the existing methods of m-commerce. In fact, it provides a simplified and secure transaction method, minimizes the number of entities involved in the transaction, and finally reduces the probability of security threats, thus reducing the risk of fraud. Unfortunately, this protocol does not solve certain security issues related to m-commerce.

SECURITY ISSUES AND CHALLENGES

Mobile commerce provides an exciting new set of capabilities which can lead to new services that enhance the end-user's experience. With these new business opportunities, the risk of new security threats also arises. New mobile devices such as PDAs and mobile phones enable easy access to the Internet and strongly contribute to the development of m-commerce services, while Smartcard platforms will enable operators and service providers to design and deploy new m-commerce services. Such technologies must guarantee a high level of security of customer information and transactions in order to be adopted and widely deployed. Thus, establishing security mechanisms which allow diverse mobile devices to support a secure m-commerce environment on a wireless Internet is a critical challenge.

There are a lot of other security issues and challenges related to m-commerce: security of the transactions, security of the payments, security of customer information, end-to-end security, authorization mechanisms, and so on. Providing security provisions for the m-commerce community is challenging due to the insecure air interface of wireless access networks, and limited computational capability of mobile devices and users' mobility (He & Zhang, 2003). The limited equipment resources require the e-payment protocol in the wireless Internet environment to be designed in consideration of the efficiency of the computing functions and the storage device. In this context, security issues, like those dealing with service and subscriber authorizations in enhanced prepaid implementations for m-commerce, must be addressed. In fact, client application and subscriber-level authentication and authorization are key mechanisms used to regulate access to and usage of content-based transactions in m-commerce. The objective is to provide an enriched rating engine and a highly configurable feature set for service and content charging on wireless networks (Cai et al., 2004).

Smartcard platforms will enable operators and service providers to design and deploy new m-commerce services. This development can only be achieved if a high level of security is guaranteed for the transactions and customer information (Renaudin et al., 2004). In this context, smartcard design is very challenging when it comes to providing the flexibility and the power required by the applications and services, while at the same time, guaranteeing the security of the transactions and the customer's privacy.

On the other hand, as the number of users of wired and wireless Internet services is increasing exponentially and m-commerce services are going to be activated, it is quite necessary to establish a wireless Internet public key infrastructure (PKI) service which accepts diverse mobile devices to support secure m-commerce environments on the wireless Internet. In this context, security/payment policy algorithms must be designed in order to dynamically adapt the level of security according to the domain-dependent properties and the independent properties to support secure m-commerce transactions and payment on wireless Internet (Kim et al., 2002).

An e-payment system for m-commerce uses existing wired systems as is. However, it implies certain security and inefficiency problems. In fact, the limited amount of equipment required by the e-payment protocol in the wireless Internet environment allows for the highest level of the efficiency pertaining to the computing function and the storage device. The issue is the basis of the design of an e-payment system for m-commerce that minimizes public key computing and guarantees anonymity concerning personal and purchasing information, as well as spatial storage efficiency (Kim, Kim, & Chung, 2003).

Another issue in m-commerce security concerns the increasing number of destructive messages with viruses that can harm mobile devices. Such an issue is truly critical in the context of mobile applications which are generally deployed by small mobile devices with limited processing and storage capabilities.

Mobile commerce involves many risks related to security and privacy (Ghosh & Swaminatha, 2004). In fact, wireless devices introduce new security threats which are specific to their mobility and communication medium. Most Web sites are not currently configured to deal with the intermittent service failures which frequently occur during wireless connections. Furthermore, the most popular implementations of the WTLS protocol do not re-authenticate principles or double-check certificates once a connection has been established. As a result, attackers can take advantage of this vulnerability and compromise the integrity of the wireless networks which support the m-commerce applications.

The most significant security and privacy risks for wireless devices involved in m-commerce applications are: platform risks, software application risks, security risks of WML Script, among others (Ghosh & Swaminatha, 2004). Platform risks are related to the fact that many manufacturers have failed to include some basic operating system features necessary to enable some kinds of secure computing: memory protection for processes, protected kernel rings, file access control, authentication of principals to resources, biometric authentication, and so forth. Without a secure infrastructure provided by the platform and used by the device running m-commerce applications, it is difficult to achieve secure m-commerce.

Software application risks are related to the capability to design and develop secure wireless applications using good software engineering and assurance methods. One of the most important issues in this context is the ability to develop software for sending and executing mobile codes and agents to wireless devices, by taking into account the need to reduce the communication load on extremely bandwidth-limited wireless links.

Security risks of WML (wireless markup language) are related to the lack of access control for WML scripts, meaning that the type of attacks that can be launched using WML script is limited only by the imagination of malicious script writers. More generally, such risks are based on a fundamental lack of a model for secure computation (Ghosh & Swaminatha, 2004).

FUTURE TRENDS

Despite the differences between wired and wireless networks, both networks are vulnerable to the same kinds of attacks. Nevertheless, wireless networks, as the core infrastructure which supports m-commerce, are basically more exposed to security attacks due to the type of communication channel used.

Future trends in this field consist of considering hardware, software, and data as elements to be protected against security attacks in mobile environments. In particular, m-commerce deals with payments over the Internet, electronically sending both services and information, storage of consumer information on resources available from the Internet, as well as all other issues related to online shopping. Much research tackles security problems related to the overall process of m-commerce. Some of these problems will likely be solved in the near future on some levels by modifications to existing protocols. In particular, problems related to the wireless application protocol (WAP) are considered highly critical. In this context, data encryption over communication channels constitutes the strongest perceived security issue in the system.

