Preface

Since the early 1990s, the world has observed a technological revolution of similar magnitude to the industrial revolution of the early 20th century. This modern revolution has provided organizations and societies worldwide with an innovative medium of communication entirely new to humankind. Researchers made the discovery that through the use of integrated computer-based telecommunication networks, information of all types and forms could be disseminated throughout the world, utilizing existing computer and communication technologies. As a result, to supplement the telephone, fax, and mail, a new medium of communication was born and is known today as the Internet.

This phenomena actually grew out of a project knows as ARPANET, funded by the U.S. Department of Defense. The primary objective of this project was to study how researchers could share research data in the case of nuclear attack. The project was later transferred to the National Science Foundation (NSF) and became known as the "Internet," initially to be used by university scholars and researchers. Subsequently, the invention of the Internet led itself to the World Wide Web (WWW), fueled by the technological advancement of computer and communication technologies combining to create a new set of technologies, better know today as Web-enabled technologies or e-technologies.

During the early days of the WWW, this medium was primarily utilized by both public and private organizations to disseminate information about the organizations' products, services, and news. As a result, organizations of all types and sizes worldwide began establishing their presence on the WWW by having their own Web sites filled with all kinds of information about their organizations. Consequently, many organizations began expanding their presence on the WWW by developing new technologies and applications to allow customers and suppliers to conduct business transactions. They discovered that through the use of this technology, customers could do business with the organization electronically, and this led to the birth of "electronic commerce," sometimes known as "e-commerce" or the abbreviated term of "EC." Then came the establishment of a new breed of e-commerce-based businesses, such as Amazon.com and eBay.com, as part of the more than one trillion dollars-a-year industry worldwide.

The innovations achieved through the use of EC during the early days of Web-enabled technologies led to the discovery of "electronic government," otherwise known as "e-government" or "eGov," where governmental organizations began using these technologies to develop various applications to serve and govern their constituencies in a fashion that was not possible a decade earlier. Today, e-government applications have allowed many government-based agencies around the globe to reach and serve their citizens in a much more timely, efficient and less costly manner.

As telecommunication technologies further advanced, they introduced new mobile technologies, also known as wireless technologies, for the need of individuals and organizations to conduct electronic transactions and communications through the use of Web-enabled technologies known as "mobile commerce," "m-commerce," or "MC." In recent years, consumers and organizations have benefited from many of the features of m-commerce technologies through numerous applications, such as conducting financial transactions, supply chain operations, advertising, portal access points, information and news services, entertainment and games, and education and training. As individuals and organizations become more mobile and virtual, it is expected that the number of m-commerce-related applications will increase significantly.

In less than two decades, Web-enabled technologies have provided organizations all over the world with tremendous new and innovative opportunities to expand their business horizons in ways that, until a decade ago, were unimaginable. Incredible cost savings have come from conducting operations electronically. Furthermore, these technologies have paved the way for the development of many other indirect applications and uses, such as the creation of virtual communities and enterprises, e-collaboration, distance learning, Web portals, and Web services. In addition, however, Web-enabled technologies have not been free of criticism and problematic issues, ranging from security, privacy, fraud, digital divide, cyber crime and terrorisms, and system incompatibilities.

To better understand the components, applications, and managerial and organizational issues of e-technologies for students, faculty, researchers, managers, public administrators and policy makers, editing an encyclopedia became an important and necessary goal. Therefore, the primary objective of the *Encyclopedia of E-Commerce, E-Government, and M-Commerce* is to provide the most inclusive and up-to-date coverage of e-technologies by compiling quality contributions that highlight current concepts, trends, challenges, applications, and experiences related to e-commerce, e-government, and mobile commerce technologies.

To provide the most comprehensive, in-depth, and up-to-date coverage of issues, technologies, and applications of e-commerce, e-government, and m-commerce, the many essential and important topics and aspects of these technologies were selected for this encyclopedia project, including: E-Collaboration Technologies and Applications, E-Commerce Technologies and Applications, E-Commerce Management and Social Issues, E-Government Technologies and Applications, E-Government Management and Social Issues, E-Healthcare Technologies and Applications, E-learning Technologies and Applications, E-Technologies Security and Privacy, Mobile Commerce Technologies and Applications, Mobile Commerce Management and Social Issues, Virtual Communities and Enterprises, Web Portals and Services.

To present applied research and coverage, submissions for this encyclopedia were grouped into three categories:

- **Concepts, Trends, and Challenges:** Entries under this category deal with the fundamental and emerging concepts related to e-commerce, e-government, and mobile commerce. Entries in this category provide coverage of current and emerging trends, challenges, problems, and solutions related to these technologies. Furthermore, the entries in this category include 7-10 technical and managerial key terms with full definitions.
- **Applications of E-Technologies:** Entries under this category describe different applications of e-commerce, e-government, and mobile commerce in business or organizational settings. These entries describe how different e-technology-based applications have been developed in support of different business or organizational functions or activities.
- **Dot-Com Experiences:** Entries under this category illustrate various dot-com businesses that either failed or succeeded. These entries describe how the dot-com entity started (history), what kind of services/products it offered (purpose), how it was directed (management), how it failed/succeeded (failure/success factor), and what lessons may be learned from these experiences.

Researchers from all over the world were invited to submit proposals describing their proposed coverage and the contribution of such coverage to the overall theme of the *Encyclopedia of E-Commerce, E-Government, and Mobile Commerce.* All proposals were carefully reviewed by the editor-in-chief in light of their suitability, researchers' knowledge on the proposed topic, and the quality of the submitted proposal. Authors of accepted proposals were notified regarding the acceptance of their proposals and were provided with a copy of the "Manuscript Organization and Submission Guidelines" for the authors to use in preparing their full submissions. Upon the receipt of full entry submissions, each submission was forwarded to at least three expert, external reviewers for a double-blind, peer review. In many cases, the review process was repeated for those manuscripts that were recommended for revision by reviewers. Only submissions with strong and favorable reviews were chosen as entries for the *Encyclopedia of E-Commerce, E-Government, and Mobile Commerce*.

Subsequently, the two-volume *Encyclopedia of E-Commerce, E-Government, and Mobile Commerce* includes more than 200 entries highlighting current concepts, applications, technologies, opportunities, issues, challenges, solutions, and future trends. More than 1,400 technical and managerial key terms with 5-50-word definitions compliment these entries and provide the readers of this comprehensive reference publication with the basic definition and description of these key terms. Furthermore, a total of more than 475 tables and figures contribute to the comprehensiveness of this publication. In addition, this two-volume encyclopedia offers a thorough reference section with over 4,400 additional research sources for the further investigations of scholars, researchers, educators, students, managers, and administrators.

To provide the best entry organization to assist readers in navigating and identifying entries in this publication, this two-volume encyclopedia is organized by listing all entries in alphabetical order by title throughout the publication, and by including the entries' titles and authors' names and affiliations in a regular "Table of Contents" in the beginning of each volume. All entries are also organized under their prospective topic area category in a second "Table of Contents by Topic," allowing readers to identify entries related to their research areas and interests. In addition, the first page of each entry consists of a labels describing the submission category. Furthermore, the first comprehensive and easy-to-navigate index of this encyclopedia assists readers in locating full descriptions and definitions of all technical and managerial terms included, and the second comprehensive index helps readers in identifying any key terms as identified by the authors.

To compliment the print version of the *Encyclopedia of E-Commerce, E-Government, and Mobile Commerce,* this publication will also be available in an online version with very easy-to-use search capabilities. As with all reference titles of Idea Group Reference, a complimentary unlimited access to the online version of this publication is provided to libraries that purchase a copy of the print version. However, for those libraries that are not interested in purchasing the print version, online subscriptions are available for a reduced price. Access to the online version will allow students, faculty, researchers, corporate managers, and public administrators to also have access to recently added entries to the first edition of this encyclopedia, allowing users to keep up with the latest coverage of emerging technologies and issues related to the coverage if this encyclopedia.

The world has witnessed fundamental change in the way people worldwide communicate with each other and share information. Alexander Graham Bell's invention of the telephone introduced a completely new means for people to communicate with each other. However, the introduction of the Internet, followed by subsequent, innovative e-technologies, has brought a completely new kind of revolution in the areas of communication and information dissemination. E-commerce, e-government, and mobile commerce technologies, in addition to a wide range of applications, have allowed the world to convert into electronic virtual communities where members may communicate, share information and knowledge, do business, obtain services, and conduct educational programs and even religious activities in ways totally unthinkable several years ago. Many researchers claim that e-technology innovations the world currently witnesses are just the beginning of a far more expansive digital revolution ahead of us, and that future generations will be the beneficiaries of these emerging technologies. It is my heartfelt hope that this encyclopedia, with its comprehensive coverage of e-technologies, will assist scholars, researchers, educators, students, managers, and administrators in learning about the current status of these technologies and also facilitate the discovery of future innovative technologies.

Acknowledgments

Editing an important, comprehensive publication of this magnitude requires significant assistance and helpful contributions from many people, both in terms of content and editing. In the area of content, I would like to extend my earnest thanks to those colleagues from all over the world who contributed their quality work to this encyclopedia and patiently worked with me and many demanding reviewers to improve the overall quality of their contribution. My sincere gratitude and admiration is also extended to the reviewers who have made significant contributions toward the overall quality of this publication. Special thanks also go to the members of the Editorial Advisory Board of this publication, including Profs. Annie Becker, George Ditsa, Yair Levy, Mahesh Raisinghani, and Edward Szewczak, for their valuable contributions and support.

In the editorial area, I would like to express my thanks to the staff and management of Idea Group Reference (IGR), including Ms. Jan Travers, Managing Director, for her endless support and encouragement, Ms. Mandy Appicello, Senior Managing Editor, for her countless attention to detail, and Ms. Michelle Potter, Acquisitions/Development Editor, for her endless and continuous efforts during the review and development process, and for keeping this project on schedule. I would also like to express my many thanks to members of the editorial team at IGR, including Ms. Sara Reed, Assistant Managing Editor, Ms. Jennifer Neidig, Managing Editor, Ms. Amanda Kirlin, Editorial Assistant, Ms. Lauren Kenes, Editorial Assistant, Ms. Kristin Roth, Development Editor, numerous copy editors, and Ms. Lisa Tosheff, Graphic Artist, for all their efforts and contributions toward this project. A special thanks also goes to Ms. Renée Davies, the former Acquisitions/Development Editor at IGR, for all her initial assistance and support for this project. Furthermore, many thanks are also due to Ms. Amanda Phillips, Marketing Manager, Mr. Dorsey Howard, Assistant Marketing Manager, Mr. Andrew Bundy, Marketing Assistant, and Ms. Hannah Gordon, Marketing Assistant, for their efforts in promoting this publication. Finally, my warmest appreciation is extended to my wife for her continuous support, wisdom, encouragement, understanding, patience, love, and for keeping up with my long hours at work. My heart also goes to my two beautiful girls, Basha and Anar, for the joy that they have brought to our life. Finally, my deepest respect and gratitude is extended to all my students and colleagues who taught me immeasurable amounts of knowledge during my scholarly life.

About the Editor

Mehdi Khosrow-Pour, DBA, is executive director of the Information Resources Management Association (IRMA), USA, and senior academic technology editor for Idea Group Inc. Previously, he served on the faculty of the Pennsylvania State University as a professor of information systems for 20 years. He has written or edited more than 30 books in information technology management. Khosrow-Pour is also editor-in-chief of the *Information Resources Management Journal, Journal of Electronic Commerce in Organizations, Journal of Cases on Information Technology,* and *International Journal of Cases on Electronic Commerce*.

Adaptive Virtual Reality Shopping Malls

George Lepouras
University of Peloponnese, Greece

Costas Vassilakis
University of Peloponnese, Greece

INTRODUCTION

Firms and organizations are increasingly exploiting electronic channels to reach their customers and create new business opportunities. To this end, electronic shops have been developed, either offering products from a single firm or encompassing multiple individual electronic stores, comprising thus electronic shopping malls. Besides development activities, electronic shopping has attracted the attention of researchers, who have studied various perspectives, including user attitude, critical success factors, security, technical aspects, and so forth (e.g., Fang & Salvendy, 2003; Wang, Makaroff, & Edwards, 2003).

Two main concerns for e-commerce are personalization and enhancement of user experience. Personalization addresses the ability to offer content tailored to the preferences of each user (Anupam, Hull, & Kumar, 2001) or user group (Wang et al., 2003). Preferences may be explicitly declared by the user, or derived by the system through inspecting user interaction; if the system dynamically reacts to changes of visitor behavior, it is termed as *adaptive*. Personalization allows customers to focus on the items they are interested in, and enables electronic shops to make targeted suggestions and send promotions to customers (Lekakos & Giaglis, 2005).

Enhancement of user experience is another major issue in e-commerce, given that 2D images and texts on the screen are not sufficient to provide information on product aspects such as physical dimensions, textures, and manipulation feedback (Park & Woohun, 2004). Major e-commerce categories that could benefit from giving a more accurate and/or complete view of the products include real estate brokers who could present detailed models of properties, furniture stores that could allow their customers to view how certain pieces would fit in the target place (Hughes, Brusilovsky, & Lewis, 2002), and clothing shops that could provide a virtual fitting room with customizable avatars (Compucloz Corporation, 2003). Multimedia presentations can also be used as a means for "information acceleration" for promoting "really new" products (Urban et al., 1997). Enhancement of user experience may finally compensate for the loss of the pleasure associated with a visit to a shopping mall (Laskaridis, Vassilakis, Lepouras, & Rouvas, 2001).

Nowadays, the technological potential of Internet systems provides adequate means for building online multimedia applications that can help e-commerce sites attract e-shoppers. Applications can be built to adapt to the user's profile and provide the user with a suitable set of information in the most efficient way. Virtual reality (VR) technologies are also now mature enough to be used for the wide public, offering vivid and highly interactive environments, allowing users to view synthetic worlds within which they can visualize and manipulate artifacts. This article aims to specify a system that exploits capabilities offered by adaptation and VR technologies to offer e-shoppers personalized and enhanced experiences, while addressing challenges related to the cost, complexity, and effort of building and maintaining such a system.

BACKGROUND

E-commerce sites nowadays expose variable degrees of sophistication, functionality, and complexity. Most e-commerce sites offer lists of available products, usually organized in categories. For each product, a brief description, the price, and possibly an image are made available to e-customers; more information items may be included depending on the e-commerce domain (e.g., customer reviews for books and music). A basic e-commerce site offers the same content to all its visitors.

The first step towards offering services tailored to the user needs is the categorization of users into groups and serving each group with specifically selected content (e.g., Arlitt, Krishnamurthy, & Rolia, 2001). Personalization provides a finer granularity for tailored content delivery, because content formulation is based on the preferences and behavior of individual users, rather than aggregate data from user groups. Preferences may be declared through *static profiling* (Datta, Dutta, VanderMeer, Ramamritham, & Navathe, 2001) where users declare their preferences through profile definition pages; dynamic profiles extend their static counterparts by incorporating information collected from user activities during the interaction sessions.

On the other hand, 3D objects and VR can greatly enhance user experience within an electronic shop. Since 3D environments are inherently more complex as compared to 2D interfaces, the issue of navigation within such an environment is important. Chittaro and Coppola (2000) discuss the use of animated products as a navigation aid for e-commerce. Hughes et al. (2002) examine the integration of ideal viewing parameters with navigation, to assist the navigation procedure. Park and Woohun (2004) present a prototype augmented reality system, enabling users to "put and feel a product" in order to find the match in the real environment.

Although adaptation and VR technologies seem promising for e-commerce, their adoption is currently hindered due to a number of challenges, mainly related to the technologies themselves. The first major challenge is *content creation*: for each item in the VR-mall, the respective representations have to be created. The virtual space for the mall must also be designed, and stands and shelves on which items will be placed must be inserted. Finally, interaction methods for each item need to be designed. These may vary from item to item depending on the type of digital representations (e.g., 3D models may be rotated; videos may be played, paused, and continued; photographs may be only viewed), and the nature and semantics of the item (e.g., for a 3D model of a camera, interaction may be provided to illustrate change of lenses, while a 3D model of a vase can be only rotated). This is a cumbersome, time consuming, and costly process (Lepouras, Charitos, Vassilakis, Charissi, & Halatsi, 2001).

A second major challenge is the overall system complexity, stemming from the diversity of its components, structures, and interactions (European Center for Virtual Reality, 2004). The system must include provisions for user profile modeling (both static and dynamic parts), selection of the items that best fit the current user profile, dynamic creation of virtual worlds (VR-worlds) in which the selected items must be placed, coupled with proper interaction methods.

A final challenge is the overall size of the VR-mall description. VR-worlds tend to be of large size, and thus their download time can be considerable. Constructing thus a single world representing the whole VR-mall will result in long waiting times, which may lead users to navigate away from the VR-mall. A more prominent approach would be the formulation of smaller VR-worlds, each one containing a subset of the VR-mall merchandise. These worlds may be interconnected using gates, teleports, or any other suitable means (when a user reaches an interconnection item, they are transferred to another VR-world constructed and downloaded at that time; thus waiting times are broken down into small portions). The proposed architecture adopts this approach, which additionally provides the opportunity to populate each VR-world with the merchandise that best fits the user interests, as this can be determined by the user activities observed so far. The details of this process are analyzed in the next section.

THE VR-MALL ARCHITECTURE

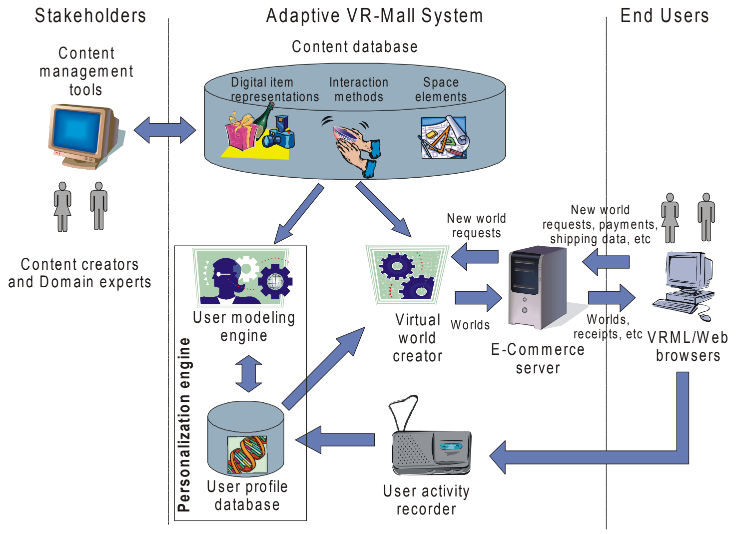
The proposed architecture provides a generic framework for building an adaptive VR-mall, undertaking the tasks related to user profiling and monitoring, selection of the items best suited to the user profile, association of the relevant interaction methods, and dynamic formulation of the VR-worlds. In this sense, the tasks that need to be performed by the VR-mall maintainers are limited to the provision of the content—that is, the digital representations of the items merchandised through the VR-mall. The proposed architecture is depicted in Figure 1.

Defining the VR-Mall Content

In the proposed system, creation and maintenance of the adaptive VR-mall is undertaken by two stakeholder groups, namely content creators and domain experts, who perform their tasks using specially crafted *content management tools*. Content creators provide the digital forms of the VR-mall merchandise in the appropriate form (pictures, 3D models, sounds, videos, etc.). Content creators additionally design the space elements that are used within the VR-mall, including rooms, halls, corridors, shelves, display cases, and stands. Space elements generally contain *merchandise placeholders*, which are replaced by appropriate merchandise items or navigation aids when an instance of the VR-mall is created. For example, shelves may contain placeholders indicating where products will be placed, whereas a placeholder within a corridor may be replaced by a sign listing the merchandise categories along the corridor. All resources can be provided in multiple *levels of detail.* High levels of detail are used for e-shoppers with broadband connections and when e-shoppers explicitly request highly detailed images of items; low levels of detail are used to reduce download times, because the size of the digital representation in low levels of detail is significantly smaller.

To enable the selection of the most suitable items for each user, the adaptive VR-mall system needs to possess certain information regarding each item, such as the item category (e.g., furniture, electric appliance, holiday pack), target age group, shopping season, and so forth. This information is provided in the form of *property-value*

Figure 1. System architecture



pairs by *domain experts*—that is, VR-mall stakeholders who have significant expertise on the merchandise. This information is stored alongside the digital representations of the merchandise and is exploited by the VR-world generator in the process of selecting the items that are considered to best match the interests of the current e-shopper.

Personalization and Adaptation

Central to the proposed architecture is the *VR-mall personalization engine*, comprising the *user profiles database* and the *user-modeling engine*. The user profiles database stores information regarding the profiles of individual users, and associations between user profiles and specific items or item properties. This information is utilized in the process of VR-mall creation to include in the mall the merchandise that most closely matches the interests of the current e-shopper. For each e-shopper, the user profiles database hosts both *static* and *dynamic* information. Static information reflects characteristics that remain constant, at least in the context of the current visit (e.g. preferred language, connection speed, age, etc.). This information is either entered by the user (e.g., a response to a "Language selection" prompt) or deduced by the system (e.g., connection speed is estimated by measuring the download time for an image of known size). Dynamic information pertains to the interaction of the user with the virtual environment and is collected by the *user activity recorder*. This information describes certain actions that the e-shopper has performed in the VR-mall, including moving close to an item and moving away from it, start and end of item manipulation, resetting activities (probably due to disorientation problems), acquiring and losing visibility for items, requesting specific resources or resource types, and so forth. This information is collected within the user browser, and communicated to the user activity recorder periodically. When the user activity recorder receives a group of event information, it first arranges to combine "activity beginning—activity end" records, to compute the duration of each activity. For events that are instantaneous by nature (e.g., request for an image of a product), only the count of these events is computed. The combined information is inserted into the user profiles database, and the user-modeling engine is invoked to update the profile of the user.

The user-modeling engine is a separate architectural module that examines the user activities observed within the virtual environment, and deduces the preferences of the user towards certain items or item categories. Upon invocation, the user modeling engine extracts from the user profiles database the records that describe activities of the current user and processes them as follows:

1. Items that have come into visibility are assigned a grade in the range of (-5) to (10), depending on the time that they have attracted the visitor's attention (-5 = not at all, 10 = very long).
2. If for some item some resources have been explicitly requested (e.g., 3D models, detailed text, images), an extra amount is added to the item's interest grade (1 to 3, depending on the time the extra resource was viewed).

3. Items that have not come into visibility are not assigned any grade, as the user may ignore altogether that the items were present in the VR-world.

The final grade for each item is computed by multiplying the above computed grade with an *aging factor*, which ranges from 1.0 (for recent activities) and 0.1 (for activities that occurred a long time ago). This step effectively assigns a greater importance to recent activities, allowing for modeling of *changing user interests* (Kilfoil, Ghorbani, Xing, Lei, Lu, Zhang, et al., 2003).

The last phase of the user profile update procedure is the mapping of the grades computed in the previous step to preferences towards item categories, or—more generally—*item properties*. To this end, the semantic information associated with the items (in the form of *property-value* pairs) is extracted from the digital items representation repository. For each property-value pair retrieved, the grades of all items associated with it are summed up to form the score of the specific property-value pair. This information is finally inserted into the user profile database. Similar algorithms are used to deduce user preferences towards specific media types and interaction methods.

Generating Virtual Worlds

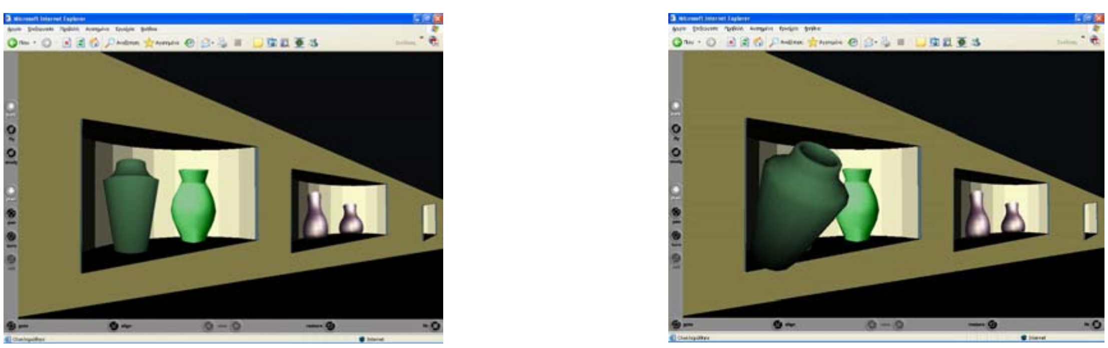
When a user reaches a "VR-world interconnection" point (gate, teleport, etc.), a request is issued to the VR-world generator, which will create the next "portion" of the VR-mall to be sent to the user. This request contains the user identity and—possibly—expressly stated user preferences (e.g., "I want a high-quality environment" or "I am interested in velvet textiles"). The VR-world generator additionally retrieves from the user profile database the preferences and information for the specific user (either statically stated or deduced by the VR-mall personalization engine). Afterwards, the VR-world generator accesses the content database to extract the items that will be placed in the new VR-world. The initial list of the items to be placed in the new VR-world is formulated in either of the following two ways: (a) the user selects to visit an "e-mall department" (e.g., furniture, clothing etc.), in which case the items belonging to the selected department are chosen; or (b) the user requests to see "matching items" to some designated merchandise (items within the shopping cart or some explicitly specified), in which case the items having common properties with the designated merchandise are chosen. The initial item list is sorted in descending order of the sum of scores corresponding to the property-value pairs within each item. The VR-world generator has also an upper limit regarding the number of items that will be placed in a VR-world, and another upper limit pertaining to the download size; if either limit is exceeded, items are removed from the list until the restrictions are met. When the item list has been determined, a proper space element is selected from the content database (one with enough placeholders for the selected items and matching the user preferences), and the items are positioned at the placeholder locations, arranging for "similar" items to be placed in clusters (Lepouras, 2004). At this point, the VR-world has been fully created and can be sent to the user.

Figure 2 presents two screenshots from the VR-mall. The first one illustrates movement along an isle, while in the second screenshot an object has been "grabbed" and is examined.

FUTURE TRENDS

New technologies offer to e-commerce sites the possibility of creating enhanced and highly personalized user experiences, increasing the site potential to attract more e-shoppers. One issue that has to be settled in this context is the *time to adapt*—that is, how much time elapses from the instant that some user behavior is observed to the

Figure 2. The VR-mall environment: (a) moving along an isle with vases; (b) examining a specific vase



a. *b.*

instant that the system changes the user environment. In the proposed architecture, the environment will change only when a new VR-world is requested. Some users may find this reaction delayed; most users, however, have been found to react negatively to constant changes in their environment (e.g., items disappear to be replaced ones considered to be more interesting to the user (Schneidermann, 1997)). A viable approach to a more timely reaction would be use of *navigation clues* that will direct users to an interconnection point (where change of environment *is* expected); navigation clues may appear when the system decides that the user's environment should be changed. In order to support either form of a more timely reaction, certain portions of adaptability mechanisms have to be executed at the client side, eliminating the requirement for creation and transmission of new content. The use of more sophisticated methods for item selection, with possible integration of AI techniques, is also an interesting research direction. Finally, the possibility of allowing multiple users to simultaneously enter a VR-mall and interact with each other while shopping will be investigated.

CONCLUSION

The architecture proposed in this article allows e-commerce sites to benefit from the advantages of adaptive and VR technologies, and simultaneously addresses a number of challenges usually associated with such systems. The proposed system incorporates modules that undertake user monitoring, deduction of preferences, selection of the most prominent items, and dynamic formulation of the VR-world, limiting the tasks that the e-commerce site stakeholders need to perform to content provision and the semantic tagging, which are performed via specifically crafted content management tools. Effectively, this architecture limits the cost and effort associated with the creation and operation of an adaptive VR-mall, opening up the potential to more e-commerce sites to offer their customers vivid, lifelike, and personalized experiences.

KEY TERMS

Activity Recorder: Software that monitors important user activities within the virtual environment and records this information into a database for later perusal.

Adaptive VR-Mall System: An e-commerce site that offers an immersive or semi-immersive environment for e-shoppers to navigate in, and tailors the content delivered taking into account the individual e-shopper preferences and interests.

Digital Item Representations: Multimedia content related to the merchandise of the VR-mall, coupled with semantic information that describes and categorizes each item.

Interaction Methods: The ways that an e-shopper can manipulate items within the VR-mall. The interaction methods may vary, depending on the type of item representation (video, 3D model, photograph), the item semantics, and the preferences or expertise of the user.

Personalization Engine: A system component that exploits information regarding user activities to derive user preferences and interests, and to tailor the content to be delivered according to these.

Space Elements: Halls, corridors, shelves, and other items representing physical shopping mall components, which are used together with the multimedia representation of the merchandise to formulate the VR-mall worlds.

Virtual World Generator: A system component that uses space elements and digital item representations to dynamically create a virtual environment, which is sent to the user.

Application Service Providers

University of Massachusetts Boston, USA

INTRODUCTION

Technological changes within the last decade have dramatically changed the business climate. The use of Internet by firms has lead to global production, consumption, and competition. Electronic commerce, or e-commerce, "is a modern business methodology that addresses the needs of organizations, merchants, and consumers to cut costs while improving the quality of goods and services and increasing the speed of service delivery" (Kalakota & Whinston, 1996, p. 1). The benefits of e-commerce include cost savings, direct and quick interaction with the (potential) customer, competitive advantage through business intelligence, digital production sales and distribution, collaborative development with partners, new product development, direct sales, marketing and advertising, publicity, customer service and enhanced customer relationship, and communication.

Small businesses play an important role in the nation's economy. They are the fastest growing segment of all business types. The importance of small businesses to the U.S. economy can be gauged from the following statistics provided by U.S. Small Business Administration (SBA):

- Small businesses represent 99.7% of all employers, employ 50% of all private sector employees and account for 44.3% of total U.S. private payroll;
- Small businesses generate 60 to 80% of net new jobs annually; and
- Small businesses are employers of 39% of high-tech workers.

Researchers have argued that the use of Internet has created a level playing field whereby a small business can compete effectively against larger competitors. Studies have shown that larger firms have made significant progress in e-commerce. But, the same cannot be said of small businesses. In a 2001 report, SBA noted that less than 2% of Internet use is directed at e-commerce. The lack of progress in e-commerce adoption by small businesses has been cited in several studies (Mathiyalakan, 2002, 2004).

Small businesses face numerous e-commerce technology adoption barriers and as a result the pace of adoption has been slow. In addition to capital and access to latest technology, employees' knowledge, expertise, and experience is an important determinant of technology adoption (Kwon & Zmud, 1987; Rogers, 1983). To overcome the technological and skill limitations identified above, several strategic options are available for small businesses. These include the use of external consultants, outsourcing, and the use of ASP amongst others. The focus of this article is on examining issues related to the use of ASP by small businesses. This article is organized in terms of five sections. After this introduction, we provide a background to ASP. Thereafter, we identify and discuss issues that are pertinent to the use of ASP by small business. This is followed by a discussion on future trends and our concluding remarks.

BACKGROUND TO APPLICATION SERVICE PROVIDERS

The roots of ASP go back to the concept of "time sharing." A review of literature on ASP definition (see Table 1) indicates that there exists a multitude of definitions of ASP. Although all researchers agree that ASP provide software applications and services exist, a consensus does not exist on other key features of ASP. Although some have stressed that ASP is akin to a rental agency (ASPstreet.com, 2005; Bennett & Timbrell, 2000), others advocate a broader and management oriented role (Deloitte Research, 1999; Webopedia.com). A common theme across many of the definitions is the use of the Internet to distribute the software applications (ASPstreet.com, 2005; Bennett & Timbrell, 2000, p. 196; Brian, 2005; Kern et al., 2002) who reviewed other definitions of ASP in an attempt to distinguish them from outsourcing note "it is difficult to distinguish a modern ASP from the 1963 Payroll Bureau Service provided by Ross Perot's Electronic Data Systems to Frito Lay and Blue Cross."

The ASP uses the Internet to make applications available to firms. It is essentially delivers and manages the applications and services through the Internet and other networks. Examples of applications that can be used through ASP are payroll, travel and expense accounting, desktop productivity, messaging & collaboration services, information distribution, e-commerce, product configuration, sales force automation, manufacturing, logistics, and supply chain management.

Table 1. Definitions of ASP

Source	Definition
Benett and Timbrell (2000)	A form of selective outsourcing where a third-party organization rents generally available packaged software applications and related services.
Kern, Kreijger, Willcocks (2002)	These are service firms that provide on contractual basis, rental based or 'pay-as you-use' access to centrally managed applications made available to multiple users from a shared data center over the Internet or other networks.
Smith and Kumar (2004)	A single point of contact for all telecommunications, hardware, software, and consulting services necessary to deploy, run, and maintain hosted applications remotely.
ASPstreet.com	Offer individuals or enterprises access to software applications and related support services over the Internet.
Brian (2005)	Companies that supply software applications and /or software-related services over the Internet.
Deloitte Research	A service firm that deploys, hosts, and manages application solutions for rent to businesses residential customers.
Information Technology Association of America	An Application Service Provider, or ASP, is any company that delivers and manages applications and computer services to subscribers/clients remotely via the Internet or a private network.
Webopedia.com	A third-party entity that manages and distributes software-based services and solutions to customers across a wide area network from a central data center.

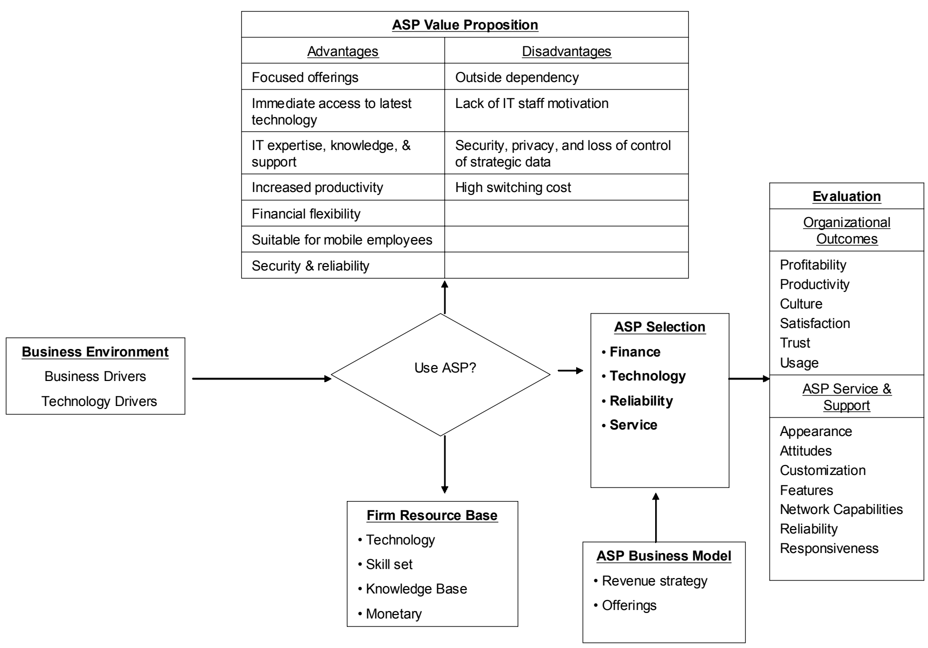
ISSUES IN THE USE OF ASP BY SMALL BUSINESS

In Figure 1, we present our framework. We use this framework to identify issues of concern to both academics and small business managers. The noteworthy features of our framework are: (a) drivers within the business environment that precipitate the need for the use of ASP, (b) firm resource base, (c) ASP value proposition, (d) ASP business model, (e) ASP selection, and (f) Organizational outcomes and ASP evaluation. Next, we discuss each of these issues in detail.

Drivers Present in the Business Environment

Rapid developments in the global marketplace, including technological advances, mushrooming consumer de-

Figure 1. Model for ASP selection, use, and evaluation



mands, new products, escalating globalization, and the implications of corporate reengineering and the restructuring, have fundamentally transformed the contemporary business climate. To compete in this changing business and technology environment, small businesses are constantly revising strategies to better manage their businesses. ASP are seen as a way for a small business to overcome its technology, knowledge, and monetary limitations and compete with much larger firms.

Firm Resource Base: Why Use ASP?

Larger businesses have a greater access to capital (money, material, employees, technology, and knowledge) and have greater freedom to engage in new technology adoption. Larger firms can easily overcome their technical expertise limitations by hiring additional staff, using consultants, or using third-party vendors. Small businesses are different from large businesses in many areas such as capital availability, access to capital markets, technical capabilities and availability of professionals. In small businesses, very few people or possibly an individual may function as the IT staff. Premkumar and Roberts (1999) asserted that firms without the required employee skills may not be aware of new technological innovations or may fear the risk associated with adoption of such technology within their organization.

Lack of access to education and training within small business may affect their willingness to adopt new technology (Fariselli, Oughton, Picory, & Sugden, 1999). Hiring suitably qualified personnel or motivating them to work within a small business setting may be a daunting task for a small business decision maker. For developing a home page or for other less knowledge and/or capital-intensive task, a small business may make use of off the shelf books, software, and tutorials. Small businesses with restricted technical expertise may require the use of external expertise or personnel in the form of consultants, vendor support, outsourcing, or the use of ASP.

ASP Value Proposition: Advantages and Disadvantages of Using ASP

Prior to using ASP, a small business decision maker who faces technical and skilled personnel limitations needs to decide on whether to use ASP to avail the opportunities in the marketplace. Both the advantages and disadvantages must be carefully considered and evaluated prior the decision on ASP use is made. The advantages of using ASP are as follows:

- ASPs are aimed primarily at small business (Paraskevas & Buhalis, 2002) and thus the ASP can have more focused offerings.
- A small business (or a startup) can have immediate access to the latest technology.
- A small business has the access to the same technology that their large counterparts have and thereby levels the playing field.
- ASP provides IT expertise and eliminates the need for a large and technically capable IT department to deal with support, maintenance, and upgrades.
- By using ASP, small businesses can focus on using the applications immediately to support their business activities and eliminate the learning curve and the time and cost associated with installing and managing applications. A small business does not have to expend time and money in software development and thereby the small business can increase its IT productivity.
- Rather than purchasing hardware and software, and acquiring relevant personnel (new or trained) which necessitates in capital outlay, small businesses can “rent” ASP and thereby decrease initial capital requirements, lower the total cost of ownership, and provide financial flexibility. Further, as managing and supporting the applications and services falls within the purview of the ASP, small businesses do not have to provide extensive IT staff training.
- ASP provides viable solutions for a small business with mobile and or distributed employees as the applications are hosted on remote servers.
- There is a reduced risk for technology obsolescence as small businesses are renting the applications.
- There is a greater provision of security and reliability.

The disadvantages of using ASP are as follows:

- By depending on outside parties, small businesses face the risk of high switching costs, access to organizational strategic asset by external parties, lack of security and privacy, and potential collapse or downfall of their ASP.
- By depending on external IT staff, small businesses face the risk of alienating internal IT personnel who may feel that they are relegated to performing routine mundane tasks with no avenue for career advancement or for learning new technology.
- A small business decision maker may fear that perhaps due to their lack of or limited IT knowledge ASP may pursue their own agenda (Yao, DeSouza, & Watson, 2004).

ASP Business Models

A business model specifies how a firm will generate money to sustain its operations and to generate the desired rate of return. Business models usually specify how the firm will generate revenue and the specific tactics it will use to operate within the industry. An ASP generates a revenue stream either through monthly fees or through per user fees. Based on target markets and products, ASP may be classified into Enterprise ASP, Local/ Regional ASP, Specialist ASP, Vertical Market ASP, and Volume Business ASP (ASPnews.com). Enterprise ASP deliver high-end business applications such as enterprise resource planning software, e-commerce applications and supply chain management applications. Local/Regional ASP supply wide variety of application services for smaller businesses in a local area. Specialist ASP provides applications for a specific need, such as Web site services, human resources, customer-relationship management software. Vertical Market ASP provides support to a specific industry, such as healthcare, finance etc. Volume Business ASP supply general small and medium-sized businesses with prepackaged application services in volume.

ASP Selection

It is important that ASPs are selected after a careful study of the needs and requirements and the capabilities. A small business decision maker must carefully consider issues related monetary, technological, reliability, and service during the section of the ASP. Focacci, Mockler, Gartenfeld, and Dologite (2003) provide 10 guidelines that can form the basis for ASP selection. These 10 guidelines deal with business strengths of the ASP, capabilities and certification of ASP personnel, architecture, data center and infrastructure analysis, recovery and backup plans, security, service and support, scalability, pricing, guarantees on system availability. Grover, Teng, and Cheon (1998) suggested that as ASP possess more technical knowledge than a typical small business manager they may play a dominant role during negotiations leading to a lower degree of control by the small business. Such a loss of control could result in incomplete or inflexible contracts (Kern et al., 2002). Yao et al. (2004) pointed out that such a lack of control could lead to ASP pursuing its own agenda.

Organizational Outcomes and ASP Evaluation

It is important that periodic evaluation be made both of the organizational outcomes and services and support provided by the ASP. Given the newness of the ASP concept, there exists a dearth of studies that have as their primary focus the evaluation of services and support provided by the ASP (Ma, Pearson, & Tadisina, 2005). There is also no agreement among researchers on the ways to define and operationalize quality (Reeves & Bednar, 1994). However, a good starting point is the study of Ma et al. (2005) who identified seven dimensions (features, availability, reliability, assurance, empathy, conformance, and security) for evaluating the service quality of ASP. Trust is also an issue that may affect ASP choice and usage (Seltsikas, Currie, & Tebbourne, 2002). The task of a small business decision maker is to ensure that the use of the ASP results in net positive outcomes. In addition to quantitative factors such as performance, productivity and usage, we argue that a small business decision maker must use nonquantifiable measures such as culture, satisfaction (with both the process and outcomes) and trust to assess the impact of the ASP.

FUTURE TRENDS

The research firm of IDC expects the ASP market to by 92% over the 5-year period 1999 to 2004 to an estimated $7.8B in 2004[1]. However, this forecast represents a drastic reduction from the earlier estimate of Gartner Research Group, who predicted that the market would be around $22B (Mears, 2003). While there are many different estimates on ASP spending, it should be noted that all of them have revised their estimate downward from the projections made in late 1990s.

A possible reason for the downward revision of ASP spending could be due to the crash of many dot-com firms in early 2000. In late 1990s, many firms entered the ASP market with a lot of fanfare and with the expectation that the premise behind their business model of customers renting software applications over the Internet would hold true. However, the collapse of the dot-com firms in part has lead to the demise of many ASP. Those that do remain can be considered as the survivors. This second generation ASP have altered their business model and have changed their tactics to provide more and high quality offerings and superior service.

CONCLUSION

Small businesses face resource limitations. Both academics and practitioners have suggested that ASP can be used to overcome financial and technical limitations experienced by small businesses. However, it should be noted that ASP should not be thought of as panacea for all the problems experienced by small businesses. A small business decision maker must carefully consider the value proposition offered by the ASP prior to engaging its services. Performance requirements must be carefully specified prior to the start of the contract and constant monitoring and evaluation is necessary. In this study, we presented a framework that may be of use to both academics and practitioners in identifying issues and considerations in use of ASP by small businesses.

There are several opportunities for additional research. It would be interesting to develop a profile of firms that use ASP and the applications they use. Information, education, training, and supplier incentives have a positive effect on adoption (Deeter-Schmelz, Bizzari, Graham, & Howdyshell, 2001) and thus studies should also focus on how the small business decision maker characteristics impacts ASP use.

Studies should focus on identifying ASP usage barriers. Mathiyalakan (2004) found that as the size of the firm increases, the knowledge about ASP also increases. But this knowledge does not get translated into use of ASP possibly suggesting the existence of barriers other than knowledge. There may be several reasons for the lack of use of ASP by small businesses (Mathiyalakan, 2004). First, a small business decision maker may be concerned with security, privacy, and loss of control associated with ASP usage. Second, a small business decision maker may fear that perhaps due to their lack of or limited IT knowledge, ASP may pursue their own agenda (Yao et al., 2004). Third, a small business decision maker may not believe in an ASP's value proposition as evidenced by Roberts (1998), who found that many small businesses have problems in using computers and translating IT investments into business value. Therefore, future research should focus on whether additional barriers to ASP usage exist and the ways to overcome such barriers. We also note that there is a need for research that is longitudinal in nature as technology adoption and implementation is often an ongoing process.

Auto-Personalization WAP Portal

Jon T. S. Quah
Nanyang Technological University, Singapore

Vincent L. H. Seet
Nanyang Technological University, Singapore

INTRODUCTION

WAP (wireless application protocol) has failed to take off exponentially as anticipated by industry players over the last few years with the slow acceptance by the consumers. The big players of WAP mobile phone manufacturers and mobile operators had over-hyped the advantages of using WAP to access the Internet ubiquitously. This had led to a mismatch in the consumers' expectations when they eventually realized that user experience in surfing the Internet with WAP phones was not what was perceived earlier. The perceived experience was equated with that of surfing the Internet with desktop personal computers, browsing Web sites with rich multimedia contents. The reality is, WAP phones have limited screen real estate, and these came with monochrome displays initially. Thus, WAP contents have to be specially coded to suit the small screens for browsing. WAP phones with color displays were only available in quantity and variety since late 2002. Much of the WAP content available has not yet redesigned to take advantage of the new color displays.

The attainable bandwidth for WAP surfing is only a small fraction when compared to broadband access. The bandwidth attainable by surfing WAP over GPRS (General Packet Radio Service, a 2.5-generation GSM packet data technology) is between 20 kbps to 40 kbps, whereas it is 256 kbps to 1,024 kbps for broadband. Prior to the availability of GPRS, WAP was carried over CSD (GSM Circuit Switch Data) and had an attainable bandwidth of merely 9.6 kbps. With these limiting factors, rich multimedia contents are simply not applicable to WAP at the moment (Gehlen & Bergs, 2004; Bai, Chou, Yen, & Lin, 2005). The limited screen real estate of WAP phones has also created navigation problems which involved many selections and too many moves between cards for consumers to achieve their goals. It was said that WAP is the "Wrong Approach to Portability," and it is a technology designed *by* techies *for* techies, without the best interests of the consumer at heart (George & Sarch, 2001). Others said that WAP's days were numbered and soon it would R.I.P. (rest in peace) (Saymour et al., 2001). It is certain that some amount of guidance is required for the less techie consumers during their initial encounters with WAP. Nevertheless, WAP is a good technology that allows one to access handy information in a timely fashion and ubiquitously. Like it or not, WAP will be around for some time, but much improvement is needed to make WAP surfing a less painful experience for consumers (Mahmoud, 2004; Sriskanthan, Meher, Ng, & Heng, 2004; Yeo, Hui, & Lee, 2004; Ma & Irvine, 2004; Radhamani & Siddiqi, 2004; Hung & Chang, 2005; Albastaki & Alajeeli, 2005; Gilbert & Han, 2005).

Mobile Internet browsing using WAP phones has created unique problems of its kind. One of the challenges that consumers faced is that they are only equipped with a small screen for browsing WAP contents. This makes navigating to WAP sites of interest on WAP portals a hassle. WAP portals served as consumers' gateway to the WAP sites offered by third-party content providers. These portals usually organize the list of WAP sites into a multilevel tree hierarchy structure. Consumers are required to navigate deep down the tree to access their favorite sites. This article proposes methods for making WAP portals adaptive. Such portals reduce time spent by consumers in navigation, hence there is more time for content browsing. The proposed methods do not require explicit consumers' input for adaptation, but rather they implicitly track consumers' navigation activities among WAP sites and use this input to form the basis of consumers' preferences for adaptation. The methods had also taken into account possible drift of consumers' interests over time, and weighted computation is used to achieve adaptation that will be of relevance to consumers at any point of time. Preliminary experiments with mobile users have yielded promising results.

DESCRIPTION OF THE SYSTEM

Personalization refers to the process of creating a customized consumer experience that is unique to each target consumer by making use of the preferences of these consumers as inputs to the process. Much research has been done in this area (Quah & Yong, 2002; Jelekaninen, 2004; Saleh, Avery, & Siddiqui, 2004; Wu, Chung, & Moonesinghe, 2004; Lin, Wang, & Liu, 2005; Yin & Leung, 2005; Ezeife & Lu, 2005; Tee, 2005; Ueno, Ishikawa, Suzuki, Sumino, & Takahashi, 2005) to devise methods that will be efficient in delivering the customized consumer experience.

In order to relieve consumers of the hassle of customization, an adaptive WAP portal is proposed. The adaptive WAP portal requires no explicit consumer input. Its adaptation is enabled by examining consumers' history of WAP site access. Adaptation is achieved by the following means:

- adaptive link sorting,
- adaptive recommendation, and
- navigation shortcuts.

Consumers' usage data or access history is acquired implicitly by tracking the WAP sites that are accessed during each WAP portal navigation session. The data collected for each access consists of consumer's mobile number, identification number of WAP site accessed, timestamp of access, session identification number, and optionally the duration of visit to the site (in minutes).

Information on the duration of visits to the sites is gathered from the WAP gateway of the mobile operator of the Adaptive WAP portal. It is the best node to retrieve such information since WAP gateway proxies all the requests from WAP phones to the WAP sites requested. The usage of "duration of visits" information is an optional feature, as in some implementation this information is difficult to retrieve. Commercially deployed WAP gateways usually store logs of the WAP sites that were accessed by consumers for charging purposes. In system implementations with the absence of the "duration of visits" information, the number of hits to WAP sites is used. The rationale of using "duration of visits" information is to produce adaptations that closely reflect consumers' WAP browsing behaviors. WAP sites where consumers' frequently spent more time browsing should be made easily for the consumer to revisit in the future.

Preferences or interests of consumers can be inferred over time, based on the collected usage data that will be used to adapt consumers' WAP surfing experiences. Consumers' interests tend to drift over time. This behavior has been taken into account in the proposed adaptation methods by introducing temporal weights which influence the relevance of a site accessed in the past. What this essentially means is that a site accessed in the past has less influence in the adaptation as compared to those sites that were accessed recently.

Temporal weights are calculated with respect to each of the past WAP portal navigation sessions. The adaptation methods will take into consideration usage data of a target consumer for the last N sessions, where N is predefined by the mobile operator of the adaptive WAP portal. Having identified the last N sessions used for adaptation, the proposed methods will calculate the temporal weights of each of these sessions using Equation 1:

$$W_S = \frac{1 + Timegap_{oldest} - Timegap_s}{Timegap_{oldest}}$$

(Equation 1)

Adaptive Link Sorting

This method reorganizes the tree structure by sorting the links according to individual consumer's past accesses to these links. Specifically, the method will enable links in a category that are accessed by a consumer to be sorted based on the consumer's preference model that was generated using usage data in the past sessions. The original order of the links within the category accessed is overridden. The motivation behind adaptive link sorting is to reduce the number of scrolling (upwards and downwards directions) that is needed on the limited screen real estate of WAP phones. These phones typically can only display three to four lines of text within the display area of the screen.

The algorithm will use the target consumer's usage data (similar to that of Figure 2) of the last N sessions for computing the access scores of each link.

The algorithm used by the method is presented as follows.

Let ***L ε {links in category X}*** where X is the category that is accessed by a target consumer and the links in this category are to be re-sorted. The algorithm will use the target consumer's usage data (similar to that of Figure 2) of the last N sessions for computing the access scores of each link L denoted by $\mathbf{Score_L}$.

Let ***S ε {last N sessions}***. N is a configurable input parameter to the algorithm that is decided by the mobile operator of the WAP portal.

For each ***L ε {links in category X}***, the respective access scores will be computed using Equation 2:

$$\mathbf{Score_L} = \sum_{S=1}^{N} W_S \cdot A_{LS}$$

(Equation 2)

$\mathbf{W_S}$ denotes the temporal weights as presented in Equation 1.

$\mathbf{A_{LS}}$ denotes the total duration of visits to link L in the S^{th} session. In implementations where information on duration of visits is not available, $\mathbf{A_{LS}}$ will then denote the total number of access (i.e., clicks) to link L in the S^{th} session.

Upon computing the access scores, $\mathbf{Score}_L$ for each ***L ε {links in category X}*** over the span of the last N sessions, the links in category **X** will then be sorted according to these scores in descending order.

Adaptive Recommendation

This method generates an adapted list of recommended WAP sites that are popularly accessed by target consumers. Content-based filtering technique is the recommendation mechanism implemented which uses the target consumer's usage data of WAP sites that were accessed in the past as the basis for making recommendations for similar sites.

The algorithm will then compute the access scores to these categories in the last N sessions using the target consumer's usage data. The access scores of the predefined categories are computed by taking into account the past accesses to the WAP sites that are the descendants to these recommended categories.

The algorithm used by the method is presented as follows:

Let ***C ε {predefined recommended categories}***. The algorithm will then compute the access scores to these categories denoted by $\mathbf{Score}_C$ in the last N sessions using the target consumer's usage data. The access scores of the predefined categories are computed by taking into account the past accesses to the WAP sites that are the descendants to these recommended categories.

Let ***S ε {last N sessions}***. N is a configurable input parameter to the algorithm that is decided by the mobile operator of the WAP portal.

For each ***C ε {predefined recommended categories}***, the respective access scores will be computed by using Equation 3:

$$\mathbf{Score}_C = \sum_{S=1}^{N} W_S \cdot A_{CS}$$

(Equation 3)

$\mathbf{W}_S$ denotes the temporal weights as presented in Equation 1, which yields weights that favor descendant sites of the predefined recommended category C that are accessed in the last N sessions. This will help to capture the consumer's drift of interest over time and used it as the basis to recommend undiscovered WAP sites of the same genre.

$\mathbf{A}_{CS}$ denotes the total duration of visits to descendant WAP sites of the predefined recommended category C in the S^{th} session. In implementations where information on duration of visits is not available, $\mathbf{A}_{CS}$ will then denote the total number of access (i.e., clicks) to the descendant WAP sites of the predefined recommended category C in the S^{th} session.

Apart from specifying the predefined recommended categories, mobile operators will also need to define the maximum number of link recommendations to be generated by the algorithm. Let **M** denote the maximum number of WAP site recommendations to be made. This list is a mixture of sites that are the descendants of each of the predefined recommended categories. Prior to the generation of this list, the algorithm will move on to compute the number of WAP sites that are to be recommended from each of the predefined recommended categories.

Thus, for each ***C ε {predefined recommended categories}***, the number of links to be recommended denoted by $\mathbf{TotalLinks}_C$ will be computed as follows (Equation 4):

$$\mathbf{TotalLinks}_C = \left\lceil \frac{Score_c \times M}{TotalScore} \right\rceil$$

(Equation 4)

TotalScore denotes the sum of all access scores, $\mathbf{Score}_C$ for all the recommended categories. With the $\mathbf{TotalLinks}_C$ computed for each ***C ε {predefined recommended categories}***, the list of WAP sites will be generated accordingly to form the recommendation list. The decision on which WAP sites to recommend within a predefined recommended category is bases on their age since launch (newest descendant sites in that category will be recommended). Recommended sites are picked from those that have yet to be discovered by the target consumer.

Navigation Shortcuts

This method produces shortcuts to WAP sites that are frequently accessed by a target consumer. These shortcuts are placed at the very top level of the WAP portal. The motivation behind *navigation shortcuts* is to reduce the number of click-throughs needed for consumers to access their favorite WAP sites. WAP surfing is usually goal oriented. That is to say, most of the time consumers who surf WAP wish to accomplish certain tasks such as reading e-mails, viewing the latest stock prices, weather and traffic condition updates, and so forth. These tasks are usually executed repeatedly over time, thus it makes sense to provide *navigation shortcuts* to these frequently visited WAP sites upfront.

The algorithm used by the method is presented as follows:

Let ***L ε {Distinct sites accessed by target consumer}***. The algorithm will use the target consumer's usage data of the last N sessions to compute the access scores of each L denoted by $\mathbf{Score}_L$.

Let $S \in$ ***{last N sessions}***. N is a configurable input parameter to the algorithm which is decided by the mobile operator of the WAP portal.

For each $L \in$ ***{Distinct sites accessed by target consumer}***, the respective access scores will be computed using Equation 5:

$$\textbf{Score}_L = \sum_{S=1}^{N} W_S \cdot A_{LS}$$

(Equation 5)

$\mathbf{W_S}$ denotes the temporal weights as presented in Equation 1, which yields weights that help to reduce the influence of sites that were accessed in the past compared to the present accesses.

$\mathbf{A_{LS}}$ denotes the total duration of visits to a site L for the S^{th} session. In implementations where information on duration of visits is not available, $\mathbf{A_{LS}}$ will then denote the total number of accesses (i.e., clicks) to the site L for the S^{th} session.

Upon computing the access scores, $\mathbf{Score_L}$ for each $L \in$ ***{Distinct sites accessed by target consumer}*** over the span of the last N sessions, the *navigation shortcuts* will be generated, with these sites sorted according to their respective scores in descending order. The number of such shortcuts to be generated is a configurable input to the algorithm. This is decided by the mobile operator of the WAP portal.

IMPACT OF APPLICATION ON MOBILE USERS

It was discussed in the previous sections that temporal weights $\mathbf{W_S}$ reduces the relevance of sites accessed in the past and focuses on recently accessed sites. Therefore, it is important that the algorithm deployed by the proposed methods will not overreact to consumers' usage data of WAP sites in the recent past. Various ways could be implemented to maintain the stability and adequate sensitivity of the proposed methods.

The variable **A** in Equations 2, 3, and 5 are calculated by summing up the duration of visits to WAP sites for past sessions of interest. This approach takes into consideration the time spent by the consumers equating to their level of interests in these sites. In addition, it is more accurate than the approach where the number of clicks made to access these WAP sites for the past sessions of interest are used in computation (i.e., the number of times a WAP site is accessed in a single session). This is to prevent an excessive number of unintended clicks to WAP sites that would affect the computation of the proposed methods thereby generating inaccurate adaptations.

A series of experiments was conducted with five consumers over a one-week period to evaluate the effectiveness of all the proposed adaptation methods implemented in the IntelliPortal prototype. These consumers are familiar with WAP and have been using WAP for more than a year. The experiments effectively demonstrated the following adaptive features of the prototype:

- Creation of *navigation shortcuts* containing a list of WAP sites that were frequently accessed by the consumers.
- Recommendation of WAP sites of similar genre to those that were accessed by the consumers in the past.
- Reordering of the links on the directory pages such that these links are presented in decreasing order of frequency-of-access.

RESULTS

The objective of the navigation shortcut experiment was to measure the reduction in the click distance with the use of *navigation shortcuts*. Five consumers were asked to access IntelliPortal over a period of one week to build up their respective list of *navigation shortcuts*. The click distance to consumers' favorite WAP sites using *navigation shortcuts* is always "1" since the shortcuts are located upfront under the homepage of IntelliPortal.

An analysis of the *navigation shortcuts* experiment is shown in Table 1. The savings in terms of total click distance reduction with the use of *navigation shortcuts* were computed. Total click distance refers to the number of clicks between menu pages that are needed to navigate to all the consumers' favorite WAP sites via the IntelliPortal. It was shown that consumers were able to save an average of 53.95% on the total click distance. Thus, with the significant amount of navigation time saved (as a result of click distance savings), consumers were able to spend more time browsing the actual contents found on their favorite WAP sites.

The objective of the *adaptive recommendation* experiment was to measure the effectiveness of the adaptive recommendations made to the same group of five consumers. The effectiveness of adaptive recommendation was measured by tracking the number of recommended WAP sites that were visited by these consumers. The recommended WAP sites for the consumers were similar to those that were accessed in the past. An analysis of the *adaptive recommendation* experiment is shown in Table 2. The total number of recommended WAP sites varied between each consumer since these were made based on their respective access history. "Total Visited" accounted for the number of recommended WAP sites that were repeatedly visited (more than three repeated visits within

Table 1. An analysis of navigation shortcuts experiment

	Consumer A	Consumer B	Consumer C	Consumer D	Consumer E	Average
Total Click Distance (without shortcuts)	14	15	15	17	15	15.2
Total Click Distance (with shortcuts)	7	7	6	8	7	7
% Savings	50%	53.33%	60%	47.06%	52.94%	53.95%

Table 2. An analysis of the adaptive recommendation experiment

	Consumer A	Consumer B	Consumer C	Consumer D	Consumer E	Average
Total Recommended WAP Sites	8	8	3	8	7	6.8
Total Visited	5	4	2	3	4	3.6
% Effectiveness of Recommendation	62.5%	50%	66.67%	37.5%	57.14%	54.76%

Table 3. An analysis of the adaptive link sorting experiment

	Consumer A	Consumer B	Consumer C	Consumer D	Consumer E	Average
No. of Scrolling Before Re-sorting	22	11	13	19	15	16
No. of Scrolling After Re-sorting	6	2	2	4	4	3.6
% Reduction of Scrolling	72.73%	81.82%	84.62%	78.95%	73.33%	77.5%

the one-week experiment period) by these consumers upon recommendation.

The effectiveness of *adaptive recommendation* made for each consumer was computed. It was shown that an average of 54.76% of the recommended WAP sites were repeatedly visited by the consumers upon recommendation. The result is encouraging, as it showed that *adaptive recommendation* is an effective avenue for mobile operators to expose yet-to-be-discovered WAP sites that could be of interest to the consumers, thereby increasing the latter's usage.

The objective of the *adaptive link sorting* experiment was to measure the effectiveness of the *adaptive link sorting* made to the same group of five consumers. Five WAP links were tracked for each consumer and the number of *downward scrolling* that was needed to access these links before and after *adaptive link sorting* was recorded. Downward scrolling refers to the action of pressing a scroll key to move the cursor downwards to highlight the desired WAP link on the microbrowser. For example, a total of three downward scrollings are needed to highlight the WAP link "Digital Look." The first link of any menu page is usually highlighted by the microbrowser. The effectiveness of *adaptive link sorting* was measured by computing the percentage of reduction in the number of downward scrollings needed before and after the re-sorting. An analysis of the *adaptive link sorting* experiment is shown in Table 3.

It was shown that with *adaptive link sorting*, consumers were able to reduce the number of downward scrollings by an average of 77.5%. This was a significant reduction, as the WAP links accessed by these consumers were made more accessible to them. Thus, the amount of time saved could be well spent in content browsing.

CONCLUSION

The previous chapters have presented methods that were designed to make WAP portals more usable for consumers. Mobile phones are deemed to be of relatively small size to ensure consumers' convenience in carrying these devices everywhere they go. It is unlikely that screens of these phones will get larger in the future, while still keeping the phones pocket size; further, navigation within the WAP portal will continue to be a pain for consumers if these portals are to remain as they are today.

Therefore, it is critical that these portals should adapt to the changing needs of the consumers without requiring them to state their preferences explicitly. By doing so, the WAP surfing experience will be significantly improved. This has been shown with the experimental evaluation of the proposed adaptive methods implemented on the prototype. Adaptive link sorting was able to reduce an average of 77.5% of downward scrollings. Adaptive recommendation was able to encourage repeated visits to an average of 41.18% of the recommended WAP sites. Navigation shortcuts provided an average of 54.55% savings in the total click distance needed to access consumers' favorite WAP sites.

With the encouraging results shown in the evaluation, it is hopeful that new consumers' take-up rate for WAP services will improve and encourage multiple repeated visits. Financially, this means that mobile operators of adaptive WAP portals will benefit with the increase of ARPU (average revenue per consumer) and reduce the chance of consumer churn by building consumer loyalty.

The proposed adaptive recommendation method uses content-based filtering as the recommendation mechanism. It would be interesting to make recommendations based on a collaborative filtering technique where consumers could be asked to rate the WAP sites that they had visited. Consumers could be grouped and WAP sites recommended based on the similarity in the ratings.

Current WAP portals organized WAP sites in multilevel hierarchical tree structures as discussed in this article. Apart from the adaptive methods proposed in this research project, research work could be carried out to explore new grounds to break the hierarchical organization of these WAP sites with some innovative methods, where relevant content information from certain WAP sites could be presented to consumers up front without having them to navigate to these sites.

INTRODUCTION

This project experiments with the designing of a Web site that has the self-adaptive feature of generating and adapting the site contents dynamically to match visitors' tastes based on their activities on the site. No explicit inputs are required from visitors. Instead a visitor's clickstream on the site will be implicitly monitored, logged, and analyzed. Based on the information gathered, the Web site would then generate Web contents that contain items that have certain relatedness to items that were previously browsed by the visitor. The relatedness rules will have multidimensional aspects in order to produce cross-mapping between items.

The Internet has become a place where a vast amount of information can be deposited and also retrieved by hundreds of millions of people scattered around the globe. With such an ability to reach out to this large pool of people, we have seen the expulsion of companies plunging into conducting business over the Internet (e-commerce). This has made the competition for consumers' dollars fiercely stiff. It is now insufficient to just place information of products onto the Internet and expect customers to browse through the Web pages. Instead, e-commerce Web site designing is undergoing a significant revolution. It has become an important strategy to design Web sites that are able to generate contents that are matched to the customer's taste or preference. In fact a survey done in 1998 (GVU, 1998) shows that around 23% of online shoppers actually reported a dissatisfying experience with Web sites that are confusing or disorganized. Personalization features on the Web would likely reverse this dissatisfaction and increase the likelihood of attracting and retaining visitors.

Having personalization or an adaptive site can bring the following benefits:

1. Attract and maintain visitors with adaptive contents that are tailored to their taste.
2. Target Web contents correspondingly to their respective audience, thus reducing information that is of no interest to the audience.
3. Advertise and promote products through marketing campaigns targeting the correct audience.
4. Enable the site to intelligently direct information to a selective or respective audience.

Currently, most Web personalization or adaptive features employ data mining or collaborative filtering techniques (Herlocker, Konstan, Borchers, & Riedl, 1999; Mobasher, Cooley, & Srivastava, 1999; Mobasher, Jain, Han, & Srivastava, 1997; Spiliopoulou, Faulstich, & Winkler, 1999) which often use past historical (static) data (e.g., previous purchases or server logs). The deployment of data mining often involves significant resources (large storage space and computing power) and complicated rules or algorithms. A vast amount of data is required in order to be able to form recommendations that made sense and are meaningful in general (Claypool et al., 1999; Basu, Hirsh, & Cohen, 1998).

While the main idea of Web personalization is to increase the 'stickiness' of a portal, with the proven presumption that the number of times a shopper returns to a shop has a direct relationship to the likelihood of resulting in business transactions, the method of achieving the goal varies. The methods range from user clustering and time framed navigation sessions analysis (Kim et al., 2005; Wang & Shao, 2004), analyzing relationship between customers and products (Wang, Chuang, Hsu, & Keh, 2004), performing collaborative filtering and data mining on transaction data (Cho & Kim, 2002, 2004; Uchyigit & Clark, 2002; Jung, Jung, & Lee, 2003), deploying statistical methods for finding relationships (Kim & Yum, 2005), and performing recommendations bases on similarity with known user groups (Yu, Liu, & Li, 2005), to tracking shopping behavior over time as well as over the taxonomy of products. Our implementation works on the premise that each user has his own preferences and needs, and these interests drift over time (Cho, Cho, & Kim, 2005). Therefore, besides identifying users' needs, the system should also be sensitive to changes in tastes. Finally, a truly useful system should not only be recommending items in which a user had shown interest, but also related items that may be of relevance to the user (e.g., buying a pet => recommend some suitable pet foods for the pet, as well as suggesting some accessories that may be useful, such as fur brush, nail clipper, etc.). In this aspect, we borrow the concept of 'category management' use in the retailing industry to perform classification as well as linking the categories using shared characteristics. These linkages provide the bridge for cross-category recommendations.

DESCRIPTION OF SYSTEM

In this article, we seek to provide an adaptive feature using a fast and cost-effective means. The aim is to provide adaptiveness in the sense that when a visitor selects the next link or a new page, the contents of the page generated will have relatedness to previous pages' contents. This adaptive feature will be immediate and will not experience delay or repetitive computational filtering problems, as compared to using mining or collaborative filtering (Claypool et al., 1999; Basu et al., 1998).

The rules-based technique offers an excellent and flexible mechanism to specify rules that map categories that exhibit relatedness among themselves (IBM, 2000). Adding new product lines is simple, by just adding new sets of rules to map the new products accordingly. For direct item-to-item relatedness mapping, it is not so scalable and feasible to implement through use of the rules-based technique. Instead we will use content-based filtering for generating direct item-to-item mappings. The content-based technique (Claypool et al., 1999; Basu et al., 1998) allows item-to-item mapping to be implemented in a scalable manner by just defining the item's attribute, and the recommendation engine will automatically generate or match items of same attribute without involving user efforts (Basu et al., 1998).

In order to facilitate the deployment of these recommendation techniques, the Web domain is structured into their respective categories that exhibit relatedness among them. For example, pet dog would have relatedness to books on dogs. Each of the categories is given a unique ID value. The relatedness rules make use of these IDs to generate recommendations. The Web site domain is structured into supernodes (SA, SB…) which branch into child nodes (A1,A2…An;…K1,K2…Kn). These supernodes are a representation of products on the Web site, and the child nodes are used to represent the breakdown of the products into categories. Below each of the child nodes are the sub-child nodes (Aa1,…Axm,…Ka1,Ka2,…Kxm) that represent the items. Each of the child nodes (A1,A2…An;…K1,K2…Kn) is identified with its corresponding ID value. With this structure, rules-based mapping can be easily identified and applied among the child nodes by defining the IDs that will result into a recommended page.

The syntax of a relatedness rule is:

IDa:IDb:…=>Target page

The entries IDx represent the IDs of Web pages that have relatedness and thus can be mapped directly to the Web page (link) identified as target page. A rule is considered matched when any of the Web page IDs in the rule is also found to exist in the selector's list (visitor's profile). The selector's list is compared against all the rules in the rule file. Only one of the rules will be used, and that is the rule that has the most number of IDx elements matching the selector's list. In the event of tie, the rule which matches with selector entry that carries the higher points will be used, or if they still tie, then precedence of rule entry in the rule file will be used to determine the final rule to use.

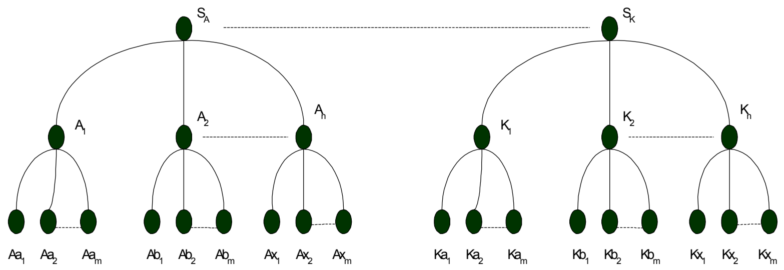
Mappings across sub-child nodes are done based on their attributes (content based). A file will be used to define the list of items (or contents) of each Web page (at category level) and also any of attributes for each of the items. The syntax for this item list file is:

Idxa:idxb:…:attra:attrb=>display.html

The entries idxx are indexes to the html page that contains all the information regarding the item. An example of these indexes could be the type of pet. The information about each type of pet is found in the corresponding html file. An item sorter engine will, at startup, sort out the indexes and their corresponding html files. This will allow the page contents to be arranged or displayed based on any of these indexes. The other set of entries attrx define the attributes of the item. When the visitor selects any of the items for browsing, the corresponding attrx will be tracked. Whenever the visitor browses a new page, the recommendation engine will check for items that have the same attrx and automatically include the corresponding html file for display (see Figure 1).

Our prototype system also incorporates means of generating a dynamic profile that changes as the visitor browses through the Web site. Implicit tracking does not require any explicit inputs or intervention by the visitor. Conventionally this is done either through use of user authorization, hidden form fields, URL rewriting, or cookies (Hunter et al., 2002). Although cookies offer an elegant

Figure 1. Web domain structure



solution to the stateless HTTP protocol when compared to the other three, it is also frowned upon by some visitors and as such are disabled (Mobasher et al., 1999; Cooley, Mobasher, & Srivastava, 1999). Instead, the tracking of visitors' activities is implemented through use of a session object on the server side (Hunter et al., 2002). This object will be used to record all the Web pages (tagged with IDs on the server side) browsed by the visitor during the current session, hence obtaining the profile of the visitor. However, a cookies mechanism is still implemented to provide the "remember" feature, in the sense that if the cookies feature is enabled on the visitor's browser, the activities on the Web site from the most recent visit will be available (and retrieved) during the next visit. This allows the system to build the visitor's profile immediately. Hence we are able to combine the static profiling (from cookies) with the dynamic one (tracked by session object) to build a profile that can "remember" a visitor's previous preferences and dynamically change itself as the visitor continues browsing the Web site.

In order to give priority to activities that occur more often and recent, a point system is used whereby the current session log is given heavier weight than those retrieved from the cookies so that the current activities will be more likely to be nominated into the visitor's latest profile. The activities log tracked by the session object will be given higher consideration during profiling in order for the system adaptiveness to be reflected accordingly and immediately to the changes in the visitor browsing behavior. In this design, a total of three activities logs are used (two from cookies if available, and the remaining one is from the current session object that tracks the current activities).

In order to demonstrate the adaptiveness feature, the Web site domain should consist items or products that have the following characteristics:

1. Products that can be easily categorized.
2. Selection of items or products should be able to reflect the taste or preference of visitor.
3. Certain form of relatedness between the products.

With the above considerations taken into the account, we implemented a Web portal using an online shop named My-Pet that sells the following products:

1. Pets
2. Books on pets
3. Accessories for pets
4. Food for pets

To demonstrate how the system functions, we selected the following list of categories:

Pets:	Bird, Dog, Cat, Hamster, Fish
Books:	How to care…, Diseases of…, Nutrition for …
Accessories:	Pet wears, Toys, Restraints
Foods:	Meals, Snacks, Supplements

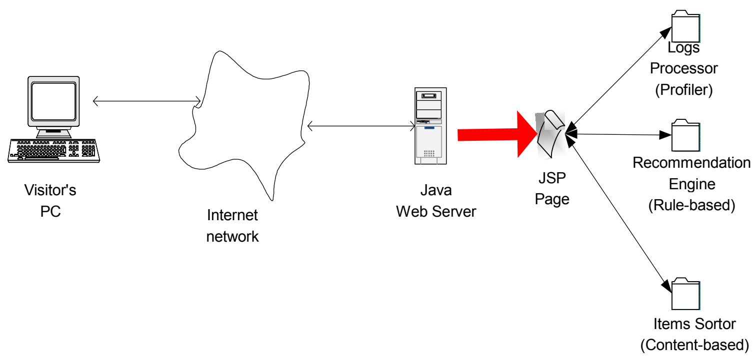
The My-Pet recommendation engine is based on the relatedness determination among its products. The relatedness determination for My-Pet is defined at three levels:

1. Relatedness between categories across products (e.g., pet dog and dog food and books on dogs);
2. Relatedness between categories in the same product (e.g., books on how to care for dogs and books on diseases of dogs and books on nutrition for healthy dogs); and
3. Relatedness at items level across products (e.g., food and accessory items from the same company/brand).

Items (1) and (2) are achieved based on the rules-base technique, while content-based filtering is used for item (3).

The server software architecture is decomposed into independent modules that have very similar structure. Each product has its own module that is responsible for presenting and generating its dynamic Web page con-

Figure 2. Software architecture



tents. The development platform chosen is Java Server Pages (JSP), which offers object-oriented components deployment. By developing the whole Web program in JSP and Java, the server program is OS-platform independent.

Each module is made up of the following components:

- JSP Page
- Logs Processor (JavaBean)
- Recommendation Engine (JavaBean)
- Item Sorter (JavaBean)

The JSP page is responsible for delegating the tasks to the respective components, and at the end presenting the results into HTML format for viewing by the visitor.

The Logs Processor component serves to log all the activities by the visitor and process the activities logs before submitting to the Recommendation Engine. It plays the role of profiling the visitor's activities. The Recommendation Engine is mainly used for determining product-to-product mapping based on the selector's list (profile) generated by the Logs Processor. The Items Sorter's main function is to read the list of product items and sort them such that they can be retrieved via means of indexing or key. This component is also used to retrieve an item attribute that is used for Content-Based filtering, based on the input determined by the Logs Processor component (see Figure 2).

IMPACT OF SYSTEM

The prototype system is implemented using a Java Server from JRUN which provides the container for running JSP and JavaBeans classes. The database stores all external data inputs. The Web server PC is installed with JRUN and the Web application. Customers can access the Web site using any Web browser.

To illustrate the effectiveness of this system in providing dynamic content generation, a series of user inputs and the subsequent system responses are tabulated.

From the trial run results obtained, it was observed that the system behaved as expected, providing the adaptive feature of generating Web contents based on users' activities on the Web site (see Table 1).Browsing Activities Web Content Generated

The system is able to demonstrate the following adaptiveness features:

Table 1. Results obtained from trial runs

Browsing Activities	Web Content Generated
Customer initially selects Dog category under the Pet section and chooses from the choice of displaying dogs based on the friendliness/loyalty. The customer then chooses Cat category under Pet section.	The system automatically displays the choices of cats for selection. The cats are displayed based on the degree of friendliness/loyalty to owners.
In continuation from above, the customer then selects the choice of displaying Cats based on feeding habits. User then re-selects the Dog category.	The system automatically switches from presenting cats to presenting dogs based on their feeding habits.
Customer selects Dog category under the Pet section. Customer then chooses Book product.	The system automatically presents books that are related to dogs.
Customer selects Supplements category under Food section. Visitor then selects Petsfriend (from the list of brands) and clicks the item "Best Choice Dog Cookies". Customer then chooses Book product.	The system automatically brings the customer to Nutrition category under the Book section and also displays the option for viewing book titles related to dog nutrition from Petsfriend.
Customer selects Dog category under Accessories product and then chooses Dog category under Books as well. Customer subsequently closes the browser before restarting again to browse the Web site again, but this time around selecting the Food product instead.	The system automatically forwards the visitor to the Dog category when the Food product was selected in this new browsing session.

1. the ability to automatically present the choice of viewing items in a page (e.g., what type of pets) based on visitor's previous preference;
2. the ability to automatically present Web contents that display the category that exhibits relatedness (as defined in Rule Files) to other products' categories browsed by the visitor previously;
3. the ability to generate an option to view list of items that has relatedness to other items that the visitor has visited or selected; and
4. the ability to generate a recommendation based on cookies retrieved from the visitor's PC.

CONCLUSION

We have developed a system that can adapt its Web contents based on visitors' activities on the Web site through combining rule-based with content-based filtering techniques—resulting in an implementation that is both flexible and can rapidly adjust its recommendations. Rule-based structure offers cross-product mapping. Content-based filtering takes the items' attributes into account when generating recommendations. The system transparently and seamlessly tracks the visitor on the server side and does not require explicit inputs (ratings or purchases or login account) to determine the visitor's profile dynamically.

My-Pet's system design utilizes the concept of category management, which is widely practiced in brick-and-mortar shop fronts and maps product taxonomy into a cyberspace virtual environment. The key to using category management is that it makes system expansion systematic and easy. In our illustration, we included a handful of products and categories. However, the system architecture provides a structure that allows more products or categories to be added easily. Sub-categories can also be added as long as each of them is given a unique ID page. A new set of relatedness rules can then be defined for these newly added elements. This is in fact a strength of rule-based implementation, where new linkages between product categories and subcategories can be added and removed as need arises. Rules may also carry different precedence values.

Such a highly adaptive system does have a weakness—it has taken away some navigation control from the user. It was noted in a 1998 survey (GVU, 1998) that 17% of Web users experience difficulty in returning to pages visited before. A system with an auto-recommendation feature is likely to fair worse in this aspect. Therefore, for future improvement to the system, a feature could be added to the system whereby a link page is created and this page contains all links to pages that were previously browsed by the user.

In addition, a search option can also be included. This search option indirectly provides a way for the visitor to tell the system his/her taste or preference. This serves as an excellent and accurate input in building a profile that even more closely reflects the visitor's preferences. Hence the system will be able to use a more accurate visitor's profile when generating recommendations.

KEY TERMS

Category Management: Classify and manage items based on some predetermined categories.

Clickstream: A sequence of mouse clicks.

Collaborative Filtering: Unveiling general patterns through "sniffing" through user's past activities.

Personalization: Customization to individual user's preferences and needs.

Portal: The entry node/point of navigation semantic unit for a Web site.

Profiling: Capturing individual user's interests and needs.

Self-Adaptive: Ability of a Web portal to automatically adjust its presentations to perceived user's preferences.

Session Object: Information items that capture characteristics and activities of a user during a Web session.

B2B E-Business

Robert J. Mockler

St. John's University, USA

INTRODUCTION

Every organization can be viewed from two perspectives. There are external processes such as procurement and sales, and internal processes such as management and operations, finance, marketing, and human resources.

This article primarily focuses on external, commercial e-business processes. B2B (business-to-business) e-business is the sale of products or services, or information exchange, among two or more businesses through electronic technology, usually involving the Internet, through a public or private exchange. The following background section gives a very brief general overview of B2B e-business history. In the main thrust of this article, we discuss making the B2B decision by examining key B2B business requirements and benefits, as well as describing basic approaches to B2B e-business implementation. In the subsequent section, the article provides a future outlook for e-business.

BACKGROUND

During the technological explosion of the late 1990s, virtually every company in the world was talking about B2B. The concept was sound and the possibilities were endless, so many companies rushed into implementing something, anything that would make them part of this new business revolution. As often happens when concepts are implemented, many unforeseen problems arise during the early stages of their application. Although the development of B2B e-business has provided opportunities for organizations to improve their purchasing systems and so enhance performance and profitability, it is not the magic solution once believed, but rather just another useful business tool when implemented under the right circumstances.

Despite the burst of the dot.com bubble and the global recession, online B2B trading exchanges continue to expand. Online B2B e-marketplaces have remained resilient by providing valuable advantages over off-line transactions, including lower costs for buyers, greater access to customers for suppliers, and increased transparency throughout the supply chain for all participants (Krell, 2002). For example, members of the WorldWide Retail Exchange, an online B2B exchange, have saved over $1 billion since 2000 when the exchange was founded ("Survey," 2004).

Internet-based B2B e-business tools help companies master a multitude of objectives, ranging from reducing raw material, process, and transaction costs as well as cycle times, error rates, and inventory, and it improves transparency (Hartman, Salehi, & Vallerien, 2003).

In 2001, B2B e-business represented about one third of all e-business volume on the Internet, but it was expected to grow at an accelerated rate and eventually become the largest segment of e-business.

MAIN THRUST OF THE ARTICLE

Before the appropriate B2B e-business implementation approach can be determined, a company needs to identify key business requirements and benefits. Once this has been established, the company can then choose from various implementation approaches the one that fits the determined requirements and benefits. The B2B implementation approaches discussed in this article have been derived from researching thoroughly company experiences as well as theoretical studies. Based on these experiences and studies, the ways companies have targeted their B2B implementation endeavors can be grouped into four basic approaches, which will be discussed later in this section.

Identifying Key Business Requirements and Benefits

Planning is the first step to the successful application of any e-business strategy. A company needs to identify key or core business processes in its specific company situation, and the benefits to be derived from e-business B2B applications within these key processes. A well-designed B2B e-business system can be extremely valuable in achieving basic strategic management objectives in many different areas of profit-generating enterprises including increasing efficiency and reducing costs, improving management control, and expanding revenues.

Improve Purchasing Efficiency and Reduce Procurement Costs

This was initially and continues to be a major application area for B2B. Procurement in its conventional form is a costly, labor-intensive, paper-based process. Purchasing personnel often complain that a high percentage of their time is spent on non-value-added activities such as data entry, correcting paperwork errors, expediting delivery, or solving quality problems. Managing supply chains through public or private online B2B exchanges enables companies to (a) directly improve their order-to-fulfillment cycle by streamlining work-flow and business processes so as to achieve better order processing and tracking, (b) better leverage company spending and increase return on investment, and (c) ultimately optimize overall procurement efficiency. This can literally save a company millions of dollars.

For example, Unilever, a major consumer-products company, was able to cut $902 million in procurement costs over a 2-year period, and by the end of 2002, was expected to have achieved more than $1.58 billion in total savings from procurement efficiencies with its new B2B system. These improvements were achieved through Unilever's replacement of a hodgepodge of procurement systems in use across dozens of product divisions with standardized e-procurement, online-auction purchasing management, and demand-planning systems (Hicks, 2002).

Improve Overall Controls

The information exchanged among companies and their suppliers through B2B portals creates a strategic partnership environment that identifies and builds partnerships with new suppliers worldwide, strengthens relationships and streamlines sourcing processes with current business partners, and rapidly distributes information and specifications to business partners. Internet-based buy sites enable companies to manage inventory levels more efficiently by providing access to demand levels through B2B portals. Through B2B exchanges, companies can receive rapid responses, shorten fulfillment cycles, and implement just-in-time procurement strategies, which help reduce lag times and allow companies to more effectively control inventory levels and so carry less inventory reserves on hand.

A good example of this is Cisco Systems. The sharing of information between Cisco Systems, a large Internet product provider company, and its suppliers on customer demand, product defect rates, and engineering reportedly enabled them to substantially reduce manufacturing recycle times and build better products (Corbitt, 2002).

Expand Revenues

The public exchange of information provided through B2B exchanges has allowed many companies that sell to other companies to reach a greater number of potential commercial buyers of their products, which has lead to increased sales. It also provides greater visibility between customers and suppliers. Web exchanges enable customers and suppliers to peer into one another's operations via a secure Internet connection, and decrease the suppliers' time to market with new products. Also, sellers gain instant access to global buyers, with over $1 billion in purchasing power.

B2B E-Business Implementation Approaches

There are four general B2B implementation approaches in use. The first is independent B2B marketplaces, such as Commerce One, Ariba, and Freemarkets. The second approach discussed is the private B2B approach, such as the one found at Unilever and Cisco. A third commonly encountered B2B implementation approach involves consortiums, as have been formed in the auto, aviation, chemical and petroleum, building-materials, aerospace, and retailing industries. There is a fourth, transitional approach that was implemented by GE (General Electric), for example.

Independent B2B Marketplaces

The first approach discussed, which involves an existing company finding an independent B2B marketplace (e-marketplace), is a commonly encountered one. Many companies begin the B2B integration process by focusing on the purchasing cycle. Obtaining goods from suppliers using independent B2B marketplaces very often is the fastest and most economical way to acquire B2B capabilities. This is done by selecting an independent B2B provider, such as Commerce One, Ariba, or Freemarkets, to come in and integrate the company's internal systems with the selected independent market exchanges (e-marketplace).

An independent B2B marketplace or e-marketplace is an Internet destination where businesses from around the world can come together to buy and sell goods and services in an auction format. The destination and the auction are controlled and managed by the independent B2B provider. Buyers prepare bidding-project information and post them on the site. Suppliers then download the project information and submit their bids. Buyers evaluate the suppliers' bids and may negotiate electronically to achieve the best deal. The buyer then accepts the bid of the supplier that best meets their requirements, and the sale is finalized. Purchasers and suppliers can either pay a general fee, a per-transaction fee, or a combination of the two to the B2B provider, otherwise known as the Web host. Each one of these B2B providers has its own software applications and host Web sites.

For example, Commerce One uses its trademarked Enterprise Buyer proprietary software to link companies to all e-marketplaces of the Global Trading Web community on its Web site CommerceOne.net. Commerce One's Global Trading Web is the world's largest B2B trading community and provides unprecedented economies of scale for buyer organizations (http://www.commerceone.com/company/global_trading.html). This software can be purchased and installed by an existing company in order to obtain access to the Global Trading Web community that enables commercial transactions to take place between e-marketplaces.

Private B2B Exchanges

The second approach discussed is private B2B exchanges. A private B2B exchange is an e-marketplace created by a single company to provide e-business capabilities to its business units and preferred trading partners (http://www.commerceone.com/company/global_trading.html). In 2000, in the early stages of e-business development, many companies trying to be ahead of the curve jumped into public B2B marketplaces usually run by third parties. They soon discovered that there were many inherent problems. Although at times they were obtaining better prices, many times the diminished quality and increased rate of defects in the products were hurting their bottom-line gain. There were also problems in returning defective items, receiving orders when promised, and maintaining continuity in the supply chain (Prince, 2001).

Today, more and more businesses with the necessary resources are developing their own private exchanges. The e-market focus of some companies, such as Wal-Mart, has turned away from public exchanges because finance, supply chain, purchasing, and IT managers realized that, in many cases, their systems and employees were ill-equipped to handle the technical and procedural requirements of large public exchanges (Krell, 2002). Wal-Mart has invested in middleware or enterprise application integration (EAI) technology to link its internal applications together and to a few (up to 12) critical suppliers in the supply-chain process. The real value of e-procurement, e-billing, and electronic supply-chain initiatives is realized through real-time, hard-coded integration (Krell).

Other companies, such as Siemens AG, have turned to private exchanges in order to limit access to procurement information (Konicki, 2001). Siemens prefers a private exchange because it does not want its competitors to have access to its production plans. Private exchanges are gaining momentum because, for those companies that have the resources to develop them, they are able to deliver the capabilities many public e-marketplaces promised but have not delivered: the ability to centrally manage procurement across many business units, the ability to enable real-time design collaboration and integration with back-end systems, and the linkage of production-, inventory-, warehouse-, and order-management systems.

Consortium

The third B2B implementation approach discussed is a consortium: a quasipublic online marketplace approach. A consortium is a group of companies within a particular industry establishing an exchange connecting each of them and their suppliers. Today, there is a consortium exchange in almost every industry. Consortium members fund most of these exchanges.

One example of a consortium is found in the auto industry. Ford, General Motors, and DaimlerChrysler together established Covisint.com as a global, independent e-business exchange. Covisint is the central hub where original equipment manufacturers (OEMs) and suppliers come together to do business in a single business environment using the same tools and interface. Covisint enables companies to compress planning cycles and enhance supply-chain planning (http://www.covisint.com/about/). In February 2002, Covisint was handling 100 million supply-chain procurement transactions per month. These transactions take place between the exchange's members and more than 2,000 of their suppliers (Krell, 2002). In 2004, however, Covisint experienced some major problems that led to the acquisition of the company by two other firms, Compuware Corp and Freemarkets, Inc. (Sullivan & Dunn, 2004).

Transitional

The fourth approach involves an existing company moving from a private B2B exchange to an independent, external marketplace venture. A good example of this would be General Electric (http://www.gegxs.com/gxs/about). General Electric, given its vast capital resources and diversity across many industries, decided to develop and establish its own B2B software and private B2B operations. Subsequently, it used this experience to set up its own external, independent B2B exchange (called GE Global eXchange Services) to compete with the likes of Commerce One and Ariba in the B2B provider market. This type of approach would require a large amount of resources and is therefore not practical for many smaller businesses. Even for businesses the size of GE, the resources necessary to maintain such an exchange can become cost prohibitive (Barlas, 2002).

FUTURE TRENDS

B2B e-business experienced an initial boom based on unrealistic projections and expectations, followed by a few years of gloom based on the process of a new technology outgrowing its adolescent phase of development.

Recent projections by *Standard & Poor's*, however, indicate that the future of B2B e-business looks bright. The growth of B2B e-business is forecasted to reach $3.6 trillion in 2005, $4.9 trillion in 2006, and $6.4 trillion in 2007 (Kessler, 2004).

One of the more successful B2B implementation approaches for the future seems to be that of large, private exchanges, such as Ariba and Freemarkets. According to Ordanini, Micelli, and Di Maria (2004), large, private B2B exchanges especially represent a promising phenomenon and offer superior capabilities of generating higher turnovers than smaller niche exchanges.

Electronic B2B transactions, as shown earlier, are already improving the competitiveness of enterprises through sinking costs, faster information, and enhanced flexibility, among other benefits. In the future, however, B2B will be not only the application of technologies, but also a motor of change for economic processes and industry structures: B2B applications have an enormous potential for the alteration of economic processes in the direction of the knowledge society (Schedl & Sülzle, 2004).

In the B2B e-business arena, increased activity through mergers and acquisitions is expected to continue into the future, not only in the middle market among small- and medium-sized competitors, but also among the larger B2B exchanges ("M&A Outlook," 2005).

In the near future, more and more companies, especially finance and investment firms, will be adding multilingual dimensions to their B2B e-business strategies ("IndyMac Bank," 2004).

Manoj Nigam, president of Micro-D, predicts that in 2005, we will see leading retailers and manufacturers "completing the implementation of what we define as a 'full-circle' B2B" (Carroll, 2004). Nigam describes this as a sales and transaction process that begins with accurate and standardized electronic catalogs from manufacturers and flows through to purchase orders and PO acknowledgments.

Because of these and other trends not mentioned here, B2B e-business seems to be on the path to a healthy recovery, ensuring a profitable marketplace for its many competitors.

CONCLUSION

The recent economic downturn has forced companies, with reduced budgets and shrinking bottom lines, to perform internal analysis in order to determine which B2B implementation approach, if any, to select and integrate in order to achieve the maximum benefits of e-business. Especially in light of the upcoming B2B e-business recovery and the positive future trends in this industry, as indicated above, a company should carefully select and integrate B2B e-business into their existing business in a way that is most appropriate for the company's current situation, which makes this process a situational, contingency-based one. Organizations should be aware that although e-business may provide many benefits and the future looks bright, it is not the magic solution it was once assumed to be but rather just another potential business tool to be implemented under the right circumstances.

KEY TERMS

Back-End System: The support components of a computer system. It typically refers to the database-management system (DBMS), which is the storehouse for the data.

Business-to-Business (B2B) E-Business: The sale of products or services, or an information exchange, among two or more businesses through electronic technology, usually involving the Internet, through a public or private exchange.

Consortium: A group of companies within a particular industry establishing an exchange connecting each of them and their suppliers.

E-Business (Electronic Business): The administration of conducting business via the Internet. This would include the buying and selling of goods and services, along with providing technical or customer support through the Internet. E-business is a term often used in conjunction with e-commerce, but it includes services in addition to the sale of goods.

Enterprise Application Integration (EAI): The process of coordinating the operations of various applications across an enterprise so they can perform as an integrated, enterprise-wide system. This term also refers to the set of commercial applications designed to facilitate this process.

E-Procurement: E-procurement is the business-to-business purchase and sale of supplies and services over the Internet. An important part of many B2B sites, e-procurement is also sometimes referred to by other terms, such as supplier exchange. Typically, e-procurement Web sites allow qualified and registered users to look for buyers or sellers of goods and services. Depending on the approach, buyers or sellers may specify prices or invite bids. Transactions can be initiated and completed. Ongoing purchases may qualify customers for volume discounts or special offers. E-procurement software may make it possible to automate some buying and selling. Companies participating expect to be able to control parts inventories more effectively, reduce purchasing agent overhead, and improve manufacturing cycles. E-procurement is expected to be integrated with the trend toward computerized supply-chain management.

Independent B2B Marketplace (or E-Marketplace): An Internet destination where businesses from around the world can come together to buy and sell goods and services in an auction format.

Middleware: Software that sits between two or more types of software and translates information between them. Middleware can cover a broad spectrum of software and generally sits between an application and an operating system, a network operating system, or a database-management system.

Private B2B Exchange: An e-marketplace created by a single company to provide e-business capabilities to its business units and preferred trading partners.

B2C Success at Wishlist.com

Delyth Samuel
University of Melbourne, Australia

Danny Samson
University of Melbourne, Australia

BACKGROUND OF THE BUSINESS

This article explains how and why, during and through the dot.com bubble that was built and burst, one new economy company in Australia survived and prospered. The challenges were severe. The infrastructure, funding for development, and consumer behavior were key challenges that had to be overcome.

Between 1999 and 2000, around 190 Australian companies evolved selling something over the Web. In early 2000, local e-tailers such as Dstore, ShopFast, ChaosMusic, TheSpot.com, and Wishlist.com.au were being discussed as shining examples of a new way of retailing: smart, aggressive companies that were showing traditional retailers how to operate in the new economy (Kirby, 2000). Then it all started going wrong. Examples are as follows:

- ChaosMusic's shares, issued at $1.40 in December 1999, finished from 1999 to 2000 at $0.28 as the online music retailer slashed its marketing budget and staff.
- The share price of Australia's other online music retailer, Sanity.com, peaked at $2.05 soon after the company was listed in December 1999; on June 30, 2000, it was $0.44.
- On June 29, 2000, Australia witnessed its first major e-tailing failure when the department-store retailer David Jones acquired the assets of TheSpot.com, a toy and health and beauty products e-tailer that ran out of money after spending $12 million in 14 months.

Later in the same year, on November 28, 2000, the founders of Wishlist.com.au, Huy Truong and his sister Jardin Truong, accepted an award at the Australian Internet Awards ceremony for the most entrepreneurial Internet site, an award given for an Australian Internet-related achievement that is innovative, provides strong current or future financial returns, and demonstrates rapid business expansion via a unique business strategy. The site also won as the best e-commerce site on the Web. The head judge said, "Wishlist didn't follow the standard supermarket model on the Internet. It's an adaption of a gift store buying presents for other people not just for yourself."

He said the judges were impressed with the novelty of the delivery model, whereby Wishlist.com.au had arranged with the oil company BP to deliver parcels to BP service stations that can be picked up by customers at anytime (Lindsay, 2000). Huy Truong was also awarded *B&T Weekly's* 2000 e-Marketer of the Year Award.

Golden, Hughes, and Gallagher (2003) conducted a descriptive study that examined the key success factors related to e-business in the retail sector of Ireland. Through their postal survey, they found that the early adoption of Internet technologies and information systems expertise were important factors in contributing to success. Loane (2004) has suggested that there is now significant evidence that many new firms are embracing the use of the Internet from their inception. This is clearly the case with Wishlist.com. They suggest that the Internet is not just an improvement tool but a core capability, including IT competency.