Finally, other research directions address the setup of a trustworthy relationship with customers in order to deliver the service in due time. This also includes security issues related to the lack of anonymity and the possibility for an attacker to gain access to the users' account number and their identities, particularly in the context of payments with credit cards.

CONCLUSION

This article analyzed some major security issues in mobile commerce. After a presentation of background, some security issues and challenges, then future and emerging trends in secure m-commerce were outlined. A set of privacy risks were also mentioned and their relationships to software development were outlined. In fact, the nature of the communication medium requires a degree of trust and cooperation between nodes in wireless networks. There is a certain risk that trust and cooperation are exploited by malicious entities to collect confidential information and disseminate false information. Other risks are related to the platform, the software application, and the WML scripts. The most significant risk to m-commerce systems is related to a malicious code which has the ability to undermine other security technologies as it resides on the device, thus having all of the owner's privileges. For all these reasons, encrypted communication protocols are necessary to provide confidentiality, authentication, integrity, non-repudiation, and authorization of services for m-commerce applications.

KEY TERMS

Authentication: Technique by which a process verifies that its communication partner is who it is supposed to be and is not an imposter. It makes sure that the parties engaging in business are who they claim to be. Integrity allows the system to verify whether modifications have occurred; it does not ensure that information was not altered.

Authorization: One or many access rights assigned to an entity by a certification authority (CA). Authorization does not make sure that messages received really do come from a given counterpart.

Confidentiality: Assures that the exchange of messages between parties over wireless access networks or global networks is not being monitored by non- authorized parties.

Electronic Commerce (E-Commerce): Set of transactions or processes which can be carried out between two parties based on data transmitted over communication networks. E-commerce relies upon users' interventions to initiate a transaction and select the main steps of the process.

Integrity: Allows the system to verify whether modifications have occurred; it does not make sure that information was not altered.

Mobile Commerce (M-Commerce): Refers to an ability to carry out wireless commercial transactions using mobile applications within mobile devices, such as mobile phones and personal digital assistants (PDAs). It is generally defined as the set of transactions or processes which can be carried out over a wireless mobile network.

Mobile Middleware: The functional layer of software provided by application developers to link their e-commerce applications to an OS and various mobile networks to allow their applications to bypass certain mobility issues.

Non-Repudiation: Makes sure that the business transactions the parties engaged in are legally binding.

Public Key Infrastructure (PKI): Security mechanism based on public key cryptography used to provide end-to-end security required for the information, services, and means of access. The core component of a PKI is the certification authority (CA). This authority is trusted by the end entities in its administrative domain and is responsible for the status of the certificate it issues.

INTRODUCTION

Access to general purpose information and communication technology (ICT) is not equally distributed on our planet: developed countries represent about 70% of all Internet users, while its percentage of Internet hosts has raised from 90% in 2000 to about 99% in 2002.

Things change dramatically if we look at mobile and wireless technology: developing countries already represent about 40% of mobile connections in 2000, with a foreseen growth rate that is faster in developing countries than in developed ones in the period 2000-2005 (mainly due to India and the People's Republic of China). This trend is driven by the new perspectives offered by mobile electronic technology applications that provide an alternative to poor telecommunication infrastructures still common in many developing countries. The technological evolution in wireless data communications is introducing a rich landscape of new services relying on three main technologies:

- proximity (or personal) area networks (PANs), composed of personal and wearable devices capable of automatically setting up transient communication environments (also known as *ad hoc* networks);
- wireless local area network technologies (WLANs); and
- a third generation of mobile telecommunications (3G), gradually replacing General Packet Radio Service (GPRS) and the related set of technologies collectively called "2.5 Generation" (2.5G).

PAN is a new technology bringing the "always connected" principle to the personal space. On the other hand, 3G systems and WLANs have coexisted for a while; what is new is their interconnection, aimed at decoupling terminals and applications from the access method. 3G mobile networks already provide video-capable bandwidth, global roaming for voice and data, and access to Internet-rich online content.

Thanks to their increasing integration, PANs, WLANs, and 3G networks will extend the user's connectivity in a complementary and hierarchical manner; in the fullness of time, they will provide all the functionalities of an *Integrated Services Multimedia Network* (ISMN), enabling a whole set of new business models and applications.

The fusion of these technologies will eventually result in an ultimate ubiquitous wireless system that will be operated from anywhere, including homes, business locations, vehicles, and even commercial aircrafts.

However, although wireless communications provide great flexibility and mobility, they often come at the expense of security. Indeed, wireless communications rely on open and public transmission media that expose new vulnerabilities in addition to the security threats found in wired networks. A number of specific open issues and even inherent dangers, some of which had been already identified and described in the early stages of wireless technology adoption, are yet to be solved (Howard, 2000). For instance, with wireless communications, important and vital information is often placed on a mobile device that is vulnerable to theft and loss. In addition, information is transmitted over the unprotected airwaves, and finally, 3G networks are getting smaller and more numerous, causing opportunities for hackers and other abusers to increase.

BACKGROUND

2G and 2.5G Mobile Authentication

GSM 2G systems introduced the *Subscriber Identity Module* (SIM) cards containing the user's identity and an authentication key (i.e., a shared secret key) supposed to last for the entire duration of the subscription. SIM-based authentication does not require any user action, other than entering the familiar four-digit *Personal Identification Number* (PIN) into the terminal. With GSM, a temporary user identity is allocated by the area operator where the user is located and is reassigned to another user as soon as the original requestor leaves the area. With the advent of 2.5G systems, enhanced by the *General Packet Radio Service* (GPRS), overlaying, certificates-based authentication became possible (Smith, 2002).