Global Reviews, Australia's online retail performance and reliability gauge for e-consumers, in December 2001 stated that Wishlist.com.au was the standout Australian online retailer, achieving an overall score of 97%, with a perfect rating in four of the five evaluation categories: fulfillment, site usability, security, products, and customer service.

DESCRIPTION OF THE BUSINESS

According to cofounder Huy Truong (personal communication, September 15, 2003), Wishlist has succeeded because it is "[n]ot just a Web site you go to for a discount. We are building an online shopping experience around important events in people's lives."

Wishlist also provided a convenient corporate gift-giving service, which proved popular. Companies can give employees and customers goods and services, which might often be seen as nice indulgences, purchased as gifts from Wishlist.

The Truong Family

Jardin Truong and her brother Huy were young when they arrived in Australia in 1978 after escaping Vietnam in a leaking fishing boat with their parents, younger sister Dinh, younger brother Cameron, and five other families.

Getting Started

Jardin Truong dreamt up the idea for a business that could take orders for gifts using the Web, making sure that deliveries met deadlines. Wishlist was founded in late 1998 to realise this idea.

Gift giving was an opportunity that was already being exploited in the United States, but Jardin and Huy recognized that people did not always find it a fun and enjoyable process, sometimes forgetting special occasions and finding themselves in the pressured situation of trying to get the right gift in a short amount of time. They thought they could "[p]ut the fun back where it ought to be, which is in the giving of the gift, and then for everything else before that [they would] use technology" (Huy Truong, personal communication, September 15, 2003).

The idea captured the imagination of the cofounders, including Huy Truong and his wife, who is a management consultant and e-commerce expert with Price Waterhouse Coopers, and their brother-in-law David Pope, a multimedia expert, who would design the site.

The business plan was developed in January 1999, and the cofounders left their jobs in March and April 1999 to start work on its implementation. Between them, they invested around $80,000 along with free labor, and worked from a room in North Melbourne with a weekly rent of $35. They also gained seed funding of around $1.25 million.

Money was successfully raised on the basis of their business plan, which predicted that profitability would be achieved in 4 years, by 2003, and of the high-calibre team that would be managing the venture.

The Wishlist.com.au Web site was first launched in July 1999. At around the same time, the team undertook a further round of capital raising to get the funds that would enable them to rebuild and scale up the site, and to launch a campaign for Christmas 1999.

The site had 50,000 to 60,000 people visiting each month in its first 3 months of operation, and by Christmas 1999, Wishlist.com.au was delivering gifts to around 30,000 homes.

In April 2000, they successfully raised a further $15 million in capital to scale up the business, making investments in online ordering and fulfillment operations in terms of staffing and infrastructure, followed by another $10 million to buy out the failing Dstore 18% shareholding in Wishlist.

The founders have evolved their business model through various alliances and acquisitions, and through the development of other services and reward programs for partners.

According to Huy Truong (personal communication, September 15, 2003):

What we are doing is a totally new industry with few established rules—we have had to invent it as we have gone along. Although we had access to capital markets, technology and customers like any other business, it is how we have harnessed it to benefit the company and customers. There is no "corporate DNA" which defines why and how we do things—we are in the process of creating our own.

Truong (personal communication, September 15, 2003) also said, "You must have a strategy—not a 100 point plan. The sustainable competitive advantage is being able to change—the environment today is different to when we started. Strategy evolves."

Developing a Customer Base

Huy and Jardin decided that there were two options for their online retail business: Be really product driven or build a business around a consumer need. They thought that the latter would be a higher risk but was more sustainable in the long run.

From the outset they counted on two revenue streams: corporate gifts and individual gifts for customers located mainly on the eastern seaboard of Australia. Another distinct customer segment also emerged when orders started arriving from Australians overseas who wanted a gift delivered to friends or family in Australia in their absence.

Getting Traffic

Wishlist had to compete for consumer attention at a time when competitors like Dstore were spending big dollars, believing that a large marketing budget would generate sales growth that would then lead to profit. From June 1999 to June 2000, Dstore reportedly spent $4 million on media advertising, with 40% of it spent on television, resulting in unprompted customer awareness of 20%, but apparently only resulting in $250,000 in sales (Howarth, 2000).

The Truongs preferred to take a less costly approach to building their brand, believing that there were much smarter ways to drive revenue and attract and keep a loyal customer base. They implemented a number of coordinated strategies that provided discount incentives to get customers online and ordering from them, and believed that combining this with a superior shopping experience and customer service would give them the best chance of getting customers back again without the discount incentives.

They launched an associate program in September 1999 giving small Internet service providers and other Web sites the right to use the Wishlist logo and earn 15% commission on any sales they generated. With a goal of 1,000 associates by Christmas 1999, within days of the announcement, 30 associates had joined up. This campaign was combined with a customer offer of a $10 voucher for all purchases over $30 to create pull from the other direction.

The Truongs view was that spending big on marketing would not only add to their costs, it would also take their focus off the main game, preventing them from investing in the core of the business: the technology, the people, and automation. They preferred to build slowly and steadily from the ground up, managing growth so that the customer experience would not be compromised. The key issue would then be how to retain customers.

The concept of membership was developed to offer a number of benefits to those that signed up, including the following:

- Member discounts on products in every department
- A gift reminder service where members receive e-mails to remind them of special occasions
- The ability to save gift ideas for friends and family so that they are easy to find again and can be purchased later
- An account summary that lets customers track past purchases and current orders, as well as change membership details
- A gift registry that customers can set up to let friends and family see it from anywhere in the world and order gifts from them
- A newsletter letting members know about the latest news and gift ideas

Membership would allow them to collect data on how their site was being used, which could be used as input to site and service upgrades.

One of Wishlist's unique features in the early days was the site itself: clean, uncluttered, and easy to use, with a sophisticated search function to search by age, relationship, interests, occasion, price range, and personality type to help customers find what they are looking for, and a simple, user-friendly payment process that stores customer details so that they do not have to be reentered when ordering again. Drop-down boxes clearly tell the customer what he or she will have to pay for delivery and when to expect the item to arrive, and also give an express-delivery option for an extra charge.

This was vastly different from many other e-tail sites at the time, which were cluttered, difficult to navigate, and consequently plagued by "abandoned shopping trolleys": half-made customer transactions that just got too hard to complete.

Developing the Technology

According to Huy Truong (personal communication, September 15, 2003), much of Wishlist's success rests on creativity and ideas, and then on implementation and execution:

Whilst there are lots of amazing ideas to do with the Internet and technology there is a tension between being innovative and just getting on with it and with balancing what's an investment and what's an ongoing part of the business. You need to pick 1 or 2 of the best ideas and run with them.

As Huy Truong (personal communication, September 15, 2003) put it, "Wishlist wants to be leading edge, not bleeding edge." In an era when the technology and its possibilities were and are very enticing, Wishlist has remained very pragmatic about not letting technology run the business when the business' case does not actually justify it, although everyone in Wishlist is still expected to know how to use the technology.

The company uses technology to gear up the whole business around unparalleled service levels instead of competing primarily on price, even though they often sell at 5 or 10% below retail. This explains to a large extent why much of the process, including most technology and design work, is retained in house.

Some of the failures of the "tech wreck" were attributed to businesses that had searched for a new business model in order to try and take advantage of the new technology, presuming that just because e-tailing was technically possible, it would also be successful, and that through rapidly building a customer base and revenues, profits would follow. The problems arose because the cost of acquiring customers was greater than the revenues that could be generated (Bartholomeusz, 2001).

Others tried to use e-commerce technology to automate existing business, another approach that has not worked very well, especially in terms of the logistics of fulfillment (Kirby, 2000). Traditional retailers were finding it difficult to implement a successful e-tailing site, according to Huy Truong (Needham, 2000), because "they're no good at web development; their distribution is geared to in-store sales and the behaviour of on-line consumers is foreign to them."

Wishlist, on the other hand, has consistently worked with a clear business plan, and while technology is central to the business model, it is used as a means to an end. It has mastered the technology and online selling so well that it now helps other retailers build areas within Wishlist and is providing them with the fulfillment infrastructure as well as helping them to understand online consumer behavior.

Taking Control of the Consumer Experience

Rowley and Slack (2001) have considered the important factors required to better understand both theoretical and practical issues in e-retailing and distribution. They argue that the critical factors to better understand are the following.

- Cognition, which relates to how consumers respond to the e-interface
- Customerization, which refers to the personalization of the Web site
- Accumulation, which looks at the overall and cumulating effect of consumer behavior and context, and analyses the relativities between the old and new that economy retailing offers

Ishikawa, Ohta, Yokoyama, Nakayama, and Katayama (2002) suggest that the complexity of Web sites can be a limiting factor in their effectiveness; elements such as ill-structured design or indeed having too many pages can detract from the effectiveness of this channel of communication and sale. To deliver on its promise of a superior customer-service experience, Wishlist recognized that it needed to have control over the whole end-to-end consumer experience, at least to start with, because in the beginning its success would be determined by its ability to convert consumers from traditional shoppers to online shoppers.

A shopper's first experience would be a critical determinant of whether he or she would return. Once customer confidence had been achieved, the company would be able to look at the efficiency side of the business to control costs, but above and beyond all was the belief that it was the consumer experience that mattered, not the cost.

The Consumer Experience

The consumer-experience concept is a core guiding principle for Wishlist, and timely delivery with a product looking like it was supposed to was central to this.

After visiting various warehouses that packed clothing or technology parts for businesses, Huy found that their staff and operations were so focused on cost and efficiency that they would find it difficult to change their approach for dispatching Wishlist orders. Whilst competitors like Dstore were saying that there was no way any e-tailer could make the economics of fulfillment and logistics work if it did it on its own (Howarth, 2000), Huy Truong disagreed, seeing control over fulfillment as essential to ensuring customer satisfaction and being able to develop a loyal customer base.

Huy decided that Wishlist would fill its own orders and allocate the cost of packing and delivery to its marketing budget. Over the Christmas period in 1999, 120 students were recruited for presentation skills to work in the warehouse. They were responsible for writing dictated messages on cards accompanying gifts, as well as packaging the gift in the wrapping paper selected by the customer and tying the bows.

At this time, Wishlist used Australia Post to pick up parcels and deliver, but late deliveries at Christmas prompted the need for faster delivery, and they changed to TNT, primarily a business-to-business courier, who could offer three pickups a day, although at the time they primarily operated in the business-to-business market and did not offer after-hours delivery.

Automation is a key part of Wishlist's strategy for fulfillment, too. In October 2000, Wishlist upgraded its warehouse to speed up its distribution process, with new conveyor belts and robotic machinery installed, enabling it to handle 40,000 transactions a week.

Getting Over the "Last Mile" Problem

Ping and Chang (2004) propose a model of e-business strategy in which they argue for a holistic dynamic and dialectical properties. They argue for the use of strategic alliances and for the e-business approach to be connected to the business' overall strategy and business model. Wishlist has done this with its alliances with oil retailer BP, airline Qantas, and numerous other companies that enhance its marketing and distribution capabilities and reach.

Perhaps the most innovative move made by Wishlist was when it announced its strategic alliance with BP in August 2001, creating a delivery network initially of 250 inner city BP petrol stations, operating 24 hours a day, 7 days a week. With 1,200 BP outlets Australia-wide, Wishlist will eventually have after-hours delivery to most parts of Australia, and customers will have a much better delivery service, being advised via their mobile phones that their gifts have been delivered and are available for collection. Leonard and Cronan (2003) have pointed to the importance of supply chain management in electronic commerce and also in EDI (electronic data interchange) aspects of distributor-retail relationships. They point to the required core capabilities in replenishment as being critical to e-business success in both retailing and industrial procurement.

Exclusivity was an important component of being able to integrate technology systems and enable the tracking of products once they had left the Wishlist warehouse. This is what Wishlist refers to as the "last mile" of fulfillment, in which most of the problems associated with delivery occur and where e-tailers were failing to deliver on their promise to customers. As Huy Truong (personal communication, September 15, 2003) said on the announcement of the alliance,

Australian customers have embraced the convenience of purchasing online but the issue of controlling the "last mile" (delivery into the hands of the customer) has been a challenge for the whole e-tailing industry since day one. I believe this alliance will provide the ideal solution for our customers.

Indeed, around 30% of all of Wishlist's customers now use the BP-Wishlist service, making it the most widely used delivery system that Wishlist operates.

The Right People

Wishlist is the brainchild of Jardin Truong, but much of the success of the business can be attributed to the whole family, in particular the working relationship of Huy and Jardin. For Huy and Jardin, working together has been an experience. When they first started, they found that the family relationship was an enormous benefit because there was an established trust and a single focus that allowed them to start building the business.

Wishlist's structure is flat, with only three layers. Huy tries to keep people fully informed of what is going on, even at the risk of information overload. Huy says that as the business has grown, they have brought in skills from outside, with as many as 350 employees and contractors working for them during peak periods.

Setting Up Retail Alliances

Huy Truong always anticipated that in time, off-line retailers would move online. Having a gift site was important as it would mean that they would not be competing head to head with such retailers, and in fact could potentially be in a position to help them build their e-tailing businesses. This approach has already enabled them to offer off-line retailers such as OshKosh B'Gosh, Lego, Sony, Esprit, Fisher Price, Alessi, Kodak, Scanlan & Theodore, and Jan Logan a new avenue of distribution complimentary to their current channels.

Having developed the credibility and performance record to give other retailers confidence in its e-commerce ability, Wishlist wants to expand its technology provider service.

Most significantly, on December 1, 2000, Wishlist announced that it had made just such an alliance with Country Road. The Country Road site that would be developed would exploit the marketing and merchandising strengths of Country Road and the e-commerce and infrastructure strengths of Wishlist.

Following this, in June 2001, Wishlist and Sanity Music announced the imminent launch of a cobranded online store, offering Australia's largest range of music and DVDs online.

LESSONS LEARNED

When asked what it is that has made Wishlist survive the tech wreck and its competitors, Huy Truong points to a number of factors that he believes has influenced its survival and growth.

- **Focus:** They have never tried to be all things to all people. From the outset, they decided they would be a gift service and had to perform against the various critical success factors that entailed. They have never tried to be a department store or a traditional business using e-commerce, and whilst they have adapted their business plan, the company core purpose is still the same: gifts. They have always been realistic about what they would achieve and when, and have kept faith with their investors with this approach.
- **Revenue Streams:** They always planned for two revenue streams: corporate and retail. At first, retail accounted for around 70% of their business, but the ratio evolved to more like 50:50.
- **Relationships:** They have the ability to make partnerships, such as building and operating the Country Road e-commerce site, giving them an additional service revenue stream, access to inventory, and a share of the customer base. It is a Country Road site, but is branded jointly with Wishlist.
- **The Quality of Customer Service:** This has been crucial right from the word *go*. They encourage their call-centre staff to spend time with their customers to make sure problems are resolved rather than getting customers off the phone as quickly as possible.

KEY TERMS

Customerization: The personalization of a Web site.

Fulfillment: The capability to deliver that which is transacted.

Infrastructure: The underlying resources that provide the necessary capability for achieving outcomes.

Security: The capability to be reliable in delivering goods and information, and to keep confidential and safe that information and resources.

Strategic Alliance: An agreement between two or more to engage in business transactions, or shared resources or ventures to their mutual benefit.

Benchmarking Local E-Government

Tan Yigitcanlar
Griffith University, Australia

Scott Baum
Griffith University, Australia

INTRODUCTION

Increasingly, almost everything we do in our daily lives is being influenced by information and communications technologies (ICTs) including the Internet. The task of governance is no exception with an increasing number of national, state, and local governments utilizing ICTs to support government operations, engage citizens, and provide government services. As with other things, the process of governance is now being prefixed with an "e". E-governance can range from simple Web sites that convey basic information to complex sites that transform the customary ways of delivering all sorts of government services. In this respect local e-government is the form of e-governance that specifically focuses on the online delivery of suitable local services by local authorities.

In practice local e-government reflects four dimensions, each one dealing with the functions of government itself. The four are: (a) *e-services,* the electronic delivery of government information, programs, and services often over the Internet; (b) *e-management,* the use of information technology to improve the management of government. This might range from streamlining business processes to improving the flow of information within government departments; (c) *e-democracy* the use of electronic communication vehicles, such as e-mail and the Internet, to increase citizen participation in the public decision-making process; (d) *e-commerce,* the exchange of money for goods and services over the Internet which might include citizens paying taxes and utility bills, renewing vehicle registrations, and paying for recreation programs, or government buying office supplies and auctioning surplus equipment (Cook, LaVigne, Pagano, Dawes, & Pardo, 2002).

Commensurate with the rapid increase in the process of developing e-governance tools, there has been an increased interest in benchmarking the process of local e-governance. This benchmarking, which includes the processes involved in e-governance as well as the extent of e-governance adoption or take-up is important as it allows for improved processes and enables government agencies to move towards world best practice. It is within this context that this article discusses benchmarking local e-government. It brings together a number of discussions regarding the significance of benchmarking, best practices and actions for local e-government, and key elements of a successful local e-government project.

BACKGROUND

Local e-governance is like other advancements involving the use of ICTs. It is seen as somewhat of a revolution, with many researchers considering e-governance as part of a new vision of local government for the 21st century (Jones & Crowe, 2001; Kearns, Bend, & Stern, 2002; Lenk & Traunmuller, 2002; Macintosh, Malina, & Whyte, 2002; OECD, 2001; Pardo, 2000; Socitim & IDeA, 2002). The definitions of local e-governance differ but read something along the lines of "the use of ICTs by local councils to enhance the access to and delivery of local services to benefit citizens, business partners, and employees" (VanDermeer & VanWinden, 2003: pp. 411), and tend to include those activities such as the type referred to above. According to Mahizhnan and Andiappan (2002, p. 1), local e-governance means more than simply technologizing government.

It requires a fundamental rethinking of governance itself and ... a re-inventing of local government ... e-government re-examines the organizing principles of bureaucracy and governance, re-defines the objectives and deliverables of local government and re-deploys the resources available.

The history of local e-government technology applications goes back to the 1990s, to the early days of the Internet. For example in UK, e-government efforts started in November 1996 with the publication of the "Government Direct Green Paper" (Government Direct: A prospectus for the Electronic Delivery of Government Services), outlining the way in which Government might make fuller use of ICTs within Government departments (including local councils) and in its dealings with citizens and businesses. Publication of the first version of the "e-Government Interoperability Framework (e-GIF)" in October 2000 set out national and local governments' technical policies and standards for achieving interoperability and information systems integration across the public sector. In particular, it adopts XML (extensible markup language) as the primary standard for data integration and presentation on all public sector systems. It also defined the essential pre-requisite for joined-up and Web enabled government, the e-GIF is a cornerstone in the overall e-government strategy. And the launch of the "UKonline.gov.uk" citizen portal, the "one-stop shop" for electronic public services for citizens in December 2000 was one of the most important steps of establishing e-government for UK (IDGES, 2005) (see Relyea & Hogue, 2004 for more information on the history of e-government).

As local e-government practices are becoming more wide spread, governments have realized the significance of developing standards and benchmarking local e-government. The benchmarking efforts and developed standards are working as a visionary guide for federal, state, and local government authorities to adopt ICTs for their e-governance practice.

Benchmarking Local E-Government

Benchmarking can be described as the process of searching for, and achieving, excellent levels of performance. This is achieved through a systematic comparison of performance and processes in different organizations, or between different parts of a single organization, to learn how to do things better. Its purpose is continuous improvement in levels of performance, by identifying where changes can be made in what is done, or the way in which things are done (CIPFA, 1996). The effective use of benchmarking can lead organizations to a best value.

Benchmarking of e-government projects, special local government procedures, as well as technical operations (e.g., data exchange formats) will result in uniform best-practice solutions. This will also prevent redundant developments, thus enabling a considerable increase in the economic efficiency of local e-government.

Benchmarking of e-governance practices and processes has tended to take two forms. There are those who have attempted to benchmark the readiness of societies and local councils to adopt e-governance (Yigitcanlar, 2003) and those who have looked at the e-governance tools and content (Mahizhnan & Andiappan, 2002). The former is aptly illustrated in the United Nation's Online Network in Public Administration and Finance's global e-governance readiness report (www.unpan.org/egovernment4.asp). That report, released in 2004, presents an index ranking of the countries of the world according to two primary indicators: (a) the state of national and local e-governments' readiness; and (b) the extent of e-participation. Countries including the United States, Denmark, and Sweden score highly on the e-government readiness index, while the UK, the United States, Canada, and Singapore score highly on the e-governance participation index.

Reflected in this index of e-governance "readiness" is the suggestion that in developing a comprehensive set of e-governance tools societies pass through several stages. Four stages have been suggested: emerging, enhanced, interactive, transactional, and seamless. *Emerging* is when a local government Web presence is established through a few independent official sites and information is limited, basic, and static. *Enhanced* is when the content and information is updated with greater regularity. *Interactive* is when users can download forms, contact local council officials, and make appointments and requests. *Transactional* is when users can actually pay for services or conduct financial transactions online. *Seamless* is when total integration of e-functions and services across administrative and departmental boundaries takes place.

As of 2001, 88% of the UN Member States have made a legitimate effort to commit to some form of national and local e-government; that is 169 countries have an established online presence with official government Web sites. However, for over a quarter of the countries, the content of official Web sites consisted of static and insufficient information often of a public relations nature and consistently with strong political overtones. Such sites can hardly be described as service delivery or considered citizen-centric since they are not a medium to elicit useful feedback (UN, 2002). Although there are different stages of e-government, some of the countries' e-government schemes did not fit in any of them.

Benchmarking of the processes and content of local e-governance is often of more importance as this aids government departments in building world class e-governance presence and is often associated with best practice examples. The process of benchmarking can involve several steps, but the key factors that appear to be critical to the effective use of benchmarking can be summarized as follows (IDeA, 2004):

- Developing an organization's capacity to learn from other operators in the field or market, or from others who have carried out a similar service or thematic best value review,
- Orientating an organization's future to be open to new ideas on how to do things,
- Effectively and routinely collecting service and process data to enable valid comparisons to be made,

- Connecting appropriately with market leaders or service providers recognized as best in class, and
- Acknowledging that benchmarking is not an end in itself but more a critical component or even building block in continuous service improvement processes.

Formal benchmarking of e-government process can be seen in the results of the Annual Global E-Governance Report (www.insidepolitics.org/egovt04int.html). Developing an index based on the content of government Web sites across 198 nations around the world. The specific areas of interest included in the index include the extent to which Web sites offer publications and databases, the extent to which they offer online services such as online transactions and the extent to which the Web sites include visible statements regarding privacy and security. An index based on how the 198 nations ranked overall provides nations with a means of benchmarking their performance and comparing it across time (indices prepared for 2001, 2002, 2003, and 2004). The top country in the ranking for 2004 was Taiwan at 44.3%, suggesting that for each Web site analyzed, Taiwan has just less than half of the features important for information availability, citizen access, portal access, and service delivery. Other nations that score well on e-government include Singapore (43.8%), the United States (42.9%), Canada (40.3%), Monaco (39.0%), China (37.3%), Australia (36.7%), Togo (36.0%), and Germany (35.0%).

Over and above benchmarking exercises the process of identifying best practice examples is also important. There are several examples of best practice in e-governance. The Annual Global E-governance Report discussed in the previous paragraph outlines several examples including Taiwan, Singapore, and the U.S. The Singapore government, for example, has purposely pursued a strong e-government policy. A Singapore government tag-line reads "many agencies, one government". The strategy to achieve this, as set out in the e-Government Action Plan, is to deliver integrated electronic services that are customer centric and accessible online, anywhere, anytime. For local governments, best practice examples are also present and local e-government in Minnesota (U.S.) can be given as an example. In Minnesota, large local governments are far more likely to already offer e-government than small ones. The main reasons behind the success of e-government in Minnesota were that before implementing e-government, the local governments of Minnesota set-up their standards and ongoing resources and weighed the potential costs against likely benefits. Additionally citizen access to computers and the Internet is expanding rapidly, and Minnesotans are more likely than residents of most other states to have access to the Internet.

For benchmarking at the local government level, best practice examples are also present and German *MEDIA*@Komm-Transfer Project can be given as an example. The participating municipalities in Germany have combined in the national *MEDIA*@Komm-Transfer network to standardize a selection of their e-government schemes. This portal supports the transfer of e-government know-how to the municipalities. In this regard it can be seen as a good practice in levering local e-government.

Another local e-government benchmarking initiative is the eEurope project. The objective of this project is to develop modern public services and a dynamic environment for e-government and e-business, and benchmark e-government for EU member countries (ECDG, 2004). One of the many successful outcomes of that project is the "National Planning Portal" for UK (www.planningportal.gov.uk). That portal provides online town planning services and indicates the e-level of the local authorities. It also allows residents to submit their building permission applications electronically, add attachments, and pay online.

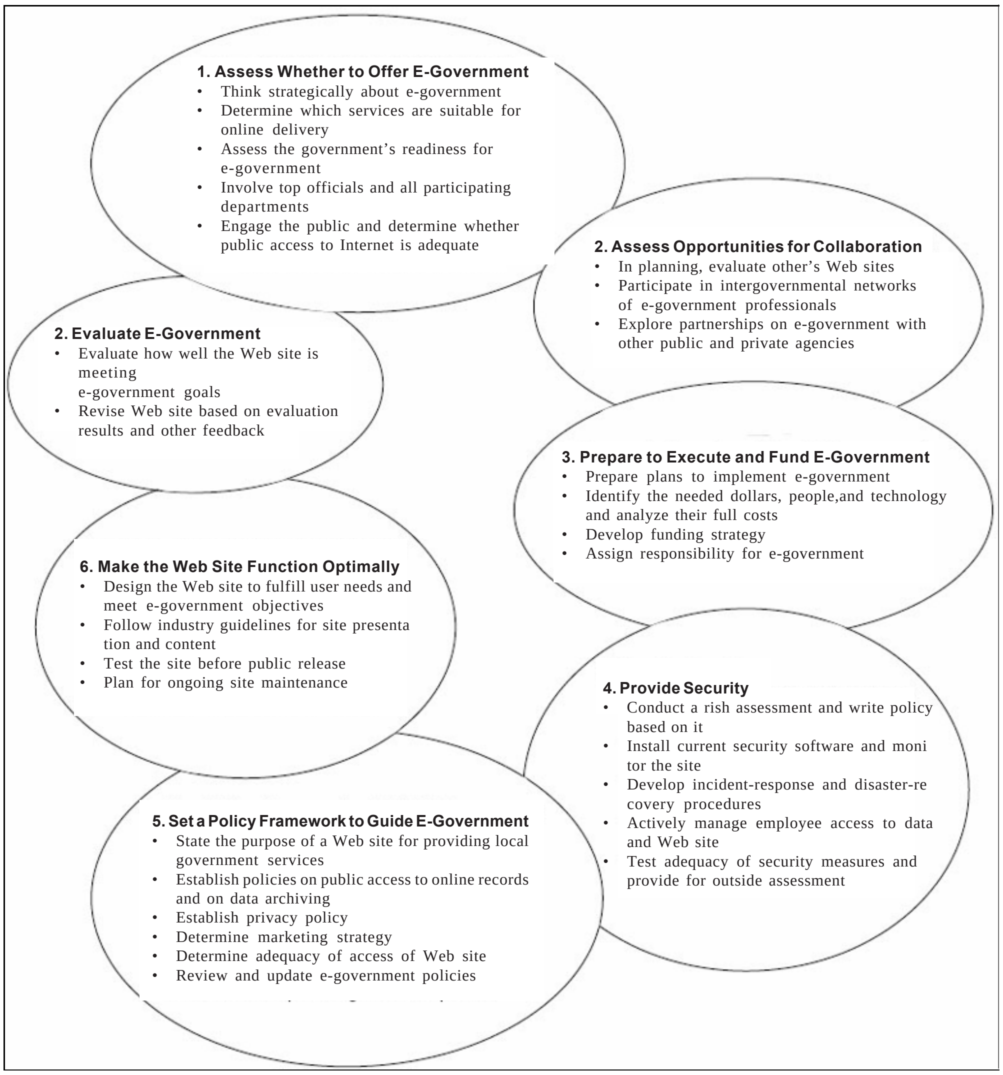
Seven best practices are necessary for effective local e-government. Local governments that fail to consider all of these best practices may not reap the benefits of effective Web sites and run the risk of posting Web sites that are counterproductive. The best practices are cyclic in nature because e-government is not a discrete, one-time initiative. The seven best practices are shown in Figure 1 (OLA, 2002).

FUTURE TRENDS

Current trends are indicating that to form ideal governance, benchmarking will continue to keep its importance. Hence, in the near future e-democracy and ethical local governance concepts are going to have more importance than e-government. Briefly e-democracy can be counted as a version up or reinforcement of the process of democracy by virtue of ICT. With e-government counted as one of the triggers to e-democracy, the future direction of local e-government would likely be "how e-government should be profiled in the process of democracy versioned up by virtue of ICTs."

Without a doubt, benchmarking local e-government and establishing e-democracy will provide administration and politics with the chance to improve their accessibility and image, offer better transparency, and modernize administrative and political processes. Many local administrations have already realized how important e-government and e-democracy will be for the future success of a community to set up an appropriate e-government strategy, scrutinize best practices and start adopting new technologies, introducing new workflows, and publishing their own Web sites.

Figure 1. Best practices for successful local e-government (OLA, 2002, pp. 16)



The technological developments in terms of hardware, software, and network will likely be making development and utilization of local e-government services cheaper and easier. Especially the increasing availability of viable and credible "Open Source Software" for e-government can expand the choices available to public sector organizations and can generate significant savings in hardware and software costs for infrastructure implementation. It can also reduce the licensing costs and hardware refresh requirements for desktop implementation.

CONCLUSION

It has been well acknowledged that the traditional portrait of government agencies worldwide is changing and this change is just as important at the local government level as others. This change, especially as it applies to e-governance, is about governments working better. Peters (2001, p. 35) states that:

…the definition of 'working better' may differ across governments, and even across components of the same government. The basic point, however, is that if government is to be able to overcome the discontent and distrust of its citizens, it must find ways to become more efficient and effective in the processes of making and implementing policy. At the same time, however, there are also pressures for government to become more responsive to the public and to be more transparent in the way in which it makes decisions.

Successful local e-governance depends on a range of processes including the ability of potential users to access e-governance tools (preparedness) and the ability of governments at all levels to develop appropriate e-governance tools (Web site content, etc.). To aid in developing "world best" practice, benchmarking of e-governance tools has become an important part of the development process. Benchmarking has been acknowledged as one of the key elements needed to allow a successful local e-government project (ODPM, 2002) and various benchmarking tools have been developed. Over and above benchmarking measures, best practice examples are also important and there are plenty of examples from national and local governments.

Local governments should get involved with e-government only after determining that they have the wherewithal to develop and, more importantly, maintain a Web site. They must think strategically about what e-government can do, decide which services are suitable, and assess their readiness for it. In the planning stage, local governments should look for partnership opportunities and explore work done by others. They have to plan how to implement and fund e-government. Security measures are essential; they should be based on a thorough assessment of security risks and tested. Local governments also need to set policies that will guide decisions on privacy, marketing, protecting sensitive data, and using the Web site to conduct business (OLA, 2002). In developing the site, local governments should focus on fulfilling users' needs and meeting their own e-government objectives. Local governments should also evaluate their Web sites and be prepared to revise them periodically.

KEY TERMS

Benchmarking E-Government: Is the continuous process of measuring products, services and practices against the successful governments and making comparisons with them and then learning the lessons that those comparisons throw up.

E-Democracy: Refers to relations of two-way and horizontal power—using technologies to enhance democratic practice. It is about: interconnecting citizens amongst themselves; participation; empowering those in the margins; inclusion; creating and maintaining responsiveness; accountability; maintaining universality; and openness.

E-Government: Refers to relations of top-down power—governing populations through use of online information and services. It is more about transforming government services to provide more effective and more efficient services and also coming to the realisation that those services have to be customer-centric.

Ethical Local Governance: Refers to a government that members and staff recognize the importance of ethical standards in local governance thus enabling the authority to construct and develop an ethical culture and values for the authority.

Local E-Government: Refers to information, services or transactions that local governments provide online to citizens using the Internet and Web sites. It is also the realization of the e-governance vision at the local level, at the point where the vast majority of services are delivered.

Local E-Government Standards: Are being established to ensure that National Local E-Government Strategies are supported with effective and appropriate standards and mechanisms to exploit existing projects, products and services. Their primary aims are to provide: easy access to comprehensive and authoritative best practice; information on local service interoperability standards; analysis and development of standards; and scrutiny of e-government projects.

Open Source Software for E-Government (OSS): Is a viable alternative to commercial proprietary software, with potential significant value for money benefits for e-government. It is based on the principle of software products made available by the OSS developer community licensed for use with or without a fee. OSS licenses generally give the user the freedom to use, copy, distribute, examine, change and improve the software.

INTRODUCTION

This article presents a case study on the world's first nationwide portal, BigTrumpet (BT), which showcases an early adoption of the evolving Web-services technology. BT is intended as a community portal that will touch the lives of Singaporeans through the concept of multiagency participation. BT is unique due to the technology behind it, the connectivity enabled by BT's applications, and the collaborative partnerships in its implementation.

Web-Services Overview

Web services is a new, emerging technology that is increasingly being called the next driver of growth in the IT arena. Gartner (2003) estimated that global spending on Web services and portals by the year 2005 would amount to $156 billion, and IDC (2002) expects Web services to drive total software, services, and hardware opportunity to $34 billion by year 2007. Web services hold much potential, like EDI (electronic data interchange), but without the associated problems of rigidity, a fixed data representation, or the requirement of expensive, specialized software (Glikson, 2003; Hartman, Flinn, Beznosov, & Kawamoto, 2003).

Technically, a Web service is a software application identified by a URI (uniform resource identifier) whose interfaces and binding are capable of being defined, described, and discovered by XML (extensible markup language) artifacts. It supports direct interactions with other software applications using XML-based messages via Internet-based protocols (Adams, Gisolfi, Snell, & Varadan, 2002).

Web services are a standards-based technology (Oei, 2003) that leverages on Internet technologies like the hypertext transport protocol (HTTP). Web-services standards define the format of the message, specify the interface to which a message is sent, describe conventions for mapping the contents of the message into and out of the programs, implement the service, and define mechanisms to publish and discover Web-services interfaces (Newcomer, 2002a, 2002b). The four basic Web-services standards consist of XML, the simple object access protocol (SOAP), the Web services description language (WSDL), and universal description, discovery and integration (UDDI).

The key benefit of Web services is that they enable interoperability between diverse applications and platforms (Tan, 2003). Furthermore, the use of HTTP makes Web services pervasive as even firewalls are designed to allow HTTP access (Bochsler, 2003).

Interoperability means unfettered information flows and therefore better integration of disparate internal and external IT applications. A reduction in integration complexity can help build better relationships with customers and external partners, and also lead to improved cycle times (Oei, 2003).

Interoperability also gives companies the flexibility to adopt the technology that is most suited to their own needs without having to take into consideration their partners' systems. Considerations of using the .NET or J2EE (Java 2 Platform, Enterprise Edition) platforms need not be made with reference to the systems of others (Hartman et al., 2003). Hence, Web services using XML provide a flexible model for data interchange with partners while at the same time allowing a company to build a tailored IT infrastructure internally.

BT Background

BT was initiated with a vision to unite the three *P*s: people, the private sector, and the public sector. It was designed to be a one-stop solution for a wide range of services delivered in a personalized manner using the Web-services technology.

BT was a combined vision of the software giant Microsoft and IDA,[1] both of whom wanted to promote and build a showcase Web-services project. It was created within a broader framework called .NETMySingapore crafted between the two stakeholders in 2002.

The BT portal is hosted by NTUC (National Trade Union Congress) Income (also referred to as Income), who has championed the project and become the main service aggregator for the portal. Though initiated by IDA, BT has been implemented as a private-sector initiative with decisions and actions governed by market demands. BT is therefore very different from another platform called E-Citizen (Ke & Wei, 2004), which is an e-government showcase championed, funded, and developed entirely by public agencies in Singapore.

NTUC Income

NTUC Income is Singapore's only insurance cooperative, which was formed in 1970. It has grown rapidly over the years, having over 1.5 million policyholders by the end of 2002. In addition to insurance plans, Income also offers special benefits like loans, 24-hour repair services, house-moving services, tuition services, health screenings, fitness-center memberships, and will-writing services. Its broader mission is to help improve the quality of life of Singaporeans.

Income has always been at the forefront of using technology. It was the first insurer in Singapore to install a mainframe computer system in 1980. Since then, it has enhanced its IT capability regularly in order to raise the level of service to its policyholders.

Income was the first insurer to launch an Internet Web site in 1995. Today, the Web site attracts over 7 million hits per month and about 4,500 visitors per day.

DESCRIPTION OF BT

The BT portal offers a wide range of services to consumers who no longer need to visit different sites to perform many common tasks. A total of 16 services, called Web-services scenarios, have been implemented in BT so far. These services pull data from 14 different agencies at the back end: 6 from the government sector and 8 from the private sector. All services, for the most part, are synchronous in nature whereby users get an instant response after sending their request from the BT portal. These 16 services also demonstrate how collaboration, aggregation, and orchestration can be used to offer distributed services from one, single, common platform.

Before describing each Web-services scenario in more detail, it is important to discuss some general core services that form an important component of BT design.

Core Services

The BT portal offers five general core services that can be utilized together with any Web-services scenario at the users' convenience. They are Calendar, Profile, List, Contacts, and Alerts. All these services allow the users to store personalized information.

- **Calendar:** This service provides users with a digital organizer that allows them to record important events or appointments at their ease. Relevant dates relating to any of the Web-services scenarios can be tagged onto the user's personalized calendar.
- **Profile:** The profile service enables users to store their personal profiles, search preferences, and upload their resumes. In addition, users can customize their Web page via subscription and management of various e-capsules available.
- **List:** Users can store three different types of lists under this service: a shopping list, job list, and course list.
- **Contacts:** It allows users to store, categorize, and control access to their businesses and personal contact information.
- **Alerts:** This last core service offers users a choice of notification via either electronic mail, short message service (SMS), or the BT Web page.

Web-Services Scenarios

BT offers 16 Web-services scenarios that were implemented in three phases. Five scenarios were implemented in Phase 1, which was completed in October 2002.

Phase 1 Web Services

- **myCareer:** This scenario is provided in collaboration with the Ministry of Manpower (MOM),[2] which opened up its back-end job databank and exposed it as a Web service. Users can search for jobs in accordance to their preferences that are stored in their profile.
- **myClub:** This scenario consists of different forums based on different interests, schools, activities, and hobbies made available for discussion.
- **myFolder:** This allows users to store their important documents online such as wills, school certificates, or transcripts in a safe and trusted manner. myFolder is essentially the backbone of myWill as the online will stored in this folder is accepted in the eyes of court as the original copy. The electronic will is stored in a trusted vault located at TrustedHub's[3] premises.
- **myHome:** This scenario aims to help users locate a range of domestic improvement services for their home. For example, users can search for a suitable tutor or register themselves as a tutor. Similarly, electricians, plumbers, and renovation contractors can be contacted according to users' preferences. myHome also includes online shopping through a joint effort with FairPrice[4] that has over 5,000 grocery and household items.
- **myMoney:** This service aims to help users keep charge of their monetary matters. Users can check

the status of their insurance application, fix an appointment with insurance agents, and purchase home and travel insurance online.

- **myInsurance:** This scenario allows users to find out how much they need to save for retirement, how to invest their central provident fund (CPF)[5] and cash savings, and how to identify suitable investments based on their risk appetite.

Phase 2 Web Services

Six further scenarios, as listed below, were implemented in Phase 2, which was completed in May 2003.

- **myBill:** This scenario allows users to pay recurrent bills through the online e-payment gateway.
- **myCar:** This scenario provides aggregated car announcements, avenues for the payment of fines, and other car-related services including seasonal parking, motor insurance and vehicle maintenance, and rental service. In this scenario, the Web services of both the URA[6] and HDB[7] are consumed to extract information on enquiries on car parking fines.
- **myHealth:** The three main functions that are offered under myHealth include aggregated health announcements, health insurance, and healthy lifestyle tips. While Income's servers process insurance applications, BT serves as the platform to retrieve the health-insurance policies and details by consuming the Web-services of Income. Similarly, the search for sport facilities is enabled by consuming Web services of the Singapore Sports Council.
- **myMagazine:** This allows users to view some preferred magazines online free of charge and download others at a fixed charge per copy. Content owners who register with Income as service providers can publish magazines online on the portal.
- **myTravel:** It provides aggregated travel announcements, an avenue to get tour packages, travel insurance, travel loans, travel tips, and country visa information. It also allows national service men travelling out of Singapore for a holiday or business to send a notification as required by MINDEF (Ministry of Defence).
- **WillTrust:** This, together with myFolder, allows the safe and confidential keeping of wills in the electronic vault of TrustedHub, a BT partner. Wills can now be reviewed anytime, anywhere by users who log in using encrypted passwords.

Phase 3 Web Services

In the final phase of the project, five new scenarios were added (listed below). This phase was rolled out in October 2003 and it marked the completion of the BT project.

- **myChild:** This scenario provides parents with a suite of child-related services such as searching for child-care centers, tutors, recreation avenues, child insurance, and the provision of information required to prepare children for school. The Ministry of Community Development and Sports and the Ministry of Education provide the data for this service.
- **myLearning:** In this scenario, users can state their course preferences and store them as part of their profiles. They can search for courses offered by the People's Association[8] using keywords and course categories.
- **myMaid:** The services provided include searching for both full-time and part-time maids, paying for maid insurance, and renewing foreign maids' work permits and booking their air tickets.
- **myRecreation:** This service provides users with information about five areas of general interest: sports, entertainment, food, reading, and shopping. Users can view concert and S-League (soccer league) schedules, and book their tickets online via SISTIC.[9] Similarly, information on books at the National Library Board and Amazon.com are also provided; in fact, users can add books they want directly into the shopping cart of Amazon.com.
- **VIP Club:** This is a virtual membership club that offers shopping deals on a wide range of products and services.

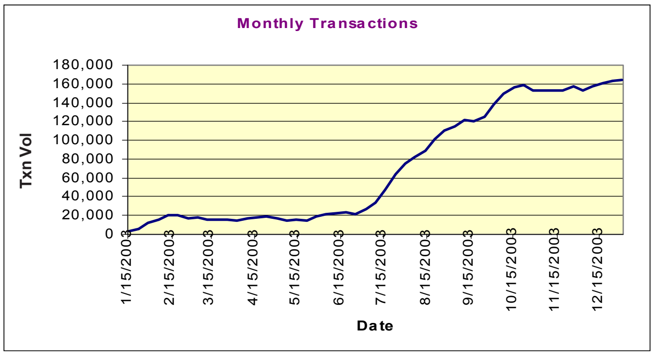
IMPACT OF BT

The BT platform and architecture provides a single user interface through which a range of common services from multiple parties can be accessed in a synchronous manner. There is no need for users to access multiple sites, learn multiple interfaces, or integrate diverse data. All of it is done from one site and in a manner that is transparent to the users. The motto of BT is "One user, one interface, one platform." It is the beginning of a new way in which users can interact easily and seamlessly with an array of Web sites and databases at the back end without ever moving out of a single, personalized site that tracks, monitors, and aggregates their needs.

Web Services: An Illustration

The *myCar* service has greatly benefited the 600,000 car owners in Singapore. Prior to the implementation of BT, car owners needed to put aside considerable amount of time to physically go down to two different places to pay the annual road tax and renew car insurance. Now, the two transactions can be completed via a single interface, thus saving time and improving user convenience.

Figure 1.



Since the launch of BT, the portal has enjoyed significant user growth, reaching about 300,000 at the end of 2003 (in a short span of 3 months). During the same time frame, there was also a tremendous growth in transactions as well, as shown as follows. This trend continues today.

Key Lessons Learned

- **Project Profile:** The BT project, right from the start, started as a high-profile project. It was launched by none other than Singapore's prime minister and Microsoft's CEO (chief executive officer). This high profile created a climate where the stakeholders knew that they could not afford to fail. The visibility from participation was also what led to external partners' cooperation to expose their data through the various Web services. Though recent research (Thamhain, 2004b) shows that project visibility has only a weak influence on project success, our findings strongly indicate otherwise; this can be further investigated by future studies.
- **Partnerships:** The BT project was carried out by multiple parties who collaboratively pooled their expertise together. Unlike most government contracts that are awarded to single vendors, BT was implemented through strategic technology alliances, which are commonplace in business (Zoller, 1999). Though partnerships increase coordination costs, they do allow for best-of-breed solutions. For BT, Microsoft was the key provider of the Web-services framework and technology. HP was chosen to build the technical infrastructure. A local technology vendor, National Computer Systems, acted as the systems integrator. NTUC Income provided project-management services and hosted the BT portal. A solutions provider called TrustedHub was brought in to provide its secure solutions platform for the management of digital content.
- **Formal Project-Management Structure and Project Leadership:** BT deployed more than 100 people in various teams. Most people were handpicked by their organizations as the best talent to work on the project. Managing them was a challenge. A formal project-management office was created to monitor the progress of the venture. The entire BT project was supervised and chaired by the CIO (chief information officer) of NTUC Income (James Kang) and supported by three cochairs from partner vendors. James walked the fine line between maintaining a strict project schedule, coordinating multiple technology partners, and still being flexible with business partners who were providing data for BT. His leadership style conforms well to the new role of leaders in technology teams (Thamhain, 2004b, p. 36): "Often the project manager becomes a social architect who understands the organisational and

behavioural variables, facilitates the work process, and provides overall project leadership for developing multidisciplinary task groups into unified teams, and fostering a climate conducive to involvement, commitment, and conflict resolution."

- **Project Design:** As compared to other IT projects involving Web-services deployment (Milroy & Doyle, 2002), this project was large in scale as it had involved multiple external agencies. The time frame of 18 months for deployment was also a major challenge; in fact, the programmers only had 11 weeks in the first phase to write up to 200,000 lines of code!
  As a strategy, the project adopted a "think far, start small, and scale fast" approach. This explains why a three-phase approach was adopted. The team started with high-level planning of the 18-month delivery, focusing on detail planning for Phase 1. On the delivery of Phase 1, they gathered feedback from the users and used the feedback information to plan the details of the following phase.
- **Open Channels:** The requirements of the project were complex on both the organizational and technological dimensions (Xia & Lee, 2004). The project used brainstorming extensively to discuss key issues and thrash out technical and business needs. For example, brainstorming sessions were conducted with NTUC Income executives to understand how they interacted with external partners. Such brainstorming sessions brought the business and IT people together. Furthermore, requirement workshops were held at the beginning of each of the three phases so that the technical team could derive the desired system functionality. Future studies can more formally look at such strategies for dealing with project complexity, a critical research area in IT project management (Xia & Lee).
- **Buy-In:** Perhaps the most critical challenge faced by BT was to persuade external parties to buy into the BT vision and provide services through the portal. Web services are an emerging technology, and many companies and government agencies were reluctant to adopt them due to issues related to security, which remains a global concern (Anonymous, 2002; Westbridge Technology, 2003), as well as concerns about interoperability, standards maturity, and the overall cost benefits. Government agencies were further reluctant to work with NTUC Income as it is a private organization.
  The challenge was resolved through extensive education aimed at the private and government agencies. Regulatory government agencies like IDA were roped in to alleviate concerns and to reconcile the sometimes-conflicting national and commercial interests related to the project. Microsoft provided training to the agencies to alleviate technical and other concerns. Thus, an extensive process of buy-in through persuasion, education, and coercion worked to ultimately convince 14 agencies to come on board.

CONCLUSION

The BT portal is one of the largest implementations of Web services in the B2B (business-to-business) and B2C (business-to-consumer) domains. It stands as a unique platform that is changing the way ordinary citizens gain access to electronic services in an integrated, personalized, and one-stop manner. It is also an exemplar of collaboration between the public and private sectors. Many lessons can be learned from the BT experience in both the technical aspects of integration and Web services, as well as leadership for managing IT and business alliances.

KEY TERMS

Orchestration: The process that sequences, coordinates, and manages conversations among Web services.

Service Provider: This organization hosts the Web service that any application can consume.

SOAP (Simple Object Access Protocol): A protocol that applications use to communicate in a distributed environment. SOAP can be used to exchange data between applications created using any programming language and deployed on a computer running on different platforms.

UDDI (Universal Description, Discovery and Integration): UDDI, initiated by Ariba, IBM, and Microsoft, is an industry standard for registering, publishing, and discovering Web services in a central registry called a UDDI directory.

Uniform Resource Identifier (URI): Identify abstract or physical resources. A resource can be a collection of names that has been defined by some organizations, or it can be a computer file that contains that list. The most familiar form of URI is the uniform resource locator (URL).

WSDL (Web Service Definition Language): An XML-based language that is used to provide information about a Web service to requesting applications. This information includes a description of the Web service, a location of the Web service, binding information, a method for accessing the Web service, and a way to exchange data by using the Web service.

XML (Extensible Markup Language): A text-based markup language that describes data in a document. Since XML is a platform-independent language, it is used as the standard format for transferring data over a network using Web services.

ENDNOTES

1 IDA (InfoComm Development Authority) is a government agency that regulates and promotes the IT industry in Singapore.

2 MOM is a government body that controls labor supply and demand in Singapore.

3 TrustedHub provides managed services in the secure creation, storage, and management of electronic documents in compliance with the Electronic Transaction Act and Evidence Act of Singapore.

4 FairPrice is the leading supermarket retailer in Singapore. It has a retail network of more than 100 stores island-wide.

5 The central provident fund is a comprehensive social-security savings plan that seeks to provide many working Singaporeans with a sense of security and confidence in their old age.

6 The URA (Urban Redevelopment Authority) is Singapore's national planning authority.

7 The HDB (Housing Development Board) is a government board responsible for public housing in Singapore.

8 People's Association is the leading Singapore government agency that promotes government-to-people connectivity.

9 SISTIC is a real-time ticketing Web site with facilities to book tickets online.

INTRODUCTION

Governments are using the Internet and e-commerce technologies to provide public services to their citizens (Watson & Mundy, 2001). In so doing, governments aim to form better relationships with businesses and citizens by providing more efficient and effective services (Al-Kibisi, de Boer, Mourshed, & Rea, 2001). E-government provides opportunities to streamline and improve internal governmental processes, enable efficiencies in service delivery, and improve customer service (Bannister & Walsh, 2002). As a result, achieving successful e-government delivered over the Internet has become a key concern for many governments (Eyob, 2004). Additionally, there are privacy, security, and trust issues for citizens interacting with government services compounded by the electronic nature of the interaction. Biometric identifiers may present a solution to some of these concerns, leading to increased levels of secure, private, and trusted e-government interactions.

BACKGROUND

E-Government Challenges

The Internet can be used to provide access to centrally stored data to support services and transactions and can help the efficient running of government and provide convenient services to citizens. However, the permanent storage of confidential and personal data present significant security challenges (DeConti, 1998). International data protection reforms recommend security measures to protect sensitive information, and in doing so present potential restrictions for government agencies on the usage of data in transactions and the storage of citizen information (Dearstyne, 2001).

With e-government, citizens are exposed to threats to data privacy and the security of information, similar to those encountered in an e-commerce environment. Privacy, security, and confidentiality are thus natural concerns for businesses and citizens in this context (Layne & Lee, 2001). Furthermore, the design of e-systems may also deter some citizens from using the electronic medium, preferring the familiarity of traditional physical interactions (Jupp & Shine, 2001). These factors necessitate the building of trust between citizens and government to ensure successful levels of adoption of Internet-based e-government services (Bellamy & Taylor, 1998).

The development of biometrics has ignited widespread interest by citizens, businesses, and governments, on how these technologies operate and the implications of their usage. In addition, the development of new technologies has the potential to develop citizen trust by offering advanced levels of security (Dearstyne, 2001; Dridi, 2001).

Biometrics

Biometrics is the application of computational methods to biological features, especially with regard to the study of unique biological characteristics of humans (Hopkins, 1999). As an emerging technology, biometrics offers two related and important capabilities: first, the reliable identification of an individual from the measurement of a physiological property, which provides second the ability to control and protect the integrity of sensitive data stored in information systems (Oppliger, 1997).

As the levels of worldwide information system security breaches and transaction fraud increase, the imperative for highly secure authentication and personal verification technologies becomes increasingly pronounced. Governments are concerned about user verification and system security in developing e-government services particularly with moves towards combined, seamless services, which are delivered electronically. As a result the potential benefits of biotechnologies, in particular identification issues and security, are gaining importance on political agendas for e-government development (UK Government Strategy Unit, 2002).

Biometrics and Authentication

Three general categories of authentication exist with respect to electronic systems: (1) PINs (personal identification number) or passwords, (2) keys, smart cards, or tokens, and (3) biometrics (Liu & Silverman, 2002). Passwords are the most commonly used means of authentication in information systems (Furnell, Dowland, Illingworthand, & Reynolds, 2000). However, this authentication technique is often insecure, as users tend to choose passwords that are easily guessed or breakable by hackers (Bradner, 1997). Jain, Hong, and Pankanti (2000) describe token-based security and verification approaches as physical entities an individual possesses to make a personal identification, such as a passport, a driver's license, ID card, and so on. Such identification entities are currently widely used as methods of authentication for numerous applications worldwide. However, Ratha, Connell, and Bolle (2001) argues that the process of biometric authentication can be automated, and unlike token- or password-based methods, physiological characteristics cannot be lost or stolen.

Emerging Issues in Biometric Adoption

Biometrics is an emerging technology. There are a number of implementation issues pertinent to its widespread development and diffusion. Furthermore the lack of international biometric standards together with privacy and security concerns are relevant as potential inhibitors affecting the growth, deployment, and effective delivery of e-government services. However, recent international developments, for example the U.S. visa waiver scheme, have put biometrics on numerous political agendas in the context of enabling e-government, and have consequently fuelled rapid growth in interest in biometric technologies over recent years.

As a result of the "Enhanced Border Security and Visa Entry Reform Act " and new U.S. border control policy, countries currently eligible for the visa exemption program, including all current EU countries, must set up a programme to issue their nationals with biometric passports (IDA, 2003). European countries which have started to update their border control policies incorporating the use of biometric authentication include; the UK (UKPS, 2004), Bulgaria (EBF, 2004a), France, Germany, and Italy. In Australia, the Customs Service (ACS) has revealed a biometric passport recognition pilot (ENN, 2004). Elsewhere, the Japanese government plans to introduce biometric features in passports (EBF, 2004b).

INTERNATIONAL STANDARDS

Due to the relative youth of biometric technologies, as well as the fragmented nature of the biometric industry, a lack of international standards has impeded many types of biometric implementation and has slowed the growth of the biometric industry (Nanavati, Theime, & Nanavati, 2002). In order to gain acceptance in both commercial and government environments, biometric devices must meet widely accepted industry standards, which in turn would stimulate increased funding and developments in the industry (Nanavati et al., 2002; Ryman-Tubb, 1998). The development of standards would reduce the implementation and development risks of biometric solutions, making their deployment more attractive to risk-averse government-run public sector environments.

Privacy Concerns and Trust

Biometric technologies have the potential to provide governments and other organizations with increased power over individuals, thus threatening personal entitlements and civil liberties (Clarke, 2001). As such, privacy concerns are an important consideration in successful biometric implementation and uptake amongst citizens. These privacy issues relate to data collection, unauthorized use of recorded information, and improper access and errors in data collection (Smith, Milberg, & Burke, 1996). Biometric technologies have the potential to be more privacy invasive in cases where it involves the storage of personal information without the knowledge or consent of the individual (Crompton, 2002).

Trust is a central defining aspect of many social and economic interactions; it is the belief that others will behave in a predictable manner. In e-government, threats to data privacy and the security of information necessitates the building of trust between citizens and government to ensure successful adoption levels of e-government services (Bellamy & Taylor, 1998). Specifically, trust should be developed in e-services to allay fears that information collected for one purpose is not used for secondary purposes without prior authorization from the individual, and to ensure the non-repudiation of services (Tolchinsky et al., 1981). Governments also have an interest in developing trust in electronic transactions, since electronic mechanisms require the capability to uniquely identify the individual to prevent fraud.

Range of Biometric Technologies

An "ideal" biometric should be universal, where each individual possesses the characteristic; unique, where no two persons should share the characteristic; permanent, where the characteristic should neither be changed nor alterable; and collectable, the characteristic is readily presentable to a sensor and is easily quantifiable (Jain et al., 2000). In attempts to satisfy these requirements, a diverse and varied range of different biometric technologies have become available from recognition-based scanning systems measuring iris and retinal patterns, fingerprint layout and hand geometry constitution, to methods that gauge the accuracy of human sense-based output, such as voice patterns and olfactory sensing.

BIOMETRICS FOR E-GOVERNMENT SERVICES IN IRELAND

Background

In 2001, the Irish government set up a Biometric Task Force, under the auspices of the Department of Communications, Marine, and Natural Resources (DCMNR), to consider the use of biometrics technology in the delivery of government services. In order to assess governmental attitudes towards biometric services and the underlying biometric technologies available to enable these services, four in-depth structured interviews were conducted with management personnel working in the area of biometrics in the DCMNR and management personnel within the Irish government's Biometric Task Force. Complementing the interviews previously mentioned, supplementary data sources included two report documents produced by the Irish government's Biometric Task Force (one from 2002, the other from 2003), and informal discussions outside of interview contexts with management working in the area of biometrics in the DCMNR and within the Biometric Task Force.

Developing a Framework for E-Government Services

In June 2003, the European Council stated that a coherent approach is needed in the EU for the standardization of biometric identifiers. In response to requirements of the European Commission, the development of a European Biometrics Forum has been implemented in Ireland. In 1999, the Irish government released its first action plan on the Information Society; this plan made specific reference to the need to develop e-government initiatives and outlined an initial commitment to e-enable the delivery of public services. In March 2002, the Irish government further committed itself to placing all appropriate services accessible via the Internet by 2005 (Government of Ireland, 2002).

The concept of a portal-based public service broker (PSB) was subsequently adopted as the central mechanism for delivering the e-government agenda, as this was identified as the most efficient model to provide mediated, citizen-centred services (Government of Ireland, 2002). An online prototype of the PSB known as "reachservices", was officially launched and implemented in 2002. A tendering process has also been completed for the construction of the full version of the PSB and a complete installation of the PSB is for 2005.

Potential Role for Biometrics

At present, user authentication on reachservices is limited to a user name and password provided by the government. As part of the procurement process for the construction of the PSB however, the use of biometrics has been included as a mandatory feature for development. In order to provide more sophisticated security for user identification and verification, biometric identifiers are highlighted as an essential component of the services intended for the PSB.

A Regulatory Framework for Biometrics

The Irish government has progressed data protection legislation in line with EU recommendations, to govern how citizens can be identified and to define and govern how citizen data can be used by service agencies. The Irish government's commitment to data protection is evidenced by the legislative acts that have recently been implemented: Data Protection Act (1998), EC (Data Protection and Privacy in Telecommunications) Regulations (2002) and the Data Protection (Amendment Bill) (2002). The concept of a single unique identifier (termed a "PPS number", that is, a Personal Public Service number), which is compulsorily allocated to all citizens at the registration of a birth, was motivated by the need to uniquely identify citizens and in response to EU directives, to provide the citizen with the ability to decide what information is stored about them and to determine the conditions of that information's usage.

Various legislative procedures have also been progressed to support the introduction of biometrics in facilitating and enabling e-government services. For example, The Social Welfare Act 2002 provides for the creation of a public service identity (PSI), which consists

Table 1. Principles for biometric implementation

Principle	Description
Implemented biometrics must be accurate	Biometric technologies should significantly increase the accuracy of personal identification measures already in use or adaptable from other applications to e-government services.
Strong forms of authentication methods are necessary for e-government provision. As such, biometric technologies are a necessary authentication measure	Inherent in the effective provision of usable e-government services is a dependable and effective authentication process.
Biometrics are an important component in the provision and delivery of e-government services, in addition to other applications	Biometric technologies are fundamental to the effective interaction between citizen and state inherent in the secure handling and execution of e-government services. Biometric identifiers are also appropriate for other applications, such as driving licenses and health-related matters.
Biometric implementations for e-government must address privacy and citizen trust	Biometric systems should not become a de-facto standard for personal identification without consideration of citizen perceptions and attitudes towards potential infringements into privacy. Potential biometric implementations for e-government services should use a framework that encompasses both privacy and trust as components central to effective deployment and acceptance.
The Irish government needs to be aware of internationally external factors influencing advances in biometric deployments	The adoption and usage of various biometric technologies are heavily influenced by international politics, such as concerns over immigration, terrorism, requiring accurate means of user identification. The Irish government must be cognizant of biometric developments in other countries, so that Irish systems equivalent to international measures of personal identification are not 'lagging'. Also, the Irish government needs to be aware of technological advances in some forms of biometric technologies over others, spurred by external factors, which could impact upon the methods and tools used in Ireland to provide electronic government.

of the PPS number and associated identity data. This act allows for the inclusion and legal recognition of biometric data as part of the PSI identity data set. In turn the PSI is intended to act as the key component of registration and authentication used by the PSB.

Key Issues in Biometric Implementation

With respect to electronic, biometric-involved citizen-to-government interactions, the key issues influencing successful biometric implementation encompass governmental views on privacy, security, and trust, both from planning and implementation standpoints. Although the development of governmental policy governing the use of biometrics in Ireland is at an early stage, there have been a number of distinct areas of growth. Specifically these areas recognize the potential role for a range of biometric technologies as enablers of public service delivery. Table 1 presents a number of key principles for successful implementation of biometrics and a description of the challenge each presents.

Privacy, Security, and Trust

Results of interviews with members of the DCMNR and the Biometric Task Force indicate that to effectively provide citizens with secure electronic access to public services and indeed for e-government to be successful, it is imperative that the underlying systems can instantly and accurately validate the claimed identity of any individual. Furthermore, a strong form of authentication, such as those facilitated via biometric methods, is a key enabler in the delivery of online public services.

In terms of privacy and trust, the interviews suggest that the Irish government should not try to impose biometric technology on citizens, but that a challenge exists to develop reliable high-trust biometric mechanisms for citizens to interact securely and privately with e-services in through well-planned, well-designed, usable, and non-threatening implementations that are tuned with existing legislation on data privacy and access. Findings here indicate that the deployment of biometric technologies facilitating e-government provision should not result in citizens feeling that their government are overreaching themselves in terms of invasion of their personal privacy.

Interviewees also stressed the influence of external factors, such as the measures initiated by U.S., UK, and other governments regarding security and immigration controls post September 2001, as key to recent increases in interest in biometric technologies, their uses and their potential. These interviews suggest that the Irish government must not only be aware of developments in relation to international biometric standards, but additionally that the Irish government should monitor the current situation in relation to the use of biometric technologies to ensure that Irish citizens will not be excluded from international or EU-based e-services because their government has not kept pace with international policy and developments.

FUTURE TRENDS

Range of Biometric Technologies

The range of potential biometric technologies being considered for differing situations to support the provision of services has an important impact on the likely success of the implementation effort. The task force identified that each technology has particular strengths and weaknesses and as such no single technology is likely to suit all applications. The two variables that influence the implementation of biometrics in the public domain were identified as (a) public perception of the technology, and (b) performance of the technology. Fingerprint scanning was identified as being the most accurate technology; however, it has the lowest public acceptance rate given the associations with criminality. The technology with the highest level of public acceptance is facial scanning; however, this is the weakest performing technology, as there are difficulties in distinguishing between similar facial images. The technology that satisfies both public perception and performance criteria is iris scanning. This application does not require physical contact and is accurate; currently trials are underway at UK's Heathrow and The Netherlands' Schipol airport under the auspices of these countries' governments.

CONCLUSION

Increased security concerns associated with global terrorism are currently driving the need for biometric enhanced passports as the standard, minimum documentation required for international travel. As a result, citizens will have little choice but to participate in biometric identification schemes, as determined by their passport issuing authority. Given the fact that in most developed countries a very high percentage of citizens hold passports, it will be tempting for governments to extend the use of biometric technology beyond passport identification. While the implementation of biometrics to e-government services offers many advantages for both citizen and government alike, the extended use of biometric identifiers needs to be carefully evaluated.

In this study, some critical factors have been highlighted relevant to the implementation of biometric identities as a necessary enabler of e-services. Public acceptance of the technology is imperative for although strong forms of authentication have been shown to be a prerequisite for effective e-service provision, the deployment of biometric technologies must be cognisant of a number of issues. Biometric mechanisms must not only be reliable and user friendly but also appropriate to the service. An indiscriminate application of biometrics to government services may exacerbate public fears that personal privacy is being unnecessarily compromised. Hence, a central question in the context of utilizing biometrics in e-government service provision is the extent of verification deemed necessary and appropriate to access a particular service. The issue of implementing biometrics is further complicated by the need to adhere to strict EU laws on data protection, which protect data integrity but also challenge the design and operation of authentication mechanisms.

The use of biometric technologies by governments is being accelerated by technological developments and the need for increased security. However, while it will become beneficial for governments to use biometric identification procedures outside the realm of international travel and associated security issues, such an extension needs careful consideration. Further research into citizen acceptability, and citizen trust of biometric identifiers would add significantly to the current debate on biometric usage.

KEY TERMS

Authentication/Identification: Biometric identifiers operate either in verification (authentication) mode or in a recognition (identification) mode. A verification system authenticates a person's identity by comparing the captured biometric characteristic with the person's own biometric "original". In a recognition system, the system establishes a subject's identity by searching the entire template for a match, without the subject initially claiming an identity.

Biometric Identifiers: The use of biometric data to enable the reliable identification of an individual from the measurement of a physiological property which provides the ability to control and protect the integrity of sensitive data stored in information systems.

Biometrics: The application of computational methods to biological features, especially with regard to the study of unique biological characteristics of humans.

Fingerprint Scanning: Enables the identification of an individual based on the analysis of unique patterns and ridges found in a fingerprint.

Iris Scanning: Enables the identification of an individual based on the analysis of the colored tissue surrounding the pupil.

Portal: The provision of integrated services, combining personalisation features via the Internet.

Privacy: Measures or regulations created to protect the individual in relation to data collection, unauthorised use of recorded information, and improper access and errors in data collection.

Speech Recognition: Enables the identification of an individual based on the analysis of a "voiceprint" derived from the digital acquisition of unique patterns found in individual speech patterns.

Trust: The provision of adequate measures to ensure the security of private or sensitive data thus providing confidence in the reliability of electronic services.

Branding on the Internet

Mary Lou Roberts
University of Massachusetts Boston, USA

Eric Schwaab
Visual Narrative, USA

INTRODUCTION

Marketers have regarded the Internet as the consummate direct-response medium. The ability to interact one-on-one with customers and the ability to track their every move allowed precision targeting never before possible. More recently it has become clear that the Internet can also be used in *branding* efforts. The ability to blend direct-response and branding efforts is the Internet's greatest benefit and its ultimate challenge to marketers.

This article reviews evidence for the branding impact of online marketing activities. It also looks at the key concepts of *interactivity* and *consumer experience* online. It then presents a construct we call interactive brand experience and describes the Internet-specific techniques that can be used to orchestrate brand experience on the Web. It concludes by summarizing the implications of using the Internet for brand development and discussing the way in which branding on the Internet is evolving.

BACKGROUND

The most comprehensive and best-known study of branding effort on the Internet is the Cross Media Optimization Study of the Interactive Advertising Bureau. Begun in 2002, the study includes more than 30 leading brand marketers, and on- and off-line publishers as participants. Methodology builds on established off-line metrics by adding accepted online measures. Selected studies provide evidence that Internet advertising does affect various brand metrics.

- One of the earliest was conducted in conjunction with the introduction of Unilever's Dove Nutrium brand. The basic research design was to run print advertising only in week 1, add online in week 2, and television in week 3. The study concluded that keeping the total advertising budget constant but increasing online spending from 2 to 15% would produce an 8% increase in overall branding impact and 14% increase in purchase intent (http://www.iab.net/xmos/pdf/xmosdatadove.pdf).
- Another study focused on Kimberly-Clark's introduction of the Kleenex Soft Pack. The media allocation was 75% to television, 23% to print, and 2% to online. It found that online advertising reached the 42% of the target audience that is not reached or only lightly reached by television (http://www.iab.net/xmos/pdf/xmosdatakleenex.pdf).
- A recent study for Volvo used the Sponsorship Effectiveness Index to compare the effectiveness of shared sponsorship (multiple ad placement on a single Web page) with exclusive sponsorship in which no other advertising is present on that particular page at that particular time. The study concluded that shared exposure resulted in no significant lift in brand inclusion in the consideration set, while exclusive sponsorship resulted in a 6.1% increase in brand inclusion in the consideration set (http://www.iab.net/resources/iab_volvo.asp).

Other organizations report similar results. The British marketing research firm Taylor Nelson Sofres Interactive conducted four separate studies during 2000 and 2001. The studies showed that online advertising generally did increase brand awareness, more for unfamiliar and less for familiar brands. However, higher levels of ad recall were not always correlated with higher levels of brand awareness (Hughes, 2002). A 2003 study by the agency Advertising.com monitored conversions from a credit card offer over a five-day period. They found that about 33% of the conversions occurred on the same day as ad exposure, but only 11% occurred within three hours. In another study, when viewer activity was monitored for 14 days after initial impression, as many as 85% of the conversions occurred more than one day after exposure (Advertising.com, 2003). This delayed impact is taken as evidence that brand develop can and does occur online. There is also evidence that brand development does not always take the same route. In recent years two complimentary models of brand development have emerged. While neither one was developed specifically for the Internet, both apply to the online as well as to the off-line environment.

Brand Equity

Arguably the most widely accepted brand development model is Keller's Customer-Based Brand Equity Framework (Keller, 1998, pp. 68-83). It is composed of tools and objectives (brand elements, marketing programs, and secondary brand associations) that are mediated through knowledge effects (brand awareness and associations), with resulting enhancements of brand equity that include larger margins and greater brand loyalty. Keller expanded on the static model by providing a series of steps for creating a strong brand: establish the proper identity, create the appropriate brand meaning, elicit the right brand responses from customers, and forge strong relationships with them (Keller, 2001).

Ilfeld and Winer (2002) studied the development of brand equity on the Internet. They used a traditional hierarchical approach, adapted to take Internet differences into account. This allowed them to test three models: persuasive hierarchy (Think-Feel-Do), low-involvement (Think-Do-Feel), and no-involvement (Do-Think-Feel). Overall, the Think-Do-Feel model performed significantly better on all measures, suggesting that awareness is followed by site visitation, which, in turn, is followed by brand equity. They liken Web visitation (the dependent variable) to mature, frequently purchased product categories (low involvement) in which advertising is useful in building awareness and driving usage, and note that both online and off-line efforts are required.

Brand Relationship

A different approach is taken by Fournier (1998). In a study of how consumers develop relationships with their brands, she advances the concept of brand relationship quality (BRQ). BRQ is a multidimensional construct composed of positive affective feelings (love/passion, self-connection), behavioral ties (interdependence, commitment), and cognitions (intimacy and brand partner quality). BRQ is mediated by a number of psychosocial filters with the outcome determining the stability and durability of the consumer/brand relationship.

Thorbjornsen, Supphellen, Nysveen, and Pedersen (2002) operationalized the BRQ dimensions and tested whether customer communities (person-to-person interaction) or personalized Web sites (machine-to-person interaction) were most effective in building BRQ for hypothetical products. They found that for less experienced consumers, customer communities were more effective. For more experienced users, personalized Web sites were more effective.

Fournier's model specifies an outcome—the quality of the relationship that consumers have with their brands. It is an outcome predicated both on consumers' own life experiences and brand-related marketing actions. Marketers cannot control consumers' life experiences, however they can create and exercise control over customer experience. We therefore turn next to the concept of consumer experience.

Customer Experience

The concept of customer experience as a key to brand learning predates the Internet. Hock and Deighton (1989) characterize it as a type of learning, a four-stage information processing model. They postulate that consumers formulate working hypotheses for testing, are exposed to evidence about the product, encode information based on their own familiarity and motivations, and finally integrate new evidence into their existing belief structure. They distinguish between learning by description (most advertising falls into this category) and learning from experience, which is recognized as more effective.

Pine and Gilmore popularized the concept of customer experience, saying that "companies stage an experience whenever they engage customers, connecting with them in a personal, memorable way" (Pine & Gilmore, 1999, p. 3). The word "stage" is important and reflects Hoch and Deighton's (1989) contention that marketers can control the experiential learning of consumers.

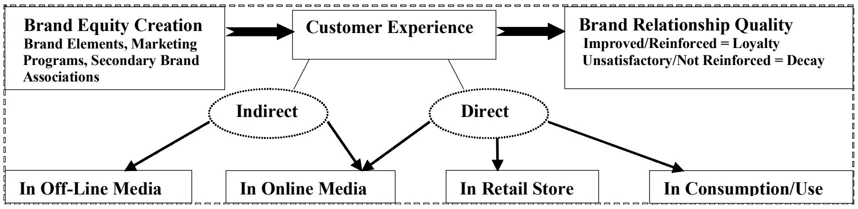
Li, Daugherty, and Biocca (2001) argue that virtual experience is similar to indirect experience in that it is mediated. It is also similar to direct experience in that both are interactive. Their research found virtual experience to be an active psychological process. It was accompanied by three other characteristics: presence (which they define as a sense of being in another place generated by indirect experience), involvement, and enjoyment. They conclude that virtual experience consists of vivid, involving, active, and affective states that are closer to direct than to indirect experience. That supports the research by IAB and others that finds the Internet to be a useful channel for brand development. It also leads to a construct in which customer experience is the central focus of brand development on the Internet.

Creating Interactive Brand Experience

The concept of customer experience encompasses all the marketer-initiated activities that influence brand equity. Learning, or indirect experience, takes place in the traditional media. Direct experience is gained at the point of purchase and in actual use. Experience gained through interactive media, particularly the Internet, has characteristics of both direct and indirect experience. Figure 1 summarizes the relationship of the brand development

B

Figure 1. The role of customer experience in brand development (Roberts, 2005)



concepts. It identifies customer experience as the mediating factor between the marketer's efforts to create brand equity and the consumer's perception of the quality of relationship with the brand.

INTERACTIVE TECHNIQUES

In 2000 consultants at McKinsey identified interactive tools that can be used to create digital brands—*personalization, customization, co-creation, purchase-process streamlining, self-service, product design toolkits*, and *dynamic pricing* (Dayal, Landesberg, & Zeisser, 2000). Research has also demonstrated that *brand community* can be built or strengthened on the Web (e.g., Bagozzi & Dholakia, 2002). Astute use of these tools and techniques creates an *interactive* environment in which meaningful dialog can take place between marketer and customer in a way that enhances brand development.

It is important to keep in mind that these techniques are available in addition to the traditional brand elements and secondary associations identified by Keller. Elements like the brand name and logo, and associations like the company and its channels of distribution, are the foundations of all branding activities, online and off-line.

Before we look at the specific interactive techniques, we should consider the concept and importance of interactivity itself.

Interactivity

In an early and influential study, Hoffman and Novak (1996) introduced the concept of the computer-mediated environment (networks) in which both machines and persons could interact in a one-to-one or many-to-many fashion. There are still interactive media that do not directly involve the Internet—CD-ROMs ATMs, and kiosks come to mind—but higher access speeds have made the Internet the focal point of interest in interactivity.

Liu and Shrum (2002) found that higher interactivity provided a more involving experience that led to greater user learning. Their definition of interactivity includes three dimensions: active control by the user, two-way communication, and synchronicity (simultaneous input and response). In a later study, Liu (2003) developed an interactivity scale using the three dimensions that were shown to have both validity and reliability. An empirical study of interactivity by McMillan and Hwang (2002) revealed three dimensions that are similar, but not precisely the same. They called their dimensions real-time conversation, no delay, and engaging.

These studies support the conventional marketing wisdom that asserts that well-done interaction engages the visitor, enhancing learning and increasing the likelihood of immediate response (purchase or other action) or delayed response (brand experience).

We now turn to a brief description of each tool with examples of its application.

Personalization

Database marketers have personalized communications with name and targeted content for at least two decades. Applications range from greeting an identified user by name when she enters a site, to using active server pages to deliver content targeted to the user's known interests, to serving advertising on the basis of anonymous profiles or those of registered users.

There are some situations in which personalized customer contact produces a profitable return and some where it does not. A study by Jupiter Communications did not find that personalization of Web sites influenced consumers to purchase more. Easy navigation was, however, found to be effective. The study also points out that personalization of e-mails does generate greater impact (Gonsalves, 2003). Holland and Baker (2001) suggest that personalization is effective for both task-oriented and experiential Web site users if it permits them to better fulfill their objectives. Amazon.com has led the way in deep personalization of site content.

Customization

It seems reasonable that the next step after personalization of content would be customization of products and services. There is, however, confusion between definitions of personalization and customization that renders this statement hard to evaluate. Nunes and Kambil (2003) define personalization as reliance on algorithms that uncover patterns in customer data and extrapolate to make recommendations directly to consumers or to personalize Web page content. They contend that customization lets site visitors specify the desired content. Wind and Rangaswamy (2001) carefully use the term "mass customization" to refer to products that are made to the customer's specifications using flexible manufacturing techniques. Ansari and Mela (2003) call the process of providing individualized content "e-customization." Their research indicated that optimization techniques that varied both content and order of presentation in persuasive e-mails could increase the click-through rate.

It seems reasonable to employ the term "mass customization" to refer to made-to-order products (Pine, Victor, & Boynton, 1993). Then personalization can be used to describe marketer-initiated individualization (either machine-to-machine or person-to-machine), and customization can be reserved for customer-initiated choice of content alternatives in computer-mediated environments. Using this distinction, one can point to applications like the NikeID site, on which visitors can build their own customized athletic shoe from menus of options (www.nikeid.com).

Co-Creation

Sawhney and Prandelli (2000) called the phenomenon "communities of creation" in which knowledge is created in a distributed network. Prahalad and Ramaswamy (2000) applied the concept to marketing when they pointed out that consumers have become active players in creating content through focused dialog, software tools such as collaborative filtering, and online communities. They state that customers can help to co-create their own experiences and, in so doing, determine the level of involvement they wish to have with the brand. Whether the process involves direct personal contact as occurs in eBay auctions, or is machine based like Amazon's use of collaborative filtering, co-creation can be a highly engaging activity. The proliferation of blogs on the Internet is a prime example of consumer co-creation of content.

Dynamic Pricing

Priceline in the consumer marketplace and auction sites for B2B procurement provide evidence that dynamic pricing can be a key element of an Internet business model. Wyner (2000) points out that customers experience price in a different way on the Web. In the physical world, price is most often a take-it-or-leave it feature. On the Internet consumers have a range of options they can use to search for the best prices and to decide which e-retailer to patronize. For marketers who cannot offer lowest prices, turning to a differentiation technique like product self-design may be an option.

Product Self-Design Tools

A *choiceboard* can be used to implement product self-design. Bovet and Martha (2000, pp. 76-79) state that a choiceboard has four key elements: a communication process, the ability to capture real demand, real-time choice management, and the resulting configured-to-order product. Customer product self-design is likely to experience rapid expansion in the coming years. The NikeID example may be an early indicator of this phenomenon. It allows consumers a wide range of latitude in configuring their own product, but it does not allow them to change the basic design of the shoe model they are purchasing.

Purchase-Process Streamlining

The best-known example of purchase-process streamlining is Amazon's 1-Click process. Their customers can enter information about purchaser and payment method, which is then stored for future use. It is also the most controversial example, because Amazon applied for and received a patent for the underlying software that has been disputed by other Internet retailers (Gleick, 2002). Nevertheless, other sites have implemented processes that make it easy to purchase, increasing the likelihood of repeat visits.

Self-Service

Self-service, either on the Internet or through other electronic technologies, is a growing force as companies try to provide customers with more service alternatives at the same time they lower their service costs. Meuter, Ostrom, Bitner, and Roundtree (2000, p. 54) found 56% of their respondents describing satisfactory self-service encounters and 44% reporting unsatisfactory encounters over a broad range of technologies. Moon and Frei (2000) suggested that, in order to make self-service satisfactory, companies must limit the range of choices and streamline the self-service process. It appears that consumers are willing to use self-service options when they solve a difficult problem, are better than the alternatives, and work properly (Bitner, Ostrom, & Meuter, 2002).

Transitioning Internet customers from more expensive service options like call centers to self-service is in the economic best interest of marketers, as demonstrated by Federal Express and their ever-growing array of customer self-service options. However, they need to ensure that the service options are robust, and that they include human interaction if self-service cannot resolve the customer's issue.

Brand Community

Defined as a "structured set of social relationships among admirers of a brand" (Muniz & O'Guinn, 2001), brand community is not an Internet-specific phenomenon. The H.O.G. (Harley Owner's Group) association of motorcycle enthusiasts has been extensively documented (see especially Fournier, McAlexander, & Schouten, 2000). McAlexander, Schouten, and Koenig (2002) studied the Jeep user group. Muniz and O'Guinn (2001) studied Saab and MacIntosh user groups, noting the importance of product-related Web sites in group activities. Holland and Baker (2001) note that many Web sites are encouraging the development of virtual communities in the belief that they promote brand loyalty. The communities of interest on the women's portal iVillage provide a robust example of building community on the Internet.

FUTURE TRENDS

The development of techniques that promote satisfying interactive brand experience is still in the early stages. Both marketing creativity and technological developments will continue to add to the array of interactive options. Marketers are in even earlier stages of learning to use these techniques in a way that engages and satisfies their customers and thereby promotes brand development. The objective must be to embed the brand message in experience-producing activities that customers are motivated to engage in and even to seek out.

We are beginning to accumulate valuable data about Interactive brand experience. The research to date, however, focuses almost exclusively on individual tools in individual channels. Except for the IAB studies, there is virtually no published research on the effect on brand development of executions of the same message in various channels or the use of different, supporting messages in diverse channels. Understanding interactions between channels and messages, both online and off-line, is critical to success in multi-channel marketing. Increased understanding of the interactions will help marketers meet the challenge of using the right combination of tools to create Interactive Brand Experience that supports and enhances overall customer experience and fosters the development of strong brand equity.

CONCLUSION

The Internet has provided marketers with another channel for communicating and transacting with their customers. Research indicates that brand development can take place as a result of customer exposure to online marketing activities in ways that are similar to the branding effects of off-line marketing activities. Customer experience provides the focal point for the branding messages received from both online and off-line sources.

The interactive environment of the Internet has generated a set of techniques, some that are new and some that predate the Internet but have found new richness and vitality there. Marketers are still learning to use the interactive techniques in customer-pleasing ways. They then face the challenge of integrating the online and off-line experiences into a single cohesive branding effort. All of this takes place in the context of a media environment undergoing change, both off-line and online. The business case for engaging in brand development efforts online as well as off-line, however, is compelling.

KEY TERMS

Brand: As defined by the American Marketing Association, a name, term, sign, symbol, or design—or a combination of them—intended to identify the goods and services of one seller or a group of sellers, and to differentiate them from those of competition.

Brand Equity: The value of a brand, measured in financial terms.

Choiceboard: An interactive, Web-based tool that lets customers design their own products and services by choosing from a menu of options.

Customer Experience: The target customer's overall outcome, which includes both results and image factors, after using a product or visiting a retail store or a Web site.

Interactivity: Media or channels that permit two-way communication whether the format is one to one (telephone), one to many (interactive television), or many to many (the Internet).

Multi-Channel Marketing: Using more than one channel of distribution to reach the customer; for example, a bricks-and-mortar retailer who also has a Web site and perhaps also a paper catalog.

BSC-Based Framework for E-Business Strategy

Fen Wang
University of Maryland, Baltimore County, USA

Guisseppi Forgionne
University of Maryland, Baltimore County, USA

INTRODUCTION

E-business is far more about strategy than technology (Raisinghani & Schkade, 2001). An effective e-business strategy is concerned with e-business multidimensional characteristics associated with different levels, parties, elements, and growth pattern features (Bakry & Bakry, 2001). In the process, the strategy must incorporate the effects of the instant and global Internet communication mechanism on the company's business management architecture. The global reach and interconnectivity of the Internet have spawned new models of e-business strategy and radically transformed existing ones (Pant & Ravichandran, 2001). Indeed, what distinguishes many of the dot-coms is not their new technical power, but the radical new business models (Hamel, 2000).

Aided by such innovative e-business models, managers will be able to identify the major decision factors involved in their business strategies and generate strategies that would improve their overall performance and profitability. In the current context, four essential perspectives are identified to be associated with an e-business strategy: financial, customer, internal processes, and learning and growth. These four perspectives were first introduced in early 1990s as the balanced scorecard concept (BSC) (Kaplan & Norton, 1992). Because the BSC methodology explicitly focuses on links among business decisions and outcomes, it is intended to guide strategy development, implementation, and provide reliable feedback for management control and performance evaluation. This BSC rationale is thereby appealing to managers who face new challenges in the current turbulent e-business climate.

The real challenge is to determine how the BSC can be successfully applied in the context of e-business's constantly changing environment of interdependencies (Hasan & Tibbits, 2000). E-business introduces new business objectives and strategies and the old measures of success may no longer apply. It is anticipated that the departure from the original BSC for a strategic e-business management framework would be more radical than the existing BSC adaptations (e.g., Martinson's balanced IS scorecard; Martinsons, Davison, & Tse, 1999).

BACKGROUND

Few, if any, precise and complete e-business strategy models are available from the literature (Dubosson-Torbay, Osterwalder, & Pigneur, 2001). There are a few theoretical academic studies with some empirical evidence on e-business models success (Horsti, Tuunainen, & Tolonen, 2005). Generally, these e-business model studies fall into two categories: subsystem research and generic frameworks. Examples of the subsystem research include modeling for price structures (Liu, Wynter, & Xia, 2003), customer needs (Olsson & Karlsson, 2003), process synchronization (Park, 2002), and knowledge sharing (Koh & Kim, 2004). Since these subsystem models deal with a particular aspect of e-business, they do not offer a global and complete view of e-business strategy.

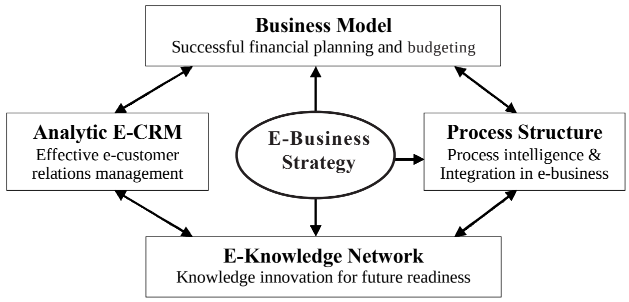
There are several generic frameworks for the development and analysis of e-business models. Whelan and Maxelon (2001) proposed that an e-business architecture requires product, channel, customer management, resource management, and information elements. Afuah and Tucci (2001) presented a more detailed list of components including scope, customer value, revenue sources, connected activities, and so forth, but like Whelan and Maxelon, they did not specify the interrelationships. Hamel (2000) specified a complete four-part framework with bridge components that is geared toward guiding strategic choices of management. Similarly, Dubosson-Torbay et al. (2001) used a framework with four principal components to analyze e-business: product innovation, customer relationship, infrastructure management, and financial aspects. Going beyond the segment frameworks, De, Mathee, and Abraham (2001) developed a pragmatic framework that offers different perspectives for the analysis of e-business including transaction costs, switching costs, infrastructure investment, and revenue models and so on.

For the most part, the generic models offer theoretical, not analytical, decision guidance for practitioners. One exception is the BSC-based e-business framework, with preliminary empirical evidence, proposed by Hasan and Tibbits (2000). Their empirical evidence, which was gathered from a case study in an Australian state-government utility, gave four high-level perspectives but no specific and explicit measures with each perspective. Currently, there is no comprehensive and concrete investigation that applies the traditional BSC to e-business strategy.

EBBSC FRAMEWORK SPECIFICATION

Considering a wide range of factors and relationships in this fast-changing e-era, we adapt the original BSC methodology into a comprehensive e-business strategy framework (EBBSC) consisting of four updated perspectives: business model, analytical e-CRM, process structure, and e-knowledge network (see Figure 1). The EBBSC framework links business strategies to a broad range of innovations and measures, examines important business issues facing e-business managers, and provides a complete view of e-business strategies. The framework can be better understood by examining the components in detail.

Figure 1. Adapted four perspectives of e-business strategy

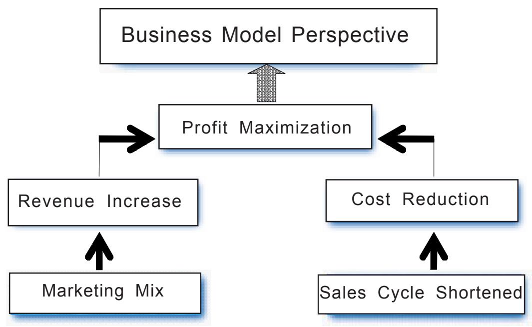


Business Model Perspective

Although e-business models differ from the traditional brick and mortar models in various ways, the fundamental needs of consumers and businesses remain much the same. Consumers want the best deal by price and service comparison, while businesses want to grow sales by targeting the right e-shoppers. On the other hand, traditional rear-view and static planning and budgeting cycles don't measure up to the dynamic, competitive, and compressed business cycles in the global e-era. E-business managers need to focus on a future-oriented profit maximization strategy that will support on-the-spot decision making at the turning points.

- **Profit Maximization:** Profit is equal to the difference between the revenue and cost. Many intangible and tangible factors may affect profit by influencing revenue and cost directly or indirectly, creating risk or uncertainty in achieving the company's profitability (Palmer & Wiseman, 1999).
- **Revenue Increase:** Revenue increase refers to expanding and re-pricing product and service offerings to achieve a higher value added mix. According to economics theory, revenue equals the product of the purchases and price. Purchases equal the minimum of the product quantity offered (quantity supplied) and quantity customers are willing and able to purchase (quantity demanded). Quantity demanded is treated as a function of the customer retention, marketing mix, and competition. Customer retention measures the company's customer stickiness or loyalty. The marketing mix includes the company's major marketing decisions. Competition represents the rivalry between the company and other businesses in the target market. Determinants of the quantity supplied include price, capacity, supply chain management efficacy, and staff proficiency. E-business capacity measures not only the limit imposed by the equipment and/or available personnel, but also the limit associated with the network technology. Supply chain management efficacy refers to the effort of the company in managing relationships with its suppliers.
- **Cost Reduction:** The Internet age enables businesses to reduce unnecessary or redundant buyer–seller costs. Generally, cost is composed of fixed cost, which in an e-business context can include e-business system development and maintenance expenses, and variable cost, which equals the product of unit cost and quantity supplied.
- **Marketing Mix:** Marketing effort helps in identifying market opportunities and generating marketing strategies that support attainment of e-business objectives. The major factors involved in the marketing mix include people, promotion, price, product, presentation, and distribution effort. The original "Place" factor is decomposed into presentation and distribution effort to represent e-market reality. Presentation refers to the effort involved in online product presentation and distribution. Distribution effort facilitates the connection of the product with the target customer.
- **Sales Cycle Shortened:** The sales cycle consists of the time that elapses between the customer interest and the purchase decision. In e-business, a shorter sales cycle enables management to respond promptly to emerging opportunities or threats. The major factors that impact the sales cycle include the customer profile, product, price, promotion, and presentation. A customer profile is a composite vari-

Figure 2. Business model perspective for e-business strategy



able that reflects the customers' demographic characteristics, preferences and behavior patterns. Generally, the more positive the customer profile index, the lower the product price, the higher the product quality, the better promotion methods and efforts, and the more preferable presentation formats, the shorter the sales cycle would be. Figure 2 summarizes the business model perspective in the framework.

Analytic E-CRM Perspective

The Internet enables customers to conveniently shop online, have a broader selection, get competitive pricing and greater access to critical business information (Chen et al., 2004). Online retailing, however, is impeded by security and privacy concerns, downloading time and other technology barriers (Chen, Gillenson, & Sherrell, 2004). Furthermore, customers can switch to other competitive URLs in seconds with minimal financial cost, which makes successful customer management vital in e-business.

- **New Customer Acquisition:** Customer acquisition depends on precise and timely targeting that delivers valuable offers to prospects. The factors involved in customer acquisition include the company's marketing mix, e-service quality, the customer profile and competition. Competition represents the company's external relationship with the supplier, availability of other distribution channels, entry barriers, and product substitutes. When addressing the factor, we have converted the original customer perspective from an external view (Kaplan & Norton, 1992) into a relationships perspective (Hasan & Tibbits, 2000).
- **Customer Satisfaction:** Satisfaction is influenced by lead time, product quality, service quality and competitive pricing (Kaplan & Norton, 1992). Lead time measures the time required for the company to meet its customers' needs, sometimes referred to as "order-to-delivery cycle time." A product with high quality and customization level and relatively lower price may increase the degree of the customers' satisfaction. E-service quality represents the level of the service offered in e-business.
- **Customer Retention:** Satisfied customers are not necessarily loyal customers. Loyal customers, who repeat their purchases, are valuable assets of the business. We identified customer satisfaction, goodwill, customer profile, channel flexibility, and competition as the major determinants of retention. Satisfied customers are more likely to return for repeat purchases. Goodwill, the favor or prestige that a business has acquired beyond the mere value of what it sells reflects the cumulative customer satisfaction (Jennings & Robinson, 1996). Companies need to identify and retain customers based on their profile. Channel flexibility refers to the availability of distribution channels besides the Internet. According to Reichheld, Markey, and Hopton (2000), the seamless integration of different channels can prove to be valuable.
- **Customer Profitability:** Succeeding in customer acquisition, satisfaction and retention does not necessarily ensure the company profitable customers. The focus of the business's customer strategy, then, should be on profitability. Although the purchase margin is straightforward, specific customer initiated cost is not that obvious and tends to be hidden in the customer support, marketing and sales functions. Those costs uniquely traceable to customers include the customer transactional cost, customer service/support cost, packaging delivery and post sales costs. The ratio of the customer purchase margin to the serving cost is revealing when compared on an individual customers basis, or by segment or channel basis (Schoeniger, 2003). Figure 3 summarizes this analytic e-CRM perspective.

Process Structure Perspective

With increasingly competitive global markets, efficiency remains vitally important. E-business processes must be timely, flexible, and dynamic. A generic value chain is illustrated in Figure 4, which offers an abstract description of the processes within any type of business. To be feasible in e-business, the internal process view should consider the flexibility and intelligence of the process structure (Hasan & Tibbits, 2000). This view implies that e-business process perspective affects not only internal business processes but also the whole business structure.

Figure 3. E-CRM perspective for e-business strategy

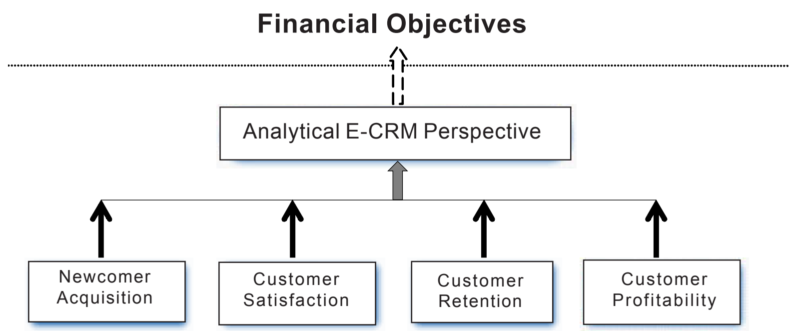


Figure 4. A generic value chain (From Lewis, 2001)

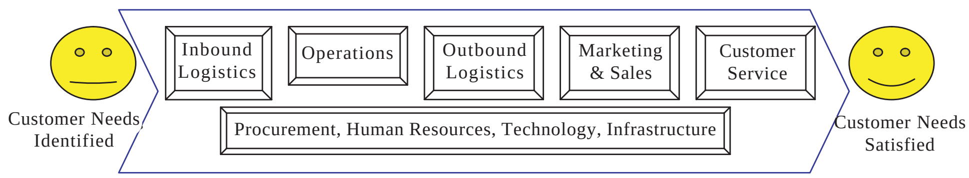
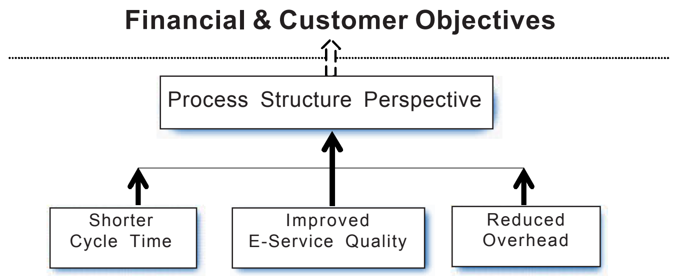


- **Shorter Cycle Time:** The notion of shorter cycle time can be directly translated into bottom-line revenue for nearly all companies. General cycle time measures the time to plan and stock (inbound), inventory and scheduling (operations), lead time (order-to-delivery time) and invoice a particular product (outbound). Effective process integration and intelligence can optimize this cycle, measurably reducing inventories and matching market desires. Wherever there are manual and sporadic tasks in the cycle, there are chances for overhead costs, delays, and errors, which can all contribute to a longer cycle.
- **Improved E-Service Quality:** E-service is the glue that holds the e-business process together. According to Voss (2000), customer service generally involves three levels:
  - The minimum necessary services, such as site responsiveness, site effectiveness, and order fulfillment. Network performance and infrastructure can ensure the basic services customers would expect.
  - Customer-oriented services, which can promote retention and satisfaction, fall into two categories: (a) informational capabilities: help information availability and interactive communication with the service representatives; and (b) transactional capabilities: order customization and tracking, complete support during ordering process and after purchase period.
  - Value-added services are extra services such as location sensitive selling/billing or online training. Overall, value-added services provide operational and administrative synergy among other levels of services.
- **Reduced Overhead:** Every dollar saved from overhead adds to profit. Being agile and flexible, the virtual process of e-business replaces the traditional product inquiry and physical clearinghouse process and provides greater operating advantages that may lead to reduced overhead. Process integration and intelligence reduce the need for a well-defined organizational structure and often whole layers of staff. As a result, e-business initiatives have resulted in a flatter organizational hierarchy, which leads to higher process efficiency, visibility and transparency. Figure 5 summarizes this process structure perspective.