3G Authentication and On-the-Air Confidentiality

In the design of 3G systems like UMTS, a new security architecture was introduced (Blanchard, 2000). The new approach maintained backward compatibility with GSM, while trying to overcome some perceived weaknesses of 2G systems. Like in 2G systems, 3G systems identify users by means of the identity stored in the SIM. Differently from 2G systems, 3G authentication was designed with the following features:

- **Mutual Authentication:** Both the user and the network operator are identified in the authentication exchange.
- **Key Freshness:** Assurance that authentication information and keys are not being reused.
- **Integrity of Signaling:** Protection of service messages, for example, during the encryption algorithm negotiation.
- **Strong Encryption:** Strong cryptography, obtained via a combination of key length and algorithm design, is performed inside the core network rather than at the periphery.

Early Identity Management Systems

Starting from the late '80s, many examples of *Identity Management (IM)* systems have been proposed. In 1985, Chaum (1985) considered a device that helps the user with payment transactions and upholds the user's privacy. Clark (1993) proposed the *digital individual*, the individual's data shadow in the computer system which can be compared to user's identity.

Digital security and, more generally, digital identity management have grown fast in recent years, especially in mobile scenarios where personal communication and new computing devices will generate new security and integrity requirements for users and service information (Jendrike et al., 2002; Roussos & Patel, 2002).

MOBILE IDENTITY MANAGEMENT

Personal Identity Management in 3G Mobile Systems

Privacy and security issues related to mobile systems have been often described in terms of traditional security functionalities (e.g., access control, integrity, authentication, non repudiation, availability, and confidentiality). However, recent developments in ICT-based business models revealed the necessity to approach the concept of privacy and security more broadly, embracing not only the technical aspects, but also socioeconomic issues (Kagal, Parker, Chen, Joshi, & Finin, 2003). The ongoing transition from monolithic and localized systems, mainly based on single technology and weakly opened to integration, towards multi-application, multi-access, multi-player, distributed, and heterogeneous scenarios, is generating a context in which mobile applications and systems could play a strategic role. In other words, technology and business must be strongly Internet-worked with users' social dynamics, standards, policy, and regulation to create a digital identity management framework where digital identity is conceived as "an electronic representation of individuals' or organizations' sensitive information" (Damiani, De Capitani di Vimercati, & Samarati, 2003). Support offered by this framework is crucial for building and maintaining trust relationships in today's globally interconnected society because it:

- offers adequate security and availability;
- permits the presentation of a different subset of the users' identity depending on the ongoing and perceived application and communication context;
- guarantees that identity, personal data, and user profile (including location-based information) are safeguarded and no thefts will happen.

A *Digital Identity Management Framework* is realized by taking into consideration both the architecture of the framework, and those external elements that may influence an identity manager (e.g., regulations, standards, and so on). In particular, with respect to the framework's architecture, the following main elements can be recognized.

User

The service requestor associated with a profile. The digital identity management framework should let the user keep her desired level of privacy depending on the situation, presenting multiple user "appearances'' in different circumstances. In a mobile scenario, a portable user identity might include the following information:

- *Profile information* that consists of a number of static (e.g., date of birth, place of birth) and dynamic (e.g., technical skills and role) attributes.
- *Usage preferences* (e.g., browser settings) and other personal preferences that do not depend on the system (e.g., UK or U.S. English spelling).
- *Behavioral information* that may be derived by an history of previous interactions with the system.

Service Provider

The supplier of network services and applications.

Context

The particular situation in which users interact with the system. It includes the channel information (e.g., device and network features), the location information (e.g., cell, country, town), and time information.

Communication

This is based on well-known mechanisms to enable anonymity and confidentiality. With regard to anonymity, it is interesting to see that is possible for users to remain anonymous even in a world of SIM-based authentication. The authentication step is not repeated when roaming, because a user holds a reusable, temporary identification provided by the local mobile network. At the network level, therefore, mobile users have no fixed device address and, in principle, are identified only by the location.

Device

The terminal that provides the physical layer services (e.g., a radio interface) used to communicate data and to interact with context and service providers. Moreover, the device becomes the physical place where the user profile, context, and communication could be revealed and analyzed. For this reason, the terminal must be able to change the information it discloses much in the same way as the user.

The relevant external aspect that may most influence the Digital Identity Management Framework is as follows.

Shared Principles

Mobile privacy and identity management are realized to implement the following main principles:

- **Confidentiality:** Information must be accessible only by the intended receiver. Confidentiality can be split into three main elements: confidentiality of the message content, protection of location information, and support for sender/receiver anonymity.
- **Integrity:** Transmission of information is carried out by means of cryptographical mechanisms to identify and detect tampered data.
- **Notice:** An alert service must be available to draw the user's attention to situations in which privacy and security could be affected. Notice mechanisms should be manual whenever automatic solutions could compromise the user's security.
- **Data collection:** Users should be able to actively manage their own data, deciding whether and which identity is presented to devices and applications (Ceravolo, 2003). Data collection must be inspired to the principle of data minimization, by which data should only be collected for a specific purpose.

Wireless Heterogeneous Environments: Toward Ubiquitous Networking

One of the most challenging goals in the field of mobile services is the integration of different wireless technologies, like 2.5 or 3G cellular networks and WiFi (IEEE 802.11b and 802.11g) into the more general landscape of *ubiquitous networking*. Ubiquitous networking is aimed at addressing the users' need of seamlessly roaming from one connection mode to the other without impairing their ongoing operations. Accordingly, multimode cards (e.g., LAN-WLAN-GPRS cards) have been launched on the market and are becoming increasingly affordable. In particular, the advent of 3G is likely to make those multimode cards rapidly evolve to the LAN-WLAN-3G setting thus transforming portable devices—cellular phones, laptops, and PDAs—in *multimode devices*.

However, to foster effective mobility and ubiquitous computing through networks built on different wireless technologies, many fundamental issues need to be taken into consideration. An important one is the integration at link level between WiFi and GPRS/3G, which could result in a uniform network level. Realizing a uniform network layer between WiFi and GPRS/3G, in turn, may facilitate *transparent mobility*, that is, the possibility for users to automatically switch from one wireless network to another (possibly based on a different technology) without any detriment to ongoing Internet transactions or application service provision. There are many high-value mobile application services that will greatly benefit from transparent mobility such as telemedicine, Intelligent Transport Systems (ITS), and mobile Geographical Information Systems (mGIS).

More precisely, transparent mobility is characterized by successfully migrating live TCP connections during the handoffs through different wireless technologies (WLAN à GPRS/3G handoff and GPRS/3G à WLAN handoff). To do this, not only is a seamless inter-network handoff mechanism sufficient, but also the connectivity (as devices keep moving across environments while still minimizing any disruption to ongoing flows during switchovers) is another important aspect.

A mechanism that enables this has to exhibit a low handoff latency, incur little or no data loss (even in highly mobile environments), scale to large inter-networks, adapt to different environments, and act as a conjuncture between heterogeneous environments and technologies without compromising on key issues related to security reliability (Vidales, Patanapongpibul, & Chakravorty, 2003). For all these reasons, transparent mobility is indeed one of the most challenging goals of ubiquitous computing in wireless heterogeneous environments.

Network technologies that are actively used for such systems are: *Mobile IPv4* (MIPv4) and *Mobile IPv6* (MIPv6) (Chakravorty, Vidales, Subramanian, Pratt, & Crowcroft, 2003). MIPv4 is the network technology traditionally used to foster seamless roaming for ubiquitous computing systems, mainly due to its compatibility with the wired IP-based network infrastructure. Nevertheless, MIPv4 limitations have forced the development of overly complex systems and protocols. MIPv6 promises to overcome some of MIPv4 limitations and improve security, although it has other disadvantages in high mobility scenarios (Chakravorty et al., 2003; Perkins, 1996). An IETF working group, called *Seamoby* (Kempf, 2002), has been formed aiming to resolve complex interactions of parameters and protocols needed for seamless handoffs and context transfers between nodes in an IP access network.

Multihop Hotspots

Hotspot providers in public areas represent key components of a heterogeneous wireless infrastructure for mobile users, which could be used to access WLAN services while moving. *Multihop hotspots*, in particular, are hotspots through which users could roam seamlessly. Considering heterogeneous environments, users could hop through hotspots that are either physically contiguous, thus directly switching from one hotspot to another, or through a sequence of multimode handoffs between hotspots and GPRS/3G cells (Balachandran, Voelker, & Bahl, 2003).

With respect to security, hotspots still have significant open issues. One is *authentication* that is currently implemented with different and incompatible techniques by commercial WiFi networks. For instance, since hotspots are often under the control of different providers, users will have to repeat the authentication procedure (possibly different for each hotspot) at each hotspot location. Also, some commercial hotspot providers offer access to users through preestablished accounts, while others offer scratch-off cards containing a one-time login and password. A uniform and shared authentication infrastructure is fundamental for effective multihop mobility since highly mobile users cannot be required to cope with different authentication schemes, mechanisms, and configurations at each handoff. Clearly, the goal of providing fast and seamless authentication, while simultaneously ensuring user accountability, raises several research problems that are today still unsolved:

- **Ease of Access:** Single-Sign-On (SSO) features encompassing multihop hotspots are needed to support transparent mobility and reduce the latency.
- **Identity Management:** The mobile identity a user presents to each network provider could change according to context-related information such as provider reputation, QoS, location, or another contextual attribute.
- **Third-Party Authenticators:** Should authentication be delegated to dedicated third parties offering such a service for the whole multihop infrastructure?

Mobile User Recovery

VanderMeer, Dutta, Ramamritham, and Navathe (2003) addressed the problem of recovering Internet transactions initiated by mobile users. The issue is new and relevant since it presents many differences with respect to classical database transaction recovery techniques. Also, it appears extremely important in the context we have considered, since there is not only the case of recovery after a network failure, but there is the peculiar situation of recovery user activity after a handoff. This aspect is an additional novel issue to the most general problem of mobile user recovery.

This issue also has significant links with security and privacy since mobile user transactions and mechanisms for recovery could carry security risk and be targets of network attacks and subversion attempts. If network attacks would eventually succeed, it will be possible for an intruder, for example, to subvert the recovery mechanism and then recover transactions of other users, possibly gaining their privileges. By attacking a recovery mechanism, it could also be possible to access transactions' state information that still could let intruders impersonate users or gather sensitive information. Denial-of-service towards recovery systems is another threat that might severely impair the benefits of the infrastructure for ubiquitous computing and transparent mobility.

Security research in this area is still at the beginning since even operational features, like mobile user recovery, are in their initial stages. Despite this, the issue looks extremely important for the future evolution of ubiquitous computing and transparent mobility (VanderMeer et al., 2003). Several important issues that may affect security arise:

- **Secure Storage and Access to Logs and Recovery Procedures:** There could be different choices, from storing logs and procedures locally to the device, storing them at network gateways or at specialized recovery hosts. Indeed, a support to recovery features from the network infrastructure is needed. This introduces security issues related to trust relationships and authentication, with third parties or networked components in charge of user sessions recovery.
- **Trustworthy Generation, Management, and Usage of Users, Logs and State Information:** State information must be protected from tampering and disclosure since network components in charge of generating and storing state information are possible points of attacks.