E-Knowledge Perspective

Because success targets keep changing, the company must make continual improvements to survive and suc-

Figure 5. Process structure perspective for e-business strategy



ceed in this intensive global competition. Knowledge innovation and management facilitates continuing business readiness in the "new world" of e-business. Organizations are now creating Internet-based knowledge networks to facilitate improved communication of data, information, and knowledge, while improving coordination, decision making, and planning (Warkentin, Sugumaran, & Bapna, 2001). Figure 6 highlights some of the characteristics of e-knowledge networks.

This enhanced e-knowledge network will lead to greater back-office efficiency, flexible adaptation to market changes, greater customer intimacy, and other organizational benefits. In other words, the intangible effect of e-knowledge networking is reflected through the tangible measures of the other perspectives. There are additional implications of staff proficiency, process integration, and process intelligence.

- **Staff Proficiency:** Specific manager proficiency and employee skills are required in the new competitive e-business environment. The e-knowledge network offers a repository where new knowledge is created and collected while existing knowledge archived in data warehouses is renewed and updated. Management and operational judgment, knowledge, and experiences are shared and managed to facilitate improved communication, coordination, decision making and planning. Also, staff with higher qualifications can work more efficiently and effectively, while training can be utilized to improve their skills and keep them updated with the technology shift.
- **Process Integration:** Process integration enables a company to unify every aspect of its back-end infrastructure and increase responsiveness to changes by integrating disparate business processes. E-knowledge innovation and management facilitates the integration process by creating e-knowledge networks that are characterized by automated capture and exchange of rich knowledge to direct the operation of key interactive processes. The flattening of the organizational hierarchy also contributes to process integration, which leads to higher process efficiency, visibility and transparency.
- **Process Intelligence:** Process intelligence facilitates matches between the company's offering and target customers, competitors, and the current business by automating the decision and action processes and initiating real time analytics of sales and business alerting (Park & Park, 2003). The e-knowledge network generates and stores immediate knowledge about internal and external processes, customers and markets, strategic partners, and supply chain partners. Effective communication with trading partners across different platforms can help represent, implement and track the external business processes in a dynamic and flexible way (Park & Park). Figure 7 summarizes the e-knowledge network perspective.

Figure 6. E-knowledge networks characteristics (Adapted from Warkentin et al., 2001)

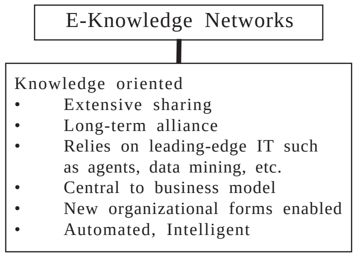


Figure 7. E-knowledge network perspective for e-business strategy

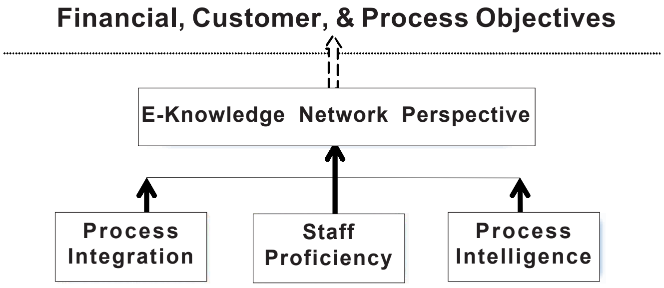

Figure 8. Simplified EBBSC framework overview

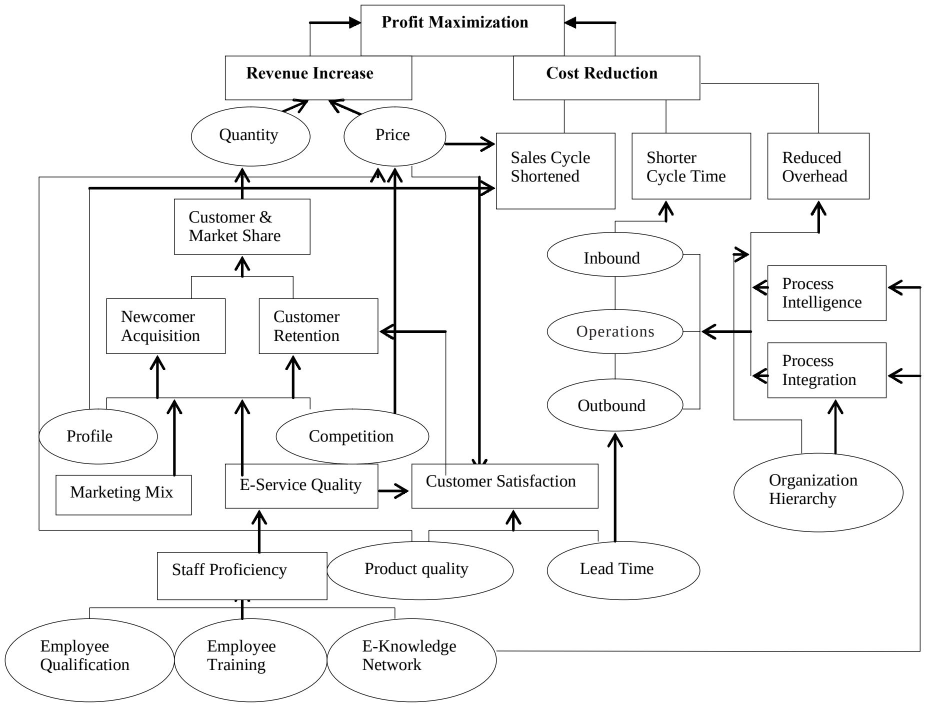

EBBSC IMPLICATION AND FUTURE TRENDS

Figure 8 summarizes the major measures (Square) and the corresponding decision factors (Oval) and relationships (Arrow Lines) identified in the proposed EBBSC framework.

At the conceptual level, the framework offers e-business managers a big-picture perspective that is critical in generating and evaluating effective e-business strategies. As an illustration, consider an e-business company that seeks to acquire more prospective customers in the next planning period. The manager first will locate the strategic measure of Newcomer Acquisition in the framework and identify the relevant decision factors. As the EBBSC framework indicates, these factors include the Customer Profile, Competition, the Marketing mix, and E-service Quality. Next, the manager can formulate a tentative strategy plan. In this case, the framework suggests that the company needs critical information regarding the prospective customer population and the competitors. Based on the collected information, management must decide on a specific marketing mix and e-service solution.

Starting from the market mix or e-service quality, the EBBSC framework suggests the steps to follow to create the mix and quality plan. Having the priority of the strategic objective at each stage, the manager can allocate the available resources more effectively to achieve these objectives.

As an innovative and exploratory framework for e-business strategy, the framework offers directions for future endeavors. First, empirical research is needed on the specification of the measures, factors, and relationships in each e-business perspective. Such effort will lead to a more precise and explicit model that offers e-business manager concrete and quantified support in generating strategies. The EBBSC framework also can be adapted to nonprofit e-business applications. The conceptual framework is feasible and directive in both profit-driven and non-profit Internet-using organizations. Different performance measures will be identified under each adapted e-business perspective, and the corresponding factors and relationships will be updated accordingly.

CONCLUSION

In closing, this EBBSC framework for e-business strategy contributes to both theory and practice. From a theoretical standpoint, it explains how the adaptation of BSC offers a methodology to formulate and evaluate e-business strategy. The framework also offers an evaluation model for strategic e-business decision support. In practice, it provides a means of identifying business opportunities and threats, analyzing current business capabilities and resources to address the opportunities and threats, and generating effective e-business strategies that would improve overall performance and profitability. In addition, the framework provides a stable reference for companies to understand and manipulate the fundamental changes introduced by e-business initiatives, and it enables e-business managers to plan and allocate resources more effectively and align strategic objectives with performance results.

KEY TERMS

Channel Flexibility: The convenience and availability of distribution channels other than the Internet which contributes to increased profit and customer retention.

EBBSC: A balanced scorecard based framework to formulate and evaluate e-business strategy consisting of four perspectives: business model, analytic e-CRM, process structure, and e-knowledge network.

E-Business Strategy: An elaborate and systematic plan of action intended to accomplish specific e-business goals, which considers e-business multidimensional characteristics

E-Capacity: The limit of the e-business company's ability to produce or perform that is imposed by the equipment and/or available personnel and the network technology and performance.

E-Knowledge Network: A repository where new knowledge is created and collected while existing knowledge archived in data warehouse is renewed and updated.

E-Sales Cycle: The time that elapses between the customer initiating the buying process online, and the point at which a decision is made on which product to buy.

E-Service Quality: Customers' overall perception and experience of the three levels of the service offered in e-business: foundation of service, customer-oriented services, and value-added services.

Process Integration: The degree of problem critical information sharing and transmission across different departments and the combination of two or more stages in producing or distributing a particular product.

Process Intelligence: The ability of the business processes to perceive and act in the surrounding environments, to respond to the prevailing circumstances in dynamic business situation, and to learn and improve the process with prior experiences.

Building Government-to-Government Enterprises

Luiz Antonio Joia
Brazilian School of Public and Business Administration
of Getulio Vargas Foundation & Rio de Janeiro State University, Brazil

INTRODUCTION

Electronic government has proven a watershed in the domain of public administration, despite being difficult to pin down precisely. Indeed, the government-to-government (G2G) arena is one of the least studied aspects of this newly established field of knowledge, despite its importance in fostering cooperation and collaboration between government agencies, mainly with respect to the management of their knowledge, in order to increase the effectiveness of public administration.

The main scope of this article is to present some key success factors for building G2G enterprises successfully. It also aims to show how public agencies themselves can benefit when they are electronically linked to others, thereby innovating and streamlining their working processes, in order to achieve greater agility and efficacy at reduced cost.

In order to pinpoint the key G2G success factors, a single explanatory and successful case study approach was used, namely one involving the Brazilian Central Bank (BCB) and the Brazilian Justice Department (BJD). The BacenJud system developed by the Brazilian Central Bank was analyzed in a more detailed manner. This case—considered a success—shows how this G2G project made it possible for both the Brazilian Central Bank and the Brazilian Justice Department to achieve greater agility and effectiveness regarding the processing of legal demands made by the Brazilian Justice Department, thereby handing down its sentences at reduced cost.

Furthermore, this study examined the factors that had a clear nationwide impact on the success of this endeavor in the realm of the Justice Department.

Therefore, this article intends to answer the following research question: From the case study analyzed, what are the key success factors in the implementation of government-to-government processes between public agencies in Brazil?

BACKGROUND

The Incremental Effects of Information Technology in Organizations

According to Henderson and Venkatraman (1993), the contribution of IT to business was affected by skepticism in the early 1990s due to the failure to achieve the promised results. In view of this perception, Venkatraman (1994) pointed out the pressing need to create and develop new criteria to evaluate the impact of IT on business, duly reappraising automation logic, cost reduction and internal operation efficiency-based logic, which had prevailed until that time and might well no longer be relevant parameters.

In order to overcome this hurdle, the author developed a referential model in which five levels of IT-enabled transformations in organizations were described: localized exploration; internal integration; business process redesign; business network redesign and business scope redefinition.

The first level, localized exploration, is the basic one for leveraging IT functionality within a business. The second level, internal integration, is a logical extension of the first, reflecting a more systematic attempt to leverage IT capabilities throughout the entire business process. The third level, business process redesign, reflects a strong view that the benefits from IT functionality are not fully realized if superimposed on the current business processes, however integrated they may be. The fourth level, business network redesign, represents the redesign of the nature of exchange among multiple participants in a business network through effective deployment of IT capabilities. The fifth level, business scope redefinition, directly addresses the question: What role—if any—does IT play in influencing business scope and the logic of business relationships within the extended business network?

According to Venkatraman (1994), the first two levels are evolutionary, whereas the latter three are revolutionary. His main thesis addresses the fact that the use of IT associated to evolutionary levels only has a very slight impact on business change, despite the complexity of the technological infrastructure used. Consequently, the real benefits of IT in business only arise from the revolutionary levels, that is, the redesign of business processes and also of business networks and the redefinition of business scope.

Internet technology-enabled organizations to rethink ways of doing business (Evans & Wurster, 1999). As regards the G2G realm, the redesign of business networks among public agencies is now a reality (Andersen, 1999) and the bedrock for G2G enterprises, as will be seen in the case study presented as follows.

E-Government: An Idea Lacking a Clear Definition

E-government is still an exploratory knowledge field and is consequently difficult to define accurately. Moreover, it encompasses such a broad spectrum that it is difficult to find one expression that encapsulates exactly what e-government really represents.

According to Zweers and Planqué (2001), one can say that "E-government concerns providing or attainment of information, services or products through electronic means, by and from governmental agencies, at any given moment and place, offering an extra value for all participant parties" (p. 92).

Lenk and Traunmüller (2001), on the other hand, choose to see e-government as a collection of four perspectives based on citizens, processes, cooperation and knowledge management, which is obviously merely taxonomy developed to help researchers study this field. Naturally, there is a great deal of interdependence among the facets quoted, and they can seldom be studied individually.

Other authors define e-government in a broader sense (see, for instance, Kraemer & Dedrick, 1997; Perri 6, 2001; Traunmüller & Wimer, 2004). For them, e-government encompasses a broad gamut of activities, from digital data and electronic public service to online pool, e-democracy, and e-governance. Yet, the most recent definitions see e-government as the various ways government uses information and communication technologies to remain relevant in the knowledge society (ITAC, 2002), that is, to support government operations, engage citizens, and provide government services (Dawes, 2002).

Currently, we detect substandard efficiency, efficacy and effectiveness, and at a high cost, in the traditional governmental processes between two or more public agencies. Faced with this reality one question arises: If enterprises have discovered the enormous benefits that the Internet can generate for them through linkages among themselves, why do public agencies not use this technology and the integration it provides, in order to become more responsive at reduced cost? As public budgets are shrinking all over the world and society is increasingly calling for more accountable public administration, integrated electronic processes between public agencies, via the Internet, known as government-to-government, can be the answer to this question (Cavalcanti-Neto 2002; Lutz & Moukabary, 2004).

CASE STUDY

The Brazilian Federal Constitution grants very few institutions right of access to the bank accounts of both citizens and companies or, indeed, the power to freeze financial assets of either. One such institution is the Justice Department, which intervenes by means of judicial orders handed down by the judges of several courts nation wide.

As required, a judge can either freeze or liberate the bank accounts of both citizens and businesses and even declare the bankruptcy of a company. Judges are further empowered to suspend a decreed bankruptcy or request financial information about organizations and citizens under scrutiny.

When it issues orders relating to information about the financial assets of either citizens or institutions, the Justice Department sends them directly to the Central Bank, which then forwards the orders to the specific recipients, namely either an institution or the Brazilian Financial System. It is almost impossible for the Justice Department to know precisely where the request should be sent.

As there was already a computerized system in the Central Bank linking it to the Brazilian Financial System (JUDNET, 2001), it was relatively easy to meet the Justice Department's requests. However, the increasing demand for this kind of information made by the Justice Department obliged the Central Bank to involve several employees on a full-time basis and expend considerable financial resources just to deal with this requirement. Over the years, the number of claims has increased dramatically. In the meantime, the Central Bank's Legal Department issued an opinion alleging that the Central Bank had no constitutional duty to assist the Justice Department with these specific demands. However, in order not to jeopardize its relationship with the Justice Department, the Central Bank decided to rethink its *modus operandi,* in order to continue giving assistance to the Justice Department.

Consequently, the Central Bank acknowledged the need to redesign this working process, by streamlining it and achieving greater efficiency and responsiveness at reduced cost. At a time when the Federal Government has reduced the public spending budget and society is demanding greater efficiency, efficacy and accountability from the public agencies, it was of paramount importance to achieve this.

An Innovative Process

By 1999, the Central Bank realized it was no longer feasible to process this operation manually, that is, receiving claims on paper and feeding them into the communication systems linked to the National Financial System. In 2000, the Central Bank received 300 claims per day, totaling 71,775 claims in that year. A team of 23 people working full time on this task was unable to meet the Justice Department's demands in time, thereby causing problems in terms of efficacy. The Bank was spending approximately US$1 million per year to process these requests, including wages, equipment and so forth.

The Bank soon realized that there was a pressing need to develop an information system where the Justice Department itself could formulate its requests that could then be forwarded directly by the Central Bank to the financial institutions.

The Bank looked into the possibility of a revised information flow, seeking to take advantage of the deployment of the existing Internet access in most Brazilian courts. A Web-based system was developed in order to centralize the interaction of the judges with the Bank so that they could file their requests directly. A Web-based system was selected such that the judges would not have to install any specific software on their desktops, thereby reducing costs involved in the process.

Process Architecture

From the moment a court signs an agreement with the Central Bank, it designates a professional in charge of managing the system on its premises. This manager is supposed to conduct operations including: adding users; altering data; changing passwords; granting permission to judges to access the system and withdrawing this permission when necessary. These operations are done through the system itself, which has a dynamic interface, according to user profile. Users can then access a restricted site on the Internet and after their identity is verified, the system offers Web templates to allow them to fill out their requests. These are recorded directly in the Central Bank's corporate database.

At 7 p.m. every day, all requests received during the course of that day are processed and forwarded to the financial institutions as electronic files. Each institution then replies directly to the judge involved. The process allows the institutions to standardize their answers and send them directly to the judges' e-mail addresses.

Key Success Factors

Thus, by consolidating information from all the observations, interviews and questionnaires, it can be seen that access and information security, organizational culture, and training were the key success factors in this G2G enterprise, as detailed in the following.

Access and Information Security

As the Internet has become a very important link between governmental agencies, it is of paramount importance to avoid security flaws, such as information violation by "crackers," breakdowns in communication and so forth. Losses caused by such problems are more than just financial, as they can cause loss of confidence and acceptance by users and even involve the interruption of a given communication link (Endler, 2001).

In G2G processes, the issue of security is even greater, as confidential information can leak and be made public. Most of this information is protected by laws of secrecy under Brazilian legislation.

Thus, as was shown generically above, it is clear that security is one of the key success factors for a G2G endeavor. An authentication failure can allow any person to issue a legal request and expose the private life of citizens and relevant organizational information to all and sundry. Several courts insisted on seeing how the process worked before actually deciding to join the network proper.

Organizational Culture

Another factor that influences the success of an electronic governance model is the culture of the public agency in which it is developed. New processes of electronic governance, at different levels within the public administration, demand changes in organizational culture (ITAC, 2002).

The influence of the culture is even more relevant when two different public agencies are working together, concurrently. The changes required in the organizational cultures in order to integrate different internal processes demand very clear prior definition of leadership and respective function. This role, itself, demands that a clear path be followed and precise judgement so as to make innovative workflows feasible (Kieley et al., 2001).

Hence, as seen above, the success of the use of a new process depends on the culture within the organizations involved, in this case, the culture of the courts nationwide. It was observed that the courts that already had a culture of using computerized processes assimilated the new *modus operandi* very rapidly and naturally. On the other hand, courts without Internet access or that barely used information systems in their daily activities have resisted greatly in joining the G2G process.

Training

New technologies, new processes and new models of electronic governance require the acquisition of new knowledge not just by the persons involved directly in the process, but also by the persons in charge of administrating them. Consequently, public agencies must assess their human capital carefully, as it is mandatory to train personnel before deployment of G2G enterprises (Dujisin, 2004).

When the process involves more than just one public agency, all players must implement training efforts, in order to leverage the knowledge of the personnel in the agencies involved equally.

Insufficient training can lead to misuse of the electronic processes hindering the potential benefits that might be attained by this new model.

Although the system was developed based on a user-friendly environment via a web interface, the Central Bank felt it necessary to make presentations to judges across the country, in order to explain how the system worked and explain the best practices associated with this new workflow.

In October 2001, the Central Bank started to make presentations to the judges in the courts in a state where only 10 judges had joined the system and a mere 8 requests had been generated until that moment. In the two months following the presentations, 130 judges joined the system and nearly 100 requests were generated. Interviews made by the researchers have shown that the use of the G2G process by trained people is increasing, proving the efficacy of the training strategy.

FUTURE TRENDS

In the business sector, when all the tasks and procedures of an undertaking are centralized in a single company, it is simpler to organize and assess knowledge accrued from a project. The problem is that a handful of different players may now be involved in any major project. Consequently, the question that arises is: how is it possible to manage and store the knowledge generated during a given venture in such a way as to use it in the course of a specific project and also manage to access it for use on future projects?

Some very important research has already addressed several aspects of this issue, such as Badaracco (1991), Bahrami (1992), and Baker (1994), to name but a few.

However important these articles are in their own right, the scope of this research just touches on how to create, deploy, transfer, store and retrieve the intelligence of an undertaking encompassing a handful of different companies, in different places, with different, although important, duties. Therefore, the next logical step includes expanding the research to ongoing and ad-hoc inter-organizational groups.

Government as a collection of public agencies, each of them having their own information and knowledge, needs to ensure that these agencies are linked so as to share their explicit knowledge. It can be said that government is (or should be) similar to metabusinesses—quasi-firms, or virtual firms, created via digital links between several companies—in such a way that it is almost impossible to define their precise boundaries (Joia, 2005).

This is the main reason why knowledge management within public administration cannot be adequately researched and studied other than in the G2G realm. Thus, a future trend is to study G2G processes as enablers in the deployment of knowledge management initiatives within government. Knowledge management in public administration is still in its infancy (Lenk & Traunmüller, 2001, pp. 70-71).

CONCLUSION

From the case study analysis and interviews, it is possible to conclude that responsiveness to a G2G process is far greater than that obtained in traditional processes. This agility, itself, is of paramount importance in deploying more effective and efficient public policies. Besides, the security issue in a G2G process is a critical factor, as breakdowns arising from it can cause losses not only for public agencies, but for society as a whole.

Moreover, to overlook the organizational culture of a public agency by concentrating efforts on a technological facet of a G2G project may cause the undertaking to fail. Nonetheless, public administration is ruled by the same legal agenda and must comply with similar procedures and rules. However, each public agency has its own identity, values and culture, leading it to develop different workflows, sometimes far different from workflows addressing a similar process in another public agency. To analyze the culture and values of a public agency is of paramount importance to the success of a G2G enterprise.

Finally, although technology offers people a user-friendly interface and, in some cases, the technology is already being used in the public agency, a G2G enterprise involves a *modus operandi* that is new for most of the people involved. It is necessary to show the benefits this new process can bring and the best *praxis*, as important steps for proper implementation of G2G projects (Joia, 2004).

The case study addresses the “process” and “cooperation” dimensions in the e-government taxonomy proposed by Lenk and Traunmüller (2001), as presented earlier in this article, as well as allowing public agencies to attain levels 3 (Business Process Redesign) and 4 (Business Network Reconfiguration) regarding the use of Information Technology, according to the model proposed by Venkatraman (1994).

This is a very recent knowledge field; therefore far more research is needed. This article attempts to make a contribution in this very challenging area, in the hope that the results achieved may benefit societies worldwide.

KEY TERMS

BacenJud: An Internet-based linkage between the Brazilian Central Bank and the Brazilian Justice Department.

Business Processes: The interaction, coordination, communication and decision choices made by organizations in order to transform inputs (resources)—personnel, equipment, technology, information, energy, capital, and so forth—into products or services of added value to the customer/citizen.

E-Governance: The application of electronic means in the interaction between government and citizens and government and businesses, as well as in internal government operations to simplify and improve democratic, government and business aspects of governance.

E-Government: The various ways government uses information and communication technologies to remain relevant in the knowledge society.

G2G (Government-to-Government): The digital-enabled collaboration and cooperation perspective among distinct government agencies.

Knowledge Management: Techniques and tools for collecting, managing and disseminating knowledge within an organisation.

Metabusiness: A *quasi*-firm created through digital links among several companies, in such a way that it is almost impossible to know exactly its boundaries.

INTRODUCTION

Business-process management (BPM) is nowadays a key technology for the automation and support of processes in medium-sized and large organizations. This technology has been successfully applied to business-to-consumer (B2C) and business-to-business (B2B) e-commerce since the '90s, and it is now being applied also in e-government for the management of administrative procedures. As stated in Aalst, Hofstede, and Weske (2003), the origins of BPM technologies can be found in the '70s with the research on office information systems. Research in this area was almost stopped in the '80s, but it rose again in the '90s under the name of work-flow management. Now it is evolving with a more integral approach and a new name: BPM. It is defined in Aalst, Hofstede, and Weske (2003, p. 4) as "supporting business processes using methods, techniques, and software to design, enact, control, and analyze operational processes involving humans, organizations, applications, documents and other sources of information." The main functionalities provided by a BPM system are defining business processes, automatically enacting them, controlling their enactment, and analyzing them. This article is focused on the last functionality: business-process analysis (BPA).

BPA can be defined as a set of technologies that provide support for obtaining relevant properties of business-process models in order to reason about them, detect functional errors, or improve their performance.

BPA was a neglected area in the work-flow management systems developed in the '90s. Will van der Aalst (1998) was one of the first researchers in this field. He proposed the use of petri nets for modeling business processes and the application of the analysis theory developed for this formalism to demonstrate the correctness of the developed processes, analyze performance, and so forth. Since then, other approaches, based on formal methods, were proposed. BPA is important for BPM because it provides the technology for improving the reliability and efficiency of the business process of organizations. Reliability considerably reduces expenses caused by errors in transactions. Efficiency reduces expenses caused by an inefficient use of resources and can improve the satisfaction of customers.

The next section provides a background on the most important analysis technologies: functional verification and performance measuring. Then, the discussion is focused on functional verification. An overview on how different authors applied functional verification to business processes is presented. Then these works are analyzed and an open, modular, and extensible architecture for the functional verification of business processes is presented. Later, the future trends on this topic are outlined. Finally, the conclusion highlights the main concepts introduced in this article.

BACKGROUND

BPA technologies help process designers to reason about process models in order to guarantee a desired level of quality. The objectives of BPA can be classified into two main groups: functional verification and performance measuring. Functional verification consists of checking if the process is consistent with its functional requirements; that is, the process does always what it is supposed to do. Results of this type of analysis are used to correct functional errors in process models. Performance measuring consists of obtaining statistics about the performance of the process from the point of view of the customer (response times) or from the point of view of the organization that performs it (usage of resources). Results of this type of analysis can be used to obtain statistics, or to identify parts of the models that should be reengineered in order to improve performance. Depending on the type of reasoning needed, different analysis techniques are used. They are normally adapted from other fields like computer science. This section provides an overview of some of these techniques and shows how they are being applied for analyzing business processes.

Functional verification is an active area of research that is being applied to different fields, such as software engineering, digital-circuits design, or protocol design. As stated in Clarke, Grumberg, and Peled (1999), the main techniques for functional verification are guided simulation, testing, deductive verification, and model checking.

Performance analysis is used, for example, for designing telecommunication networks, operating systems, or manufacturing processes. Techniques for performance analysis are normally based on queuing theory and simulation (Gross, 1998).

Guided simulation and testing are two traditional and widely used approaches for verification. Guided simulation is performed by executing the process model in a fictitious environment provided by a simulator. The designer can, for example, guide the simulation, view or modify the content of variables, or put break points into the process definition. Testing consists of checking the correct behavior of the process in the real business-process management system before its definitive deployment. Although they are very useful analysis techniques, simulation and testing cannot, in general, analyze the behavior of all the possible execution traces of a process. In addition, they require too much human intervention and cannot be automated.

Deductive verification and model checking are techniques based on formal methods. They can be used to prove that a given property is true (or false) for every possible evolution of a process model.

Deductive verification is based on the use of mathematical axioms and rules for proving properties of models with the assistance of semiautomatic theorem provers. Deductive verification can be used to prove properties even in infinite-state process models. However, its main disadvantages are that it must be performed by trained experts, it requires a large amount of time, and it is an error-prone technique (Wang, Hidvégi, Bailey, & Whinston, 2000). These problems could be solved in the future with the development of more powerful theorem-proving algorithms. Formalisms like Z (Spivey, 1992), the B method (Abrial, 1996), or VDM (Jones, 1990) can be used for this purpose.

Model checking is a powerful technique for automatically verifying finite-state, concurrent systems. Verification can be performed using efficient algorithms. This technique was born in the early '80s with the development by Clarke and Emerson (1981) of the first algorithm for verifying CTL (computation-tree logic) properties in finite-state models. Since then, model checking has been an active area of research and much more powerful algorithms have been developed, like symbolic model checking or bounded model checking, combined with simplification techniques like abstraction. Nowadays, they can be applied to process models with a very large number of states (Clarke et al., 1999). Another advantage of this technique is the rich expressiveness of the temporal logics, like LTL (linear-time logic) or CTL, used to define the verification properties. There are several widely used open-source model checkers, like Spin, SMV (Symbolic Model Verifier), or NuSMV, which provide implementations of the most important state-of-the-art model-checking algorithms.

Business processes are modeled using specific languages and formalisms. Each BPM system normally defines its own proprietary language. Although there are several initiatives that try to establish a common language like XPDL (XML [extensible markup language] process definition language), BPML (business process modeling language), or BPEL4WS (business process execution language for Web services), none of them have succeeded until now. Deductive verification and model checking are based on low-level state- or transition-based formalisms, like, for example, petri nets or finite-state machines. Therefore, state- or transition-based formal semantics should be added to process models in order to be analyzable with these techniques. When using queuing theory for performance analysis, transformation algorithms should be defined in order to obtain queue net models from process models.

Several research works have demonstrated the feasibility of formal methods for verifying business processes. In the following, we describe briefly some of the approaches that apply formal methods to BPA.

Aalst (1998) was a pioneer in this area. He proposed petri nets as a formalism for modeling business processes. He states that petri nets can model complex business processes, and that the powerful analysis techniques developed for them can be used to prove the correctness of business processes. These analysis techniques can be applied both for functional verification and performance measuring. On the one hand, they can be used to prove functional properties (safety properties like invariants, or liveness properties like the absence of deadlocks). On the other hand, they can be used to calculate performance measures like response times, waiting times, occupation rates, and so forth. Woflan (Aalst, 1999) is a tool that demonstrates the feasibility of this approach.

Eshuis and Wieringa (2002) realized that, although UML (Unified Modeling Language) activity diagrams were gaining popularity as a business-process modeling language, they were not suitable for performing analysis on them because of their lack of formal semantics. They designed specific semantics for modeling business processes using UML activity diagrams. Verification was performed by automatically transforming UML activity diagrams into verifiable SMV models.

In Wang et al. (2000), the authors use VerySoft and the model checker Spin to verify processes in e-commerce applications. The main problem of this solution is that it cannot be automated because it requires the modeler to code the verification models.

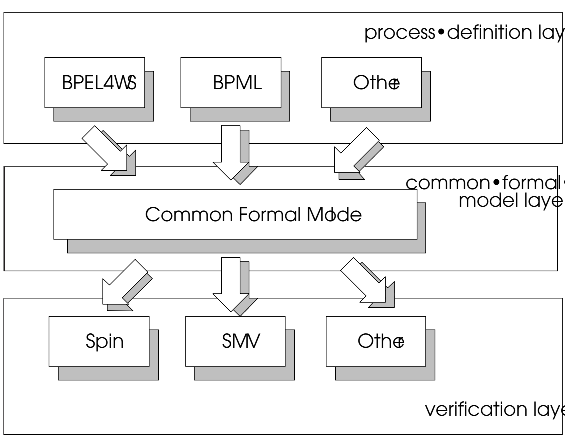
The field of the verification of Web-services compositions and coordinations has similar problems to those of BPA. There are several related works in this area. In Narayanan and McIlraith (2002), petri nets are applied to verify Web services defined using DAML-S (DARPA Agent Markup Language for Web Services). In Foster, Uchitel, Magee, and Kramer (2003), the authors propose the verification of BPEL4WS compositions by transforming them into LTSA (Labeled Transition System Analyzer) verification models.

ARCHITECTURE FOR BUSINESS-PROCESS ANALYSIS

The large number of business-process modeling languages and formalisms used now in BPM systems makes it difficult for the development of BPA systems to not be tied up to specific modeling languages. This is a big barrier for the commercial development of high-quality BPA systems. It also precludes the broad adoption by the industry of these kinds of tools. The situation can change in the long term if the BPM industry is capable of developing a commonly accepted modeling language. However, despite the fact that several attempts were made, this seems to be hardly possible for the short term. Therefore, BPA technologies have to face a great challenge in the short term: the development of BPA architectures in which different business-process modeling languages can fit.

VERBUS (Verification for Business Processes) is a first step toward this objective (Fisteus, Sánchez Fernández, & Delgado Kloos, 2004). It is based on an architecture that disconnects process-definition languages from verification tools by means of an intermediate layer. This layer provides a low-level state- or transition-based formalism specially designed for business processes. Process-definition languages can be integrated in this architecture by defining their semantics using the intermediate formalism of VERBUS and, based on these semantics, providing a translator from this language to the language of VERBUS. Once process models are translated to the VERBUS language, they can be translated to the input language of different verification tools. The current prototype of VERBUS provides translation tools to the input languages of Spin (Promela) and SMV, and can verify business processes defined with BPEL4WS. Figure 1 shows this architecture.

Figure 1.



VERBUS defines and uses its own intermediate formalism, which is formally defined in Fisteus, Marín López, and Delgado Kloos (2004). There is not yet research analyzing the expressiveness of this formalism, that is, if the formalism is expressive enough to be applied to any process-definition language. Future research should perform such an analysis based on work-flow patterns (Aalst, Hofstede, Kiepuszewski, & Barros, 2003). Other different formalisms, like petri nets, should also be considered for this intermediate formalism.

FUTURE TRENDS

An ideal BPA tool should be modular and extensible, enabling the installation of plug-ins for any process-definition language or analysis tool (performance-measuring tools, human-guided simulators, model checkers, etc.). It should be also easily integrable with BPM process-definition environments.

However, BPA is nowadays an emergent research area, and the proposed solutions are far from this ideal tool. There are only a few tools. Although there are too many business-process definition languages, the existing tools are, in general, designed for a specific language and verification tool. VERBUS is a first step toward this ideal solution, but it is only a research work in its first stages of development, and it is not clear if the intermediate formalism is expressive enough to model all the most used process-definition languages.

Research in this area should be focused on several areas. One area is the development of an intermediate and neutral formalism for representing business processes. This formalism should be expressive enough to be capable of representing processes modeled with major modeling languages. It should be also suitable for both functional verification and performance analysis. The achievement of this objective is difficult because of the variety of business-process modeling languages and formalisms used now in commercial BPM tools. Another area of research is the identification of generic properties to be verified in business processes. This research can be done by continuing the work of Aalst (1998) in WF-Nets (Workflow Nets). This would help to simplify the verification of processes by nonexpert people, and to integrate automated verifications in BPM tools.

CONCLUSION

Business-process analysis is an emerging technology that can provide many benefits to business-process management. It permits one to prove mathematically properties of business processes and to measure performance. This analysis can be applied at design time, or later as a diagnosis tool for reengineering processes.

Formal methods provide the foundations for BPA. Their feasibility for BPA has been demonstrated in multiple research works. However, BPA is not integrated yet in many BPM systems. In part, this is due to the fact that BPA tools are normally designed for specific business-process modeling languages, and that the research in this area is yet immature. Therefore, research in this area is needed in order to make BPA practical. An intem of special interest is in the development of a platform that could integrate many different process-definition languages in order to make them interoperable with proprietary BPMs.

KEY TERMS

Business-Process Analysis (BPA): Set of technologies that provide support for obtaining relevant properties of business-process models in order to reason about them, detect functional errors, or improve their performance.

Deductive Verification: Technique that, based on models of systems defined as sets of axioms and rules, verifies them by mathematically proving propositions and theorems.

Formal Methods: Set of tools and notations (based on formal semantics) used for unambiguously specifying the requirements of computing systems that allow one to prove properties of specifications and to prove the consistency of implementations with their specifications.

Formal Verification: Act of proving or disproving the correctness of a system with respect to a certain property (specification) using mathematical formalisms and methods.

Model Checking: Technique for the formal verification of temporal-logics properties on finite-state, concurrent systems using efficient algorithms.

Petri Nets: Process-modeling technique based on directed bipartite graphs with two node types called places and transitions that are connected by arcs.

Queuing Theory: Mathematical study of waiting lines (queues and networks of queues) normally applied for designing telecommunications networks and transports.

Businesses and Consumers as Online Customers

INTRODUCTION

The emergence of e-commerce as a way of doing business has created an environment in which the needs and expectations of businesses and consumers are rapidly evolving. Marketing managers must decide how often and how radically to adapt to the dynamics of the marketplace. Firms may simply offer a Web site, or they may embrace change as evidenced by frequent and/or major updates to obtain the maximum potential from e-commerce activities. Managers need to continuously evaluate their marketplaces to assess how much adaptation makes sense. The more managers know about customers' expectations and their likely reactions to e-commerce activities, the better they will be able to attract, satisfy, and retain online buyers.

BACKGROUND

Early adopters of innovation provide revenue needed to pay for research, development, and launch costs involved in bringing a new product to the market. This is true for adopters of a new e-commerce channel, as well. Further, although it is necessary to acquire new customers continuously to replace those who leave, attracting new buyers is not enough. Firms must retain at least a portion of first-time purchasers to remain viable. Loyal, satisfied customers add value for the firm because they tend to increase spending over time, spread positive word-of-mouth, and provide valuable feedback regarding the Web site (Reichheld & Schefter, 2000).

How are companies using Web sites to reach potential and current customers? Liu, Arnett, Capella, and Beatty (1997) examined the Fortune 500 to identify motivations for adopting e-commerce: the results include reduced costs of market coordination and improvements in efficiency, communication, and information processing. The presence of a Web page and revenues are often related (Liu et al., 1997)—this makes sense because, typically, homepages provide overview information about the companies and descriptions of products. The Web sites of smaller sized firms tend to focus on direct selling and immediate revenue generation, while larger firms' Web sites focus on communications, with apparent goals of building awareness and relationships. A focus on selling may neglect the need to communicate and assist potential customers in developing a relationship with a firm—this may be part of the reason so many smaller firms failed in the dot-com bust of 2000.

Although many of the critical issues are the same in business and consumer marketplaces, customer needs and behaviors differ for each of these types of markets. Pertinent observations are summarized in Figure 1 for convenient reference.

Characteristics of Business Online Buyers

Potential business online customers need to obtain specific information, including pre-sale support, delivery conditions, pricing options, documented quality, and post-sale service (Gattiker, Perlusz, & Bohmann, 2000). Search attributes (including product price, brand name, and warranty) and recommendations from others have greater influence online than in a brick-and-mortar retail store where other product features can be readily evaluated. As Web sites began to provide more of the necessary information, the business-to-business (B2B) marketplace exhibited phenomenal growth, far surpassing consumer online revenues. According to *E-Stats* (2002, 2003, 2004, 2005), an online publication of the U.S. Department of Commerce, B2B e-commerce in the U.S. totaled $913 billion in 1999, $997 billion in 2000, $1.01 trillion in 2001, $1.42 trillion in 2002, and was projected at $1.57 billion for 2003. In sum, B2B exchange is typically 94% of all e-commerce activity.

Figure 1. Overview of online buyer attraction, satisfaction, and retention

TYPE OF INTERACTION	Business-to-Business (B2B)	Business-to-Consumer (B2C)
Attraction	Marketing mix Customer demographics Convenience, efficiency Use of digital data transfer Availability of specific info Documented quality Support services Warranty	Marketing mix Consumer demographics Consumer psychographics (e.g., innovativeness) Positive attitude toward online buying Prefer online functionality Prefer online experience
Satisfaction	Lower prices On time, correct delivery Excellent communication Met expectations Lack of problems or opportunistic behavior	Positive online experience Outcome meets expectations Reduction of functional, financial, social, and psychological risk Recovery in case of failure
Retention	Repeated satisfying experience Consistent delivery Convenient re-buy Provide added value Customer relationship management (CRM)	Repeated satisfying experience Consistent delivery Post-sale support Frequent Web site updates Loyalty programs and CRM Building of trust

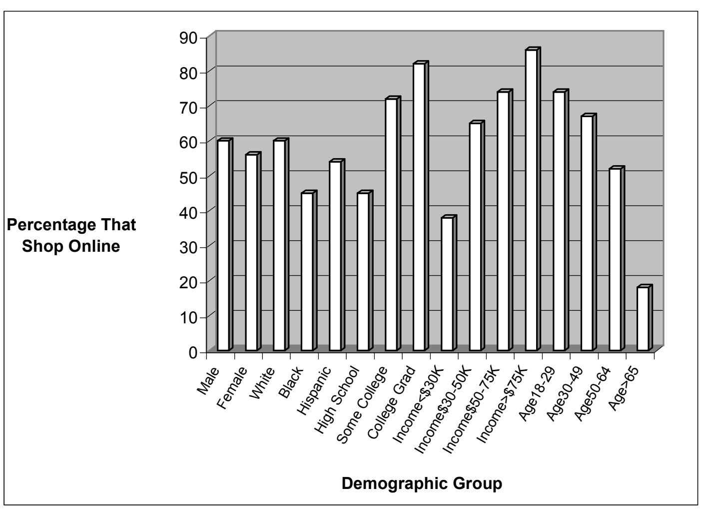
Some industries are more inclined to utilize e-commerce than others. *E-Stats* (2005) notes that 70% of all manufacturing e-shipments occur in only five industries, including transportation equipment, chemicals, computer and electronics, food, and petroleum and coal products. Merchant wholesaler e-sales were concentrated in only three industry groups, with drugs and druggist sundries, motor vehicle parts and supplies, and professional and commercial equipment and supplies explaining 61% of the total. There may be greater opportunities for increasing B2B e-commerce in industries that are not yet heavily represented.

Characteristics of Consumer Online Buyers

Shopping online has been adopted by increasing numbers of consumers each year, representing various demographic groups. Figure 2 relies on information from Lenhart et al. (2003) to provide a picture of Internet shopping behavior by demographic group.

Total business-to-consumer (B2C) online commerce, including services and retail trade, was $40 billion in 1999, $65 billion in 2000, $70 billion in 2001, $86 billion in 2002,

Figure 2. Online shopping by demographic group



and was projected to reach $106 billion in 2003 (*E-Stats*, 2002, 2003, 2004, 2005). Consumer trade represents only about 6% of the total e-commerce activity in the U.S. Four industry groups account for 45% of e-revenues in B2C services, including travel arrangement and reservation, publishing (including software), securities and commodities contracts intermediation and brokerage, and computer systems design and services (*E-Stats*, 2005).

Retail e-sales are concentrated in only two groups that total over 90% of this marketplace; these are non-store retailers, and motor vehicle and parts dealers. Retail e-sales grew 25% between 2002 and 2003, as compared to total retail sales growth of only 4% (*E-Stats*, 2005). Merchandise categories having the highest percentage of online sales include books and magazines, and office equipment and supplies. This is consistent with previous research, which suggests that books and CDs are common items for initial online purchases (Florsheim & Bridges, 1999). Other product categories are more likely to be purchased by more experienced online shoppers, and thus may have greater potential for e-tailer entry and growth.

ATTRACTING AND RETAINING ONLINE BUYERS

Attracting Business Buyers

Business buyers tend to purchase in large volumes and B2B sellers tend to have fewer, but larger, customers than B2C sellers. They are quite used to direct channels, and the Internet represents another mechanism for facilitating the supply chain. Further, they are typically motivated to find least-cost solutions, subject to meeting minimum requirements. When the same products are purchased repeatedly through a standard process, there is no need to interact with order takers or sales representatives. Of course, a number of personal selling encounters might be required before two firms agree to engage in automatic e-commerce. But then, a routine re-buy would certainly be flagged as the type of purchase that might be completed automatically, reducing both time requirements and the potential for human error. Thus, buyers tend to move online more easily for routine than non-routine purchases.

For a new purchase, the buying process might include protracted negotiation, reciprocity, or leasing; thus, it may be complex. Firms typically initiate a process of search and evaluation, possibly aided by information available on one or more Web sites. However, particularly if the product requires a large investment (such as capital equipment), it may be necessary to involve purchasing agents, sales representatives, engineers, and other personnel in a rather complex purchase process. The firms' online interaction may still be a part of the process, because it can provide information, reduce search costs, and facilitate relevant communication and post-sales follow-up activities. Companies also use the Web for many types of post-purchase support, ranging from reviewing technical specifications and ordering spare parts to participating in user group discussion forums.

Large firms are more likely than small firms to invest in installation of automated supply chain management and inventory control, such as an enterprise management system (Min & Galle, 2003). Moreover, firms in more information-intensive industry sectors are more likely to purchase online than those in less information-intensive sectors. Thus, firms that can best benefit from e-commerce are those that stand to gain the most from digital data transfer, enhanced supply chain efficiency, real-time information regarding product availability, inventory level, shipment status, and production requirements.

In summary, structural and economic factors drive businesses to switch to e-commerce. Such factors include newness of the type of purchase, specific inventory requirements, and benefits that might accrue from having a single hub.

Attracting Consumers Online

Online marketspace presents many advantages to consumers, including 24/7 availability, selection, perceived lower prices, online customer service, ability to personalize, no pressure from salespeople, and ease of search and comparison (Goldsmith, 1999; Hofacker, 2001; Xue, Harker, & Heim, 2000). Of course, there are also potential disadvantages, such as loss of privacy or personal information, delayed gratification owing to slow delivery, possible errors in order fulfillment, and inability to inspect or experience the product prior to purchase.

Individual attitudes and personal predispositions are important influences in consumer decisions regarding Web-based shopping (Goldsmith & Bridges, 2000). Further, buyers are more confident than non-buyers that orders will be filled accurately and promptly, that online merchants have good return policies, and that buying online offers good value. Goldsmith and Lafferty (2002) observe that innovative consumers tend to view online shopping as quicker, cheaper, and more fun than traditional shopping. Further, such consumers buy more online, report a greater likelihood of future online purchases, and believe themselves to be knowledgeable about online buying.

Factors that encourage consumers to buy online include utilitarian characteristics related to Web site usefulness and ease-of-use, and hedonic features related to enjoyment of the experience. Childers, Carr, Peck, and Carson (2001) use a technology acceptance model (TAM) to understand how characteristics of the Web influence its adoption. Although noting that usefulness is the primary determinant of a decision to adopt technology, Childers et al. (2001) anticipate that process dimensions of the online experience, and enjoyment in particular, may play a greater role than previously thought in a consumer's decision to shop online. Specifically, they postulate that context may differentiate the importance of various antecedents of technology adoption—their results indicate that usefulness is more related to shopping online when the goals are instrumental, while enjoyment is more related when the shopping value is hedonic.

What Web site design elements lead to increased buying? Flexibility in navigation, convenience, and substitutability of the Web site visit for personal examination of the product are critical (Childers et al., 2001). Further, the online experience must be intrinsically enjoyable, while it offers some improvement over the physical retail store. Design elements include structural attributes (e.g., frames, graphics, text, pop-up windows, etc.), media (graphics, text, audio, etc.), and site layout (organization of product offerings). Web site design may influence buying behavior by encouraging a state of "flow" in Web site visitors (Hoffman & Novak, 1996). This is corroborated by Goldsmith, Bridges, and Freiden (2001), who find a significant relationship between reported online buying and two key elements of flow—confidence and fun. Korzaan (2003) also observes an impact of flow on purchase; specifically, being in flow positively influences a customer's intention to buy online.

In summary, marketers must make efforts to address the needs of their respective target markets. Innovative shoppers view e-commerce as convenient, quick, and safe, and Web sites should be designed to facilitate search, selection, and purchase. Because some consumers enjoy the activity of online browsing and buying, enhancing the aesthetic and entertaining aspects of Web sites makes them attractive to consumers with hedonic goals.

Retaining Online Buyers

Attracting new buyers to online sites is only part of the job of the e-marketer; it is also important to generate customer satisfaction to retain those customers who have made purchases, and to build loyalty. This is difficult owing to intense competition and low switching costs in online environments, which provide customers opportunity and motivation to switch vendors (Xue et al., 2000).

Customer relationship management (CRM) systems are often recommended to enhance customer retention. These systems allow online collection of customer data and convenient interaction. Adopting an e-CRM system is often assumed to be a good way to draw together all of the elements of marketing strategy to obtain customer satisfaction, sales, and profit. However, recent research shows that although product customization ability is important, and the presence of some e-CRM features is positively related to customer satisfaction with a Web site, e-CRM activities are unrelated to success in attracting and retaining buyers (Feinberg & Kadam, 2002).

Retaining Business Buyers

Many of the characteristics of B2B relationships in traditional marketplaces continue to be of interest when building online relationships. For instance, the Internet may be used to facilitate collaboration between supply chain partners (Downes & Mui, 1998). Because it is difficult to develop and maintain trust in the online environment, a critical success factor in online business relationships is the absence of opportunistic behavior by either firm (Williamson, 1994). Freytag and Bridges (2003) observe that more dynamic marketplaces, characterized by changing relationship structures, require the firms involved to invest both financially and otherwise to obtain continuing relationships. Because online markets are so new and involve innovative players, they are inherently dynamic; thus, they would be expected to require continuing investment in order to be successful.

As the popularity of online B2B marketplaces grows, sellers may be expected to compete more strongly through differentiation that provides added value. By customizing the product to provide added value and integrating customers into its own systems and procedures, a firm may create switching costs that act as a barrier to leaving the relationship. Thus, an online B2B relationship strategy can create bonds between companies to the benefit of all involved.

Retaining Consumers Online

Providing the utilitarian and/or hedonic attributes desired by target segments may mean changing the Web site continuously, so it appears fresh and alive, and utilizing timely specials that appear at unpredictable intervals. Firms can also add value by offering information (e.g., product usage tips, specifications, manuals, parts lists, glossaries, histories) or by providing opportunities to interact with other buyers (e.g., games, chat rooms, and idea exchanges), which enhance flow and lead to more favorable attitudes toward the site and the sponsoring company.

Firms should prepare for rapid growth if they engage in marketing activities intended to draw new customers.

When online sales increase quickly, and firms are unable to sustain the aggressive pace, service quality erodes and the firm is vulnerable to competition. This may lead to price competition when it is least affordable (Oliva, Sterman, & Giese, 2003). Thus, the firm must set prices at a level to attract a sufficient number of customers, but also make a profit while continuing to provide quality service. Finally, it is important for B2C online vendors to build customer trust, because consumers are more likely to trade with online businesses that they trust (Gefen, Karahanna, & Straub, 2003).

FUTURE TRENDS

Web site design is crucial in attracting and retaining online customers—it is important for future research to address how best to do this. Hopkins, Raymond, and Grove (2003) suggest that available information and entertainment strongly influence customer attitudes and purchase intentions. Interestingly, they also find that site layout and functionality influence attitudes but not intentions to buy. Korzaan (2003) recommends that Web site designers attempt to enhance elements of flow associated with control, challenge, and stimulation. Specific ideas include eliminating error messages and dead links, and increasing interaction speed. Huang (2003) finds that complex Web sites are perceived to be useful (but distracting), while interactivity creates flow through control, curiosity, and interest. Thus, to attract online customers, the Web site should be designed to provide access to information/entertainment desired by the customer base, while meeting needs for control and stimulation.

To retain customers, e-commerce managers must cultivate a culture of service, by providing information and advice, and emphasizing promptness, helpfulness, and knowledge. Firms can also sponsor the development of online communities in which customers provide product feedback, information to each other, and recommendations that relieve the risk associated with online buying and encourage purchase (Hagel, 1999). Investigating how best to develop a culture of service online is another important direction for future research.

CONCLUSION

Unique features of the Internet allow tailoring of business strategy to match the needs of individual customers, driving attraction and retention. Many e-marketers are less successful than they should be in personalizing interactions because they do not match the extent of their (financial and time) investments to the levels desired by their customers (Moeller, Egol, & Martin, 2003). These authors suggest that, to create value and retain customers profitably, managers should optimize the entire customer interaction process to add variety to offerings, develop a deeper understanding of customer needs, and tailor business streams to provide value.

In summary, attracting and retaining customers online is much like accomplishing these tasks offline. Old recommendations are still true. Know your customers, create value, and provide satisfaction. Thus, managers should use research results to learn what customers need and want, and how they interact with the new media. Online marketplaces offer substantial advantages not available elsewhere, including the ability to provide information conveniently, to receive orders 24/7, and to unobtrusively gather customer database information for use in customer relationship management. Thus, over time the Internet will assume a place alongside other types of marketplaces, customers will shop and buy successfully, and businesses will thrive by adapting to this new reality.

KEY TERMS

Buying Process: In B2B settings, buying raw materials, maintenance, repairs, and operating supplies is a necessary business activity involving multiple decision makers and formal vendor selection and evaluation procedures.

CRM (Customer Relationship Management): Refers to retaining and using information about customers in databases, to develop customer loyalty and increase sales.

Flow: A psychological state in which one is so focused on an activity that one loses a sense of self and of the passage of time.

Hedonic: Referring to the senses, feelings, and emotions.

Re-Buy: The B2B buying process may vary in complexity from a new task buying situation, to a modified rebuy where the firm shops for a new vendor of a current product, to a straight re-buy, which is a periodic, perhaps automated repurchase situation.

Supply Chain: This includes the sequence of activities and participants involved in the process of developing, producing, marketing, delivering, and servicing a product.

Utilitarian: Plain, practical, useful.

Challenges and Policy Imperatives for E-Government in Africa

Wole Michael Olatokun
Africa Regional Centre for Information Sciences (ARCIS), Nigeria

INTRODUCTION

Government is a system of social control under which the right to make laws, and the right to enforce them, is vested in a particular group in society. Organizationally, governments may be classified into parliamentary or presidential systems, depending on the relationship between executive and legislature. Government may also be classified according to the distribution of power at different levels. It may be unitary—that is, with the central government controlling local affairs—or it may be federated or confederated, according to the degree of autonomy of local government. When this system of social control is being implemented to a large extent on the platform of information and communication technology (ICT), then we have an electronic government (*e-government*).

E-government refers to the provision of online public services to citizens and businesses. Services for citizens include registration to government services, such as health care, education or employment benefits. For businesses, e-government services can take the form of online alerts for public procurements or funding opportunities as well as information and support on applicable legislation in a given sector. E-government is widely viewed as an extraordinary opportunity for administrations to cut down their costs, speed up procedures and, therefore, increase their efficiency and reactivity. No doubt, e-government has grown in the past decade worldwide. Its efforts can vary from Web portals to online license renewals to experimentation with online voting. E-government is generally recognized as a means of making government more efficient while allowing it to be more responsive to customer needs (Jeffery, 2005).

The growth in e-government has been rapid. For example, in the United States, the percentage of local governments with Web sites increased from 8.7% in 1995 to more than 80.0% in 2000 (Holden, Norris, & Fletcher, 2003). Advances in ICT are helping to make the growth in e-government a global phenomenon. A United Nations report shows that governments around the world are moving towards higher levels of e-government to better serve their citizens (UN-ASPA, 2002).

In Africa, e-government is not yet widespread. However, some African countries have embarked on e-government initiatives and have recorded varying degrees of success. This article aims at reviewing some of these initiatives and ultimately recommends the way forward in terms of policy issues and strategies that African governments must put in place for their e-government projects and initiatives to be worthwhile.

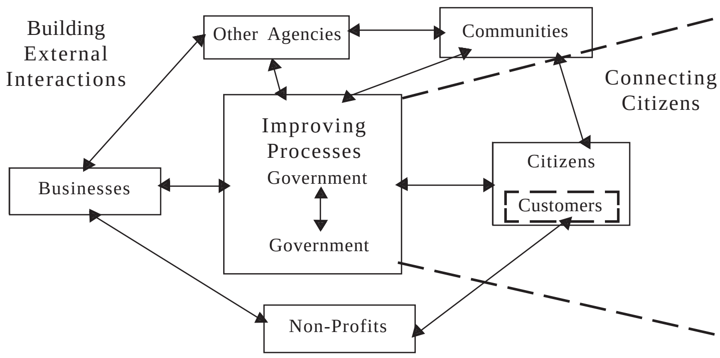
BACKGROUND

There is no unique, agreed definition of e-government. The term is being used extensively nowadays to refer to the use of ICT by government agencies. It is the application of ICT to improve efficiency and effectiveness, create transparency and accountability of informational and transactional exchanges within government, between governments and government agencies at national, state and local levels (G2G), citizens (G2C) and businesses (G2B) (Heeks, 2001a). According to Abet Open University (2004), G2C, G2B and G2G e-government is all about government agencies working together to use technology so that they can better provide individuals and businesses with government services and information. Much of it is about: establishing common standards across government; delivering services more effectively; and providing ways for government agencies to work together, all using the best technologies available.

Put differently, e-government refers to the use by government agencies of information technologies (such as Wide Area Networks, the Internet and mobile computing) that have the ability to transform relations with citizens, businesses and other arms of government. These technologies can serve a variety of different ends: better delivery of government services to citizens, improved interactions with business and industry, citizen empowerment through access to information, or more efficient government management. The resulting benefits can be less corruption, increased transparency, greater convenience, revenue growth and/or cost reductions (Abet Open University, 2004).

According to Heeks (2001b), e-government is the use of ICTs to improve the activities of public sector organizations. He holds that all digital ICTs are included, as well

Figure 1. Domains of e-government initiatives (Source: Heeks, 2001b)



as all public sector activities. He holds that there are three main domains of e-government, illustrated in Figure 1:

- **Improving Government Processes:** e-administration
- **Connecting Citizens:** e-citizens and e-services
- **Building External Interactions:** e-society

Respectively, these particularly address the problems that government is too costly, too inefficient and too ineffective (e-administration); too self-serving and too inconvenient (e-citizens and e-services); and too insular (e-society).

HIGHLIGHTS OF E-GOVERNMENT INITIATIVES IN AFRICA

An e-government project in Nigeria was the management information system (MIS) to assist with management of the university sector in Nigeria. The MIS was originally planned to run on a PC using dBase software, with a PC placed in the administrative sections of every Nigerian university, and further PCs at the federal-level Nigerian Universities Commission (NUC). The application was supposed to perform the following functions: to act as the central point for collection of data from individual Nigerian universities on students and staff, building a comprehensive statistical database; to have that data utilized by the NUC and Federal Ministry of Education for the purpose of planning and development of infrastructure, and for the production of statistics such as student registrations, staff/student ratios, gender and geographical distributions; and to provide support to individual universities for the purpose of processing examination results and transcripts.

The project began in 1993, and despite the significant sums that have been invested, it has still not been able to achieve the objectives that were set, leading it to be seen as a white elephant and a waste of money. No university has been able to generate either transcripts or correct enrollment data from the system, and the NUC has stopped the funding of the project in a number of universities. The project has been largely unsuccessful, considering its long duration and the level of achievements recorded. This was due to the fact that the project and its design given by the individual universities were not well used by the project coordinating unit within the NUC and to frequent changes in political leadership, which was mirrored by a lack of continuity within the government policy-making body overseeing the use of data and ICTs in the university system (Anonymous, 2002a).

In Mozambique, the Beira Executive Council (the local government authority for the city of Beira in Mozambique) initiated development of a decision support system, with a simple geographic information system (GIS) interface. Jackson (2002) reported that the data for the main database was based upon the register of city land plots, their zoning (open space, industrial, residential) and their status (vacant, under development, built on). The application produced information in two forms: a database report with information on plot status, and a digitized map of city plots that spatially represented the database. A common database package was used to hold the database, which was run on two stand-alone PCs linked to a digitization tablet and two printers.

The operation of the database produced politically sensitive information about plot usage, some of which was used as an excuse to settle old scores. However, the application never properly worked, it never replaced the old system and it was never updated after initial implementation. Its impact on operational decisions was negligible. Thus, the project failed to influence decision-making as anticipated and, therefore, can be deemed a total failure. However, the installation introduced computer literacy into the Registry and, as an adjunct, greatly increased use of word processing (Jackson, 2002).

In Uganda, there was the electronic voter registration project, which was a citizen service to take photographs of all citizens of voting age using digital cameras. The photographs were then to be loaded onto a voters' register database. The database was supposed to be maintained on a mainframe at the Interim Electoral Commission (IEC) headquarters, which would be connected to District Electoral Commission offices through the Internet. It was supposed to be used as the basis for voter identification at polling stations for the 2001 election. There were no formal benefits, because the system was not put to use for the 2001 elections.

The project has been described as a total failure due to the fact that things went wrong at an early stage with the hardware, with criticism that the tenders for procurement of the digital cameras were not transparent, leading to problems with the equipment delivered, and with reports that a number of the cameras were stolen from what should have been a safe government store. Although citizen photographing did proceed, it took place within a very short time and many people were not captured by the system. There were complaints from opposition parties that security agency staff had intervened in the workings of the computer system (Anonymous, 2002b). The initiative failed largely because it was a technical instrument introduced into a highly politicized situation; a situation in which there was a perceived lack of political will from government to implement the system as intended; a lack of political awareness on the part of many Ugandan citizens; and a lack of capacity on the part of the IEC to create conditions in which the system would not only be used impartially, but be seen to be used impartially.

In South Africa, there was the e-government initiative of supporting democracy with ICTs by South Africa's Independent Electoral Commission. This was the use of ICTs to manage the electoral process in South Africa during the 1999 parliamentary and presidential elections. The technology was used for voter registration, the polling process, relaying of ballot collection and verification, and relaying of results of the elections throughout the country. The hardware and software used included a satellite-enabled wide area network (WAN), plus connection to fax machines. These were used to enable people in rural areas to participate in the electoral process. Bar code readers enabled voters to be registered as well as votes to be counted. A GIS was used to draw up boundaries around the districts. An election center with a set of heavy-duty servers was linked to a giant call center to collect and display results to the public. The application was used to manage the electoral process (Mutula, 2002).

According to Mutula (2002), the positive impacts of the e-government application are claimed to be: enhancing the free and fair democratic process in South Africa; increasing transparency of the electoral process; putting in place an enduring infrastructure for future elections, for example, the WAN; and increasing the efficiency of the voter registration and polling processes, among others. It was largely successful, as the electoral process was expeditious, long queues during voting were not experienced, and the electoral process was accepted by the great majority of stakeholders as transparent, free and fair.

Also in South Africa, there was a Personnel Information System (PIS) for Southern African Government. This was an integrated PIS—consisting of a basic data entry/storage component and an MIS component—that would handle details of all public servants. Its introduction has been largely unsuccessful. Though it was implemented, it was hardly used. More than 3 years after the system was finally introduced, personnel data was only being updated by the ministry's staff. After some initial attempts, staff in the ministries and departments reverted back to their manual personnel records.

Another e-government initiative in South Africa was the Computerised Integration of Two Pension Funds in Southern Africa. The national Welfare Agency administers a variety of social security funds, including a National Pension Fund (NPF) paid to those who retired normally from work, and a Workers' Compensation Fund (WCF) paid to those forced to retire because of workplace injury, or to their dependents in case of death. The application was the planned introduction of IT into the Welfare Agency in order to computerize and integrate and decentralize the previously separate, previously manual, previously centralized operations of the NPF and WCF. This involved a national network of PC workstations and servers using a single national database of contributors and claimants (Kekana & Heeks, 2003).

According to them, the project was partly successful and partly not. In terms of successes, the project has improved service delivery. For instance, for fairly simple benefit claims, lead times have come down dramatically and employers now receive a single unified monthly bill for the two Funds that is generally accurate and timely. This has made debt-chasing a faster and more confident process. Also, numbers of complaints have been reduced, and business can be transacted directly at a local office (Kekana & Heeks, 2003).

POLICY ISSUES AND STRATEGIES FOR THE SUCCESS OF E-GOVERNMENT INITIATIVES IN AFRICA

From the preceding section, it is noteworthy that the e-government initiatives in the African countries reviewed did not record the same level of success. Only one in

South Africa was actually successful, one was partially successful and the third was unsuccessful. None of those in other countries was successful. Why is this the case?

Heeks (2002) submitted that e-government in Africa is essentially a concept based on imported designs. There are growing numbers of e-government projects, some of which are contributing to public sector reform and delivering gains of efficiency across a broad agenda. However, this positive picture must be set alongside significant challenges. E-government is only slowly diffusing within Africa because of a lack of readiness. According to Heeks (2002) e-government projects in Africa arise particularly because e-government concepts and designs have their origins in the West. The challenges, he submitted, are the following:

- E-government solutions designed for one sector or country are being forced directly into a very different reality, creating failure.
- Many of the key players—donor agencies, consultants, IT vendors and African civil servants—are complicit in the continuing importation of inappropriate, Western e-government models and systems.
- The gulf between IT professionals and mainstream public servants/politicians is one root cause of design-reality gaps and, hence, of failure in African e-government projects.
- Successful projects are those where key stakeholders cross this gulf by being hybrids: those who understand the technology and the business of government and the role of information in government.

Failure will remain the dominant theme for e-government in Africa unless the above challenges can be addressed and appropriate policies put in place. In specific terms, therefore, policy options for the success of e-government in Africa should address the following:

- **Vision and Strategic Agenda:** African societies keen on using ICTs to improve governance must build a shared vision backed by a strategic agenda. This must include, among other things, broad principles on the nature of the information society they plan to build, the form of governance, the character of government and the role of the people, with a strategic agenda for ICTs in making the vision a reality. Preceding each ICT project to improve governance, the "governance goals" to be addressed must be selected. In addition, the goals must be specific and measurable. In developing the ICT project, formulating the strategic agenda and selecting the objectives, the following steps could be followed: Select and prioritize improvement goals, develop and evaluate alternative ICT solutions and develop the implementation plan, with monitoring, evaluation and feedback (Bhavya, Gaumer, & Manhica, 1999).
- **Building the Infrastructure:** A key challenge that must be addressed if African countries are to be able to exploit the opportunities provided by ICTs for improved governance is the lack of infrastructure. Telecommunication infrastructures will have to be upgraded and extended to where there are none right now. With little financial resources, creative solutions can be found. The satellite revolution holds considerable promise for African countries in this regard. Wireless technology, such as cellular telephony, is already making a difference in some parts of the continent, and this could be exploited for the success of e-government.
- **Creating Data Banks:** Data banks designed to serve critical economic sectors are of the utmost importance in harnessing the power of IT for e-government projects and initiatives. Data banks should be set up that will serve as repositories of accurate and reliable socioeconomic data about the activities of government in the different sectors. The development of a government-wide or country-wide data bank presupposes the availability of resources to make this work. Thus, African governments should make provision for a national data bank and an integration of the data bank with related systems; availability of manpower and tools to manage the databases and information network; improved awareness of and provision of user-friendly access to the data bank and so forth. The National Data Bank in the respective African countries, where they exist, should be strengthened and put in charge of this sector, and be created where they are nonexistent (Olatokun, 2004).
- **Human Resources and Institutional Capacity Building:** Human and institutional capacity will have to be built to facilitate the use of ICTs for improved governance in Africa. At the institutional level, African countries will need effective institutions that can set and implement policies, provide the regulatory framework, manage the policy environment to encourage competition and facilitate universal access. At the human level, policy makers will have to build their skills and develop an understanding of what it takes to implement ICT projects for improved governance. Likewise, educational curricula from primary schools through to universities must include computer training. Women and youth, those left out traditionally, must also be targeted.
- **Building the Right Policy Environment:** The role of governments in creating an information society that

can seize the opportunities provided by ICTs is crucial. In this connection, governments must help create the right regulatory and public policy environment based on stakeholders' participation and consensus building. African governments will also have to ensure that their ICT strategies and actions play a catalytic role.

FUTURE TRENDS

E-government is about opportunity. For both governments and citizens, clearly its advantages far outweigh the risks of investment. With a regional index of 0.84, Africa's e-government capacity could be described as deficient (Ronaghan, 2002). Clearly, this reflects a near total absence of the core areas necessary to sustain an enabling e-government environment. But despite the region's appalling lack of an adequate telecommunications infrastructure, nearly all Sub-Saharan countries have some form of Web presence. Seventy-five African countries offer only static information Web sites. There are, however, several notable exceptions: South Africa (1.56), Djibouti (1.35), Gabon (1.17), Cote D.Ivoire (1.05), Nigeria (1.02), Ghana (0.98), the Central African Republic (0.98), Congo (0.94), Mauritania (0.91) and Kenya (0.90), all of whom exceed the regional Index of 0.84.

As demonstrated above, e-government is no longer an experiment in administrative reform but a crucial part of the governing process in some African countries. In some, however, efforts have to be geared towards effective adoption of e-government. Yet, how a country chooses to approach, design and ultimately implement e-government is dependent upon its capacity to put the right policies in place and sustain an enabling environment with a view to addressing the needs and priorities of its citizens. Hopefully, in the few years to come, many more African countries will have adopted e-government in their operations by upgrading their online services, while many more will be striving to find the best possible approach to the adoption of e-government.

CONCLUSION

E-government has already arrived in some African countries, as some of them have embarked on e-government projects. However, there are several challenges that could be addressed through customization of e-government practices to match African realities. Consequently, we submit that it is imperative for deliberate policy strategies to be implemented to make e-government initiatives a success. Areas of concern for such policy strategies should include a clear-cut vision and strategic agenda, infrastructure development, human resource capacity building and the building of the right regulatory and policy environment. It is hoped that if these policy issues could be addressed in the respective African country's ICT policy, the future of e-government in Africa cannot be but bright.

KEY TERMS

Africa: The second largest continent; located south of Europe and bordered to the west by the South Atlantic and to the east by the Indian Ocean.

E-Administration: E-government initiatives that deal particularly with improving the internal workings of the public sector.

E-Citizens: E-government initiatives that deal particularly with the relationship between government and citizens; either as voters/stakeholders from whom the public sector should derive its legitimacy, or as customers who consume public services.

E-Government: The use of information and communication technologies (ICTs) to improve the activities of public sector organizations.

E-Society: E-government initiatives that deal particularly with the relationship between public agencies and other institutions—other public agencies, private sector companies, nonprofit and community organizations.

Information and Communication Technology (ICT): Includes technologies such as desktop and laptop computers, software, peripherals and connections to the Internet that are intended to fulfill information processing and communications functions.

Initiative: The characteristic of originating new ideas or methods.

Policy: A course of action developed for the achievement of a set of goals.

Strategy: A plan or method for obtaining a specific result.

Classification Systems

Sven Abels
University of Oldenburg, Germany

Axel Hahn
University of Oldenburg, Germany

INTRODUCTION

Classification systems are an easy way to assign objects such as products, services, or even company profiles to a category. Classifying information offers many advantages when dealing with a large amount of different information. For example, it enables one to find information by group or to easily detect similar items. They are meaningful wherever a large set of different, but sometimes similar information is managed. In order to clarify the meaning and the application of classification systems, the following text starting with an example in the area of electronic product catalogs. Important background information about classification systems is given as well as a list of typical classification systems. The text will describe the advantages of classification systems and their meaning for future e-commerce scenarios. The main problem of classification systems today is focused as is the compatibility of classification standards and therefore the reclassification process.

BACKGROUND INFORMATION

The area of product classification gains more and more importance in the e-commerce domain. Within the e-business domain, e-commerce is practically not feasible without the usage of classification mechanisms. The increasing stress of competition of the last years leads to shorter product cycles and to an increasing amount of products. An assignment of products into an organizational structure helps to keep an overview about a large amount of products (see Hentrich, 2001). An essential characterization of e-business is to offer products from more than one manufacturer in a single electronic catalog, for business-to-business relationships as well as for business-to-consumer commerce. There are often catalogs, containing a large number of different products from various manufacturers. In order to group similar products, it is necessary to arrange products into product groups. Classifying products with the help of classification systems can boost this process. When adding classification data to a product description, those products can be found faster and easier and a comparability of products is supported as described in Wollin (2002) and Ramakrishnan (2000). In order to classify them, a number of different classification systems were developed, which differ in their purpose, domain and general structure; that is, in using hierarchical structures. An overview about established classification systems is for example given by Omelayenko and Fensel (2001a) and a short overview is also given within this section. Abecker, Tellmann, and Grimm (2001) can be recommended for an overview about common B2B standards. A product catalog that is based on a classification system provides a large economy of time when searching products and comparing them to similar products. An integration of new products into an existing e-business catalog is eased significantly, since all products contain information about their category. Groups and classes are unchangeably defined by a classification system (see Grabowski, Lossack, & Weißkopf, 2002), which means that all products can be classified based on the defined categorization of the classification system. The advantage is that a single string is sufficient to classify a product. For example the string *49-23-15-13* in the UNSPSC-System[1] means that the product is classified as a *toy train*. Integrating new products into an existing group structure is simplified when interpreting classification information. For example, if you own a web shop and you already defined a category *toys*, then you can simply add all products, starting with the classification string *49-23-15* to your category if they are classified using the UNSPSC-System.

Product classification is only one example for the usage of classification systems. There are also a broad number of other use cases. For example, classification systems are often used to classify services in registries such as web services in UDDI- or ebXML registries (see Dogac, Laleci, Kabak, & Cingil, 2002). The North American Industry Classification System (NAICS)[2] can be used for classifying business establishments. For example, the classification code *339932* in NAICS identifies *Game, Toy, and Children's Vehicle Manufacturing*. There are many other situations where classification systems are used. In general its usage is meaningful wherever a large amount of different but sometimes similar objects are managed including product catalogs, service registries and company catalogs.

Managing Different Terminologies and Taxonomies

When dealing with a big amount of similar information, as done in electronic product catalogs or registries such as UDDI or ebXML, there are many ways to organize and group similar items. For example, in the domain of product catalog, there are product groups, defined within each catalog. A product group contains several products. It can contain a set of sub-groups and can therefore be connected to a parent-group. This makes it similar to classification systems. There is, however, a significant difference. Classification systems are defined independently from the concrete catalog or registry. Contrary to this, product catalogs and similar concepts are defined for each set of objects separately. For example, in many cases, each product catalog defines its own catalog groups with its own structure (taxonomy) and its own names for categories (terminology). This means, that taxonomy and terminology differs from catalog to catalog. When using classification systems, only a reference to an entry of a classification system is added to the object. For example *49-23-15-13* is added to the product data. This means that there are no conflicts in the terminology and no different taxonomies since the same element is referenced, independent from the concrete catalog. This makes an integration and combination of multiple catalogs or registries much easier. Hence, it is very advisable to add additional classification information, even when using other concepts such as catalog groups.

Vertical and Horizontal Classification Systems

Classification systems are developed for usage in a defined domain, such as the classification of products or the classification of services. As described in Omelayenko and Fensel (2001b) classification systems can be divided into two different groups:

The first group consists of horizontal classification systems. Those try to cover all areas of a certain domain. Well-known examples are the ECl@ss-system and UNSPSC. UNSPSC is a hierarchical system, based on four hierarchical levels. It consists of more then 12,000 different product groups, which are located on the fourth level (for details, see Ramakrishnan, 2000). UNSPSC is the best known international classification system for products. A direct competitor is ECl@ss, which is based on four hierarchical levels, too. Furthermore, ECl@ss defines attributes for all of the >12,700 categories.

Although the number of categories is very high, horizontal classification systems are not detailed enough for all applications. For example the number of categories for classifying toys might not be high enough for a company that is specialized on producing toys. This manufacturer will not need any other classification area than those dealing with toys. For this purpose, the usage of vertical classification systems is common. Vertical classification systems concentrate on a certain part of a domain but they tend to define this part in a very detailed way. An example for a vertical classification system is ETIM, which was defined for classifying electro-technical products. Figure 1 shows the mentioned concepts graphically.

Structure of Classification Systems

The easiest way of defining a classification system is by providing a simple table with classification codes and their description. Many classification systems are, however, structured more complex. In order to use advantages derived from inheritance information, most classification systems have a hierarchical structure. For example, UNSPSC contains a category *toys*, which contains a subcategory *musical toys* and *toy vehicles*. This hierarchical structure enables not only a selection of entries that belong to a certain category but also to select all entries that belong to a parent category.

Figure 1. Horizontal and vertical classification standards

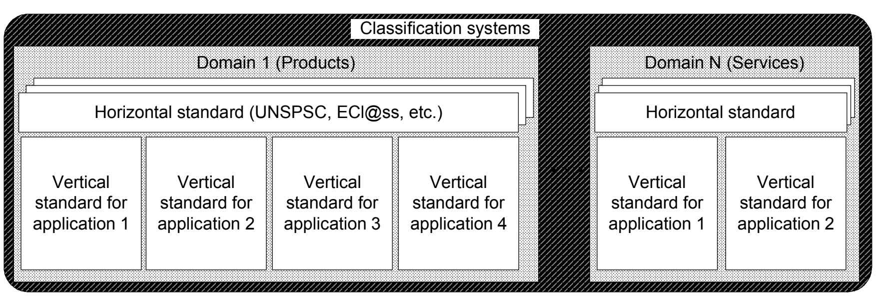

Figure 2. The structure of a classification system

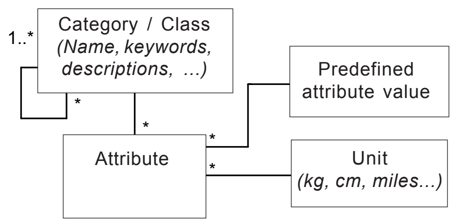

Additionally, some classification systems allow the usage of attributes for a category, which will be inherited by the products classified in the subcategory. Those attributes are used to express more details such as the color or the shape of a product or its manufacturer (see Hepp, 2003). Some classification systems even provide a set of units such as [kg] of [inch] for those attributes.

The eCl@ss system defines keywords and synonyms for each category and provides this information in multiple languages. The usage of attributes, keywords and synonyms as well as a more detailed description of a category can simplify the classification process for enterprises. It helps to avoid confusions and misunderstandings for similar categories. Figure 2 shows the structure of a classification system providing those concepts.

Overview about Existing Standards

The following table shows a selection of standards in the domain of classification systems. Because there are many different classification systems for different domains, this table only summarizes the most popular standards. Since identification standards are often used within the same area, the table also contains some identification standards. For example, DUNS is often recognized as a universal standard for identifying and keeping track of businesses. Unlike this, classification systems are used "To assign each product to a product group corresponding to common attributes or application areas" (Leukel et al., 2002, p. 1).

CHALLENGES OF CLASSIFICATION SYSTEMS

In future e-commerce scenarios, classification systems can play an important role because they enable to process data automatically by defining semantics, up to a certain degree. In the domain of product catalogs, this means that companies could easily integrate product catalogs of business partners into their own catalog or into an existing e-procurement system (see Hentrich,

Table 1. Important standards

Name of standard	**Type** (classification / identification)	**Body**
EAN.UCC	Identification	EAN International and Uniform Code Council *http://www.ean-ucc.org*
EGAS	Classification	ECCMA Global Attribute System *http://www.eccma.org*

2001) with respect to their own product groups and without adding manual work. It also means that it is easily possible to find similar products and to make products comparable. There are, however, several challenges and problems that have to be solved. Those will be addressed in the following sections.

Compatibility between Standards

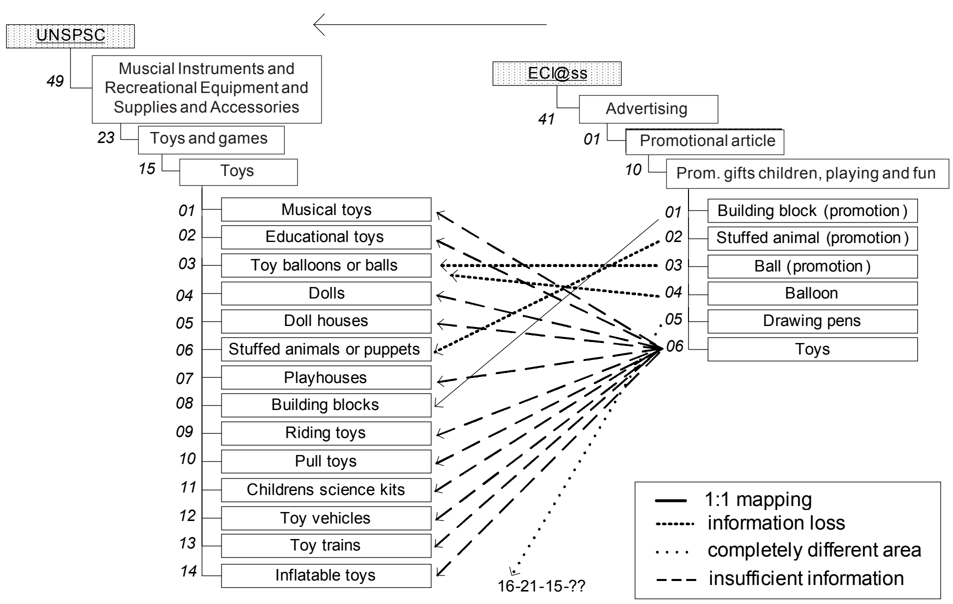
A usage of classification systems has a high potential and many advantages for all participating companies, as described in the last paragraphs. If both use the same classification system (e.g., UNSPSC), an automatic integration of is possible.

Because of different needs and requirements for classification systems, there is no common standard, used by all companies. As explained in the last paragraph, there is a coexistence of many different classification systems (horizontal and vertical), which are sometimes directly competing. Furthermore, many enterprises are using their own (proprietary) classification system to classify their objects (services, products, etc.) for internal usage.

Because of different scale, different structures and various semantics, most classification systems are incompatible, as noted in Schulten et al. (2001). This leads to problems in integrating data when using heterorganic software systems. To reach an automatic or semiautomatic integration of, for example, products into a product catalog of an e-business partner, an interoperability of all participated systems is needed, as described in the introduction. Interoperability in this context can be defined as the ability of two or more systems or components to exchange information and to use the information that has been exchanged" (IEEE, 1990). According to this, not only is a syntactical exchange of data needed but a way to use this data is also needed, which basically means an understanding of semantics. A nontrivial transformation in form of a reclassification of data is needed, whenever two systems are based on different classification systems. For example, it might be necessary to integrate an object, which is based on UNSPSC into a system, which needs eCl@ss information. This means, that a reclassification has to be performed. In case that an unknown classification was used or in case that the objects were not classified at all, an initial classification has to be performed. Therefore, the challenge is in performing a semantic integration transformation of data, based on one standard into another one.

It should be stressed that the needed integration is not just a syntactical integration of the data format, such as BMEcat or any other XML format, but an integration of the classification information, which needs a semantic analysis of data. While converting the data format could be performed with a number of transformation and mapping approaches on the model layer (such as XSLT or the usage of converters, see Omelayenko & Fensel, 2001a), the semantic integration has to consider the data and a more complex number of information. In most cases, a mapping of structures is not satisfying, but an interpretation of data is needed to classify and reclassify information. Figure 3 shows a part of a possible mapping between ECl@ss and UNSPSC.

Figure 3. A possible mapping between ECl@ss and UNSPSC



A direct mapping of categories is only possible in the two different categories, which are displayed as green lines in the figure. The blue lines of the figure are representing mappings that can be performed without problems but which are causing a loss of information, because several products ("Ball [promotion]" and "Balloon") will be included in a single category, which will make it impossible to decide between them any longer. More problematic are the red colored lines, which indicate mappings that can not be performed without knowledge of the data: Products of the category *toys* in ECl@ss could be mapped to more then one category in UNSPSC such as *toy trains* or *musical toys*. It is therefore necessary to perform an analysis of the data itself to make a case-based decision. This means that it is not possible to develop a converter between classification standards without analyzing each product separately.

Approaches for Automatic Classification and Reclassification

When looking at classification systems, an important task is the classification process itself. Beneventano and Magnani (2004) noted that a manual approach is not only tedious, but also cost intensive and error prone. For example, in the area of product classification, Wollin (2002) identified costs of approximately 0.25 USD per product, which is a high expense factor when integrating thousands of products into a large catalog. This means that the usage of classification systems would not be feasible for a large amount of low-cost products, especially since the classification process needs to be repeated for every new classification system, which is an unacceptable hurdle.

In order to foster the usage of classification systems and to make the integration of classification information as cheap and comfortable as possible, a number of approaches and tools were developed in the last years. Those solutions should help to improve the process by performing either an automatic classification/reclassification of product data or by offering a semiautomatic environment to add classification information into electronic product catalogs.

Approaches to automating classification can be found in several software products such as Storeserver (see http://www.storeserver.net) in the area of product classification. Most of them are performing a textual analysis of the objects description. Leukel (2004) stated that most of these textual analyses adapted for product classification are mainly algorithms and tools for classification in general (i.e., VSM [Vector Space Models] or Bayesian classification). Hence, most existing products concentrate on performing their analysis based on interpreting the textual descriptions of products.

The biggest problem of those solutions is the extraordinary high number of possible classes in the classification process. Naïve Bayes and other machine-learning approaches have proven to work quite well to classify data into a limited number of clearly separated classes. For example they are often successfully used to classify spam see Androutsopoulos, Koutsias, Chandrinos, and Spyropoulos, (2000). In the scenario of classifying products into classes of a classification system, it is much harder to classify documents because:

- the number of possible classes is high (e.g., eCl@ss has more than 24,000 different classes),
- the semantics of classes is sometimes very similar,
- the amount of information for each class is low (in most classification systems, it is only a one-line-description for each class), and
- in many cases there are not enough objects to generate a learn-effect for machine-learning approaches.

Hence, solutions for automatic product classification have to use a large training set of similar products. For example the GoldenBullet approach described in Ding et al. (2002) achieves a precision of 78% with one a Naïve-Bayes classification to classify 40% of the products, while they used the other 60% of the same product catalog as training data for the algorithm. They testified that this rate is already higher or at least equal to the error rate of a manual classification.

In order to lower the number of necessary training data and to perform a more accurate classification, research is under progress. For example, the Apricot framework (see Abels & Hahn, 2005) intends to interpret synonyms and to consider information that can be extracted from existing classification information, which is often neglected in existing solutions. This is especially important when having to perform a reclassification of objects. For example, if a product needs to be classified based on the eCl@ss system but has already been classified using the UNSPSC standard then a broad amount of additional information could be used to perform an automated reclassification; that is, the description of the UNSPSC-class or its hierarchy information.

FUTURE TRENDS

Classification systems have proven as a common way of integrating objects into a common catalog or into existing software solutions such as e-procurement systems. The usage of classification system got more and more attractive in the last years. For example, the classification specification of NAICS and UNSPSC are included within most ebXML and UDDI registries. Most e-procurement systems are able to handle UNSPSC as well. There are several standards in this domain that tend to have a broad support by companies. In the domain of product classification systems, UNSPSC is one of the most important standards with worldwide usage. The second important standard is eCl@ss, which has an increasing popularity but is less used than UNSPSC from a global point of view. For classifying business establishments, NAICS became the most popular international classification systems.

A major problem of classification systems today is the complete incompatibility between standards, even if they are defined for the same domain such as product classification. In order to resolve this, it is either necessary to agree on a common (worldwide) standard or offer a way of transforming information, based on one classification system into another standard. The first solution, agreeing on a common standard, is very unlikely since every company got its own needs and therefore it is very probably that there will be several horizontal and vertical classification systems. Unfortunately, the other solution (providing a transformation) cannot be performed easily because of the different breadth and depth of standards and their different semantics. This prevents from performing a simple conversation and forces to perform a case-based (i.e., product based) reclassification.

CONCLUSION

Classification information provide a comfortable way to define the category of objects without depending on the transportation format, language or company defined categories. For example, they help to:

- arrange objects into groups;
- find similar objects;
- process information independent from the language of the description;
- integrate objects, such as products into existing structures, such as existing catalogs or e-procurement systems;
- support the development of quick searches for classified objects; and to
- provide a uniform coding convention for categories.

Because of this, classification information can be found an increasing amount of applications.

The major problem of classification systems today is the complete incompatibility between standards. Further research in this area can improve these problems and lead to a better interoperability between solutions, based on classification systems. Furthermore, approaches for performing an automated classification of data are a key to success of future classification systems.

KEY TERMS

Classification Process: The classification process describes the manual, semiautomatic, or automatic assignment of products into a class of a classification system. Within this process, each product is completed with a code of a class. For example, the code 49-23-15-13 in UNSPSC could be added to a product, which means that this product is classified as a "toy train."

Classification System: A classification system consists of a list of categories (called "classes"), which can be ordered hierarchically. Classification systems sometimes provide a set of keywords, descriptors and attributes for each class. Product classification systems are used to classify products or electronic catalogs. They are used "to assign each product to a product group corresponding to common attributes or application areas" (see Leukel, Schmitz, & Dorloff, 2002). Figure 3 shows an example for two classification systems. Well-known product classification systems are for example UNSPSC, ETIM or eCl@ss. Classification systems are also used in many other areas within the e-Commerce domain, such as the classification of services or profiles, as done in UDDI- and ebXML-registries.

Clustering: Clustering is the process of identifying groups in data. In the classification all groups are predefined in the classification system and products are arranged into the existing group structure. Contrary to this, the clustering process identifies groups based on the product data. This means that the groups change depending on the product data.

E-Procurement Ssystem: E-procurement stands for "electronic procurement" and means the process of electronically managing the procurement of goods. An e-procurement system cares about this process and offers interfaces to perform typical activities such as ordering products or browsing a list of available products from product suppliers. A more detailed introduction can be found at Hentrich (2001).

Horizontal Classification System: Classification systems can be divided into horizontal and vertical classification systems. Horizontal classification systems try to cover all areas of a certain domain. Well-known examples are the ECl@ss-system and UNSPSC that try to provide classes for all manufactured products. Figure 1 shows the mentioned concepts graphically.

Product Group: A product group contains several products. Furthermore, it can contain a set of sub-groups and can therefore be connected to a parent group. Typically, each electronic product catalog contains at least one set of product groups. Each product should be located in at least one product group and product groups are often compared to classification systems because of their similar nature. Both offer a set of categories to arrange items. Product groups are dependant on the catalog creator. Normally, each catalog has its own taxonomy and terminology and therefore defines its own set of groups. Contrary to this, classification systems are standardized and do not change from catalog to catalog.

Reclassification Process: The reclassification process has to be performed whenever a product was classified based on a classification system A but is needed to be classified based on another classification system B. The difference between re-classifying and classifying a product is the fact that in the reclassification process, the existing information of classification system A is used to determine the class of classification system B.

Vertical Classification System: Classification systems can be divided into horizontal and vertical classification systems. Vertical classification systems concentrate on a certain part of a domain but they tend to define this part in a very detailed way. An example for a vertical classification system is ETIM, which was defined for classifying electro-technical products. Figure 1 shows the mentioned concepts graphically.

Clicks and Mortar

David L. Bahn
Metropolitan State University of Minnesota, USA

INTRODUCTION

"Clicks and mortar" signifies the use of electronic commerce (clicks) in combination with traditional (brick-and-mortar) operations. In the domain of business strategy and operations, this has also been known as "bricks and clicks," referring to the deployment of electronic commerce alongside conventional business operations in a manner that best utilizes the strengths of each channel in a complementary and synergistic manner (Stuart, 2000).

BACKGROUND

Balancing business strategy and operations between electronic commerce and traditional brick-and-mortar channels is one of the most significant challenges facing organizations in recent years. At a strategic level, this challenge raises some significant questions for executives. To achieve success in traditional retail operations in combination with business-to-consumer electronic commerce, it is desirable to achieve a synergy between what optimizes the costs and benefits of each channel. How can business volume grow through electronic commerce without cannibalizing growth in established retail channels? What should be the balance of investment in each channel? Is it possible to establish an interactive relationship such that electronic commerce and the conventional brick-and-mortar business operations are mutually supportive?

At an operational level, there are some even more fundamental questions that are raised by this challenge. First, organizations must distinguish those business activities that can be performed online from those activities whose execution requires a high-touch interaction with the customer and must therefore continue to be performed through brick-and-mortar operations. If certain retail activities such as marketing and presales operations can be performed through electronic commerce, then will the same brick-and-mortar facilities still be required, or will they be reduced or reshaped? If manufacturers adopt electronic commerce to sell directly to consumers, will this enhance the disintermediation of retailers, or will it enhance opportunities for potential cooperation between manufacturers and retailers?

CLICKS AND MORTAR: RECENT RESEARCH

The current research literature describes several perspectives on how firms can successfully deploy electronic commerce in synergy with parallel brick and mortar. Gulati and Garino (2000) state that the degree of integration between the two channels is manifest on several dimensions: the actual business processes used to execute the firm's transactions, the brand identity of the firm, and the ownership and management of each channel. A firm could own and manage brick-and-mortar operations in conjunction with electronic commerce and yet still not integrate the brand identity or business processes of each one. Alternatively, a firm like Barnes and Noble might integrate the brand identity of its traditional retail operations to its electronic commerce and yet still not integrate the business processes used to execute transactions within each channel.

De Figueiredo (2000) asserts that the characteristics of a firm's products or services are what primarily determine how electronic commerce can be integrated alongside traditional business operations. He sees the key determinant characteristics as being the degree to which a product varies in quality and the degree to which a potential customer can easily evaluate a product's quality. Commodity products are of fairly uniform quality, are therefore easy for customers to assess, and hence would lend themselves readily to a clicks-and-mortar approach to electronic commerce. Conversely, "look and feel" products are more difficult for customers to evaluate and will be less likely to be purchased through electronic commerce.

Some recent studies have described that a far more complex synergy exists between electronic commerce and traditional brick-and-mortar business operations. Wilcocks and Plant (2001) assert that there are two distinct paths firms can take in arriving at a synergistic approach to electronic commerce. One path encompasses the creation or extension of an organization's traditional brand identity into electronic-commerce operations. A less risky path is for firms to utilize electronic commerce primarily as a means to create service and quality improvements in the traditional brick-and-mortar arena.

Bahn and Fischer (2003) contend that there are several very different strategies that firms employ in achieving a clicks-and-mortar approach to electronic commerce. These strategies vary according to several dimensions of business constraints that include not only the characteristics of a firm's products, but also the relationships that a firm has with its supply chain partners and the capability of a firm to articulate a strategy that is distinct from its brick-and-mortar strategy. Bahn and Fischer also found that due to these constraints, many firms find it strategically appropriate to minimize their involvement in electronic commerce and relegate it to an auxiliary channel that supports brick-and-mortar operations.

At a deeper level, underlying all of these approaches is a conceptual debate about whether electronic commerce harbingers a fundamental revolutionary change in business (Useem, 2001). Michael Porter (2001) contends that although electronic commerce is indeed superior to many prior forms of information technology, its advent nevertheless renders many traditional brick-and-mortar business processes more essential to successful strategy execution rather than less. Don Tapscott (2001) has vociferously taken issue with this view, arguing that electronic commerce is engendering fundamental change by enabling previously unthinkable business partnerships and process-coordination mechanisms that will eventually completely reshape how most organizations conduct their business operations.

One pertinent case example of the phenomenon of clicks and mortar is manifest in the realm of higher education. Higher education is increasingly perceived as a service-delivery business by providers (educators) and consumers (students) alike (Shepard, 2005). In this particular industry, both the service and the brick-and-mortar facility are being redefined by electronic commerce. Many of the issues and questions cited in the business research about how to strike an effective balance in clicks and mortar are clearly manifest in higher education.

The growth of distance education capabilities through the Internet has generated a number of forms of online education in colleges and universities. Hybrid (Young, 2002) or blended (Voos, 2003) courses feature the reduction (but not elimination) of classroom sessions and the replacement of this class time with online learning activities. Hybrid courses are typically taught over the same time duration as regular courses. Hybrid courses are seen as offering the best of the rich face-to-face experience of regular college instruction juxtaposed with the interactive and student-driven learning of online classes (Hopper, 2003). Traditional teaching activities like discussions, group activities, and some lectures that benefit from a direct and personal experience are still conducted in the classroom, but the repetitive transmission of facts, submission and grading of student assignments, self-paced tutorials, and testing can be moved online. There is some debate over what degree of reduction in regular class sessions is necessary to qualify a course as being hybrid. Some have defined a minimum reduction of at least half of the number of class meeting sessions as the defining criteria for hybrid courses (Leh, 2002), while others have taken a looser approach (Garnam & Kaletta, 2002; Hopper 2003). Furthermore, the reduction of classroom-based learning can be manifest as a reduction in time spent in each scheduled class session or a reduction in the total number of class meeting times, a confusion that has also served to obscure the precise definition of a hybrid course (Aycock, Garnam, & Kaletta, 2002).

In respect to facilities, hybrid courses have conserved scarce classroom resources in overcrowded urban colleges, and have been reported as yielding improved student learning outcomes over traditional classes and reduced dropout rates in comparison to purely online classes (Young, 2002). Despite these preliminary findings, little empirical research has been done to determine the optimal way in which hybrid courses or campus facilities that support these courses should be implemented. Moreover, some have warned that hybrid courses can cause confusion in students who may attend class meetings but insufficiently comprehend the significance of the online components of the curriculum (Reasons, 2004).

FUTURE TRENDS

Whether in the general sphere of business or in the specific arena of higher education, the emergence of clicks and mortar raises significant questions about the future requirements for physical space and the nature of its utilization. In terms of the value chain, if businesses can conduct much of their pre- and postsales activities (as well as a large share of their sales) through the Internet, then what becomes the purpose of brick-and-mortar facilities (Bahn & Fischer, 2003)? Even if some brick-and-mortar facilities are required for business operations, would the same amount of retail space be needed?

If we think of these questions in the specific sector of higher education, it might well be asked whether colleges need to build fewer classrooms. If they are delivering a significant portion of their courses online, then do they need the same campus facilities, or a different set of buildings and classrooms (Bleed, 2001)?