FUTURE TRENDS

Ubiquitous computing in wireless heterogeneous environments and the ever-increasing interoperability between heterogeneous technologies are some of the most relevant trends in the field of mobile systems. However, such systems need operational features and security requirements that still have to be provided (Vidales et al., 2003). For instance, two interesting and fundamental open issues are the following:

- **Link-Switch Decision Rule-Base:** Current schemes that regulate handoffs operate based on link layer information, such as signal strength. However, this could be insufficient to assist the handoff process in heterogeneous environments. Signal quality, costs, and security requirements might be other parameters that need to be evaluated to decide the handoff.
- **Context-Awareness:** A mobile device context involves aspects such as physical context variables (e.g., device location, movement direction, velocity, and so on), application characteristics, and of course, user-based preferences. Context-awareness is necessary to take informed decisions about switching to a different network and provider.

CONCLUSION

The amount of mobile computing is expected to increase dramatically in the near future. As the users' demands increase with the offered services of mobile communication systems, the main expectation on such systems will be that they provide access to any service, anywhere, at anytime. Indeed, in today's highly connected and highly mobile environments, the secure transmission of information is imperative for every enterprise, and will grow in significance as mobile devices, networks, and applications continue to advance. However, the promise of mobile computing technologies further increases privacy and security concerns. In this article we have discussed the need for privacy and security in mobile systems and have presented technological trends that highlight that this issue is of growing concern.

KEY TERMS

3G: The third generation of mobile communications technology.

Digital Identity Management System: A system related to the definition and lifecycle of digital identities and profiles as well as environments for exchanging and validating this information.

Multihop Hotspots: Hotspots through which users could roam seamlessly.

Privacy: Socially defined ability of an individual to determine whether, when, and to whom personal information is to be released.

Security: The combination of integrity, availability, and secrecy.

Ubiquitous Computing: A vision where computers are made available throughout the physical environment, but effectively invisible to the users.

Wireless Local Area Network: Local area network that uses radio waves as its carrier.

Semantics for E-Commerce Applications

Jorge Cardoso
University of Madeira, Portugal

INTRODUCTION

A few years ago, e-commerce applications were mainly focused on handling transactions and managing catalogs. Applications automated only a small portion of the electronic transaction process, for example: taking orders, scheduling shipments, and providing customer service. E-commerce was held back by closed markets that could not use distributed services, due to the use of incompatible communication protocols.

Recently, business needs are evolving beyond transaction support to include requirements for the interoperability and integration of heterogeneous, autonomous, and distributed service. Enabling technologies and business-centered design methodologies have addressed the shortcomings of contemporary e-commerce applications. New technological development such as Web services, Web processes, and semantics have allowed the creation of a new bread of e-commerce applications which can orchestrate cross-organizational and distributed services.

Web services and processes refer to a set of technologies that can universally standardize the communication of applications in order to connect systems, services, business partners, and customers cost-effectively through the World Wide Web. Semantics provide an agreed understanding of information between and among Web services encouraging the development of interoperable systems that can help create and support new collections of services to better meet the demands and expectations of customers.

In this article, we present seven reasons why semantics should be an integral part of Web services and Web processes technology managing e-commerce applications.

BACKGROUND

As organizations are increasingly faced with the challenge of managing e-commerce applications, important technological development such as Web services, Web processes, and semantics are emerging.

The main idea of Web services is to encapsulate an organization's functionality or service within an appropriate interface and advertise it in the Web using the Web service definition language (WSDL) (Christensen, Curbera, Meredith, & Weerawarana, 2001). Web services are a very general model for building distributed applications which can be used to link together computer programs from different suppliers and technologies. The principles behind Web services are very simple:

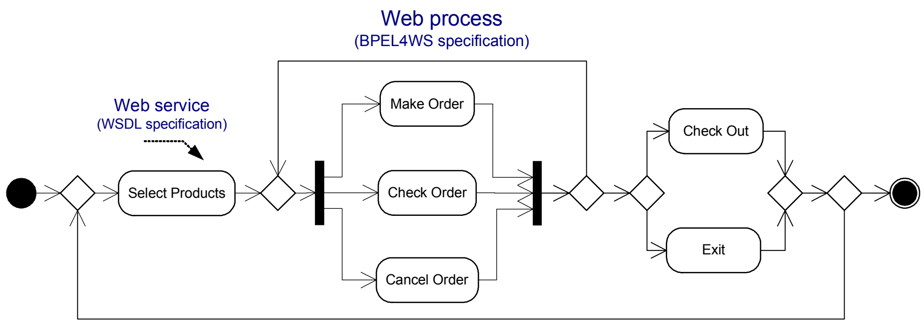
- A provider defines a standardized format for requests and responses for its Web services.
- A computer makes a request for the Web services across the network.
- The Web services perform some action and send the response back.

While in some cases Web services may be utilized in an isolated form, it is natural to expect that Web services will be integrated as part of Web processes. A Web process is an abstraction of a business process. It comprises a number of logic steps (i.e., Web services), dependencies among services, process flow, routing rules, and logic to control and coordinate services and partners. The most prominent solution to describe Web processes is BPEL4WS (BPEL4WS, 2003). BPEL4WS (Process Execution Language for Web Services) is a specification that enables a business process to be performed using a number of Web services, possibly provided by several companies. Figure 1 illustrates how a Web process can model an e-commerce application.