CONCLUSION

Studies of commercial real estate (Muhanna & Wolf, 2002) have indicated so far that no significant changes have been observed yet in the aggregate demand for brick-and-mortar space as a consequence of electronic commerce.

Nevertheless, recent trends in library architecture emphasize the augmentation of meeting and social space

(Young, 1997) and the minimization of shelf space. These trends may offer some tantalizing hints as to what will be the future of retail space and of classroom space in the emerging world of clicks and mortar. Some kinds of brick-and-mortar facilities that enhance an organization's relationship with its customers (and the customers' experiences) may become more critical to strategic success. Conversely, brick-and-mortar facilities or traditional business processes that are routine and that do not enhance the customers' perceptions of the organization or its services or products may well be replaced with electronic-commerce channels where possible.

KEY TERMS

Brick and Mortar: The direct physical (nonvirtual) channel for conducting business or exchanging value, typically requiring a specific location.

Channel: A course or pathway through which information is transmitted or business is transacted.

Commodity: A generic and largely undifferentiated product that is usually bought or sold by itself without bundled value-added services or differentiated features.

Electronic Commerce: The use of the Internet to transact the exchange of value (even as just information) between organizations and their customers, partners, or employees without time or geographical restrictions.

Hybrid Courses: University or college classes that contain a reduced number of face-to-face class meetings between the instructor and students while concurrently offering significant learning activities though the Internet.

Traditional Retail Operations: The exchange of value directly with consumers through store locations and facilities.

Value Chain: The visualization of an organization as a sequential array of processes or activities that convert unfinished inputs into finished outputs.

INTRODUCTION

Nowadays the Web comprises a significant advance in technology, and the rapidity of its acceptance has been remarkable. It is a powerful tool that has changed the way of conducting business, providing companies and customers with limitless options and opportunities. Online catalogs, 24/7 service availability, a cut down in transaction costs, reduction of customer service time, personalized features, and absence of paper and personalization features are only a few of the advantages. Companies, in an effort to stay competitive in the new global economy, are increasingly expanding their activities to this new communication channel, which features as a factor of major profit potential.

As a direct consequence of e-commerce spreading, we are witnessing the emergence of a new consumer type, the online consumer or e-customer that uses the Internet for purchasing products/services (Solomon, 2001). The online consumer is empowered with new, exciting capabilities: he can search globally for products/services, compare available options, find additional information, read the opinion of other people who have bought the product/service, or proceed with the transaction. All these options are available from his office or home and can be used conveniently and fast, while all alternative e-shops are only a few clicks away.

As in the case of trivial customers, ensuring e-customer satisfaction is not a simple task. To a certain degree, e-customers (expect to) behave online similarly to how they behave off-line (in traditional real-life shops); but in order to fully understand their behavior, one should explore issues like the reasons why people use the Internet for their purchases, the benefits/drawbacks of online buying, and the identification of clusters of customers who share common attitudes, behavior, and preferences online (Blackwell, Miniard, & Engel, 2000). According to Seybold and Marshak (1998), consumers prefer the Internet because it offers easier and faster shopping. Convenience, timesaving, moneysaving, greater options, and fun are among the top reasons, and this kind of knowledge is of great value for dictating efficient e-marketing strategies and motivating e-commerce use with twofold objective: turn non-shoppers into shoppers and increase shopping of current shoppers.

This article presents the overall consumer purchase decision cycle and investigates the issues that affect Web users, from selecting a specific e-shop to the delivery of the product and the overall assessment of the shopping experience. This process has been divided into 13 states referring to customer behavior: outside the e-shop, inside the e-shop, and after sales. Special focus is set on identifying the potential abandonment factors thus leading to practical guidelines for all those whose decisions and objectives affect the online shopping experience (e-shop owners, marketing specialists, Web site designers, and developers).

BACKGROUND

Understanding the process of decision making behind online shopping behavior is important for developing e-business strategies and can provide guidance for deploying adequate marketing tools for persuading visitors to buy online (Underhill, 2000). The traditional consumer purchase decision cycle has six stages according to Windham and Orton (2000): stimulate (realize the need), consider (collect ideas for potential solutions), search (choose category), choose (make selection), buy (make purchase transaction), and buy again (repurchase as needed). There also exist variations, since in some cases stages are merged, collapsed, or skipped. Adapted to the Web context, this cycle is merged to three stages: confidence building, where a consumer realizes that there is an alternative option for buying products or services; skirmish, when he purchases for the first time; and war, when he keeps on buying products or services (Zaltman, 2003).

Lee (2002) presented a behavioral model for the e-customer. The model is based on three distinct phases: building trust and confidence, online purchase experience, and after-purchase needs. The first phase examines issues connected to the Web site's brand name, authentication, reliability, credibility, privacy, and security. Intuitive navigation, searching facilities, product information, payment modes, usability, and convenience are among the consumer requirements that affect the second phase. The last phase relates to on-time delivery, customer support, technical support, availability of product warranty, and so forth. The combination of the three phases releases a behavioral model that increases consumer trust and leads to more online purchases. Different other cases have also been recorded in the international literature presenting parts of the behavior of the online customer (Mowen & Minor, 2000; McEnally, 2002).

ONLINE CONSUMER'S MODEL

The model in Figures 1, 2, and 3 describes the way an online consumer interacts with an e-shop. The whole process has been divided into the following 13 states.

Figure 1. From the purchase stimulus to entering an e-shop

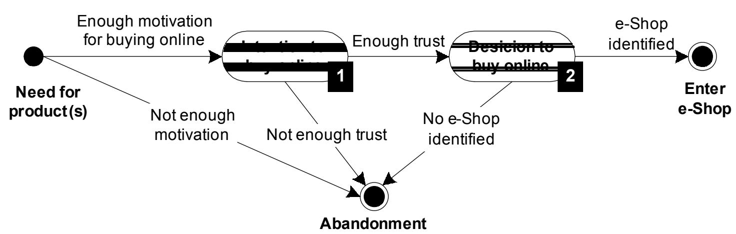

Figure 2. The shopping process from entering to leaving the e-shop

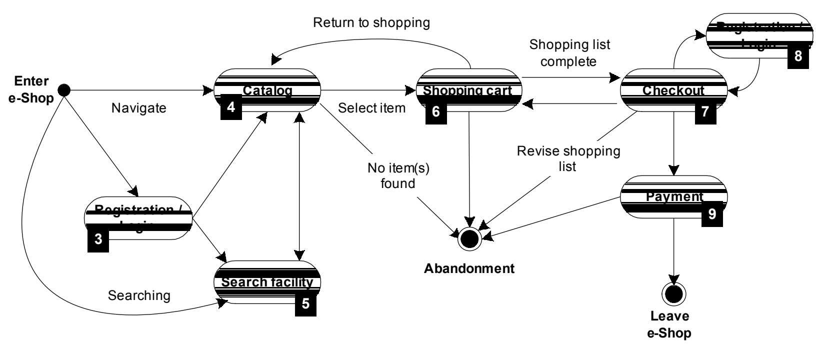

Figure 3. Product receipt, customer support, and overall assessment

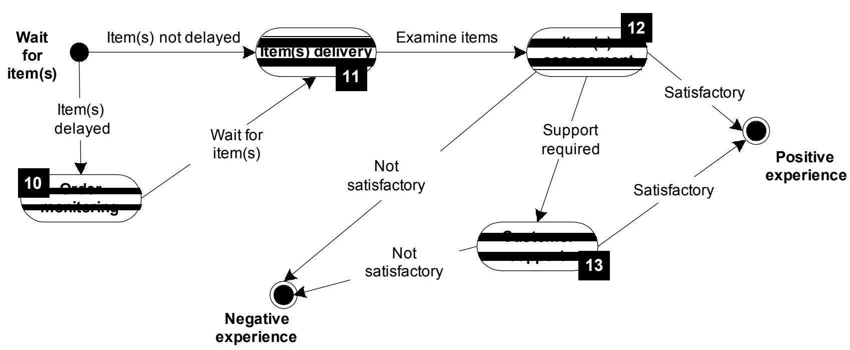

State 1: Intention to Buy Online

Firstly, the motivation of the consumer should be defined. The need of a specific product can be the basic motivation for buying it. However, the choice of online shopping mode relates to the consumer's general attitude and familiarity with computers and the Web, prior personal experiences, experiences of others (friends, colleagues), or brand intimacy (motivation of trust).

State 2: Decision to Buy Online

When the consumer decides to buy online, the next step is to locate the e-shop. Generally, online consumers are: looking for a reliable and well-known brand behind the e-shop, attracted by an aesthetically and consistent Web site design, enjoying navigating through a well-structured and usable site, convinced when receiving accurate content, and feeling reassured by privacy statements and seals of secured transactions. Additional factors that influence them include pricing, quality of products/services, promotions, offers, after-sales support, personalization, and so forth. There are also customers who chose an e-shop because a search engine returned this link high in its results list. This forces companies to use multiple communication tactics for succeeding Web site awareness, such as affiliate programs with other sites, mass advertising, banner ads, links on related product pages, marketing e-mails, and search engine promotional actions. The aim is to give them an incentive to visit the Web site for the first time. For unknown customers a survey for identifying their characteristics could be helpful; however, direct contact is the most effective strategy. For users with prior e-shop purchase experience, the issue of trust extends to e-loyalty. Thus the Web site should try to capture as much data as possible in order to use them when users are revisiting the site. This allows companies to personalize the content and support online communities. Without significant motivation and trust, the potential customer fails to identify an e-shop and abandons the process of online shopping, before actually entering it.

States 3 and 8: Registration/Login

Registration is an optional state, but the majority of e-shops use it for tracking individual consumers. First-time visitors are asked to provide personal information such as name, age, sex, income status, educational background, occupation, marital status, and other demographics, as well as preferences, requirements, shipping address, billing details, and so on. Login is the process a user has to go through in order to be identified by the system in each subsequent visit (after registration). It is an effective and secure way to overcome the typical problems IT experts have in identifying the same user entering a Web site from different IPs or distinguishing different users from the same IP. The general guideline is to ask users to fill in as little information as possible, in a simple, straightforward manner, providing drop-down lists for those questions that have a limited and known range of answers (e.g., country of residence) in order to reduce typing and prevent spelling mistakes. Since Web site visitors are reluctant to reveal personal information and are insecure about its use, e-shops should provide clear statements on their policy for the use of the collected information (disclosure policies) and the security precautions they have taken (authentication seals). The registration/login state may be postponed for right before checkout (State 8). This way, consumers are able to browse anonymously and identify themselves only when it is absolutely necessary.

State 4: Online Catalog

The online catalog is e-shops' interactive front-end to potential customers. It offers a listing of all available products, combined with classification and retrieval support, in addition to interfaces to other e-shop services. Users spend most of their time looking for products and use the feedback from this process to decide whether they will go on with the payment, or leave their shopping cart at the cash register and exit. Failure to locate the item(s) means one less customer and a hard-to-estimate spreading of disrepute. Either way (by browsing the catalog or using the search utility of State 5), the customer sooner or later ends up at a product page (which in some cases may contain a group of products) with details, pictures, features, pricing, and even comparisons, offers, ratings from the customer community, ratings from experts, recommendations, and so forth.

State 5: Search Facility

Another way that consumers find interesting items to place in their shopping cart is through the search facility. It is true that Web users are familiar with the notion of searching and the typical mechanism of browsing through search results. Thus, regardless of how well structured and efficient the catalog is, an e-shop must also provide a search function, and keep it available and visible on all pages so that customers may resort to it whenever in need. The general guideline is that search should operate the way customers expect it to. It should be tolerant to minor misspellings, allow for synonyms and string keywords, and return an easily interpretable results page and links to product pages. Furthermore, in the case that a search fails, the response page should clearly indicate that no actual results are returned and, where possible, provide a way for customers to refine their search until they locate products (provided that the e-shop has them available). The combination of States 4 and 5 is of great importance, not only because selecting products is an integral part of every purchase, but also because it determines the user's impression and a first-level assessment of the e-shop.

State 6: Shopping Cart

The shopping cart refers to a single page in an e-shop listing the items the customer has chosen to purchase. On that page customers should be allowed to remove one or more items, change item quantities, and automatically recalculate costs. In addition, a "return to shopping" link should exist to transfer them back to where they were before adding the last item to the cart (Markellou, Rigou, & Sirmakessis, 2005b). This logic reflects the real-life paradigm exactly: while walking the corridors of a supermarket, we pick up items, put them in the cart, and keep on walking until we find the rest of the items in our shopping list. In fact, the real-life situation has a drawback: we cannot easily calculate the total cost of our cart contents, and we cannot change quantities and recalculate just by a mouse click. Thus, it is a good idea to construct an effective shopping cart taking advantage of all conveniences offered by IT, stressing this comparative advantage over traditional shopping.

State 7: Checkout

After looping through States 4, 5, and 6 as many times as required, customers proceed to checkout. This is the phase where they are asked to fill in information about delivery (recipient's mail address, date of delivery, packaging details, shipping options, etc.). If the user has not yet logged in (or is not obliged to login), the checkout phase asks for additional data that would otherwise be filled in automatically. Again, typing should be kept to a minimum, as in the previous cases, and all optional fields should be clearly and consistently marked.

State 8: Registration/Login

See "States 3 and 8: Registration/Login".

State 9: Payment

Payment involves filling in forms with the required data for charging customers with the cost of their order. It requires simplicity, clarity, certificates, reassurance, and a sense of professionalism and safety. Security in transactions is not negotiable. There must be detailed information about the measures taken to guarantee security, and be available on every page of the payment process for whomever wants to view it. Upon successful completion of payment, the customer should be informed about it, through a response page that provides a code number (which uniquely identifies the submitted order) and the estimated delivery time. This information may alternatively be sent via e-mail. Using the order code number, the customer should be able to trace the status of the order at any time before receiving the product(s).

State 10: Order Monitoring

In the typical scenario, after successfully leaving the e-shop, customers enter the state of waiting to receive the goods. In the case that the order is not delivered by the pre-specified time, the customer usually invokes the order monitoring procedure. It is also possible to have a customer that enters this state before any delay, just to check if everything proceeds according to the initial schedule. It is the e-shop's task to serve all customers that require feedback on the state of their order regardless of the reason why each one does so.

State 11: Order Delivery

In this state the consumer receives the product(s).

State 12: Item(s) Assessment

Upon receiving the order, the customer proceeds with assessing whether the products are in good condition and of satisfying quality. If the result of the assessment is negative, so is the impression of the online shopping experience and the specific e-shop. The e-shop has lost a customer and the same probably goes for those he shared this unpleasant experience with.

State 13: Customer Support

There are many cases of "merchandise" sold online (e.g., computer hardware or software) that require after-sales support. In such cases, the overall customer impression of the e-shop may be re-evaluated. It may prove that, even if the product itself has been satisfactory, the lack of adequate support results in unwillingness to repeat analogous purchases and thus the e-shop fails to keep the customer coming back to buy more.

FUTURE TRENDS

A user may abandon an e-shop for many reasons that do not necessarily have to do with the e-shop itself. However, the factors that are the e-shop's responsibility and can be controlled include:

- **Missing Product(s) or Product Details:** This is caused by either the fact that the shop does not actually sell the product (in which case the customer must be clearly informed), or that the product is misplaced and the search mechanism is either missing or not functioning well. Search should be provided in combination with the catalog in order to serve customers who know from the outset what to buy.
- **Unreliable/Inefficient E-Shop Operation:** The e-shop—as any Web application—should be a 24/7 system, able to function under extreme traffic conditions, providing fast interaction and effective navigation schemes.
- **Inconsistency in Function or Appearance, Out dated Technology, Bad-Quality Graphics, Hard-to-Read Text:** These are all indications that are interpreted as lack of professionalism and result in loss of trust on the customers' part.
- **Missing Seals of Approval, Non-Existent/Insufficient Details on Security and Disclosure Policy, Unclear Company Identification:** These factors amplify the security concerns that remain among the large obstacles towards the wider acceptance of e-commerce.

Avoiding the aforementioned abandonment conditions does not suffice for answering the actual challenge of providing quality of service and assuring customer satisfaction that leads to loyalty and long-term profits. Modern e-shops face the fierce competition of the global electronic market that raises the standards of customer services.

Personalization may play a central role towards enhancing the online shopping experience. Typically, a personalized Web site recognizes its users, collects information about their preferences (during State 3 or 8), and adapts its services, in order to match user needs. In the e-commerce domain, personalization has spread widely, and provides mechanisms to learn more about customer needs, identify future trends, and eventually increase customer loyalty. Personalization may be used in numerous ways for enhancing the online shopping experience (Markellou et al., 2005a). In the simplest scenario, the e-shop recognizes and salutes the user upon revisiting, or automatically pre-fills all data the user has already provided in registration (e.g., name, contact details, even credit card numbers) during checkout and payment. Using more sophisticated approaches (Markellou et al., 2005c), an e-shop may provide personalized product recommendations and marketing, personalized pricing, as well as personalized product configurations. The biggest challenges though remain the lack of trust on the customer side and the lack of customer data on the e-shop side to base the personalization decisions upon. Research in the area of mining Web usage data (Sirmakessis, 2004) should be accompanied by security preservation methods to increase consumer confidence in the use of the Internet for selling and buying.

In the cases of Web marts (large e-shops that sell a wide variety of products), consumers need intelligent tools to answer their product enquiries and speed up their decision-making process. Filtering tools are used for narrowing a large itemset down to a subset that satisfies a number of criteria (price ranges, brands, colors, sizes, etc.), a process that resembles the "search within search results" function. Nielsen, Farrell, Snyder, and Molich (2000) refer to this category of tools as "winnowing tools." Apart from filtering, there are cases of products that are difficult to compare, even when the list of similar products along with their attributes is available and thus the purchase decision needs further assistance. Comparison tools typically offer summarizing tables with similar products on one dimension and features on the other; the tools simplify comparisons on a feature-by-feature basis (e.g., Nokia phones at nokia.com).

Last but not least, an effective way to improve customer opinions about an e-shop is the formation and maintenance of a customer community that stores customer opinions about a purchased product, product ratings given by experts, or customer experiences with the helpdesk and the technical support of the e-shop. Such information is perceived well by customers, as it is considered to be less biased (compared to the features of a product as described by its manufacturer or trader). Moreover, ratings—and in general the opinion of other buyers or experts—are positive signs for the credibility of an e-shop, and the opinions of returning customers are considered important for visitors or new customers.

CONCLUSION

In this article we studied the behavior of online customers, assuming it is triggered by a stimulus to purchase a certain item or set of items. Based on this assumption we drew a set of recommendations for all those that relate to online shopping, including e-shop owners, marketing specialists, Web site designers, and developers. The diagrams presented, along with the investigation of the factors that determine the transition between states, also complied with this condition.

In conclusion, e-commerce has opened up a new spectrum of potential by expanding local markets to worldwide ones. E-loyalty is the key to making this huge step forward. Commerce on the Internet may be frictionless and remote, but it need not—and should not—be impersonal. E-loyalty aims at humanizing digital loyalty and developing intimacy. The question is how to gain customer loyalty. A bad first experience with an e-shop can kill the millions spent on the application of an e-loyalty strategy. No e-loyalty program though, regardless of its sound planning or execution excellence, can overcome a bad Web site design, poor product quality, or unreliable delivery.

KEY TERMS

Customer Satisfaction: Measure or determination that a product/service meets a customer's expectations, considering requirements of both quality and service.

E-Community: A group of people sharing common interests, ideas, and feelings in the Internet or other collaborative networks. E-communities exist in discussion groups, chat rooms, newsgroups, and so forth.

Electronic Marketing: Using electronic means and the Internet to market products/services.

E-Loyalty: The degree to which online consumers are predisposed to stay with a specific e-shop and resist competitive offers.

Personalization: A set of techniques and services that aim to solve the information overload problems Web users face, by providing them with what they want or need, without having to ask (or search) for it explicitly.

Web Mining: The use of data mining techniques for discovering and extracting information from Web documents and services. It is distinguished as Web content, structure, or usage mining depending on which part of the Web is mined. Web usage mining examines usage data typically in the form of server logs.

Collaborative Commerce

Ta-Tao Chuang
Gonzaga University, USA

Kazuo Nakatani
Florida Gulf Coast University, USA

Duanning Zhou
Eastern Washington University, USA

INTRODUCTION

In the past few years, collaborative commerce (c-commerce) has been widely touted by practitioners and has caught researchers' attention. The business press constantly reported successful stories of c-commerce in which companies in various industries employed collaborative technologies to reap potential benefits. A recent report on the software market for c-commerce indicated that software for creating c-commerce would be the next stage of growth in the enterprise application business (Bellini, Gravitt, & Diana, 2001). The report estimated that the size of the c-commerce market would grow from $5.8 billion in 1999 to $36.5 billion in 2004 (estimated by AMR and IDC). Another report (Ferreira, Schlumpf, & Prokopets, 2001) showed that about 60% of 356 survey respondents considered c-commerce as critically important to their businesses in the year of 2001-2002 and 78% of the companies planned to implement c-commerce to improve supplier and customer interaction. Meanwhile, findings of academic research on issues surrounding c-commerce have been sporadically reported. Welty and Becerra-Fernandez (2001) investigated the issue of managing trust and commitment in collaborative relationships. Kumar (2001) delineated the features of information and communication technologies for supporting c-commerce. Chuang and Nakatani (2004) identified different types of c-commerce and the driver for each type of c-commerce.

Extending the concept of inter-organizational collaboration (Himmelman, 1996), Chuang and Nakatani (2004) defined c-commerce as an IT-enabled process in which organizations share information and resources, adjust their activities and augment each other's capabilities in order to reap mutual benefits while assuming common responsibilities, risks, and rewards. Johnson and Whang (2002) used the term "e-collaboration" to refer to the collaborative activities between businesses; however, Johnson and Whang placed emphasis on the role of the Internet and the concept of sharing. It is worth noting that while there are overlappings between the boundaries of collaborative commerce and electronic commerce, the difference between both lies in the fact that c-commerce is focused on joint intellectual effort, but e-commerce is oriented to more transaction processing, such as selling/buying activities.

Even though c-commerce could be considered as one of ramifications of electronically conducting commerce over the Internet, its emergence is most likely driven by the globalization of economy, the competition, the need for efficient customer response, and the advent of collaborative technology. From the managerial perspective, globalization means that decisions on allocation and/or acquisition of resources are considered and made on a global scale. Thus, international sourcing is commonly considered as an option for improving organizational performance, which subsequently necessitates the need for collaborative planning (Fliedner, 2003).

The fierce competition on global economy spurs businesses on to create strategic partnership with complementary enterprises in which creating collaborative advantage is as, if not more, important as creating competitive advantage (Spekman, Kamauff, & Myhr, 1998). The proliferation of strategic partnerships has resulted in the appearance of competition between business networks or between supply chains (Kumar, 2001). In this context, paradoxically, the fiercer the competition is, the more important collaboration becomes. Meanwhile, fierce competition redirected businesses' energies toward the fulfillment of customer's needs and the reduction of operating cost accrued through the supply chain (Fliedner, 2003). Finally, the availability of greater bandwidth of telecommunication facilitates the use of network and the Internet to connect businesses and create a collaborative platform on which "advanced planning systems" are employed to analyze and optimize the flows of supply chain (Kumar, 2001). In brief, the emergence of c-commerce could be driven by business needs and sophisticated IT capability.

BACKGROUND

Although inter-organizational collaboration has long been a commonly studied topic among researchers in the areas of business and public policy disciplines (Himmelman, 1996; Spekman, Kamauff, & Myhr, 1998), research in c-commerce is in its early stage and its findings have been sporadically published. Existing literature of c-commerce is focused on two themes (Chuang & Nakatani, 2004): (1) presenting successful anecdotes and potential benefits of c-commerce, and (2) describing the prescriptive features of c-commerce software or information technology infrastructures for building c-commerce. Exceptions to these two themes include Welty and Becerra-Fernandez (2001), Kumar (2001), and Chuang and Nakatani (2004).

C-commerce technology could be employed in the project that involves highly intellectual activities. For example, Boeing improved its production productivity from 228 airplanes per year in 1992 to 620 expected in 2002 by using collaborative e-marketplace (Fingar, 2001). In order to build a new family of supersonic stealth fighter planes in four years, Lockheed Martin Aeronautics Co. created a collaborative platform in which more than 80 suppliers located at 187 locations cooperatively designed and built components of the Joint Strike Fighter (Keenan & Ante, 2002). Additionally, c-commerce has changed the way firms in the food industry conduct business. For example, by using collaborative planning, forecasting, and replenishment (CPFR), Nabisco and Wegman's significantly increased sales revenue, service level, and market share (Walton & Princi, 2000). In the manufacturing sector, Microsoft and Flextronics created a Web-based collaborative system in which personnel from design, manufacturing, and engineering departments worked together to develop and test the prototype of Xbox video game console (Keenan & Ante, 2002). These cases demonstrate that c-commerce is generally employed in projects that involve knowledge exchanging and management. While efficiency and cost reduction are two major benefits of c-commerce, even more importantly, c-commerce facilitates product and process innovations or the reduction of cycle time.

Extant literature of c-commerce also placed an emphasis on the discussion of applications and IT infrastructure that support the development of c-commerce. Bellini, Gravitt, and Diana (2001) classified the enterprise application software for c-commerce into three categories: supplier relationship management, knowledge management, and product life-cycle management. Fou (2001) considers c-commerce as a continuum of applications of information technology, ranging from Web-enabled single-dimensional and single-process c-commerce, to B2B exchanges-based, single-dimensional and multiple-process c-commerce, to Web service-based, multiple-dimensional and multiple-process c-commerce. The Web service-based collaborative architecture consists of four tiers: c-commerce vendors, Web services, business rule engine, and multi-dimensional c-commerce enterprise Web portal.

While the above documents focus on the role of information technology, Derome (2000) emphasized that c-commerce capabilities should be illustrated from a functional standpoint. He defined c-commerce as a three-layer architecture: free-form collaborative services, process collaboration layer, and the structured data exchange category. The IT environment, duration of collaboration, and goal of collaboration vary from category to category. Likewise, Ramachandran and Tiwari (2001) studied the air cargo industry and proposed a collaborative supply chain consisting of connectivity layer, knowledge layer, and functionality layer that could offer better economic global air cargo services.

Additionally, several studies were focused on the importance of business strategy, collaborative models, and relational development. Mulani and Matchette (2002) proposed a product development life-cycle collaboration framework that ties the mutual strategic objectives of trading partners to actual inter-company execution. Li and Williams (1999) found that companies that had cooperated at the transactional level tended to develop a collaborative partnership at the strategic level. Welty and Becerra-Fernandez (2001) presented a business interaction model in which interaction technology (i.e., c-commerce software) is adopted to nurture mutual trust between partners and in which customer satisfaction is integrated into business processes. It is customer satisfaction rather than the delivery of goods or the payment that closes a business transaction loop. Chuang and Nakatani (2004) also emphasized the importance of trust and commitment in c-commerce. They asserted that existing inter-organizational relationship (IOR) and the level of trust between collaborators might affect the establishment, structure, and conduct of a c-commerce.

DEVELOPMENTAL PERSPECTIVE, APPLICATIONS, AND CURRENT ISSUES OF C-COMMERCE

The Roadmap of C-Commerce

Although extant literature of c-commerce documents numerous benefits and delineates a prescriptive form of c-commerce, there are several barriers, including trust issue between trading partners (Spekman, Kamauff, & Myhr, 1998; Welty & Becerra-Fernandez, 2001), existing relationship between prospective partners (Chuang &

Nakatani, 2004), and application and system integration necessary for supporting c-commerce (Derome, 2000; Kumar, 2001; van der Aalst, 1999; Park, Suh, & Lee, 2004).

While several approaches, such as technological (Fou, 2001), functional perspective (Derome, 2000), and progressive approach (Chuang & Nakatani, 2004), could be adopted to overcome the barriers, the framework named c-commerce roadmap proposed by A. T. Kearney for Grocery Manufacturers of America (GMA/FMI Trading Partner Alliance & Kearney, 2002) explicitly delineates underlying technology and progressive commerce activities. This framework has been used to support UCCnet and Global Data Synchronization Network (GDSN) managed by two international standards development organizations: Uniform Code Council, Inc. (now called GS1 US) and EAN (European Article Numbering) International (now called GS1). The c-commerce roadmap has seven stages: (1) common data standards, (2) single item registry, (3) item synchronization, (4) collaborative transaction management, (5) collaborative supply chain management, (6) collaborative sales and promotion planning, and (7) collaborative insight and product development. These seven steps present a progressive path that collaborators could take as the mutual trusts grow. They also represent different forms of c-commerce, as suggested by others (Chuang & Nakatani, 2004; Derome, 2000).

The first three steps (i.e., common data standards, single item registry, and data synchronization) provide an essential technological foundation for global collaboration. The standards and data synchronization enable companies to cooperate at the simplest level: transaction-oriented collaboration. The companies who register their products in the global registry will be able to collaborate on global scale, the significance of which is that geographic proximity might not be a critical factor for collaboration. The standards allow companies to speak the "same language." Thus, the management of transaction-oriented collaboration becomes more efficient. With the collaborative transaction management in place, collaborators could expand their partnership to include third party logistics to form collaborative transportation/logistics management (Esper & Williams, 2003). Collaborative supply chain (logistics) management could improve the accuracy of fulfillment, reduce the frequency of out-of-stock, and reduce inbound and outbound logistic costs. Combining with RFID (Radio Frequency Identification) technology, real-time product tracking can be realized. Sales information collected at a POS system can be instantly shared with distributors and manufacturers for Collaborative Planning, Forecasting and Replenishment (CPFR) (VICS, 2004), which is the essence of collaborative sale and promotion management. The implementation of CPFR fosters high level of interdependence and information sharing between partners (Stank, Daugherty, & Autry, 1999) and consequently, requires a high level of trust and commitment between partners.

The essence of CPFR lies in the integration and sharing of multiple parties' intelligence in the planning and fulfillment of customer demand (VICS, 2004). The intelligence shared in CPFR is more about the understanding of the status quo of the market rather than the potential opportunity, such as new business or products. Thus, the next level of collaboration will be that partners share their insights of the business and cooperatively develop new products that serve a market opportunity. This form of c-commerce may demand sharing of "know-how" of production techniques or knowledge of product design. This form of c-commerce appears to be the highest possible level of collaboration because the sharing of such knowledge might result in negative reverse impact (Loebbecke & Van Fenema, 1998).

Applications of C-Commerce

Although the c-commerce roadmap presented above provides a prescriptive course that businesses could follow to reap the benefits of c-commerce, existing successful cases indicate that most, if not all, of companies that initiated c-commerce didn't follow the prescription. Instead, most of them would create a form of c-commerce suitable for their existing practices. Thus, those applications are relatively diverse and, on the surface, share very limited similarity. This section attempts to categorize those applications by adopting McGrath's task classification as a basis. It should be noted that by no means the classification is intended to be exhausted. Instead, we admittedly acknowledge that c-commerce is still in its infancy, so different applications and end products may emerge and when more applications are available, the classification should be revised.

McGrath (1984) classified the types of tasks performed by a group of people into four categories: generating alternatives, choosing alternatives, negotiating issues, and executing works. Under each of the four categories, McGrath further classified into two subcategories, as shown in the second column in Table 1. In each category, a few c-commerce examples from Phillips and Meeker (2000) and literature reviewed above are added to demonstrate the applicability of the classification.

While the definition of each category is self-explanatory, the category of execution might need further elaboration. The two subcategories of execution are contests/battles and performance. Contests/battles refer to resolving conflicts of power or competing for victory, while performance means undertaking psychomotor tasks to meet objectives or absolute standards of excellence. An example of battle is the relay race of 1600 meters, in which several teams of four members compete against one another for victory. While this type of activity is not entirely intellectual effort, the four runners of each team need to evaluate their strengths and weaknesses and then determine their positions in the race. In the context of c-commerce, an example of contest/battles would be the competition in some aspects (e.g., demand and supply planning, distribution, and fulfillment) or the whole of supply chain management between two or more camps led by a focal company (or "the lord of chain" in Kumar's words (2001)). Under such a circumstance, the basic assumption is that each supply chain has its own plan ready and what those supply chains compete on includes the excellence of their plans as well as how well they could execute their plans.

Key Issues in C-Commerce Research

There are several key issues that need to be addressed in order to further our understanding of c-commerce. We identified the following that deserves researchers' attention in the near future.

1. **Theoretic Development of C-Commerce:** As the topic of collaboration has been investigated in other disciplines, such as public policy and marketing, theoretic development has been underway (Wood & Gray, 1991). In contrast, because c-commerce is an emerging business practice, not much, if any, research has been done in the development of c-commerce theory. Since c-commerce is one special case of business-to-business e-commerce, researchers tend to adopt the transaction cost approach to examine issues surrounding c-commerce. However, due to the criticism to the transaction cost approach, several researchers have suggested that other perspectives, such as the business network (Johanson & Mattsson, 1987), should be employed to investigate c-commerce practice.
2. **Configurations of Collaborative Network:** Philips and Meeker (2000) claimed that the basic architecture of c-commerce is in the form of hub and spoke; however, Chuang and Nakatani (2004) suggested that there are, at least, three different configurations of collaborative network and that specific configuration varies depending on the nature of projects, the profile of participants, and the industry. The choice of configuration of c-commerce could be an issue to be addressed.
3. **Design and Implementation of C-Commerce Infrastructure:** Established software vendors are extending their products to incorporate features that would support c-commerce. Derome (2000) indicated that c-commerce should be defined from functional standpoints rather than from the technology; thus, a technology supporting c-commerce could be as simple as e-mail (Derome, 2000) or as sophisticated as "advanced planning systems" (Kumar, 2001). Therefore, an issue regarding the design and implementation of c-commerce infrastructure is the choice of an integrated solution vs. "the best of the breed." A relevant issue is the choice of generic collaborative technologies vs. specialized c-commerce solutions. While the consolidation of the c-commerce software market will certainly narrow down the space of choice, many options are available in the market.
4. **Coordination Mechanisms in C-Commerce (Chuang & Nakatani, 2004):** The c-commerce process involves communication, cooperation, and coordination among partners. The features of the IT infrastructures proposed by extant research might be sufficient for supporting communication and cooperation yet the issue of coordination has not be fully studied. Thus, another issue surrounding c-commerce is the conceptualization of coordination mechanisms.

Table 1. Products and examples of c-commerce

Category	Type	Definition	Examples in C-Commerce
Generate	Planning tasks	Generating plans for actions	Planning, scheduling and forecasting
	Creative tasks	Generating ideas	Product conception and development
Choose	Intellective tasks	Solving problem with a correct answer	Payment reconciliation, or complex pricing, route optimization
	Decision-making tasks	Dealing with tasks for which the preferred or agreed upon answer is the correct	Collaborative promotion planning, campaign management
Negotiate	Cognitive conflict tasks	Resolving conflicts of viewpoint (not of interests)	Resolving difference in the method used for forecasts of demand for products
	Mixed-motive tasks	Resolving conflicts of motive-interest	Contract negotiation and management
Execution	Contests/battles	Resolving conflicts of power	Supply chain management
	Performance	Competing against objective standards	Mortgage application processing

FUTURE TRENDS

Paradoxically, the fiercer the competition becomes, the more distinguished the value of collaboration will be. For a long time, businesses have been cooperated in one form or another. With the potential presented by information and communication technologies (ICT), businesses will certainly be creatively applying ICT to explore collaborative opportunities. In the future, a few trends are noteworthy.

First, more and more companies will apply c-commerce in higher level of c-commerce, such as joint product development. As indicated previously, joint product development is the form of c-commerce with the greatest benefit. As the mutual trust and commitment among partners increase along with their collaboration, they will certainly attempt to reap the greatest potential of c-commerce.

Second, the scope of c-commerce applications in terms of the number of partners or amount of expertise will be broadened. This trend could be attributed to economic globalization and outsourcing. In the context of c-commerce, globalization and outsourcing have two effects: one is that each business will focus on its core competence and the other is that in order to cope with the complexity of today's business environment, those companies with different core competences will need to collaborate. Thus, the scope of c-commerce applications will be broadened.

Third, as the bandwidth of telecommunication increases, multimedia and data visualization technologies will be employed in c-commerce. This trend is the result of two forces: pull from the market and push from the technology. The proliferation of higher level of c-commerce, such as joint product development, will demand multiple presentations and representations of data.

CONCLUSION

Several forces, such as the economic globalization, the competition, the need for efficient customer response, and the advent of collaborative technology have driven the emergence of c-commerce. This article reviews the current status of research in c-commerce, discusses the developmental framework of c-commerce, and attempts to classify c-commerce applications. As c-commerce is still in its infancy, more research is needed in order to improve our understanding of the new business practice. There are several issues of c-commerce that need to be addressed: the theoretical development of c-commerce, the configurations of collaborative network, the design and implementation of c-commerce infrastructure, and the coordination mechanisms in c-commerce. These issues present plenty of research opportunities.

KEY TERMS

Business Network Approach: An approach to the research of strategic management that considers the firm embedded in social, professional and value exchange networks (Johanson & Mattsson, 1987).

Collaborative Commerce: An IT-enabled process in which organizations share information and resources, adjust their activities and augment each other's capabilities in order to reap mutual benefits while assuming common responsibilities, risks, and rewards (Chuang & Nakatani, 2004).

Collaborative Commerce Roadmap: A framework that prescribes the technological foundation for c-commerce and different forms of c-commerce (GMA/FMI Trading Partner Alliance and Kearney, 2002).

Collaborative Planning, Forecasting, and Replenishment: A business process in which multiple partners share and integrate their intelligence of the market in the planning and fulfillment of customer demand (VICS, 2004).

Collaborative Transportation Management: Is the process in which order forecasts developed via CPFR are converted into shipment forecasts and accurate fulfillments of them are assured (Esper & Williams, 2003).

Data Synchronization: The ability of making data describing entities (e.g., products or services) or activities (e.g., design, production, or delivery) in collaborative domain identical.

E-Collaboration: The Internet-enabled information sharing and joint decision making between businesses (Johnson & Whang, 2002).

Collaborative Filtering for Information Recommendation Systems

Anne Yun-An Chen
University of Southern California, Los Angeles, USA

Dennis McLeod
University of Southern California, Los Angeles, USA

INTRODUCTION

In order to draw users' attention and to increase their satisfaction toward online information search results, search-engine developers and vendors try to predict user preferences based on users' behavior. Recommendations are provided by the search engines or online vendors to the users. Recommendation systems are implemented on commercial and nonprofit Web sites to predict user preferences. For commercial Web sites, accurate predictions may result in higher selling rates. The main functions of recommendation systems include analyzing user data and extracting useful information for further predictions. Recommendation systems are designed to allow users to locate preferable items quickly and to avoid possible information overload. Recommendation systems apply data-mining techniques to determine the similarity among thousands or even millions of data.

Collaborative-filtering techniques have been successful in enabling the prediction of user preferences in recommendation systems (Hill, Stead, Rosenstein, & Furnas, 1995, Shardanand & Maes, 1995). There are three major processes in recommendation systems: object data collections and representations, similarity decisions, and recommendation computations. Collaborative filtering aims at finding the relationships among new individual data and existing data in order to further determine their similarity and provide recommendations. How to define the similarity is an important issue. How similar should two objects be in order to finalize the preference prediction? Similarity decisions are concluded differently by collaborative-filtering techniques. For example, people that like and dislike movies in the same categories would be considered as the ones with similar behavior (Chee, Han, & Wang, 2001). The concept of the nearest-neighbor algorithm has been included in the implementation of recommendation systems (Resnick, Iacovou, Suchak, Bergstrom, & Riedl, 1994). The designs of pioneer recommendation systems focus on entertainment fields (Dahlen, Konstan, Herlocker, Good, Borchers, & Riedl, 1998; Resnick et al.; Shardanand & Maes; Hill et al.). The challenge of conventional collaborative-filtering algorithms is the scalability issue (Sarwar, Karypis, Konstan, & Riedl, 2000a). Conventional algorithms explore the relationships among system users in large data sets. User data are dynamic, which means the data vary within a short time period. Current users may change their behavior patterns, and new users may enter the system at any moment. Millions of user data, which are called neighbors, are to be examined in real time in order to provide recommendations (Herlocker, Konstan, Borchers, & Riedl, 1999). Searching among millions of neighbors is a time-consuming process. To solve this, item-based collaborative-filtering algorithms are proposed to enable reductions of computations because properties of items are relatively static (Sarwar, Karypis, Konstan, & Riedl, 2001). Suggest is a top-*N* recommendation engine implemented with item-based recommendation algorithms (Deshpande & Karypis, 2004; Karypis, 2000). Meanwhile, the amount of items is usually less than the number of users. In early 2004, Amazon Investor Relations (2004) stated that the Amazon.com apparel and accessories store provided about 150,000 items but had more than 1 million customer accounts that had ordered from this store. Amazon.com employs an item-based algorithm for collaborative-filtering-based recommendations (Linden, Smith, & York, 2003) to avoid the disadvantages of conventional collaborative-filtering algorithms.

BACKGROUND

Collaborative-filtering techniques collect and establish profiles, and determine the relationships among the data according to similarity models. The possible categories of the data in the profiles include user preferences, user behavior patterns, and item properties. Collaborative filtering solves several limitations of content-based filtering techniques (Balabanovic & Shoham, 1997), which decide user preferences only based on the individual profiles. Collaborative filtering has been expressed with different terminologies in the literature. Social filtering and automated collaborative filtering (ACF) are two frequently referred-to terminologies. Collaborative-filtering-based recommendation systems are also referred as to as collaborative-filtering recommender systems and automated collaborative-filtering systems.

Several collaborative-filtering-based recommendation systems have been designed and implemented since the early '90s. Collaborative-filtering techniques have been proven to provide satisfying recommendations to users (Hill et al., 1995, Shardanand & Maes, 1995). The GroupLens project, a recommendation system for Netnews, has investigated the issues on automated collaborative filtering since 1992 (Konstan, Miller, Maltz, Herlocker, Gordon, & Riedl, 1997; Resnick et al., 1994). In the system design, better bit bureaus (BBBs) have been developed to predict user preferences based on computing the correlation coefficients between users and on averaging the ratings for one news article from all. MovieLens is a movie recommendation system based on the GroupLens technology (Miller, Albert, Lam, Konstan, & Riedl, 2003). Recommendation Tree (RecTree) is one method using the divide-and-conquer approach to improve correlation-based collaborative filtering and perform clustering on movie ratings from users (Chee et al., 2001). The ratings are extracted from the MovieLens data set. Ringo (Shardanand & Maes) provides music recommendations using a word-of-mouth recommendation mechanism. The terminology social information filtering was used instead of collaborative filtering in the literature. Ringo determines the similarity of users based on user rating profiles. Firefly and Gustos are two recommendation systems that employ the word-of-mouth recommendation mechanism to recommend products. WebWatcher has been designed for assisting information searches on the World Wide Web (Armstrong, Freitag, Joachims, & Mitchell, 1995). WebWatcher suggests to users hyperlinks that may lead to the information the users want. The general function serving as the similarity model is generated by learning from a sample of training data logged from users. Yenta is a multiagent matchmaking system implemented with a clustering algorithm and referral mechanism (Foner, 1997). Jester is an online joke recommendation system based on the eigentaste algorithm, which was proposed to reduce the dimensionality of off-line clustering and to perform online computations in real time (Goldberg et al., 2001). The clustering is based on continuous user ratings of jokes.

One of the most famous recommendation systems nowadays is the Amazon.com recommendation (Linden et al., 2003). This recommendation system incorporates a matrix of the items' similarities. The formulation of the matrix is performed off line. Launch, music on Yahoo!, Cinemax.com, Moviecritic, TV Recommender, Video Guide and the suggestion box, and CDnow.com are other successful examples of collaborative-filtering-based recommendation systems in the entertainment domain.

Many methods, algorithms, and models have been proposed to resolve the similarity decisions in collaborative-filtering-based recommendation systems. One of the most common methods to determine similarity is the cosine angle computation. The Amazon.com recommendation system (Linden et al., 2003) uses this cosine measure to decide the similarity between every two items bought by each customer and to establish the item matrix, which contains item-to-item relationships. Several algorithms that combine the knowledge from artificial intelligence (AI; Mobasher, Jin, & Zhou, in press), networks (Chien & George, 1999), and other fields have also been implemented in recommendation systems. The genetic algorithm along with the naïve Bayes classifier is used to define the relationships among users and items (Ko & Lee, 2001). The genetic algorithm first completes the clustering for discovering relationships among system users in order to find the global optimum. On the other hand, the naïve Bayes classifier defines the association rules of the items. Then, similarity decisions can be performed to match the clusters of users or clusters of items, and the system can decide the final user profiles. The user profiles only consist of associated rules. The expectation maximization (EM) algorithm (Charalambous & Logothetis, 2000) provides a standard procedure to estimate the maximum likelihood of latent variable models, and this algorithm has been applied to estimate different variants of the aspect model for collaborative filtering (Hoffman & Puzicha, 1999). The heuristics of the EM algorithm can be applied to latent class models to perform aspect extracting or clustering.

Meanwhile, hierarchical structures are employed to describe the relationships among users (Jung, Yoon, & Jo, 2001). The preferences of each user can be described in a hierarchical structure. The structure represents the index of categories, which are the labels of the nodes. Matching one structure to another with all category labels results in each node containing a group of users with similar preferences. Hierarchical structures can also be applied to similarity computations for items (Ganesan, Garcia-Molina, & Widom, 2003). Edges in the structure clearly define how items are related for the item-to-item relationships. A hierarchical structure, a tree specifying the relative weights for the edges, provides information on how much two items are related. A method of the order-based similarity measurement has been proposed for building a personal-computer recommendation system (PCFinder; Xiao, Aimeur, & Fernandez, 2003). Instead of using 0/1 for the search, this method uses the concept of fuzzy logic to estimate the similarity.

Two popular approaches, the coefficient correlation computation and the nearest-neighbor algorithm, have limitations in scalability and sparsity. Clustering (Breese, Heckerman, & Kadie, 1998), the eigentaste algorithm (Goldberg et al., 2001), and singular value decomposition (SVD; Sarwar et al., 2000b) are introduced to collaborative-filtering-based recommendation systems to break these barriers. The eigentaste and genetic algorithms enable constant-time computations for online processes. Item-based collaborative-filtering algorithms are proposed to further decrease the computation time (Linden et al., 2003).

MAIN THRUST OF THE ARTICLE

Privacy Issues and User Identification

Do users always agree on being monitored by systems? Not every user is comfortable if each page he or she visits is recorded. Some users even disable the cookies in their browsers. Recommendation systems usually require user registrations in order to utilize user data for future recommendations. There exist users that prefer not to log onto systems every time they visit. Can the behavior patterns of random users be included in data-mining processes? It depends on the properties of the similarity models. Unregistered users only provide few continuous behavior patterns. These data may hardly be useful if the similarity models require the quantity of the behavior patterns to reach a certain level. At the same time, these data may be treated as neighbors and be included in the clustering processes for the recommendation computations. The computational time will be increased when more neighbors are included. The necessity to include the data of segmental user behavior patterns depends on the following: If enlarging the data coverage enables an increase in prediction accuracy, there is a trade-off between the computation-time length and the coverage scale.

Drawbacks

There are still several drawbacks of collaborative filtering. First, the lack of information affects the recommendation results. For relationship mining, new items not yet rated or not yet labeled can be abandoned in the recommendation processes. The second problem is that collaborative filtering may not cover extreme cases. If the scales of the user profiles are small or the users have unique tastes, similarity decisions are unable to be established. The third problem is the update frequency. If any new information of users has to be included in the recommendation processes in real time, data latency will increase the waiting time for the query result. The complexity of the computation for the recommendation affects the waiting time of the user directly. Synchronization is another issue of profile updating in the systems. When hundreds of users query the system within a very short time period, two new problems occur: who should be considered in one certain clustering process, and how to pipeline the computational power of the system server.

Hybrid Methods

A new approach is designed to comprise both content-based- and collaborative-filtering techniques in order to provide the accurate prediction of user preferences. How accurate the predictions are depends on the subjective opinions from the users. A recommendation system including both technologies is a hybrid recommendation system (Balabanovic & Shoham, 1997). Hybrid methods solve the problem of extreme-case coverage that collaborative-filtering techniques are unable to handle.

The Next Evaluation Tool for Information Retrieval

Precision and recall are two conventional measurements of data accuracy. User satisfaction has become an important issue in the information-retrieval (IR) area since a decade ago. Recommendation-system developers need to focus on what the users prefer and avoid what the users dislike. Evaluating user satisfaction is not an easy job. There are two ways to perform the evaluation of user satisfaction. The first one is to survey the users. The problem of this approach is that frequent surveys would cause a lot of disturbance in the online searching experience. The second approach is to decide the criteria to quantify the degrees of user satisfaction. One criterion is the involvement-time length for the search result. However, the starting- and ending-time points are hard to be determined in the Web environment (Shahabi, Zarkesh, Adibi, & Shah, 1997).

FUTURE TRENDS

An ideal recommendation system should be dynamic, which indicates that the updates on profiles can be performed approximately in real time. Although innovations in hardware design advance computational speed, algorithms and techniques with low-time computational complexity are expected in recommendation-system developments. User data flow every second. In order to keep the profiles up to date, online computations require many resources, such as memory and computational power. Therefore, it is important to maximize the off-line computations. The computation time depends on two factors: the number of items and the number of users in the database. The impact of the first factor, the number of items, may be reduced. The items usually are not added into the databases continuously (the opposite is the data stream, e.g., a video stream). However, the decision on the frequency of updates on user profiles is more complex. How often should the updates be performed in order to keep track of the user preference trends? If the updates are required to be performed approximately in real time, an algorithm or a technique with low-memory computational complexity is essential to reduce system loading and eliminate the potential effects on system synchronization.

CONCLUSION

Different collaborative-filtering techniques have been proposed to decrease processing time and data latency. The results from different recommendation systems indicate that collaborative-filtering techniques afford the systems enough ability to provide recommendations to users. Consequently, the recommendation systems can predict user behavior patterns without any knowledge of the user in advance, and can evaluate accuracy by comparing the prediction and the reality. If clustering is performed by the genetic or nearest-neighbor algorithms, or the algorithm developed is based on any of these two, the gaps among the data affect the accuracy of the prediction a lot. This means that missing data lowers the accuracy of the prediction. The situation is the same for EM approaches. This is because EM approaches perform better when the probability space is more complete. The accuracy of predictions performed by hierarchical approaches may also be affected since the recommended items would be too general due to the lack of detailed categorizations. These statements indicate that the reduction of missing or insufficient data is not simple, and that some approximations are required to be performed in order to provide better predictions of user preferences.

An approach to decrease online computational time is to allow recommendation systems to perform clustering off line (Chee et al., 2001). Several algorithms and techniques proposed perform computations in constant time (Goldberg, Roeder, Gupta, & Perkins, 2001; Lemire, 2003). These algorithms and techniques provide the possibility of real-time updates on profiles in the recommendation systems.

KEY TERMS

Clustering: A task that segments objects into groups according to object similarity.

Collaborative Filtering: An approach to provide recommendations based on the preferences of similar users.

Content-Based Filtering: An approach to provide recommendations based on the individual's preference.

Data Latency: An experienced time delay when a system or an agent sends data to a receiver.

Nearest-Neighbor Algorithm: An algorithm that determines and ranks the distance between a target object and any other available object.

Profile: An organized data set of information on users or items.

Recommendation System: A system that retrieves information based on users' preferences.

Similarity Model: A set of schematic descriptions that specify the measurement standard for the degrees of being similar.

Comparative Shopping on Agent Web Sites

Ming Wang
California State University, USA

INTRODUCTION

The enormous amount of commercial information available on the Internet makes online shoppers overwhelmed and it difficult to find relevant information. The recent development of shopping agents (bots) has offered a practical solution for this information overload problem. From the customer's point of view, a shopping agent reduces search complexity, increases search efficiency, and supports user mobility. It has been proposed that the availability of agent Web sites is one of the reasons why e-markets should be more efficient (Mougayar, 1998).

Shopping bots are created with agent software that assists online shoppers by automatically gathering shopping information from the Internet. In this comparative shopping environment, shopping agents can provide the customer with comparative prices for a searched product, customer reviews of the product, and reviews of the corresponding merchants. The agent will first locate the merchants' Web sites selling the searched product. Then, the agent will collect information about the prices of the product and its features from these merchants. Once a customer selects a product with a merchant, the individual merchant Web site will process the purchase order and the delivery details. The shopping agent receives a commission on each sale made by a visitor to its site from the merchant selling the product on the Internet.

Some auction agent Web sites provide a negotiation service through intelligent agent functions. Agents will represent both buyers and sellers. Once a buyer identifies a seller, the agent can negotiate the transaction. The agents will negotiate a price and then execute the transaction for their respective owners. The buyer's agent will use a credit card account number to pay for the product. The seller's agent will accept the payment and transmit the proper instructions to deliver the item under the terms agreed upon by the agent.

BACKGROUND

The software agent with roots in problem solving and knowledge representation was not a new concept, but had not grown until the past decade when the Internet created a perfect environment for e-commerce. Dr. Pattie Maes, founder of the MIT Media Lab Software Agent Group, and other researchers have developed a number of intelligent shopping agents. Based on the customer buyer behavior (CBB) model, Maes and Guttman (1999) identified and implemented six stages of the buying process: need identification, product brokering, negotiation, purchase and delivery, product service, and evaluation. Need identification characterizes the buyer's need. Product brokering includes retrieval of product recommendations to help determine what to buy. Merchant brokering utilizes merchant ratings to help determine whom to buy from. Negotiation considers how to settle on the terms of transactions. Purchase and delivery signal termination of the transaction process. Product service and evaluation involve post-purchase services and evaluation of satisfaction with the overall buying experience and the decision.

Shopping agent technology has been accepted by a large number of e-commerce practitioners in recent years. The popular shopping bots are bestWebBuys, bizRate, dealTime, kelkoo, mySimon, nextTag, and priceGrabber. A 2002 report from bizRate.com found that 77% of U.S. online shoppers said that they use comparison shopping bots when shopping online (Laudon & Traver, 2003). More and more merchants have subscribed to agent Web sites to attract online shoppers. The number of listed member merchants has increased exponentially. PriceGrabber, which added software agents and raised the standard for online shoppers' comparison Web sites on November 8, 1999, had 1,050 subscribed merchants by the end of October 2003 and 5,925 subscribed merchants by May 2005. PriceGrabber achieved a fifth place standing in the 2004 Deloitte Technology Fast 500, a ranking of the 500 fastest growing technology companies in United States. Rankings are based on the company's percentage revenue growth over five years, from 1999-2004.

SHOPPING AGENT ESSENTIALS

Most shopping agent Web sites currently offer online shoppers three features: customer reviews of a product, competitive prices of the product, and ratings of the merchant who sells the product. These features help customers select an appropriate product within a reasonable price range and choose merchants they can trust and feel comfortable shopping with.

Issues

Product Reviews

The product reviews on an agent Web site are contributed by customers shopping on the agent Web site. The product review system is able to provide a large volume of product reviews. Avery, Resnick, and Zeckhauser (1999) studied the potential of a market for evaluations and indicated that personal experience with products is enormously powerful in forming the customers' decisions.

Behavioral research suggests that consumers view recommendations of unfamiliar products negatively (Park & Lessig, 1981). Ganesh and Amit (2003) focused their research on how product review systems affect customer preferences of unfamiliar products since recommendations of unfamiliar products represent an important new source of business. The result demonstrates that positive contextual recommendations based on a customer's prior purchase interest do not always produce positive effects on the sale of new products. Contextual recommendations may be beneficial when they are known to be attractive to the customer and are likely to be perceived as similar to the target item. The context can be provided in a manner that makes it salient when customers first encounter the unfamiliar recommendations. Conversely, new recommendations should be presented when little is known about the shopper and when familiar recommendations are likely to be perceived as different from the unfamiliar recommendations. It is important that designers of shopping agent Web sites create contexts judiciously and offer tentative guidelines for product review systems.

Competitive Price

Internet technology has increased price transparency of a product. Online customers are likely to compare prices to other Web sites and traditional stores. Most shopping agents claim to eliminate search necessary to identify the right product at the best price offered by each of the merchants. They take a query, visit their member e-tail stores that may have the product sought, bring back the results, and present them in a consolidated and compact format that allows for comparative shopping at a glance. The impact of this comparative price system lowers the search cost not only for consumers, but also for merchants who wish to find out what prices their rivals are charging. This makes it more difficult for merchants to undercut each other secretly (Vulkan, 1999).

Merchant Reputation Ratings

In addition to obtaining competitive prices and product recommendations, many shopping bots have developed systems to keep track of merchant reputation ratings as well as service quality, simply because consumers want to know that the merchant with whom they are transacting an order is reliable, will deliver the product as specified in the delivery schedule, will maintain confidentiality, and will have appropriate product packaging and handling arrangements. So far, the merchant reputation system is best known as a technology for building trust and encouraging trustworthiness in e-commerce transactions by taking past behavior as a publicly available predictor of likely future behavior (Dellarocas, 2003).

Resnick, Zeckhauser, Friedman, and Kuwabara (2000) have defined a reputation system as one which collects, distributes, and aggregates feedback about merchants' past behavior. Though few producers or consumers of the ratings know one another, these systems help people decide who to trust and also encourage trustworthy behavior. The merchant reputation has significant impact on customers' trust and on their intentions towards adopting e-services (Ruyter, Wetzels, & Kleijnen, 2001). In February 2003, Jeff Bezos, the CEO of Amazon.com, decided to cancel all plans for any television or general print advertising because he believed that his company was better served by word-of-mouth generated through the Internet than by paid advertising.

Problems

Despite its undeniable importance and widespread adoption of agent technology, the current shopping agent Web sites still encounter problems: fraud risk management, rating consistency, and biased rating. These problems are discussed in the following section.

Fraud Risk Management

Key facets of the usefulness and successful adoption of emerging reputation systems are their accuracy, consistency, and reliability. A group of academic scholars conducted research on the risk management of merchant reputation systems. Kollock (1999) states that online rating systems have emerged as an important risk management mechanism in the e-commerce community. Dellarocas (2000) identified several scenarios ("ballot stuffing," "badmouthing," positive seller discrimination, negative seller discrimination, and unfair ratings "flooding") in which buyers and sellers can attempt to "rig" an online rating to their advantage. One party could blackmail another by threatening to post negative feedback unrelated to actual performance. Friedman and Resnick (1998) discuss risks related to the ease with which online community participants can change their identity. They conclude that the assignment of a lowest possible reputation value to newcomers of agent Web sites is an effective mechanism that discourages participants from misbehaving and, subsequently, changing their identity.

Some important management mechanisms have been developed. Most agent Web sites have developed countermeasures to counteract the above potential threats in various ways. Some have created registration systems to restrict online evaluation writers only to its member customers. Member customers have to log on to their accounts before they evaluate their merchants. Some agents have claimed that they are able to detect and eliminate fraudulent ratings by using a combination of sophisticated mathematical algorithms and a large number of reviews from a variety of sources that have been checked for consistency.

Rating Consistency

As an increasing number of online reputation systems become available in the shopping agent Web sites, one customer may be exposed to multiple online merchant reputation systems for the same merchant. Since different reputation systems may provide different ratings for the same merchant, customers may get confused. Thus, questions are raised on the consistency of the ratings provided by different reputation systems. It is crucial for online customers to get to know the reliability ratings of merchant service quality from merchant reputation systems before they make a purchase decision. Consistent ratings are able to provide more reliable evaluations of a merchant. Wang and Christopher (2003) conducted an empirical study on the rating consistency of reputation systems using three sets of data collected online from two popular merchant reputation systems. The results of the study showed that individual customer ratings are not consistent for the same set of merchants across reputation systems. However, the averaged customer ratings are consistent on the same merchant across different merchant reputation systems. The averaged customer ratings on different occasions in the same reputation system are consistent, too.

The solution to the rating discrepancy problem across different reputation systems is to develop a new agent Web site listing the averaged rating for each merchant on different reputation systems as a comparison-at-a-glance reference resource for customers.

Biased Rating

Customers with exceptionally positive or negative views of merchants are more likely to respond than the general customer population. The implication is that those customers who wrote an online comment are strongly opinionated. This results in a biased response that would be more likely to identify current quality problems than a controlled survey of equal sample size. The customers who remained neutral might not be motivated to rate the online store. People may not bother to provide feedback at all, since there is little incentive to spend another few minutes filling out the form. Most people do it because of their gratitude or their desire to take revenge. Some people do it because some reputation systems reward them. Further research needs to be done on the portion of customers who did not choose to either express or share their post-shopping satisfaction.

Table 1 presents a frequency distribution of 106 overall star ratings classified by customers' post-shopping satisfaction level. This exhibit lists the frequency of occurrence of each classification of rate. The total number of given ratings was 106. The percent of the total was computed by dividing the number in each level by the total number of ratings.

Table 1. Overall rating classified by satisfaction level

Level of Satisfaction (Overall Rating)	Number of Overall Rates at Satisfaction Level	Percent of Total
Very Satisfied	53	50.0
Somewhat Satisfied	9	8.5
Neutral	0	0.0
Somewhat Dissatisfied	3	2.8
Very Dissatisfied	41	38.7
Total Reviews	106	100.0

FUTURE TRENDS

Future agents could automatically build models of shoppers, recommend products to shoppers, and negotiate on behalf of shoppers through the development of intelligent agent functions. These intelligent agent functions take the concept of the shopping agent beyond that of a purpose-built search engine. The future agents will reside on individual computers, create personal accounts for the owners, learn about their owners' shopping preferences, create a personalized "virtual store," and perform more efficient inquiries and purchases in subsequent requests.

Much of the relationship between merchants and customers in the future may be conducted via handheld mobile devices such as palm computers and cellular phones. PDAs already are combined with mobile phones from which users can log on to the Internet. Mobile agents are well suited for e-commerce, since a commercial transaction may require real-time access to remote resources. Lang and Oshima (1999) specified seven main benefits for using mobile agents. They reduce the network load, overcome network latency, encapsulate protocols, execute processes asynchronously and automatically, react autonomously to changes, provide optimal conditions for seamless system integration, and are robust and fault tolerant. Therefore, the design and development of the future mobile shopping bots should suit the need of m-commerce.

CONCLUSION

Shopping bots represent the newest trend in e-marketing technology and have been accepted by a large number of e-merchants and online shoppers. Recent research has shown that consumers prefer to shop and buy on the Internet for three major reasons—convenience, time savings, and comparative shopping (Oz, 2002). Shopping bots provide online customers with an informative, convenient, and comparative shopping environment. The development of agent technology makes it possible for online shoppers to search hundreds to thousands of merchants' stores from a single Web site efficiently. The shopping agent Web site is built with customers' shopping experience and comments. The comments on products and merchants from previous customers are a valuable asset to other prospective customers. Customers who have finished shopping with merchants listed on the agent Web sites are invited to post product reviews and merchant evaluations. In response, the agent Web site will display them online.

Merchants can benefit from shopping bots as well. Merchants can receive feedback in the form of online evaluations from customers posted on merchant reputation systems. Positive evaluations will draw more customers to the evaluated merchants. Negative evaluations will help them to learn lessons and to improve their service quality. Member merchants who have registered on a shopping agent Web site can receive the shopping agent's market report. The report provides brands, price trends, market share, and customer buying habit information based on real-time data from the database that monitors actively traded products.

KEY TERMS

Comparative Shopping Environment: Offers three features: customer reviews of a product, competitive prices of the product, and ratings of the merchant who sells the product. These features help customers select an appropriate product within a reasonable price range, and choose merchants they can trust and feel comfortable shopping with.

E-Marketing: Achieving marketing objectives through use of electronic communications technology.

Merchant Reputation System: A system that collects, distributes, and aggregates feedback about merchants' past behavior from customers. Though few consumers of the ratings know one another, these systems help people decide whom to trust and also encourage trustworthy behavior.

Mobile Commerce (M-Commerce): Electronic transactions and communications conducted using mobile devices such as laptops, PDAs, and mobile phones, and typically with a wireless connection.

PDA (Personal Digital Assistant): A small handheld wireless computer.

Shopping Bots: Also called shopping agents; programs that search the Web and find items for sale that meet a buyer's specifications. These shopping bots take a query from an online customer, search online stores, and then report back on the availability and pricing range in a consolidated and compact format that allows comparison shopping at a glance. Not only do these shopping bots bring comparative product and price information from individual merchants' Web sites, but they also provide the online merchants' ratings.

Software Agents: Software programs that assist humans by automatically gathering information from the Internet or exchanging data with other agents based on the query provided by users.

Comparison–Shopping Agents and Online Small Business

Yun Wan
University of Houston, Victoria, USA

BACKGROUND OF SMALL BUSINESS

Since the commercialization of the Internet in the 1990s, online retailing has increased steadily. According to the most recent Department of Commerce Census Bureau report,[1] retail e-commerce sales in the first quarter of 2004 were $15.5 billion, up 28.1% from the first quarter of 2003. E-commerce sales in the first quarter of 2004 accounted for 1.9% of total sales, compared with 1.6% of total sales for the first quarter of 2003.

An important trend in this growth in B2C (business-to-consumer) e-commerce is the participation of small business on the Web. Considering that in the United States small business comprises more than 99% of employer firms,[2] this trend is significant.

Though the Web offers huge potential to these small businesses for growth and prosperity, and also offers them a very low entry cost, Web visibility becomes the major barrier for them. Small businesses often have difficulty putting up enough funding to compete with brand-name businesses in promotion. So small businesses are desperately in need of a less costly channel for increasing their Web visibility.

In the past 4 years and especially since the economic slowdown in 2000, comparison shopping has become more and more popular among online shoppers. Because of the low cost of being listed on comparison-shopping Web sites and the relatively high conversion rate for online shoppers who use comparison shopping, many small businesses found this an ideal channel to increase their Web visibility. As a result, many early participating small businesses gained a customer base in the competition by displaying their products and service prices on comparison-shopping Web sites.

Now, it is more and more clear that comparison shopping provides a unique opportunity for small businesses to reach a large customer population with relatively little cost. To help readers better understand this phenomenon, we give a comprehensive introduction to comparison-shopping agents and summarize recent research on their impact in e-commerce.

DESCRIPTION OF COMPARISON-SHOPPING AGENTS

Definition

Comparison-shopping agents, also called shopbots, are those Web-based intelligent agents that can collect product and service information, especially price-related information, from multiple online vendors, aggregate them, and then provide value-added service to online shoppers to assist their online shopping.

Comparison-shopping agents are information intermediaries. They play the role of information brokers in the information supply chain that connects online vendors to consumers on the Web (Etzioni, 1997; Haubl & Trifts, 2000). Comparison-shopping agents are intelligent software applications (Wooldridge & Jennings, 1995; Wooldridge, Müller, & Tambe, 1996). There is a general three-tier design for these agents (Kushmerick, Weld, & Doorenbos, 1997). Based on the information they provide, comparison-shopping agents can be classified into three categories: differentiation agents, evaluation agents, and preference-identification agents (Wan, Menon, & Ramaprasad, 2003).

Technical Review

The efficiency and effectiveness of comparison-shopping agents are mainly determined by their technical rationality, which is manifested through two aspects: their ability to extract and aggregate information from heterogeneous data sources (online vendors), and their ability to provide appropriate information and information-processing support to consumers. These two aspects are implemented in their three-tier design as described below.

Data-Retrieval Tier

The data-retrieval tier is responsible for collecting data from external heterogeneous data sources on the Web or proprietary partner network.[3] Because the data format of the information the comparison-shopping agents retrieve is HTML (hypertext markup language), which is a semistructured language, we have to employ a "wrapper" technology (also called "screen scraping" in the popular press) to retrieve data and transform it from an incompatible data format into a format that can be understood by the agent (Adelberg, 1998; Ashish & Knoblock, 1997; Firat, Madnick, & Siegel, 2000; Kushmerick et al., 1997; Madnick, 1999). XML (extensible markup language) and other more structured solutions may transform the design of this tier in the near future (Rosenthal, Seligman, & Costello, 1999).

Information-Processing Tier

The information-processing tier, the heart of the agent, performs three major tasks: filtering the data retrieved, categorizing them, and indexing them.

This tier is needed to make the data format consistent. For example, to compare price information for the same book from two vendors in two countries, we have to convert one country's currency into the other's by using the current exchange rate (Zhu, Siegel, & Madnick, 2001). Sometimes, certain products may be queried repeatedly, so a cache database could be utilized to store the most frequently requested information for fast retrieval. The categorization of information is important because it is also an indexing process and makes the retrieval of records more efficient.

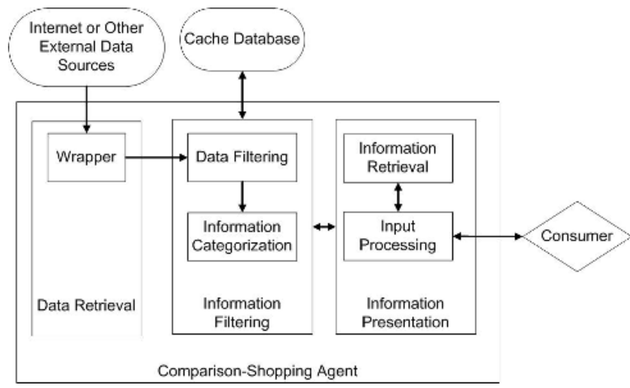
Information-Presentation Tier

The information-presentation tier is the interface between consumers and the agent. It provides the interaction interface for consumers and translates the consumer's input into a query for internal processing.

This tier is able to present the information in a customer-friendly format that will assist consumers in the product-comparison process. There are two core functioning parts in this tier: the information-retrieval part and the input-processing part. The information-retrieval part is responsible for processing the consumer query and getting it back to the consumer; the input-processing part will collect the consumer input and translate it into a query to the information-retrieval part.

Figure 1 is a demonstration of the internal structure of a comparison-shopping agent with the three tiers we described above.

Figure 1. Structure of comparison-shopping agent



Historical Review

BargainFinder was the first comparison-shopping agent to catch media attention and was later widely regarded as the predecessor of the Web-based comparison-shopping agent. It could search and retrieve prices from up to nine online music stores (Krulwich, 1996).

BargainFinder was developed by Andersen Consulting's research lab and Smart store to measure the market reaction to comparison. It was implemented via the wrapper technique (Doorenbos, Etzioni, & Weld, 1997; Krulwich, 1996).

Pricewatch.com, a contemporary of BargainFinder though it received almost no media attention, was one of the first commercial comparison-shopping agents that could retrieve computer-product pricing information from hundreds of small online vendors. Compared with the short presence of BargainFinder, Pricewatch.com has grown steadily through the years and has become one of the major comparison-shopping portals.

From 1996 to 1998, several innovative comparison-shopping agents like Jango, Junglee, and CompareNet emerged. However, soon almost all of them were acquired by already-established portals. For example, Jango, based on the prototype of ShopBot designed by three researchers at Washington State University (Doorenbos et al., 1997), was acquired by Excite for $35 million in October 1997. Others were acquired in like manner: Junglee by Amazon in 1998, CompareNet by Microsoft in 1999, and mySimon.com by CNET in 2000. Only a few remained independent; Pricescan.com was among them (Anonymous, 1998) and it survives through the revenue generated from advertisement on its Web site.

Comparison shopping came into mainstream B2C business in 2000 with the emergence of new agents like Dealtime.com or the now Shopping.com.[4]

From 2000 to 2004, intensive marketing, and frequent merging and acquisition by their peers characterize comparison-shopping agents. Dealtime.com was among the first group of comparison-shopping agents to use intensive marketing efforts to build the concepts of comparison shopping in consumers (White, 2000). It also acquired resellerratings.com, an evaluation agent, in February 2003, and epinion.com, a preference-identification agent, in March 2003 to increase its service coverage. In Europe, Kelkoo engaged in multiple mergers with other small comparison-shopping agents to become Europe's largest e-commerce Web site after Amazon and eBay, and the largest e-commerce advertising platform both in the United Kingdom and Europe.

Meanwhile, the comparison-shopping population had risen from less than 4% (Baumohl, 2000) of online shoppers before 2000 to 15% in 2003.[5] And popular comparison-shopping portals began to rank among other established online portals. For example, Shopping.com ranked fourth (behind eBay, Amazon, and Yahoo Shopping) among U.S. multicategory e-commerce sites in November 2003 in terms of unique monthly visitors. During Mother's Day week in 2004, the number of unique visitors to comparison-shopping site mySimon.com increased 14% from 274,000 to 311,000.[6]

So, we can expect that in the near future comparison-shopping agents will gradually become a major channel for online shopping, which has significant implications for online vendors.

IMPACT OF COMPARISON-SHOPPING AGENTS ON SMALL BUSINESS

Depending on how small businesses react to the emergence of comparison-shopping agents, the impact of these agents on small business could go either direction.

On one hand, the emergence of comparison-shopping agent provides a potential channel for small online vendors to increase their Web visibility so as to compete head-to-head with brand-name online stores. As a result, we can observe significant price drops due to competition. For example, through an empirical study, Brown and Goolsbee (2000) found that the rise of comparison-shopping sites reduced average insurance prices for the group by as much as 5% in the 1990s. However, prices did not fall for insurance types that were not covered by the comparison Web sites. This study indicates that the growth of the Internet has reduced term life prices by 8 to 15% and increased consumer surplus by $115 million to $215 million per year and perhaps more. However, this trend is not consistent in other product categories. Iyer and Pazgal (2003) collected pricing data from up to seven comparison-shopping sites for homogeneous products like CDs (compact discs) and books. They found that the emergence of comparison-shopping agents did not lead to intensive pricing competition among online vendors because the purposes of participating in comparison shopping among online vendors varied. Brynjolfsson and Smith (2001) confirmed the findings: They found that online shoppers were not absolute bargain finders; many visitors to the Web site chose to buy from the brand-name stores instead of those unknown stores that offered the lowest prices. Based on their calculation, branded bookstores on average command a $1.41 price premium over unbranded retailers for each book.

Thus, the impact of comparison-shopping agents on competition between small business and brand-name portals is still not clear in terms of different product categories, which may serve as one future research direction.

On the other hand, the emergence of comparison-shopping agents puts considerable pressure on small businesses that are not participating in comparison shopping. These businesses previously may have survived with their small loyal customer base. However, when a customer is equipped with a comparison-shopping agent, he or she may easily identify a number of similar small businesses to buy from; thus, the chance of switching increases dramatically. This means small businesses have to make the decision to deal with this new environment. If they choose to participate, how to compete with other small businesses becomes critical. Through the collection of the daily price data of uVision, a comparison-shopping agent for CDs, Crowston (1997) found that most small vendors might not benefit from comparison shopping because a few vendors consistently have the lowest price for all products. Later, Crowston and MacInnes (2001) confirmed the "cheapest-for-all" phenomenon. They also found that the prices converge over time for comparison-shopping participants.

Apart from the direct impact on small business, comparison-shopping agents also have the potential of fundamentally changing the online shopping behavior of consumers, thus reshaping the landscape of the B2C electronic market. Several studies found that using comparison shopping increases the efficiency and effectiveness of decision making significantly (Alba, Lynch, Weitz, Janiszewski, Lutz, Sawyer, & Wood, 1997; Benbasat & Todd, 1996; Clark, 2000; Haubl & Trifts, 2000). So online shoppers have the incentive to use comparison-shopping agents whenever they are available.

With large numbers of small businesses participating in comparison shopping, we can expect a differentiation of the market by comparison-shopping agents. For example, pricegrabber.com has already adopted programs like having a featured merchant to place those small businesses that pay a premium price in prominent positions in the comparison list. This manipulation of comparison information could subtly change consumers' decision outcomes, as confirmed by a controlled experiment by Haubl and Murray (2003).

Thus, more investigations are needed to understand how consumers make decisions when choosing to use comparison shopping instead of going to a brand store directly, as well as how they use comparison-shopping agents in making decisions. Several new studies in this direction provide us with some preliminary results. For example, Montgomery, Hosanagar, Krishnan, and Clay (in press) found that consumers might still choose to use the brand-name store instead of the comparison-shopping agent because using a comparison-shopping agent may incur additional costs, like waiting for a response and so forth. So a better designed comparison-shopping agent is a necessity to success.

For the time being, the limitations of recent studies include the following:

- First, the scope of the product and agents they covered is highly restrained. The e-commerce field of comparison-shopping agents developed swiftly in the past 4 years. The product coverage being compared has already extended from homogeneous commodities like books and CDs to almost all categories of products one can find in any online shopping center. Coverage also extended to services like finance, tourism, and so forth. However, few research projects systematically study the impact of comparison shopping in these new areas. It is possible that the pricing behavior for book and CD vendors might be different from pricing behaviors for airline tickets (Allen & Wu, 2003).
- Second, most of the studies in this area failed to capture the dynamic nature of comparison-shopping agents, though some of them tried to develop some innovative models (Jin, Suh, & Lee, 2003). For example, a considerable number of studies make the prediction that comparison shopping may not prosper because it only provides price information. However, it took less than 2 years for almost all comparison-shopping agents to provide online vendor ratings and product quality review information. Thus, how to make a better Web-based business model that could predict the development trend of comparison shopping becomes relevant.

CONCLUSION

Comparison-shopping agents as a new technology have increasingly influenced the behavior of small business. Research in this area is still in its infancy stage. For the time being, empirical research indicates comparison shopping may not necessarily result in Cournot equilibrium (Cournot, 1838). Brand-name portals can charge a premium price because of their reputation. Small businesses are pressured to participate in this channel, and they need to compete not only in price but also in other strategies.

Relatively more research in the behavior aspects of consumers using comparison-shopping agents has been conducted. We found that comparison-shopping agents can improve decision efficiency and effectiveness in general, especially in reducing searching costs. However, we also found that comparison-shopping agents can influence the decision outcome by manipulating the format of information or overloading the consumer by providing too many choices. These findings may provide strategic aspirations for small businesses.

KEY TERMS

Comparison-Shopping Agent: A Web-based service that can collect product and service information, especially price-related information, from multiple online vendors, aggregate them, and then provide value-added service to online shoppers to assist their online shopping.

Differentiation Agent: Comparison-shopping agent specializing in collecting price-related, impersonal information, for example, Pricewatch.com.

Evaluation Agent: Comparison-shopping agent specializing in collecting product and service rating information, for example, Bizrate.com.

Intelligent Software Agent: A software agent that uses artificial intelligence (AI) in the pursuit of the goals of its clients.

Preference-Identification Agent: Comparison-shopping agent specializing in collecting personal product and service review information, for example, epinion.com.

Web Visibility: The popularity of a Web site among online shoppers.

Wrapper: An application routine that can retrieve and transform data from one format into another.

Computer Security in E-Learning

Edgar R. Weippl
Vienna University of Technology, Austria

INTRODUCTION

Although the roots of e-learning date back to 19th century's correspondence-based learning, e-learning currently receives an unprecedented impetus by the fact that industry and universities alike strive to streamline the teaching process. Just-in-time (JIT) principles have already been adopted by many corporate training programs; some even advocate the term "just-enough" to consider the specific needs of individual learners in a corporate setting.

Considering the enormous costs involved in creating and maintaining courses, it is surprising that security and dependability are not yet considered an important issue by most people involved including teachers and students. Unlike traditional security research, which has largely been driven by military requirements to enforce secrecy, in e-learning it is not the information itself that has to be protected but the way it is presented. Moreover, the privacy of communication between teachers and students.

For a long time students and faculty had few concerns about security, mainly because users in academic areas tended not to be malicious. Today, however, campus IT-security is vital. Nearly all institutions install firewalls and anti-virus software to protect campus resources. Even the most common security safeguards have drawbacks that people often fail to see. In Stanford the residential computing office selected an anti-virus program. However, the program can be set to collect data that possibly violates students' privacy expectations; therefore many students declined using it (Herbert, 2004).

Whenever servers that store personal data are not well protected, they are a tempting target for hackers. Social security numbers and credit card information are valuable assets used in identity theft. Such attacks were successful, for instance, at the University of Colorado (Crecente, 2004). A similar incident happened at the University of Texas; the student who committed the crime was later indicted in hacking (Associated Press, 2004).

The etymological roots of *secure* can be found in *se* which means "without", or "apart from", and *cura*, that is, "to care for", or "to be concerned about" (Landwehr, 2001). Consequently, *secure* in our context means that in a secure teaching environment users need not be concerned about threats specific to e-learning platforms and to electronic communication in general. A secure learning platform should incorporate all aspects of security and dependability and make most technical details transparent to the teacher and student. However, rendering a system "totally secure" is too ambitious a goal since no system can ever be totally secure and still remain usable at the same time. The contribution of this chapter is to

- Define and identify relevant security and dependability issues.
- Provide an overview of assets, threats, risks, and counter measures that are relevant to e-learning.
- Point to publications that address the issues in greater detail.

BACKGROUND

While there a many definitions of the primary requirements of *security*, we will start with the classical *CIA requirements*. CIA is the acronym for confidentiality, integrity, and availability. All other requirements can be traced back to these three basic properties. Confidentiality is defined (Avizienis, Laprie, Randell, & Landwehr, 2004) as *the absence of unauthorized disclosure of information*, integrity as *the absence of improper system alterations* and availability as *readiness for correct service*.

Dependability is a broader concept that encompasses all primary aspects of security save confidentiality:

- Availability
- Reliability refers to the continuity of correct service
- Safety is defined as the absence of catastrophic consequences on the user(s) and the environment
- Integrity
- Maintainability is the ability to undergo modifications and repairs

For many universities e-learning systems have become production critical assets. It is therefore essential that all of the aforementioned generic requirements are evaluated during a process of risk assessment. The first step in such a process is to understand security and dependability as enabling technology. Only when systems work reliably will users trust and use them.

The obvious ultimate goal of an assessment is to implement cost-effective controls to avoid faults. Looking at all possible threats of a given application and subsequently mitigating the most important ones is a process that is called *threat modeling* (Swiderski & Snyder, 2004). The first step is to *decompose* the application and to determine how data is processed. This can best be done by creating data flow diagrams (Baskerville, 1993).

The second step is to *enumerate all threats*. There are eight dimensions along which faults can be categorized (Avizienis et al., 2004). Even though it is not required to categorize threats in this stage the eight dimensions are helpful to cover many different aspects and to avoid forgetting some.

1. **Phase of Creation:** Development faults vs. operational faults
2. **System Boundaries:** Internal faults vs. external faults
3. **Phenomenological Cause:** Natural faults vs. human-made faults
4. **Dimension:** Hardware faults vs. software faults
5. **Objective:** Malicious faults vs. non-malicious faults
6. **Intent:** Deliberate faults vs. non-deliberate faults
7. **Capability:** Accidental faults vs. incompetence faults
8. **Persistence:** Permanent faults vs. transient faults

The third step is to *rank the threats* according to the probability and potential damage. The forth and final step is planning and implementing *mitigation strategies* (Swiderski & Snyder, 2004).

RELEVANCE TO E-LEARNING

In this section we will first look at all requirements and highlight typical threats that are relevant in the context of e-learning. The final subsection highlights solutions and points to publications that address specific areas in greater detail.

Requirements

Availability

Attacks by insiders on servers delivering e-learning content are not as likely as on servers used for examinations. Students are in general interested in learning and will thus have little incentive to actively attack the system; non-malicious faults, however, might still occur. Obviously this does not mean that students will never attack an e-learning system used for studying, but examination systems are certainly more attractive targets. During learning, availability is not as important as, for instance, during online exams. A downtime of a few hours is acceptable for content servers but clearly not for exam servers.

For exams, the threat profile is different because students are likely to attack the system once they realize they might fail the exam. If they could crash the server their exams cannot be graded and they will have a second chance. Even if students cannot crash the server they might try to attack the availability of the local PC they use during the exam. Briefly unplugging it will cause a reboot and give them a good excuse for not being graded.

Reliability

When exams or assignments are graded automatically reliability is important; while multiple choice questions can be evaluated easily, reliability is more difficult to address the more sophisticated the evaluation algorithm is.

Keyword-based grading of free text answers will generally work well for technical exams that require precise answers but not for subjects with long and very free answers such as studies of literature.

Safety

In most cases there will be very little safety considerations required when introducing e-learning programs unless the subject taught is inherently critical. For instance, wrong instruction on how to operate certain machinery will in consequence create safety hazards once people operate the machinery.

Confidentiality

In many cases confidentiality is not a major requirement when creating e-learning content. The knowledge taught is generally widely available in text books. It is the way the content is presented and the effort of creating simulations and other interactive learning environments that are worth protecting.

For exams and assessments, confidentiality, however, is essential. Exam questions need to be kept secret until the exams commences; the correct answers need to be concealed until the exams are handed in.

Even if learning content contains few secrets, there are still elements that require protection against unauthorized read access. Discussion boards and forums are commonly used not only to discuss organizational issues but also course content. When controversial topics—such as pro-life vs. pro-choice—are discussed students' privacy needs to be protected.

Integrity

Data integrity is one of the most important requirements. During the learning process content should not be modified by unauthorized people as minor modifications might be difficult detect. For exams the integrity of questions, students' answers and correct answers clearly needs to be protected—before, during, and after the exam.

Secondary security attributes such as non-repudiation require system and data integrity. Non-repudiation refers to the fact that users cannot plausibly deny having performed an operation. For instance, students should not be able to deny having handed-in an exam.

Maintainability

As e-learning systems become part of the critical infrastructure maintainability is important. Not only needs the system to be maintained but also exit scenarios are required. Once a lot of e-learning content has been created it is too late to evaluate whether a migration can be made to another platform. It makes little difference whether a commercial or an open-source e-learning platform is used, one has to carefully plan how content can be extracted and migrated to another platform. Even if both the new and the old platform support e-learning standards such as SCORM a migration is not necessarily easy.

Human-Made Faults

Since the majority of system faults are human-made it is necessary to distinguish them further. Human-made faults are either *non-malicious* or *malicious*. All malicious faults or obviously deliberate.

Non-malicious faults can be either caused by mistakes (*non-deliberate*) or by bad decisions (*deliberate*). Non-deliberate mistakes can occur because of accidents or incompetence. Deliberate faults can also be traced back either to accidents or incompetence (Avizienis et al., 2004).

Solutions and Related Publications

Being aware that security and dependability are relevant is the first important step. However, all the mentioned issues need to be addressed in detail. In this section we will point to related publications that touch all of these issues in the context of e-learning. Since Web-based e-learning applications all run on a server, we assume that security measures typical for any server maintenance are implemented. This includes software updates and installing patches, data backups, and redundant hardware.

Security Risk Analysis

Weippl (2005b) provides a first introduction to a security risk analysis for e-learning. Similarly, (Weippl, 2001c) argues why security is an enabling technology in the move to m-commerce. With the rise of m-learning the rationale for improving security for mobile devices is important for e-learning as well. Even though e-learning may in many aspects be seen as just another form of e-commerce there are special requirements regarding security. In (Weippl, 2005a) the requirements specific to e- and m-learning are elaborated in detail.

Privacy

In Weippl and Essmayr (2003) an improved model to manage security and privacy of personal data on mobile devices is presented. The main idea is to keep data separated in different compartments and only allow a limited number of system functions to transfer data between these compartments. Threats to students' privacy when using e-learning applications are analyzed in Weippl and Tjoa (2005).

Mobile Security

As mobile devices are being widely used by students and faculty, they can also be used as authentication tokens. In Weippl, Essmayr, Gruber, Stockner, and Trenker (2002) a concept for mobile authentication is proposed that allows personal devices with wireless connectivity to identify and authenticate their owners to other services.

Database Security

With the proliferation of PCs in all departments of universities, local databases are used by numerous staff and faculty to manage students, courses, registrations, etc. It may seem very inefficient to store data multiple times and disregard integrity.

However, unlike tightly controlled companies, universities should enable and even promote decentralized and heterogeneous environments, even for organizational processes. Nonetheless, central administration, registrar's offices, etc., require some information on students' activities (e.g., which courses a student really attends).

When integrating databases, it is advantageous if administrators of existing databases are not required to change the schema of their local database. As owners of databases (i.e., individual lecturers, professors, etc.) are most probably not willing to give up their autonomy, they want to have control over who has access to which information in their database (Weippl, 2003a).

Database agents (Weippl et al., 2003) can be used to solve this problem (i.e., to integrate heterogeneous databases). Agents are especially well suited to address the issue of security which is even more relevant in distributed environments. While migrating, DB agents are wrapped into Java agents that take care of many issues regarding security and migration.

Role-Based Access Control

Role-based access control (RBAC) is a widely used in database systems. In programming environments, however, RBAC and other access control models are often not well supported. Application programmers regularly have to implement the controls from scratch. The GAMMA framework allows programmers to specify arbitrary access control policies in XML. Programmers only need to derive their classes from specific base classes to automatically protect access to restricted method calls.

Weippl (2001a) proposes to wrap content in cryptographic containers and use RBAC mechanisms to permit or deny operations such as reading, printing, modifying, or distributing content. Weippl (2001b) goes into detail and shows an architecture to securely distribute course content and enforce access control even when distributing content over the Internet.

If different systems are integrated as described in Weippl et al. (2003) it is essential to provide a way of mapping identities and roles of one system to another system. The challenge is to correctly map groups and roles into (legacy) systems that do not support such mechanisms and vice versa. To minimize user errors when setting up access rights, mandatory access control mechanisms can be used. In Weippl (2005a) a security model for e-learning is introduced to model a MAC approach in an RBAC environment—similar to Osborn et al. (2000).

Availability

When delivering e-learning content for asynchronous studying, availability is not as important as during real-time interaction (i.e., chats, broadcast sessions, online exams, etc.).

To avoid frustrated users, downtime of self study section should obviously not be too high. Nonetheless, by clearly communicating how long a site might be unavailable user will usually accept this without problems. For periods with real-time communication, other channels of communication should be provided as a backup. By giving students, for instance, a telephone number to call when they experience problems during a chat or broadcast session user acceptance can be greatly increased.

Backups are essential to ensure availability of data after system failures. While backups are a routine task of server maintenance there are some specific requirements in the context of e-learning. Typically an entire server is backed up and monthly backups are archived for quite some time. For effective learning, however, privacy of personal communication in e-learning platforms can be essential (Weippl & Tjoa, 2005). Backups and log files are threats to the individual learner's privacy. By clearly stating the privacy preferences of a system, users know how personal data is used and for how long it is archived; they can thus decide what information to post on the platform and when to use other means of communication.

FUTURE TRENDS

Recently, security in the context of learning and teaching receives more attention. In most cases security of campus networks is improved to protect personal information of students and faculty and to discourage copyright infringements through P2P file sharing.

Moreover, Moodle, a major open-source e-learning platform, recently launched a security initiative[1] that makes systematic code reviews to improve code security. Increasingly, researchers and practitioners attend tutorials on security in e-learning.[2] The author of the chapter anticipates that within the next few years security considerations will be essential when decisions about implementing e-learning programs will be made.

CONCLUSION

During the last few years, e-learning systems became widely-used system not only to support distance learning but also to supplement and improve presence teaching. Increasingly, users and administrators become aware that large e-learning systems need be secured and dependability is an issue. Many requirements are similar to those of other Web-based services; however, privacy and freedom of academic research and teaching also requires new approaches. Content authors want to protect their e-learning content from copyright infringements, while teachers need to protect systems from students who may undermine their evaluation system by cheating. Students should not be too closely monitored by their teachers when using e-learning software. Since these intertwined requirements are not met by existing systems, new approaches are needed; this article provides many references for interested readers to follow. The book *Security in E-Learning* (Weippl, 2005c) contains many more details.

KEY TERMS[4]

Dependability: Is a broader concept that includes availability, reliability, safety, integrity, and maintainability but not confidentiality. A system is *available* if it is ready to perform a service. It is *reliable* if it continues providing a correct service. *Safety* refers to the absence of catastrophic consequences for users and the environment. A system's *integrity* guarantees no unauthorized modifications. When systems can be modified and repaired easily they are *maintainable*. *Confidentiality* means that information is not disclosed to unauthorized subjects.

E-Learning: Dating back to the hype of the term e-commerce, e-learning is widely used in different ways; for instance, E-Learners Glossary[3] defines e-learning as any form of learning that utilizes a network for delivery, interaction, or facilitation. E-learning covers a wide set of applications and processes, such as Web-based learning, computer-based learning, virtual classrooms, and digital collaboration. It includes the delivery of content via Internet, intranet or extranet, audio- and videotape, satellite broadcast, interactive TV, and CD-ROM. The "e" in e-learning stands for electronic and thus all forms of learning that involve electronic components should be considered to be e-learning in the broadest sense; obviously e-commerce mainly refers to commerce conducted via electronic networks, and e-learning therefore has strong ties with communication networks. Because computers no longer exist without networks, however, these stand-alone learning applications will eventually cease to exist. For instance, today, even the simplest CD-ROM courses contain links to the Web. Trainings can either be *self-based* or *instructor-led* (ILT). E-learning is *computer-based* (CBT) if a computer is used. If the computer is connected to the Internet and a Web browser is used to access the e-learning platform, it is considered to be *Web-based* (WBT).

Exploit: An exploit is a program that uses a vulnerability to attack the system's security mechanisms. Exploits usually compromise secrecy, integrity or availability and often lead to elevation of privilege.

Risk: A risk is the relative likelihood that a bad thing will happen (Schneier, 2003). In other words, risk is defined as the probability that a vulnerability is exploited and results in a damage.

Security: Encompasses the primary aspects of availability, integrity, and confidentiality.

Threat: A threat is a bad thing that can happen (Schneier, 2003), such as a server being stolen.

Vulnerability: A vulnerability is system's weakness or error that might allow to penetrate the security barriers.

Consumer Trust in E-Commerce

Benoit Jeanson
University of Sherbrooke, Canada

John Ingham
University of Sherbrooke, Canada

INTRODUCTION

The lack of trust toward different elements of e-commerce has been recognized as one of the main causes of the collapse of a large number of dot-com companies. The concept of consumer trust has since been the object of many studies in the field of e-commerce. These studies permitted a better understanding of the role of trust in e-commerce, but an examination of the literature reveals that our understanding is limited due to important gaps in the ontological aspects of the trust concept, among which are (a) a lack of consensus concerning its definition, (b) a unidimensional as opposed to a multidimensional conceptualization of the construct, and (c) a confusion between trustworthiness and trust. The goal of this article is to identify these gaps and present ways of reducing their size and impacts.

BACKGROUND

In spite of the youth of this knowledge field, a review of the literature on trust in e-commerce is interesting because of its richness, probably because of the interest raised by trust in the e-commerce scientific community as well as in others. The background of consumer trust is looked through the definition, the dimensionality, and the conceptualization given to the concept in research.

Definition

Trust was traditionally difficult to define (Rousseau, Sitkin, Burt, & Camerer, 1998), particularly because of its many different meanings (McKnight & Chervany, 2001a). For this reason, and in spite of many significant efforts in research, there is not yet a universally accepted definition of trust (Chen & Dillon, 2003) and the state of the definitions of trust belongs to what Lewis and Weigert (1985) call a "conceptual confusion."

In the field of e-commerce, definitions of trust abound and are mostly borrowed from the fields of marketing and information systems. In turn, these fields draw their definitions from disciplines such as psychology, sociology, and economics, thus leading to contradictory conceptualizations harming research that is carried out (Bhattacherjee, 2002; Gefen, Karahanna, & Straub, 2003a). Moreover, according to Bigley and Pearce (1998), efforts made to propose a consensual definition of trust led to even more meaningless and diverse conceptualizations of trust with little empirical utility.

Each discipline identifies many different factors influencing the level of trust and produces its own concepts, definitions, and results. The definitions are adapted to their context, and each discipline has its own paradigm that enables it to understand certain things and that also acts like blinkers in certain circumstances (Rousseau et al., 1998). Thus, psychologists define trust as a propensity to trust, sociologists and economists broadly define it as a characteristic of the institutional environment or as a calculus-based evaluation, and social psychologists define it as reasoning in connection with another party. This proliferation of types of trust encouraged several researchers to develop composite definitions of trust (Doney & Cannon, 1997; Mayer, Davis, & Schoorman, 1995; McKnight & Chervany, 2001a, 2001b; McKnight, Choudhury, & Kacmar, 2002a; Rousseau et al., 1998).

Dimensionality

Trust is studied by several disciplines because it is a phenomenon of which nature is cognitive (reasoning), emotional (affect), and conative (tendencies) (Lewis & Weigert, 1985). It is a multidimensional phenomenon, it is related to the idiosyncratic perception of risk, and it is dependent on the context of the individuals and the implied objects. Moreover, the construction of trust is a dynamic process including several stages (Shapiro, Sheppard, & Cheraskin, 1992). On this subject, Lewicki, McAllister, and Bies (1998) say that trust is a multifaceted, changing concept, with few of its interrelationships being static and its dynamics being modified with the passage of time. Consequently, the understanding of trust is only partial and, as sociologist Uslaner (2002) states, it is in fact to the social reports what chicken soup is to influenza: It has positive effects, but the reasons for this are enigmatic.

As a result, trust is considered to be a complex phenomenon. The situation is not different in an e-commerce context, and that makes its study as much complex. This is why it is difficult for the study of trust in e-commerce to hold account of all the aspects of this complex phenomenon. Papadopoulou, Andreou, Kanellis, and Markatos (2001) add that because of this complexity and owing to the fact that research on trust in e-commerce is recent, trust is studied from various points of view and on different levels of analysis, which contributes only partially and in a fragmented way to our understanding and makes it thus difficult to apprehend its extent and its complexity. Moreover, this difficulty of apprehension makes its definition (Hosmer, 1995; Rousseau et al., 1998) and conceptualization (Gefen, Karahanna, et al., 2003a) problematic.