WSDL and BPEL4WS specifications are shallow and focus only on syntactical descriptions of Web services and Web processes. As a consequence, these descriptions are inadequate for an automated discovery or composition of Web services. Much richer and deeper machine-processable descriptions are required.

Several researchers have pointed out that Web services should be semantically enabled (Cardoso & Sheth, 2003; Fensel, Bussler, & Maedche, 2002; Martin et al., 2004). Semantics are indispensable to develop distributed e-commerce applications over the Web due to its heterogeneity, autonomy, and distribution. Semantics articulate a well-defined set of common data elements or vocabulary allowing a rich description of Web services and Web processes which can be used by computers for an automatic or semi-automatic processing and management of e-commerce applications.

Figure 1. Example of a Web process modeling an e-commerce application



THE IMPORTANCE OF SEMANTICS FOR E-COMMERCE APPLICATIONS

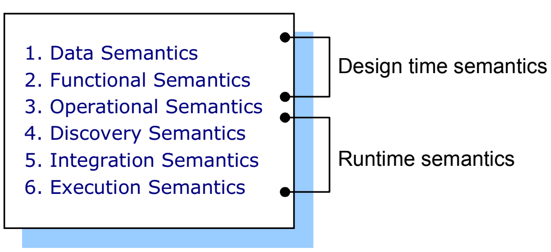
Semantic Web services will allow the automatic search (Klein & Bernstein, 2001), discovery (Verma et al., 2004), composition (Cardoso & Sheth, 2003), integration, orchestration (WSMX, 2004), and execution of inter-organizational services, making the Internet become a global common platform where organizations and individuals communicate among each other to carry out various e-commerce activities and to provide value-added services.

The idea of the "Semantic Web" (Berners-Lee, Hendler, & Lassila, 2001) catches on and researchers, as well as companies, have already realized the benefits of this great vision. Major companies and others are interested in creating industry-wide open e-business specifications for Semantic Web services and processes.

Different types of semantics can be used to enhance e-commerce applications. Semantics increase the description of capabilities, requirements, effects, and execution of Web services using ontologies (Gandon, 2002). E-commerce applications can benefit from six different kinds of semantics as illustrated in Figure 2.

These different types of semantics are discussed in the following sections.

Figure 2. Different types of semantics for e-commerce applications



Data Semantics

As e-commerce applications interconnect enterprises, Web services need to become available across systems, departments, and organizations. When organizations try to access and use local and remote Web services, they realize that their interfaces refer to incompatible data schema and cannot be called without a translation effort. In general, there is no common understanding which allows the data schema present in Web services' interfaces to be systematically manipulated.

Despite the fact that Web services use the same standardized technology, this incompatibility arises from semantic differences of data schema. In an e-commerce application, all the Web services take a set of data inputs and produce a set of data outputs represented in a WSDL specification file. However, the specification provides only syntactic and structural details of the input/output data. Each data schema is set up with its own structure and vocabulary. For example, a Web service may contain an output structure called "client" which includes the name, address, city, country, and telephone of a client; another Web service may have an input structure called "customer" and subdivides it into first name, last name, address, and tel. In such a scenario, how can the data output of the first Web service be transferred to the input of the second Web service? While the two structures do not match syntactically, they match semantically. To allow Web services to exchange data at the semantic level, the semantics of the input/output data has to be taken into account. Hence, if the data involved in Web service operations is annotated using an ontology (Patil, Oundhakar, Sheth, & Verma, 2004), the added semantics can be used in matching the semantics of the input/output of Web services when exchanging data, which was not possible when considering only syntactic information.

Functional Semantics

The goal of specifying the functionality of a service has a long tradition in computer science and includes work in the fields of program methodology, formal programming language semantics, and software engineering. The problems are complex, but the potential payoff is enormous.

Web service specifications are based on the WSDL standard that only defines syntactic characteristics. A WSDL document contains a set of definitions describing Web services using input and output messages, and operations. The signature of an operation provides only the syntactic details of the input data, output data, and operation's name.

Technological solutions to construct e-commerce applications based on Web services' operations signatures are not sufficient since services' functionality cannot be precisely expressed. Two services can have an operation with the same signature even if they perform entirely different functions. For example, a Web service called "add" that performs the addition of two integers taking the numbers as input and producing the sum as output (i.e., *add(x,y)=x+y*) will have the same signature of another service with the same name that performs the logarithmic addition of two numbers that are provided as input (i.e., *add(x,y)=log x+ log y*).

As a step towards representing the functionality of a service, Web services can be annotated with functional semantics. This can be achieved by having a functional ontology in which each concept/class represents a well-defined functionality.

Operational Semantics

When Web processes model e-commerce applications, suppliers, and customers define a binding agreement between the two parties, specifying operational constraints, also known as quality of service (QoS) requirements, such as goods to be delivered, deadlines, and cost of services or products.

The autonomy of Web services does not allow for business analysts to identify their operational metrics. When developing e-commerce applications it is indispensable to analyze and compute the QoS of the services and processes available to customers (Cardoso, Miller, Sheth, Arnold, & Kochut, 2004). This allows organizations to translate their vision into their business processes more efficiently, since Web processes can be designed according to QoS metrics. The management of QoS directly impacts the success of organizations participating in e-commerce applications. A good management of quality leads to the creation of quality products and services, which in turn fulfill customer expectations and satisfaction. To achieve these objectives, operational metrics need to be described using operational semantics which represent the QoS model of services and processes.