Because of this complexity, there is an important tendency in e-commerce research to treat trust as being unidimensional (Gefen, Rao, & Tractinsky, 2003; Papadopoulou et al., 2001). A result of this is, first, that the notion of process is often evacuated from the creation of trust and, second, that its study often leaves the experiential nature of trust beside to lean only on initial trust and institutional credibility. Another consequence is that the studies often present a reductionistic view of trust because of the fragmented vision they offer of it and of its antecedents, and because of the lack of consideration they have for the dynamics of trust building.

Conceptualization

There is an important problem of conceptualization concerning trust and trustworthiness in e-commerce. Trustworthiness is clearly a factor of trust (Lee & Turban, 2001), but there is often confusion between the two (Corritore, Kracher, & Wiedenbeck, 2003; Einwiller, 2003; Gefen, Rao, et al., 2003; Lee & Turban; March & Dibben, 2003; Mayer et al., 1995). Mayer et al. formulate the difference between the two in indicating that trustworthiness is a characteristic attributed by the truster to the trustee, based upon extrinsic cues about the trustee, whereas trust is referred to as an attitude of the truster toward the trustee, based upon how the truster perceives the trustworthiness of the trustee. This distinction between trust and trustworthiness is related with the theory of planned behavior (Azjen, 2001) that differentiates between attitudes and beliefs as different factors of a person's intention to perform a certain behavior.

Only a limited number of the numerous models of trust proposed in e-commerce research clearly establish the distinction between trust and trustworthiness (among those is Lee and Turban's model, 2001). As Gefen, Rao, et al. (2003) and Mayer et al. (1995) underline, this problem of conceptualization is reflected in the confusion that often exists with regard to the two parties involved in the transaction, that is, the truster and the trustee. This creates difficulty with the recognition of the parties involved in the relation. But since trust and trustworthiness are two different concepts and the antecedents and consequences of trust are indeed not the same as those of trustworthiness, to confuse both inevitably leads to problems of modeling and of between-model comparison if their conceptualizations are different. If there is confusion between the two concepts or if both are depicted as being one, the logic behind the relations in the models is disturbed and the models lose both their comparability and credibility.

ONTOLOGICAL ASPECTS OF E-TRUST

As discussed earlier, the fact that the studies concerning e-trust are carried out and influenced by many disciplines and fields does not have only positive effects. Indeed, the review of ontological aspects of e-trust presented in Table 1, which shows the definitions, the dimensionality, and the conceptualization given to consumer trust in e-commerce in selected studies realized and published since the year 2000, reveals that there are also negative effects.

Definition

As reported in Table 1, 32 different definitions of trust were found among the 24 identified e-commerce papers, each comprising at least 1 definition of the trust concept. Most definitions are contextual and seem adapted to the papers' goals. Furthermore, they come either from marketing or IS, or directly from other reference disciplines. As can been seen in Table 1 as well, most definitions differ in their level of completeness, bringing difficulties in their reuse in other empirical studies. The addition of reference disciplines above marketing and IS in e-commerce research speaks to the issue of the complexity of trust per se and recognizes the need to refine our view of the construct.

Dimensionality

Despite the important tendency in e-commerce research to treat trust as being unidimensional, trust has clearly more than one dimension, according to Mayer et al. (1995). These dimensions can be summarized in three sets of characteristics: those of the truster, those of the trustee, and those linked to the context. Characteristics of the truster are factors that affect his or her propensity to trust, and are thus linked to psychological, personal, experien-

Trusting behavior (occurs) when a person relies on another, risks something of value, and attempts to achieve a desired goal	So & Sculli (2002) (information systems)	Giffin (1967) (psychology)		X	X

tial, or cultural traits affecting the likelihood of the party to trust other parties. Characteristics of the trustee are those factors that make possible a subjective evaluation from the truster of how another party is trustworthy. These factors of trustworthiness are recognized to be the ability, the benevolence, and the integrity of the trustee. Finally, characteristics linked to the context are those factors that are inherent to the perceived level of risk and vulnerability, and that depend on elements such as the balance of power in the relationships, information asymmetry, and alternatives available to the truster.

Table 1 identifies the three dimensions of trust (propensity to trust, evaluation of the trustee, and perceived risk) the definition should include in order to be exhaustive (Mayer et al., 1995), and shows that most of the definitions of consumer trust in e-commerce include only one or two of these three dimensions. In fact, 16 (50%) of the 32 identified definitions contain only one dimension, while 13 (41%) contain two; only 3 definitions (9%) contain the three required dimensions. This means most of these definitions consider trust as a uni- or bidimensional phenomenon but not as the complex concept it is. This simplification prevents them from considering the conative, cognitive, and emotional nature of trust to which its three dimensions of propensity, evaluation of the trustee, and perceived risk in the context are respectively related.

Conceptualization

The e-commerce research community takes its inspiration from other fields. Some of these fields, such as management, seem to distinguish trust and trustworthiness, while others, such as marketing, do not seem to clearly make the distinction between the two. As reported in Table 1, the presence of the concepts of integrity, benevolence, and ability in definitions of trust (Chen & Dhillon, 2003; Einwiller, 2003; Gefen, Karahanna, et al., 2003b; Kolsaker & Payne, 2002; Warrington, Abgrab, & Caldwell, 2000; Yousafzai, Pallister, & Foxall, 2003) shows indications of a defective conceptualization of the idea since these are rather factors of trustworthiness. Consequently, there are problems of conceptualization among some definitions took from the marketing field, where antecedents of trust are confused with factors of trustworthiness. In this way, it induces a conceptual framework where trust and trustworthiness make one unique concept whereas the antecedents, moderating factors influencing them, and consequences are different elements.

FUTURE TRENDS AND DIRECTIONS

Research on the understanding of the phenomenon of consumer trust in e-commerce suffers from problems dependent on the definition, the dimensionality, and the conceptualization of the concept. This reflects the fact that the e-commerce knowledge field is still on its way to reach maturity, and this is why researchers, according to the goals of their study and by whom and by what field they are influenced, still favor a particular definition of trust and the dimensions behind it.

Definition

If the studied concept was the same from one study to the other, a better convergence between the definitions would ensure a better comparability of the models. By agreeing on a single definition of e-trust, the e-commerce research community could address the problem of relying on different definitions. Such a definition needs to reflect the parties and the context in which e-commerce transactions take place and, as such, address the elements studied by psychology, sociology, economics, and social psychology.

The result of this exercise would be a shared definition of trust in the e-commerce research community, a definition inspired from other disciplines but applied to the e-commerce context. It is a necessary step toward both the reinforcement of a certain paradigm in this field of research and its maturation. It could resemble the one used by Lee and Turban (2001, p. 79): “the willingness of a consumer to be vulnerable to the actions of an Internet merchant in an Internet shopping transaction, based on the expectations that the Internet merchant will behave in certain agreeable ways, irrespective of the ability of the consumer to monitor or control the Internet merchant.”

This definition reflects the complexity of the concept of trust and can adapt to most of the studies undertook in the e-commerce field.

Dimensionality

Because trust is a multidimensional concept, its definition also needs to take into account the three dimensions behind it: those of the truster, those of the trustee, and those linked to the context. Such a definition would ensure a better completeness of the concept. Because it incorporates those three sets of characteristics, the definition cited just above and proposed by Lee and Turban (2001) meets this need. It reflects the three dimensions of propensity, the evaluation of the trustee, and perceived risk in the context of an e-commerce transaction and, as such, is complete.

Conceptualization

The conceptualization problem of trust is linked to the confusion between trust and trustworthiness, their antecedents, and their consequences. The e-commerce community can address this problem by taking care not to use integrity, benevolence, and ability as antecedents of trust unless it is made clear they are factors of trustworthiness. Furthermore, this gives the opportunity to better reflect the dynamics of trust building by allowing the introduction of moderators between trust and trustworthiness, and by clearly identifying the two parties committed in the transactions.

The recognition of the confusion between trust and trustworthiness also leads to an important observation: In many cases, instead of speaking of trust building in e-commerce, one should speak of trustworthiness building, which, according to the way it is perceived by the consumer, has a more or less positive effect on his or her trust feelings concerning the merchant, with trust being understood here as a psychological state toward the other party. In the same way, one should not conceive trust as perceived trust since perception rather applies in this case to trustworthiness, and because the psychological state of trust depends partially on the perceived trustworthiness of the other party. An important consequence of this distinction between the two concepts would be better and more comparable models of trust-building dynamics.

CONCLUSION

The weaknesses in the conceptualization of the concept of consumer trust in e-commerce research is being more and more recognized as a problem that prevents, to a certain degree, a better understanding of the topic by this knowledge field. The issues of the number of definitions, the lack of dimensionality, and the confusion between trust and trustworthiness discussed in this article offer many insights that are likely to help in reducing the size and impacts of gaps identified in the conceptualization of the trust phenomenon in e-commerce. First, there is a need to agree on a single definition of trust in the research community, a definition that would correctly reflect the context of e-commerce. Second, this definition should incorporate the three dimensions attributed to trust: those of the truster, those of the trustee, and those linked to the context. The definition proposed by Lee and Turban (2001) is suggested. Third, there should be no confusion between trust and trustworthiness and, from there, no use of the factors of trustworthiness as direct antecedents of trust.

With greater emphasis being placed on a better conceptualization, consumer trust on the Internet will be easier to understand and easier to address.

KEY TERMS

Ability: A group of skills, competencies, and characteristics that enable a party to have influence within some specific domain (Mayer et al., 1995).

Benevolence: The extent to which a trustee is believed to want to do some good to the truster, aside from an egocentric profit motive (Mayer et al., 1995).

E-Commerce: The carrying out of business activities that lead to an exchange of value where the parties interact electronically using network or telecommunications technologies (Jones, Wilikens, Morris, & Masera, 2000).

Integrity: The truster's perception that the trustee adheres to a set of principles that the truster finds acceptable (Mayer et al., 1995).

Propensity to Trust: A general tendency to trust others (Rotter, 1971).

Risk: A consumer's perceptions of the uncertainty and adverse consequences of engaging in an activity (Dowling & Staelin, 1994).

Trust: "[T]he willingness of a consumer to be vulnerable to the actions of an Internet merchant in an Internet shopping transaction, based on the expectations that the Internet merchant will behave in certain agreeable ways, irrespective of the ability of the consumer to monitor or control the Internet merchant" (Lee & Turban, 2001, p. 79).

Trustee: The e-merchant in which trust is placed.

Truster: The individual who willingly enters into a commercial transaction and expects the trustee to fulfill the contract underlying the transaction.

Trustworthiness: The perceived likelihood that a particular trustee will uphold one's trust (Chopra & Wallace, 2003).

Context and Concept of Web Services

INTRODUCTION

Web Services Defined

The term Web services has as many definitions as there are people who have worked on it. The different definitions, in general, stress various aspects of Web services. The diverse nature of these definitions confirms the diverse interpretations of Web services ("Evolution of Integration Functionality," 2001; Freger, 2001; Infravio, 2002; Ogbuji, 2002; Stal, 2002; Wilkes, 2002). The big computer giants such as Microsoft and IBM promote Web services, and the definitions offered by them are as follows.

- **IBM:** "A Web Service is a collection of functions that are packaged as a single entity and published to the network for use by other programs...[They are] self-describing, self-contained, modular applications..." (Glass, 2000).
- **Microsoft:** "Web Services are a very general model for building applications and can be implemented for any operating system that supports communication over the Internet and represent black-box functionality that can be reused without worrying about how the service is implemented...[They use] building blocks for constructing distributed Web applications..." (Kirtland, 2001).
- **World Wide Web Consortium (W3C):** "A software system identified by a URI [uniform resource indicator], whose public interfaces and bindings are defined and described using XML [extensible markup language]. Its definition can be discovered by other software systems. These systems may then interact in a manner prescribed by its definition, using XML based messages conveyed by internet protocols" (W3C, 2002).

This article attempts to clarify these generic definitions into language that is tangible and meaningful to the reader. To do so, background is given on the systems, applications, and architecture that led to the need and development of Web services.

BACKGROUND

The advancement of technology in computer systems and business applications in the current era are unprecedented. The rapid pace of application development has led to the development of disparate applications and services. In an era of mergers, acquisitions, and virtual integration, there is an increasing need to link disparate applications and services. The information needs to be shared not only within a business, but between businesses. We are moving from an era of working within applications intraenterprise to working between applications interenterprise. Employees, customers, and partners require easy access to information and services whenever they need it.

Considering the risks involved, technology integration is one of the principal challenges in enterprises (Raczkowski, 2002). Web services promise a new level of interoperability between applications and enable the integration of enterprise applications. Web services are expected to get a major share of business-integration expenditures and are expected to grow in the next 5 years (Raczkowski). Web services, being a subset of the application-integration market, will experience high growth and, according to *IDC* ("Cautious Web Services Software Adoption," 2004), spending on Web-services projects will reach $11 billion by 2008.

MAIN THRUST OF THE ARTICLE

Web services, while still in their infancy, show potential. However, they are not a panacea to all the business problems today, and some issues remain needing resolution. In this article, the historical context of Web services positions them with previous technologies. Web services are not the first approach to streamlining enterprise application integration. There is a history of numerous approaches to integrating enterprise applications. After positioning Web services in their proper context, the article discusses the concepts that underlie Web services and how they are applicable. The architecture and protocols used in Web services are discussed next. Finally, future Web-services issues are identified.

Object-Oriented Paradigm

The procedural programming paradigm emerged in the 1970s because of intricacies in understanding assembly language programs. Though procedural programming proved useful, it fell short of providing the necessary tools needed to model real-world entities; thus, the software-development process became enormously cumbersome, which led to the development of object-oriented programming. Programmers could now reuse the software units by implementing a packaging scheme. This scheme focused on application areas, facilitated the reuse of software components, and led to the development of distributed systems and distributed object models.

Distributed Computing Systems

The technological advances in the computer engineering discipline resulted in the emergence of powerful computers and computer networks. Computing was distributed over the networks instead of being performed on a single, centralized computer. This led to the development of the two-tier architecture, more commonly known as the client-server architecture. In the two-tier architecture, the operations were decomposed into two parts, with one part, the client, initiating a distributed activity, and the other part, the server, carrying out the activity.

The centralization of activities presented some problems in terms of scalability and flexibility. Thus, the three-tier architecture was proposed by adding an additional tier to separate the application tier into the presentation and data tiers (Gunzer, 2002). The three-tier architecture imparted unprecedented flexibility and provided a feasible alternative to deal with the issue of scalability. This formed the basis for distributed application development and distributed computing. Some of the popular middleware technologies are discussed below.

Common Object Request Broker Architecture (CORBA)

CORBA is an open-standards-based solution to distributed computing. The Object Management Group, an industry consortium, developed the specifications for CORBA. The primary advantage of CORBA is that clients and servers can be written in any programming language. That is possible because the objects are defined with a high level of abstraction provided by the interface definition language (IDL). After defining an IDL file, a compiler takes care of the mapping of the IDL file to a specific programming language. Though advantageous, compatible object request brokers are needed on both of the connections to make the client and the server objects communicate (Gunzer, 2002; Ogbuji, 2002).

Distributed Component Object Model (DCOM)

Microsoft's DCOM has a layer that sits on the top of a remote procedure-calling (RPC) mechanism and allows calls to remote objects that interact with the COM run-time services. The DCOM server publishes its methods to the clients by supporting multiple interfaces. These are written in the interface definition language, which is similar to C++ (Gunzer, 2002; Ogbuji, 2002).

Remote Method Invocation (RMI)

RMI enables one to create Java-to-Java applications, in which the methods of remote Java objects can be invoked from other Java virtual machines. A Java program can make a call on the remote object once it obtains a reference to the remote object. Programming with RMI is straightforward once the programmer has gained some experience with the Java and distributed applications. On the other hand, RMI may only be used when Java exists on both sides of the connection (Gunzer, 2002; Infravio, 2002; Ogbuji, 2002).

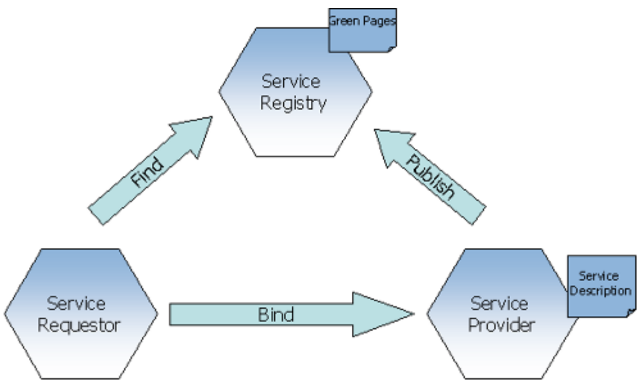
World Wide Web

The advancements in the distributed object models proceeded in parallel with the development and establishment of the World Wide Web architecture. This gave rise to some standard protocols that were widely accepted. The transmission control protocol/ Internet protocol (TCP/IP) formed the common base protocol for connectivity. This was followed by the advent of various protocols like the hypertext transfer protocol (HTTP), file transfer protocol (FTP), and Gopher for specific needs.

HTTP became the common communication protocol. The emergence of the World Wide Web brought about the acceptance of a standard Web architecture. Thus, a platform was set in terms of standards, and the advancements in distributed object models saw the surfacing of Web services.

In terms of presentation, the hypertext markup language (HTML) established itself as the standard. The capabilities of HTML were very limited and did not provide any structure or programming ability. To counter these deficiencies, XML was created. XML provided the ability to program over the Web as an addition to presentation.

Figure 1. The Web-services architecture



Web Services Architecture

Web services are based on the service-oriented architecture (SOA; Leymann et al., 2002). All agents or participants are identified as service modules. A requestor is a software agent requesting a service, and a provider is the owner of a service who is willing to offer the service to requestors. Thus, the roles in the Web services architecture can be described as follows (Freger, 2001).

- **Service Requestor:** This is the agent that requests a service. From the business perspective, this is the entity requiring certain functions to be satisfied. From an architectural perspective, this is the application that is looking for and invoking or initiating an interaction with a service.
- **Service Provider:** This is the owner of the service. From the business perspective, this is the business that is the owner of a service, willing to share that service with others.
- **Service Registry:** This is a registry that contains all available services. The service providers publish the services. The requestor may search for specific service descriptions.

The service operations of the service roles are as follows:

- **Publish:** For a service to be accessible, a service description needs to be published so that the service requestor can find it. The requirements of the applications determine where the service description is published in the public service registry or the service registry of the vertical industry.
- **Find:** During the find operation, the service requestor retrieves a service description directly or queries the service registry for the type of service required. The goal of this operation is to get the service description of the service as required by the service requestor. The find operation generally involves two phases for the service requestor: one to get the service description of the service provider, and another at run time to retrieve the binding information and the location description for invocation.
- **Bind:** Once the service requestor has the service description of the service provider, he or she needs to invoke the service on the service provider. This generally occurs during run time using the binding details in the service description to locate, contact, and invoke the service.

Web Services Protocols

Web services use the following protocols for specific operations.

- **Service Invocation and Communication:** Simple object access protocol (SOAP)
- **Service Description:** Web services description language (WSDL)
- **Service Discovery:** Universal description, discovery and integration (UDDI)
- **Standard Transport Protocol:** HTTP
- **Underlying Protocol:** XML

Understanding Web Services

Web services can be viewed from two different aspects: Web aspects and service aspects (Fremantle et al., 2002). The Web aspects of Web services are the following attributes.

- **Web-Based Protocols:** Web services are based on HTTP and thus are designed to work over the public Internet.
- **Interoperability:** The XML-based protocols used for communication in SOAP define a common standard that allows differing systems to interoperate.

The service aspect has the following attributes (Fremantle et al., 2002).

- **Modular:** The service components are useful, are reusable, and can be combined to form larger components.
- **Available:** Services are available to systems that wish to use them.

- **Described:** Services have service descriptions, which are also machine readable to identify the interface of the service.
- **Implementation Independent:** The service interface must be available in a way that is independent of the ultimate implementation.

Simple Object Access Protocol

Web services are run in a heterogeneous environment, and the protocols should be independent of the run-time environment and implementations. SOAP is the communication protocol that satisfies the required characteristics and thus is used in Web services. SOAP is based on XML and also has the GET and POST capabilities of HTTP.

SOAP provides a simple and lightweight mechanism for exchanging structured and typed information between peers in a decentralized and distributed environment using XML. SOAP does not itself define any application semantics such as the programming model or implementation-specific semantics; rather, it defines a simple mechanism for expressing application semantics by providing a modular packaging model and mechanisms for encoding data within modules. This allows SOAP to be used in a large variety of systems ranging from messaging systems to RPC.

SOAP consists of three parts (Apache Software Foundation, 2005):

- **SOAP Envelope Construct:** Defines an overall framework for expressing what is in a message, who should deal with it, and whether it is optional or mandatory.
- **SOAP Encoding Rules:** Define a serialization mechanism that can be used to exchange instances of application-defined data types.
- **SOAP RPC Representation:** Defines a convention that can be used to represent RPCs and responses.

The use of SOAP allows software processes to change without requiring changes to the other party. A Web-service implementation can change with no impact on the users of the service as long as the request and response messages do not change. The first implementation of the service provider could be a thin wrapper around legacy code, allowing a planned replacement to be developed over time. When the new code is ready, the change is invisible to users of the service.

Web Services Description Language

WSDL provides documentation for distributed systems and has the goal to enable applications to communicate with each other in an automated way. SOAP provides the communication between the requestor and a provider, and WSDL describes the services offered by the provider and is used as a means to generate the proper SOAP messages to access the services. The information definition language provides the same functionality as WSDL for Web services. WSDL consists of two groups of elements: abstract definitions (types, messages, and port types) and concrete definitions (bindings and services).

Universal Description, Discovery, and Integration

UDDI is a standard designed to facilitate a searchable directory of service providers. This resides at the service registry. Thus, service requestors search for the available services at the service registries. UDDI contains support for the following (Freger, 2001; Gunzer, 2002).

- **Yellow-Pages Taxonomies:** Here, searches can be done according to a particular industry, sector, or product category.
- **White Pages:** This contains address information, contact information, and the phone numbers of service providers.
- **Green Pages:** This contains the technical details about the service provider. It tells the service requestor the details as to how to invoke the request with that particular service provider.

FUTURE TRENDS AND WEB-SERVICES ISSUES

Web services growth is driven by the emergence and mainstreaming of service-oriented business applications (SOBAs; Smith & Abrams, 2004). With that growth emerges popularity. A recent Yankee Group survey revealed that CIOs (chief information officers) say implementing Web services is their number-one priority (LaPlante, 2004), while The Butler Group predicts that "Web Services are the future of IT and can deliver cost savings within months" (Huber, 2004).

Though Web services show much promise and CIOs now believe them to be their main focal point, how much they actually deliver is unclear. Rapid growth in a technology usually creates some problems. Web services are no different. Security, reliability, and standardization are some of the main issues in implementing Web services.

- **Security Issues:** Web services operating on Web standards are accessible by anyone; thus, the traditional security measures have to strengthen. Web services security must be addressed at three levels: identity management, authentication, and confidentiality. Identity management refers to the issue of who uses those Web services resources. Authentication guarantees that a sender of a Web services is who they say they are. Web services must provide authentication of both the sender and the receiver of the service. Confidentiality provides a guarantee that information will only be seen by the authorized party and will not be visible to unauthorized parties (Infravio, 2002; Malhotra, 2001; Ogbuji, 2002).

- **Reliability Issues:** The performance of the service is dependent on the traffic and the bandwidth available. Converting applications into Web services by the use of a wrapper layer is no longer the same as the native component, and the response time is much greater (Malhotra, 2001; Ogbuji, 2002). In business applications, the response time is very crucial, especially when doing business online.
- **Standard Protocol Issues:** With the flexibility that Web services bring, complexity follows, and, potentially, chaos ensues. The simplicity of programming in standard HTML led to the rapid adoption of HTML as a Web standard early in the Internet growth stage. Thus, the adoption of a standard protocol is critical to the rapid implementation of Web services.

CONCLUSION

Placing Web services in their historical context reveals that they are the result of an evolution of Web technologies. As connectivity increased and presentation became more complex, programming the Web became a necessity. Thus, Web services were created. The emergence, visibility, and impact of Web services are not in doubt. Solving the security, reliability, and standardization issues could make Web services more widely adopted.

KEY TERMS

Common Object Request Broker Architecture (CORBA): An open-standards-based distributed computing solution.

Distributed Computing Systems: Computing distributed over networks instead of on single computers.

Distributed Component Object Model (DCOM): Sits on top of the remote procedure-calling mechanism and allows calls to remote objects interacting with COM services.

Remote Method Invocation (RMI): Enables the creation of Java-to-Java applications in which the methods of remote Java objects can be invoked from other Java virtual machines.

Simple Object Access Protocol (SOAP): The communication protocol that satisfies the required characteristics used in Web services. It is based on XML and has the GET and POST capabilities of HTTP.

Universal Description, Discovery and Integration (UDDI): A standard designed to facilitate a searchable directory of service providers. UDDI resides at the service registry.

Web Services (IBM Definition): "…[A] collection of functions that are packaged as a single entity and published to the network for use by other programs…[They are] self-describing, self-contained, modular applications…" (Glass, 2000).

Web Services Description Language (WSDL): Provides documentation for distributed systems and has as its goal to enable applications to communicate with each other automatically.

Coordination of a Service Oriented Architecture

INTRODUCTION

As e-commerce models and applications have been widely employed in today's business environment, a new movement to so-called *dynamic e-business* has been urged to advance e-commerce applications to the next level: simplifying business interaction over the Web through effective and widely accepted messaging and data encapsulation standards (Chen, Chen, & Shao, 2003). Gisolfi (2001) defined *dynamic e-business* as the next generation of e-business focusing on the integration and infrastructure complexities by leveraging the benefits of Internet standards and common infrastructure to produce optimal efficiencies for intra- and inter-enterprise computing.

Infrastructure for both inter- and intra-organizational computing has undergone a significant maturation process from centralized mainframe computing to early distributed client/server environments, and most recently taking on a service orientation (Roure, 2003). Service-oriented architecture (SOA) represents the framework for the latest generation of service-based computing where once proprietary and monolithic applications are broken down into components and exposed through open standards for use by both internal and external enterprise partners. The SOA paradigm is argued to include in its list of benefits a higher return on investment, increased software reuse, and the capability to support dynamic service assembly (Stevens, 2005).

An increased return on investment is achieved through the componentization of application capabilities. The argument goes that the usefulness of a component (defined here as bounded by its functional capabilities to one distinct business domain) outlives the usefulness of an application (since applications are developed to support a subset of processes in a domain while a component is not constrained, by definition, to any particular process set).

Within the SOA paradigm, the development of applications to support a set of business processes is replaced with the connecting of components from distinct business domains in order to address the computational needs of a particular process. It is clear, then, that SOA has a positive impact on software reuse as components are leveraged across many configurations to address the specific computational needs of many different processes. To this end, one can map the reusability of components in an SOA context to the third argued benefit—dynamic service assembly.

Dynamic service assembly means that components are not developed with the complete set of application scenarios in mind. Instead, components are created to exemplify the information and computational contribution of a specific business domain. The choice of how these components are used later on is therefore not limited to assumptions of usage made at the development stage. Indeed, it is possible that the most valuable use for any given component may not exist at the time of component development. As business processes evolve dynamically over time and business needs for information and computational support change, a service orientation leveraging components that are developed in the absence of constraints for how they might be utilized allows for dynamic reconfiguration of services in order to adapt to changes in the business processes themselves. This ability to reconfigure increases reuse and extends the lifetime (from a value perspective) of the components that are developed. This, in turn, feeds back to an increased return on the investment in software development which is typically the primary motivation for buy-in to the SOA paradigm.

Similar to the shift from a mainframe to a client/server architecture (Malone & Smith, 1988), however, the shift to a service-oriented architecture requires consideration of costs associated with coordinating activities in this new environment. Management of these coordination costs will be necessary in order to preserve the purported increases in return on investment. Put simply, if the return on investments in software development increases but the costs associated with leveraging the developed information technology artifacts for business value also increases, then it is possible that the value created will be diminished or even overrun by the operational expense of coordinating use. In order to ensure that this is not the case, this article leverages a coordination theory approach to first understand the impact that a shift to service-oriented architecture will have on the cost of coordinating activity both within and across the firm, and second to make recommendations for how these coordination costs can be addressed to preserve the return on investment from a shift to service-oriented architecture.

BACKGROUND

Client/Server and Associated Shifts in Cost

In order to understand the impact of a fundamental shift in information technology architecture, one can observe an historical shift of this type in that of mainframe computing to client/server models. The client/server computing paradigm came about as a response to the need for computational flexibility to support changing environments (Kavan et al., 1999). In this sense, the historical goals motivating a shift to client server map well to the contemporary goals that motivate a shift to SOA. In the client/server context, it was noted early on that the purported cost savings in terms of infrastructure were frequently overrun by management, support, and training costs (Diamond, 1995). History has shown, however, that the increased management costs were characteristic of early client/server adoptions, while best practices for management of the new architectural paradigm were being discovered in real time (Borthick & Roth, 1994).

Critical to the understanding of how a shift such as this impacts costs and organizational effectiveness, coordination theory has much to say regarding the movement from mainframe to client/server architectures (Malone, 1987; Malone & Smith, 1988; Malone & Crowston, 1994; Shin, 1997). In essence, mainframe computing flourished in the era where computational power was expensive and should therefore be conserved and used efficiently. By centralizing computational power, demand for computation was aggregated and benefited from a smoothing effect due to the pooled variance of computational requests. This allowed firms to run their computational resources efficiently by making capacity decisions that minimized unused processing power, since the demand for processing held relatively stable.

The trade-off to a centralization of computational power preserving on computing costs was an increase in the cost of coordinating computation and communicating across the organization. Examples of these costs include the cost of transmitting data and processing requests to a distant centralized processor, latency in the time between request submission and receipt of computational results, overhead related to scheduling and planning the execution of processing requests, and the existence of centralized computer centers to oversee scheduling, governance, and maintenance of a large and centralized computing platform. The emergence of the personal computer signaled a dramatic decrease in the per-unit cost of processing. Suddenly, the importance of efficiently managing processing capacity in order to minimize processing costs became relatively insignificant. Organizations found themselves in a new environment where processing power was cheap and could be spread across the firm to support the computational needs of individuals with reduced latency for the execution of a processing need.

But early adopters, as mentioned above, suffered from cost *increases* with the switch to a client/server model. Coordination theory suggests that the process of driving out such cost increases began with the realization that focus must shift from processing costs to coordination costs. Management practices and organizational design and governance must adapt along with the architecture in order to balance the trade-offs between processing and coordination costs. As processing became less expensive, focus turned towards the coordination of processing, and firms came to realize the value potential for a client/server model by adjusting their management and governance structures and policies to economize on coordination costs.

The Emergence of SOA

Service-oriented architecture represents the next major architectural shift for organizations currently existing in a client/server model of computation. In order to understand the cost, management, and governance implications of such a shift, it is first necessary to understand the current state of SOA as an emerging technology. Papazoglou and Georgakopoulos (2003) identify a set of service layers which can be considered a foundation for the SOA stack, as depicted in Figure 1.

Web services have become the foundational technology for the service-oriented architecture paradigm

Figure 1. SOA technology stack

Architecture Management (SLA enforcement, service support, etc.)
Component Composition and Process Mapping (Coordination, search & discovery, monitoring, etc.)
Component Foundational Technologies (Web Services: UDDI—Discovery WSDL—Dynamic Coupling SOAP—Standardized Data Format TCP/IP—Standardized Communication Platform)

Figure 2. UDDI improvements across versions (Software Research and Development Center, 2005)

VERSION	DATE	KEY OBJECTIVE
1.0	September 2000	Create foundation for registry of Internet-based business services
2.0	June 2001	Align specification with emerging Web services architectures and provide more flexible taxonomy
3.0	July 2002	Support wide interaction of private and public implementations

(Leymann & Roller, 2002). In brief, Web services represent an open set of standards for the development of loosely coupled components or services, including specifications for how data should be formatted (SOAP), how the invocation of components should be described (WSDL), and how components can be discovered for use (UDDI). The component foundational technologies layer of the SOA stack is the most complete of the three layers in the current state of the evolution of SOA.

The ability to develop and dynamically invoke components, however, is only part of the SOA vision. This vision is completed by a level of abstraction for component composition to support business processes, and further abstraction for management and support across compositions spanning the complete architectural landscape. Component composition (layer 2 in the SOA stack) is currently the area of primary focus for continued efforts to improve the SOA value proposition. Two critical areas for support in this layer include execution management across compositions and evaluation of composition alternatives for supporting business processes. The former seeks to improve the management of existing compositions through the introduction of fault or error recovery, the evaluation of performance across defined alternative services in order to improve composition execution, and the orchestration of message passing between services that make up a composition. An example of technology developed to fill these needs is IBM's Business Process Execution Language for Web Services (BPEL4WS) (Weerawarana & Curbera, 2002). The latter involves evaluation of alternative means to support a business process through heterogeneous compositions of services that may differ in the number of services included, the type or domain of each service, and the characteristics of each service including but not limited to performance data. To date this capability remains unaddressed. Figure 2 provides a depiction of the evolution of UDDI as an effort to begin to meet these needs.

Initially, UDDI was developed to support simple search for services through a centralized repository. Through versions 2 and 3, the standard has been improved to provide greater flexibility with regards to the metadata describing services and the ability to map repositories together for interaction. While these improvements have provided much-needed enhancements for the search and instantiation of an individual service, the ability to search a repository of services to identify potential *compositions of services* that would serve to provide the needed support for a business process has not been addressed. The analysis of composition alternatives is currently a manual process. As the size of a repository grows, discovering suitable service compositions to transform a given input to a required output becomes a combinatorially difficult problem. As will be shown in the following section, composition search and discovery to support emerging business process needs represents a critical factor for coordination that will preserve returns on an SOA investment as the implementation matures.

The third layer of the SOA stack, architecture management, is also relatively unaddressed in today's instantiations of SOA. This level of abstraction looks to automate the enforcement of service level agreements (SLAs) and provide support for the use of a component in an execution composition. Currently, these aspects of the SOA environment are handled manually and represent an additional maintenance and monitoring overhead cost for SOA implementations.

COORDINATION IN SERVICE ORIENTED ARCHITECTURES

By analyzing the SOA stack, one can observe that a major trend in the shift from client/server to SOA is that client/server coordination issues, such as application development and maintenance to satisfy a set of business users, have been replaced with the costs of coordinating components into compositions for utilization in emerging business requirements. To understand this shift, consider a mature SOA implementation. The number of components is likely to be very large, and just as business domains overlap in some ways, capabilities of components may overlap as well. However, the approach to any given capability is likely to vary across components as a function of the approach taken in that component's mapped business domain. These components are not, therefore, homogeneous in the sense that one can be replaced for the other seamlessly. The exchange of one component for another may require additional manipulation or transformation through the invocation of additional components to map the output of one component to another. In this case, the output of one component may be equivalent to the output of a composition of different components. That composition represents an alternative to the original component of interest. The coordination process of identifying and evaluating execution alternatives to support business processes becomes critical to allocate resources effectively in an SOA context, as well as to map emerging business requirements into existing components through dynamic composition discovery in order to avoid unnecessary component development to meet business demands.

Early work in coordination and SOA includes that of Pankaj et al. (2003), who leverage a service modeling approach to search for redundant service components that can be seamlessly swapped into a composition. While this approach allows for the dynamic evaluation of compositions based on performance data, it does not address the ability for heterogeneous service compositions to be interchangeable as it focuses on redundant homogeneous services. The identification and comparison of heterogeneous service compositions that support a common business process remains an unaddressed SOA capability that will increase in importance as an SOA implementation grows and matures.

As an SOA implementation matures, the return on investment of SOA adoption can only be preserved to the extent that layers 2 and 3 of the SOA stack support low-cost identification of alternative compositions, as well as identification of configurations that support emerging business needs. If this support does not exist or is expensive or complex from a coordination perspective, then reuse will diminish as redundant components are developed to address business needs that could have been met through a composition of preexisting components. As this occurs, the return on investment for a shift to service-oriented architecture is reduced because the develop-to-order paradigm of the client/server architecture reemerges due to the complexity and cost associated with discovering and coordinating execution alternatives in a very large SOA environment. From a coordination theory perspective, the actual cost of development (i.e., the cost of creating compositions from preexisting components) is reduced in an SOA context. However, the cost is reallocated to the process of composition search and discovery, making this the primary target for systems, management, and governance adaptation in order to fully realize the purported return on investment of the SOA paradigm. The success of a SOA implementation is therefore dependant on the ability of an organization to address this new composition search and discovery issue as the SOA architecture grows large, representing the incarnation of coordination cost in an SOA context.

FUTURE TRENDS

Ongoing work in service-oriented architecture research will likely begin to recognize the importance of the composition search and discovery issue in SOA stack layer 2 as a critical enabler to SOA implementation success. Industry has already begun to recognize this need in its increased utilization of metadata and centralized service description repositories in order to facilitate component composition and process mapping. However, as the size of the SOA infrastructure grows, the need for system-level automated support for search and discovery will become apparent. Successful implementations will address this issue and continue to achieve the returns on their architectural investment that convinced them to convert from a client/server model. Implementations that grow significantly in size and complexity, but fail to address this issue, will likely see their costs return to that of client/server as they adopt a develop-to-order component model and their return on investment slips away.

CONCLUSION

While the foundational technologies for the base layer of the SOA stack are approaching maturity, the higher layers of the SOA stack require additional support. The grand vision of Web services-oriented architecture is that Web services can be composed and invoked dynamically to support business processes within and across enterprises. Hence, the component composition and process mapping layer of the SOA stack is particularly important and is the focal point of this article. This layer consists of standards that specify how individual Web services can be composed to support business processes. A number of new standards have been introduced to address this Web services composition issue, including BPEL4WS

(Business Process Execution Language for Web Services), WSCI (Web Services Choreography Interface), and BPML (Business Process Modeling Language). On the other hand, further efforts should also be spent on the architecture management layer, which is relatively unaddressed in today's instantiations of SOA.

The transition from mainframe to client/server reduced the cost of processing power and reoriented management focus towards coordination costs. SOA promises to do the same for development costs, but only to the extent that composition search and discovery, the new cost of coordination in an SOA context, is supported by systems, management, and governance. Composition search and discovery represents the critical incarnation of coordination cost in the new era of service-oriented computing. Service-oriented architecture can provide firms a continued return on investment if the focus shifts from reducing development costs to reducing the cost of composition search and discovery.

KEY TERMS

Coordination Theory: Assumes that the introduction and use of information technology will modify both the structure of the interaction between human agents and the overall organization of work. Organizations should understand the nature of coordination, establish what kinds of structures of organizations already exist, and discover the appropriate coordination processes.

Service-Level Agreement: A formal agreement (between a service provider and its customers) describing the level of service quality (e.g., availability, performance, timeliness) that will be provided.

Service-Oriented Architecture: Represents a computational paradigm wherein services (commonly Web services) become the basic building blocks for service compositions that address specific business process needs. The service-oriented paradigm consists of three layers of technology addressing requirements from low-level technical specification to high-level service management.

SOAP: Simple object access protocol is the messaging protocol that facilitates Web services to invoke software method in remote systems.

UDDI: Universal description, discovery, and integration is a registry standard for Web services providers to publish their Web services. It may be used by a Web services consumer to discover (search) Web services developed by Web services providers.

Web Services: Self-contained, self-describing, modular applications that have open, Internet-oriented, standards-based interfaces and can be published, located, and invoked across the Web.

WSDL: Web services description language defines Web services for distributed systems to support the automatic creation of client-side stubs or proxies, and the binding to the Web services. It describes the interfaces to a Web services implementation in terms of format of the messages, binding of the abstract messages to a concrete protocol, and address of the endpoint.

Customer Goals Online

Thomas W. Porter
University of North Carolina Wilmington, USA

INTRODUCTION

Marketing managers charged with developing effective e-marketing strategies need to understand the implications of goal-directed behavior online. Traditionally, the marketer's job has involved capturing the customer's attention and communicating a message about products or services. The customer is essentially a passive receiver of the marketer's message with little control over the marketing messages they are exposed to. Contrast the traditional approach to marketing with a Web site. Online the customer arrives at the marketer's Web site with a goal. The customer has something that he or she wants to accomplish, whether it be to acquire information about a product, to make a purchase, or to just be entertained. By understanding the customer's purpose for a Web site visit, the Web marketer is in a position to develop a Web site that provides significant value. Furthermore, a failure to deliver a Web site that enables customers to accomplish their goals is likely to result in dissatisfaction and defection to other more useful Web sites.

Understanding customer online goals is critical because it gets at the heart of what the Web site should or could "do." The challenge for e-marketers is that for most businesses, there are likely to be multiple goals that represent the "reason why" customers could come to the Web site. For example, an e-tailing site might be very effective for customers who already know the specific product they want to purchase. However, there are likely to be many other goals that could lead people to visit the site, such as selecting the appropriate product form a large product line, selecting an appropriate gift, or perhaps receiving customer service. If important customer goals are not supported by the Web site, the firm is at risk of losing a significant amount of business. Other times businesses compete in markets where there may be little apparent reason for a consumer to visit a Web site. As a result, and because firms feel they should have an online presence, many e-marketing sites are created that offer little more than online reproductions of the marketer's off-line advertising. The purpose of this article is to help e-marketers better understand the nature of customer goals online so that they may be prepared to create the types of Web site experiences that provide value to their customers.

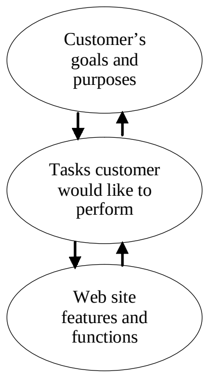
BACKGROUND

A growing number of Web design professionals, committed to the principles of user-centered design, seem to truly understand how to create highly usable, customer-centered Web sites. User-centered design (UCD) is an approach to designing computer interfaces that places the user of the system at the center of the design effort (Karat & Karat, 2003). UCD practitioners strive to improve the usability of a system by focusing on the various tasks and activities users would like to perform when interacting with a system. Focusing on users is critical in design because systems appropriate for one user group may be completely inappropriate for another set of users. For example, a travel Web site created for frequent business travelers wanting a fast and easy way to schedule business trips would not be appropriate for a person planning a vacation and wanting to learn about various vacation package options. By emphasizing users and their tasks, UCD aims to create systems that provide the appropriate functionality and are easier to use (Henneman, 1999).

Usability is the ultimate goal for Web designers who are practitioners of UCD. Creating a highly useable Web site means that the Web site matches what the site visitors need and want. Usability as defined by the ISO 9241 (ISO, 1997) standard is "the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use." As can be seen from this definition, the concept of user goals is central to understanding usability.

Customer value (Levenburg, 2005; Adelaar, Bouwman, & Steinfield, 2004) is a concept from the marketing literature that is conceptually similar to usability when considered within a value-in-use perspective. The value in use perspective (Woodruff & Gardialm, 1996) emphasizes the instrumentality of products in achieving the customer's goals. As a result, value in use involves an evaluation of the effectiveness of a product within a particular usage context. The work of Woodruff (1997) on value hierarchies is particularly relevant for understanding customer behavior online. Web sites are used by site visitors to accomplish their goals. Thus using a means-end approach to conceptualize online value provides a way to explain how online customers derive value from their usage experiences. Building on the work of Woodruff, Porter (2005) defined online value as:

Figure 1. Perceived Web site value (Porter, 2005)



…a customer's perceived preference for and evaluation of those Web site features and functions that facilitate (or block) the performance of the tasks that are instrumental in achieving the customer's goals and purposes associated with the Web site visit.

Porter's model of perceived Web site value (see Figure 1) integrates concepts from user-centered design and marketing using means-end theory. The perceived value of a Web site is assessed based on the extent to which it allows the customer to achieve his or her online goals. Likewise the perceptions of the effectiveness of goal accomplishment are influenced by the degree to which the Web site supports the necessary tasks or subtasks the consumer would like to perform in order to accomplish the goal. Finally, the effectiveness of task accomplishment is related to the features, functions, and characteristics of the Web site. An implication of the model is that consumer perceptions of Web site value are related to the consumer's expectations regarding what the Web site should do and what they would like to accomplish online. The more knowledge the e-marketer has about the customer's goals, the better chance he or she has of creating a Web site that is truly valuable to the consumer.

ONLINE CUSTOMER GOALS AND TASKS

A key challenge for Web marketers is to understand the customer's goals that motivate (or could motivate) a Web site visit. Research on goals suggests that goals occur in the form of a hierarchy with more abstract, higher-order goals closely related to an individual's personal values at the top and specific action-oriented subgoals at the bottom (Bagozzi & Dholakia, 1999). For example, an individual has the goal of meeting the right person and getting married. This higher-order goal represents a "problem" that is somewhat unwieldy. Therefore to address this goal, the customer develops more concrete goals that can be used to help accomplish the higher-order goal. Thus, to achieve the goal of "finding a partner for a committed relationship," the individual sets more action-oriented subgoals like socializing with friends more often, keeping in shape, or visiting an online dating Web site. Thus a goal hierarchy serves as a way for a customer to break down a complex problem into a series of smaller, easier-to-manage problems (Pieters, Baumgartner, & Allen, 1995).

The goal a site visitor has when arriving at a Web site tends to be very action oriented. If the visitor has never visited the site before, the goal may simply be to evaluate the Web site and figure out what the site is and if it is of interest. On the other hand, if the visitor has reached the site as the result of a directed search or is a repeat visitor, the customer's goal is likely to be specific and functional. For example, Wolfinbarger, and Gilly (2001) found 71% of online purchases were planned.

The online goals that customers have when arriving at a Web site are clearly related to the concept of tasks in the UCD literature. Just as goals can be understood in the form of a hierarchy, tasks can also be represented hierarchically. The hierarchical levels associated with tasks can be seen in the design methodology of task analysis (Richardson, Ormerod, & Shepherd, 1998). By breaking down the various tasks a user would perform in pursuing a goal into finer grained subtasks, the system designer begins to understand how a user would like a system to perform. The process occurs iteratively, because subtasks can in turn be further decomposed until the system designer can capture all the different steps that the user would want to perform in accomplishing the task. By understanding the specific tasks and subtasks that would be performed, the system designer can identify the features and functions the system needs to support.

Identifying Online Goals

The responsibility of the Web marketer is to understand the goals that could motivate a Web site visit. Sometimes this appears fairly straightforward because the nature of the business almost dictates the different types of goals that consumers have when visiting the site. Thus the nature of the business may largely dictate the critical goals that consumers have when arriving on the Web site. For example, a large percentage of the visitors to ticketmaster.com go there with the goal of finding and purchasing tickets to a particular musical or sporting event. Clearly ticketmaster.com needs to make its site as suitable as possible for the accomplishment of this goal. However, finding and purchasing tickets is not the only goal that might bring customers to the site. A certain number of site visitors may be seeking to return tickets, track down missing tickets, or receive some other type of customer service. Some visitors may "use" the ticketmaster.com site in unanticipated ways, such as to find out who will be appearing at various venues. Designing the Web site to make it useable for all the critical goals motivating a Web site visit is the key to developing a Web site that provides value to customers.

For other businesses it can be difficult to identify a goal that would compel a significant number of customers to the Web site. Take a restaurant as an example. Many restaurants have developed sites with the objective of promoting their businesses online. These Web sites typically include information such as location, photographs of the facilities, hours, and menus. While there are many very attractive restaurant Web sites of this type, few generate a significant volume of traffic. The problem is an inherent mismatch between the design of these sites and customer goals. The design of these sites would be appropriate *if* there were a group of customers looking to learn about the restaurant online. However, unless the restaurant were new to an area or located in a tourist destination, few customers would have that kind of goal. This does not mean that restaurants should not have Web sites, but rather that to provide value to customers, restaurant Web sites needs to consider the types of goals that would prompt a Web site visit. Some restaurants have created high-value Web sites by supporting customer goals such as to place takeout orders, make reservations, track customer rewards programs, or to learn about catering and banquet facilities.

Another example of a business in which it can be difficult to think of a meaningful online customer goal is consumer packaged goods companies. Yet many popular branded consumer goods have Web sites. Often these sites receive little traffic because there are few obvious customer goals that prompt visits to these sites. To provide value, e-marketers might consider the higher-order goals of their customers. For example, Kraft foods knows that a significant number of their core customers have the higher-order goal of providing healthy meals at home. As a result Kraft has created a Web site designed to help time-pressed meal planners find tasty and nutritious recipes for a family dinner. Because the site provides customers with the opportunity to accomplish a meaningful goal, Kraftfoods.com is one of the most highly trafficked consumer packaged goods Web sites.

Customer Goals across the Customer Services Life Cycle

In order to avoid developing Web sites that capture only a subset of the goals that customers might have, researchers suggest it may be useful for the Web designer to consider how the needs of customers change as they move from being a non-customer to an existing loyal customer (Saeed, Hwang, & Grover, 2003). One framework for understanding the changes in customer needs over time is the customer service life cycle (Ives & Mason, 1990). The customer service life cycle (CSLC) suggests that customers go through a four-stage cycle in purchasing and using products and services: requirements, acquisition, ownership, and retirement.

In the requirements stage, customers make decisions about their product requirements. Customers coming to a Web site while in the requirements stage will have goals related to acquiring information. They will want to learn about the product or service, its benefits, and the merits of a particular service provider. Almost every firm has the need to bring in new customers, therefore designing the site to address requirements stage goals is fundamental to most Web sites.

In the acquisition stage, customers attempt to select their preferred product, pay for it, and if relevant get it delivered. Customers in the acquisitions stage know what they want, and they want to use the Web to facilitate the transaction. Frequently, customers will browse off-line but purchase online to take advantage of potential cost savings. Clearly online retailers must address the acquisition stage goals of potential customers. However, the acquisition stage is relevant for many service providers as well. For example, new online banking customers may have the goal of setting up an account online to avoid having to drive to a brick-and-mortar facility.

In the ownership stage customers have previously purchased a product. Customers in the ownership stage have often encountered some kind of problem with relation to their utilization of the product or service. These customers arrive at the Web site with the goal of finding solutions to their problems. Not all ownership stage goals are customer service related though. Some companies have found the Web a viable way to enhance the product-ownership experience by offering product-related news and events, and a way to interact with other customers. For example, the Harley Davidson Web site includes an "experience" section which allows customers to join a Harley Users Group, learn about upcoming events, or sign up for a rider's education course, among many other things.

Ultimately, creating a Web site that allows customers to accomplish their goals is not enough. The Web site should also allow the firm to accomplish important business objectives, such as to increase sales or enhance customer relationships. Fortunately, creating a Web site that allows customers to accomplish their goals usually provides benefits to the marketer. For example, if a firm makes it easier to shop and buy online, the result should be more completed online sales. However, the goal-directed nature of online customer behavior means that the marketer may not be able to use the Web to accomplish some of its most important marketing objectives. For example, one of the challenges for a business might be that advertising costs have spiraled. In response a marketer might want to place marketing materials online. However, most customers are unlikely to go online just to see a firm's promotional materials. The implication is that Internet marketers need to set the objectives of their Web sites to be consistent with the goals that customers bring to the site.

FUTURE TRENDS

Marketing and UCD have a great deal in common. Both emphasize understanding and serving human needs as part of their discipline's core philosophy. Furthermore, both the marketing and UCD literatures characterize human behavior as purposeful. Despite the similarities, there has been remarkably little cross-pollination between the two disciplines. Porter's (2005) model of perceived Web site value incorporates insights from both disciplines. In addition to the theoretical contributions that the field of user-centered design can offer marketing, there are practical contributions as well. User modeling tools (Clemmensen, 2004) such as customer personas, customer scenarios, and task analysis, which are based on the notion that consumers are goal directed, hold significant promise for Web marketers as practical means of developing Web sites that provide value to customers. Ultimately, both disciplines would profit from further integration of knowledge, theory, and techniques designed to understand and meet the needs of goal-directed customers.

CONCLUSION

There is a high degree of consensus among marketing academics and practitioners that online customer behavior is goal directed. However, the implications of the goal-directed nature of customer behavior online are less well understood. As a result, a large percentage of commercial Web sites fail to truly take advantage of the opportunities that technology allows for providing value to customers. While marketers have been struggling with creating effective Web sites, UCD professionals have taken the lead in creating Web sites that meet the needs of goal-directed Web customers. The model presented here represents an attempt to bridge the gap between two disciplines with the same agenda—better serving the needs of people.

The model of perceived Web site value conceptualizes customer online value as a means end chain that integrates the customer's goals, tasks with the tangible features, functions, and content of the Web site. The model has significant implications for Internet marketers. By understanding the consumer's online goals and related tasks, the Web marketer is in a position to create a Web site that delivers value to customers and provides high usability for the tasks that online visitors want to perform. Since customer online goals represent the starting point for Web design efforts, this article has attempted to highlight the nature and types of goals that e-marketers might consider when planning what their Web sites should do in order to create online customer value.

KEY TERMS

Customer Services Life Cycle (CSLC): A framework that describes the stages (requirements, acquisition, ownership, and retirement) that a customer goes through when purchasing and using a product or service.

Goal-Directed Behavior: The concept that individuals are motivated to expend time and energy to achieve some desired objective (the goal). A significant amount of online consumer behavior is goal directed.

Means-End Theory: A theoretical framework based on the idea that consumers seek out or prefer specific products and product attributes because they serve as a *means* to achieve desired *end* states.

Online Customer Value: A customer's perceived preference for and evaluation of those Web site features and functions that facilitate (or block) the performance of the tasks that are instrumental in achieving the customer's goals associated with the Web site visit.

Online Goal: The customer's objective or purpose of the Web site visit.

Tasks: "The activities undertaken to achieve a goal" (Maguire, 2001).

Usability: "The extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use" (ISO, 1997).

User-Centered Design: An approach to the design of system interfaces that seeks to ensure technology matches users' needs and supports the tasks that users would like to perform.

Cyber–Identity Theft

INTRODUCTION

Internet technology facilitates "faceless" transactions. At the same time, a new set of risks arises. In this article, we focus on the Internet-related risks associated with identity theft. Specifically, our objectives are to explain electronic-based identity theft (i.e., cyber-identity theft) and to explore the impact of cyber-identity theft on consumers, businesses, organizations and public policies. Our article makes two specific contributions to the identity theft literature: (a) it explains identity theft as it relates to the Internet and (b) it defines key methods of cyber-identity theft.

BACKGROUND

We first present a brief background on this emerging issue. Identity theft is broadly defined as the practice of using the identity of another to obtain credit (Sovern, 2004). Specific to U.S. federal law[1], identity theft is the "unauthorized use of another person's identification with the intent to commit another crime" (U.S. Code, Chapter 47, Title 18). Any individual who violates federal identify law and obtains money or property valued at or over $1,000 over a one year period may be sentenced to up to 15 years in prison.

In extant studies, attention primarily focuses on legal aspects and avenues for future legislation and policy. Linnhoff and Langenderfer (2004) review the Fair and Accurate Credit Transactions Act (FACTA). As the 2003 Act currently stands, most of the financial risk is borne by the victim (Sovern, 2004). Simply stated, identity theft victims bear most of the costs of reestablishing their "good names" after an identity theft. Notably, some purchases made by identity thieves show up on the victim's credit report and may be difficult to remove. Critics claim that, at present, the law provides insufficient incentives for financial institutions to take preventative measures against identity theft (Lee, 2001; Sovern, 2004). Sovern (2004) argues that consumers should stand up to credit bureaus and creditors who fail to delete fraudulent transactions from victims' credit reports.

Identity theft has the potential to wreak havoc on consumers' social and financial lives. At present, U.S. consumers have rather extensive access to public records (e.g., birth certificates, marriage certificates, tax documents), and consumers may be reluctant to sacrifice these rights. For instance, a survey conducted at Washington State University finds that a majority of individuals in the state of Washington support continued individual access to public records (Cuillier, Passey, & Hinz, 2003), despite the presence of identity theft. Similarly, business organizations do not welcome laws concerning their security policies (Knowledge at Wharton, 2005; Lacey & Cuganesan, 2004).

Next, we explore how identity theft relates to the Internet. *Cyber*-identity theft involves the use of electronic (e.g., via the Internet) means to carry out any form of identity theft. Close et al. (2004, p. 48) define cyber-identity theft as "the online or electronic acquisition of personal information with the purpose of utilizing such information for deceitful activity either on the Internet or offline."

Currently, cyber-identity theft is the most common Internet-related crime reported to the U.S. Federal Trade Commission (FTC). Victims of cyber-identity theft often suffer socially, psychologically and financially. Businesses and organizations are also victimized by this type of Internet crime.

Academic research is beginning to emerge on the topic of identity theft; however, to date scholars have published relatively few studies specific to Internet-related identity theft. Close et al. (2004) present an overview of cyber-identity theft with an emphasis on the implications for public policy. Policy and online behavior must change to combat cyber-identity theft. Internet-related identity theft is, in part, a function of an individual's risky online transactions (Milne, Rohm, & Bahl, 2004). Consumers' online behaviors may increase or even decrease the risk of becoming a victim of identity theft (Milne et al., 2004). Each consumer differs in the extent to which he or she protects his or her online identity and privacy. This difference may be attributed to the Internet user's demographics, attitude, and online behaviors (Milne et al., 2004).

CYBER-IDENTITY THEFT: KEY METHODS

Common methods of cyber-identity theft include: (a) phishing, (b) employee abuse, (c) mass rebellion, (d) disposal, (e) pranking/posing, (f) spyware, and (g) a scam within a scam. In Table 1, we define and provide examples of these methods. In the table, we use the term *broad scope* to refer to methods that have a negative, simultaneous effect on *multiple* consumers. Broad scope methods often make use of automated tools to facilitate identity theft (McCarty, 2003). In the table, we also describe "narrow scope" methods, which refer to methods that affect *individual* consumers (see Table 1).

Table 1 reveals a number of implications for policymakers; in order to protect consumers it is necessary: (a) to inform consumers about related dangers, (b) to provide safe environments for conducting electronic exchanges, (c) to assist victims, and (d) to implement public policy remedies and legal action. Unfortunately,

Table 1. Key methods of cyber-identity theft (Reprinted with permission from Enhancing knowledge development in marketing*, published by the American Marketing Association, edited by Bernhardt, Boles, and Close, written by Zinkhan, and Finney, 2004, pp. 48-55)*

Method	Definition	Example
Broad Scope*		
Hacking	Breaking into a computer database personal or business/organization/government	Wiring another's funds
Employee Theft	Employees utilizing or selling their company database for fraudulent means or without permission	Pilfering office files
Dictionary Programs	Automatically search all dictionary words for a possible password	Checking all works A to Z
Spyware	Software, often disguised, that may install itself with other legitimate or free downloads, to collect personal information	Weather-bug, Gator
Skimming	Copying information from a magnetic strip, and subsequently using the information to create a duplicate	Credit cards
Tapping	Monitoring computer systems to extract key information	Restaurant computers for credit card numbers
Pre-approved	Taking another's per-approved credit and SSN to open an unauthorized account	Mailed credit card offers
Mass Rebellion	Peer-to-peer networks built to exchange music or media files. At present, the future of such sites is unclear, and some users are being taken to court (e.g., by the music and film industry)	peer-to-peer sites (e.g., Kazaa, Napster)
Narrow Scope		
Carelessness	Prowling for users who use their computer or Internet access carelessly	Saved Passwords, logoff may not go through
Disposal Abuse	Obtaining information from another's disposed / sold hardware or software	Dumpster-diving, leaving personal information on old computer via junk-yard, garage sale
Autofill Abuse	Obtaining information from computer programs that "memorize" and complete typing on another's machine	Type in a few letters until cleared
Phishing	Establishing a fake Web site designed to look like a company's actual site or sending official-looking messages	"Official" request for SSN
Phony	A phony machine that copies personal information	ATM
Pre-text	Calling a prospective victim, posing in an attempt to obtain personal information	Bank. Credit card company
Posing	Unrightfully representing another individual	Bank rep., computer exams
Pranking	Posing as another online to play a joke or for fun	E-dating
Fraudulent Job Posting	Posting a job that does not exist to collect personal information	"Manager Wanted: Apply Online"
Shoulder Surfing	Peeking for information as another enters it on a computer screen; physically watching passwords	Passwords, Account numbers
Intercepting	Receiving online traffic intended for another	IM (Instant Message), E-mail

the number of cyber-scams is limited only by the considerable imagination of cyber-thieves. Thus, cyber-crooks constantly invent new ways to steal identities. As a result, consumers and organizations should constantly invent new ways to protect consumers' identities from the creative crooks and cyber-crooks.

FUTURE TRENDS

From a business perspective, organizations implement a strategy of customer relationship management (CRM) to collect, maintain, and use information on their current customers. Accurate customer information and timely retrieval of this information is an asset and a source of competitive advantage for a firm. Organizations frequently exchange consumer information among themselves, in order to create databases pertaining to customers' purchasing habits and lifestyles. While these databases may assist organizations in becoming more "customer-centric" (e.g., by providing personalized purchase recommendations, by electronically storing shipping addresses, by remembering consumer preferences), this "everyday" business practice also creates risks because such databases increase the probability of large-scale identity theft.

Organizations are also potential victims of cyber-identity theft. For example, an identity thief may acquire a company's CRM database and contact the customers under false pretenses. As a result, the onus is on customers to decide whether or not electronic communications emanate from legitimate sources. Consumers need not be vulnerable (Langendefer & Shimp, 2001). In the future, customers may look to third-parties to provide authentication. In many aspects, combating cyber-identity theft is a cost of modern business (Hemphill, 2001). In the age of information technology, identity theft and customer privacy are likely to remain major concerns (Thompson, 2002).

CONCLUSION

For 21st-century consumers, cyber-identity theft is a fact of life; identify theft is unlikely to disappear in the foreseeable future. Human identification is often based on an association of data with a given human being (LoPucki, 2001). This is a key premise of human identity theory (LoPucki, 2001). We note that understanding human identity as it relates to the Internet is much more complex. On the one hand, consumers can harness new technologies to create multiple identities via chat rooms, e-dating services, e-mail, and other virtual spaces (Close et al., 2004). On the other hand, all Internet users must be mindful of the potential downside of going online and exchanging electronic information.

KEY TERMS

Cyber-Identity Theft: The online or electronic acquisition of personal information with the purpose of utilizing such information for deceitful activity either on the Internet or off- line.

Disposal: Even disconnected computers may lead to cyber-identity theft. Careless handling or disposal of discarded computers can lead to identity theft. Furthermore, disposed hardware and software may lead to cyber-identity theft. If a user fails to take precautions such as data deletion or physical destruction of a machine, the data are readily accessible for the next user—whoever may find it.

Employee Abuse: Employees, especially those employees who believe that they are treated unjustly, may provide the data necessary for cyber-identity theft. With e-mail and databases full of consumer information, an employee or other insider can pass spreadsheets along to thieves. Employees may divulge personal information unintentionally, or intentionally. Also related to cyber-identity theft and the workplace is the possibility of phony job-listings online in order to obtain consumer information.

Hacking: Hacking, or entering another's computer, is a common method of the cyber-identity thief. Saunders and Zucker (1999) note that the most common (cyber) identity theft tactic is to hack into a computerized database and take personal information. Hacking has evolved to "phishing."

Mass Rebellion: Cyber-identity thieves may use decentralized, mass rebellion sites. These peer-to-peer environments (e.g., Kazaa Media Desktop) allow individuals to share files over the Internet. Cyber-identity thieves may use such peer-to-peer networks to install virus software, which records data such as Web site visitation and any information that is entered to a nonsecure site.

Phishing: With phishing, identity thieves establish a fake Web site designed to look like a company's actual site; unsuspecting customers are drawn to the site and asked to disclose personal information.

Pranking/Posing: Cyber-identity theft may also include seemingly "lighthearted" pranks—a less sinister form of identity theft. Such instances have occurred where the e-prankster registers (complete with photograph) a friend or colleague to an e-dating site (e.g., match.com) (Close & Zinkhan, 2004). Phony e-dating profiles may be a result of an online prank, causing false expectations for interested e-daters. Posing as another on instant messenger (IM) is another prank where users misidentify themselves- often to obtain information not privy to the cyber-identity thief.

Scam within a Scam: Our final mention of methods of cyber-identity theft involves a scam within a scam. For instance, a cyber thief may pose as an attorney or a governmental employee and mass e-mail a database of past identity theft victims, requesting personal information for evidence to assist them in a potential court case. In this way, some theft victims may be victimized in more ways than one.

Spyware: Personal information is sometimes collected via spyware. Spyware is a group of programs that are (sometimes inadvertently) downloaded along with legitimate or free programs (e.g., Weatherbug, Gator). Spyware then runs in the background and functions whenever the Internet user is online for market research purposes.

ENDNOTE

Data Warehousing and Data Mining Lessons for EC Companies

Neerja Sethi
Nanyang Technological University, Singapore

Vijay Sethi
Nanyang Technological University, Singapore

INTRODUCTION

Internet companies are now in the second stage of evolution in which the emphasis is on building brands (Campman, 2001) and retaining customers rather than just transactions. There is also an imperative for multidimensional Web performance monitoring (Earls, 2005) and a continual fine-tuning of sites for optimal navigation, increased stickiness and transactional efficiency. Such research as the relationship between customer profiles and navigational characteristics (Garatti, Sergio, Sergio, & Broccab, 2004) and techniques for seamlessly aggregating Web data with corporate data (Wood & Ow, 2005) also testify to the importance of holistic data analysis for knowledge discovery. The technologies that are becoming critical in this fight for customer retention are data warehousing, data mining and customer relationship management.

This article presents two case studies, one on data warehousing and the other on data mining, to draw some very specific lessons about management support, organizational commitment and overall implementation of such projects. These lessons complement past recommendations that these technologies are more about organization change (Kale, 2004), about a single unified view of the business and, ultimately about building a shared data model of the enterprise.

We start with a brief overview of data warehousing and data mining. The two cases are discussed next, using a similar analytical structure to facilitate comparison among them. In the conclusion, we describe the key lessons learned from the two cases and implications for future research.

Data Warehousing and Data Mining

Data Warehousing

Data warehousing is the process of creating an integrated and summarized copy of an organization's transactional data for the purposes of data analysis and decision support. The Data Warehousing Institute (TDWI) has played an active role in highlighting and popularizing best practices in the industry. It has produced a Data Warehousing Roadmap (Barquin & Edelstein, 1997) to guide would-be implementers. Another methodology exists, called the Metis Methodology (Kelly, 1997), developed by Sean Kelley, founder of the Data Warehouse Network. This has been further refined into the Hadden-Kelly Methodology.

A key aspect of data warehousing development is rapid application development (RAD) that is best used when it is impossible to fully specify the system's requirements accurately. However, this does not mean that no part of the system is fixed. Key high-level components, such as warehouse architecture, data model, data dictionary and other logical and conceptual components, should remain reasonably stable, standard and well defined. What evolves continuously are the applications and the data in the warehouse. A useful metaphor is that of shipbuilding, where the design of the hull remains immutable, but various ships (e.g., aircraft carriers, cargo haulers) are built on the same hull. Benefits of the rapid application development approach include the ability to manage the inherent risk of a data warehousing project, the ability to prioritize resources and the continuous delivery of business functionality.

Another way to mitigate risks is to build data marts, which are essentially smaller, more focused data warehouses that cater to the needs of a single business line or function. Data marts are often marketed as quick fixes to an organization's data management problems, and many organizations implement them as part of a longer-term plan to roll out a data warehouse.

Data Mining

Once an organization has an integrated data warehouse, its members can use a variety of tools, such as online analytical processing (OLAP) applications and SQL, to query and analyze the data (Inmon, 1996). OLAP refers to the technique of performing complex, multi-dimensional analysis in an ad-hoc manner and ranges from basic navigation and browsing (often referred to as "slice and dice") to more complex modeling and calculations. SQL analysis requires users to have a requirement or hypothesis that provides a clear and bounded focus to the data exploration.

Data mining can be done in a variety of ways, and these are often applied jointly (Chan & Lewis, 2002). Association is a method that aims to find affinities among records in a data set and is used in applications such as Market Basket Analysis. Sequential patterns are used, among other things, to detect buying patterns of individual customers. If records in a data set have been divided into various classes, classification can be used to describe the characteristics of each class. If, on the other hand, the records are not classified, clustering can be used to segment the records according to some criteria. Some of the mathematical techniques employed include rule induction, artificial neural networks, fuzzy logic and decision trees.

DESCRIPTION OF PROJECTS

Case: Data Warehousing

Company Overview

The project was implemented at the regional center of a multinational bank that employs 30,000 people globally in more than 50 countries. Its regional center was started in 1859, employs more than 2,000 people and provides the full range of Consumer Banking, Corporate and Institutional Banking and Global Markets products and services. The bank offers a complete range of Internet banking services, where users can set up personalized home pages, choose financial consultants, open online accounts, and select a variety of banking information.

Goals and Scope

The bank turned to data warehousing due to the increasingly competitive environment that had resulted in thinning profit margins. It came to the conclusion that it had to identify its most valuable customers and leverage them to use a broader range of banking services. Developing customer profiles, one of the key drivers of Internet banking as well, was important. Moreover, the bank would also need to use data mining techniques to discern trends and forecast the success of its marketing campaigns.

But customer information was scattered among various departmental databases and it was difficult to identify and profile these customers. A system called customer information management (CIM), which was meant to give each customer a unique ID, existed side-by-side with the various departmental databases. However, not every department used it and customers had different IDs in different systems; thus, CIM was reduced to mapping its IDs to the IDs in the other databases.

The IT Department of the bank decided on a data warehouse package called *Collage*. It was decided that *Collage* would only hold the customer IDs from CIM. Data from various sources would first be mapped to a customer ID in CIM and then loaded into a separate database. The data would be transformed to standardize the naming conventions and then it would be stored in the data warehouse to allow individual applications and departments to pull out whatever data was required.

Project Development and Management

The objectives of the development process were fourfold: (1) to understand the data available, (2) to prove that banking indicators—for example, credit limits—could be integrated around customers, (3) to demonstrate inconsistencies in the current data, and (4) to create an all-encompassing data warehouse with a few data marts around it. These data marts would provide the necessary subsets of information required by individuals or groups and would be located in closer proximity to the users. The deliverables included a logical data model, a data dictionary, the physical database structures in the data warehouse, a sample set of data instances for validation purposes, a validation of the database schema and integration methodology, and an action plan to address any issues that arose.

Once the project was accepted, a task force was formed and given 4 months to develop the data warehouse. The project team decided to build a prototype to test the robustness and validity of the underlying assumptions. It spent a significant amount of time evaluating various hardware and software combinations. As a result, planning itself took 4 months and it was another 2 months before data could be loaded into the warehouse. A prototype containing data for the top 30 customers was evaluated and considered successful. Full-scale development followed, and it went smoothly, according to the schedule drawn up.

Implementation

Though the system was complete, no one came forward to use it! After a period of time, the Marketing Department showed an interest in it. But while their data mart contained customer details such as reference, revenue and balances, they required customer segmental information. Modifications, thus, had to be made, and to better articulate requirements, Marketing actually assigned its own staff member to the development team. In about 2 months, the data mart was redesigned according to new specifications. An important reason, beyond user involvement, why the IT group was able to modify the data mart quickly was because much time had been spent on planning the first iteration of the data warehouse project.

After the success of the Marketing data mart, other departments began to come forward. Subsequently, two other data marts were created relating to customer profitability and the tracking of customer liability. Aggregated weekly and monthly transaction-level information was also added to the data warehouse. It is worth noting that since its inception, the main logical data model has remained intact. This success can be attributed to the detailed planning done by the development team and the selection of the right tools for data warehousing.

Case: Data Mining

Company Overview

The data mining project was undertaken by the regional headquarters of a prominent international bank with European roots. In Asia, the bank has a 175-year history and in the country where the project was implemented, it is the oldest foreign bank.

The bank has one of the most sophisticated Internet banking facilities, with all customers given a personal handheld portable device that generates dynamic passwords for added second-level access authentication. It has also rolled out a number of online products catered to high net-worth individuals and niche segments.

Goals and Scope

The data mining project was driven by two changes. First, the business model of banking was changing from product- and revenue-centered to customer- and profit-centered. This transformation required implementing new technology to support the changes in business processes. Second, the role of managers had changed with the times and they were now required to think multi-dimensionally, and not focus only on their own narrow lines of business. Hence, rather than rely on dedicated analysts to provide them with reports, it was more effective for them to do their own analysis. This had not only freed up the analysts but also managers who could now create tailored reports suited to their needs rather than be tied to the same standard reports every financial period.

Reporting within the bank had to change to keep abreast of these changes, and business intelligence applications, which displayed information multi-dimensionally, were needed urgently. Combined with the knowledge that there were "sweet spots" of information (the most valuable bits of information) available in the company's data that management had to get at to improve its decision-making, the stage was set for the bank to implement data mining.

Project Development and Management

The initial champion for the project was the Finance department. Financial analysis had primarily focused on the production of routine reports and discovery of discrepancies between reports. This department saw only a limited slice of the business and, hence, could only guess at what was driving the discrepancies. This meant that the ROI on analysis was very low and managers could not receive prompt replies to ad-hoc queries.

The solution proposed was a redesign of the report data as five data cubes. These cubes included the multi-dimensional income statement and balance sheet, the profit drill-down statement, the financial ratio listing and the cash flow statement. The redesign allowed any manager to perform most analyses quickly and easily. Moreover, managers could explore previously unconsidered business angles, thereby increasing productivity.

Implementation

The development team began by creating a prototype. They chose the profit drill-down cube for this project and were given a time frame of 90 days. The cube was to have dive dimensions and two reports—income stream and costs—both to be analyzed by markets and products.

Once the application was successfully implemented locally, the next step was to roll it regionally. This meant educating users to first change their view of data from a geographic one to a functional one and then implementing the cubes in their offices. The team began by building small applications and, as users became familiar with the technology, their information needs expanded, resulting in a steady increase in the applications, as well.

The throughput of the Finance Department increased dramatically as a result of the simplification of the analysis process. Tedious manual steps, such as re-keying data from paper reports into spreadsheets, were eliminated. Work changed from analysis and report preparation to information distribution. In fact, the department was able to provide Relationship managers with "sweet spots" of data. Furthermore, as a result of the simplification, some analysis tasks could be offloaded to other departments. Relationship managers were given the ability to navigate the data cubes and they strongly promoted multidimensional analysis within the bank so users would be able to create and view reports according to their individual preferences.

IMPACT OF PROJECTS

In the data warehouse project, the bank was able to reduce the operational costs involved in preparing the quarterly internal report, improve the accuracy of information available to the group credit department and leverage the investments in its existing CIM system. Bank processes became more effective, knowing the profitable and unprofitable market segments and having customer profiles. The bank also realized that, contrary to its thinking, corporate customers were profitable, trade financing was much more profitable than cash transactions, and customers' offices in the United Kingdom gave much lower margins compared to the offices in Asia-Pacific region.

In the data mining project, the use of five multidimensional cubes had a significant impact on the bank's operations; the regional controller, in fact, commented that they had "… cut analysis time from man-days to minutes." Key trends in the bank's operations were revealed and managers were able to compare important ratios against industry benchmarks. The ability to drill-down to the detailed data enabled users to discover the source of deviations and, hence, improve their forecasting and operational planning. The new tools also aligned the activities of the relationship managers with corporate goals. Previously, they concentrated on increasing market share rather than on profitability. Now, the data cubes gave managers the capability to measure the profitability of customers and of marketing campaigns and, thus, better adapt their strategies.

Key Lessons Learned

Management Support

One of the key lessons is how the level of management support affects the design of the technology solution. In the case of the data warehouse implementation, the project was mainly driven by the IT department, which was its champion. Despite rallying calls by senior IT management, business support was not very forthcoming, as most functional groups were too occupied with other projects. Since the warehouse was designed without any functional area in mind, it turned out to be "business-unit neutral." This apparent lack of design specificity turned out to be a blessing, as none of the business units felt threatened by it. As a result, they were all willing to share data, something they might not have done for the fear of their data being owned by the championing unit in case the project had been driven by a single business unit.

It is thus clear that in order to avoid conflicts and reduce business anxiety about proprietary data, a common, flexible, neutral platform is essential, even though it comes as the price of a generic design that requires further customization for use. Brick-and-mortar companies that have a significant online presence might have to adopt such solutions as they move towards integrating online and offline data with the goal of a single, unified view of the customer. On the other hand, Internet startups, by virtue of being nimble and having focused, inherent advantages that allow them to exploit disruptive innovations (Carr, 2005; Bower and Christensen, 1995) will likely deploy more tightly integrated solutions. Empirical research can look at this issue further.

User Involvement and Support

The data mining project had the clear support and backing of the users. It was keenly sponsored by the Finance team and built to its specifications. Therefore, there were no delays in deployment and the application met users' needs fully. Thus, both design and adoption were much easier because of user involvement and user ownership. In line with past results on IT adoption (Jiang, Chen, & Klein, 2002), our study shows that users should play a significant role in such projects right from the start.

Implementation: Formal Methodology

One of the striking commonalities in both cases was the adoption of formal guidelines. Both used formal methodologies (Barquin & Edelstein, 1997) and, as recommended, assessed users' needs, evaluated competing products, developed prototypes and deployed the projects as small scale whose scope was only enhanced once users were comfortable and also when success was evident to the organization. The small-to-scale approach was quite explicit for the data mining project that started with the Finance department and then expanded to other groups. For the data warehouse project, the formal planning took a long time, as its aim was to create a broad and encompassing platform. Such a design allowed a smooth integration of smaller data marts that were created later for functional areas. Thus, the adoption of formal guidelines, such as spending enough time on analysis and design, paid off in both cases. These considerations are important lessons for Internet companies, where time is critical due to the high-velocity environment in which they operate (Rajgopal, Venkatachalam, & Kotha, 2002). Still, they need to realize that architectural platforms, such as data warehouse projects, require a critical amount of time for an effective long-term solution.

CONCLUSION

Creating large, customer-focused platforms is a tough implementation challenge—as many as 60%-80% fail to achieve their objectives (Kale, 2004). The two cases described here outline how user and top management support can affect the design of data warehouse and data mining projects. They show trade-offs in design—generic, flexible solutions or a tightly focused design centered on the needs of a functional unit. The benefit of adopting a formal implementation methodology is also demonstrated. Internet companies can learn from some of these lessons as well as from past empirical studies, such as Hwang et al. (2004), as they now move into a new era of electronic commerce with customer-focused strategies and platforms.

KEY TERMS

Data Cube: A data cube is a type of multidimensional matrix that lets users explore and analyze a collection of data from many different perspectives, usually considering three factors (dimensions) at a time.

Data Dictionary: A part of a database that holds definitions of data elements, such as tables, columns and views.

Database Schema: The physical model or blueprint for a database.

Drill Down: A method of exploring multidimensional data by moving from one level of detail to the next.

Logical Data Model: A logical data model is an abstract representation of a set of data entities and their relationship, usually including their key attributes.

Prototype: A preliminary type, form or instance of a system that serves as a model for later stages or for the final, complete version of the system.

Rapid Application Development (RAD): An iterative prototyping development approach, where requirements and analyses are continuously refined throughout the life cycle of a project.

Deception in Electronic Goods and Services

Neil C. Rowe
U.S. Naval Postgraduate School, USA

INTRODUCTION

Deception is a frequent but under appreciated aspect of human society (Eckman, 2001). Deception in electronic goods and services is facilitated by the difficulty of verifying details in the limited information available in cyberspace (Mintz, 2002). Fear of being deceived (often unjustified) is in fact a major obstacle to wider use of e-commerce and e-government by the public. One survey reported consumers thought fraud on the Internet was 12 times more common than offline fraud, and 3 out of 5 people thought their credit card number could be stolen in most online transactions (Allen, 2001); both are overestimates. We assess here the nature of the deception threat, how deception can be detected, and what can be done about it.

BACKGROUND

Deception is common in many areas of human endeavor (Ford, 1996). Deception is in fact essential to the normal operation of business, law, government, and entertainment as a way to manipulate people (Nyberg, 1993). But there is a complex boundary between acceptable deception and unacceptable or illegal deception.

Deception can occur with either the purveyor (offeror) of goods or services or with the customer (buyer), and it strongly affects trust in a transaction (Friedman, Kahn, & Howe, 2000). Some examples in online activities include:

- A customer provides a fake credit card number for a transaction.
- A Web site takes a customer's money but never provides a promised good or service.
- A Web site solicits a customer's e-mail address for spamming them but claims it is for potential "problems with your order".
- A Web site incorrectly says they can legally sell you a drug without a doctor's prescription.
- A customer with a grudge posts false health reports about a product on a Web bulletin board.

Usually the motivation for deception in goods and services is financial gain, but other reasons include revenge and self-glorification.

Unfortunately, the rather anonymous nature of cyberspace encourages deception. One problem is that the communications bandwidth, or amount of information that can be transmitted between people, is considerably less than in face-to-face human interactions, even with videocameras. Studies indicate that people are more deceptive the smaller the bandwidth (Burgoon, Stoner, Bonito, & Dunbar, 2003); for instance, people are more deceptive on the telephone than in videoconferencing. The detection of deception in online interactions is made difficult by the absence of many useful visual and aural clues; careful studies of consumer behavior have confirmed this difficulty (Grazioli & Jarvenpaa, 2000). This raises problems for electronic commerce and government.

DECEPTION METHODS AND COUNTERMEASURES

Categories of Deception in Electronic Goods and Services

We can distinguish five major categories of deception in online transactions: Puffery or overstated claims, insincerity of promises or claims, trespassing, masquerading, and fraud (Grazioli & Jarvenpaa, 2003). Most instances happen with the World Wide Web, with some occurring in e-mail and other uses of the Internet.

Puffery includes mostly advertising since it rarely accurately summarizes the merits of a product or service. Deceptive advertising is encouraged by the nature of online interaction: It is hard for a customer to know with whom they are dealing. An impressive Web site is no guarantee of a reliable business, unlike an impressive real-world store or shop. Furthermore, the customer cannot hold and touch the merchandise, and the images, audio, or video provided of it are typically limited. So it is tempting for an online purveyor to make unsupportable claims. Puffery also includes indirect methods such as a Web site for a children's television show that is designed to sell a particular toy, or people who endorse products in online discussion groups without revealing they work for the purveyor ("shilling").

Insincerity has many forms online. Many Web search engines list pages they have been paid to display but that are not the best matches to the given keywords. A purveyor can promise "extras" to a sale they have no intention of delivering, or a customer can promise large future purchases. Emotions can also be faked, even love (Cornwell & Lundgren, 2001). False excuses like "being busy" are easy to make on the Internet. Negative puffery, where a customer or other business says bad things about a product or service (Floridi, 1996), as for revenge or to manipulate stock prices, are another form of insincerity. And "Remove me from the mailing list" links can actually be scams to get your name onto a mailing list.

Trespassing is breaking into computer systems to steal its time, memory, or other resources, and is usually by deception. It is commonly associated with "hackers", people breaking in for fun, but is increasingly practiced by spyware, and by criminals to obtain staging sites for attacks on other computers (Bosworth & Kabay, 2002; Chirillo, 2002).

Masquerarding or "identity deception" is pretending to be someone that one is not. There are many forms online:

- Customers can steal passwords or identification numbers, then use them to steal goods and services.
- Purveyors can also pretend to be a different entity than they really are. This is facilitated by the lack of regulation of Web sites and their claims, and by the ability to give false return addresses in e-mail and false link text on Web sites.
- A serious problem of this type is "phishing", inviting or threatening people to induce them to visit a decoy Web site where they are asked to supply personal data such as credit card numbers and bank-account numbers for subsequent theft. An example enticement is to claim to be the government tax office needing information about a tax return.
- Counterfeit Web sites try to mimic familiar Web sites to steal from customers. Classic tricks are names confusable with those of well-known sites, like "googl.com" instead of "google.com", or numbers in the address instead of letters to prevent recognition.
- Both deceptive Web sites and deceptive e-mail can steal professional-looking graphics and fonts from legitimate sites and e-mail to look more convincing.
- A site may even "hijack" business from another by using the same Internet (IP) address, but this will only work for a short time before it is discovered and stopped.
- Data, such as credit card numbers could possibly be stolen from packets traversing the Internet, but this is becoming very difficult as many commercial sites now encrypt such sensitive data.
- Fake online documents are hard to detect, since most clues to forgeries like handwriting style and provenance are not available, but style inconsistencies can still help (Kaza, Murthy, & Hu, 2003).

The most serious electronic deceptions in goods and services are crimes of fraud (Boni & Kovachich, 1999; Loader & Thomas, 2000). McEvoy, Albro, and McCracken (2001) and Fraudwatch (2005) survey specific popular techniques. Unscrupulous Web purveyors can collect money without providing a promised good or service since it is easy to appear and disappear on the Web; fake charities are a notorious example. Purveyors may not feel much consumer pressure because it is hard for customers to complain about long-distance transactions. The Internet is well suited to many classic scams, notably the many forms of the "Nigerian letter" asking for money in the promise of receiving much more money in the future. Electronic voting is a special concern for fraud (Kofler, Krimmer, & Prosser, 2003).

The Ethics and Legality of Deception

Online transactions benefit from the trust of the participants. Deception subverts trust and makes online businesses less efficient because of the subsequent need to check credentials and promises. Because of similar costs to society in general, ethical theories usually claim that most forms of deception are unethical (Bok, 1999), and laws in every society identify some forms of deception as fraud legally. American law uses the doctrine of "implied merchantability" to say that a contracted good or service must be provided adequately or the money must be refunded. Waivers of responsibility that consumers must approve before proceeding on a Web site do not have much weight in court because consumers rarely can be said to give informed consent. But there are many other issues; see the many Internet-related publications of the U.S. Federal Trade Commission (FTC, 2005).

Detecting Deception in Goods and Services

Studies have shown that most people are poor at detecting deception (Ford, 1996). Thus in cyberspace with its limited bandwidth, deception is even more of a problem. Most training of people (such as law-enforcement personnel) to recognize deception in human interactions focuses on clues that are absent in cyberspace such as the visual ones of increased pupil dilation, blinking, and self-grooming, and vocal clues such as higher voice pitch, more frequent speech errors, and hesitation. However, some traditional clues to deception do apply to cyberspace (Zhou & Zhang, 2004), including:

- Short responses, concealing lack of knowledge;
- Increased use of negatives, concealing lack of knowledge;
- Overgenerality, concealing lack of knowledge;
- Errors in spelling, punctuation, or grammar, indicating lack of knowledge or a deliberate attempt to get past spam filters;
- Obvious random selections, indicating program-generated text;
- Overly quick responses, indicating preplanned strategies;
- Overly slow responses, suggesting ongoing planning;
- Increased hyperbole or abusive language, inducing emotional responses as decoys; and
- Increased irrelevance, offering misdirection.

All these are common in deceptive advertising, as in "Never need a proscription [sic] again with Viocks, the secret of celebrities [sic] long health!!!!" Here is a real phishing e-mail with deliberate randomness and both deliberate and accidental spelling and punctuation errors (and invisible "normal" text as camouflage for spam filters):

Besides "low-level" clues which reflect the difficulty of the deceiver controlling all their channels of indirect communication, cognitive clues reflect the difficulty of constructing and maintaining deceptions (Heuer, 1982; Whaley & Busby, 2002). Logical inconsistencies are the most important of these. The above example shows inconsistency between the e-mail address of the sender, their name, and the company they claim to represent; inconsistency between the two parts of the sender's name; and inconsistency between the company, the clickable link text "uxqydujs", and the site the link actually takes you to, www.qolkamdnt.com. The Web registry, www.whois.sc, reports that this site was registered in Baku, Azerbaijan, for only 21 days, so it is unlikely to be a reputable lender for mortgages in the United States, the country to which it was sent. In addition, it is logically inconsistent to solicit a mortgage and also say "Your application is approved."

Lack of links from reputable Web sites is another clue that a site is suspicious, and that can be checked with a Web browser. The cliché that "If it's too good to be true, it probably is" is always helpful. Techniques derived from crime investigations are helpful for detecting dangerous deceptions (MacVittie, 2002) including computer forensics (Prosise & Mandia, 2001) and criminal profiling (Wang, Chen, & Akabashch, 2004).

Responding to Deception and Preventing It

Because deception can occur in such a range of online activities, a variety of countermeasures should be considered:

- **Ignoring It:** Deceptive businesses and sites should not be patronized, and this is helped if they are not indexed or linked to, based on critical review. Ignoring works well against lesser deceptions.
- **Education:** Both customers and purveyors can benefit from learning about possible deceptions. For instance, people should know not to give their passwords or identification numbers to anyone, no matter what emergency is alleged. Posting of statements of "netiquette", or etiquette for the Internet, also can educate customers as to acceptable behavior.
- **Passwords:** To reduce identity deception by users, passwords can be required in accessing a resource such as a Web site.
- **Encryption:** To maintain data privacy, sensitive data like credit card numbers should be encrypted in files and in transmission on the Internet (Schneier, 2000). Most Web vendors implement this for transactions.
- **Signatures:** To authenticate a message (prove who it came from), an unforgeable electronic signature can be attached to it. This encrypts a complicated function of the contents of the message, and can be decrypted by the receiver to prove that the message came unmodified from the sender.
- **Intrusion Detection:** Trespassing that breaks through first lines of defense can be recognized by software called intrusion-detection systems (Proctor, 2001).
- **Third-Party Escrow:** Utilities like PayPal can manage contracts between customers and purveyors as a neutral third-party broker.
- **Protocol Design:** Deception in electronic commerce can be reduced with good "protocols" (scripts and rules) for interactions. For instance, interruption of an online purchase at any time should not

allow other users to see private information, and this can be aided by "cookies" and time limits on responses.

- **Reputation Management Systems:** eBay and a number of Internet businesses have buyers and sellers rate one another. Observed deception affects these ratings which are visible to future buyers and sellers (Yu & Singh, 2003). While there are ways to deliberately manipulate ratings, they are difficult.
- **Automated Deception Detection:** Some automated tools assess text for deception (Qin, Burgoon, & Nunamaker, 2004). Some tools eliminate advertising in displaying Web pages (Rowe et al., 2002).
- **Manual Web Site Assessments:** Several organizations rate Web sites (e.g., the U.S. Better Business Bureau's "BBB Online Reliability Program"). Adequately-rated sites get a "seal of approval" which they can display on their sites, but such graphics are easy for a malicious site to copy. Pacifici (2002) offers suggestions for rating sites yourself.
- **Getting Background on a Web Site:** The sites www.whois.sc and www.betterwhois.com provide information about who registered a U.S. Web site and where, its description, certification, and "blacklist status". Similar information is available for most countries; see www.iana.org/cctld/cctld-whois.htm
- **Alerting Authorities:** Deceptive electronic commerce should be reported to government or consumer agencies.
- **Legal Recourse:** Particularly bad cases of deception should be handled by the courts. But jurisdictional conflicts can occur when the parties are in different countries or administrative areas.
- **Counterattacks and Revenge:** Not recommended because they are usually illegal, risk escalation, and may attack an innocent target because of the difficulty of confirming identity in cyberspace. Counterattacks have been tried in the form of deliberately garbled files posted to music-sharing utilities (Kushner, 2003).
- **Defensive Deception:** One can deceive a deceptive user to entrap or monitor them. For instance, one can post fake credit card numbers online and see if trespassers use them. "Honeypots" (The Honeynet Project, 2004) are fake Internet sites that entrap trespassers to collect data about them.

FUTURE TRENDS

The suitability of the Internet and the Web to particular kinds of deception means that this phenomenon will be with us for a long time. But a variety of new technology will increasingly provide help in combatting it. Rating and information services will be increasingly available for Web sites and other Internet business methods, and operating systems will offer increasingly effective built-in protection against hidden attacks. Laws eventually catch up with new technology, so we expect that legal recourses will steadily improve as precedents are gradually made for cyberspace. How quickly the customers and purveyors will overcome their fears of being deceived is another story, however. It may just take time, much in the way that automobiles were not trusted by the public for a long time simply because new powerful technology often looks dangerous.

CONCLUSION

Deception is always a danger in electronic transactions involving goods and services. Much of the public is reluctant to buy or contract online for this reason. But quite a variety of methods can detect deception and, better yet, prevent it. Wider use of these methods, and greater familiarity with them, can build public trust in online transactions. Trust is a key, but complex issue for societies (Sztompka, 1999).

KEY TERMS

Deception: Conveying or implying false information to other people.

Fraud: Criminal deception leading to unjust enrichment of the deceiver.

Honeypot: A deceptive computer system that entraps trespassers into revealing their methods.

Identity Deception: Pretending to be someone or some category of person that one is not.

Intrusion-Detection System: Software for detecting when suspicious behavior occurs on a computer or network.

Netiquette: Informal policies for behavior in a virtual community, analogous to etiquette.

Phishing: Inducing people (often by e-mail) to visit a Web site that steals personal information about them.

Shilling: Making claims (pro or con) for something without revealing that you have a financial stake in it.

Signature, Electronic: A code someone supplies electronically that confirms their identity.

Social Engineering: Using social interactions to deceptively steal information like passwords from people.

Designing Service-Based Cooperative Systems

Colette Rolland
CRI, France

Rim Samia Kaabi
CRI, France

INTRODUCTION

The connectivity generated by the Internet is opening opportunities for services composition. As a consequence, organizations are forming online alliances in order to deliver integrated value-added services. However, due to the lack of methodologies and tools, the development of such composite services across organizations is usually ad hoc and raises a number of issues, especially in the identification, composition, and orchestration of services. The objective of this article is to propose a goal-driven approach to understand the needs of different organizations for a new added-value composite service, and to model the cooperative process supporting this service provision in a declarative, goal-driven manner. The goal model called a map is then used for service elicitation, composition, and orchestration. The article presents the approach and illustrates it with a distance learning cooperative service.

BACKGROUND

Web standards and distributed technologies and platforms allow the development of new business paradigms such as *virtual organizations* and *virtual enterprises* (Georgakopoulos, 1999). Within such paradigms, different organizations pool together their services to offer more composite added-value services made easily accessible through network technologies and the Internet.

The support for such new paradigms is offered by cooperative applications. By using an approach based on interorganizational business-process coordination, the cooperation between organizations is obtained by sharing, composing, and orchestrating services across networks. Such services, usually referred to as *e-services* or *Web services* (Casati & Shan, 2001), are exported from the different organizations involved in the cooperative application. Such an e-service corresponds to a semantically well-defined functionality that allows users and applications to access and perform tasks offered by back-end business applications. Then, the cooperative application consists of a set of distributed applications that integrate the e-services offered by the participating organizations. Such integration raises some interesting points regarding service identification and composition.

A composition of e-services addresses the situation when a client request cannot be satisfied by available e-services but by a composite e-service, obtained by combining a set of available component e-services. Composition involves two different issues. The first issue is related to the elicitation of the composite service itself and the identification of e-services that will enter into this composition. Whereas this first issue is requirements driven, the second issue relates to the means to express the coordination between the various component e-services of the composite service. The former is referred to as composition whereas the latter is referred to as orchestration.

Several recent works address the second issue. In Casati, Georgakopoulos, and Shan (2001), an e-service that performs the coordination of e-services is considered a meta e-service, referred to as a composite e-service that can be invoked by clients. In Fauvet, Dumas, Benatallah, and Paik (2001), a composite e-service is modeled as an activity diagram, and its enactment is carried out through the coordination of different state coordinators in a decentralized way through peer-to-peer interactions. In Mecella, Presicce, and Pernici (2002), the orchestration of e-services is addressed by means of petri nets. In Bultan, Fu, Hull, and Su (2003), an e-service is modeled as a mealy machine processing a queue of input messages into output messages. Finally, in Shegalov, Gillmann, and Weikum (2001), the coordination of e-services is obtained by an enactment engine interpreting process schemas modeled as state charts.

The first issue still remains largely unexplored. However, Hull, Benedikt, Christophides, and Su (2003) propose to classify composition into three categories: (a) the peer-to-peer approach, in which the individual e-services are equal, (b) the mediated approach, based on a hub and spoke topology, in which one service is given the role of process mediator, and (c) the brokered approach, where process control is centralized but data can pass between e-services. In Aiello et al. (2002), a way of composing e-services is presented based on planning under uncertainty and constraint-satisfaction techniques, and a request language, to be used for specifying client goals, is proposed. In Fauvet et al. (2001), an approach to model service composition is introduced in which a composite service is defined as an aggregation of other composite and elementary services, whose dependencies are described through a state chart. Finally, in Yang and Papazoglou (2002), the issue of service composition is addressed in the context of Web components as a way for creating composite Web services by reusing, specializing, and extending existing ones.

Despite these attempts, an overall approach for eliciting, distributing, and orchestrating e-services into cooperative applications is still lacking. There is undoubtedly a need for a methodological approach toward service composition and cooperative application development.

Based on this observation of the current state of the art, our position is that the interorganizational composition of services should be tackled in a requirements-driven manner. In this article, we introduce a requirements-centric approach to understand the needs of different organizations that want to develop a cooperative information system implying service composition. We propose to use a goal-driven approach to (a) elicit functional requirements for a cooperative interorganizational process, (b) identify services that should be provided by each organization, and (c) design the coordination between those services to achieve the purpose of the cooperative process. The article presents the approach and illustrates it with an e-learning cooperative application.

MODELING THE COOPERATIVE PROCESS WITH MAPS

In this section, we introduce the map representation formalism (Rolland & Prakash, 2000) to model a process in goal and strategy terms, and illustrate the use of a map to model the cooperative process to provide distance learning in a virtual university. The map formalism has been practically validated in a number of large professional projects such as the FUSE project to model the business processes in the financial branch of Renault (Nurcan, Etien, Kaabi, Zoukar, & Rolland 2004), the ELEKTRA (Electrical Knowledge for Transforming Applications) project to conduct a change project (Nurcan & Rolland, 1999), and for the alignment of an Enterprise Resource Planning (ERP) functionality to the needs of Société Nationale des Chemins de Français (SNCF) (the French national railways company; Zoukar & Salinesi, 2004).

Introducing the Map

A map is a labeled, directed graph (Figure 1) with intentions as nodes, and strategies as edges between intentions. The directed nature of the graph shows which intentions can follow another. An edge enters a node if its strategy can be used to achieve the corresponding intention. Since there can be multiple edges entering a node, the map is capable of representing the many strategies that can be used for achieving an intention.

An intention is a goal to be achieved by the performance of the process. Each map has two special intentions, start and stop, to respectively start and end the process.

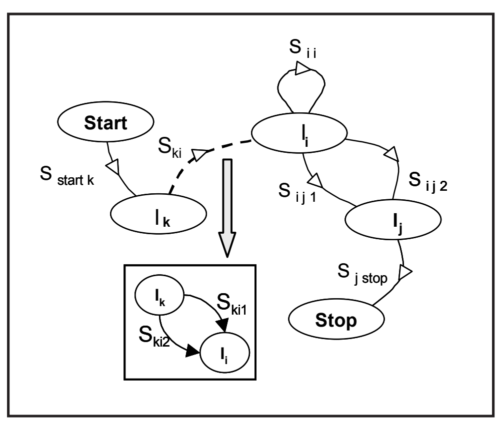
A strategy is an approach, a manner to achieve an intention.

A section is the key element of a map. It is a triplet $<I_i, I_j, S_{ij}>$ and represents a way to achieve the target intention I_j from the source intention I_i following the strategy S_{ij}. The strategy S_{ij} characterizes the flow from the source intention I_i to the target intention I_j, and the way I_j can be achieved once I_i has been achieved. Thus, each section of the map captures the condition to achieve an intention and the specific manner in which the process associated with the target intention can be performed.

It can be noticed that in general, a map comprises several paths from start to stop. This is due to the fact that (a) there might be several threads between a couple of intentions and (b) different combinations of sections can form different paths between two nonadjacent intentions.

Several strategies between a couple of intentions are usually related by an and/or relationship, with one or several of the set being applicable in a given situation. In cases of an exclusive *or* relationship, it is possible to bundle the set of alternative strategies as shown in Figure

Figure 1. A map



1 with the section $<I_k, I_i, S_{ki}>$ (the bold dashed line). This section is a bundle of $<I_k, I_i, S_{ki1}>$ and $<I_k, I_i, S_{ki2}>$, as shown in the figure.

The Example Case Map

We consider a European virtual university called e-U aiming to support the distance learning of students geographically distributed over Europe. E-U is a result of the alliance between universities in different European countries who want to cooperate to offer to European students a more competitive IT program than any of those that they currently, individually provide. E-U will take advantage of Web technology to develop an e-learning application as a composite service reusing local services such as university registration and diploma delivery.

In order to figure out what the requirements for the cooperative process were, an e-U committee composed of faculty, and administrative and pedagogical experts from the different partners' universities met together and modeled the e-learning map shown in Figure 2. They started by identifying the goal of the cooperative process and decided that it should be to provide a European IT program to students. Then, they brainstormed to identify the subgoals to be achieved to get the global goal achieved, and identified four of them, namely, to offer a course catalogue, manage course registration, teach courses, and validate courses, as shown in Figure 2. Thereafter, reasoning about the different manners to achieve these goals lead to the identification of a number of strategies, resulting in the map in Figure 2.

For example, since offering a course catalogue is an intention, the ways in which the course catalogue can be constructed become strategies for its achievement. This is shown in Figure 2 by the four strategies (a) from scratch or by reuse, (b) by adaptation, (c) by inspection, and (d) by evolution.

The first strategy is a bundle consisting of the from-scratch and reuse strategies; the former consists of building the catalogue from nothing, whereas the latter reuses some existing courses to define the new ones. These strategies are enacted by course authors.

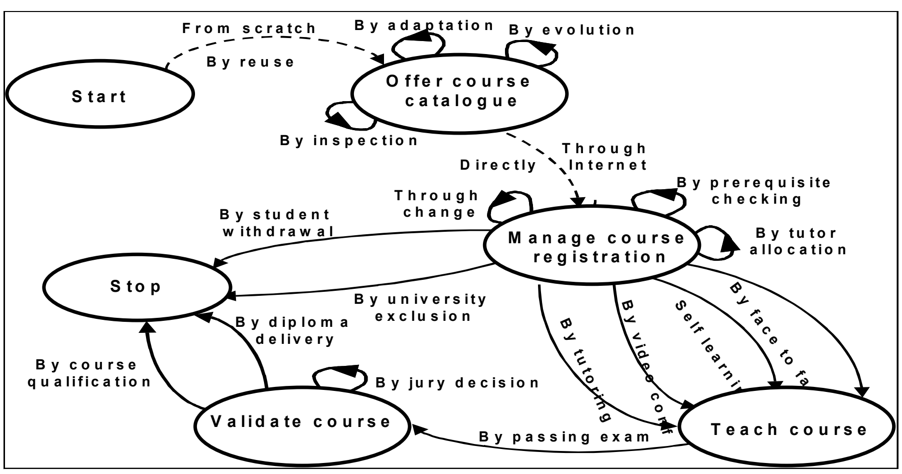
The inspection strategy reflects the decision of the e-U committee members to assure the quality of the courses offered to students, and to delegate this responsibility to a scientific committee.

The e-learning program can be modified or evolved according to the requirements of both course authors and the scientific committee. This is respectively modeled through the adaptation and evolution strategies. Any adaptation or evolution requires the validation of the scientific committee before the updated program is offered to the public.

At anytime, the curriculum can be removed by the scientific committee. This is shown in Figure 2 by the curriculum-withdrawal strategy that directly connects the intention to offer a course catalogue to the stop intention.

There is only one thread between the intentions to offer a course catalogue and to manage course registration that uses the Internet or direct strategy. This strategy is a bundle consisting of the Internet and direct strategies, which both allow students to register. The decision was to let students decide the university where they would register in and get their degree from. However, each of the e-U participating universities must provide the facilities for the student to register, access course material, attend examinations, and get the degree. Of course, the facilities provided to the student for distance teaching, which means the acquisition of knowl-

Figure 2. The e-learning map



edge and skills through mediated information and instruction, must respect the standards of distance learning set up by the scientific committee. For instance, tutoring shall be provided.

Managing course registration is the second key intention of the map. It can also be achieved using three other strategies: (a) through change, (b) by prerequisite checking, and (c) by tutor allocation.

The through-change strategy corresponds to the fact that students are allowed to change their selection of courses at least during a certain period. In order to ensure that students register for a course that they are able to follow, there is a check of the ad equation between the course requirements and the student profile. This is modeled by the prerequisite-checking strategy.

The university has the responsibility to affect tutors to e-learning modules and to remunerate them according to the number of students they tutored. This is shown in Figure 2 by the tutor-allocation strategy.

For sake of space, we leave the reader to interpret the remaining parts of the map. Also see Rolland and Prakash (2000).

It can be seen that the map allows us to represent the cooperative process in intentional terms: through intentions and strategies to achieve them. Therefore, the partners involved in the cooperation can reason on what they want to achieve and why without being bored with the details of how to do it. The directed form of the graph highlights the precedence relationships between intentions, therefore providing the process view of the expected cooperation in a declarative manner. Overall, e-U partners can discuss in their familiar terms and not be bothered by the technology that will be used to make the map work. Besides this, partners can easily change map intentions and strategies, add new strategies, and remove others during the design process itself and also during its evolution over time.

In the next section, we will discuss how the map serves as the basis for technical development using Web technology.

DESIGNING SERVICE COMPOSITION

The overall approach to develop the application by service composition and orchestration comprises four steps to (a) identify the services provided by the virtual organization, (b) specify these services, (c) identify legacy e-services, and (d) orchestrate their composition at run time. For sake of space, we present and illustrate briefly the three first steps. A detailed presentation of the approach including guidelines to perform the activities of the four steps can be found in Kaabi, Souveyet, and Rolland (2004).

Step 1: Identifying Services from the Map

The e-learning map was drawn in a business perspective. However the map-representation formalism has been designed to provide a means to combine in a single representation the business viewpoint and the system viewpoint. In other words, a map provides two faces: one for understanding the business viewpoint, and the other for the system viewpoint (Salinesi & Rolland, 2003). In order to establish a direct coupling between the business goals and the system functionality, we propose to associate each section of the map to a software service.

Applying this rule to the e-learning map leads us to identify 20 system services, each of them corresponding to a section of the map. Table 1 shows four of them related to sections S1 to S4 dealing with the achievement of the intention to offer a course catalogue.

Step 2: Defining Services

Once the services have been identified, their functionality shall be specified. We propose a scenario-driven approach inspired by the L'Ecritoire method and tool (Rolland, 2002; Rolland, Souveyet, & Ben Achour, 1998), which is part of the use-case theory. L'Ecritoire is based on a bidirectional coupling between goals and scenarios. In the forward direction, a scenario is seen as a concretization or realization of a goal, whereas in the backward direction, a scenario serves to discover subgoals of the initial goal. Scenarios are textual scenarios written in natural language. L'Ecritoire supports their conceptualization through linguistic analysis and interpretation, and provides two types of rules to (a) transform and complete a scenario (Rolland & Ben Achour, 1998) and (b) reason on the scenario contents for deriving subgoals, therefore helping to explore the functionality,

Table 1. Services underlying sections S1 to S4 of the e-learning map

Code	Service	Service description
S1	Course catalogue construction service	This service aims to help the different authors to construct the teaching support for the various e-learning modules.
S2	Adaptation service	This service consists of a set of facilities to support modifications and updates of the catalogue.
S3	Inspection service	This service consists of a set of check procedures carried out by the scientific committee in order to assure the right level of quality of the e-learning program.
S4	Evolution service	This service consists of a set of facilities to support the insertion and deletion of courses in the catalogue by authorized persons.

discover its variants, discover exception cases, and so forth. We illustrate the approach with the goal to manage course registration through the Internet of the e-learning map. The textual scenario of Table 2 is the initial scenario written by users as their vision of the normal way to achieve the goal through the enrollment of students in courses.

Using the L'Ecritoire software tool leads us to transform the above scenario into a conceptualized one showed in Table 3. As it can be seen, the tool helps first in explicating the conditions through which the course of actions is valid. This leads us, for example, to add the log-in condition (PIN [personal identification number] is valid), the prerequisites condition (if prerequisites are satisfied), the schedule-completeness condition (if the schedule is complete), as well as the scenario preconditions (student has a PIN; course registration is opened). Second, the conceptualization principle forces the writer to replace any anaphoric reference with an explicit noun; for example, "he has the necessary" has been replaced by "the student has the necessary." Third, the linguistic interpretation rules transform any initial sentence as an instance of the appropriate linguistic pattern; this leads us, for example, to transform the atomic action "the system verifies that he or she has the necessary prerequisites" into a communication action between the e-system and the university, where the student is registered in the phrase "the system asks the university to verify that the student has the necessary prerequisites." Fourth, the scenario-completeness rules help to complete the text with atomic actions performed by the system; the phrase "E-system checks the validity of the PIN" is one example of such an addition.

When the scenario has been conceptualized, L'Ecritoire analysis rules help in discovering new facets, variants, and exceptions related to the service functionality. For example, rules based on the analysis of scenario conditions will lead to the discovery of four alternative courses of actions that the service must be able to handle, namely, that the student PIN is invalid, the prerequisites for courses are not satisfied, course registration is not opened, and the schedule is not complete. Each of these cases corresponds to a subgoal to be handled, which yields a new scenario to be written and conceptualized, and so forth. In addition, rules based on the analysis of preconditions of the scenario help in discovering new functionality involved in the service, namely, the student log in, open course registration, and closed course registration.

A systematic application of L'Ecritoire rules guides toward a complete specification of the functionality em-

Table 2. Initial scenario

Course of actions: Students requests a new schedule. The system prepares a blank schedule form and pulls in a list of open and available courses from the Course Catalogue. Student selects primary and alternates courses from the available offerings. Fro each course, the system verifies that he has the necessary prerequisites and adds him to the course, making the student as 'enrolled' in that course. When the student indicates the schedule is complete, the system saves the schedule.

Table 3. Conceptualized scenario

Precondition: Student has a PIN; course registration is opened
Course of actions:
1. Student logs in the e-system and identifies herself or himself
2. E-system checks the validity of the PIN
3. If the PIN is correct, the system displays the menu
4. Student requests a new schedule
5. E-system prepares a blank schedule form and pulls in a list of open and available courses from the course catalogue of partners' universities
6. Student selects primary and alternate courses from the available offerings
7. For each course, the e-system asks the university to verify that the student has the necessary prerequisites
8. If the student satisfies the prerequisites, the e-system enrolls the student to the course
9. End $_{\text{for each}}$
10. The student pushes the validate button
11. If the schedule is complete,
12. E-system asks university to save the schedule
Post condition: Student has the PIN and is enrolled to courses; course registration is opened

bedded in the service. It also supports the discovery of the part of the service that can be reused from the legacy information systems. A detailed evaluation of L'Ecritoire can be found in Tawbi, Velez, Ben Achour, and Souveyet (2000).

Step 3: Identifying Legacy Services

In order to take advantage of the Web-services technology, this step aims to identify parts of existing legacy information systems (those of the entities involved in the virtual organization) that can be packaged as e-services and reused as such in the new cooperative application. Scenarios from the previous step are the basis for this identification. We developed a rule that searches for actions in the scenario that are communication between actors across the system. The rule determines who is asking what. The latter serves to elicit the candidate e-service, whereas the former leads to identifying the e-service call.

In the above scenario, there are three communication actions that involve a third actor in the interaction between the end user and the system, namely, Actions 5, 8, and 12. This leads us to identify three e-services that can be provided by the universities' legacy information systems, namely, to get available courses, check course prerequisites, and register student the schedule.

All other e-services of the entire e-learning map have been identified following the rule illustrated above.

FUTURE TRENDS

Starting from a technical viewpoint to solve issues of Service Oriented Architecture (SOA), namely, a service description language (Web Service Description Language [WSDL]), service repository (Universal Description Discovery Language [UDDI]), conversation (WSCL), choreography (Web Service Flow Language [WSFL]), and orchestration (XLANG), research as well as commercial tools are moving toward models to specify collaborations between business partners (Business Process Execution Language [BPEL], ebXML framework) and interorganizational work flows (Wise, CrossFlow, etc.). However, a holistic and integrated view is still lacking.

There are future research opportunities on the overall interorganization process specification and on methodological issues. Requirements engineering for interorganization composite services remains a key problem both from the functional point of view (in a similar way to the article's approach) as well as from the nonfunctional viewpoint, even though it exists in some initial works (Zeng, Banatallah, Dumas, Kalagnanam, & Sheng, 2003).

Identifying reusable and modifiable portions of legacy systems and combining them with new services for the construction of new business applications remains an open and critical issue. As noted by Heuvel, Hillegersberg, and Papazoglou (2002), tools, techniques, or guidelines on how to use legacy functionalities are not provided.

There are also specific architectural and enactment issues to support peer-to-peer distributed-service execution, the dynamic evolution and substitutability of services, and long-running transaction management. Peer-to-peer execution seems to be an appropriate architecture to support the distributed enactment of services (Fauvet et al., 2001). However, efforts remain to be made to improve performance, standardize tools, and improve rules for distribution.

Mecella, Pernici, and Craca (2001) introduced the interesting problem of the substitutability of services, which is critical to support the dynamic adaptation of a composite service to face the occurrence of threat and needs for change.

Long-term transaction enactment is evidently an issue related to composite services, which require monitoring over a long period of time (Christophides, Hull, Karvounarakis, Kumar, Tong, & Xiong, 2001).

CONCLUSION

Composition is a promising concept but is quite unexplored and difficult to use in practice. We believe that composition can offer a competitive advantage to organizations by giving the possibility to develop an added-value service just by assembling services they already possess. The contribution of this article's approach is in providing a methodological support to the development of such composite services across organizations that helps in (a) capturing the virtual organization's requirements and expressing its wishes and goals in terms that are familiar to the stakeholders so that they can understand and reason about them easily, and (b) easing the elicitation of e-services that permit the software-application development.

The method presented herein is still in an experimental stage. However, two case studies that we already conducted using the method seem to demonstrate its feasibility and practicability. In one of these projects, the implementation has been done with success and effectiveness using the .NET environment to program services, and Microsoft's BizTalk to orchestrate them.

Multiple industrial case studies are planned to experiment with and validate both the approach and the method foundation while considering both success stories and possible antipatterns. Our focus is also on the development of an enactment mechanism by which the composite-service execution at run time is driven by the goal model.

KEY TERMS

E-Learning Application: An application that includes the development of teaching and learning materials, tools for managing the distant use of these materials by students, a platform for the delivery of courses, and standards and policies to be followed by users.

Interorganization Cooperative Process: An abstraction of a complex business process involving different organizations that cooperate with one another to offer complex services. The interorganization cooperative process is supported by an application that helps in the coordination of services.

Scenario: A use case is described by a set of scenarios, each of them being a sequence of interactions that yields a measurable result for the primary actor. The collection of use-case descriptions describes the system's complete functionality.

Service Composition: The ability of one business to provide value-added services through the composition of basic Web services, possibly offered by different companies.

Service Orchestration: Describes the interactions that two or more services have with each other to achieve a common goal, and the relation between these interactions.

Use-Case Model: Consists of actors, use cases, and the relations among them. Actors represent roles of agents who require services from the system (primary actor) or who contribute to the delivery of these services (supporting actor). A use case represents a service to be provided by the system in reaction to the primary-actor solicitation.

Virtual Enterprise: A temporary alliance of existing enterprises or organizations that share skills, competencies, and resources in order to better respond to some common business goals and whose cooperation is supported by computer networks.

Web Services: Software components that are self-containing, self-describing, modular applications that can be published to, located on, and invoked across the Web. They allow applications to interoperate in a loosely coupled environment, discovering and connecting dynamically to services without any previous agreements having been established between them.

Developing a Viable Product for an Emerging Market

Ron Craig
Wilfrid Laurier University, Canada

INTRODUCTION

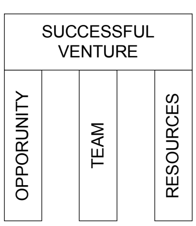
Launching an e-comm, dot-com, or Internet-based venture carries significant risk, and unfortunately failure is often the result. Yet, given the possibilities of large profits, entrepreneurial teams continue to come forward with new venture proposals, and venture capitalists continue to fund them. This case example illustrates the challenge and risk of developing a new product for a potentially emerging market. In this instance, the market did not evolve as expected and there were no profitable customers. An attempt to redefine the product/market focus was also unsuccessful. In the period of some two years, the company went from concept to start-up to closure.

This article starts with a brief review of venture creation and business model literature, considers an unsuccessful start-up, and concludes with lessons learned. References and a glossary follow.

NEW VENTURE FOUNDATIONS

Timmons and Spinelli (2004) identify three pillars upon which a new venture is built (Figure 1). All three are necessary; none are sufficient alone. First, an opportunity must exist. This opportunity must include a product/service for which a viable market exists (customers, distribution channel(s), sales and service support, etc.). With technology ventures, a 'whole product/service' is often required—a comprehensive package of products and services needed by customers to achieve the desired result, including such things as installation, training, and system integration support. High-tech ventures usually start with a concept that needs to be developed into an actual product/service. This requires significant time and effort, with a risk the market may reject the product/service, or a competitor may get there first. Second, a team is needed. This team must capably cover both technical and business sides of the venture, from conception to launch to successful market penetration. An ideal team has prior experience in developing and taking products to market. It is common for the initial team to be heavy on the technical side, with additional expertise added as the venture progresses. Third, sufficient resources are needed to carry the venture through the development phase and into active marketing, to at least the point of positive cashflow. These resources include financing, people, the business plan, and other assets. Venture capital sources exist to fund high-growth potential ventures through successive rounds of financing. So financial resources will follow, rather than lead, in venture creation.

Figure 1. New venture foundations



Every new venture needs to be built around a specific business model, supported by these three pillars, and articulated in a written business plan. There has been considerable confusion about the terms *business plan, business model, e-business model, Internet business model,* and *business strategy*. Sometimes the terms are used interchangeably. Other times they are used in a broad or narrow sense.

Chesbrough and Rosenbloom (2002) provide an excellent discussion of business models, identifying six functions (Table 1). A less detailed view of business models is articulated by Magretta (2002), who says, "A good business model begins with an insight into human motivations and ends in a rich stream of profits." To her, a business model contains a story (narrative) that explains how the enterprise will work. A financial model (pro forma P&L, etc.) supports this narrative and shows the numbers side. There are two tests to apply (Table 2).

Others have suggested alternatives. Clarke (2004) succinctly states a business model answers the question, "Who pays what, to whom, and why?" Hoppe and Breitner (2004) apply business models to e-learning, distinguishing three interdependent submodels (market, activity, asset) which comprise the holistic model. Mahadevan

Table 1. Functions of a business model (Chesbrough & Rosenbloom, 2002)

1. Articulates a customer value proposition
2. Identifies a market segment (*who* will use the technology for *what* purpose; specifies the revenue generation process)
3. Defines the venture's specific value chain structure
4. Estimates the cost structure and profit potential
5. Describes the venture's positioning within the value network linking suppliers and customers (includes identification of potential complementors and competitors)
6. Formulates the venture's competitive strategy

Table 2. Testing a business model (Magretta, 2002)

Narrative Test	Numbers Test
Does the business model tell a logical story, explaining who the customers are, what they value, and how the venture will successfully provide them with that value?	Does the pro forma P&L make sense? Are the assumptions reasonable?

(2000) sees three streams: the value stream (value propositions for various stakeholders), revenue stream (plan for assuring revenue generation), and logistical stream (addressing various issues related to supply chain design). Singh (2002) defines a business model as a method of doing business, and provides a taxonomy of current and emerging e-commerce models (emphasizing technology and participants). Weill and Vitale (2002) identify eight different 'atomic e-business models', each describing a different way of conducting business electronically and supported by various IT infrastructure capabilities.

On the strategy side, Porter (1996) provides several frameworks to guide firms in selecting their strategy and business model. His "5-forces" model, physical value chain network, and generic strategies are useful frameworks. Rayport and Sviokla's (1995) virtual value chain framework is particularly useful for firms using the Internet.

A complementary approach to viewing venture creation and growth is given by frameworks which segment evolution of the new firm. Kaulio (2003) identifies four perspectives: (1) milestones and time-pacing, (2) venture capital financing, (3) growth stages, and (4) market entry focus. Depending upon one's purpose, any (or all) of these frameworks can be useful. For purposes of this article, a growth stages model is considered: conception, start-up, growth, maturity; our emphasis here is on the first two stages, whereby the venture establishes itself and its business model.

Building upon this introduction, the following section tracks the history of an entrepreneurial team and its software venture. Initial failure during execution of the team's business plan led to refinement of the business model (a change in the product/market focus). This also proved unsuccessful.

BACKGROUND OF THE BUSINESS

The founders had backgrounds as independent application developers. While their university education was not in computer science or information systems, together they had well over a decade of experience in application development. Two of the team members had run a multimedia company for three years, developing advanced multimedia sales applications. The third founder had spent seven years running his own development firm, providing contract information systems design and marketing automation solutions for a diverse group of customers. In 1998 they joined forces and founded Ardesic. Their product was to be an eRM (electronic Relationship Management) package, aimed at the B2B e-comm market.

Developing this product would be expensive, and the founders did not have sufficient funds to even resource the development of a beta product. Timing was critical, and the market opportunity could be filled by competitors. The contribution of the venture team was the product concept and their preliminary work. This was sufficient to find financial backing, and in late 1999 a local venture capital firm agreed to provide seed financing (initial funding used to develop a business concept). Most of the funds were for product development, to get the code to beta stage. The remainder of funds were primarily for working capital, with a small amount for marketing and business development. If the market was responsive to the beta product, first-round financing would follow, with development of a fuller product and more intensive marketing.

A study by Forrester Research confirmed the venture team's foresight. Their report on "The Demise of CRM" (Forrester, 1999) concluded:

- A single view of each customer is cited (by the companies interviewed) as a critical or very important business need, but only 2% of firms have it today.
- Most firms feel that CRM vendors like Siebel and Vantive can help solve the problem, but Internet channel executives are not so sure.
- CRM will not work. Firms need eRM to synchronize cross-channel relationships.
- eRM applications will reshape the vendor landscape.

Ardesic's product, eMarketMinder, was aimed at this evolving eRM market.

DESCRIPTION OF THE BUSINESS

Ardesic started as a pre beta software company working on creating a solution for the emerging 'electronic Relationship Management' (eRM) space. The objective was to synchronize all customer-facing applications including, but not limited to, CRM and e-comm applications. Their business strategy aimed at partnering with incumbent vendors and extending the functionality of existing software products. Their product was to incorporate a messaging architecture that allowed a high degree of interoperability with existing enterprise applications. Because the software worked by passing messages between applications based on predetermined business rules, the software would allow customers to continue use of existing applications while realizing extended benefits. Table 3 provides a chronology for this venture.

At start-up time the CRM marketplace had large, well-financed vendors that one would not want as competitors. The perceived opportunity was to establish a strong first-mover presence in the eRM sector, become an attractive target for an established vendor, and be bought out. Since Forrester saw the introduction of eRM solutions to be 1-1½ years away, and expected eventual wide adoption, there appeared to be an excellent window of opportunity.

With seed financing, Ardesic developed a beta version of their eMarketMinder specifically designed for online B2B exchanges. Their burn rate (monthly rate of cash depletion) quickly consumed the seed funds. First-round financing followed in August 2000 and raised $10 million. Additional rounds of financing would likely be required, and would be conditional upon proving Ardesic's business model. However, as the months went by, the target market showed little interest. Target customers consisted mainly of start-up firms, which were either closing down or severely rationing their cash. The dot-com boom was turning into the dot-com bust. During the second quarter of 2001, the difficult decision was made to modify the product to support partner relationship management (PRM). The initial product would take six months to develop, and a further six months to add greater functionality. Later in the year it became evident that this new product could not gain customer traction and hence the business model was untenable. The decision was made to move into salvage mode.

Table 3. Chronology of events for Ardesic

Date	Event
'98	Firm founded by three partners with custom multimedia s/w background; B2B e-comm market focus
Q3, '99	Firm makes initial contact with local venture capitalist (VC)
Q4, '99	Seed round investment of $500K; employees hired; objective is to develop code to beta stage, while seeking first-round financing
Q2, '00	Product in beta testing, and two other initial prospects found; term sheet received from larger VC; CEO hired
Q3, '00	1st round financing of $10M by VC consortium
Q4, '00	VP Sales in place and sales force being hired; additional beta sites; market space moving rapidly; plan move to larger offices
Q1, '01	Sales force in place; difficulty gaining sales; Out-of-Cash (OOC) = 12 months
Q2, '01	Target customer base (e-markets) has evaporated; CEO replaced; staff & spending reduced; alternate options considered; OOC = 18 months
Q4, '01	Unable to gain customer traction; firm in salvage mode and shuts down; physical assets transferred to new firm; financial assets go to VCs; one of the founders starts a new venture

MANAGING THE BUSINESS

Three technically astute university graduates founded Ardesic. While not formally trained in computer science, they developed their skills as custom programmers for local businesses and organizations. While none had experience in developing a high-growth venture, they all had successful small business and IT project management experience. The lead entrepreneur drove the vision, found the funding, and became President.

Information technology projects are notorious for coming in late, over budget, and without the desired functionality (Standish Group, 2003). However, Ardesic did not flounder here. Development of the beta product proceeded fairly smoothly. As the beta product neared availability for customer consideration, the company emphasis shifted from product development to a mix of development plus marketing. With the President's strengths in technology, a CEO was hired in March 2000 to manage marketing of the product.

Experiencing increasing marketing difficulty, a new CEO came on board in April 2001. One of his first actions changed the culture and processes of Ardesic. Approximately one-third of the development and programming staff were replaced, and two of the original three founders left. Developing the new PRM product required a critical mass of experienced developers. Consequently, a group of mature computer science graduates, already experienced in developing enterprise software products, was hired to spearhead this effort. In contrast, the previous development group comprised many more college and anecdotally educated "heroic young programmers."

Ultimately, the VCs made the windup decision. Given the risk and cost of developing a comprehensive PRM product suite for an unresponsive and unproven market, it was safer to walk away from sunk costs and save remaining funds.

SUCCESS/FAILURE FACTORS

Ardesic placed a bad bet on a prospective market, but did so at a time when the bet seemed reasonable and funding was easily accessible. Their start-up timing was fortuitous, as venture funding more than quadrupled during 1999 (PricewaterhouseCoopers, 2004) from earlier years. Over a period of two years, from Ardesic's initial funding, it became evident the expected market did not exist. Concurrently, venture funding dropped back to pre dot-com boom levels.

The venture team, while strong on the technical side, was weak on the business side. This was recognized from the start, and resources (experienced business growth people) were added to the firm as it transitioned through the concept and start-up stages. While certain resources could have been brought in a little earlier, it would not have changed the final outcome.

VCs played an important role, providing much more than just financing. They supported the venture team through the initial product development stage, arranged first-round financing, and then brought in successive CEOs—the first to push marketing, and the second to make a final turnaround effort. Neither CEO succeeded. While Ardesic failed, losses were kept to an acceptable minimum.

LESSONS LEARNED

Several generalizable lessons are brought out by this case, relating to the risks of technology start-ups, development of viable business models, and the role of venture capitalists.

Ardesic started with two of the necessary three foundations (a team and a product concept), added the third (financing), and then worked on refining their business model. Using a "rifle" approach, the company developed a single product for a specific market. When it became evident this potential market did not exist, the firm shut down. The trade-off here is between focusing resources on a single high-risk goal vs. spreading resources around and pursuing several targets. Most new ventures do not have the luxury of taking the latter approach, and the result is a higher failure rate.

This case also illustrates venture stages and business model development. Ardesic started at the concept stage and did not get beyond start-up. A critical component of a viable business model is the ability to generate revenue, and Ardesic's eMarketMinder could not do this. Yet, it was only through development of the beta product that the market potential could be properly tested. Conceptually, their product looked attractive, and experts such as Forrester Research expected the marketplace to move to such products. Clearly, even experts can be wrong, and the marketplace changes over time.

Feedback received during product development and beta testing was invaluable in refining the business model—developing a fuller understanding of the market (whether or not it exists, and in what form; what it values, what additional products/services are needed to provide a "full product", and how much it will pay for the product/service), clarifying the value proposition for the potential customer, and ultimately proving the firm's competitive strategy. In Ardesic's case, this feedback disproved their business model.

Venture teams with good ideas can attract the necessary financing. Venture capitalists are willing to risk money, on the basis of anticipated returns. This willingness will continue through various rounds of financing, providing the venture is able to execute its business plan and refine its business model. Venture financing is usually obtained on an iterative basis of "rounds" (successive stages of funding) and "tranches" (a funding milestone, whereupon funds are advanced; it is rare for a deal amount to be paid as one lump sum). Proven success in moving forward with the business model leads to additional financing, which in turn allows further refinement. When progress is slow, the next financing round may value the venture less (a "down round"). When progress supports the business model, an 'up round' is more likely. Ardesic followed this usual model, first obtaining seed capital and then (on the basis of their beta product) first-round financing. This was an 'up round' for the backers. However, Ardesic did not get to second-round financing. By the time they determined a viable marketplace did not exist, the venture capital market had turned and backers chose not to support further development of an alternate product for a market that no longer was attractive.

Sometimes new ventures start without a written business plan (the "learn by doing" approach advocated by Gumpert (2003)). Kanter (2001) shows that dot-coms can be categorized in terms of style and substance. The former focuses on personality and style of the founder(s), and their ventures tend to follow an evolutionary path. In contrast, the latter focus on execution of a clear business model, with strong attention to the 'bottom line'. Ardesic was in this latter class. From a financing perspective, venture capitalists want this group. Firms of the first type must find other financing methods (such as bootstrapping or angels).

There are both benefits and costs in dealing with venture capitalists. Besides financing, they can add value-added services. Developing a successful high-tech venture is difficult, and firms need all the support available. Investors who can add significant value to the firm's development, beyond their financial investment, are one of the keys to success. Methods of adding value include identifying key management members to round out the team (especially as the firm grows), linking the firm with support organizations (lawyers, accountants) and potential suppliers and/or customers, and assisting with future rounds of financing (including government grants). VCs also extract a price, in terms of control and a significant share of any realized profits. With Ardesic, two of the three founding team members left during the start-up phase, as market problems became evident. There were no profits to share.

The dot-com boom was an exciting time to launch a venture. Financing was readily available, and the press reported on a seeming multitude of dot-com millionaires. Many in the industry felt that business rules had changed and a new era had started. The dot-com bust brought these people back to reality. As Rayport (1999) states, "In the end an e-business is just another business." Porter (2001), in response to the question of whether or not the Internet renders established rules of strategy obsolete (as some proposed), answers that it makes strategy more vital than ever. He concludes, "In our quest to see how the Internet is different, we have failed to see how the Internet is the same."

A final lesson is that venture failure is seldom fatal—future opportunities usually arise. The lead entrepreneur with Ardesic quickly found another opportunity and started a new venture.

KEY TERMS

Angel Investor: An affluent person who provides start-up capital for a new venture in exchange for partial ownership; typically does not pool money as does a venture capital fund, but sometimes is part of a network or group which shares information and investments.

Burn Rate: Rate at which a new venture is using up its capital.

Out-of-Cash Time: Length of time a new venture will take to use up its current funding; usually stated in months.

Seed Financing: Initial financing for a start-up venture; used for proof-of-concept, market research, and/or initial product/service development.

Traction: Successfully putting a business model into operation, proving its viability

Venture Deal: Statement of what entrepreneurs are giving up and what the new venture is receiving in return; covers financing amount(s), method and timing of release(s), terms and conditions, equity given up, etc.; usually starts with a 'term sheet'.

Whole product/service: Direct product/service provided by a firm, augmented by everything else required by customers (installation, training, support, integration, etc.).

Development and Deployment of Web Services

Radhika Jain
Georgia State University, USA

Balasubramaniam Ramesh
Georgia State University, USA

INTRODUCTION

A Web service is an interface that describes a collection of operations that are network accessible through standardized XML (extensible markup language) messaging specifications such as SOAP, WSDL (Web service description language), and UDDI to provide open, XML-based mechanisms for application interoperability, service description, and service discovery (Kim & Jain, 2005). They are self-contained, modular units of application logic that provide business functionality to other applications via an Internet connection (Srivastava & Koehler, 2003). Although Web services are a relatively new concept, they provide a solution to the set of serious problems that have plagued enterprise systems using a service-oriented architecture (SOA). Web services address a similar set of problems that middleware technologies such as CORBA, RPC, COM, and RMI address by providing a tightly coupled and vendor-driven proprietary environment for implementing SOA.

BACKGROUND

Web services are based on open standards and are designed to promote loosely coupled interactions between service providers and consumers to provide an interoperable environment (Gisolfi, 2001b). Loosely coupled Web services provide modularity and flexibility in complex, distributed IT environments (Kreger, 2003), emerging as a catalyst for SOA. A service is a unit of work such as a business function, a business transaction, or a system service (Channabasavaiah, Holley, & Tuggle, 2003) completed by a service provider to achieve desired end results for a service consumer. A well-designed SOA is therefore likely to be comprised of a relatively large number of modular, focused Web services that can be swapped in and out as needed to respond to changing needs.

Organizations can exploit Web services to enhance their ability to (a) respond quickly and reliably to special requests from customers and suppliers, (b) improve the agility of business processes to respond to various situations and changes in the marketplace, and (c) automate and integrate business processes across organizational boundaries (Seybold, 2002). As various standards related to Web services become mature, Web services are becoming basic building blocks of the service-oriented architecture from which new applications can be composed. For this vision to realize its full potential, several issues need to be addressed. The range of these issues includes quality of service (QoS; performance, availability, security, etc.), semantic matchmaking, and the development of services-based applications.

This article is organized as follows. In the next section, we discuss in depth these various issues. We categorize them in three groups: Web services matchmaking, Web services quality of service, and the development of services-based applications. In the final section, we present the implications of these issues for dynamic e-businesses and provide concluding remarks.

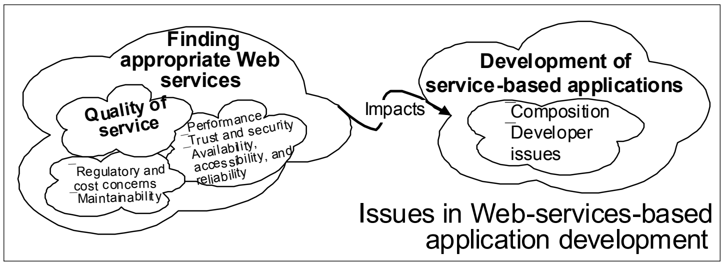
ISSUES IN THE DEVELOPMENT AND DEPLOYMENT OF WEB SERVICES

In this section, we present a discussion on a diverse set of technical, social, and regulatory issues faced by organizations that intend to deploy Web services. Figure 1 depicts these various issues in service-based application development efforts.

Matchmaking of Web Services Capabilities

The huge number of Web services already available on the Internet makes it almost impractical, if not impossible, for a human being to analyze and combine them efficiently (Matskin & Rao, 2002). One of the major tasks when using Web services for today's service-oriented business application development is their discovery and the degree of match between the tasks that a service can accomplish and the requirements of the consumer. This requires the capability to match Web service descriptions with the service requirements.

Figure 1. Issues in Web services-based application development for dynamic e-business



Matchmaking is a process by which parties that are interested in having an exchange of economic value are put in contact with potential counterparts. It is carried out by matching together the features required by one party with those provided by another. A common problem in this process is that different Web services may use the same name or term with different meanings. The challenge is then to mediate between these different contexts (Hansen, Madnick, & Siegel, 2002) and to select a Web service that provides accurate, complete, consistent, and correct functionality. Since Web services exist in an open environment, semantic matching is more natural (Matskin & Rao, 2002). By semantically enhancing the functional description of the Web service, more accuracy in service discovery can be achieved. This matchmaking process should ideally support the following: (a) functional matching, (b) input and output interface matching, and (c) matching the order of the subtasks' execution as it can potentially affect the QoS expectations such as compliance with requirements to follow a specific process.

Quality-of-Service Issues for Web Services

As businesses continue to assess the viability of Web services for enterprise-strength applications with their growing recognition and proliferation, a major issue is maintaining adequate levels of QoS. QoS, an important complement to the operational description of work flows supported by Web services, describes nonfunctional properties of a work flow (Cardoso, Sheth, & Miller, 2002). Delivering QoS on the Internet is a critical and significant challenge because it is dynamic and unpredictable in nature while applications with very different characteristics and requirements compete for scarce network resources. Changes in traffic patterns, denial-of-service attacks, infrastructure failures, low performance of Web protocols, and security issues over the Internet create a need for Internet QoS standards (Mani & Nagarajan, 2002) for Web services. The management of QoS directly impacts the success of organizations participating in e-commerce activities enabled by Web services. QoS issues should be assessed from the perspective of the providers as well the users of Web services. It is important to have some mechanisms for monitoring Web services and their deployment environment in real time to ensure their auditability (Seybold, 2002).

Performance

The performance of Web services is measured in terms of throughput and latency. Higher throughput and lower latency values represent good performance of a Web service (Mani & Nagarajan, 2002). One component affecting performance is the task time or the time taken to transform inputs into outputs. Other factors affecting performance include accessibility, availability, and reliability. When composing applications from Web services, care must be taken regarding the possibility that a Web service may time out (Myerson, 2002). In other words, the response time of a Web service will affect the performance of an application. This will involve making careful choices about when to use asynchronous vs. synchronous processing.

Maintainability

Sheth, Cardoso, Miller, and Kochut (2002) highlight the importance of taking into consideration the time taken to maintain a Web service when failures or changes take place (also known as the time taken to repair ;Mani & Nagarajan, 2002). A related concern is versioning (Myerson, 2002), that is, how new builds will affect the functionality of the existing Web services and applications that rely on them. Also, another issue is the ability to consistently serve the service consumers' requests despite variations in the volume of requests.

Trust and Security

Organizations that consume and provide Web services need to be in a relationship strong enough to warrant investing in understanding each others' processing systems (Seybold, 2002). Therefore, the first wave of Web services implementation is likely to occur between trusted trading partners. Providing confidentiality and nonrepudiation by authenticating the parties involved, encrypting messages, and providing access control (Clabby, 2002; Menascé, 2002; Myerson, 2002) will affect an organization's confidence in Web services for critical applications. A related concern is task fidelity, which reflects how well a product is being produced and how well a service is being rendered (Cardoso et al., 2002).

Availability, Accessibility, and Reliability

Availability represents whether or not a Web service is present and/or ready for immediate use. Accessibility represents the degree to which a Web service is capable of serving and is typically expressed as the probability of successful service instantiation at a point in time. Finally, reliability represents the ability to maintain the service and service quality (Mani & Nagarajan, 2002). It is possible that a Web service is available but not accessible at a given point in time. The accessibility of Web services can be improved by developing highly scalable systems.

Regulatory and Cost Concerns

Since Web services can be accessed from anywhere on the Web, they need not be located within the user organization. This raises the issues of the degree of compliance with rules, laws, and regulation, and the degree of compliance with standards and established service-level agreements (Mani & Nagarajan, 2002). Service providers and consumers need to provide mechanisms to enact and ensure compliance.

Another issue is the cost of services provided and consumed. Cardoso et al. (2002) break down the cost into two components: the enactment cost (EC) and the realization cost (RC). The enactment cost is associated with the management of the Web services and the monitoring of their execution. The realization cost is the cost associated with the run-time execution of the task, which is further broken down into direct labor cost, machine cost, direct material cost, and setup cost.

Development of Service-Oriented Applications

This section focuses on the issues related to the composition of Web services and the issues faced by the developers of service-oriented applications.

Composition of Web Services

While the functionality provided by Web services can be consumed as independent operations, Piccinelli and Mokrushin (2001) suggest that the realization of the full potential of Web services depends on the ability in two critical areas: composition and interaction orchestration. Composing Web services into complex service-oriented business applications will become increasingly crucial for organizations that use this technology to become more agile and responsive. The platform-neutral nature of Web services creates the opportunity for building composite Web services using existing elementary or complex services (Yang & Papazoglou, 2002). When composing applications, various constraints need to be addressed. First, it is necessary to ensure the interoperability of the Web services. The output of one Web service should be compatible with the input requirements of the Web service that consumes these outputs. In other words, one needs to ensure the compatibility of the service-oriented application and that there exists no conflict of interest (CIR; Hung, 2004) when Web services interact with and delegate tasks to other Web services. Delegation will be a common scenario, especially when activities are decomposed into many subactivities that are executed by multiple Web services.

There has been growing interest in how composition can be accomplished, leading to various standards such as WSDL, the business process execution language (BPEL) developed by IBM in conjunction with other industry giants, and DAML (DARPA agent markup language) Services (developed under the DAML program). While BPEL offers the definition of business protocols and supports fault handling and compensation, it does not address conformance and quality-of-service issues (Milanovic & Malek, 2004). Additionally, using BPEL alone, the properties of composition cannot be verified. Aral (2004) and McIlraith, Son, and Zeng (2001) suggest that for many of the automated reasoning tasks envisioned by semantic Web services, BPEL may not be sufficient. Although the ontology Web language for services (OWL-S) provides semantics allowing for reasoning about a service and takes an important step toward the ultimate goal of dynamic service discovery and usage, it is still not mature for use in describing Web services. Sabou, Richards, and Spluter (2003), based on their experiences in using DAML-S, suggest that DAML-S is difficult to learn and has an imprecise underlying conceptual model leading to multiple modeling possibilities and parametric polymorphism. Zeng, Benatallah, and Dumas (2003) suggest that the selection of component Web services during composition should be carried out during the execution of a composite service rather than at the design time. They consider multiple criteria such as price, duration, and reliability, and also take into account global constraints and preferences such as budget limitations. These above approaches assume the presence of predefined steps of various tasks and activities, and can work as long as the existing composition is unchanged. However, the existing composition may need to change for a variety of reasons. Kim and Jain (2005) present a task and business rules dependency-based approach to handling such composition efforts.

Since there may be various ways in which a given service-oriented application may be composed, one needs to select the composition that also exhibits a higher degree of QoS from its designers' perspective. In addition to various criteria mentioned earlier, it may also be necessary to identify a new set of QoS criteria to evaluate the goodness of such composed applications. For example, how flexible is the resulting composition and how easy is it to swap out one Web service with another one? It may also be interesting to keep a close eye on the total number of Web services as it may ultimately affect the performance and reliability of the service-oriented business application.

Developer Issues

The primary difficulty in creating Web services and applications with a service-oriented architecture is getting developers and architects to think about loose coupling and asynchrony (Seybold, 2002). The transactions that client-server developers are accustomed to building typically take place in tightly coupled and synchronous systems. Thus, developers will need to be well trained to use Web services to fully exploit the capabilities of a service-oriented architecture.

Based on the discussion presented in the preceding sections, Table 1 lists the various issues that an organization involved in creating and using Web services needs to address for their successful implementation. In the next section, we briefly discuss the implications of these issues for dynamic e-businesses and provide concluding remarks.

FUTURE TRENDS

The growing importance of Web services and a service-oriented architecture will change business application-

Table 1. List of issues in each of the three areas of Web services development

Area	Issue
Matchmaking	❑ Does the service provider support semantic matchmaking? ❑ Is a common vocabulary used in service descriptions? ❑ What should be the precision of matching?
Quality of Service	❑ Who will monitor and keep track of the quality-of-service parameters provided by various Web services? ❑ How should the cost of the overall composition be obtained? How will problems faced when the overall composition fails due to the noncompliance of one Web service be handled? ❑ Which QoS parameters should be taken into account, or how should they be combined to find appropriate Web services? ❑ Will there be one central repository? Will it be broadcast, or will it be part of the Web services description? ❑ How often will such QoS information on availability, reliability, and accessibility be updated and made available to the service requesters? ❑ If the overall QoS changes, how will it affect the application performance while the composition is executing? ❑ What are the implications when the service provider upgrades the version of the service that is currently being used by various applications? Will the service provider need to maintain different versions?
Development of Service-Based Applications	❑ What criteria should be used for composition? Should these criteria be context specific? ❑ How stable will the given Web services composition be in terms of the quality of service of the overall composition? ❑ How often does one need to change the composition, and when changes do occur, what are the things that one needs to keep record of? ❑ What support mechanisms and/or tools will the developers need to handle the dynamic composition of Web services? ❑ Will making available the knowledge embedded in past compositions make the development task any easier?

integration strategies affecting e-business dynamics. Gisolfi (2001a) defines dynamic e-business as the next generation of e-business focusing on the integration and infrastructure complexities of B2B (business-to-business) transactions by leveraging the benefits of Internet standards and a common infrastructure to produce optimal efficiencies for intra- and interenterprise computing. The benefits of adopting Web services over traditional business-to-business applications include faster time to production, the convergence of disparate business functionalities, a significant reduction in the total cost of development, and the ease with which business applications for trading and the supply chain can be created (Hung, 2004). This has the potential to improve the agility of various business processes within and across organizational boundaries by providing the ability to respond to a wide range of internal and external events.

CONCLUSION

Despite these potential opportunities presented by service-oriented technologies, organizations face a diverse set of issues as presented earlier. Without a carefully thought-out plan for development and deployment to address these issues, service-based applications may not attain their full potential. In summary, we identify various issues, listed in Table 1, that need to be addressed to practically realize the vision of dynamic e-business by any organization involved in the development and deployment of Web services.

KEY TERMS

DAML (DARPA Agent Markup Language): DAML is an extension of XML and the resource description framework (RDF) providing constructs with which to create ontologies and to mark up information so that it is machine readable and understandable.

Dynamic E-Business: The next generation of e-business focusing on the integration and infrastructure complexities of B2B by leveraging the benefits of Internet standards and a common infrastructure to produce optimal efficiencies for intra- and interenterprise computing.

Matchmaking: Web service matchmaking is a process by which the parties that are interested in having an exchange of economic value are put in contact with potential counterparts by matching together the features required by one party and provided by another.

Quality of Service (QoS): QoS is a set of service requirements that the provider must meet in order to guarantee an adequate level of service provision.

Service-Oriented Architecture (SOA): A service-oriented architecture allows the designing of software systems that provide services to other applications through published and discoverable interfaces, and in which the services can be invoked over a network.

Web Services Composition: Web services provided by various organizations are interconnected so that they interact with each other in a way to realize some important business functionality.

WSDL (Web Services Description Language): WSDL provides a model and an XML format for describing Web services. It enables one to separate the description of the abstract functionality offered by a service from concrete details of the service description such as how and where that functionality is offered.

Digital Government Development

Richard Knepper
Indiana University, USA

Yu-Che Chen
Iowa State University, USA

INTRODUCTION

Effective implementation of digital government requires a well-articulated and sound strategy. Having a sound strategy is considered as the first and most important step in securing the success of information technology projects (Fletcher, 1999). Unfortunately, failures in the form of cost overruns, delays, and implementation problems are commonplace in digital government projects (Heeks, 1999). If executed properly, a strategic plan can help public organizations realize the full potential of an information technology investment. The framework proposed in this article attempts to identify the factors behind the successful design and development of a national digital government strategy, taking a normative perspective of policy and institutional design with emphasis on informing policymakers. A national strategy is the critical first step in building digital government. National digital government strategies, such as UK Online, e-Japan, and e-Korea, are commonplace.

Critical success factors have been identified in other research which examines individual IT projects at both state and local levels (Heeks, 1999; Dawes et al., 1997). Since national strategic plans provide the framework in which most digital government projects are prioritized, designed, and implemented, it is important to study these large-scale plans. However, there is a shortage of research-based frameworks for guiding the development of a national strategy. The comprehensive framework proposed in this article with a short illustration of application to a cross-country comparison offers policymakers a number of suggestions for developing sound national digital government strategies.[1]

BACKGROUND

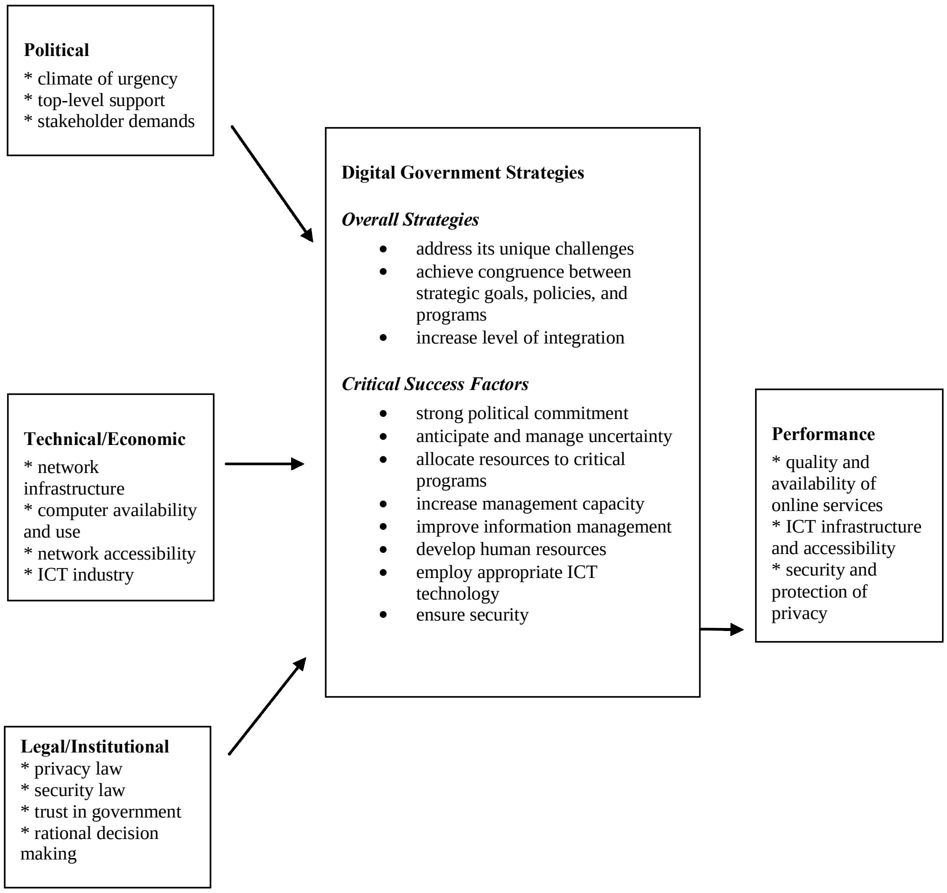
Digital government refers to the use of information and communication technology to improve the relations between government and its employees, citizens, businesses, nonprofit partners, and other agencies by enhancing access to and delivery of government information and services.[2] Digital government strategic plans are national plans designed to guide the development of a country's efforts to deliver information and services via digital means.

To gain a better understanding of the development of digital government strategies, it is important to look at the environmental conditions under which the strategy is developed and implemented. Political forces and institutional settings play a significant role in national digital government efforts. Digital government plans and projects need to be attentive to political considerations and governmental processes at all levels of government (Rocheleau, 2003). Moreover, legal and institutional incentives and constraints shape the design and use of information technology in the public sector (Fountain, 2001; Landsbergen & Wolken, 2001). Strong administrative and legal institutions support the creation of national digital government plans, guide their design and implementation, and provide mechanisms for measuring performance as well as addressing the physical environment (Ostrom, 1990; Farris & Tang, 1993). Institutions shape not only the selection of digital government projects, but also their design and implementation (Fountain, 2001). The link between institutions as an incentive structure and performance is another important insight (Ostrom, 1990; Ostrom, Schroeder, & Wynne, 1993). Institutional incentives are critical for soliciting cooperation from individual public employees and agencies as a whole to share information and resources.

Citizens and their participation also constitute an important environmental element of digital government (Marchionini, Samet, & Brandt, 2003; UN/ASPA, 2002; Schedler & Scharf, 2001). When an active civil society and a well-established information and communication infrastructure is in place, an e-government strategy that is more responsive to citizen needs is more likely to be implemented.

In addition to the environmental factors mentioned above, a national digital government plan needs to consider several unique characteristics of government. First, every government has multiple objectives, usually in competition with each other. Second, the planning horizon needs to correspond with election cycles, so the

Figure 1. A framework for the development of a national digital government strategy



planning horizon is shorter than the one used by the private sector (Guy, 2000). Lastly, stakeholders' involvement is regarded as critical for the successful implementation of an information system strategic plan.

A FRAMEWORK FOR DEVELOPING DIGITAL GOVERNMENT STRATEGIES

The framework described in Figure 1 is organized into digital government strategies (center) in response to environmental conditions (left) to generate performance results (right). Digital government strategies describe the contents of a given plan for national development. Environmental conditions are circumstances surrounding a plan for national development that have an impact on success or failure. Performance results describe the outcomes produced by the digital government development plan.

Four principles govern the development of the framework. First, a good strategic plan addresses the unique challenges posed by the environmental circumstances facing a national digital government effort. Second, there is a set of principles and success factors which will increase the likelihood of success. Third, the framework acknowledges the evolutionary nature of digital government efforts, in which strategies adapt to and affect the environment in which they are designed and executed. Lastly, performance measurement of digital government is necessary to trace the effect of strategies on outcomes.

Environmental Factors

Political Considerations

Three political drivers, as shown in the top left box of Figure 1, set the stage for the development of a national digital government strategy. External pressures, such as preconditions for membership in an international organization or for external assistance, may cause impetus for the drafting of a national plan. Another driver for a national digital government plan is the administration's policy agenda. Administrators may view digital government as a means to revitalize public services (Snellen, 2000) or increase competitiveness. A country's national legislature and executive branch might provide the support for a digital government plan, making the plan subject to the election cycle.

Stakeholder demand is another driver for digital government (Kamarck & Nye, 2002). Citizens, accustomed to the convenience and efficiency accompanied by e-commerce, demand the same efficiency and convenience of government. Businesses may speed up the adoption of digital government by offering better interoperability, and governments may feel internal pressure from staff and managers. Client demand also involves both electronic voting and civic participation in the government decision-making process, also known as electronic governance. This is an important area of development for a digital government plan to pay attention to (Marchionini et al., 2003). From a management perspective, electronic democracy should be integrated into the core mission of digital government. The extent to which civic participation may shape a national digital government plan in this way depends on the power of democratic institutions in shaping public policy.

Technical/Economic Conditions

Several technical/economic conditions, as shown in Figure 1, are relevant for the design and formulation of a national digital government strategy. National information and communication technology infrastructure is the first critical element for assessment. In particular, the UN/ASPA (2002) report has pointed out the importance of network availability, an important indicator of an infrastructure's maturity.

Second, computer availability and use determines whether the information and communication infrastructure is utilized. Accessibility to e-government services depends on the information and communication infrastructure of a country (UN/ASPA, 2002), which varies greatly around the world. For example, in the United States, more than half of the population has a computer, whereas in Brazil less than 5% of the population has one (UN/ASPA, 2002).

Third, the distribution of use and accessibility among various groups also shapes national digital government strategies. Digital divide is usually the term used to capture this issue. Lastly, the existence of a viable domestic IT industry is beneficial to the design and implementation of a national digital government strategy, providing a positive spillover effect on the affordability of computers, the establishment of an information and communication network, and the viability of building e-commerce applications for government use.

Legal and Institutional Issues

Two prominent legal and institutional issues pertaining to digital government are privacy and security (see Figure 1). These two issues have been identified as important by various levels of U.S. government (ICMA, 2000, 2002; GAO, 2001). The European Union (EU) has also developed Directive 2002/58/EC on Data Protection and Privacy (EU, 2002) to specify policies for the protection of individual data. Privacy laws govern the use and distribution of information by government and businesses. Security is a major concern when government information systems store vital information about individuals and government units. A national digital government strategy needs to address both privacy and security to win the trust and willingness of citizens and businesses to submit personal information and conduct transactions online, passing relevant laws and regulations where needed.

As a governmental effort, digital government also relies on the institutional capacity of government to be efficient and rational. If such capacity does not exist, a national digital government strategy needs to make this a high priority and incorporate it into its plan.

Digital Government Strategies

Digital government strategies have two components (see Figure 1). The first component is overall strategies that a country should follow to address its unique environmental challenges. Having a congruent strategic plan and striving for a high level of integration of electronic services are two additional indicators of a sound strategic plan. The second component includes critical factors for the success of a national digital government strategy. These factors include strong political support, management of uncertainties, allocation of resources, development of management capacity, the use and quality of managed information, the development of human resources, utilization of an appropriate level of technology, and the protection of privacy and security.

Overall Strategies

A successful digital government strategy needs to have the following three characteristics. First, the strategy needs to address its unique environmental conditions, focusing priorities on areas which are the foundation for further development, such as infrastructure. Second, strategic goals, policies, and programs should be congruent with one another. Internal consistency between goals, policies, and program as three integral components of a strategic plan are the preconditions for successful implementation. Congruence can be seen when policies and programs support the outlined strategic goals. Thirdly, the integration of government networks and infrastructure is the foundation for seamless e-government services, which usually involves a common platform for all government services and protocol for information and resource sharing. This is also a sign of maturity in the development of digital government (Layne & Kim, 2001).

Critical Success Factors

In order for a digital government plan to be successful, it requires firm political support. A good strategic plan addresses the constraints of political authority, mobilizing support for digital government, particularly high-level support. In addition, it reflects citizen demands and other political considerations. Another critical success factor of a national strategic plan is the anticipation and management of political and technological uncertainties.

A strategic plan needs to identify and anticipate political uncertainties caused by turnover of officials and rapid changes in policy. Another source of uncertainty is the rapid pace of technological development. Moreover, a strategic plan needs to allocate necessary resources to critical programs. A strategic plan also needs to address the recruiting and training of IT staff for critical programs. The building of human infrastructure for the use of information technology is as critical as building the physical one. The International City/County Management Association has conducted two e-government surveys of local government and each time has ranked the lack of IT personnel as the number two barrier to e-government (ICMA, 2000, 2002).

Quality and security of government information resources is at the center of any successful national digital government strategic plan. The management of government information resources has been discussed as a critical component for a national digital government plan (Fletcher, 2003). Government information is the underlying content base on which information and transaction services are created. The protection of privacy and security is critical for winning citizens' trust in government and for them to conduct transactions online (Edmiston, 2003).

Rational decision-making and implementation capacity are central to a national strategic plan, as various studies of e-government projects around the world have suggested (Heeks, 1999). This institutional capacity affects both the design and implementation of a digital government plan. With this capacity, a national government is able to identify what is lacking in its political, economic/technical, and institutional conditions, and develop a plan to address those gaps.

Performance

The performance of digital government has multiple dimensions (see Figure 1). The main indicators include the availability and quality of online services, the maturity of national information and communication infrastructure, online service accessibility to diverse groups of citizens and businesses, and finally security and protection of privacy. The availability of online services can be measured by the number of government information and services online, and the extent to which these online services are meeting citizens' needs. A developed national information and communication infrastructure will help improve efficiency and access of digital government services. Examples include establishing national communication infrastructure for all public agencies and providing free Internet access at public offices even at remote locations to serve disadvantageous groups. Moreover, a high-performing digital government also needs to win trust from citizens whose personal and confidential information is in the government's possession. Rigorous security measures and privacy policies are essential to accomplish that.

Application of the Framework

In order to demonstrate the utility of the framework for making determinations about national digital government plans, the authors made an in-depth comparison of the plans of Poland and Taiwan (Chen & Knepper, 2005), two countries with different levels of digital government development, making their experience applicable to a range of different situations. Taiwan was ranked as number one in a 2004 report comparing digital government performance in countries around the world, while Poland ranked 46th out of 198 (West, 2004). When the framework was applied to each government's e-government plan, although the difference between the two countries was clear, they also shared some common challenges.

In overall strategies, Poland was found to be slightly behind Taiwan in meeting external challenges. Taiwan's plan has benefited from a strong ICT infrastructure, and some goals have been met ahead of schedule. Poland's goals may be too high to reach in the short time allotted. Both the Taiwanese and Polish plans lack an ability to scan changes in the external environment for external changes. In the area of congruence between goals, policy, and programs, both countries score well. Moving on to integration issues, both countries scored similarly. Turning to the critical success factors laid out in the framework, Taiwan scored better than Poland in several areas, although both countries share some common problems. Poland and Taiwan both had weaknesses in uncertainty management, well-trained staff, and security. Poland was also victim to problems with funding, technology, and information management.

Judging from the areas examined in the framework, Taiwan appears to be in a much stronger position overall. The global e-government performance ranking by West (2004) confirms this. Although these countries appear far apart along the curve of digital government development, both have strengths in the area of information management, management capacity, security, and the use of technology. Both plans are faced with problems with risk management, training, and security. By identifying problem areas that are common to many digital government efforts, public managers can look for solutions that are applicable in a variety of cases.

FUTURE TRENDS

Privacy and security concerns will continue to be an important part of digital government plans for the foreseeable future. As a result, a successful national digital government strategy must address privacy and security on both wired and wireless networks. Another security measure is the implementation of a "quality seal" by which users verify official information and services. A comprehensive digital government strategy should also deal with the legal and institutional issues that surround security and privacy directives required by governing bodies.

Client-oriented design, in which citizens and businesses have information and services tailored to their needs, will become more prevalent. Client-oriented design should guide the development of digital government strategies. To be more client-centric, a successful digital government strategy can follow guidelines in the proposed framework, such as increasing the level of service integration. Multilingual populations, at various levels of ability and computer literacy, require "design-for-all" (Aichholzer, 2004). The increasing variety of platforms by which citizens interact with government will require multichannel delivery, so that citizens can make use of services via computer, in person, by telephone, cell phone, and PDA. Digital government strategies must decide on a particular mix of services which best fits their citizens' needs and the available resources.

Electronic governance is becoming more integral to a comprehensive digital government strategy. One of the first main issues for electronic governance to address is digital divide. This requires a national strategy that focuses on building ICT infrastructure issues and developing human resources. Electronic governance in the form of e-voting, e-rulemaking, and e-consultation opens up ways for government to engage citizens in making public policy decisions (Macintosh & Coleman, 2003). This holds the potential for government to be truly citizen-centric in setting policy priorities and providing needed information and services.

CONCLUSION

The framework for digital government strategy outlined in this article serves as a tool to guide the development and evaluation of national strategic digital government plans. The framework describes environmental concerns which affect every digital government plan. The critical factors listed in the framework provide guidance for drafters and implementers of digital government plans. If these factors are not addressed, the results of the process may not be satisfactory. A number of conditions must be right for a strategy to be implemented successfully. A strategy must scan its situation and address areas that are particularly needed. Finally, the individual components of a digital government strategy should be complementary.

As a tool for making judgments about national strategic digital government plans, the framework can be used as a means for either comparing two different plans or finding gaps in a plan that might weaken its prospects for achieving all of its goals. The framework may be useful in pointing out missing areas not covered by a plan. As the future trends mentioned above take place, the framework's focus on underlying elements and uncertainty management allows plan drafters to create plans that are responsive and flexible in the face of technological change. The framework's emphasis on privacy and security, as well as issues of access, focus on areas that will become increasingly important, allowing the framework to remain relevant despite a rapid rate of change.

KEY TERMS

Client-Centered Transaction Environment: A service portal with available services that cross agency boundaries organized by their relevance to a client's situation. For citizens, these may be organized by "life events" such as marrying, employment, or health care.

"Design-for-All" Principle: Design principle in which services are able to be used by all members of society. This includes multilingual and services for the disabled.

Digital Government: The use of information and communications technology to improve the relations between government and its employees, citizens, businesses, non-profit partners, and other agencies by enhancing access to and delivery of government information and services.

Electronic Governance: The use of information and communication technologies to make public policy decisions. Examples include electronic voting to elect public officials (e-voting), electronic commenting on regulatory rules (e-rulemaking), and deliberating on public policy issues (deliberative e-democracy).

Multi-Channel Delivery: Provision of the same or similar services on different platforms, such as computer, PDA, mobile phone, and in person.

National Digital Government Strategy: A plan for digital government development at the national level, which may include infrastructure, training, security and privacy, digital divide, service provision, access, and publication initiatives. Examples include UK Online, e-Japan, and e-Korea.

Quality Seal: A virtual seal placed on a government Web site or form which allows citizens to know that the item in question is legitimate and not a "phishing" site designed to gather information for use in identity theft.

ENDNOTE

[1] Due to space limitations, the framework is described here in brief. A more complete illustration of the framework, including the full findings of the cross-country comparison, can be found in Chen and Knepper (2005).

INTRODUCTION

Digital rights management (DRM) provides digital content creators and owners with a range of controls over how their information resources may be used. It is a fairly young discipline yet is becoming increasingly important as digital content can be copied and distributed so easily that the piracy of them is growing critical. In addition, with the rapid adoption of the Internet as an e-content delivery channel, complex DRM systems are required to protect the digital content besides the distribution channel. Risking their intellectual property (IP) rights, many major e-content providers are relying on DRM to not only protect the packaged digital products, but also to promote the e-content market over the Internet.

As a multidisciplinary technology, DRM has advanced innovative research and development in various fields such as biometrics, watermarking, security protocols, smart-card technology, forgery detection, and secure collaboration and data sharing. Commercially, DRM provides the e-content market with a significant impetus to grow, where secure e-content distribution is essential. Despite its short history, many DRM tools have already been developed by IBM, Sony, Real Networks, Intertrust, and Thomson. These products need be compatible with existing standards for contents, consumer electronics, and often times, different DRM systems. Standardization efforts in industry are ongoing to ensure the interoperability of DRM products and services.

Another important impetus is the legal and regulatory framework. Technical measures provide an effective hurdle for limiting abuse, but legal actions against violators can prevent organized piracy from infringing. With a properly integrated legal, technological, and commercial framework, we expect that the DRM products and services will greatly foster the growth of the e-content market that is eagerly awaited by content providers and consumers. Without proper DRM technologies and laws, the creative industries that create digital products such as DVDs, business software, music recordings, theatrical films, and digital TV programs will suffer from piracy and would be reluctant to support Web-based commerce. The socio-economic impact of DRM is huge.

In this article, DRM techniques using cryptography, data hiding, and biometrics are discussed. Also covered are the standardization issues, emerging trends, and challenges in DRM-related technologies, commerce, and legislative regulations.

BACKGROUND

The beginning of DRM systems was in 1996 when the launch of the DVD raised copy protection concerns from the motion picture industry. The Copy Protection Technical Working Group (CPTWG) was created to address the copyright issues. CPTWG generated a series of commercial solutions, including the following.

- The content scrambling system (CSS) for DVDs in 1996
- Digital transmission content protection (DTCP) for securing compressed content across the IEEE 1394 interface in 1998
- High-bandwidth digital content protection (HDCP) for securing uncompressed content across the DVI (DVI, 1998) in 1999

Nowadays, e-technology providers, including IT and consumer electronics (CE) industries, produce DRM systems with respect to various e-business models. The interest in DRM comes from not only the copy protection of mass-distributed digital content like CDs and broadcast, but also from the promise of using the Internet as a content distribution infrastructure. Because DRM offers a means of setting up a contract between consumers and content providers, it can achieve much more restrictive and fine-grained usage rights than fair use defined by the U.S. Digital Millennium Copyright Act (DMCA, 2000).

Integrating Technological, Commercial, and Legal Measures

Technologically, encryption and watermarking are the pillars of most DRM systems. But they alone cannot prevent the systems from being attacked or circumvented. A serious vulnerability lies in key management. This may be addressed using biometrics for personal key generation or an additional layer of security in accessing the content.

We believe effective DRM systems should be based on a combination of technical means, legal agreements between the different parties, and the consumers' ability to access the digital data only on DRM-compliant devices. The concept of the compliance of devices refers to a common set of rules or policies agreed on by device manufactures, content producers, and consumers. This necessitates, among others, not only the regulation of the commercial activities of device manufacturers and e-content providers, but also the establishment of industrial standards governing the interoperability and behaviors of products and services.

Effective DRM systems should integrate technological measures, commercial products and services, business models, and legislative regulations. The interleaving of them shall enable the organic growth of DRM and thus the e-content market.

Legislative Aspects

The recognition and protection of IP rights is an international concern and effort. The World Intellectual Property Organization (WIPO), with 179 member states, enforces and protects IP around the world. Two WIPO treaties (1994, 1995) and other international treaties and conventions set up a complex framework invoking copyrights, neighboring rights, and exceptions. Correspondingly, most national laws recognize similar types of exceptions via restrictive lists or through general provisions. The DMCA (2000) lays the very legal foundation for DRM applications in United States. It defines an exception through fair use. Exceptions exempt certain uses of IP from authorization, but they are not rights. Thus, fair use needs to be enforced under the legal provisions as well as the agreement between content provider and consumers. The proper enforcement calls for technological protection means, and thus came DRM. Not only do legislative regulations lay the legal foundation for DRM techniques, but they also forbid tampering with the DRM technical barrier and severely punish violators (DMCA).

Despite the legislative efforts to protect copyrights, there are some challenges in the context of DRM systems to apply copyright laws. The foremost is due to underdeveloped policy languages and missing attributes. The copyrights are subject to a number of exceptions, which depend on a variety of factors including the user's role, intent, purpose of use, and so forth. A primary defense to a claim of infringement of fair use is fuzzy by nature. The risks of DRM systems must be examined due to automatic enforcement. There are some transactions between copyright holders and users that may benefit from the technical mechanisms; however, many legitimate, noninfringing uses of copyrighted works by individuals may be prevented. DRM systems often include authorization authorities from which the users are required to seek permission for the desired use. Virtually all DRM mechanisms utilize encryption for transport security, ensuring that the content is managed by a trusted agent. This may require users to divulge personal information prior to using a legally acquired copyrighted work at home, which is at odds with current consumer expectations.

Cryptographic Algorithms and Key Management for DRM

DRM technological tools usually consist of cryptographic algorithms, key management, watermarking, and personal authentication using biometrics. General security and privacy policies are often enforced with strong cryptographic algorithms, protocols, and key management. The cryptographic algorithms are used in DRM systems so that the consumers can only process the digital content on a trusted device. That is, the cryptographic algorithms in DRM prevent the consumers from accessing the digital data directly. A famous example is the CSS used for DVD encryption and key management. CSS provides a weak technical hurdle in its own right, with the effective encryption key length only in the order of 8 to 16 bits. Its protection primarily comes from the legal enforcement of DMCA. Also, the cryptographic algorithms provide a means to establish trust between consumers and device manufacturers. The management of trust needs to be handled be over time and across a huge number of devices. A famous example is the xCP technologies of IBM (Lotspiech, Nusser, & Pestoni, 2002), a peer-to-peer content-protection protocol utilizing Fiat and Naor's (1994) broadcast-encryption scheme. The xCP can implement a compliant, authorized domain, which is a trusted collection or a home network of devices. It provides mechanisms for enforcing compliance without device identification or authentication. Anonymous authorization and exception mechanisms are also supported.

Watermarking-Based Techniques for DRM

For multimedia content, cryptographic measures are not enough to protect IP due to the existence of the analog hole: Because the digital content has to be rendered or presented to the end users in an analog form, it is always possible to capture and redigitize the analog signals for illegal redistribution. Thus, digital watermarking or data-hiding techniques need to be applied. By inserting imperceptible watermarks into the digital content, the usage of each digital copy can be individualized, traced, and controlled. The main players of a digital watermarking system consist of an encoder, an attacker that attempts to disrupt the watermark, and a decoder. The encoder inserts watermarks into the digital content, and the watermarks usually encode a certain amount of information with a cryptographic key. At the decoder, a key is also used to decode or detect the watermark information. If the decoding key is the same as that of the encoding, the watermarking system is symmetric; otherwise, it is asymmetric (Cheng, Wang, & Huang, 2004). Asymmetric watermarking systems potentially have higher security levels than their symmetric counterparts.

The applications of digital watermarking include fingerprinting, covert communications, copy control or protection, broadcast monitoring, and so forth. There are a number of digital watermarking techniques for different applications, such as robust watermarking, fragile watermarking, steganography, and others. From the point of view of transmitting much watermark information in applications like covert communications, the original digital content may be regarded as side information, usually available only to the encoder. Correspondingly, watermarking can be modeled as a variant of communications with side information at the encoder (Costa, 1983). This model benefits the data rate of covert communications. The spread spectrum communications model has also been applied to watermarking systems, resulting in high resilience to noise and manipulations (Cheng & Huang, 2003).

Important properties of watermarking systems usually include robustness, security, imperceptibility, reliability, capacity, and complexity. These properties may contradict mutually; for example, robustness and imperceptibility, imperceptibility and capacity, or robustness and capacity cannot be improved simultaneously. Proper balances need to be struck depending on the application. Critical are good imperceptibility and high reliability in most, if not all, applications. In copy protection and control applications, robustness is one of the key requirements. Imperceptibility needs to be traded for robustness in this case, while capacity becomes relatively less important. The reliable detection of watermarks proves to be extremely important considering the commercial or legal consequences caused by detection errors. The required error rate may be lower than 1 out of 1 million, or even 1 out of 1 billion. It poses great difficulty in experimentally verifying or guaranteeing such low error rates. Theoretical as well as practical studies have provided important guidance in predicting and estimating the error rates and achieving high reliability (Cheng & Huang, 2001; Cheng et al., 2004). Also, attackers attempt to intercept or impersonate the watermark information. Thus, the watermark security must be sufficiently high.

Biometrics-Based DRM Approaches

In a DRM system, biometrics may find an important place for personal authentication and key management. Classical user authentication systems are usually based on what the user owns or knows such as keys, identification cards, smart cards, passwords, and others. In contrast, biometrics provides a means of personal authentication based on what the user is or produces. Included are both physiological and behavioral modalities such as a fingerprint, iris, face, palm print, voice, handwriting, signature, and so on. Most biometric systems in commercial applications operate under the verification mode (Jain, Bolle, & Pankanti, 1999), which gives a binary detection decision. The verification performance can be improved by multimodal biometrics that combines several verification strategies and modalities. Common commercial biometric technologies encompass fingerprint readers, multimodal speaker verification, online signature recognizers, and so forth.

There may exist many parties in a DRM system, including end users (individuals, groups, or companies) and intermediaries (dealers, distributors, or system administrators). The consumers need different keys for encryption, decryption, and watermarking (with public and/or private watermarking keys). In practice, pass codes are usually used instead of cryptographically strong keys, but pass codes lack a direct connection with the users. Biometrics can be applied for the personal authentication of these consumers as well as key management, for example, with the creation and retrieval of electronic signatures. However, the disadvantage of a biometric pattern is that it can no longer be used once compromised. This presents a main difficulty in integrating biometrics into DRM systems. To handle this compromising problem, statistical features have been used instead of direct biometric patterns, or biometric patterns combined with secret keys are used. Alternatively exploited is dynamic biometrics such as voice and online writing (Vielhauer et al., 2002), with the advantage of the tested biometrics being different each time to void the compromise problem.

DRM SYSTEMS AND STANDARDS

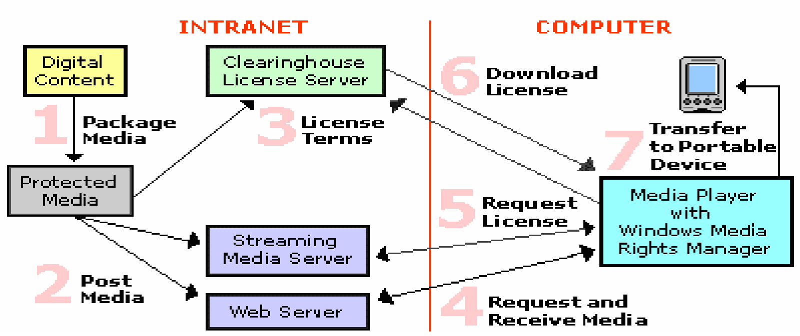
Technological measures can raise the barrier for casual violation, but they alone are not sufficient for managing and protecting digital IP rights. Concerted effort from relevant industries and legislative actions is completely necessary to enable DRM at a large or even global scale.

Despite DRM's short history, many commercial DRM tools have been developed. Real Networks developed their Media Commerce Suite for media servers that includes content encryption and run-time license generation. Macrovision has produced anticopy technologies for analog consumer videos and music CDs. Its more recent Rip Guard can prevent the ripping of video from DVDs. IBM xCP, Sony Open Magic Gate, Apple iTunes, and ContentGuard (2002) are well-known DRM tools. Currently, the most visible DRM for media protection is Microsoft's Windows Media Rights Manager, whose flow process is shown in Figure 1 (Microsoft, 2004). In the first stage, it packages the media file by encrypting and locking it with a cryptographic key. The key is stored in a license that is encrypted and distributed separately from the content file. The second stage involves the distribution of the media file through the streaming media server, CD, Web server, and so forth. In the next stage, the content provider chooses a license clearinghouse to authenticate the consumer's request for a license. At the user's side, the consumer needs to acquire the license key to unlock the content file. Windows DRM either sends the consumer's request to the media server, or downloads a license from the clearinghouse. Also, the consumer's player must support the Widows DRM to play the content file. The licenses have such rights as the allowable operation, duration, and starting time. The content can only be played according to the rules in the license, and can only be played by the person who has obtained a license.

The multiplicity of DRM systems and products has raised controversial issues of DRM interoperability and standardization. These tools often require the compliance of devices to DRM policies or contracts. Regulations are needed to govern the commercial behaviors of the device manufacturers and content providers. Industrial efforts started to incorporate various cryptographic, data-hiding, and biometrics techniques into industry standards for commercial products. Included are the following:

- The Open Platform Initiative for Multimedia Access (OPIMA), which developed hooks to allow for interoperability
- The Organization for the Advancement of Structured Information Standards (OASIS), which developed the extensible commerce markup language (XCML)
- The Open Mobile Alliance (OMA) with its rights expression language (REL)
- The Open eBook Forum with its rights grammar
- The MPEG-4 (Moving Pictures Experts Group), which developed DRM hooks, a mechanism for associating an IP identification data set (IPIDS) with audiovisual objects, the rights data dictionary (RDD), REL, and so forth
- The MPEG-21, which provides a multimedia framework

Figure 1. Flow process of Microsoft's Windows Media Rights Manager (Microsoft, 2004).



Some of these open standards are still en route to becoming international standards. Though the development of MPEG-21 is still ongoing, being a comprehensive next-generation framework for multimedia, its impact on the e-content market is prominent. MPEG-21 pays extensive attention to intellectual property management and protection (IPMP), with 4 out of 14 parts currently directly dealing with it. Kill and Bormans (2002) pointed out that the aim of the open framework is to "provide content creators, producers, distributors, and service providers with equal opportunities in the MPEG-21-enabled open market." They also noted this will benefit content consumers by "providing them access to a large variety of content in an interoperable manner." The fundamental unit in MPEG-21 is the digital item (DI) where the content is packaged and traded. The DI's declaration part is an XML (extensible markup language; Bray, Paoli, Sperberg-McQueen, & Maler, 2000) file providing identification, description, and references. The REL of MPEG-21 is based on the DRM-oriented language XrML (extensible right markup language; ContentGuard, Inc., 2002) that expresses relations between the essential entities. These entities compose a policy that is governed by IPMP. Rights within XrML are defined through XML schemas and shared among applications. Policies are mapped to grants that include actions to deny, permit, or indeterminate.

CHALLENGES

Despite the huge interest, extensive development and research, developed DRM tools, active standardization initiatives, and legislative acts, there are many challenges yet to be met. The legislative challenge has been discussed previously. A few technical and commercial challenges are the following.

Many attacks to watermarking systems have been developed, such as copy attacks and sensitivity attacks. To counterattack these attacks, watermark security poses a requirement that the attacker should have little chance to succeed. However, it turns out to be a highly demanding requirement in a very hostile environment. For example, there are many DRM frauds and attacks that DRM efforts have suffered, including the following.

- A DeCSS attack to a CSS by Johansen in 1999
- The Scientific attack to the Secure Digital Music Initiative's (SDMI) watermark technology by Felten et al. in 2001
- The PlayFair attack to Apple's iTunes Music Store's DRM in 2004

Asymmetric watermarking is a very promising technique in enhancing watermark security. In addition, new business models are proposed so that there is no incentive to impersonate watermarks. At this moment, it remains unclear what security level can eventually be achieved for DRM applications. Also, an important drawback of watermarking is that the content needs to be changed. The already released content is thus left unprotected. Even though fingerprinting has been introduced to fill this vacuum, it is still unclear to what extent it can be applied in practice.

Also unclear is how to achieve the best practice in offering interoperability in the standardization of DRM. Fully standardizing DRM systems may not be desirable; for example, CSS has been rendered ineffective, and SDMI has failed to produce any useful specifications. Standardizing components and parts of underlying infrastructures is an alternative, but the question remains whether the general principles can actually work toward DRM interoperability.

Comparatively simple, conditional access control systems are insufficient for Internet-distribution applications. To this end, MPEG has specified a set of hooks and extensions for DRM applications. The architecture is mature for MPEG-4 but unclear for MPEG-21. Without a universal architecture in current MPEG-21 specifications, also unclear is how different parts of MPEG-21 should be put together to work. Because MPEG-21 defines "a normative open framework for multimedia delivery and consumption for use by all the players in the delivery and consumption chain" (Kill & Bormans, 2002), it includes the whole life circle of digital content. Particularly included is digital-item adaptation, which allows for both resource and item adaptations. Thus, individual resources can be physically changed and/or different resources selected. A very challenging issue is how content adaptation should be properly handled by a DRM system.

A more important and bigger challenge is whether content users accept the new DRM technology that restricts the copying of contents. From the content consumer's point of view, content from any source will play on players from any manufacturer, and content users have become used to freely copying DVDs for viewing at their own home or for sharing with their friends. Many DRM restrictions will be considered a downside for consumers. For example, it may irritate consumers if the promised in-home distribution of many DRM tools is not easy to use. The DRM tools would be accepted if consumers could move the videos or music around a home network and among different machines without difficulties. Otherwise, individual consumers might try to attack DRM tools, and it may become more challenging to block the wholesale pirating of digital content.

D

FUTURE TRENDS

The evolution of DRM technology has included an increasing adoption of accepted security practice and the application of standardized protocols based on XML. Examples include XrML, ODRL (Iannella, 2001), and others. An emerging standard is the security assertion markup language (SAML; OASIS, 2002). This is an open framework and there is no commercial DRM mechanism that has been built on it. Because particular implementations of this model would incorporate various infrastructures for identification, authentication, cryptography, and metadata, we believe that a DRM system compliant to this framework will provide proper interoperability and become an indispensable part of future e-business.

DRM in home networks has mainly focused on physical links and storage protection. An emerging interest is in middleware or application layers, for example, DRM support for universal plug and play and authorized domains in digital video broadcasting. Currently, DRM is mostly concentrated in the broadband domain. In the broadcasting domain, simple, conditional access systems are often used. With the wide use of digital TV, an apparent trend is the widespread use of DRM systems in the broadcasting domain. The broadcast flag has already been adopted, but this is only the very beginning. With the growing bandwidth of mobile systems, DRM will also expand in this domain.

CONCLUSION

In the digital age, DRM is critical in the e-content distribution chain. We discuss the related concepts, trends, and challenges in this article. We conclude by emphasizing our belief: Only with an integrated legal, technological, and commercial framework can the goal of DRM be fully achieved.

KEY TERMS

Content Scrambling System (CSS): A well-known technological protection measure for the access control and copy prevention of DVDs. It is based on encryption but was broken by the Norwegian teenager Jon Johansen (and two other individuals) in 1999. The decryption program, DeCSS, allows for the copying and playback of digital content on noncompliant machines.

Digital Rights Management (DRM): It refers to the protection and management of the intellectual property rights of digital content. It offers a means of setting up a contract between content consumers and providers. Specifically, it provides content creators or owners with a range of controls over their products or services. It also offers interoperability to consumers, including end users and any intermediaries such as dealers, distributors, and system administrators.

Digital Watermarking: Sometimes also known as digital data hiding, it is a technique for inserting secret information into digital content in a seemingly innocuous and standards-compliant manner for applications of content authentication, covert communications, copyright control or protection, and so forth. In the case of covert communications, it is also called steganography.

DRM Hooks: Also known as IPMP hooks, they were developed in 1999 and standardized by MPEG-4 in 2000. They allow proprietary DRM systems to be used within an MPEG-4-compliant terminal by associating the IPIDS of an IPMP system with each audiovisual object. The IPIDS is unique for any IPMP system and is assigned by a registration authority.

MPEG (Moving Pictures Experts Group): It is an international standardization organization (ISO) for digital multimedia, especially audiovisual objects. It developed a series of international standards, including MPEG-1, MPEG-2, MPEG-4, MPEG-7, and MPEG-21.

XML (Extensible Markup Language): It is a metalanguage defining the syntax for presenting and exchanging data in Web environments. It overcomes the limit of fixed tags in HTML (hypertext markup language) and allows users to define their document structures. W3C (World Wide Web Consortium) has designated XML as the standard for Web data.

XrML (Extensible Right Markup Language): It was submitted to MPEG responding to a call for a proposal in 2001, and is the basis for the REL syntax developed by MPEG.

Distributed Workflow Management Based on UML and Web Services

Guiseppe Scanniello
University of Salerno, Italy

INTRODUCTION

The definition and the management of business processes are considered a relevant issue to support organizations in their activities. Indeed, in the last few years many organizations have been changing their business processes to keep competitive in the global market. Workflow management is an emerging technology enabling process performance improvement in a cooperative working environment. In particular, a workflow management system (WfMS) enables processes automation through the integration, the coordination, and communication of both human and automatic task of business processes. WfMSs provide a process definition language (PDL) for modeling business processes. A PDL sentence is named process model and is enacted by a component of the WfMS, namely the process engine. The main task of this component is executing the enactment rules and the activities specified in the Process Model.

A huge number of PDLs based on several formalisms have been proposed in literature. Recently, some authors suggest exploiting the unified modeling language (UML) proposed by the Object Management Group (OMG, 2002) to model business processes (Aversano, Canfora, De Lucia, & Gallucci, 2002; Di Nitto, Lavazza, Schiavoni, Tracanella, & Trombetta, 2002; Eriksson & Penker, 2000, Jager, Schleicher, & Westfechtel, 1999; Marshall, 2000). UML is a natural choice for representing business processes, as it is a well known notation that can be easily understood and used by any kind of users.

In this article, we propose a Web services-based WfMS that lets users manage and enact business processes. The proposed system offers a visual environment based on an extension of UML activity diagrams that allows to graphically design a process model and to visually monitor its enactment. Since UML does not have a well defined operational semantics and is not executable, we had to make the process model executable by appropriately enriching the syntax and semantics of UML activity diagrams. The architecture of the proposed WfMS is based on Web services to manage and enact distributed business processes.

BACKGROUND

In the last decades workflow management systems (WfMSs) (Workflow Management Coalition, 1999) have been developed by researchers to provide support to the modeling, improvement, and automation of business and industrial engineering processes (Cugola, Di Nitto, & Fuggetta, 2001; Eder & Panagos, 1999; Winograd & Flores, 1986), including software processes (Bandinelli, Di Nitto, & Fuggetta, 1996; Heimann, Joeris, Krapp, & Westfechtel, 1996; Kaiser, Dossick, Jiang, Yang, & Xi Ye, 1998).

Most of the WfMSs of the last decade are client-server systems, with centralized enactment facilities, although they do not exploit the web as basic infrastructure to ease the accessibility by remote users. Recent research on workflow management is focusing on the use of web technologies and/or specialized middleware to support distributed processes across organizations (Aversano et al., 2004; Cugola et al., 2001; Eder & Panagos, 1999; Kaiser et al., 1998; Kammer, Bolcer, Taylor, & Hitomi, 1998; Maurer et al., 2000). The new frontier for the management of distributed e-business processes is provided by Web services (ebXML, 2001; Leymann, 2001). In particular, Pautasso and Alonso (2003) propose a visual approach to compose the various services as task of a process. A process is modeled by using two different diagrams, one for data flow and another for control flow. This requires two different process views.

In general, a number of process definition languages have been proposed in the literature, based on several formalisms such as event-condition-action mechanisms (Aversano et al., 2004, Loops & Allweyer, 1998), graph rewriting mechanism (Heimann et al., 1996), Petri Nets (Bandinelli et al., 1996), etc.

Several authors have recently proposed to adopt UML (OMG, 2002) for representing business processes (Di Nitto et al., 2002; Eriksson & Penker, 2000; Jager et al., 1999; Marshall, 2000). UML is a well known notation that can be easily understood and used by a project manager. It is important to point out that UML has been conceived for the communication among people. As a consequence, it does not have a well defined operational semantics and is not executable. Indeed, most approaches proposed in the literature use UML to model business processes at a very high level (Loops & Allweyer, 1998; Eriksson & Penker, 2000; Marshall, 2000) and in some cases manually translate the UML model into the PDL of a specific workflow management system (Loops & Allweyer, 1998; Aversano et al., 2002).

In the last years some research efforts are being made to add a well defined operational semantics to UML notations to automatically derive executable process models (Di Nitto et al., 2002; Jager et al., 1999). In (Jager et al., 1999) UML class diagrams and state diagrams are used to model the structure and the behavior of a process. Semantics is attached to UML process models by mapping them to programmed graph rewriting systems (Heimann et al., 1996). In (Di Nitto et al., 2002) a process is modeled by using a subset of UML diagrams, including UML activity diagrams with object flow to model the control and data flow, class diagrams to model structural properties of the process, and state diagrams to model the behavior of activities. The XMI standard representation of these models produced using a UML CASE tool can then be translated into an executable process description for the OPSS Workflow Management System (Cugola et al., 2001). De Lucia, Francese, and Tortora (2003) have presented a case study of mapping UML activity diagrams with object flow on the process definition language of the GENESIS environment (Aversano et al., 2004). The authors showed that UML activity diagrams do not support all the control flow and data flow rules of the GENESIS process definition language. As a consequence, the syntax and semantics of this type of UML diagrams often need to be extended to make them suitable for modeling business processes in workflow management systems.

AN UML BASED DISTRIBUTED WORKFLOW MANAGEMENT SYSTEM

In this section we present a distributed WfMS that uses UML activity diagrams as process definition language (PD) and Web services for the execution of distributed automatic activities.

The Process Definition Language

UML activity diagrams provide an intuitive and easy to learn PDL. In particular, we use an extension of the activity diagrams with object-flow (OMG, 2002). UML activity diagrams are a particular variation of UML state diagrams where states represents actions (or activities) and are modeled by rounded rectangles and transitions between states depicted as solid arrows model the control flow between two activities. Activity diagrams have been enriched with object flow to depict the data flow between activities.

Although structural properties and relations between process elements, such as artifacts, activities, and roles, could be specified using other UML diagrams (Di Nitto et al., 2002), we did not include them in the proposed PDL, to avoid the use of too many diagrams. Indeed, a process modeling tool can provide other features to model these aspects, such as forms or simpler graphical notations (e.g., organizational charts for the roles). Some approaches (Di Nitto et al., 2002; Jager et al., 1999) use state diagrams for modeling the internal behavior of activities. In our approach activities may be interactive or automatic depending on if they are performed by humans or by a tool, respectively. For interactive activities, unlike other WfMSs, we do not provide a visual notation to model them. Rather, their user interface is automatically generated from the definition of the input and output objects of the interactive activity. Automatic activities are associated to Web services using Web service description language (WSDL) specification and executed on remote machines.

We needed to suitably enrich the syntax and semantics of UML activity diagrams to enable the specification and execution of particular aspects of a distributed business process. In particular, distributed processes are organized in a hierarchical way and modeled as subprocesses in UML activity diagrams (see Figure 1 for an example). A compound activity is depicted as an activity with the addition of an icon in the right lower corner denoting a nested activity diagram, see activity *A2* in Figure 1(a). In particular, Figure 1(a) shows a partial

Figure 1. Process and sub-process modeling

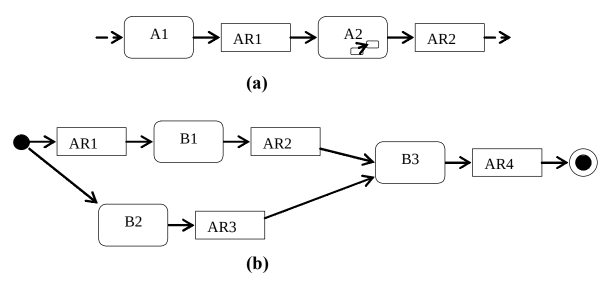

Figure 2. Activity multiplicity

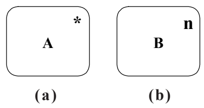

Figure 3. The pair synchronization type

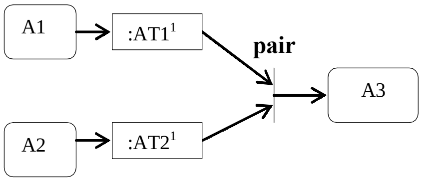

Figure 4. The traceability synchronization type

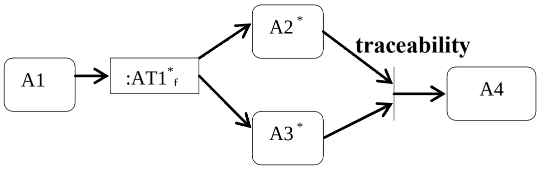

Figure 5. The all synchronization type

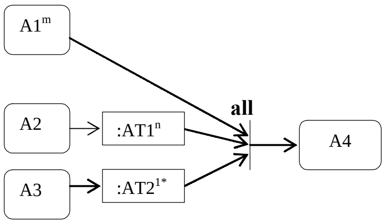


process and Figure 1(b) the subprocess associated to the composed activity *A2*. The input artifacts are transferred to the subprocess as if they were produced by the start activity. Similarly, all the output artifacts are transferred to the higher level process by assigning them to the end activity.

We also extended UML activity diagrams for modeling several aspects concerning the synchronization between groups of artifacts and activities. To this end we need to provide some basic concepts.

In UML activity diagrams it is possible to specify whether concurrent instances of the same activity can be executed and in this case their multiplicity. We can use the *(*)* symbol (*multiplicity marker*) in the right-higher corner of the activity symbol, as shown in Figure 2(a) to denote that multiple instances of the activity can be executed. This symbol indicates that the number of instances is unknown during the process modeling and will be determined at run-time. Differently, whether the exact number of instance is known the multiplicity can be specified as in Figure 2(b).

In UML activity diagrams, a specific object with a name is exchanged between two activities. On the other hand, we need to provide more flexibility, in that an undefined number of artifacts of a given type can be produced by the source activity and consumed by the target activity. Therefore, we can use for artifact names the typical UML object notation *artifact-name: artifact-type* in case the multiplicity of the artifact is one. Whenever the multiplicity of the artifact type is undefined (many), we can use the notation *: artifact-type*, without specifying the name of the artifact.

To model the synchronization between two or more transitions UML synchronization bars can be used. We associate to the join construct a different operational semantics depending on the synchronization type. We have identified four different synchronization types: *pair*, *traceability*, *all*, and *once*. The synchronization type can be depicted as a label on the top of the UML synchronization bar. Whether the synchronization type is unspecified the default value is *all*. The first synchronization type, *pair*, is allowed only if the artifacts or the activities to be synchronized have multiplicity one, as shown in Figure 3. In this case the control is transferred to the target activity only when each artifact instance is produced.