Operational semantics (Cardoso, 2002) are very important, not only because they allow to specify the QoS of services, but also because they allow the computation of the QoS of Web processes that orchestrate Web services that use, for example, different unit systems. A Web process may orchestrate two Web services, one that uses the English metric system and the other that uses the International System of Units. In order to compute meaningful values for the QoS of the overall process, a conversion of units need to be done. For example, a conversion from miles to kilometers. Operational semantics can make this conversion task automatic and very simple.

E-commerce applications that have a worldwide spread inherently need to use operational semantics to resolve the differences that exist among operational measurement adopted and followed by different countries. Two ontologies can be devised to describe operational characteristics: *Domain Independent* QoS and *Domain Specific* QoS ontologies. The first ontology, accounts for the evidence that Web services in different domains can have different quality aspects. The second ontology is to be applied to services in all domains irrespective of their functionality or specialty.

Discovery Semantics

After a Web service is developed and annotated with data, functional, and operational semantics, it has to be advertised to enable discovery. The Universal Description, Discovery, and Integration (UDDI) (UDDI, 2002) registry is a system to open doors for the success of service oriented computing.

UDDI registries enable global e-commerce by creating an organized approach to categorizing, storing, and retrieving information about the kind of services provided and who provides them. One of the major benefits of being listed in a public UDDI registry is that it provides equal exposure for all organizations. A large international organizations and a small locally owned company are listed in the same way.

Currently, UDDI only supports keyword (string) matching, which is considered the simplest type of syntactic matching. Therefore, the present discovery supported by UDDI is inefficient as services retrieved may be inadequate due to low precision (many services not wanted) and low recall (missed services that need to be considered). Effectively discovering relevant Web services in a scalable way is what is required to accelerate the adoption of Web services. To meet this challenge, UDDI registries need to support not only syntactic matching, but also semantic matching (Verma et al., 2004). Semantic matching is the process of matching requests to Web services on the basis of the requested Web services functionality (functional semantics). Here again, Web services may not match syntactically but match semantically.

Integration Semantics

Integration is a key issue in e-commerce because more and more companies are creating business-to-customer (B2C) and business-to-business (B2B) links to better manage their value chain. Automating inter-organizational Web processes across supply chains presents significant challenges (Stohr & Zhao, 2001). In order for these B2C and B2B links to be successful, Web services from multiple companies need to be integrated to interoperate seamlessly.

Compared to traditional distributed applications, Web services are highly autonomous and heterogeneous. Therefore, sophisticated methods are indispensable to support the integration of Web services. Here again, one possible solution is to explore the use of semantics to enhance the interoperability among Web services.

To achieve interoperability of e-commerce applications, it is necessary to address the problem of semantic integration—the identification of semantically similar objects that belong to different systems and the resolution of their schematic differences (Kashyap & Sheth, 1996). When Web services are put together, their interfaces (inputs and outputs) need to interoperate (Cardoso & Sheth, 2003); therefore, structural and semantic heterogeneity needs to be resolved. Structural heterogeneity exists because Web services use different data structures to define the parameters of their interfaces. Semantic conflicts occur when a Web service output connected to another service input does not use the same interpretation of the information being transferred. The general approach to semantic integration has been to map the local terms onto a shared ontology. Even though a shared ontology ensures total integration, constructing such an ontology has been costly (Rodríguez & Egenhofer, 2002). Recently however, significant progress is being made to deal with the issues of ontology evolution/management (Gandon, 2002) and multi-ontology environments (Fonseca, 2001), leading to increased momentum in developing and applying semantics to enable the integration of different systems.

Execution Semantics

Execution semantics of a Web service (WSMX, 2004) encompasses the ideas of message sequence, conversation pattern of Web service execution, flow of actions, preconditions, and effects of Web service invocation. Some of these details may not be meant for sharing and some may be, depending on the organization and the application that is exposed as a Web service. In any case, the execution semantics of these services are not the same for all services and hence before executing or invoking a service, the execution semantics or requirements of the service should be verified.

Some of the issues and solutions with regard to execution semantics are inherited from traditional workflow technologies (Cardoso, 2005). However, the globalization of e-commerce, Web services, and processes result in additional issues. In e-commerce, using execution semantics can help in dynamically finding partners that will match not only the functional requirements, but also the operational requirements. Also, a proper model for execution semantics will help in coordinating activities in e-commerce applications that involve multiple parties.

FUTURE TRENDS

According to TopQuadrant, a consulting firm that specializes in Semantic Web technologies, the market for semantic technologies will grow at an annual growth rate of between 60% and 70% until 2010, when it will grow from its current size of U.S. $2 billion to $63 billion. Existing applications that will add Semantic Web capabilities include Adobe's Extensible Metadata Platform and Oracle's database.

Semantic software is being experimentally used by banks to help them to comply with the U.S. government's Patriot Act (the Patriot Act requires banks to track and account for the customers with whom they do transactions), by a European police force to follow crime patterns, and by a telephone service provider to create applications that provides information about pay-per-view movies (Lee, 2005).

In addition to investment banks, the Metropolitan Life Insurance Company, the U.S. Department of Defense, and the Tennessee Valley Authority have also used semantic software to integrate enterprise data, to comply with federal regulations.

For Web services and Web processes to become a platform for semantic service oriented computing to fully support e-commerce application, academic and industrial researchers will need to create ontologies, terminologies, technologies, and products that enable sophisticated solutions for the annotation, advertisement, discovery, selection, composition, and execution of Web services.