Other synchronization policies have to be considered when we need to synchronize artifacts and/or activities with undefined multiplicity. The *traceability* synchronization type is used when activities or artifacts with multiplicity greater than one instantiate several artifacts (or activities) of the same type that have to be synchronized with other artifacts or activities. We need a way to distinguish the activities and the artifacts belonging to the same group. To this aim, we identify a point of the process, the *traceability fire*, where a new traceability identifier is generated. A traceability fire is depicted by adding *f* as subscript to the name of the node, as in the artifact type *AT1* in Figure 4. Here *A1* produces several artifacts of type *AT1* having a traceability fire assigned to them. Whenever a new instance of the artifact is produced, a new traceability identifier is associated to it, and the two instances of *A2* and *A3* having the same traceability identifier are activated. The edge having the traceability join as source is started when the join node receives as input two control flows deriving from two instances of *A2* and *A3* with the same traceability identifier.

The *all* synchronization type consists of waiting the availability of all the instances of each object type or activity. As shown in Figure 5, the control is transferred to *A4* only when the *m* instances of the activity *A1* are terminated, the *n* instances of the artifact type *AT2* and all the instances of the type *AT3* (whose number is known during enactment) are available. Finally, the *once* synchronization type consists of waiting that at least one artifact of each type is produced and letting all the artifacts flowing without any further synchronization.

The WfMS Architecture

The architecture of the system follows the model proposed by the Workflow Management Coalition (1999). Figure 6 shows the architecture.

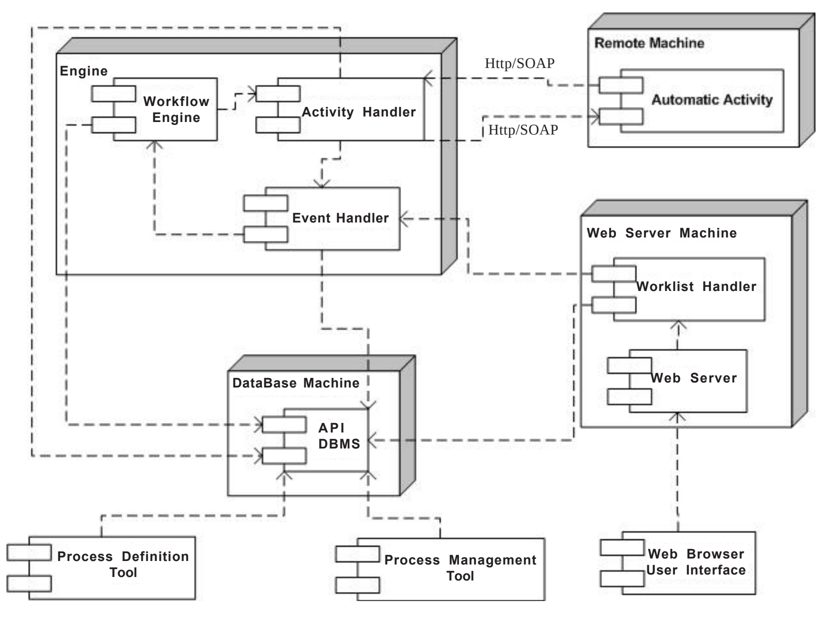
The *process definition tool* enables the definition of the process according to the UML based PDL described above. This is stored in the database in terms of the process components (activities, artifacts, transitions, etc.).

The *workflow engine* is a component whose main task is to manage the execution of process instances through the enactment rules specified in the process model. The workflow engine is in charge of instantiating both types of activities, automatic and interactive. Besides instantiating an automatic activity, the workflow engine needs to identify the corresponding Web service. To this aim the *activity handler* component is used. This is a component that is in charge to identify and select the Web service corresponding to the definition of the automatic activity. Once this has been identified and registered in the UDDI registry, the activity handler creates the instance of the automatic activity in the database and associates the URL of the corresponding Web service. The activity handler is in charge of monitoring the evolution of the activity, storing the data returned by the corresponding Web service and notifying the event handler (a component of the workflow engine) of events concerning the activity, such as its termination or the production of an object. These events are stored in the database and later processed by the workflow engine according to the workflow enactment rules.

Compound activities corresponding to subprocesses are handled as automatic activities. Whenever a compound activity has to be instantiated, the activity handler identifies the workflow management system that is in charge of executing the subprocess. The latter maintains the model of the subprocess and the data concerning the instance execution in the local database and only events concerning the change of state of the process instance or the production of output objects are monitored by the activity handler and notified to the event handler of the higher level process.

Interactive activities are simply created in the database by the workflow engine and are managed by the *worklist handler*, a component developed using Web technologies, which optimizes the assignment of human resources by considering the effort needed to accomplish each activity. The graphical interface of an interactive activity is generated through the worklist handler, and is presented through Web browser on the client machine. The worklist handler provides information on the activities that can be executed, the corresponding state (such as running, suspended, or terminated), and its input and

Figure 6. WfMS architecture



output objects. The Worklist Handler stores the objects produced by the interactive activities into the database and notifies events concerning interactive activities to the Event Handler.

Finally, the *process management tool* is the component which handles the process execution. It allows starting a process, monitoring its state during enactment and managing deviations from the process model in case of unforeseen situations (Casati & Cugola, 2001).

FUTURE TRENDS

Generally, WfMSs do not support the knowledge improvement of human resources by learning on the job and learning on demand. Thus, the human resources can only trust on their knowledge to accomplish activities belonging to business processes or use external enterprise e-learning systems, if available. This would require integrating WfMSs with e-learning systems.

Costagliola, Ferrucci, Polese, and Scanniello (2005) suggested a hierarchy of visual languages to model learning process regarding e-learning activities and their relationships. We are currently integrating the presented WfMS with this e-learning system. The process definition tool of the WfMS will associate activities of the business process with e-learning processes defined with the visual editor of the e-learning system. A key for this integration is the common UML based notation for both business processes and e-learning processes. This system also will allow business process participants to adaptively access the contents of the e-learning courses associated with their activities.

CONCLUSION

A briefly description of the main characteristics of a distributed WfMS based on an extension of the UML activity diagrams with object flow has been proposed. Future trends of our research have also been highlighted in this article.

Differently from the other approaches, we have not used many UML notations to model different aspects of a process. Making UML activity diagrams executable required some minor extensions of the UML syntax and semantics, some of them achieved using stereotypes. However, these modifications are quite simple to understand. We distinguished between automatic and interactive activities. Automatic activities are managed as Web services, whilst the interfaces of interactive activities are automatically generated starting from the specification of the input and output artifacts.

KEY TERMS

Artifact: Any object produced or consumed by an activity of a business process.

Business Process: One or more linked procedures or coordinated activities, which collectively realize a business objective or policy goal.

E-Learning: The delivery of knowledge using electronic devices.

Process Definition: The process definition consists of a network of activities and their relationships, criteria to indicate the start and termination of the process, and information about the individual activities.

Web Services: A modular self-describing software service universally accessible in a standardized and platform independent way.

Workflow: The automation of a business process, in whole or part, during which documents, information or tasks are passed from one participant to another for action, according to a set of procedural rules.

Workflow Management System: A system that defines, creates, and manages workflows by the use of software, running on one or more workflow engines, which is able to interpret the process definition, interact with workflow participants and, where required, invoke the use of applications.

Dot Net and J2EE for Web Services

Andrew Chen
Arizona State University, USA

INTRODUCTION

The capabilities of Internet technologies continue to evolve as businesses learn and implement more sophisticated e-business applications in order to adapt to dynamic environments. Web services are an industry-wide response to the need for a more flexible and efficient business collaboration environment. Supported by major institutions and industry leaders, Web services have become the promising method for making e-business information and applications programmatically available via the Internet. Web services are self-contained, modular business applications that have open, Internet-oriented, and standards-based interfaces. Chen, Chen, and Shao (2003) provide a good review of the implications and impacts of Web services to electronic-commerce research and practices.

In order for the Web-services idea to become a working reality, there must be a common agreement on how they will work. Web services rely on a set of standards to support interoperability among applications developed in different languages and running on different platforms or operating systems. Core Web-services standards include SOAP (simple object access protocol), WSDL (Web services description language), and UDDI (universal description, discovery, and integration). The basic idea of Web services is the use of the SOAP messaging protocol to invoke software methods in remote systems. A WSDL file contains service definitions for distributed systems to support the automatic creation of client-side links and the binding to the Web services. UDDI is a registry standard for Web-services providers to publish their Web services. It then can be used by a Web-services consumer to discover (search) Web services developed by Web-services providers.

The grand vision of Web-services-oriented architecture is that Web services can be composed and invoked dynamically to support business processes within and across enterprises. A number of new standards have been introduced to address this Web-services composition issue, including BPEL4WS (business process execution language for Web services), WSCI (Web services choreography interface), and BPML (business process modeling language; Arkin, 2002; Arkin et al., 2002).

Semantic matching and Semantic Web are other developments that enable greater access to services on the Web (Berners-Lee, Hendler, & Lassila, 2001; McIlraith, Son, & Zeng, 2001). The purposes for the development of an ontology of services, DAML-S (DAML Services Coalition, 2003) under the DARPA agent markup language (DAML) program, are closely related to various Web-services standards. There are very limited interactions between Web-services standards and semantic-Web research. Adding ontology support to UDDI to facilitate Web-services search is a promising direction for future research.

BACKGROUND

Organizations have been motivated to start Web-services initiatives in order to compete in the future business environment. Two major companies, Microsoft and Sun Microsystems, have developed platforms (Microsoft .NET and Java 2 Enterprise Edition [J2EE], respectively) to support Web services. In general, Microsoft .NET is a product suite that enables organizations to build enterprise-class Web-services applications. On the other hand, J2EE is a standard that facilitates building Web services with other products (e.g., used with IBM's WebSphere, HP's Web Services Platform, and Sun's Sun ONE).

Microsoft .NET

Microsoft focuses on three goals as its vision for Web services. First, everything in the system must be a Web service. Second, once these services are created, one must be able to integrate and aggregate these services in simple and easy ways. Third, one needs to have a simple and compelling consumer or end-user experience (Microsoft Corporation, 2001b). According to the Microsoft Corporation, "The Microsoft .NET platform includes a comprehensive family of products…that provide for each aspect of developing, managing, using and experiencing XML Web Services." One unique idea that the .Net framework proposes is its multilanguage support. This idea is to allow developers to program Web services in any language they feel comfortable with (e.g., COBOL, C, Java, VB, etc.). For Web applications, active server page (ASP) technology has been updated to ASP.NET, which provides advanced server-side Web controls and easy-to-create user controls. At the same time, Windows

XP is introduced as the innovative operating system that is aimed at helping consumers interact more directly with Web services. An important part of the XP system is the integration of common tasks with services available on the Internet. With these fundamental innovations, Microsoft has made substantial efforts to advocate Web-services development and implementation.

J2EE

J2EE was designed to simplify complex problems with the development, deployment, and management of multitier enterprise solutions (Vawter & Roman, 2001). The goal of J2EE is to give the user free choice in the use of other products and tools, and to encourage best-of-breed products to emerge through competition. This is the idea of the market and community that J2EE envisions.

J2EE was not originally created for Web services per se; however, J2EE supports the server-side deployment of goods and services with the J2EE application server. Typically, a J2EE application server deploys, manages, and executes three types of standard components, namely, the Web component, Web service, and EJB (Enterprise JavaBean) component. Briefly described, a Web component (e.g., a servlet component, a Java server page [JSP] component) interacts with a Web-based client by connecting with Web-services components for functionalities, and with EJB components for business logic and live business data.

COMPARISON OF .NET AND J2EE

While both .NET and J2EE help business build Web-services applications, many similarities and differences exist between them. There are many studies that compare .NET and J2EE from different perspectives such as Web services in general (Lurie & Belanger, 2002; McGarvey, 2004; Vawter & Roman, 2001), benchmark performance (Microsoft Corporation, 2004; Middleware Company, 2002), architecture (Farley, 2000), and enterprise Web application (Sheil & Monteiro, 2002). While these studies provide many insightful and interesting comparisons, in this section, these platforms will be compared on the basis of factors that can be reasonably measured or ascertained. Furthermore, we also summarize findings of benchmark-performance comparisons between .NET and J2EE at the end of this section.

Portability

Vawter and Roman (2001) state that a key difference between J2EE and .NET is that J2EE is platform agnostic, running on a variety of hardware and operating systems, such as Win32, UNIX, and Mainframe systems. This portability is real today because the Java run-time environment (JRE), on which J2EE is based, is available on any platform. On the other hand, Microsoft claims that .NET offers portability as well. Even most experts believe that J2EE possesses superior portability, but Microsoft has positioned .NET for portability by offering a two-step compilation process that allows .NET to provide run-time environments for different platforms.

Another aspect of portability is how .NET or J2EE can support a variety of implementations. Companies will likely choose between .NET and J2EE with considerations of implementations on not only intrafirm applications, but also interfirm-application integrations. As suggested by Vawter and Roman (2001), this aspect makes the future of J2EE very bright and is one of the critical differentiators between J2EE and .NET.

Platform Maturity

Platform maturity assesses the potential risk of system failure. Java has been developed and refined since the mid-'90s. The release of J2EE furthered the strength of Java by providing a stable and mature standard for Web applications. On the other hand, not until 2000 did Microsoft start to introduce its .NET strategy and subsequently offer the .NET platform. Further, many developers from different companies and technology communities have used and supported Java-oriented applications. This phenomenon results in better maturity for J2EE compared to .NET, which is young and supported by only one player: Microsoft. As suggested by Vawter and Roman (2001), J2EE is the more mature platform. They suggested that the very underlying fabric of .NET is an overhauled rewrite, and this represents enormous risk compared to the new J2EE features.

Language Support

Extended from Java, naturally all J2EE applications have to be written in Java. This single-language nature of J2EE contrasts fundamentally with .NET, which supports many different languages. While J2EE supporters can argue that a single language provides a more elegant solution, .NET offers an advantage to organizations that would like to leverage its knowledge workers' IT expertise (Lurie & Belanger, 2002). In its design, .NET's multilanguage-support concept is more appealing to a wider range of developers because it can encompass a wider variety of programmers, each knowing different programming languages. However, while a complicated application is written with multiple languages, it is very likely to cause a great deal of difficulties to maintain and modify the application.

Developer Tools and Rapid Application Development Features

Microsoft has traditionally set a strategy to provide users and developers with more comprehensive and easy-to-use tools. The success of promoting Visual Studio with multiproject debugging and ease of use has extended to Microsoft's Visual Studio.NET. This aspect for .NET-application developments has promised many features including a more powerful IDE (integrated development environment), life-cycle development tools, and VB.NET Web forms. These features can help novice developers make the transition to becoming proficient at developing Web applications for Web services. Arguably, Microsoft has held the edge in developer tools, and Visual Studio.NET holds the promise for continuing this trend of facilitating the rapid development of enterprise applications.

Sun has recently become a more viable source for development tools with its new Forte for Java. Sun has recently announced the release of Forte for the Java IDE for simplifying the development of applications for the J2EE/Sun ONE architecture. An important part of the Forte tool kit is that "a new Web service module provides automatic binding of Java technology and XML [extensible markup language] through intuitive wizards…and supports Web-based publishing to a services registry" (Sun Microsystems, 2001). Other tools such as Eclipse Platform and Eclipse SDK (Software Developer Kit) also provide an open, extensible IDE and a feature-rich development environment for building J2EE applications (Eclipse Foundation, 2004).

In summary, Table 1 provides a conclusive comparison on the factors discussed in this section.

Comparison Test

Since the emergence of .NET and the idea of Web services, empirical comparisons of .NET to J2EE also have begun. Since it is too early to tell which platform will win out in the long term, direct-comparison tests have been run to help distinguish between the two. VeriTest (2002) found that the .NET version in some instances performed as much as 10 times faster on page loads than the Java version of the online Pet Store. The Java-based application required approximately 4 times as much code as the .NET version. However, many Java developers as well as Sun, IBM, and Oracle have maintained that the comparisons to date have not been valid because the Java-based Pet Store application was not properly optimized for performance and not meant to be benchmarked. Middleware Company used an extensive new series of benchmarks based on a new implementation of the Java Pet Store, which has been extensively optimized for performance and scalability (Middleware Company, 2002). Its results still showed that the .NET version performed better than the J2EE version on, for example, peak throughput and maximum user load (supported users).

Another direct comparison was made in the testing of the Nile E-Commerce Application Server Benchmark implemented in .NET using C# and in the latest version of a leading J2EE-based application-server product. The results showed the .NET version outperformed the J2EE version by over 340% (Microsoft Corporation, 2001a). Microsoft also published comparison results for Web-services performance between the J2EE platform and .NET framework (Microsoft Corporation, 2004). Again, the report concluded that .NET performed better than J2EE on throughput and response time.

FUTURE TRENDS

Web services promise to revolutionize not only the way we develop systems, but also, more importantly, how we do business. Lurie and Belanger (2002) suggest that businesses should not be totally preoccupied with choosing a platform over the other, but should build Web services with a homogenous view of a heterogeneous environment. Both the technology and business fields look forward to more advanced cooperation and bridging between .NET and J2EE. For example, MONO is a compre-

Table 1. Comparison summary of .Net and J2EE

Feature	***.NET***	***J2EE***
Portability		X
Platform Maturity		X
Language Support	X	
Developer Tools and Rapid Application Development Features	X	

Note: X *indicates that a specific platform has better edge over the other one. For the factors that have an* X *on both platforms, it indicates that both platforms are equally good on these features.*

hensive open-source development platform based on the .NET framework that allows developers to build Unix and cross-platform applications with unprecedented productivity (Novell, Inc., 2004). On the other hand, IBM is offering an interoperability tool for Eclipse and .NET WinForms to help developers move to the Eclipse platform while making use of investments in .NET WinForms controls (IBM, 2004).

CONCLUSION

In summary, J2EE fares better in portability and platform maturity, but .NET is a favorable choice for better language support, developer tools, and rapid application development features. In general, many benchmark-performance comparison tests showed .NET-based applications perform better than J2EE-based applications.

J2EE is a standard supported by many IT players; that is, it is supported by a community and there are more choices of vendors for companies' Web-services applications. .NET is a product that is promoted and developed by one company, Microsoft, and support from others is slender. However, the implementation of .NET applications can be straightforward. On the other hand, a J2EE implementation typically involves buying tools from multiple vendors and patching them together, and can be complicated and time consuming (McGarvey, 2004).

Most businesses can benefit from .NET or J2EE in different ways. However, the choice of Web-services implementations should depend on the company's current systems and worker skills that can be compatible with either Microsoft or J2EE. Lurie and Belanger (2002) suggest that many people concede to the following rule of thumb: If you are committed to a homogenous Microsoft platform now, then choose .NET; otherwise, choose J2EE.

KEY TERMS

Electronic Commerce: E-commerce or e-business generally refers to the conduct of business transactional or managerial activities using Internet technologies via the Web.

J2EE: The Java 2 Enterprise Edition is designed to simplify complex problems with the development, deployment, and management of a multitier enterprise solution. J2EE is an industry standard that helps build Web services (e.g., used with IBM's WebSphere, HP's Web Services Platform, and Sun's Sun ONE).

.NET: Microsoft .NET is a product suite that enables companies to build smart, enterprise-class Web services. Microsoft .NET is a product strategy that serves as a platform for developing Web services.

SOAP: The simple object access protocol is the messaging protocol that facilitates Web services to invoke software methods in remote systems.

UDDI: Universal description, discovery, and integration is a registry standard for Web-services providers to publish their Web services. It may be used by a Web-services consumer to discover (search) Web services developed by Web-services providers.

Web Services: Web services are self-contained, self-describing, modular applications that have open, Internet-oriented, standards-based interfaces and can be published, located, and invoked across the Web.

WSDL: The Web services description language defines Web services for distributed systems to support the automatic creation of client-side stubs or proxies, and the binding to the Web services. It describes the interfaces to a Web-services implementation in terms of the format of the messages, binding of the abstract messages to a concrete protocol, and address of the endpoint.

Dot-Com Conversion at Egghead

William S. Lightfoot
University of Monaco, Monaco

INTRODUCTION

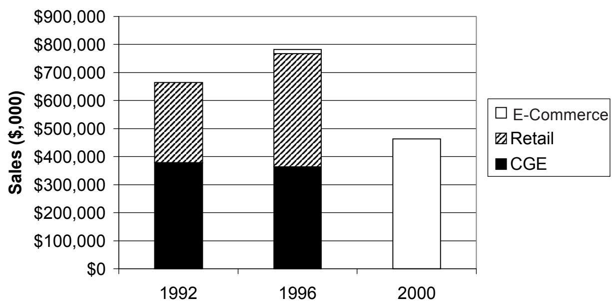
Egghead Software, Inc.'s evolution from a multichannel, traditional retailer of computer software and hardware into an e-commerce-only channel parallels the rise and fall of many e-commerce ventures. At one time, Egghead had a well-defined multichannel strategy, with a direct-sales unit focused on corporate, government, and education customers (CGE); a retail-store unit focused on early adopters of computer software and hardware; and a catalog and call-center unit that targeted consumers and small businesses. Struggling to survive in the face of increased competition and declining margins, Egghead made a series of decisions to sell its CGE unit and abandon its retail stores and catalog operations, shifting all of its resources into an e-commerce strategy. This shift was cited by many journalists and analysts as a sign that e-commerce was here to stay and highlighted Egghead.com as an example that traditional retailers should follow or risk becoming obsolete (Wilde, 1999). This article reviews the history of Egghead, focusing on the decisions and events that led to its demise.

BACKGROUND OF EGGHEAD SOFTWARE, INC.

Victor Alhadeff, a Washington-state entrepreneur, founded Egghead Software, Inc. in the early 1980s initially focusing on providing customers with knowledgeable support, competitive prices, free trials, and a liberal return policy. As one author noted, he aimed to be the high-quality service provider of software sales (Bond, 1996). In the late 1980s, Egghead added a call-center division that targeted customers not able to shop at its retail stores, and a direct-sales division that focused on selling software to corporate, government, and education customers. Its value to many suppliers was in its multichannel strategy (Figure 1), which aligned well with its customer base. It was able to surround customers with numerous points of contact that allowed the customer to buy in the manner they chose. Suppliers could deal with one channel, Egghead, and know they would reach many targeted customers in a variety of different ways.

After a disagreement with the board over the direction of the company, Alhadeff left in 1990. Egghead then went through two CEOs (chief executive officers) with little experience in high technology until Ronald Erickson took over in 1992 (Santucci, Bond, & Golding, 1999). With Erickson in charge, Egghead missed its projected sales and profit forecast. The management team attributed the results to an increase in competition, a slowdown in sales to the aerospace and military markets, and fewer new-product introductions. Egghead's gross margins also declined, causing management to apply more pressure on its retail-store managers with new performance measurements that focused on reducing the cost of returned software. At the same time, the company ran an advertising campaign that highlighted its no-questions-asked return policy (Speck, 1998). As one former store manager noted, the net result was to drive customers away by making the return of software an unpleasant experience (Speck).

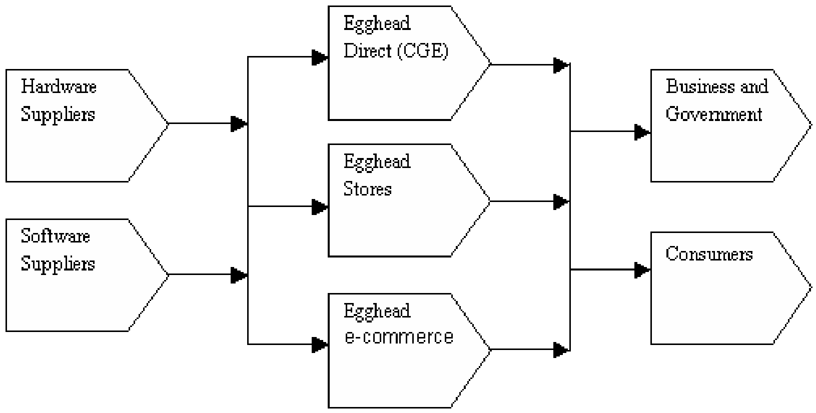
Figure 1. Revenue based on shifting channels (Compiled from Egghead annual reports)



Although margins continued to decline in 1994, Egghead implemented an electronic data-interchange (EDI) system, and signed an agreement with AT&T and Lotus to put its catalog online as part of a test for a new service (AT&T, 1994).

The following year, as sales reached $860 million, Terence Strom, a former vice president of marketing at Best Buy, Inc. was brought in as CEO to help revitalize Egghead's retail-store sales (Browder, 1996). Strom began to develop a new store concept that would average close to 5,000 square feet (twice the size of Egghead's current stores) with more hardware and software (Browder). These new "mini superstores" were designed to leverage Egghead's reputation for excellent customer support while

Figure 2. Egghead's position in the value chain as an intermediary (1983-1997)



also allowing the company to compete with other computer retailers like CompUSA and Best Buy (Browder). In 1995, Egghead had expanded its e-commerce efforts by establishing Elekom, which was charged with developing a new e-commerce system for Egghead (Browder). Egghead's position in the value chain (Figure 2) seemed secure: It would continue to leverage its existing retail locations, updating them to reflect the changing competitive environment, while extending its reach through e-commerce.

Within a year of taking over, Strom then decided that Egghead needed to focus more of its resources on the retail trade. This led to Egghead selling its CGE division to Software Spectrum, Inc. in 1996. The dismantling of Egghead's position in the market had begun.

Around the time that Strom decided to sell the CGE division, George Orban, a minority shareholder and member of the board, began to get more involved in the operations of Egghead. Believing e-commerce was the way to go, Strom, Orban, and their team started shifting efforts into this area. With cash from the sale of the CGE unit, they purchased Surplus Software, one of the early e-commerce developers and owner of the surplusdirect.com and surplusauction.com Web sites. Mixed results from Egghead's mini superstores, coupled with further declines in profitability in the traditional stores, led to the closing of 77 retail locations in 1997. While Egghead still had a strong brand name, a database full of customer information, and good relationships with many suppliers, Orban felt Egghead had to make a move or consider liquidation. Declining revenues and margins in the retail format, triple-digit growth in Egghead's e-commerce channels, and staggering growth projections for e-commerce in general by research firms such as the Yankee Group led Orban to decide the time had come to act. In late 1997, Strom left Egghead and Orban assumed the position of president and CEO.

FUTURE TRENDS: CATCHING THE DOT-COM WAVE

In January of 1998, Egghead announced that it was going to close its last remaining retail stores and focus exclusively on e-commerce through its three Web sites: Egghead.com, surplusauction.com, and surplusdirect.com. "The decision to close our brick-and-mortar retail network was made to enable the company's management and resources to focus on Internet sales and market share," said Orban (McNally, 1998). Many analysts and journalists praised Egghead for transforming its business model, holding it in the same regard as Dell and Gateway. As Erica Regulies of Giga Information Group noted, "This is the beginning of a trend. This is the first time we've really been able to say, 'Electronic commerce is here'" (Miles, 1998). Analysts called Egghead's move bold while recommending the stock as a buy. Orban said that while he also considered closing shop as an option, there were too many strengths and opportunities that led Egghead to the transition. "Egghead had a very strong brand name, great vendor relationships, and a retail culture that would help us take advantage of the Internet opportunity," Orban said. "We had the financial resources to fund the transition, and we put together a management group that was up to the challenge of exiting the traditional business and entering the new business" (Wilde, p. 92).

E-commerce competitors, like Insight.com, thought Egghead had made the right move (Miles, 1998). John Dixon, director of electronic media at Insight at that time, noted, "Retail is going to die. It's on its way out" (Miles). Some analysts were less optimistic. As Katrina Roche, general manager of supply chain solutions at Baan, noted, "it's not acceptable to have only one channel. Consumers expect to be able to buy products through a channel that meets their service needs, some that are oriented toward a higher-priced, high-service level, and some oriented toward getting product out at the lowest possible cost" (Murphy, 1999).

Positive signs continued to reinforce Orban's decision, however. Web-site traffic to the three sites Egghead operated had grown to 21 million site visits per quarter by September 1998 (Battey, 1998). Egghead.com reported that its auction service located at surplusauction.com had 242,000 registered bidders, up from 29,000 a year earlier (Battey). MediaMetrix, an online Web-site tracking service, reported that Egghead.com's Web sites were the seventh most heavily visited sites in July of 1998 (Ditlea, 1998). Revenues reached $35.1 million in the second quarter of 1998 (Battey), while the stock price hit a high of $40.25 in late 1998. One financial journalist picked Egghead.com as his "stock of the decade" (Robbins, 1998). As Egghead.com rolled into 1999, the positive press continued. In April of that year, the Sloan School of Management at the Massachusetts Institute of Technology awarded Egghead.com its Web Transformation Award (see http://mitsloan.mit.edu).

Meanwhile, in the California bay area, Jerry Kaplan, founder and CEO of Onsale, Inc., was reporting a profit of $361,000 on revenue of $14.3 million for 1996. Onsale was one of many emerging competitors that caught the attention of George Orban and his new team in late 1997.

As Egghead.com and Onsale continued to evolve and grow, both firms began to lose money and deplete their cash reserves in an effort to boost their sales. This led to Onsale acquiring Egghead.com. Just one day before the announced merger, Amazon.com issued a press release indicating that it was moving into the sales of electronics at its Web site. A new phase in e-commerce seemed about to begin.

FUTURE TRENDS PART II: FROM DOT-COM TO NOT-COM

With its strong brand name, excellent reputation for customer service, and leadership as an e-commerce business, it seemed natural that Amazon.com would begin to offer more and more products beyond books and music (Wolverton, 1999). Along with eBay, Yahoo, and AOL, Amazon.com was one of the most widely heralded e-commerce-only companies—one that many analysts and journalists believed would survive the impending shakeout.

When Onsale acquired Egghead.com, it decided to keep Egghead.com as the corporate name as the Egghead brand name was still well known. In 1999, overall sales increased to $530 million and biz-rate.com (an online rating service) gave Egghead.com a four-star rating. Sales declined, however, from 1999 to 2000 due to increased competition, a downturn in the economy, and Egghead.com's efforts to cut losses by eliminating low-margin customers. Egghead.com was able to reduce its losses from $155 million in 1999 to $62 million in 2000. Despite the decline in sales, all other trend lines were positive. Problems began to plague Egghead.com, however, as it began to receive negative reviews from customers. The University of Michigan Business School's American Customer Satisfaction Index showed that Egghead.com was significantly below off-line retailers (C. King, 2000).

In December 2000, Egghead.com received unwelcome publicity when hackers were able to access its servers and possibly obtain customer information (Enos, 2000). The security violation that resulted in the possible theft of credit-card information cost millions of dollars in direct costs according to some security experts (Lemos, 2001). It further upset Egghead.com's customers. "Any company that's going to do something as stupid as maintain credit card information online on a vulnerable server that long after the transaction, I have no reason to trust them at all," said John Groseclose of Scottsdale, Arizona. "That goes against every industry best practice that's out there" (Wolverton, 2001).

Within weeks of the security violation, Egghead's Web site ran into another problem when it was unable to handle the traffic in the week before Christmas, causing more than $1 million in lost sales according to Markus Allen, president of WatchDog247.com. Egghead's 90 minutes of downtime per day was more than twice as much as any other retail site, and over 10 times the reported downtime of Amazon.com (http://www.itsecurity.com/tecsnews/dec2000/dec410.htm). By 2001, savvy online consumers continued to spend, but did not necessarily remain loyal to one vendor. Claes Fornell, a noted professor at the University of Michigan and the principal author of the American Consumer Satisfaction Index, noted that "customer loyalty is not high" and customer defections were increasing (Morphy, 2001).

The technical and customer-service miscues, coupled with the downturn in the economy and the lack of consumer loyalty, proved too much for Egghead.com. On August 15, 2001, Egghead.com announced that it was almost out of cash and that it was filing for bankruptcy protection. In December of 2001, Amazon.com purchased Egghead.com's Web site and customer database at auction for $6.1 million.

CONCLUSION

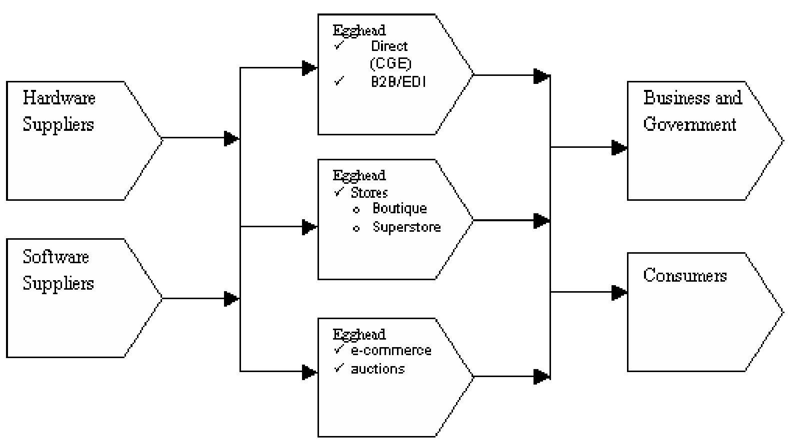
When Victor Alhadeff founded Egghead, he focused heavily on taking care of his customers, and offering fair prices and a liberal return policy. Many of the customers were early adopters and looked to Egghead to help them make the right purchases. The salespeople were considered friendly, knowledgeable, and helpful, and customers had a strong, trusting relationship with the company. Alhadeff led Egghead into new channels through a catalog-sales and call-center unit, and into the high-volume corporate, government, and education market. This increased Egghead's power with suppliers and allowed it to leverage its resources.

Within 7 years, Alhadeff and some of his key executives were forced out. The board began to assert itself, forcing more controls and greater bureaucracy on the company. The changes in the return policy upset loyal customers. This, coupled with the change in sales managers' compensation related to the return policy and the use of less knowledgeable, more sales-focused salespeople, negatively affected the image Alhadeff had worked hard to create. Direct involvement by senior management with customers as well as a fundamental understanding of Egghead's key competitive positioning might have helped Egghead's executives map out a strategy that would allow them to migrate from their supply-chain-focused EDI into a more comprehensive, e-commerce-focused enterprise progressively, limit risk, and integrate such a move with the other existing channels. It would also have positioned Egghead as an early leader with both CGE customers and consumers, and would have helped them maintain some power over their suppliers, many of whom were seeking alternative channels for software distribution.

The decision to sell the most profitable division, CGE, provided Egghead with a short-term boost in cash. Management intended to use the funds to revise the retail-store format and, possibly, to expand into e-commerce. The decision eliminated Egghead's biggest and most profitable channel, however, which affected its relationships with its suppliers. It no longer had the purchasing power or presence in large accounts to put it in a favorable position with suppliers. When it finally closed its remaining stores, Egghead ultimately became an intermediary in the highest risk, most competitive channel. Any competitive advantage it might have had based on its past multichannel approach and strong brand name was gone. Suppliers and buyers both had many other options for purchasing products. By the time Egghead went bankrupt, it was competing head-on with Amazon.com, Walmart.com, and hundreds of other online channels selling everything from computer software to coffeepots. It was one of many rather than a relatively unique, well-respected channel that meant good value, expert advice, and excellent customer service. Had management decided to maintain their multichannel approach (Figure 3), they may have been able to preserve shareholder equity while also maintaining an advantageous position with their suppliers. The brand name alone had significant value that all but dissipated due to the decision to go dot-com only.

Board members and executive management teams who find themselves in similar situations should first understand why their company is successful in the eyes of its customers. They should solicit input from employees and customers alike to make sure their decisions are in alignment with their customers' expectations. Today's consumers want to determine whom they buy from and in what format transactions takes place. Egghead's strengths lay in the off-line retail world. It was well positioned to leverage its brand name and market presence online. It had strong relationships with many customers, close to 200 locations throughout the United States, a profitable and sizeable corporate division, and a growing online presence. It also had inside information about the shift to e-

Figure 3. Egghead's potential role in the value chain (1996 and beyond)



commerce that it may not have been aware of: As Bellman, Lohse, and Johnson noted (1999), catalog buyers were more likely to share the traits of e-commerce buyers. R. King, Sen, and Xia (2004, p. 3) indicated that the "prototypical Internet shopper is time-starved and looks for convenience in buying." Perhaps if Egghead's executives had focused on the type of customers they had and how to best leverage their strengths, they would not have reacted so swiftly. Rather than leverage its multichannel approach to the market and the relationships it had with its customers, Egghead made the ultimately fatal decision to focus exclusively on an unproven channel. In their study of five companies, Rohm and Milne (2003) found that the Internet offered companies with strong brand equity expanded market alternatives and more market control. This does not suggest that a company should weaken its overall position in the market and shift entirely to an online strategy. In fact, the company should understand the source of its brand equity and make sure that what it does adds value rather than alters the value. Other retailers and wholesalers could learn from this catastrophic error by using their online presence to strengthen their off-line presence. They could provide customers with a range of channels that enable them to determine how they want to purchase products. In turn, the companies can focus on aligning their organizations so that each channel and each point of contact with the consumers maximizes the value to the customers and the profitability of the transactions.

B2B: "Short for business-to-business, the exchange of services, information and/or products from one business to another, as opposed to between a business and a consumer" (B2B, n.d.).

Channel: "In sales and marketing, the way in which a vendor communicates with and sells products to consumers" (Channel, n.d.).

Disintermediation: "Removing the middleman" (Disintermediation, n.d.).

E-Commerce: "The buying and selling of goods and services over the Internet" (Ecommerce, n.d.).

Intermediary: "Acting as a mediator or an agent between persons or things" (Intermediary, n.d.).

Multichannel: "[O]ffering customers more than one way to buy something—for example, from a Web site as well as in retail stores" (Multichannel Marketing, n.d.).

Reach: "Be in or establish communication with" (Reach, n.d.).

Category: Concepts, Trends, and Challenges

DWDM Technology and E-Government Initiatives

Marlyn Kemper Littman
Nova Southeastern University, USA

INTRODUCTION

The pervasive use of the Internet and unprecedented demand for dependable access to bandwidth-intensive multimedia applications motivate utilization of Dense Wavelength Division Multiplexing (DWDM) as a technological enabler of electronic government (e-government) operations by public agencies. In the public-sector, DWDM increasingly serves as a reliable technology for enhancing citizen access to inter-agency and intra-agency e-government programs, regulations, and policies and providing high-speed connectivity to e-government resources via optical fiber, a medium that transports voice, video, and data signals as light pulses. In addition to provisioning connections to feature-rich applications, DWDM also supports network backbone operations and accommodates bandwidth requirements for e-government interactions that take the form of government-to-government (G2G), government-to-employee (G2E), government-to-citizen (G2C), and government-to-business (G2B) exchanges (Carter & Belanger, 2004).

This chapter delineates the distinctive attributes of DWDM technology and the capabilities of DWDM in providing the capacity necessary for supporting e-government services that are responsive to citizen requirements. Metropolitan area and wider area e-government initiatives that utilize DWDM technology are described. Finally, considerations leading to effective utilization of this technology in supporting public-sector services are explored.

BACKGROUND

DWDM Technical Fundamentals

DWDM optimizes the capacity of a single optical fiber strand by dividing the optical spectrum into numerous non-overlapping lambdas or wavelengths of light to facilitate reliable high-speed transmission of vast numbers of optical signals concurrently with minimal or zero latencies. DWDM enables voice, video, and data transport at the Optical Layer, a sublayer of the Physical Layer or Layer 1 of the seven-layer OSI (Open Systems Interconnection) Reference Model in MAN (metropolitan area network) and WAN (wide area network) environments. In the public-sector, DWDM seamlessly interworks with Asynchronous Transfer Mode (ATM), Synchronous Optical Network/Synchronous Digital Hierarchy (SONET/SDH), Internet Protocol (IP), Gigabit Ethernet, and 10 Gigabit Ethernet broadband technologies.

DWDM Advantages and Limitations

With DWDM, the total amount of information transported is determined by multiplying the capacity of each lambda or wavelength of light by the total number of lambdas available (Littman, 2002). For example, in an 80 lambda DWDM network, 80 times the capacity of each 10 Gbps (gigabits per second) lambda enables transmissions at rates of 800 Gbps via a single optical fiber strand. This rate is doubled to 1.6 Tbps (terabits per second) in an 80 lambda DWDM solution featuring a pair of optical fiber strands.

It is important to note that a DWDM implementation is also subject to operational constraints. Physical barriers to DWDM optical transmission include chromatic dispersion that requires periodic signal regeneration through the use of electrical-to-optical-to-electrical conversion. Moreover, DWDM transmissions are adversely affected by unexpected temperature changes in optical equipment, the optical signal-to-noise ratio (OSNR), and manufacturing flaws in the optical fiber plant. Optical signal attenuation and crosstalk negatively impact high-volume optical throughput as well (Littman, 2002). To counter these constraints, network management systems designed for DWDM implementations monitor network performance, support fault identification and isolation, and enable system restoration resulting from optical fiber cuts and breakdowns in optical devices.

DWDM long-haul backbone networks support terabit transmission rates (Davis, Smolyaninov, & Milner, 2003). However, technical advances in the access network or that portion of the infrastructure between the home or business location and the telecommunications company central office (CO) or the first-mile do not keep pace with DWDM backbone network developments. As a consequence, transmission rates from the DWDM backbone network via the CO to the customer premise reflect the speed of the first-mile connection.

First-mile technologies including digital subscriber line (DSL) variants such as ADSL2 (asymmetric DSL2) and ADSL2+ employ sophisticated modulation techniques to optimize the transmission capacity of twisted copper pair typically found in the public switched telephone network. ADSL2 supports downstream rates at 18 Mbps (megabits per second) and ADSL2+ enables downstream rates at 24 Mbps over distances that extend to 4 km (kilometers). Increasingly popular, Ethernet in the first-mile over optical fiber broadband passive optical network (BPON) solutions foster downstream rates of 100 Mbps in fiber-to-the home (FTTH) and 1 Gbps in fiber-to-the-business (FTTB) configurations over distances that extend to 10 km (Littman, 2002).

DWDM and CWDM (Coarse WDM)

As with DWDM, CWDM is based on WDM technology and works either independently or in conjunction with DWDM. CWDM utilizes uncooled lasers that require less precise wavelength control and less costly optical components than DWDM. CWDM supports up to 16 lambdas on a single optical fiber strand whereas DWDM enables as many as 80 and potentially more lambdas to achieve terabit and petabit transmission rates.

CWDM technology is primarily used to extend the reach of optical fiber networks in local area BPONs. As with Ethernet BPONs, CWDM BPONs are immune to lightning and other transient forms of electromagnetic interference and feature greater bandwidth and fewer points of failure than first-mile broadband access network technologies such as ADSL2 and ADSL2+. Government agencies providing services in MANs and WANs also employ CWDM/DWDM configurations with an option to implement DWDM upgrades in response to traffic demand (Littman, 2002).

DWDM Standards

The ITU-T (International Telecommunications Union-Telecommunications Sector) approved Recommendations in 2001 for standardization of next-generation DWDM optical transport networks (OTNs) that provision on-demand bandwidth service. Endorsed in 2003, the ITU-T G.959.1 Recommendation describes capabilities of DWDM networks in enabling dependable high-speed transmissions at distances of 40 km and 80 km without signal amplification. In addition to the ITU-T, organizations that promote development of standards for interoperable high-capacity next-generation DWDM configurations include the European Telecommunications Standards Institute and the Internet Engineering Task Force.

DWDM E-GOVERNMENT INITIATIVES

E-government refers to the use of technology for enabling citizens to conduct online transactions and access government applications and services (Ke & Wei, 2004). In response to citizen demands for a more responsive government, public-sector entities increasingly employ DWDM to support cross-agency network consolidation, integration of fragmented and distributed processes, improvements in the quality of citizen services, and high-speed access to e-government resources and e-collaborative tools via a single interface (Bakry, Al-Bassam, & Alheraish, 2004).

The increase in multimedia traffic resulting from Internet popularity and requirements to ensure network reliability and availability contribute to the use of DWDM technology in e-government initiatives (Stoll, Leisching, Bock, & Richter, 2001). Capabilities of DWDM in enabling e-government services in metropolitan DWDM (MDWDM) networks in municipalities in Canada, Japan, and the U.S. are initially examined in this section. The role of DWDM in facilitating regional and wider area network operations in Canada, the European Union, South Korea, and the U.S. is then explored.

MDWDM Networks

Canada

Multiple factors including the pervasiveness of Web applications and demand for seamless high-speed access to interactive e-government services contribute to the use of MDWDM technology in Canada as a platform for supporting municipal e-government initiatives (Grobe, Wiegand, & McCall, 2002). For example, the City of Ottawa (2003) in the Province of Ontario administers Telecom Ottawa, a municipal public utility that provides MDWDM operations to support civic projects that include the City of Ottawa's Smart Central initiative. Sponsored by the Ottawa Center for Research and Innovation, this MDWDM-based e-government initiative interlinks public-sector agencies, research laboratories, local hospitals, businesses, schools, and post-secondary institutions and provides fast and dependable access to e-healthcare, e-learning, and e-business applications and national, regional, and municipal services. The City of Ottawa also participates in the Ottawa Rural Communities Network

(ORCnet) in extending Optical Regional Advanced Network (ORAN) broadband services to rural and remote communities (ITU, 2003).

Japan

In Tokyo, Japan, MDWDM technology provides connectivity to e-government applications with quality of service (QoS) assurances (Wang, Bretschneider, & Gant, 2005). This MWDM initiative facilitates online citizen participation in civic affairs; access to government policies; and delivery of video broadcasts, e-training sessions, e-learning applications, and security monitoring services. Similarly, the e-government MDWDM initiative in Kyotango City, Japan supports e-voting, disaster recovery and prevention services, and e-medicine consultations.

U.S.

In the U.S., municipalities that utilize MDWDM technology enlist the support of public and private entities that include K-12 schools, school districts, post-secondary institutions, housing and transit authorities, financial organizations, museums, businesses, and hospitals. For example, the MWDM e-government solution developed by the U.S. City of Santa Monica, California in conjunction with the Santa Monica-Malibu School District and Santa Monica College enables e-learning and public safety applications and access to e-services provided by utility companies and public-sector agencies.

DWDM WANs

Canada

A Government of Canada initiative, CA*net 4 (Canadian Network for the Advancement of Research, Industry, and Education, Phase 4) utilizes a DWDM infrastructure that supports connections to international peer-level DWDM networks such as GÉANT2, the second phase of the pan-European backbone WAN, and high-performance DWDM regional networks implemented by provincial governments. The CA*net 4 DWDM infrastructure facilitates deployment of e-government services including an e-voter outreach program to encourage citizen participation in elections, access to legal information through the MyLegalAnswers Web portal, and connectivity to the Flintbox initiative to assist organizations with copyright compliance (CANARIE, 2004). The CA*net 4 DWDM platform also provides links to the Electronic Courthouse to help arbitrators and adjudicators resolve contract disputes virtually, simulations for training Canadian transit workers, e-learning sessions for educators sponsored by the Canadian School Boards Association, and the Grid Canada initiative. This government-sponsored grid supports access to shared computational, simulation, storage, and visualization resources to support cross-institutional research in fields that include education and healthcare (Foster, Kesselman, & Tuecke, 2001; Littman, 2005).

European Union

A European Commission initiative, GÉANT2 enables advanced information communications and technology (ICT) initiatives in sectors that include e-government, e-medicine, e-business, and e-learning and interconnects NRENs (next-generation research and education networks) in member states and affiliates in more than 30 countries (Littman, 2002). Moreover, GÉANT2 contributes to the realization of e-Europe objectives that include development of a consolidated pan-European e-government interoperability framework to provide uniform access to secure e-government services in accordance with the e-Europe 2005 Action Plan. GÉANT2 NREN participants with DWDM implementations that provide a foundation for supporting broadband connectivity to interactive public-sector initiatives include the Czech Republic (CESNET2), the Netherlands (Surfnet6), Poland (PIONIER), Switzerland (SWITCH), and Greece (GRNET2).

South Korea

In South Korea, the DWDM e-government initiative enables citizens to readily access information on national security, defense, legislation, schools, and businesses; review public policies; and obtain personal records on birth, marriage, and death via an e-government portal that is accessible via KORNET, the nationwide DWDM Internet backbone network. When this DWDM e-government initiative is fully operational, citizens will be able to make payments online for national and local taxes, traffic tickets, health insurance, and utility services. Participating agencies include the Ministry of Government, Administration and Home Affairs; the Ministry of Construction and Transportation; the Supreme Court; and the National Tax Service.

U.S.

Despite budget cutbacks, state agencies in the U.S. continue to invest in DWDM to provide high-quality e-government services and citizen access to relevant public-sector information (Carter & Belanger, 2004). For example, the state-sponsored Iowa Communications Network utilizes DWDM technology to interlink government agencies, K-12 schools, post-secondary institutions, and medical facilities in an area that extends to 4,800 kilometers. Operated by the Oklahoma State Regents for Higher Education, Oklahoma OneNet employs DWDM technology to provide integrated access to e-government services and digital records including state legislation and judicial decisions, e-learning and e-medicine projects, virtual training sessions, and Internet2 (I2) via the Abilene DWDM backbone network. Established by universities and research centers in cooperation with industry and government, I2 facilitates development of new networking initiatives and applications in fields such as biomedicine and grid computing (Littman, 2002).

The state-sponsored Illinois Century Network (ICN) uses a DWDM infrastructure to provide equitable access to e-government applications and information resources maintained by state agencies such as the Illinois Board of Education, the State Library, and the State Department of Central Management Services. The ICN also supports DWDM links to e-learning and e-training services for health professionals, farmers, merchants, and educators and advanced optical projects such as I-WIRE (Illinois Wired/Wireless Infrastructure for Research and Education) and StarLight, a DWDM peer-level international exchange facility in Chicago that features connections to next-generation networks and serves as a testbed for assessing DWDM performance (Littman, 2005).

Multiple organizations form strategic partnerships to defray the costs of building a DWDM infrastructure. For instance, the MAX (Mid-Atlantic Crossroads) DWDM backbone network initiative is supported by a multi-state consortium. Participants in the MAX consortium include academic institutions, research centers, and federal agencies such as the U.S. Department of Agriculture, the U.S. Food and Drug Administration, the U.S. Department of Health and Human Services, and the National Institute of Standards and Technology. In addition to enabling bandwidth-intensive operations and high-speed connections to support the work of consortium participants in Washington, DC, Virginia, and Maryland, MAX serves as a traffic aggregation point for the National LambdaRail, a DWDM research and production backbone WAN that extends across the U.S. and facilitates connectivity to Abilene, the I2 backbone network.

Subsequent to the endorsement of the U.S. E-Government Act of 2002 that supports development of a federal e-government portal and elimination of redundant systems and services, U.S. government agencies that typically operated a multiplicity of separate networks involving public health, emergency management, disaster recovery, and military operations increasingly use DWDM to support cross-agency network integration to make service provisioning more efficient. Sponsored by the U.S. Department of Defense Information Systems Agency (DISA), for example, the Global Information Grid-Bandwidth Expansion initiative launched in 2004 features a long-haul mission-critical DWDM backbone network that facilitates real-time command and control information exchange and reliable access to bandwidth-intensive military applications, e-training sessions, and critical operations at intelligence and DISA facilities at more than 100 locations.

FUTURE TRENDS

Demand for robust, reliable, and scalable networks to provide multimedia services and accommodate the increase in Internet traffic flow contributes to DWDM implementation in the public-sector to improve the effectiveness of traditional government operations and provision dependable connectivity to e-government programs to meet stakeholders' expectations and priorities (Elmagarmid & McIver, 2001; Scherlis & Eisenberg, 2001). However, utilization of DWDM technology as a platform for e-government operations can also result in unanticipated and undesired outcomes such as cost overruns, security problems, inter-agency conflicts, and stalled e-government processes (United Nations, 2004).

A phased and flexible planning strategy based on a detailed analysis of workflow and a systematic inventory of core processes to identify candidate government applications that are likely to succeed in an electronic format can aid in reducing disruptive changes during the transition from conventional government services to DWDM-based e-government operations (Scholl, 2002). Stakeholders including senior management, civic leaders, professionals, government employees, and communities of interest that actively participate in e-government strategic planning sessions can play a critical role in either encouraging or rejecting adoption of DWDM-enabled e-government initiatives.

MDWDM and wider area DWDM networks support implementation of sophisticated e-government initiatives that enable citizens regardless of geographic location to interactively develop solutions to public-sector problems in the same virtual space (Foster et al., 2001). Since DWDM networks sponsored by public-sector agencies carry economically valuable data and sensitive information, policies for network security, non-repudiation of services, data protection, identification, authentication, acceptable use, and privacy must be in-place prior to full-scale e-government implementation (Joshi, Ghafoor, Aref, & Spafford, 2001). Mechanisms for monitoring network operations to ensure network availability while providing convenient access to e-government resources and support of disaster recovery services in the event of cyber-terrorism and natural and artificial disasters must also be firmly established.

CONCLUSION

Government agencies turn to DWDM technology to provide on-demand bandwidth and dependable high-speed access to citizen-centric services and public-sector applications (Medjahed, Rezgui, Bouguettaya, & Ouzzani, 2003). Public-sector agencies that build a successful DWDM infrastructure must establish attainable goals and objectives with specific milestones, a realistic timeframe for full-scale implementation, and a set of standards and guidelines to facilitate dependable G2G, G2E, G2C, and G2B interactions that conform to agreed-upon security and privacy policies. Implementation of an effective e-government solution based on DWDM technology requires a holistic view of e-government processes, a strong commitment of government funding, effective leadership, and a phased implementation of public-sector applications that are responsive to citizen requirements and equally accessible. To overcome resistance to change, gain grassroots support, and encourage widespread participation in DWDM-based e-government initiatives, public-sector agencies should also sponsor e-training sessions on how the e-government DWDM platform works, provide around-the-clock technical assistance, and assure citizens through demonstrations of practical applications that e-government transactions are conducted in a safe and trusted environment.

KEY TERMS

Attenuation: Loss of signal strength and power as a signal passes through the optical fiber medium.

Backbone Network: Long-haul networks such as CA*net 4 and GÉANT 2, Long-haul that interconnect network segments in WAN configurations to facilitate resource sharing and e-collaborative information exchange.

Broadband Passive Optical Network (BPON): Features point-to-multipoint architecture for provisioning access to high-speed broadband applications such as video-on-demand over the first-mile.

Chromatic Dispersion: Spreading of light pulses as they transit an optical fiber. Results from variations in the density of the optic fiber medium and culminates in signal distortion.

DSL: Supports consolidation of data, video, and voice traffic to facilitate broadband transmission via ordinary twisted-copper-wire pair telephone lines over the first-mile between the telephone company CO and the subscriber premise.

Ethernet: A popular local area network (LAN) technology that supports transmission rates at 10 Mbps and serves as the basis for the IEEE (Institute of Electrical and Electronics Engineers) 802.3 standard and its extensions. Newer and faster versions of Ethernet include Fast Ethernet (100 Mbps), Gigabit Ethernet (1 Gbps), and 10 Gigabit Ethernet (10 Gbps).

Open Systems Interconnection (OSI) Reference Model: Seven-layer architectural model developed by the International Standards Organization (ISO) to describe standardized network operations.

Web Portal: A Web site that serves as a gateway to distributed network resources, applications, and other Web sites.

Dynamic Planning Models for E-Business Strategy

Janice M. Burn
Edith Cowan University, Australia

Colin G. Ash
Edith Cowan University, Australia

INTRODUCTION

Much has been written about e-business and how this concept will transform industries into virtual networks of customers and suppliers working together to create value-added processes (Fahey, Srivastava, Sharon, & Smith, 2001). Typically, successful organisations will have embraced enterprise resource planning (ERP) systems to integrate e-business processes within the organisation and to underpin the creation of integrated interorganisational systems. This frequently results in new business processes, organisational structures, human resource skill requirements, management roles, and knowledge management systems (Robey et al., 2002). To be successful in this new climate, however, organisations have to learn new approaches to strategy and planning for collaborative systems and to manage e-business enabled cycles of innovation (Wheeler, 2002; Zahra & George, 2002). Few studies have explored the dynamics of e-business strategic planning and little information is available on how to implement new paradigms successfully and how to ensure more effective e-business performance as a result (Damanpour, 2001; Kallio, Saarinen, & Tannila, 2002).

This article reports on the findings from multiple case studies of e-business projects in ERP-enabled organisations. Each organisation was investigated in a three stage study over 4 years, using three theoretical models of e-business implementations to assess success. The key findings from each case study were captured into a staged model for e-business transformation and related to a dynamic planning model that can be applied across all stages of growth of the extended enterprise.

BACKGROUND

Planning for E-Business

Fahey et al. (2001) stated that:

E-business embodies the most pervasive, disruptive, and disconcerting form of change: it leaves no aspect of managing organisations untouched, it challenges long-accepted business models, and organisation leaders have little to draw on from their past experience to manage its effects. In particular, its capacity to transform business processes is no longer in dispute. Senior executives—thus confront a central challenge: How should they endeavour to capture, analyse, and project the transformational impact of e-business on their organisation's most critical or core processes? (p. 890)

Strategic planning for such systems has to encompass capabilities for managing, measuring and evaluating organisational abilities to create value across the network of alliances and hence requires evolutionary approaches which can be tailored to organisational needs at different stages of e-business growth (Ash & Burn, 2003; Wheeler, 2002). This whole process is sometimes described as IT governance, including strategic planning processes, change management processes and accountability and return on investment (Kallio et al., 2002; Patel, 2002). Planning cannot take place in isolation and must encompass all aspects of the emergent learning organisation in virtual networks of value alliances.

In order to study this environment in detail the authors embarked on a longitudinal study of organisations implementing large-scale e-business applications over a 4 year period. The 11 organisations were visited three times during this period, and a minimum of three interviewees participated on each visit. The structured interviews were focused on three separate models of business change to investigate different aspects of e-business governance, and the results from these investigations brought together into a dynamic planning model for e-business transformation. The use of three research models was specifically intended to give breadth to the study and allow the incorporation of a variety of strategic views that informed the planning process.

Theoretical Framework

E-business implementations were investigated from the perspective of three strategic theories: Virtual Organising, e-Business Change, and Benefits of B2B, where:

1. Virtual organising is measured along a continuum applied to each of the three dimensions of customer interaction, asset configuration, and organisational knowledge (Venkatraman & Henderson, 1998).
2. E-business change processes are measured across eleven interrelated components within three broad categories of organisational change, strategic management innovation, and information systems evaluation (Guha, Grover, & Kettinger, 1997).
3. Benefits of B2B are related directly to a comprehensive set of B2B models: B2B: $B2B^C$ and $B2B^S$, B2C, B2E.

Each model reflects a different business focus: organisational strategy, change management, and e-business work practices. The resulting conceptual frameworks are described in terms of an e-business strategy model and a dynamic planning model for e-business implementation. The dynamic planning approach is a strategic collaborative process between alliances where there is a continual review of alignment of the e-business transformation against business objectives. This is quite distinct from the 'one size fits all' approach of centralised planning and allows strategy to evolve with changing market conditions. This approach provides the means to explicitly define and manage relationships between supply network partners and to monitor trends and trigger a revisiting of strategic decisions across the network (Oliver, Chung, & Samanich, 2003).

Methodology

Data were gathered from three sources: primary, secondary, and tertiary:

1. **Primary Data:** From semistructured interviews conducted November 1999, June 2000, and June 2001. Three separate interviewees were identified within each organisation and revisited across the study.
2. **Secondary Data:** From company documents collected or sent via e-mails.
3. **Tertiary Data:** From case research papers written by third-party specialists.

The case material collected was used to verify all the strategic characteristics of e-business transformation and to develop the dynamic planning model.

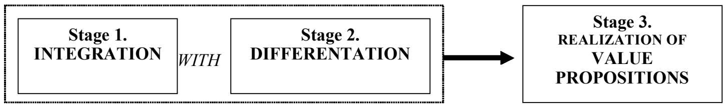
E-BUSINESS STRATEGY MODEL

The model in Figure 1 shows the focus for strategic planning shifting through three stages of development with outcomes and performance gains realised through greater progression towards extended enterprise resource planning:

Table 1. Participating organisations

Case Organistion	Industry	B2E Interaction	e-Business Project Title	No. of Users
1. Halliburton **2. UBS**	Engineering Banking	Intranet access to ERP	"Employee Tracking Intranet" "Employee Networking"	~1,100 staff ~40,000 emps
		B2C Interaction		
3. Wine Society	Retailing	Internet access to ERP	Online Ordering by Members	~60 staff
4. UNICEF Aust.	National Charity	Internet access to ERP by ASP	1st Australian Charity Web site	~35 employees +30 volunteers
		B2B Interaction	($B2B^S$ and $B2B^C$)	
5. Biotech **6. Novartis** **7. Bertelsmann** **8. Statoil** **9. Employee-Nat**	Biotechnology Chemical Media Oil and Gas Employment	ERP to supplier catalogues and Intranet access to ERP data	Staff research procurement Sales Order and Rapid Delivery Simple Ordering e-catalogue Staff travel procurement Simple Ordering e-catalogue	~240 staff ~22,000 ~28,000 ~18,000 ~14,000
10. FSC - Fujitsu Siemens computer	Computer	ERP to corporate customers	Order Request System extended to an e-Mall of 3 companies	~11,000
11. Dell corp with **LSI Logic corp**	Computer ------------------ Electronics	non-ERP with ERP	Customised online sales Integrated with customers MRO procurement	~27,000 ~14,000

Figure 1. Three stages of strategic model



- **Stage 1:** Integration of technologies is critical for cost reductions and operating efficiencies along the supply chain;
- **Stage 2:** Differentiation of products and services is critical for e-business market positioning through effective resourcing across multiple supply chains;
- **Stage 3:** Demonstration of value propositions within an inter-organisational network to design and leverage multiple interdependent communities to create superior economic value across the virtual supply chain (Singh & Thomson, 2002; Venkatraman & Henderson, 1998).

Table 2 represents a map of the issues distilled from the findings of this longitudinal three-stage study. The results of the analysis can be mapped along the e-business stages of growth as: integration of e-business technologies for e-malls and B2B commerce, differentiation of products and services for e-business positioning, and the realisation of value propositions of the e-partnerships.

In Table 2, the three shaded cells in the eBS model (3×3) indicate the "critical" elements that require a cultural shift for a real organisational transformation and so represent distinct shifts in the federated planning approach. The other elements contribute to the organisation's competitive advantage.

Stage 1: Integration

Technologies: E-ERP

The findings show that back-end to front-end enterprise application integration is essential to achieve savings and cost reduction. Integration of the system architecture is made possible through a variety of back-end, sell-side and buy-side systems; all 11 cases demonstrated this, but specifically Statoil and Siemens with their standardised ERP platform and e-business applications.

Products and Services: E-Malls

In a study of Australian e-Malls, Singh and Thompson (2002, p. 308) concluded, "it is apparent that for effective B2B exchange in Australia, standards for interoperability between business partners, and technology integration for information exchange on goods and services is essential"; for example, Fujitsu Siemens Computers (FSC)

Table 2. Stages of e-business strategy (The diagonal cells (shaded) represent the critical stages of eBP and the arrows represent real organisational transformation with e-business)

	Stages of e-Business Strategy (1999 -)	(2000 -)	(2001 -)
Business Dimensions	**Stage 1: Integration**	**Stage 2: Differentiation**	**Stage 3: Realisation of Value Propositions**
Technology (virtual infrastructure)	* ICT ERP with e-Sales & e-Procurement applns	Differential Resourcing ASP vs. cost of ownership on the outsourcing spectrum	Innovative Technologies ERP and non-ERP networks for e-marketplaces
Products & Services (virtual experience)	E-Malls E-Mall integration and information exchange	* E-Branding Customisation vs. standardisation, Brand identity & integrity	E-Communities Foster customer, supplier, and employee expertise. Emerging collaborative online communities
Business Models (virtual B2B interactions)	E-Commerce Integration B2B Integration of E-Sales & E-Procurement systems $B2B^C + B2B^S$	E-Positioning B2B positioning within a range open to private e-marketplaces	* E-Enterprise One2Many vs. One2One Distinct focus of One2One partnerships
Examples	Remote experience of e-catalogues. More tasks, "group ware" skills for online communication.	Assemble and coordinate assets through effective use of online services	Business network to design and leverage interdependent e-communities. Dependent on relationships

achieved integration of three groups' online sales systems.

Business Models: E-Commerce B2B Integration

The integration of e-business models, $B2B^C$ with $B2B^S$ is essential to maximise efficiency gains from supporting technology infrastructure, so that people can get the job done efficiently. Two cases of B2B e-business integration with a global computer supplier (Dell) and its largest corporate customer (FSC) demonstrate a more complex model. These exemplar cases demonstrate the integration of ERP with non-ERP systems using Web-based technologies to provide the infrastructure required to optimise the overall B2B value chain. Also, the study emphasizes the synergistic benefit stream from B2B integration and the interaction of interorganisation e-business solutions.

Stage 2: Differentiation

Technologies: Differential Outsourcing

Segev and Gebauer (2001, p. 249) argue "the mid points of the outsourcing continuum are the most challenging." From case observations they describe the continuum as a wide range from "do it yourself" to complete outsourcing, with an increasing number of possibilities. The one case study where the complete management of an e-ERP project was outsourced to an ASP, demonstrates the challenge for UNICEF to balance the loss of control against the cost of ownership whereas FSC partially outsourced their online sales systems to Siemens Business Systems quite successfully.

Products and Services: E-Branding

The e-business tactics for positioning in the virtual space were to:

- differentiate between corporate customers and end consumers (e.g., UNICEF and Dell);
- deliver customised products and services using standard components (e.g., Dell and FSC); and
- differentiate between brand identity and brand integrity, where e-branding becomes a critical issue (e.g., Bertlesmann, UNICEF, Wine Society, Dell, and FSC).

Business Models: E-Positioning

Biotech and Novartis repositioned to align with their largest corporate suppliers. FSC repositioned itself into the computer industry through e-sales. The tendency of these pioneers was to start with development of public relationship building and then shift to private relationship building between suppliers and buyers. This is observed to be more than a passing phase.

Stage 3: Demonstration of Value Propositions

Technologies: Innovative Technologies

Halliburton's HR Intranet ERP system demonstrated a B2E value proposition. Their technology innovation was bottom-up driven and from both sides of B2E and B2G of the value chain. This bottom-up approach provided a model for the company's global e-ERP infrastructure. Employee-Nat demonstrated the integration of ERP and non-ERP systems with Web technologies (Fan, Stallaert, & Whinston, 2000). The Wine Society found problems with a lack of internal expertise to implement Web-based innovations within their ERP system.

Products and Services: E-Communities

Statoil and UBS used Intranet employee self-service applications to develop a practice of industry-based e-communities. Dell has competence centres where customers can validate system design and configuration without disrupting their live computing network. These facilities act as collaborative online network to provide customers with systems design and application tuning support, allowing them to test various hardware and software configurations before making a purchase decision (e.g., Dell and FSC).

Business Models: E-Enterprise Model

A pilot approach demonstrating a value proposition is shown in the One2One relationship formed by Dell and LSI. Also, the case emphasizes the synergistic benefit stream from B2B integration and the interaction of inter-organisation e-business solutions. In the short term, it may be better to adopt e-commerce implementations (e-sales and e-procurement) with new customers and suppliers. This has the capability of persuading existing customers and suppliers that are more resistant to e-business change of the win-win value propositions (e.g., FSC with SAP, Dell and LSI). In these twin case studies, the focus was on building a One2One relationship. The creation of a win-win value proposition was observed to be a model for other B2B partnering.

Table 3. Stages of dynamic planning model

	Stage 1	Stage 2	Stage 3
Strategic focus	Self-service	Empowerment	Relationship building
Planning focus	Top-down Training Internal	Bottom-up Self-learning External	Collaborative Value enhancement Community
Outcomes and Performance Gains	Improved operating efficiency (ROI)	Effective resourcing (QWL)	Virtual and economic value added (EVA)

Key: Return on investment (ROI), Quality of working life (QWL), Economic value added (EVA)

DYNAMIC PLANNING MODEL

The changing strategic focus across the stages of the dynamic planning model are classified in Table 3, and viewed as interdependent and supportive of each other. This is especially so in the area of *outcomes and performances objectives* where *efficiency* through employee self-service and *effectiveness* through empowerment in customer care is used to support *value adding* activities for sustained competitive advantage. Value includes complementary benefits realised for all network partners across the virtual supply chain. The interplay between strategy, e-business, change management and evaluation is crucial to the creation of dynamic capabilities and will enable organisations to gain sustainable competitive advantage (Zahra & George, 2002).

At stage one of the extended enterprise, the focus is very much internal with top-down planning and an emphasis on training employees to become proficient in self-service to improve operating efficiencies and increase returns on investment. For example, UNICEF had to expend considerable energies on retraining staff to improve the efficiency of its operations and then experienced difficulties moving into the second stage. The first shift comes when the enterprise extends its relationships across the full supply chain for products or services. At this stage, the focus is on empowerment and self-learning through bottom-up planning within the organisation. There is also a realignment of business objectives to include external alliances across the supply chain. Halliburton found that much of their HR process could be shifted into the operational face of the organisation as hand held computers logged work hours against contracted hours and government legislation for foreign employees. This often necessitates changes in personnel since higher skill levels may be required. Finally, the focus will be directed towards reengineering the supply chain though collaborative planning to gain value enhancement throughout the networked community. This occurs with a shift of business model towards the e-enterprise.

FUTURE TRENDS

By taking a more holistic approach, executives can turn the stages of a company's transformation into the drivers of e-business excellence. So the central task for senior managers lies in understanding what drives operational excellence in the e-business realm, and then committing the necessary resources (structures, training, planning responsibilities) to the development of the drivers. To this end managers should assess the company's operations by looking at both the traditional and e-business measures. The complete model for e-business strategy can act as a comprehensive tool, for assisting managers in diagnosing the key facilitators and inhibitors of successful stages of e-business development. It is not seen as a prognostic tool. The case analyses confirmed that the more successful projects were found to have facilitators in all components of the e-business strategic framework. Barua, Konana, Whinstone, and Yin (2001) specifically refer to the success of a company's e-business initiatives coming from the readiness of customers and suppliers to engage in electronic interactions. To overcome resistance to change, each component must be aligned, along with the enabling technology, to the strategic initiatives.

Vering and Matthias (2002, p. 159) argued that in the learning organisation there is:

- a new generation of system users,
- a constant or continuous nature of change, and
- a demand for both top-down and bottom-up change.

However, change still requires that resources be matched to the business objects and tasks and, further, that planning systems are appropriate to drive organisational change through workplace implementation (van Hooft & Stegwee, 2001; Coltman, Devinney, Latukefu, & Migley, 2001). In the new business environment organisational business models are more complex, supply chain networks more flexible and agile, training is shifting to self-directed learning, and collaborative planning approaches are needed to achieve greater added value to the community network (Fahey et al., 2001). The challenge for future research will be to identify whether alignment occurs within a staged growth model of change or through a dynamic intervention from internal or external sources.

CONCLUSION

This study of e-business strategy was based around a triangulation of three independent research models: virtual organising, e-business change with critical success factors and facilitators, and complementary benefits from B2B interaction. Each model exhibits attributes that have varying influences at different stages of e-business planning and implementation. The proposed model of e-business strategy and planning can be used as a detailed criterion to direct and evaluate the progress in the virtual space for traditional organisations or new entrants. The model offers a foundational perspective of strategies, planning tactics and performance objectives for e-business implementations. These together form the basis for a dynamic planning system.

KEY TERMS

Dynamic Planning System: A three staged model identifying different approaches to planning at different stages of e-business growth.

E-Business Strategy: Comprehensive set of planning approaches that reflect the stage of e-business growth within the organisation.

ERP-Enabled Organisations: Organisations with fully implemented enterprise resource planning systems extending into B2B and/or B2C applications.

EVA: Economic Value Added, this is an attempt to measure value over and above return of costs and includes many of the intangibles. A typical approach would combine some form of ROI and QWL.

Extended Organisation: Knowledge based-organisation with links to customers and suppliers across an electronic supply chain.

QWL: Quality of Work Life, this is a measure of employee satisfaction with their working environment and can include fairly subjective measures such as self-empowerment, enjoyment, self-satisficing indices.

ROI: Return on Investment; typically, a simple calculation based on costs of systems development and implementation measured against returns on investment. Problems with this include a measure relate to the difficulties of quantifying intangible costs and benefits.

Virtual Organising: An integrated approach to becoming an extended organisation by focusing on customer assets, supplier alliances and employee empowerment through ICT enabled knowledge management.

Dynamic Pricing for E-Commerce

INTRODUCTION

Over the last decade, e-commerce has significantly changed the traditional forms of interaction among humans in conducting business by automating business processes over the Internet. Early seller Web sites consisted of passive text-based catalogs of products that could be manually browsed by potential customers. Online passive catalogs were soon replaced by dynamically updated catalogs containing detailed product descriptions using combinations of text and images that could be searched in various formats and according to different search criteria. E-commerce techniques used by sellers for operations such as price setting, negotiation, and payment have matured from manual off-line processing of sales data to automated algorithms that dynamically determine prices and profits for sellers. Modern e-commerce processes for trading goods between buyers and sellers can be divided into five stages: search, valuation, negotiation, payment, and delivery. Depending on the type of market in which the goods are traded, some of the above stages are more important than others.

There are three principal market models that are used for online trading. The most common market model used by online sellers for trading goods over the Internet is the posted-price market model. The other two market models, the auction model (Sandholm, Suri, Gilpin, & Levine, 2002) and the marketplace model (Chavez & Maes, 1996), are used for markets in which niche or specialty items with sporadic or uncertain demand are traded.

In the posted-price market model, a seller announces the price of a product on its Web site. Buyers visiting the seller's Web site request a quote from the seller. The seller responds with a quote in response to the buyers' requests, and the buyers examine the seller's quote to make a purchase decision. Unlike auctions and marketplaces, products traded in posted-price markets are no-niche items and exhibit continuous demand over time. The Web site of online book merchant Amazon (http://www.amazon.com) is an example of a posted-price market. A buyer interested in a particular book enters the necessary information through a form on Amazon's Web site to request the price of the book and receives the price in response.

Modern seller Web sites employ automated techniques for the different stages of e-commerce. Intermediaries called *intelligent agents* are used to automate trading processes by implementing different algorithms for selling products. For example, Web sites such as MySimon (http://www.mysimon.com) and PriceGrabber (http://www.pricegrabber.com) automate the search stage by employing the services of intelligent agents called *shopbots*. Shopbots enable buyers to make an informed purchase decision by comparing the prices and other attributes of products from thousands of online sellers. Automated price comparison by buyers has resulted in increased competition among sellers. Sellers have responded to this challenge by using intelligent agents called *pricebots* that dynamically determine the price of a product in response to varying market conditions and buyers' preferences. Intelligent agents are also used to enable other e-commerce processes, such as supply-chain management and automated negotiation.

In this article, we focus on the different algorithms that sellers' pricebots can use for the dynamic pricing of goods in posted-price markets.

BACKGROUND

Over the past few years, online dynamic pricing has stimulated considerable interest in both the commercial and research communities. Increased profits and rapidly clearing inventories resulting from efficient pricing have encouraged the development of software pricing tools including Azerity (http://www.azerity.com) and Live Exchange (http://www.moai.com). Automated dynamic pricing for posted-price markets has been implemented and analyzed using simulated market models (Brooks, Gazzale, MacKie-Mason, & Durfee, 2003; Dasgupta & Melliar-

Smith, 2003; Kephart, Hanson, & Greenwald, 2000). Most of these models consider the price of a product as the only attribute affecting a buyer's purchase decision. Surveys of consumers who purchase products online, reported in Brown and Goolsbee (2000) and by ResellerRatings (http://www.resellerratings.com), reveal that online buyers are frequently willing to pay an elevated price for particular product attributes such as delivery time, seller reputation, and service. Moreover, the preferences of buyers vary over time depending on exogenous factors such as sales promotions, aggressive advertising, and the time of year. Therefore, it is important for an online seller to differentiate a product using multiple attributes and to determine the purchase preferences of a potential buyer over those attributes so that the seller can tailor its offer to the buyer's requirements and improve its profits.

In online markets, a seller must determine the prices that its competitors charge for a product so that it can place its price at a competitive advantage. The rapid fluctuation of market prices can leave a seller with outdated competitor price information that can cause the seller's dynamic-pricing algorithm to function incorrectly. However, it is difficult for sellers to obtain prior information about buyers' parameters. Therefore, it is desirable if online sellers do not assume prior knowledge about market parameters, but rather use a learning algorithm (Brooks et al., 2003; Dasgupta & Hashimoto, 2004) to determine changing market parameters dynamically.

DYNAMIC PRICING USING INTELLIGENT AGENTS

In an automated posted-price market, a seller employs the services of a pricebot that dynamically calculates a profit-maximizing price of a product in response to fluctuations in market parameters, such as the prices and profits of competing sellers and the reservation prices of buyers. The seller posts the updated product price at regular intervals to attract buyers while maintaining a competitive edge.

The market model we consider is based on the shopbot economy model of Kephart, Hanson, and Greenwald (2000), which makes simplifying assumptions about the online economy that facilitate analysis while retaining the essential features of the market. It consists of S sellers who compete with each other for B buyers ($B \gg S$). Only one type of commodity is traded in the market. A seller behaves as a profit maximizer and has a sufficient supply of the commodity for the lifetimes of the buyers. Buyers return to the market repeatedly to purchase the commodity. Examples of such markets include telephone and Internet services.

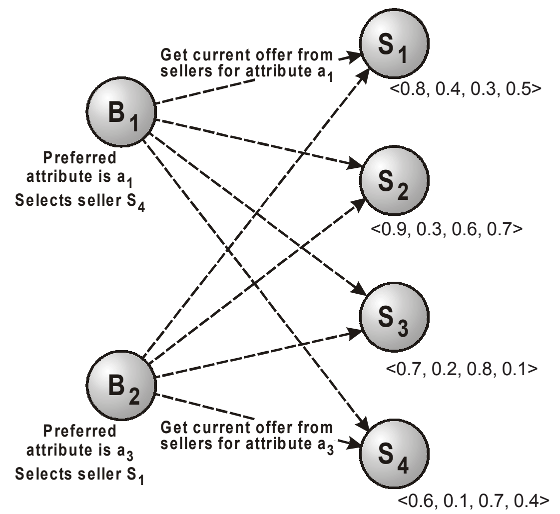
A product is characterized by multiple attributes. A seller offers a slightly different price for the product along each of its attributes. As shown in Figure 1, a buyer first requests a quote from the sellers for the price based on his or her preferred product attribute, and then selects the seller that makes the best offer. The buyer's preferred attribute is not revealed to a seller when the buyer makes a quote request. Therefore, a profit-maximizing seller must determine a buyer's preferred attribute in response to the buyer's quote request. The seller then calculates a competitive price for the product along the buyer's preferred attribute and makes an offer to the buyer.

Dynamic-Pricing Algorithms

Because online sellers are profit maximizers, the objective of a seller is to determine a price for each attribute of the product that maximizes the seller's profit. However, the pricing function of a seller cannot be stationary as there are other competing sellers who revise their prices to improve their offers and attract buyers away from each other. Therefore, the seller updates the prices it charges on different product attributes at intervals in response to competitors' pricing strategies and changes in the buyers' preferred attributes.

We describe in the following sections some pricing algorithms used by an online seller's pricebot to determine the price of a product. We omit the subscript for

Figure 1. A hypothetical market showing two buyers, B_1 and B_2, with preferred attributes a_1 and a_3, respectively, making a quote request to four sellers, S_1, S_2, S_3, and S_4, and then selecting the seller that offers the best price for the product on their respective attributes. The four-tuple below each seller denotes the normalized price on the different product attributes offered by that seller.



attribute a_i in the price and profit notation for the sake of clarity. We illustrate the algorithms for a single seller assuming that it is competing with other sellers in the market. We use p_t to denote the price charged by the seller during interval t.

Derivative-Following Algorithm

In the derivative-following (DF) algorithm, a seller uses its profit information since the last price update to adjust its price in the next interval. If the profit in the last interval has increased from its previous value, the price for the next interval continues to move in the same direction as in the last interval. On the other hand, if the profit in the last interval has decreased from its previous value, the direction of the price movement is the reverse of the direction in the last interval. The equation for updating the price during interval t+1 using the DF technique is given by:

$$p_{t+1} = p_t + \delta_t \operatorname{sign}(\pi_t - \pi_{t-1}) \operatorname{sign}(p_t - p_{t-1})$$

Here, π_t represents the profit made by the seller during interval t, and δ_t represents the amplitude of the price change and is drawn randomly from the uniform distribution $U[l, u]$, where $l > 0$ and $u > 0$.

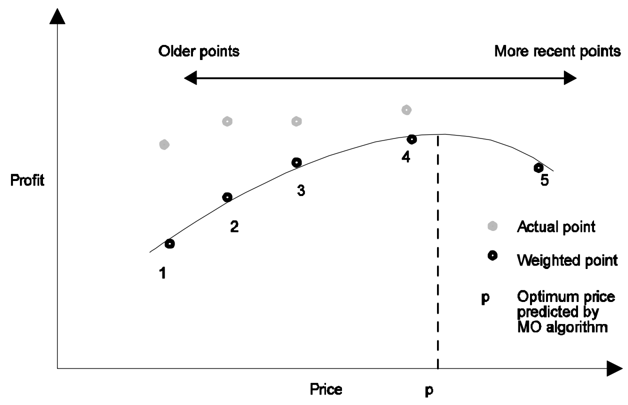
In the DF algorithm, the price of the product is updated based on the profit information from only the last interval. Therefore, the DF strategy is not very efficient in dynamically tracking the price of a product in a rapidly fluctuating market. A more efficient technique, the model-optimizer (MO) algorithm described next, employs the historical price and profit information of the seller to update the price during the next interval.

Model-Optimizer Algorithm

A seller using the MO algorithm maintains its price-vs.-profit profile over the last h intervals, where h denotes the size of the history window of the seller, as shown in Figure 2 for h = 5. The MO algorithm works as follows:

1. Assign weights to the last h points in the price-vs.-profit profile of the seller. The weight of a point expresses its relevance to current market conditions. Older points are less relevant and are assigned lower weights; more recent points are more relevant and are assigned higher weights.
2. Fit a polynomial over the h points in the history window of the seller using a nonlinear regression approach.
3. Use a nonlinear optimization scheme, like the Nelder-Mead algorithm (Nelder & Mead, 1965), to determine the price that corresponds to the maximum profit.

Figure 2. The operation of the MO algorithm with h = 5

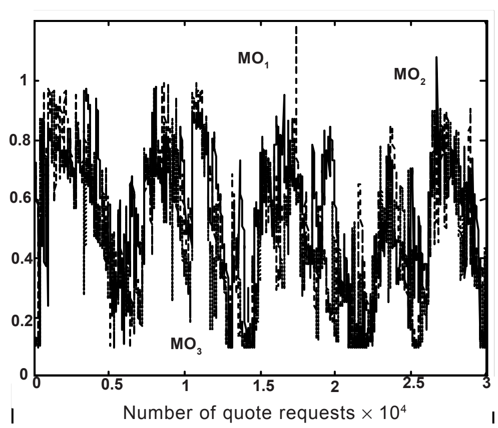


Although a large history window h might yield accurate results, it increases the time required for calculating the price for the next interval. If the seller is relatively slow in dynamically updating its price, its competitors might outperform it. Therefore, the value of h should be selected carefully to balance accuracy with rapidity in price calculation.

Figure 3 shows the variation in prices over time for three competing sellers in a market using the MO algorithm. As shown in the figure, the sellers using the MO algorithm engage in repeated cycles of price wars with each other. The reason for the price wars is that there are buyers with different preferences in the market. For simplicity, we assume that there are only two types of buyers.

- A-type buyers that do not have price as the preferred attribute. Such buyers select a seller using

Figure 3. Price-vs.-time profile of three sellers using the MO algorithm



other undetermined criteria, which we model as selection at random.

- B-type buyers that have price as the preferred attribute. Such buyers shop for the lowest price in the market and select the seller offering the lowest price.

Based on a survey of online markets (Clark, 2000), we assume that the ratio between A-type and B-type buyers in the market is 1:3. Because B-type buyers are greater in number, they generate the majority of the revenue for the sellers. Therefore, the sellers reduce the price of the commodity in successive intervals so that they can attract the maximum number of B-type buyers by offering the lowest price among competitors, thereby undercutting each other. This price war continues until each seller's price reaches the production cost p_{co} of the commodity. Each seller has zero marginal profit in such a scenario. At this point, the sellers realize that they can make more profit by increasing the price of the commodity to attract A-type buyers instead of charging p_{co} to attract B-type buyers. Therefore, the sellers reset their prices to a high value and another cycle of the price war ensues.

The drawback of the MO algorithm is that it charges a uniform price to all buyers irrespective of the buyers' preferences. However, this uniform pricing results in a loss of revenue from A-type buyers who are willing to pay a much higher price for a commodity than B-type buyers. Thus, the buyer population can be segmented into different clusters depending on the buyers' preferences, and a different price can be charged for each segment.

Although some online merchants such as Amazon have implemented dynamic pricing, it is yet to be adopted widely in e-commerce. The principal drawback of the dynamic pricing mechanism that those merchants have employed is that it offers identical products to different buyers at different prices, resulting in discontented buyers. A better pricing strategy would be to identify the preferred attribute of different buyers and charge a slightly different price for the product based on a buyer's preferred attribute as described below for the multiattribute dynamic-pricing algorithm.

Multiattribute Dynamic Pricing

As shown in Figure 1, a buyer compares the prices offered by different sellers based on his or her preferred product attribute. To make a competitive offer in response to a buyer's purchase request, a seller identifies the buyer's preferred attribute to offer a competitive price to the buyer on that attribute. The seller estimates the distribution f_{pa} of a buyer's preferences over the product attributes and then uses it to predict the preferred attribute of a buyer in response to the buyer's purchase request.

The algorithm for multiattribute dynamic pricing is based on collaborative filtering (CF), which enables a seller to predict a buyer's preferred attribute. Collaborative-filtering algorithms (Kleinberg & Sandler, 2003; Sarwar, Karypis, Konstan, & Reidl, 2001) collect potential buyers' opinions or preferences on products of interest, and recommend possible products to new or returning buyers. A seller's attribute-prediction algorithm for a potential buyer must adaptively respond to changes in the buyer's preferences. The buyer attribute-prediction algorithm described below achieves this adaptive response by dynamically updating the seller's model of the buyer's attribute preferences.

Buyer Attribute-Prediction Algorithm

In the buyer attribute-prediction algorithm, a seller constructs one buyer cluster for each product attribute. Suppose the seller maintains C clusters. A buyer with preferred attribute a_i is placed into cluster c_i with probability $w_{i,t}$ during interval t. These probabilities are updated dynamically in response to the buyer's accepting or rejecting offers made by the seller. When a buyer makes a purchase request, the prediction algorithm takes the history of $w_{i,t} - s$ and outputs the predicted cluster (preferred attribute) for the buyer. Sophisticated, rather complex algorithms have been developed for assigning buyers to clusters, determining appropriate prices for buyers within clusters, and revising assignments and prices in response to decisions by buyers to purchase or not (Dasgupta & Hashimoto, 2004).

FUTURE TRENDS

The collaborative-filtering algorithm described above enables online sellers to determine a buyer's preferences over multiple product attributes and to update the posted product prices efficiently in a competitive market. More powerful learning techniques such as Q-learning (Mitchell, 1997) and multi-objective, evolutionary algorithms (Coello, Veldhuizen, & Lamont, 2002) offer mechanisms to enable sellers to search the profit landscape more efficiently. There are various trade-offs between the rapidity and accuracy of such learning algorithms. A naive but fast learning algorithm might compare favorably against a complex and accurate but slow learning algorithm in a dynamic environment like a competitive online market.

An interesting scenario arises when buyers' purchase preferences are dependent on the prices being charged by sellers. In such a scenario, a seller can attempt to learn not only the temporally varying buyer purchase-preference distribution, but also the variation in that distribution.

Probabilistic algorithms such as hidden Markov models and moving-target functions that estimate the dependence between temporally varying functions might be applied in such an environment.

CONCLUSION

We have described different algorithms that an online seller can use for the dynamic pricing of products in a posted-price market, where the seller announces the price of a product on its Web site. We have also described techniques that an online seller can use to determine the price of a product, including multiattribute dynamic pricing and adaptive response, in which the seller's model of the buyers' attribute preferences is updated dynamically.

KEY TERMS

Auction: A type of market in which sellers post an initial price for the item being offered and a deadline by which the item needs to be sold. Buyers make bids on the offered item. The auction mechanism determines the dynamics of the prices bid by the buyers, the winner-determination strategy, and the bid-disclosure strategy. Common auction mechanisms include the English auction, Dutch auction, and Vickrey auction.

Buyer's Reservation Price: The reservation price of an item for a buyer is the maximum unit price that the buyer is willing to pay for an item. The buyer's reservation price is typically drawn from a uniform or normal distribution.

Collaborative Filtering: A technique that is used to collect user opinions or preferences for items of interest. A CF algorithm employs a correlation method to predict and recommend items to new or returning users based on the similarity of their interests with those of other users.

E-Commerce: Consists of techniques and algorithms used to conduct business over the Internet. Trading processes such as supply-chain management, strategic purchase planning, and market mechanisms for trading commodities online are implemented using e-commerce.

Intelligent Agent: Performs tasks that are given to it without continuous supervision. An agent can perceive changes in its environment and can perform actions to accomplish its tasks.

Marketplace: A type of a market that corresponds to a central location that enables buyers and sellers to rendezvous. A marketplace is typically implemented as a blackboard where sellers post information about items being offered. Buyers make offers to sellers, and sellers respond with counteroffers.

Pricebot: An intelligent agent that is used by an online seller to determine a profit-maximizing price for a product that it sells. A pricebot encapsulates the pricing algorithm used by an online seller and enables a seller to maintain an edge over its competitors in a dynamically changing market scenario.

Seller's Production Cost: The production cost of an item for a seller includes the manufacturing and procurement costs for the item, and corresponds to the minimum price that the seller can charge for the item.

Shopbot: An intelligent agent that enables online buyers to determine and compare prices and other attributes of products from different online sellers.

E–Banking Application and Issues in Abbey National PLC

INTRODUCTION

The financial service is facing a new delivery challenge in the shape of the Internet and e-commerce (Akamavi, 2005). The Internet as a channel for banking service delivery is fundamentally different from other channels such as branch networks, telephone banking, or automated teller machines (ATMs). The term e-banking is often used interchangeably with online banking, Internet banking, and PC banking. For example, Pikkarainen, Pikkarainen, Karjaluoto, and Pahnila (2004) define online banking as an Internet portal, through which customers can use different kinds of banking services ranging from bill payment to making investments. A bank's Web site offering only information without possibility to conduct any transactions is not qualified as online banking. Lbbotson and Moran (2003) use the term "electronic forms of banking", which includes telephone banking, PC banking, and Internet banking. In line with this definition, Lassar, Manolis, and Lassar (2005) refer e-banking as various formats or technologies, including telephone banking, direct bill payment, electronic fund transfer, PC banking, and online (Internet) banking. In this article, e-banking is referred to Internet banking or Online banking that it must enable Internet based transactions. This distinguishes e-banking from other electronic-based remote banking. E-banking can be carried out anywhere from a device with an Internet connection and it enables access to account information and conduct online transactions.

E-banking brings up unique types of challenges and requires novel solutions (Shah & Gupta, 2005; Southard & Siau, 2004). This article reviews how e-banking has been developed in Abbey National PLC (Public Limited Company) with a focus on the important issues when implementing e-banking applications[1].

BACKGROUND OF ABBEY NATIONAL

Abbey is one of the UK's leading personal financial services company. It was formed in 1944 by the merger of the Abbey Road Building Society and the National Building Society, two long established organizations. In 1989 Abbey National changed from a Building Society to a PLC. Abbey National PLC was acquired by Banco Santander Central Hispano SA in December 2004. The company operates in the UK, Europe, and the United States. It is headquartered in London and employs about 25,000 people. The company recorded revenues of £6171 million during the fiscal year ended December 2004. It offers a full range of personal financial services including mortgages and savings, bank accounts, loans and credit cards, long term investments policies, critical illness and unemployment cover, and household finance.

Abbey National's strategic aim is to become more customer and sales focused, growing the number of valuable customers through retention, and increasing the flexibility of offering in terms of product channel and service. The strategic aim illuminates Abbey National's e-business strategy development and implementation. Abbey National's e-business strategy is implemented through setting up a separate e-banking unit—Cahoot (www.cahoot.com) in addition to Abbey's online banking services (www.abbey.co.uk). Abbey National launched its retail e-banking service in May 2000, this allows existing customers to access their accounts via the Internet. One month late, the separately branded e-bank Cahoot was launched. Abbey National's Internet banking allows customers to: check account balance, transfer money between accounts, pay bills, and set up overdrafts. The service is available to current bank accounts, savings accounts, and credit card accounts. Cahoot offers customers current accounts, credit cards, flexible loan and share dealing. Cahoot does not allow high-risk groups (for example under 21 years old) to open accounts with them and this resulted in 40% rejection of all the applications. Customer credit rating is used to determine the acceptability of potential customers. Cahoot customers are offered with different interest rates, this is depended on the level of their credit rating and risks to the bank. The most popular product offered by Cahoot is the current account mainly due to its competitive rates.

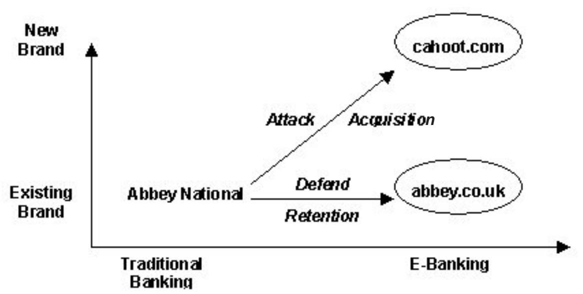
DESCRIPTION OF E-BANKING APPLICATION AND ISSUES

Abbey National's Hybrid E-Banking Model

Cahoot is owned by Abbey National PLC but with a new brand. The managing director perceives the potential to set up an online only bank in order to reach customers who do not already bank with Abbey National. Cahoot has gained Abbey National a vast amount of customers who they would not have been able to acquire by traditional banking methods. Abbey National's e-banking structure reflects a hybrid e-banking model, which is depicted in Figure 1.

Creating a new e-banking brand reflects the typical subsidiary model or spin-off model of e-business suggested by Chavez, Leiter, and Kiely (2000), who argue that the primary purpose of separating the e-banking unit is to target new market. Spinning off e-business unit has advantages in capitalization—raising funds from external sources, and running the new business independently to avoid any legacy impact from the parent company. However, Mols (1998) suggests that banks should use the Internet as an additional channel of distribution and must keep their traditional channels. This gives the banks the opportunity for a gentle transition from a branch banking strategy to e-banking strategy. Li (2001) endorses this notion by arguing that the legacy players that move

Figure 1. Abbey National's hybrid e-banking model



online seem to ultimately have an advantage over online-only startups. Despite the thorny issue of whether legacy players should spin off or integrate their online units, it is predicted that about 80% of the new economy will be dominated by the old economy companies that learn new tricks fast. Pure payers need to team up with legacy partners. The new brick-and-mortar of e-commerce is increasingly recognized as the winning formula. Pikkarainen et al. (2004) further suggests that pure online banks often use other channels as well, such as contact centers, and some have even established physical presences by establishing branch services.

Abbey National creates Cahoot with the aim to explore a new market, whilst establishing its own online banking services to retain existing customers. Cahoot's managers perceived that this model enabled Cahoot to benefit from avoiding large initial investment needed to run the banking business and the high risk of starting an online banking business. Abbey National had over one million customers sign up to their Internet banking service in less than 15 months, this makes Abbey National one of the fastest growing online banking facilities in the UK.

Customer Acquisition

In order to achieve its strategic goal of customer focus, to grow and retain valuable customers, Abbey National offered a competitive "take up" rate to attract customers to use Internet banking services. In addition, within most of Abbey's branches, Internet access computers were installed in order to increase awareness, and entice people to use the e-banking facility.

Cahoot's customer acquisition focus is to attract customers by switching to Cahoot e-banking from other banks. Within their customer base, 80% are new customers and 20% are existing customers from Abbey National. This implies that the cannibalization effect between the two brands is low. However, this strategy may face great difficulty in the long run, Datamonitor (2000) suggests that the traditional UK retail banks are all launching Internet banking operations so internet banks are going to find it more difficult to compete for customers in a saturated market. When facing with increasing attractive interest rates offered by other e-banks, the managing director commented that if people choose to bank with a bank which is offering the best rates, those customers will tend to keep moving banks as better offers come up. Abbey National aims to create long and trusted relationships with its customers.

Launching and Marketing of the Online Brand

Abbey National regards engaging in e-banking and creating an e-banking unit as innovation, which has been driving the changes of the whole group. The primary purpose to create Cahoot is to reach customers from a new market that is being created by the Internet. The managers perceive that this is an attractive segment in the market that Abbey National could not reach with its traditional banking approach. They believe that there are a number of people who are willing to deal with new brands in a digital environment, thus creating Cahoot to target the non-Abbey National customers. Abbey National has successfully gained a number of customers that would not have banked with them, if they had not created Cahoot.

Managers from the two banks hold the same view that having the Abbey National brand name behind Cahoot is essential, as reassurance and confidence are crucial in e-banking. Cahoot gained reassurance of legitimacy by stating Abbey National as the parent company for Cahoot in the Web site. One of the managing directors commented that people are more likely to use Internet enabled facilities with well-known brands. Abbey national spent millions of pounds in advertising the Cahoot new brand. The form of advertising includes TV commercials, banners, press and posters, direct mail, as well as radio media. The efforts were paid off, as Cahoot achieved 50% brand recognition and contributed 25% to Abbey National's favorable recognition. It is reflected by the managers that an Internet bank needs a large parent company, such as Abbey National, to start up the business and fund it through until it makes profit. This reaffirms Shah and Gupta's (2005) argument that having an established brand was a critical success factor in e-banking. Yousafzai, Pallister, and Foxall (2005) explained that the main reason was that a household name gives customers added confidence to conduct business online.