Three major projects will provide, in the near term, several advances in the area of Semantic Web processes. The Semantic Web Services Initiative (SWSI), an initiative of academic and industrial researchers, has been composed to create an infrastructure that combines the Semantic Web and Web services to enable the automation in all aspects of Web services. In addition, to providing further evolution of the ontology language for Web services, OWL-S (OWL-S, 2004), SWSI will also be a forum for working towards convergence of OWL-S with other research efforts in this area.

The METEOR-S (LSDIS, 2004) (METEOR for Semantic Web services) project is focused on the usage of semantics for the complete lifecycle of Semantic Web processes and targets research on four important areas, namely; annotation, discovery, composition, and execution of Web services.

Finally, DERI (DERI, 2004) is currently working on a project titled Semantic Web-Enabled Web Services (SWWS). Important objectives of the SWWS initiative include: providing a richer framework for Web service description and discovery, as well as, providing scalable Web service mediation middleware based on semantic data, process ontologies, and semantic interoperation.

CONCLUSION

E-commerce has permanently changed the manner trading activities are carried out. Consumers can now acquire services and products from a diversity of Web sites. With the spread of the Web, a new technology has surfaced for the development of e-commerce application: Semantic Web processes.

This new trend in the global economy requires the ability to deploy e-commerce applications based on Web processes from the aggregation and orchestration of distributed Web services. Several researchers agree that it is essential for Web services to be semantically enabled in order to efficiently develop and execute Web processes.

In this chapter we have presented a set of challenges that the emergence of e-commerce and Semantic Web processes has brought to organizations. Designing Semantic Web processes entails research in two areas: Web services and the Semantic Web. We have presented how applying semantics to each of the steps in the Web process lifecycle can help address critical issues such as Web services annotation, discovery, selection, integration and execution.

KEY TERMS

BPEL4WS: BPEL4WS stands for Business Process Execution Language for Web Services. It provides a language for the formal specification of business processes. It extends the Web services model and enables it to support business transactions.

Business Process: A set of one or more linked activities which collectively realize a business objective or goal, normally within the context of an organizational structure.

HTTP: The underlying protocol used by the World Wide Web. HTTP defines how messages are formatted and transmitted between Web servers and browsers.

Ontology: An ontology provides the basis of representing, acquiring, and utilizing knowledge. Ontologies consist of entities, attributes, interrelationships between entities, domain vocabulary, and factual knowledge.

Semantics: The purpose of semantics is to assign a meaning to syntactical elements. For Web services, it is the agreed upon meaning of data, functions, QoS, etc., exchanged between two or more services.

UDDI: UDDI (Universal Description, Discovery, and Integration) is a registry for businesses to list themselves on the Internet. Its goal is to facilitate online transactions by enabling companies to find one another on the Web and make their systems interoperable for e-commerce. UDDI is often compared to a telephone book's white, yellow, and green pages.

Web Process: A Web process describes the logic to control and coordinate Web services participating in a process flow to carry out a specific goal. It directly addresses business process challenges such as control flow, data flow between Web services, long-running nested units of work, faults and compensation.

Web Service: A Web service describes a standardized way of integrating Web-based applications using open standards. A Web service is defined as a remotely callable function or procedure which communicates via the HTTP (HyperText Transfer Protocol) using standardized protocols.

WSDL: WSDL stands for Web Services Description Language. It is written in XML and it is used to describe and locate Web services.

Semi-Automated Seeding of Personal Privacy Policies in E-Services

George Yee
National Research Council Canada, Canada

Larry Korba
National Research Council Canada, Canada

INTRODUCTION

The rapid growth of the Internet has been accompanied by a proliferation of e-services targeting consumers. E-services are available for banking, shopping, learning, government online, and healthcare. However, each of these services requires a consumer's personally identifiable information (PII) in one form or another. This leads to concerns over privacy.

In order for e-services to be successful, privacy must be protected (Ackerman, Cranor, & Reagle, 1999). An effective and flexible way of handling privacy is management via privacy policies. In this approach, a consumer of an e-service has a personal privacy policy that describes what private information the consumer is willing to give up to the e-service, with which parties the provider of the e-service may share the private information, and how long the private information may be kept by the provider. The provider likewise has a provider privacy policy describing similar privacy constraints as in the consumer's policy, but from the viewpoint of the provider, (i.e., the nature of the private information and the disclosure/retention requirements that are needed by the e-service). Before the consumer engages the e-service, the provider's privacy policy must match with the consumer's privacy policy. In this way, the consumer's privacy is protected, assuming that the provider complies with the consumer's privacy policy. Note that policy compliance is outside the scope of this work but see Yee and Korba (July, 2004).

Initial attempts at conserving consumer privacy for e-services over the last few years have focused on the use of Web site privacy policies that state the privacy rules or preferences of the Web site or service provider. Some of these policies are merely statements in plain English and it is up to the consumer to read it. This has the drawback that very few consumers take the trouble to read it. Even when they do take the time to look at it, online privacy policies have been far too complicated for consumers to understand and suffer from other deficiencies (Lichtenstein, Swatman, & Babu, 2003; Jensen & Potts, 2004). Still other privacy policies are specified using P3P (W3C) that allows a consumer's browser to automatically check the privacy policy via a browser plug-in. This, of course, is better than plain English policies but a major drawback is that it is a "take-it-or-leave-it" approach. There is no recourse for the consumer who has a conflict with the Web site's P3P policy, except to try another Web site. In this case, we have advocated a negotiations approach to resolve the conflict (Yee & Korba, Jan., May, 2003). However, this requires a machine-processable personal privacy policy for the consumer.