Security Issues of E-Banking

Privacy and security concerns have been regarded as significant obstacles to the adoption of online banking (Sathye, 1999). Security issues will further crush already fragile customer confidence, any security problems will affect the number of customers attracted to the Web sites (Datamonitor, 2000). Howcroft, Hamilton, and Hewer (2002) revealed that consumers' confidence in their bank in the UK was strong, their confidence in technology was weak. Shah and Gupta (2005) stress that security, which may include protection of consumers' personal data and safe transaction, is paramount for the growth of any sort of online trade including e-banking. They define e-banking security including secure transactions as well as secure front and back end systems. However, e-banking security has not been seen as a problem in e-banking leading country—Finland. Mattila, Karjaluoto, and Pento (2003) reported that security is an influential factor affecting mature customer adopting e-banking, but Finish Internet banking customers in general consider Internet banking safe in their earlier study. Pikkarainen et al. (2004) reaffirm Mattila et al.'s (2003) finding by stating that online banking channel has proven to be safe to use and no misuse has been reported by the media in Finland.

Abbey National had not experienced major security problems with the launch of their Internet add-on and Cahoot, but recognized customers' concern on the security of e-banking due to customers' lack of understanding. Hence, Abbey National had to reassure people about their security measures, that is, using high level encryption for all e-banking transactions by both Abbey National and Cahoot. In addition, Abbey National published a "Peace of mind guarantee" on their Web site stating that, if any loss is made due to Internet insecurity, Abbey National will reset the accounts into the position where they were before. The managers expressed that they were happy with their current security measures, but security can always be improved. The tightness of security measures needs to be cost effective. Cahoot also has a privacy policy, which is published on its Web site. The manager emphasized that individual had a lot to do with security. For example, the behavior of using computers for e-banking (i.e., where they access their accounts from), whether customers leave the computer unattained but logged on, whether customers keep passwords confidential and choose appropriate passwords, etc. A manager stated that security will not necessarily have a negative effect on growth, unless there are some major scandals that are well documented and wide spread, so that people may lose trust and confidence in security over the Internet as a new channel for banking.

The Risks of E-Banking

There are many risks associated with e-banking. Traditional banking risks are magnified in an electronic medium (Pennathur, 2001). Firstly, business risks may be over or under estimated. Internet banking can attract the hit and run customers, who maintain an account with an Internet only bank until special offers expire. Secondly, reputation risk due to e-banking as a new banking venture. Any hitches or failures of systems tend to be spread quickly in the media, and reflected badly on banks' reputation. Many UK banks, when launching their Internet offerings, have had problems. For example, customers from Barclays Bank reported that they were able to see other customers account details. The problem followed with an upgrade to the system (Leyden & Lynch, 2000). Cahoot's e-banking system only worked for 90 minutes and then crashed when started to launch on the first day. The system did not run smoothly until 24 hours after the incident happened. Only a few hundred people had opened accounts by the end of the first day. The problem was well documented in the media that the crash was due to the number of people trying to open the online account simultaneously, as preferential rates were offered to the first 25,000 accounts opened. Cahoot found that there was great media attention on the crash, but this was beneficial in some aspects later. When the media reported the story, it also printed Cahoot logo and the promotional interest rates. When Cahoot launched advertisements later, the campaign generated high responses of interest and applications. It seems that the negative media report actually posed some positive effects on consumers' awareness of the new brand. Lynch (2000) states that although most of these types of risks usually happen when the bank first goes online, problems tend to be remembered for a long time. Failure sticks in the mind of perspective customers, which could potentially harm their reputation. Thirdly, security risk. As Internet banking deals with sensitive financial information, critics are looking to exploit bank errors. Due to the structure and intention of the Internet to be an open network, high security risks are involved with financial transactions because of criminal intent attack: for example, hackers actively probe the bank's system to gain access to data for inappropriate use; casual hackers and flaws in the bank's Internet system, which may lead to security breaches.

Benefits of E-Banking

Benefits of e-banking can be viewed in two facets. One is for banks, and the other is for customers (Lassar et al., 2005). The notable benefit of e-banking for banks is cost saving (Pikkarainen et al., 2004). Akamavi (2005) explains that an automated Web site is accessed 24 hours a day, 7 days a week, without the need for human operators to keep it functioning. Not only does this clearly offer increased convenience to the growing number of people with Internet access, it also represents significant cost savings for the bank. E-banks can avoid substantial investments for delivery channels and the high cost of staff required to "man" these delivery channels. E-banks do not have the costs of the legacy systems as the traditional banks have. E-banking expenses are thought to be only 25-30% of traditional banking services (Hansman, Van Den Bosch, & Volberda, 2001; Lu, Liu, Jing, & Huang, 2005). Low cost can enable e-banks to offer special competitive rates to entice customers to bank with them. Secondly, e-banks can potentially reach more customers than a fixed branch network. For traditional banks, the risk of not offering Internet banking service is to lose existing customers who want to bank online. Thus Internet banking becomes an inevitable weapon to retain existing customers and to react to competition. Jayawardhena and Foley (2000) suggest that banks that are unable to respond to requests for new services risk losing existing customers to competitors. Thirdly, e-banking offers the opportunity for banks to solidify and extend their relationship with a customer (Lbbotson & Moran, 2003). The Internet enables banks to customize their products and services to suit individual customer's needs and preferences. Lastly, the Internet can be an effective way of communicating to customers (Aladwani, 2001) and expanding business into non-traditional banking areas (Colgate, 1998; Jun & Cai, 2001). For example, e-banks can cross sell motor insurance by providing interactive online services.

The main advantage of e-banking for consumers is to allow customers access their account information from anywhere with an Internet connection. Convenience, time saving, accuracy and timeliness are some of the notable benefits when customers choose online banking. Other benefits include flexible choice of banking, competitive offerings and better tools to manage and compare information.

Factors Hamper the Adoption of E-Banking

UK consumers seem cautiously stepping into e-banking and some consumers prefer a multi-channeled banking approach. MORI (2001) reported that Internet banking in Britain appears to be following the U.S. pattern, where people who do most of their banking online still want choice and the reassurance of a high street presence. Report by Datamonitor (2001) shows that 63% of UK consumers indicate personal visit is their preferred method for dealing with banking products, a figure which rises to 88% elsewhere in Europe. This is reinforced by Lbbotson and Mortan (2003), who reported that lack of personal contact is the main reason that SMEs in Northern Ireland are not using remote banking, in addition to security concern. Another reason is that pure E-banks do not have a branch network, and is lack of personal contact for immediate assistance (where additional assistance may be provided over the phone, but it is often charged with high call rates). Other factors include deposits need to be sent to the e-bank by post, which means a delay in the deposit being credited. E-banks have to use other bank's services, for example, ATMs, the usage of these services may be charged.

The Future of E-Banking

The managers hold the view that e-banking is not appropriate for all segments of the banking market, and is not suitable for all types of banking products. There are people who have never used the Internet and never want to. However, the Internet could reach a larger potential market, but this will take a long time. Internet-based banking has only been around for a relatively short period of time and branch based banking has been around for hundred of years. In terms of products suitable for e-banking, one manager emphasized that people prefer to carry out simple transactions over the Internet at the moment, but there is potential for complicated products to be offered online in the future.

THE IMPACT OF E-BANKING

The Internet is transforming the retailing banking industry as well as consumers' awareness and behavior of banking. Firstly, the adoption of e-banking strategy reshapes the bank's organizational structure. Traditional banks are largely working on a defense strategy by creating Internet add-ons to prevent customers from defection. Pure e-banks tend to work on an attack strategy by offering preferential rates to attack the traditional banks' customer bases. A successful strategy demonstrated by Abbey National is their pure e-bank is backed by the parent company, which forms a successful hybrid e-banking structure.

Another impact is on developing a deep and broader relationship with customers. Two trends emerged from launching the e-banking service: more transactions are carried out over the Internet than that in branches; more customers are moving from telephone banking to Internet banking, rather than from branch to the Internet. Abbey National's experience shows that e-banking appeals to people who are happy not to have face-to-face contact. These types of customers are empowered to bank with Abbey National or Cahoot when and where they want to.

E-banking also influences consumers' banking behavior directly. One the one hand, with more and more people are getting connected to the Internet with broadband technology, and more media exposure of online banking, more customers will be switching to e-banking in the long run. On the other hand, competitive offerings and aggressive marketing from e-banks will reduce consumers' loyalty to their traditional banks. Internet banking makes easier for customers to change bank accounts than it used to be (Clarke, 2001). This creates challenges for both online and traditional banks as to how to retain these switching customers.

CONCLUSION

E-banking is a cost-effective channel for banks to develop and deliver a broad range of products and services. E-banking also brings many benefits to customers including convenience and better products and customer services. However, the concerns over e-banking security, and the inhuman nature of e-banking hold many people back from taking the advantages of e-banking. From banking industry point of view, e-banking is becoming a common practice of banking as well as a new battlefield of competition, although at the present, only limited transactions are carried out on the e-banking platform.

Some lessons can be learned from Abbey National's experience. Firstly, develop a strategic goal of e-banking, either focusing on retaining customers through Internet add-ons, or emphasizing acquiring new customers through e-banking channel, or achieving both. The conibalization effect between the traditional banking channel and the e-banking channel needs to be continuously analyzed in order to determine the strategic direction of the company and the operational tactics of e-banking. Secondly, a new e-banking brand needs to be associated with well-known brands of the parent company, and needs effective marketing effort. Thirdly, educate consumers on e-banking security and build trust. The focus should not lie only on implementing encryption mechanism, firewall procedures, intrusion detection and virus controls, but also on reassurance of consumers of these security measures adopted publicly, and the guarantee of consumer rights including liabilities, compensation, privacy, data protection etc. It will also be beneficial to educate consumers on how to securely use the e-banking services. Fourthly, in order to reduce operational and reputation risks, accurate forecast of potential Web traffic seems essential to the smooth launching of online banking. In addition, sufficient test of the Web site with large volume of data needs to be conducted and a contingency plan needs to be in place to deal with system errors or unexpected incident. Lastly but not the least, the e-banking products and services provided should be viable and competitive to sustain long-term success. Although acquiring new customers through preferential rates proved to be successful, the challenge is how to retain e-banking customers who appear less loyal than traditional customers. Retaining customers and sustaining long term success should be on the top agenda of senior managers of e-banks.

eBay's Dominance in Internet Auctions

Sangin Park
Seoul National University, Republic of Korea

BACKGROUND OF THE BUSINESS: INTERNET AUCTIONS

Internet auctions began in 1995 and have been growing rapidly since. As of May 2001, the estimated total revenue of Internet auctions reaches $556 million. Since the beginning of Internet auctions, *eBay* has maintained a dominant leading position although the popular attention and the profitability of eBay induced entries of two biggest e-commerce firms, Yahoo!, in October 1998, and Amazon.com, in March 1999. An eBay vice president said in January 2000 that eBay's market share in the Internet auctions market remained at approximately 90% (see Lucking-Reiley, 2000). As of fall 2001, it is believed to be more than 80%.

Internet auction sites such as eBay and *Yahoo!Auctions* acts as listing agents, allowing individual sellers to register their items on their Web sites and running Web-based automatic auctions on their behalf. Actual exchanges including payment and shipment are worked out by the buyer and the seller on their own. The English auctions have been the most dominant format in Internet auctions. However, sellers usually have some control over these Web-based auctions, choosing a set of different parameters for each auction such as the duration days, an opening value, an optional secrete reserve price, and so forth.

A variety of goods are auctioned in Internet auctions, but the largest category by far has been the collectibles. Each Internet auctions site has different categories, and there is usually no one top-level category that includes all the types of collectibles. Between September 27, 2001, and November 1, 2001, 59% of listings on eBay belonged to one of the categories such as antiques and art; collectibles; books, movies, music;,coins and stamps; dolls and doll houses; or toys, bean bag plush. During the same time period, 54% of listings of Yahoo!Auctions were included in one of the following categories: antique, art and collectibles; sports cards and memorabilia; toys and games and hobbies; or coins, paper money and stamps.

Table 1. Auction mechanism

	eBay	Yahoo!Auctions
auction format for a single item	English auction	English auction
proxy-bidding	Optional	Optional
secret reserve price	Optional	Optional
duration (days)	3, 5, 7, or 10	2 - 14
feedback-and-rating	Available	Available
buy it now	Optional	Optional
early close	Optional	Optional
auto extension	Not Available	Optional

DESCRIPTION OF THE BUSINESS: eBay vs. Yahoo!Auctions

Yahoo!Auctions has kept a distant second place in the Internet auctions market although it has offered a little bit more options in *auction mechanisms* and lower *listing fees* compared to the leader, eBay. As shown in Table 1, both sites offer similar auction mechanisms (in terms of auction formats and auction parameters), but Yahoo!Auctions offers an additional option, auto extension, in the closing rule and more flexible duration dates.

Despite similar auction mechanisms between eBay and Yahoo!Auctions, these two sites charge *distinctively different* fees to sellers. During the first 17 weeks of the year 2001, eBay charged two types of basic fees to sellers: insertion fees and final-value fees. The insertion fees of eBay range from $0.30 to $3.30, depending on the opening values (called also reserve prices or minimum bid levels), whereas the final value fees are 5% of the final value (called also sale price or closing value) up to $24.99, 2.5% from $25.00 up to $1,000.00, and 1.25% over $1,000.00. On the other hand, Yahoo!Auctions charges only insertion fees ranging from $0.20 to $1.50. As indicated in Table 2, eBay charges higher insertion fees for all the ranges of opening values. A seller can ex ante choose a secret reserve price as well. If the secret reserve price is not met by the close of the auction, the item will not be sold. The fees for the secret reserve price auctions are fully refundable if the item is sold. If an item is not sold, the seller can relist the same item subject to insertion fees. On eBay, the insertion fee for the second listing is refundable if the item is sold in the second round.

Table 2. Listing fees

		eBay	Yahoo!Auctions
Insertion Fees			
Opening Value	$0.01-$9.99	$0.30	$0.20
	$10.00-$24.99	$0.55	$0.35
	$25.00-49.99	$1.10	$0.75
	$50.00-$199.99	$2.20	$1.50
	$200.00and up	$3.30	$1.50

		5%	Free
	$25-$1000	$1.25 + 2.5%	
			Free
	over $1000	$25.63 + 1.25%	Free

The basic fees of Internet auctions have not changed frequently. Indeed, Yahoo!Auctions began to charge insertion fees only from the beginning of the year 2001. At the same time, eBay raised its insertion fees a little bit to the levels shown in Table 2. As will be discussed below, these changes of fees had significant impacts on the number of listings on Yahoo!Auctions.

Despite more options in the closing rule and lower listing fees on Yahoo!Auctions, eBay's dominance is evident in terms of both the number of listings and Web site usage. The data employed in the article is unique because it is unusual to obtain the data of the number of listings and Web site usage on any auctions site other than eBay. Our data of the number of listings are obtained from the *Downtown Magazine's Wednesday Report*. The *Downtown Magazine* is an unbound magazine available via the Internet (www.dtmagazine.com) and reports its counts of the number of auction listings updated every Wednesday by noon, Eastern Time. In this counting, eBay listings do not include eBayMotors or Great Collections but include Business Exchanges and UltimateBid Tickets and Experiences, whereas Yahoo!Auctions listings include Yahoo!'s Business Marketplace.

This weekly data of the number of listings for eBay and Yahoo!Auctions were collected from the first week of the year 2001. However, from the second week of April 2001, the Wednesday Report ceased counting the number of weekly listings on Yahoo!Auctions and began to report the number of listings on a monthly basis.

As illustrated in Figure 1, during the first 17 weeks of 2001, the number of listings on eBay remained between 5 million and 5.7 million after an increase in the first week. On the other hand, the initiation of fees on Yahoo!Auctions in the beginning of the year 2001 had a dramatic impact on the listings of Yahoo!Auctions. The number of listings on Yahoo!Auctions declined drastically from more than 2 million to about 250,000 by the seventh week of the year 2001, and then stabilized around 220,000. According to the *Downtown Magazine*, Yahoo!Auctions had highs of 2.5 million listings in mid 2000. In what follows, therefore, our data analysis will focus on the period of the 7th week to the 13th week (the third week of February to the first week of April) after the changes of the fee schedules were fully absorbed in sellers' listing behavior.

The data of weekly Web site usage (measured by "*unique visitors*" and "*page views*") of these two auctions sites are obtained from Nielsen//NetRatings for the first 17 weeks of the year 2001 (except in the first week of March for eBay and the first week of January for Yahoo!Auctions). *Unique visitors* is the estimated number of different individuals who visit a firm's Web site, and *page views* is the number of unique visitors multiplied by the average unique pages viewed per visitor. This usage data from Nielsen//NetRatings is unique in the sense that the weekly usage of Yahoo!Auctions is counted separately from the entire site of Yahoo!. Unlike the number of listings, however, the changes of fees had no substantial effect on Web site usage. As illustrated in Figures 2 and

Figure 1. Listings

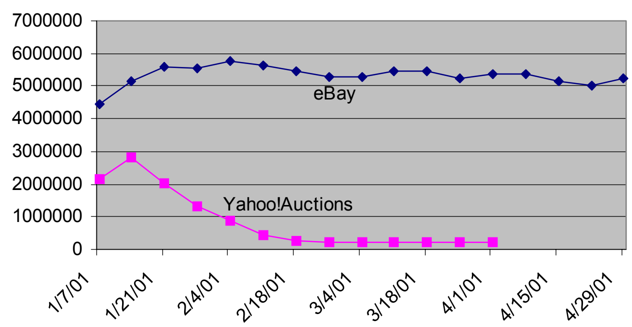

Figure 2. Unique visitors

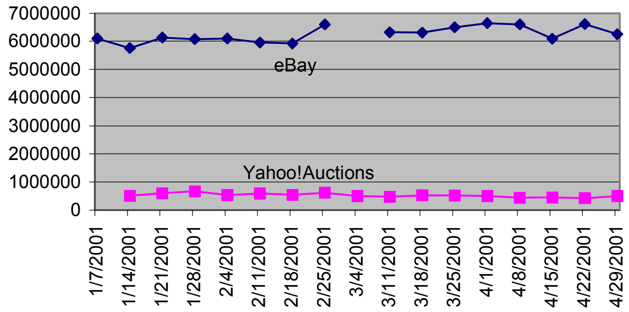

Figure 3. Page views

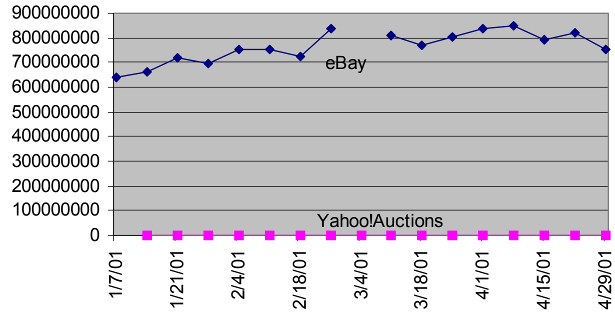

3, between the seventh week and the 13th week of 2001, eBay had about 6.3 million unique visitors and 763.6 million page views on weekly average, whereas Yahoo!Auctions had about 530,000 unique visitors and 1.7 million page views. It is quite puzzling that the initiation of fees on Yahoo!Auctions incurred the drastic decrease of listings but had no significant impact on Web site usage. One possible explanation is that before the initiation of fees, many sellers on Yahoo!Auctions might have kept listing their items over and over until they were sold and thus the number of the listings were substantially overcounted.

The data of the number of listings and Web site usage shown in Figures 1 through 3 clearly indicate that eBay has much larger Web site usage (measured by either unique visitors or page views) and much more listings than Yahoo!Auctions.

The number of *potential bidders* faced by a specific seller on an Internet auctions site, however, may not be exactly equal to the number of Web site usage of the site. Because different sellers may list similar (or substitutable) items in the overlapping time periods, we may infer that Web site usage per listed item is more relevant than the Web site usage itself.

As discussed above, Web site usage is typically measured by either unique visitors or page views. When we look into our data of unique visitors and page views as well as the number of listing, we can confirm that page views per listed item is more relevant to the number of potential bidders. It is *striking* to note that during the period in concern (the 7th week to the 13th week of 2001), unique visitors per listing are on average 1.2 on eBay but 2.3 on Yahoo!Auctions whereas page views per listing are on average 148.4 on eBay but 7.3 on Yahoo!Auctions. As reported in Bajari and Hortaçsu (2001), the average number of (actual) bidders for U.S. mint/proof coin sets was 3 on (traded) eBay auctions. Considering that unique visitors (including sellers) per listing are on average 1.2 on eBay, we can infer that unique visitors per listing may not be appropriate for the number of potential bidders. Moreover, page views reflect the multiple roles of a unique visitor in Internet auctions: A (same) unique visitor may act as a seller, a potential bidder, or both, possibly in the multiple different auctions.

Different listed items may face competitions from different groups of similar (or substitutable) items, and some buyers may not be interested in bidding some items. Hence, the number of potential bidders faced by a specific seller may be item specific. Therefore, we assume that the number of potential bidders faced by a seller is an increasing, item-specific function of Web site usage per listed item. Under this assumption, a seller faces more potential bidders on eBay. Because eBay has more listings, we can infer a *positive correlation* between the number of listings and the number of potential bidders in Internet auctions.

LESSONS LEARNED: NETWORK EFFECT AND THE FIRST-MOVER'S ADVANTAGE

Park (2005) showed that the positive correlation between the number of listings and the number of potential bidders is generated by the *network effect* in Internet auctions. As discussed, eBay, the pioneer of the Internet Auctions, has been very profitable and dominated the Internet auctions market despite less options in the closing rule and higher listing fees than Yahoo!Auctions. The positive feedback effect (or network effect) between buyers' Web site usage and sellers' listing behavior occurs because sellers list more items on the site with more potential bidders (i.e., the seller's *expected* auction revenue increases with potential bidders) and more potential bidders log on to the site with more listings. This network effect is the reason for this eBay's profitability and dominance. Refer to Katz and Shapiro (1994) and Park (2004) for the review of the literature of network effects.

To demonstrate the existence of the network effect in Internet auctions, we need to show that the eBay auctions have higher seller's expected auction revenues with more (potential) bidders. As an example, we collected the data of the Barber Quarter Dollar auctions on eBay and Yahoo!Auctions closed between November 28, 2001, and December 4, 2001. As well known, coins are a popular collectible, and collectibles are the most popular category of Internet auctions. The Barber Quarter Dollar is a particular kind of Barber Quarter coins, which have 74 regular issues between the year 1892 and the year 1916. The comparison of Internet auctions on eBay and Yahoo!Auctions, however, may not be straightforward because eBay stored all the closed (traded or not) auctions data while Yahoo!Auctions kept the data of only traded auctions. Keeping this restriction in mind, we will proceed to describe our observations.

During the time period, we observe 188 closed auctions but only 90 traded auctions on eBay whereas there were 24 traded auctions on Yahoo!Auctions. In our sample, therefore, eBay has about four times as many traded auctions as Yahoo!Auctions, and the conversion rate (the number of traded auctions divided by the number of closed auctions) on eBay auctions is a little bit less than 50%. Note that the Goldman Sachs study found about 50% conversion rate on eBay auctions. Although we do not have any direct information of the conversion rate on Yahoo!Auctions, we suspect that the conversion rate is much lower on Yahoo!Auctions. Indeed, it is reported that 22.5% of Web site users actually made purchases on eBay but only 4.4% on Yahoo!Auctions (see Nielsen//NetRatings & Harris Interactive eCommercePulse, May 2001). Because unique visitors per listing are on average 1.2 on eBay and 2.3 on Yahoo!Auctions, we infer that the conversion rate on Yahoo!Auctions is only 37.5% of the conversion rate on eBay. Hence, if the conversion rate on Yahoo!Auctions is about 19% (50% times 0.375), the total number of closed auctions on Yahoo!Auctions will be about 126.

In our sample, the average sale price (final value) of the traded auctions is $41.1 on eBay and $14.65 on Yahoo!Auctions, respectively. On average, the minimum bid level (opening value) is $26.47 on eBay and $6.55 on Yahoo!Auctions, respectively. Hence we can infer that more expensive coins of the Barber Quarter Dollar are traded on eBay, and the opening-value-to-final-value ratio is higher on eBay.

Although eBay has a higher average sale price, it does not necessarily imply that a seller's expected auction revenue is higher on eBay, because the quality of coins auctioned on these two sites may be different. To control quality differences of auctioned coins, we calculate the ratio of sale-price-to-book value. Because the data of closed auctions usually contain the description of the auctioned coins, we can find matching book values from the *Official National Bestseller 2002 Blackbook, Price Guide to United States Coins*. We found these matching book values for 17 Yahoo!Auctions and 73 eBay traded auctions. The average sale-price-to-book-value ratio turns out to 1.35 on Yahoo!Auctions and 1.36 on eBay. At a first glance, this result seems surprising. However, if we consider a possible big difference of the conversion rate between these two sites, the expected sale-price-to-book-value ratio (prior to auctions) must be higher on eBay. For instance, as discussed above, suppose that the conversion rate is 19% on Yahoo!Auctions (and 50% on eBay). Suppose also that a seller's reservation value for the coin is the book value. Then, the expected (prior-to-auction) sale-price-to-book-value ratio will be 1.07 on Yahoo!Auctions and 1.18 on eBay. Hence, in this case, the eBay premium will be about 10%.

In our sample, the average number of bidders in the traded auctions turns out to be 4.5 on Yahoo!Auctions but 4 on eBay. The maximum number of bidders is 9 on Yahoo!Auctions and 13 on eBay, but many traded auctions received only 1 bid on both sites: 45.6% (41.7%) of traded auctions on eBay (Yahoo!Auctions) had only 1 bidder. Note that, in Bajari and Hortacsu (2001), the average number of bidders for the U.S. mint/proof coin sets was 3 on eBay auctions. Yahoo!Auctions, ceteris paribus, may attract more entries of potential bidders because it offers longer duration days and has less expensive coins auctioned with lower opening values. In our sample, the average duration day of the traded auctions is 9 days on Yahoo!Auctions and 6.7 days on eBay. However, if we consider a possible big difference of the conversion rate between these two sites, the average number of bidders in all the closed auctions may be higher on eBay. For instance, as discussed above, suppose that the conversion rate is 19% on Yahoo!Auctions (and 50% on eBay). Then the average number of bidders in all the closed auctions will be 0.9 on Yahoo!Auctions and 1.9 on eBay.

To sum up, our sample suggests that eBay generates higher expected auction revenues to sellers and attracts more bidders at the same time. The expected sale-price-to-book-value ratio is 1.07 on Yahoo!Auctions and 1.18 on eBay whereas the average number of bidders in all the closed auctions is 0.9 on Yahoo!Auctions and 1.9 on eBay.

The e-commerce has been hailed as a frictionless competitive market (e.g., Bakos 1991, 1997). It is widely believed that the Internet drastically reduces buyers' search costs (for prices, product offerings, and shop locations) and lowers barriers to entry and exit. The low search costs and the low barriers to entry and exit induce strong price competition, leading to low profit margins and low deadweight losses. Consistently, some case studies have found that e-commerce has on average lower prices than the conventional retail market (for the review of these studies, see Bailey 1998; Brynjolfsson & Smith 2000). However, as argued in Ellison and Ellison (2004), the overhead costs in e-commerce may not be as low as anticipated, and thus severe price competition may lead to the Bertrand paradox (with prices so low that firms cannot cover their overhead costs). Hence, the long-term viability of the e-commerce firms is often in question. The turmoil of e-commerce firms' stock prices since the year 2000 highlights the worry of the long-term viability.

More recently, however, several empirical studies (e.g., Brynjolfsson & Smith 2000; Clemons, Hann, & Hitt, 2002; Johnson, Moe, Fader, Bellman, & Loshe, 2003; Loshe, Bellmam & Johnson, 2000) indicate some frictions in e-commerce: (a) compared to the conventional retail market, e-commerce has low prices on average but high market concentrations; (b) an e-commerce firm with the highest market share does not charge the lowest price and often charges a price higher than the average; and (c) the price dispersion is higher in e-commerce than in the conventional retail market. Hence, attentions have been directed to the possibility and sources of the *first-mover's advantage* which explains the reason that the pioneering firms, such as Amazon.com, Yahoo!, E*Trade, and eBay, have dominant market shares despite their higher prices. Some studies indicate that this first-mover's advantage may be caused by switching costs in the on-line brokerage market (Chen & Hitt, 2002) or by loyalty in the Web portals (Goldfarb, 2003). In Internet auctions, the network effect is widely considered a source of this first-mover's advantage.

The competition between eBay and Yahoo! Auctions indicates that eBay, the first-mover's in Internet auctions, took the full advantage of network effects and dominated the market despite later entrants' low prices with more features to offer. The timing of entry would be the most important factor of success in e-commerce when network effects are significant.

E-Business Planning and Analysis Framework

Ben Clegg
Aston University, UK

Boon Tan
Sunderland Business School, UK

INTRODUCTION

This article reports on a framework that has been successfully used to analyze the e-business capabilities of an organization with a view to developing their e-capability maturity levels. This should be the first stage of any systems development project. The framework has been used widely within start-up companies and well-established companies both large and small; it has been deployed in the service and manufacturing sectors. It has been applied by practitioners and consultants to help improve e-business capability levels, and by academics for teaching and research purposes at graduate and undergraduate levels.

This article will provide an account of the unique e-business planning and analysis framework (E-PAF) and demonstrate how it works via an abridged version of a case study (selected from hundreds that have been produced). This will include a brief account of the three techniques that are integrated to form the analysis framework: quality function deployment (QFD) (Akao, 1972), the balanced scorecard (BSC) (Kaplan & Norton, 1992), and value chain analysis (VCA) (Porter, 1985). The case study extract is based on an online community and dating agency service identified as VirtualCom which has been produced through a consulting assignment with the founding directors of that company and has not been published previously. It has been chosen because it gives a concise, comprehensive example from an industry that is relatively easy to relate to.

BACKGROUND

Kalakota and Robinson (2001) argued that organizations must bear in mind not to focus too much on the 'e' component, but also on the business requirements. The greatest threat to an organization is either failing to deploy the Internet, or failing to deploy it strategically and therefore without efficacy (Porter, 2000). Organizations should deploy an e-service only if it is concordant with its strategic needs. Not all e-business mechanisms are right for every organization (Lord, 2000). The correct application must be chosen or developed with both the process it supports and the strategic objectives of the company in mind. A deadly assumption would be to believe that technology is the answer to all process and strategic weaknesses; in response to this concern, this e-business planning and analysis framework was developed.

There are many types of analysis frameworks available (Ballantyne & Brignall, 1992). According to Wu (1992), good frameworks should be able to guide managers towards a method or solution uniquely suitable to a particular situation in question. On the whole, frameworks should not be too complex to use, and information interaction within the framework should be clear and concise to avoid information overload. Lee and Ko (2000) proposed a framework for strategic business analysis, by integrating SWOT (strengths, weaknesses, opportunities, and threats), balanced scorecard, quality function deployment, and "Sun Tzu's the art of business management strategies" techniques. In a similarly proposed framework, Lee, Lo, Leung, and Ko (2000) integrate the SWOT (de Witt & Meyer, 1998) BSC, QFD, and the Malcolm Baldrige National Quality Award's (MBNQA) education criteria, to formulate policy for vocational education in Hong Kong.

While many analytical techniques such as the SWOT, SLEPT (social, legal, economic, political, technical) (de Witt & Meyer, 1998), and the BSC analyses can be used to identify the strategic needs of an organization, none provide a direct mechanism to prioritize the needs and convert them into operational processes, or to then translate those processes into a specification that can be used to develop or acquire supportive software systems. In contrast, other analytical techniques such as Porter's (1985) value chain analysis (VCA) facilitates the analysis of processes within a company, but does not provide an easy mechanism to link these to high-level business objectives. One analytical tool that does provide the ability to convert high-level business objectives ("what" the business wants), into processes ("how" the business delivers those "whats") is QFD, which has had these benefits discussed widely by Akao (1972), Mazur (1992), and more recently by Ko and Lee (2000) and Lee et al. (2000). However, QFD has its own weaknesses; two of

Table 1. The three techniques of the E-PAF

	Analysis Technique		
	Balanced Score Card (BSC)	Value Chain Analysis (VCA)	Quality Function Deployment (QFD)
Primary Purpose	Establishes strategic objectives	Establishes the high-level logic of the value-adding activities within customer facing business processes	Analyzes and manages the trade-off between business objectives ("whats") and business processes ("hows"), and *deploys* these to lower levels of definition for detailed systems design
Main Strength(s)	Sets high level business vision	Defines high-level, value-adding activities (primary and secondary)	Can deploy high-level objectives and processes (e.g., users requirements) into detailed tasks and systems requirements
Main Weakness(es)	Difficult to translate these into detailed processes or system requirements	Does not generate high-level vision; difficult to translate value-adding activities into system requirements	Difficult to generate initial business vision and high-level value chain

these lie in the initial generation of the "whats" and "hows". The analytical framework presented in this article deals with these weakness by marrying up QFD with two other complementary analytical techniques:

1. BSC to generate a set of high-level business objectives, targets, measures, and initiatives for finance, internal operations, learning and growth, and customer satisfaction. The outputs from this analysis (including the weightings) become the 'whats' in the initial QFD analysis.
2. VCA to generate detail about operational processes. The outputs from this analysis become the 'hows' in the initial QFD analysis.

The relationships between these are summarized in Table 1. Through the complementary use of the BSC, VCA, and QFD, a comprehensive yet easily understandable E-Business Planning and Analysis Framework has been developed.

THE E-BUSINESS PLANNING AND ANALYSIS FRAMEWORK

An eight-step approach is followed to apply the E-PAF as shown in Figure 1 (Tan & Tang, 2002; Tan, Tang, & Forrester, 2003, 2004). Note that more detail of Step 1 is shown in Table 2 and more detail of Step 2 in Figure 2. The eight steps are identified as:

- **Step 1:** Using BSC to develop "whats" for QFD Matrix I
- **Step 2:** Using VCA to develop "hows" in QFD Matrix I
- **Step 3:** Completing QFD Matrix I
- **Step 4:** Identifying critical business processes from QFD Matrix I
- **Step 5:** Inputting critical business processes to QFD Matrix II's 'what'
- **Step 6:** Listing e-service applications to QFD Matrix II's "how"
- **Step 7:** Completing QFD Matrix II
- **Step 8:** Identifying critical e-service applications from QFD Matrix II

The article outlines how the framework has been applied to VirtualCom, a recently established online start-up company specializing in providing community groups and dating services; it presently has relatively low e-capability maturity. It should be noted that E-PAF (Figure 1) should be applied within the initial analysis stage of a systems development lifecycle, the remaining stages being the logical design, the physical design, testing, implementation, and maintenance, which for reasons of conciseness are not discussed in this article.

Firstly, prior to applying the framework, the situational factors (e.g., political, economic, social, technological, environmental, and legal) behind the business strategy need to be established. In brief, it was observed that the majority of the environmental drivers are pro-online dating. However, despite the fact that online dating has been around since 1998 (e.g., match.com), there are still many new entrants coming in on a monthly basis, making the industry highly competitive. The nature of the competition is such that well-known, trusted online brands

Figure 1. E-business planning and analysis framework

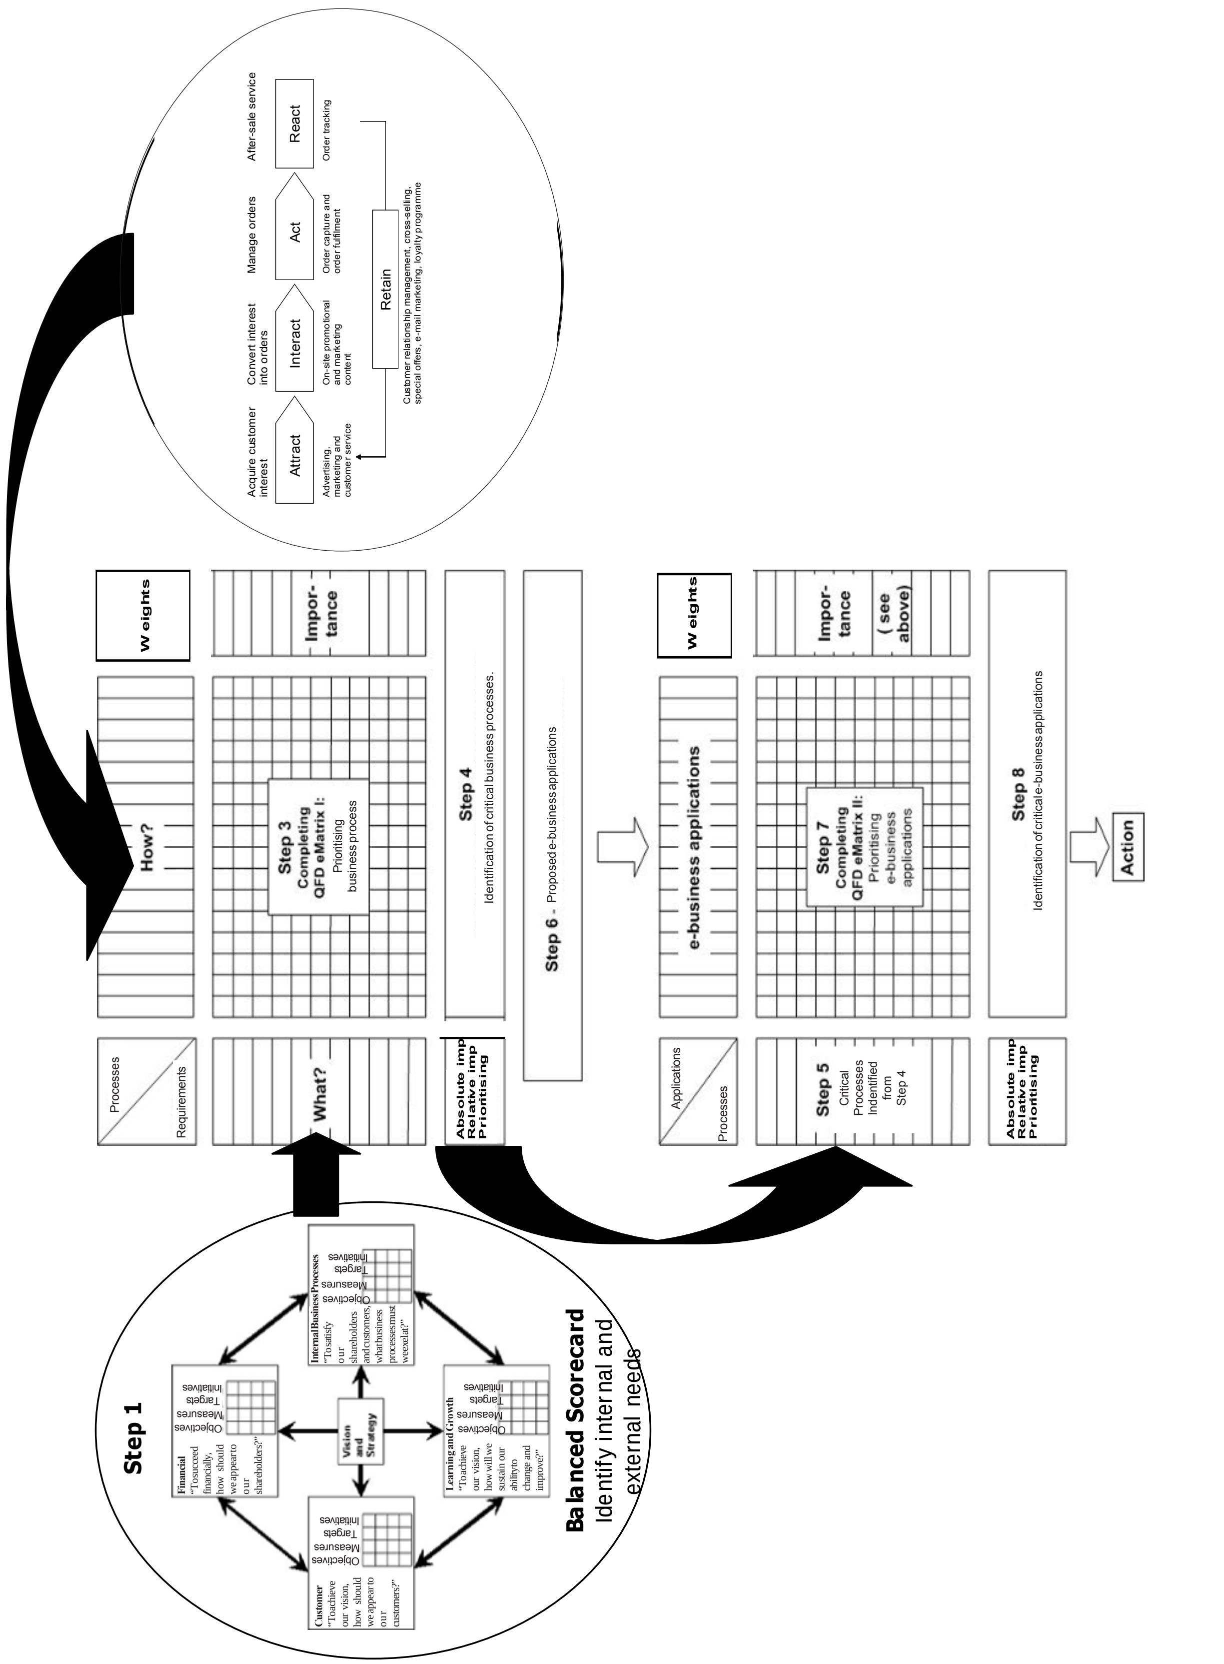

Table 2. Summary of BSC analysis

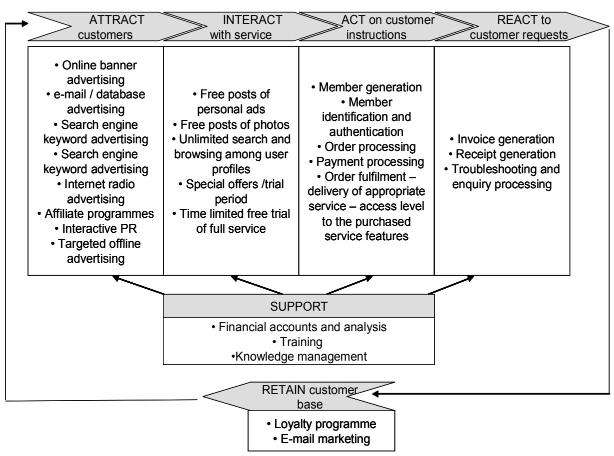
	Objectives	Measures (either increase or decrease is expected)	Target/Initiative	Weighting (1 low, 5 high)
Customer	Expand Customer Base	Increase number of new customers, build brand awareness and image, reduce attrition rate of visitors	1 year: 100,000 paying members—increase 400% from potential decrease to 20,000 3 months: attrition rate <90%	3
Internal Business Process	Quick Transactions	Increase efficiency of automation—reduce application response times, reduce database interrogation time (system resources/time)	6 months: make all Web pages max 5 clicks from login homepage. 6 months: clean database quarterly	5
Learning and Growth	Training	Increase percentage of employees at sufficient level of training for all relevant operating procedures, investment of time and costs incurred on training	1 year: retain services of online marketing agency 2 years: double technical personnel	4
Financial	Increased Profitability	Increase net contribution (daily, weekly, monthly subscriptions); monitor contribution of each different revenue stream (subscription fees, advertising revenue)	3 months: change from banner adverts and keyword sponsoring to affiliate payments	5

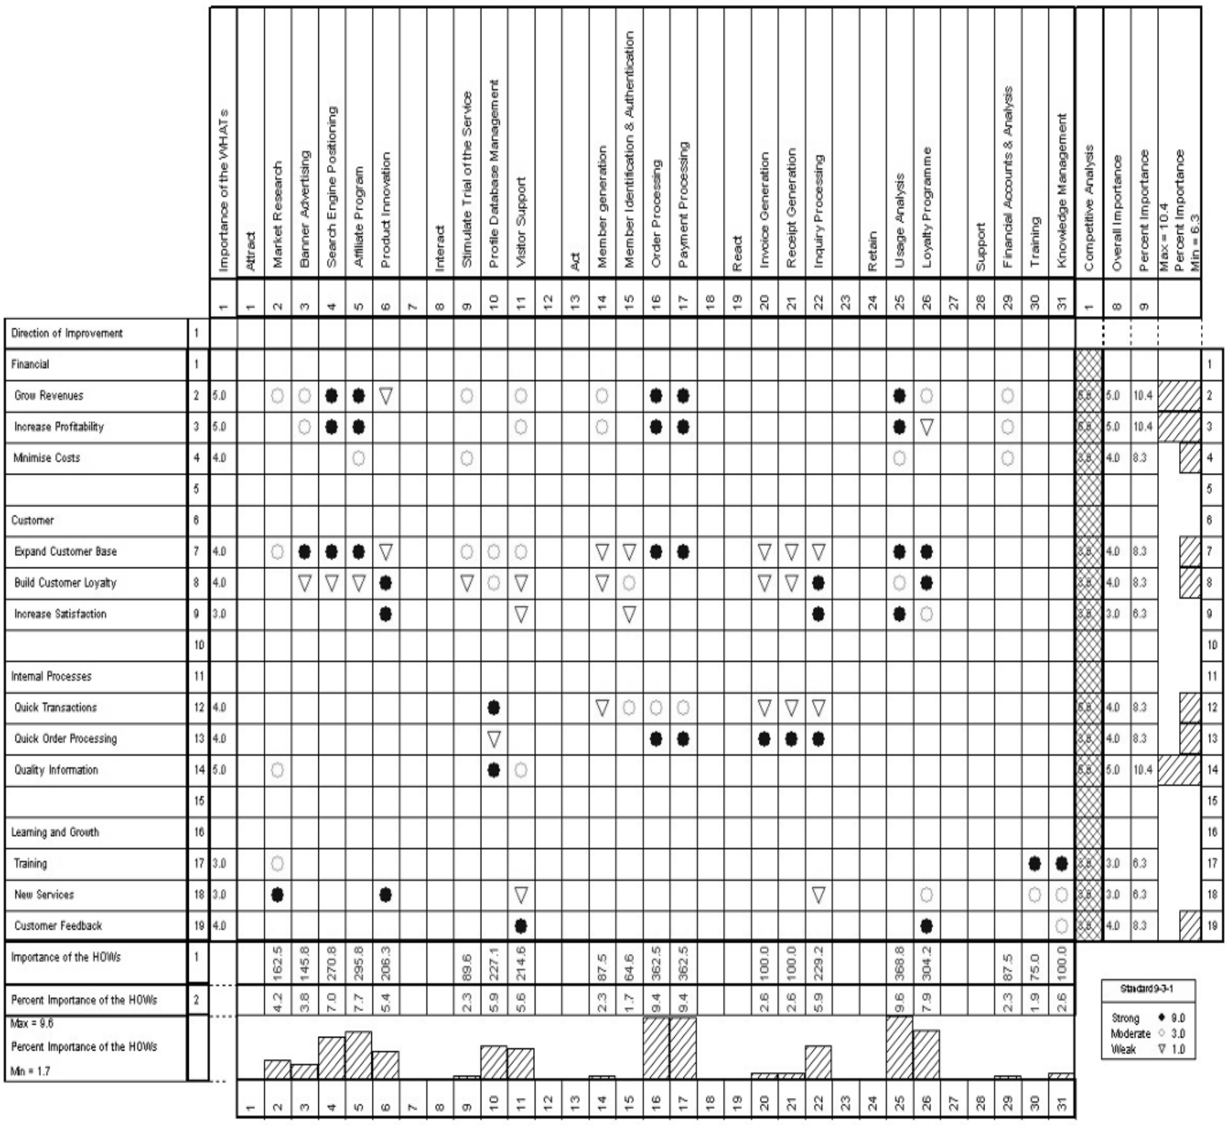
Figure 2. Key factors in VirtualCom's value chain analysis



attract most of the new users, thus becoming bigger and bigger and leaving the competition behind, as the size of a particular community is a key basis of sustainable competitive advantage. Due to the increasing number of competitors, margins are shrinking and profits decreasing. Moreover, the majority of new entrants are offering free services to attract visitors and seek revenues from other streams, such as banner advertising and database marketing. The bargaining power of customers is significant, as substitutes are just a click away, making it hard to create switching costs; any successful attempt to differentiate from the pack tend to be copied immediately, and advantage lost. The main switching barrier seems to be related to the attraction of belonging to the community itself, since users hopefully develop personal relationships, and in some cases strong feelings of belonging and even addiction.

Finally, many vendors are working on substitutes, such as mobile dating applications, taking advantage of specific mobile functions, such as location-based

Figure 3. QFD I matrix: VirtualCom's business objectives and key business processes



services (LBS) and nonstop attainability. However, there are many indicators that the most successful community services of the next decade will be those that will be able to merge Internet and mobile technologies into a seamless user experience. All of the above factors, combined with low-entry barriers, make the industry highly competitive. This means that a company must have a clear understanding of its systems development lifecycle, particularly in the initial stages. Each step is now explained further using VirtualCom as an example.

Step 1: Balanced Scorecard

A BSC analysis was conducted for VirtualCom to give objectives, targets, measures, and initiates to the financial, internal process, learning and growth, and customer perspectives; an exert of this can be seen in Table 2 (one example for each category is shown as an example; others used in the case study are simple identified by name in the QFD I).

Step 2: Value Chain Analysis

Concurrently to the BSC analysis being performed, a value chain analysis (VCA) was also generated for VirtualCom. As VirtualCom is a service-based company, it was more appropriate in this case to use the commerce value chain analysis by Treese and Stewart (1998) as opposed to the generic value chain analysis by Porter, which would be used if a manufacturing-based company were being analyzed. The factors identified for VirtualCom's

Figure 4. QFD II matrix: VirtualCom's key business processes and candidate software solutions

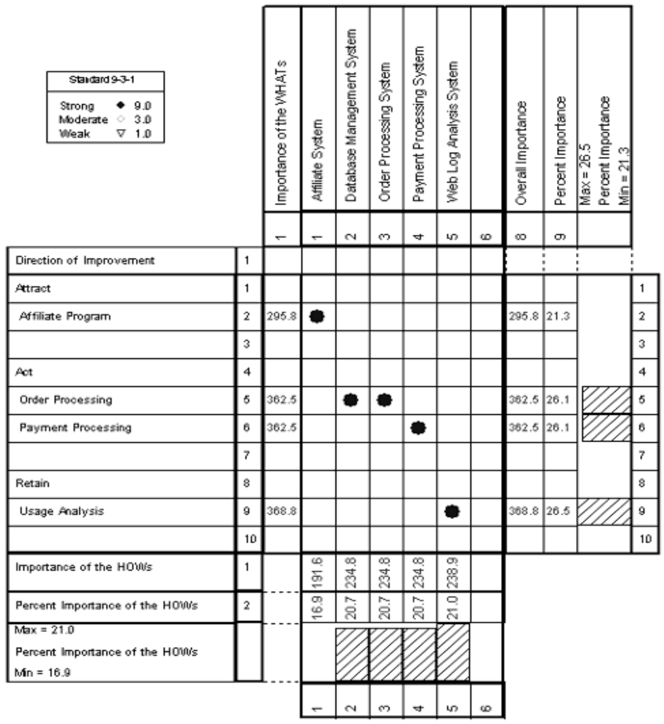


Table 3. Solution: Possible e-business application types for VirtualCom

Stage of Service Value Chain	Candidate Software Solution Types
Attract	Affiliate system
Act	Database management system
	Order processing system
	Payment processing system
Retain	Web log analysis system

value chain based on Treese and Stewart's work (1998) can be seen in Figure 2.

Steps 3-4: QFD I Matrix

The factors produced by the BSC analysis then become the "whats" in the QFD I analysis, and the factors from the VCA become the 'hows' for the QFD I analysis (Figure 3). From the QFD I analyses of the interrelationships between "whats" and "hows", the top four critical business processes identified to delivering customer needs were:

1. **Usage analyses** process (score = 368.8) ranked first. This process is critical to aligning the service with the customer's desires and thereby increasing loyalty. It is not presently performed but is of critical importance for sustainable revenue generation and providing evidence for how best to present the service to a first-time visitor.
2. **Order processing** and **Payment processing** processes jointly ranked next highly (scores = 362.5). These are both closely related to one of the new business model objectives (e.g., improvement of financial performance by the introduction of subscription fees).
3. **Affiliate program** process (score = 295.8) ranked fourth. This process is important to obtain critical pre- and post-purchase behavior of visitors and members.

The results demonstrate a high dependence on efficient order and payment processing to ensure the business survives. Additionally, usage analysis enables the online company to further understand the needs and behaviors of its users, and affiliate programs would further enhance the experience and perceived benefits by its users and members.

Steps 5-8: QFD II Matrix

Having determined the critical e-business processes, the next step is to conduct a second QFD analysis to identify critical e-business *applications*. In this step the output of QFD I becomes the input to QFD II, so that "hows" in QFDI become the "whats" in QFD II. Since VirtualCom is an existing online service, the only e-business applications considered were those that qualified as potential enablers of identified missing or under-performing e-business processes (see Figure 4).

At this stage candidate e-business application types are short-listed for VirtualCom (see Table 3). The results from the QFD II Matrix showed that the e-business applications under the heading of "Retain" came in first (score = 238.9), while the three e-business applications under "Act" came in jointly second (score = 234.8). The affiliate system, under the "Attract" heading, came in third (score = 191.6). Note that there are no application types suggested for 'React' and 'Interact', as there were no critical process identified in that stage.

The validity of these results can be further reinforced with the following explanations:

1. VirtualCom requires a tool for *site usage* analysis (e.g., a Web logger or Web transaction application) in order to determine the users' behavior. This will help to contribute in the design of the services to increase customer loyalty, as well as increasing the rate of conversion for first-time visitors into repeat customers. Thus, a Web log analysis system enables the capture of accurate first-hand data in order to understand its visitors' and customers' online behavior better.
2. The *order processing* and *payment processing* applications under the *Act* heading will enable VirtualCom to streamline order and payment processes as it replaces the existing manual processes. The database management system on the other hand will provide the necessary database upgrade to meet the new demands on the database management system, due to the introduction of different statuses and privileges of free and paying members (after the planned introduction of subscription fees).
3. The *affiliation* system will provide VirtualCom with a more cost-effective method of attracting new customers rather than using banner advertising or keyword sponsoring. This is because an affiliation system is used to pay affiliates only when they actually *deliver* new fee-paying members, whereas banner advertising and keyword sponsoring costs VirtualCom the same amount regardless of how many visitors actually convert into paying customers.

Once the initial analyses phase has been conducted, the next phases of the system's development lifecycle can commence. This will start with the logical and physical design of the system, defining what will be outsourced to external vendors and what will be developed in-house.

FUTURE TRENDS

Organizations will continue to develop their online e-business capabilities. It will not be sufficient to merely maintain existing technologies, applications, and business models. It will be necessary to continually assess changing customer requirements and competitor performance against incumbent practices and systems. It will therefore require business development managers to use a planning and analysis framework that has the capability of capturing the planned business vision and standard operating procedures, which can then be deployed down into technical requirements that are understandable to information systems designers.

The speed of change will accelerate in the future, technological solutions will become more proliferated, and inter and intra business connectivity requirements will become increasingly more important. As the emergence of mobile devices for customers and employees becomes more profound, and radio frequency identification (RFID) is increasingly applied to product and inventory management systems, it will add yet another level of complexity to e-business planning.

CONCLUSION

In conclusion this article draws together three well-established management and design tools into an integrated planning and analysis framework (referred to as E-PAF) to help develop e-business capability maturity levels. None of these tools alone meet these needs, but together they have proved to be very successful. Hundreds of examples have been produced in a combination of industrial projects, consultation and research assignments, and in academic teaching scenarios.

The outlined case given here has been taken from a practical project conducted with a new company in the service industry. It formed the analysis phase of a standard systems development approach. The E-PAF has also been applied successfully in the manufacturing sector, and has demonstrated itself effective in both large and small organizations in many countries. A suggestion of the possible outcomes is indicated by this case study.

KEY TERMS

Balanced ScoreCard (BSC): A tool for developing "measures", "objectives", "targets", and "initiatives" for "financial", "customer", "internal process", and "learning and growth" categories derived from the overall company vision statement.

E-Business Planning and Analysis Framework (E-PAF): A combination of QFD, VCA, and BSC that supports strategic e-business initiatives.

E-Capabilities: The abilities that an organization is able to leverage off in order to deliver online products and services. These are often described in terms of their "maturity levels".

E-Capability Maturity Level: The conceptual model describing how advanced an organization is in the adoption of Internet-based solutions that support their strategy and operations. The levels range from "low" (little adoption) to "high" (sophisticated levels of adoption).

Location-Based Service (LBS): A service that uses a mobile device and a location-specific transmission, usually within a relatively small personal area network (PAN).

Online Service: The provision of an intangible value-adding activity using Internet-based technology.

Quality Function Deployment (QFD): A tool for converting user requirements into functional requirements that facilitates trade-off analysis, benchmarking, and deployment of requirements from a high level down to a detailed specification. It attempts to build-in quality from the initial stages of any systems development project.

Systems Development Lifecycle: A logical and iterative sequence of activities that highlight the phases of any development project. These phases typically include analysis, logical design, physical design, test, measurement and implementation, and maintenance, and are often performed as concurrently as possible.

Value Chain Analysis (VCA): A tool for mapping business processes that are either primary to the business operations or serve as support processes. Variants of the model are produced for service and manufacturing sectors.

E–Business Process Management and IT Governance

Pallab Saha
National University of Singapore, Singapore

INTRODUCTION

E-business process management (e-BPM) entails management of e-business processes with the customer initiating the process and involves non-linear processes with strong focus on value networks leveraging collaboration and alliances, rather than just business processes within the confines of the organization (Kim & Ramkaran, 2004). E-BPM requires organizations to take a process approach to managing their e-business processes (Smith & Fingar, 2003). The advent of business process reengineering (BPR) (Davenport, 1993; Hammer & Champy, 1993) resulted in numerous organizations initiating BPR programs. While BPR aims to enhance an organization's process capability by adopting engineering discipline, e-BPM goes a step further and targets to improve the organizational process management capability (Smith & Fingar, 2004).

Organizations target end-to-end business processes that deliver maximum customer value through e-BPM (Smith & Fingar, 2003). However, by their very nature, end-to-end business processes more often than not span multiple enterprises incorporating their individual value chains (Porter, 1985; Smith & Fingar, 2003; Smith, Neal, Ferrara, & Hayden, 2002) and involve e-business processes (Kim & Ramkaran, 2004). Integrating fragments of processes across multiple functions and organizations not only involves shared activities and tasks among business and trading partners, but also the capability to integrate disparate IT systems (Kalakota & Robinson, 2003). Effective management of e-business processes depends to a great extent on the enabling information technologies. In fact, Smith and Fingar in 2003 have stated that BPM is about technology. Porter's value chain is about end-to-end business processes needed to get from a customer order to the delivery of the final product or service (Porter, 1985).

The pervasive use of technology has created a critical dependency on IT that demands for a specific focus on governance of IT (Grembergen, 2004). Explicitly or implicitly, organizations specify business activities as business processes, and without realizing these tend to be e-business processes. However, given the current business conditions and a clear understanding by organizations about the complexities of their e-business processes, management of e-business processes is taking center stage (Smith et al., 2002). In the current business scenario where e-business processes, along with information are considered key organizational assets and management of business processes a strategic capability (Kalakota & Robinson, 2003), it is imperative that organizations clearly delineate the need for relevant and pertinent information as it provides visibility and transparency. Additionally, IT being the single most important predictor of the business value of IT (Weill & Ross, 2004) drives the need to analyze and understand the implications of e-BPM on IT governance.

The key objective of this article is to investigate the implications of e-BPM on IT governance through the analysis of available literature. In particular, the article argues that a direct influence of e-BPM on IT governance performance is inevitable. While the importance of both effective e-BPM and IT governance is intuitively clear, there is currently little research on elements of IT governance that get enabled by e-BPM. More importantly, there is the lack of a theoretical framework that could be used to analyze. To address this shortcoming, the article also presents an analysis framework. The analysis framework is particularly useful as it incorporates elements from prevalent IT governance frameworks. Using the analysis framework, the article then examines the implications of e-BPM on IT governance and develops research propositions. The aim of developing the propositions is to enable further investigation and research thereby contributing to IT management theory.

BACKGROUND

E-BPM and Its Current State of Adoption

E-BPM views business processes from an end-to-end perspective (Smith & Fingar, 2003). Successful e-BPM adoption views end-to-end processes as a crucial element as these possess characteristics that make their management imperative and technology has not been able to cope with the reality to such processes (Smith et al., 2002).

According a survey conducted by the *BPM Institute*, the three most critical factors that enable organizations to gain the highest return on BPM initiatives are (BPM Institute, 2004):

- Identification of high value e-business processes in areas such as compliance and regulatory requirements, risk management, customer-facing services and supply chain operations.
- Developing metrics to achieve measurable, quantifiable results through improvements in operational efficiency, process visibility and control and business agility (Weill, Subramani, & Broadbent, 2002).
- Establishment of long-term goals to evolve from process improvement to process excellence.

It is obvious that organizations to be effective in addressing all the three critical factors mentioned above must have a high level of e-process management capability. In order to enhance their e-process management capability organizations must address it from dimensions that include the levers that have the ability to make the capability change happen and the capability levels itself (Fisher, 2004).

IT Governance

Firms manage their key assets that typically include—human assets, physical assets, financial assets, intellectual property assets, relationship assets, and information/information technology assets. Maturity across the governance of the key assets varies significantly with financial and physical assets typically best governed and information assets among the worst (Weill & Ross, 2004). IT implementations to make these happen require both large upfront and ongoing investments. Changing business needs and to some extent changing technologies necessitates this (Weill & Ross, 2004). Organizations must get acceptable value from their investments in IT. Top performing organizations generate returns on their IT investments up to 40% more than their competitors (Weill & Broadbent, 1998). Effective IT governance is the single most important predictor of the value (Weill, 2004; Weill & Ross, 2004).

Developing an Analytical Framework

Two IT governance frameworks (i.e., the COBIT Framework of the IT Governance Institute (ITGI) and the IT Governance Design Framework specified by the MIT Sloan's Center for Information Systems Research (CISR)) are considered for analyzing the implications of e-BPM on IT governance.

The CISR IT Governance Design Framework (Weill & Ross, 2004) takes a two-dimensional stakeholder approach to IT governance. It considers IT as one the six key assets needing governance as part of overall corporate governance. The IT Governance Design Framework addresses critical issues along two dimensions presented as the Governance Arrangement Matrix (Weill 2004; Weill & Ross, 2004):

- **Decision Categories:** Major categories of decisions that organizations must make in order to ensure effective management and use of IT. These are: (1) IT principles, (2) IT architecture, (3) IT infrastructure, (4) Business application needs and 5) IT investment and prioritization.
- **Governance Archetypes:** Structures and stakeholders for specifying decision rights; the framework identifies six archetypes for various decisions. These are: (1) business monarchy, (2) IT monarchy, (3) feudal, (4) federal, (5) duopoly, and (6) anarchy.

ITGI's COBIT Framework (IT Governance Institute, 2000a) takes a one-dimensional control oriented approach to IT governance (IT governance Institute, 2000a). COBIT is a business process oriented and therefore addresses itself in the first place to the owners of these processes. This approach stems from the fact that the process owners are responsible for the performance of their processes, where IT is an integral part (IT Governance Institute, 2000b). The COBIT framework provides a set of 34 high-level control objectives, one for each of the IT processes, categorized into four domains: (1) planning and organization, (2) acquisition and implementation, (3) delivery and support, and (4) monitoring.

Additionally, the COBIT Framework provides management guidelines that are action oriented and generic management directions for controlling the enterprise's information processes, for tracking organizational goals, for IT process performance monitoring and for benchmarking organizational achievements (IT Governance Institute, 2000b) through the (1) IT governance maturity model to assess and benchmark IT governance capabilities and maturity, (2) critical success factors that specify the most critical implementation guidelines to achieve control over IT processes, (3) key goal indicators that determine whether an IT process has achieved its business requirements, and (4) key performance indicators that indicate how well an IT process is performing and whether it is on target to achieve its business goals. Deeper analyses of both frameworks reveal similar underlying issues. Presented below is a proposed mapping between the two frameworks and the underlying commonalities are amply evident.

- **IT Principles:** Focuses on high-level statements on how IT is used and maps to PO1, PO3, PO4, PO6, and PO7 of the COBIT Framework.
- **IT Architecture:** Focuses on the organization logic for data, applications and infrastructure captured in a set of policies, relationships and technical choices to achieve desired business and technical standardization and integration and broadly maps to PO2, PO3, PO4, PO10, PO11, DS5, and DS11 of the COBIT Framework.
- **IT Infrastructure:** Focuses on coordination between shared IT services that provide the foundation for the enterprise IT capability and maps to AI1, AI2, AI3, AI4, AI5, AI6, DS1, DS2, DS3, DS4, DS5, DS7, DS8, DS9, DS10, DS12, and DS13 of the COBIT Framework.
- **Business Applications Needs:** Specifies the business need for purchased or internally developed IT applications and maps to PO6 and PO8 of the COBIT Framework.
- **IT Investment:** Focuses on decisions about the how much and where to invest and maps to PO5, PO9, PO10, PO11, and DS6 of the COBIT Framework.

This article analyzes the implications of BPM on IT governance by anchoring it around the above discussed governance frameworks. This approach provides three advantages.

1. The governance frameworks, though different in approaches, provide a fairly clear, stable and solid specification covering *what*, *how*, and *why* of IT governance. This enhances the probability of the analysis to have the necessary rigor.
2. The governance frameworks are based on corporate best practices (IT Governance Institute, 2000a; Weill & Ross, 2004), thereby making the analysis practical and pragmatic.
3. To some extent the differences between the governance frameworks can be bridged through identification of underlying commonalities during the analysis.

Emerging Research Propositions

The COBIT Framework clearly mentions that the 34 high-level IT processes and control objectives are primarily meant for business process owners to get relevant and pertinent information about their core e-business processes (IT Governance Institute, 2000a). Hence, the business process owners are the key stakeholders in governing IT, and that information about core e-business processes is key to managing IT (IT Governance Institute, 2000b). On the other hand, the CISR Framework identifies multiple stakeholders and groups them into six archetypes (Weill & Ross, 2004). Among the archetypes, *Federal* and *Duopoly* forms mention business process owners. E-BPM by definition is for business process owners managing their core business processes (Fingar & Smith, 2003; Smith et al., 2002). Hence the research proposition is:

Proposition 1: Organizations adopting e-BPM are more likely to favor either federal or duopoly governance structures.

Empirical evidence has revealed that most common archetype is either *Federal* or *Duopoly* (Weill & Ross, 2004). While the positive linkage between e-BPM and federal archetype has been discussed above, it is to be noted the successful e-BPM adoption and implementation depends a great deal on deploying BPM Systems (Delphi BPM Market Milestone Report, 2003; Smith et al., 2002; Smith & Fingar, 2004). This drives the need for considerable involvement of the IT group within the organization to assess, select, deploy and maintain complex BPM Systems. Hence the research proposition is:

Proposition 2: Adopting e-BPM is likely to encourage desirable governing structures thereby positively influencing IT governance performance.

In the wake of Enron, WorldCom, and Tyco episodes, there has been a renewed interest in corporate governance. This has given rise to increased compliance and regulatory requirements like the Sarbanes-Oxley Act (Moeller, 2004) and BASEL II (Chorfas, 2004). A McKinsey study found that investors are willing to pay large premiums for investments in firms with good governance standards. The Organization for Economic Co-operation and Development (OECD) has published in 2004 the "OECD Principles for Corporate Governance" to help organizations adopt best practices (OECD, 2004). Corporate governance is primarily about governance of key organizational assets, e-BPM on the other hand is about the need to govern an organization's core end-to-end business processes, a key asset (Hammer & Champy, 1993; Smith & Fingar, 2003). However, typical business processes are most likely to have elements from all other key assets. Thus governing and managing business processes, a core element in corporate governance, forces organizations to: (1) define critical and optimized business processes that provide maximum customer value, (2) specify business rules that govern the processes, (3) derive business rules from clearly defined and documented organizational policies and maintain complete traceability between them, (4) build clear accountabilities/ decision rights through enhanced process visibility, (5) define process performance measures (business measures) needed to monitor, control and improve business processes, (6) define information needs of business processes, (7) Quickly compose and execute newer processes to meet customer requirements, and (8) benchmark processes against accepted/derived standards. Hence the research proposition is:

Proposition 3: Organizations adopting e-BPM are more likely to have effective corporate governance practices.

Organizations expect good process management systems to have the capability to quickly compose e-business processes that deliver customer value by allowing them to take advantage of emerging business opportunities through agile practices (Kalakota & Robinson, 2003; Sadiq & Racca, 2003). However, in most occasions, fragments of such end-to-end (composite) business processes reside in multiple disparate IT applications and systems (Sadiq & Racca, 2003). Creating composite e-processes requires BPM systems the ability to integrate disparate IT applications in a seamless manner (Sandoe, Corbitt, & Boykin, 2001). Process owners in specifying such composite e-business processes must be fully aware of the business intent and IT capabilities required to fulfill the intent (Kalakota & Robinson, 2003). This results in closer business-IT alignment (Henderson & Venkatraman, 1993). Hence the research propositions are:

Proposition 4a: Using BPM systems to enable process driven integration of disparate IT systems and applications is more likely to result in clearer IT principles.

Proposition 4b: Specifying composite e-business processes through BPM systems is likely to result in sound expression of business application needs.

Proposition 4c: Organizations with effective process management capabilities are likely to make better decisions regarding IT infrastructure.

The Open Group Architecture Framework Version 8.1 Enterprise Edition (TOGAF) groups different aspects of Enterprise Architecture into four categories. These are business process architecture, applications architecture, data architecture and technology architecture (The Open Group, 2003). As a guideline in its Architecture Development Methodology, TOGAF recommends organizations to develop their business process architecture prior to specifying the remaining three architectures (The Open Group, 2003; Zachman 1999). This is because of the fact that data, applications and technology architectures are all driven by an organization's process architecture (Bernus, Nemes, & Schmidt, 2003; Perks & Beveridge, 2003). E-BPM fundamentally involves defining the Business Process Architecture, preferably taking advantage of industry specific and publicly available process frameworks like the supply chain operations reference (SCOR) model and the Enhanced Telecom Operations Map (eTOM) to enhance process visibility and transparency and managing those processes in a continuous manner (Poirier, Ferrara, Hayden, & Neal, 2004; Smith & Fingar, 2003). Hence the research proposition is:

Proposition 5: Organizations adopting e-BPM are likely to make better decisions regarding their IT architectures resulting in overall robust enterprise architecture.

Organizations struggle in finding suitable mechanisms that would fit their requirements and culture (Grembergen, De Haes, & Guldentops, 2004; Weill & Broadbent, 2004). Generally, organizations use a multitude of governance mechanisms. Research has evidenced that certain governance mechanisms work better with certain governance structures. Hence, decisions to choose a certain set of governance mechanisms also depends on the structures organizations prefer (Weill & Ross, 2004). Besides, one of the key leadership principles for effective IT governance is implementing common governance mechanisms across the six key assets (Weill & Ross, 2004). E-BPM demands clear policies, unambiguous rules, exception handling, optimized processes, focus on customer value, clear accountabilities, visibility and transparency, measurement orientation, and agility (Smith & Fingar, 2003). Hence the research proposition is:

Proposition 6a: Organizations adopting e-BPM are likely to find their IT governance mechanisms more effective and impacting.

Proposition 6b: Adoption of e-BPM in organizations is likely to facilitate and encourage implementation of common governance mechanisms.

While several organizations are now starting to adopt e-BPM, there are several areas of differences in adoption (Delphi BPM Market Milestone Report, 2003; BPM Institute, 2004). Some of these include: (1) the fundamental reasons for adopting e-BPM, (2) the extent of adoption (i.e., the kinds of business processes impacted, (3) process governance practices, (4) the extent to which BPM Systems are part of the overall adoption, (5) groups within the organization that are driving adoption, (6) the complexity of the e-business processes, (7) role of BPM deployments, (8) extent and complexity of systems integration desired, (9) extraction and abstraction of business rules, and (10) benefits anticipated and sought. With BPM organizations aim to move from their "as-is process management capability" to "to-be process management capability" (Smith & Fingar, 2004). Hence organizations adopting BPM assess their "as-is" and "to-be" BPM Maturity based on a specified BPM Maturity Model (Fisher, 2004; Smith & Fingar, 2004). Through the earlier research propositions the paper argued that, in general good process management capabilities positively influences IT governance performance. Further, effective IT governance is the single most important predictor of business value of IT (Weill & Ross, 2004). Hence the overall research propositions are:

Proposition 7a: Organizations with higher process management maturity levels are likely to exhibit higher IT governance maturity levels.

Proposition 7b: Organizations adopting process management are likely to have more effective IT governance practices, thereby leading to higher business value of IT.

FUTURE RESEARCH

It is suggested that research propositions in this article based on theory and exploration be verified with empirical studies. Specifically, there are at least three areas of theoretical and empirical studies that seem particularly plausible. These are:

1. Investigating the propositions in a larger field study to validate whether these propositions are applicable and whether they can be generalized for theory advancement and development.
2. Investigating the differences in process management maturity and its impact on IT governance issues like decision categories, archetypes, governance mechanisms and their impact of IT governance performance, including disadvantages and associated risks, as propositions reflect general statements. Such studies should preferably be longitudinal in nature in order to capture the long-term impacts in differing business, market and technology scenarios.
3. Development of a generic IT governance design framework along with an implementation toolkit that harmonizes e-BPM with IT governance.

CONCLUSION

The impact of e-BPM on various aspects of IT governance was examined and presented as research propositions for further exploratory research. Increasingly being faced with the phenomenon of "productivity paradox" (Brynjolfsson, 1993), and organizations struggling to justify IT investments, governance of IT assumes a critical role in this scenario. However, the first step in having a formal IT governance program and freely using it to improve the IT function and overall business performance is the recognition that information and IT are key organizational assets that need to be closely governed and skillfully managed along with five other key assets. Business process orientation provides one of the approaches to elevate the status and criticality of information and IT to an organization. The harmonization of business processes and IT is natural and logical in most enterprises because cross functional and cross enterprise composite business processes are e-business processes and depend on information flows that transcend organizational boundaries and need to be supported by the IT infrastructure. The paper discussed the implications of e-BPM on IT governance in detail and generally argued that it positively influences IT governance performance and helps organizations to extract more business value from their IT investments. The analysis also proved to be useful in briefly comparing and contrasting two prevalent IT governance frameworks. The underlying theories in these frameworks allowed deriving several research propositions.

While the overall positive influence of e-BPM on IT governance were presented and argued, it is also important to discuss and elaborate the consequences of taking this approach. Firstly, as discussed in propositions 2a and 2b, BPM is likely to favor certain archetypes and decision mechanisms for IT governance. An organization on the other hand may not be prepared for such a shift given its current culture, political environment and business needs. Hence managers need to assess this aspect very closely. Secondly, of late many organizations are using outsourcing of IT capability as a management strategy, sometimes successfully. Organizations typically outsource commodity IT services and perhaps co-source other services. Outsourcing as a quick fix motivated by frustrations with IT is a symptom of problems in IT governance. Managers in such organization (which seem to be increasing) need to carefully evaluate the role IT plays in an organizational context and then seek to address IT governance issues.

KEY TERMS

COBIT: The COBIT (**C**ontrol **OB**jectives for **I**nformation and related **T**echnologies) is an IT Governance Framework specified by the IT Governance Institute. The COBIT model describes the "control objectives" for 34 IT processes and the management guidelines, implementation guidelines and outcome measures for the processes.

Governance Archetype: Archetypes typically involve various stakeholder constituencies and their decision rights within the purview of IT governance.

Governance Decisions: These represent the most crucial domains of IT decisions that are key to good IT governance, and includes IT principles, IT architecture, IT infrastructure, Business application needs and IT investment management.

Governance Mechanism: These are approaches adopted by organizations to implement and institutionalize governance structures and practices.

IT Governance: The decision rights and accountability framework to encourage desirable behaviors in the use of IT (Weill & Ross, 2004). The locus of enterprise decision-making authority for core IT activities (Sambamurthy & Zmud, 2000).

IT Governance Maturity Model: This is part of the COBIT management guidelines and is a five stage maturity model of IT governance and a series of tool kits, audit guidelines and implementation guidelines. The levels ranging from "non-existent" to "optimized" represent progressively higher degree of effective governance practices and processes.

E-Commerce Agents and Payment Systems

Sheng-Uei Guan
National University of Singapore, Singapore

INTRODUCTION

An emerging outcome of the popularization of the Internet is the electronic commerce and payment systems, which present great opportunities for businesses, reduce transaction costs, and provide faster transaction time. Research has been conducted with new technologies, like mobile Internet used by business models (Baek & Hong, 2003). However, before using the Internet, it is essential to provide security in transferring monetary value over the Internet. Quite a number of protocols have been proposed for these secure payment systems, including NetBill, NetCheque, Open Market, iKP, Millicent, SET (Sherift & Serhrouchni, 1998), E-Cash (Brands, 1995), NetCash, CAFÉ (Mjolsnes & Michelson, 1997), EMV cards (Khu-Smith & Mitchell, 2002), and so forth. These systems are designed to meet diverse requirements, each with particular attributes.

Automation and intelligence is another issue that poses challenges in the development of e-commerce. Agent technology has been incorporated into the area of e-commerce to provide automation and intelligence for the e-trade process. Agent is a software program, which is capable of accomplishing tasks autonomously on behalf of its user. Agents must provide highly trustworthy consistency and fault tolerance to avoid eavesdropping and fraud. Also, they should have roaming capability so as to extend their capabilities well beyond the limitations of owners' computers. This article will discuss some related components under the Secure Agent Fabrication, Evolution, and Roaming (SAFER) architecture (Guan & Hua, 2003; Guan & Yang, 2004; Guan & Zhu, 2002; Ng, Guan, & Zhu, 2002; Zhu, Guan, Yang, & Ko, 2000) and propose an agent-based payment scheme for SAFER.

Different types of electronic payment systems have been developed to meet their diverse requirements, which generally include integrity, authorization, confidentiality, availability, and reliability for security requirements (Asokan & Johnson, 1997). Payment systems can be classified in a variety of ways according to their characteristics (Dahab & Ferreira, 1998), such as the exchange model (cash like, check like or hybrid), central authority contact (online or offline), hardware requirements (specific or general), payment amount (micropayment), and so forth.

Among all the available payment schemes in the market, e-cash is one of the best in terms of security, flexibility, and full anonymity. E-cash is a cash-like online system that uses electronic coins as tokens. E-cash has its unique advantages, such as flexibility, integrity, and full anonymity that cannot be found in electronic check and credit card-based systems. It uses cryptographic techniques to provide full anonymity. The agent based payment scheme for SAFER adopts some similar principles and concepts of e-cash.

Software Agents in E-Commerce

Attributes of Agent-Based Systems for Electronic Commerce

Agents are bits of software performing routine tasks, typically in the background, on behalf of the user. Gathering, filtering, and presenting information are some of the small and well-defined tasks given to simple agents. An agent distinguishes itself from any other software by its intelligence. Intelligent agents are capable of "thinking" and producing intelligent feedback (Guan & Yang, 1999; Guan, Zhu, & Maung, 2004). Agents are increasing in the degree and sophistication of automation, on both the buyer's and the seller's sides, commerce becomes much more dynamic, personalized, and context sensitive. These changes can be beneficial to both the buyers and sellers (He, Jennings, & Leung, 2003).

The requirement for continuity and autonomy derives from the desire that an agent be able to carry out activities in a manner that is responsive to changes in the environment, without requiring constant human guidance or intervention. According to (Bradshaw, 1997), agents have the following attributes, as shown in Table 1.

There are several software agent prototypes under development, which will be capable of doing even more on behalf of buyers and sellers. One is Kasbah, wherein agents would proactively seek out potential sellers and negotiate with them on the buyer's behalf, making the best possible deal, based on a set of constraints specified by the buyer, including the highest acceptable price and a transaction completion date. (Chavz & Maes, 1996). A disadvantage of this software agent is that it always accepts the first offer that can meet its asking price, when

Table 1. Attributes of software agents

Attribute	Description
Reactivity	The ability to selectively sense an act
Autonomy	Goal-directness, proactive, and self-starting behavior
Collaborative behavior	Can work in concert with other agents to achieve a common goal
Communication ability	The ability to communicate with persons and other agents
Personality	The capability of manifesting the attributes of a believable character such as emotion
Temporal continuity	Persistence of identity and state over long periods of time
Adaptivity	Being able to learn and improve with experience
Mobility	Being able to migrate in a self-directed way from one host platform to another

there might be even better offers. This disadvantage is resolved by AuctionBot, which is a general-purpose Internet auction server. *AGENTics* is another agent prototype, which develops what is referred to as "*online catalog integration for e-commerce*." AGENTics products shield the user from the technicalities of "where" and "how" the information was gathered, while synthesizing many information pieces into a coherent whole (Mougayar, 1997). Some agents can select desired items based on preferences, search databases to look for selected pieces of information, and conduct transactions. An example of such adaptive agent is the SAFER architecture for e-commerce.

SAFER is a Web-based distributed infrastructure to serve agents to query, buy, and sell goods in e-commerce and establishes necessary mechanisms to transport, manufacture, and evolve all different types of agents. The goal of SAFER is to construct open, dynamic, and evolutionary agent systems for e-commerce (Zhu & Guan, 2000). There will be SAFER-compliant and noncompliant communities coexisting in the whole e-commerce network. Each SAFER community consists of several mandatory components: owner, butler, agent, agent factory, community administration center, agent charger, agent immigration, clearinghouse, and bank. Agent community is the basic unit in SAFER e-commerce, which offers virtual regions and vehicles to host and administrate mobile agents during roaming, transaction, and evolution. An owner is in charge of all his or her agents, and making respective authorizations to mobile agents and his or her agent butler, which is a 24-hour online watcher who would handle most of the tasks on behalf of the owner. When agents are sent out roaming in the network, the butler has the responsibility of keeping track of agents activities and locations by sending and receiving messages with agents. At least one financial institution, usually a bank, which can link all value-representation to real money, must also be involved. The payment scheme designed for SAFER is expected to fulfill flexibility and interoperability, which means diverse representations of value will have the possibility to emerge in one framework for users' convenience. Given that, it is important that funds represented by one mechanism be easily converted into funds represented by others (Neuman & Medvinsky, 1995).

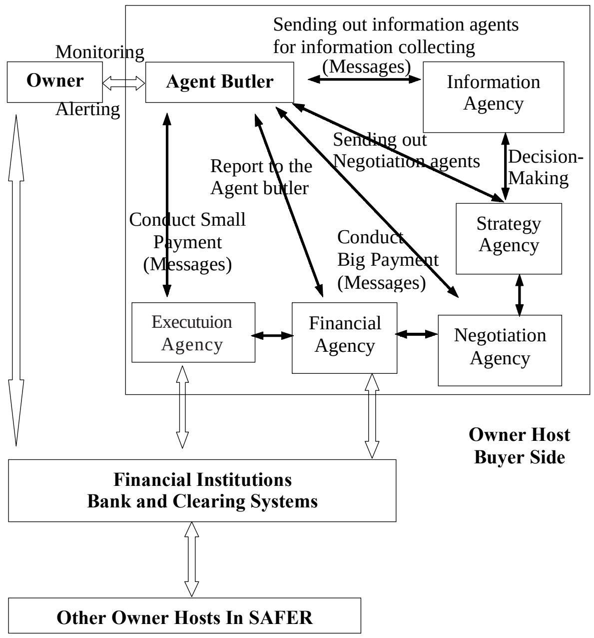
DESCRIPTION OF E-PAYMENT SCHEME

The payment module in the agent-mediated SAFER e-commerce architecture must contain several essential components: the market place, agents (including mobile agents, static agents, and agent butlers), financial institutions, and users. In SAFER, a community will offer virtual regions, factories, administration tools, vehicles to manipulate and administrate mobile agents during any activity and provide security so that users can trust it. Different types of agents fabricated by an agent factory of SAFER are running under the payment scheme for respective functions and tasks. They are briefly described in Figure 1.

In this scheme, a subsystem called "agency" is mentioned. Similar to the definition given by Dr. Larry Kerschberg in his DPSC project (Kerschberg & Banerjee, 1997), an agency can be thought as a multilayered agent group or a federation of agents with specific goal and functional role in the architecture. It is also like a collection of cooperating intelligent agents with particular expertise.

If the owner is interested in some items, he will assign tasks to his or her butler and agents. The agent butler will then send out information agents from agency, taking

Figure 1. Cooperating agents for the SAFER payment scheme



note of the items of interest, and set parameters such as due date (by which the item should be purchased), desired price, and highest acceptable price. The information agents used to sift, filter, and process information will roam in SAFER or even non-SAFER communities under a certain transport protocol, which is explained in the paper (Guan & Yang, 1999).

It can help with dozens of purchasing decisions and thus lower the cost and gain great efficiency. While roaming, agents are well tracked by the agent butler, by sending messages to report their activities and locations, which is described in detail in Zhu, Guan, and Ko (2000). After gathering enough information, the information agent forward all to the strategy agency, which will analyze the new data and settle down for decision for the user. All the recommendations will be reported to the agent butler in the first hand. Once a recommendation has been reported, the agent butler activates the negotiation agency, which will send out negotiation agents to the shortlist merchant hosts. Negotiation is defined as follows: “negotiation is the communication process of a group of agents in order to reach a mutually accepted agreement on some matter” (Green, 1997, p. 21). If the negotiation agent and the receptionist agent reach an agreement, the result will be reported to the butler in the first hand. The butler will inform the financial agency to initiate the contract for certain goods and make a transaction decision, according to the amount of money involved, the distance from host to the destination vendor, and so forth. Financial agents will take charge of the goods reception and payment transaction under the authorization of the butler. They communicate with the merchant host, autonomously make payment request, and sign contract order against the right good.

Implementation

The implementation of SAFER is under way. The overall architecture consists of several closely related but separate modules: roaming module, evolution module, fabrication module, negotiation module, and electronic payment module.

The implementation of the payment module began with the development of the agent butler, which is defined as a combination of several separate functions, as is shown in Figure 2. They are authorization manager, e-payment coordinator, transport assistant, heartbeat monitor, agent tracer, and evolution coordinator.

In the e-payment coordinator module, communication channels are set up between agent butler and all agencies of diverse functionalities, each of which is running in a separate thread. User interfaces are designed so that the user can assign tasks, define needs and requirements, check records, and read alerting messages reported by his or her agent butler.

Figure 2. Prototype of agent butler

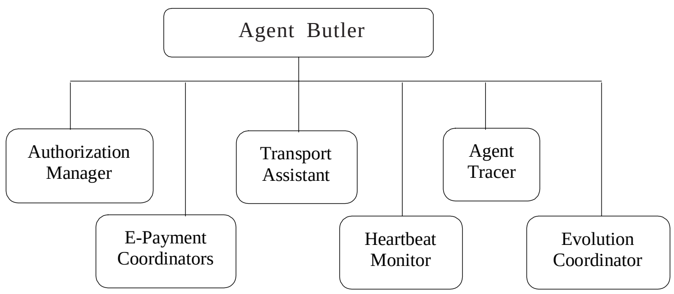


Figure 3. Payment coordinator

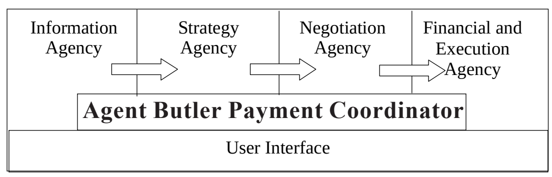

Making all types of agents and merchant hosts available to fit in the same framework will be difficult in the current research stage, because the attributes that agents require to communicate may differ. Given that, we have chosen to implement a limited number of typical agents to test the system functionality, and will consider how the work could be generalized to e-commerce in the future.

IMPACT OF SAFER-BASED PAYMENT SYSTEMS

The payment system proposed in this chapter is agent based and built for the SAFER e-commerce architecture. As such, in compliance with the SAFER architecture, this system provides a flexible and secure financial infrastructure for Internet commerce. The payment module contains several essential components to manipulate and administer the mobile agents while providing security to the users.

CONCLUSION

The agent-based SAFER e-commerce payment scheme incorporated agent technologies and took advantage of some well-known secure payment transaction protocols. It aims to simulate and even enhance physical cash and is designed to support a multitude of currency types. By incorporating the concepts of agent, the system is expected to provide security, efficiency, flexibility, autonomy, and intelligence. It is designed to provide anonymity against other parties, and audit ability (traceability) for the owner (or agent butler). At last, a number of potential improvements, practical aspects, and some open issues have been identified for future work.

KEY TERMS

Adaptability: The ease with which software satisfies differing system constraints and user needs.

Agents: A piece of software that acts to accomplish tasks on behalf of its user.

Anonymity: The degree to which a software system or component allows for or supports anonymous transactions.

Client: In this article, "client" refers to customers who pay for good and services.

Confidentiality: The nonoccurrence of the unauthorized disclosure of information.

Cryptography: The art of protecting information by transforming it (*encrypting* it) into an unreadable format, called cipher text. Only those who possess a secret *key* can decipher (or *decrypt*) the message into plain text.

Flexibility: The ease with which a system or component can be modified for use in applications or environments other than those for which it was specifically designed.

E-Commerce and Mobile Commerce Applications Adoptions

Charlie Chen
Appalachian State University, USA

Samuel C. Yang
California State University, Fullerton, USA

INTRODUCTION

E-commerce applications are primarily used at home and in the workplace. Utilitarian elements, including cognitive beliefs of perceived usefulness, perceived ease of use (at the individual level), industry pressure, organizational readiness, economics, and trust (at the business level) are key determinants contributing to the usage of e-commerce applications. Mobile devices redefine the meaning of workplace. The use of mobile services could be in and outside the workplace. Hedonic elements, such as fun, culture, life style, and hype are key determinants contributing to the usage of mobile commerce applications. The purpose of our article is to discuss and clarify immediate determinants of e-commerce and mobile commerce applications based on the technology acceptance model.

BACKGROUND

A joint study by eMarketer and Forrester (2005) estimates that business-to-customer (B2C) revenues in the U.S. will reach $229.9 billion by 2008 and business-to-business (B2B) revenue will reach $8.8 trillion in 2005. According to the Computer Industry Almanac (ClickZ Stats, 2005), by 2007 the number of Internet users will grow to 1.46 billion worldwide with the U.S. market representing only about 20% of worldwide Internet users. It is clear that e-commerce (EC) is becoming a global transactional forum.

Along with the dominance of EC comes an increased demand for mobile commerce (MC). The total number of mobile telephone subscribers in the world grew to 1.34 billion in 2003 from 317 million in 1998 (International Telecommunication Union, 2003). More than half of Americans (158 million) were mobile telephone subscribers in the United States. Unlike EC, only a very limited number of MC applications are making profit (Beck & Wade, 2002). The difference in the adoption pattern of EC and MC prompts practical reasons as well as research motives to investigate what drive consumers to purchase or use a particular EC and MC application.

The goals of adoption of EC and MC applications can be grouped into two broad categories: utilitarian (productivity-oriented) and hedonic (pleasure-oriented). *Utilitarian* elements are those determinants of productivity and usefulness that should be considered by a rational user or company before deciding to adopt a particular EC or MC application. For instance, an individual uses e-banking and online job search engine to improve personal productivity. A company adopts e-marketplace or Internet EDI applications to improve operational efficiency, reduce cost, and increase customer services. *Hedonic* elements are those determinants that are associated with personal enjoyment and pleasure. (See Table 1.) A user subscribes to a gaming or dating service to meet friends who share common interests. Knowing the dichotomizing difference between utilitarian and hedonic goals can help us understand why we accept a particular EC or MC application.

E-COMMERCE AND M-COMMERCE ADOPTION

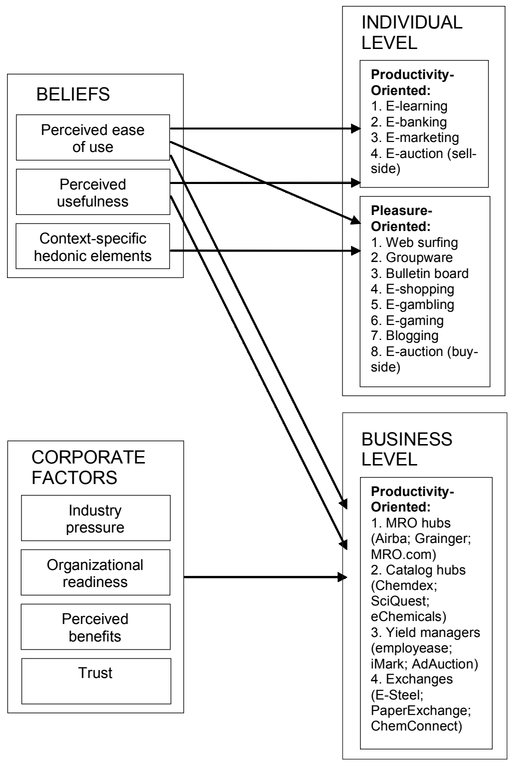
E-Commerce Adoption

Electronic commerce (EC) refers to electronic business with a broader meaning than just buying and selling on the Internet. EC is the process of transacting, transferring, or exchanging products and services over communication networks, including the Internet (Turban, King, Lee, & Viehland, 2004). Note that the underlying network may encompass different broadband (i.e., > 1 Mbps) segments such as DSL, cable modem, power line, Asynchronous Transfer Mode (ATM), and Gigabit Ethernet. Straub (2004) defined all forms of EC organizations as Net-enhanced organizations. Many EC applications are available to support the operation of Net-enhanced organizations. EC applications that are widely adopted at the individual level include e-tailing, Internet marketing, online travel services, online banking, e-grocery, online gaming, e-auction, etc. EC applications at the business level facili-

Table 1. Summary of utilitarian and hedonic factors of EC and MC adoption

	E-Commerce	M-Commerce
Utilitarian Factors (Firm)	Industry pressure, organizational readiness, perceived benefits, trust	Critical mass, perceived benefits
Utilitarian Factors (Individual)	Perceived ease of use (PEOU), perceived usefulness (PU)	Perceived ease of use (PEOU), perceived usefulness (PU), cost, perceived system quality
Hedonic Factors (Individual)	Perceived playfulness, perceived enjoyment, network size, perceived user resources	Social influence, entertainment, hype, lifestyle

Figure 1. Immediate determinants for the adoption of EC applications



tate the inter- and intra-organizational transactions over communication networks.

There are four basic types of B2B applications: sell-side market, buy-side market, many-to-many marketplaces, and collaborative commerce (Turban & King, 2003). Sell-side applications comprise of online catalog (e.g., Cisco's Connection Online service), e-auction, and online intermediary (e.g., Boeing's Part Analysis and Requirement Tracking service). Buy-side applications are primarily e-procurement management (e.g., Schlumberger's Oilfield Services), internal and external aggregation (e.g., Grainger.com and allbusiness.com), reverse auctions, and e-bartering. Many-to-many marketplaces allow many buyers and sellers to conduct transactions in an online pubic or private marketplace (e.g., epapertrade.com, mro.com, chemconnect.com, and employease.com). Collaborative commerce enables business partners to collaborate with each other by engaging in non-transactional activities.

Factors driving the adoption of EC applications can be examined at two levels of analysis: individual and business. At the individual level, both utilitarian and hedonic factors are responsible for customers' adoption of EC applications. At the business level, utilitarian factors (organizational productivity) are primarily responsible for adoption in for-profit and not-for-profit organizations (Figure 1).

Utilitarian and Hedonic Perspectives of Adopting EC Applications

The Technology Acceptance Model (TAM) (Davis, 1989) is recognized as the most robust and influential model that predicts an individual's adoption behavior of information technology (Davis, Bagozzi, & Warshaw, 1992; Venkatesh & Morris, 2000). At the individual level, the TAM provides a utilitarian perspective of EC adoption. This model asserts that perceived ease of use (PEOU) and perceived usefulness (PU) are important in forming customer attitude, satisfaction, and trust towards EC applications (Devaraj, Ming, & Kohli, 2002). Favorable attitude, satisfaction, and trust can lead to the adoption of EC applications. These two cognitive beliefs—PEOU and PU—have adequately explained the widespread adoption of personal productivity-oriented EC applications (i.e., most B2C applications).

However, the TAM is weak in explaining hedonic EC applications. Many studies extended the model to correct the weakness. For instance, along with PEOU and PU, perceived playfulness (Moon & Kim, 2001) and perceived enjoyment (Davis, Bagozzi, & Warshaw, 1992; Teo, Lim, & Lai, 1999) are immediate determinants for the adoption of the Internet. Perceived critical mass or network size is another complementary factor for the adoption of online groupware (Luo & Strong, 2000). Perceived user resources is the immediate determinant for the adoption of bulletin board system (Mathieson & Chin, 2001). Compatibility (Chen, Gillenson, & Sherrell, 2002) and intrinsic motivation of online users (Venkatesh & Morris, 2000) directly result in the adoption of virtual stores (Chen, Gillenson, & Sherrell, 2002). Social influence and flow experience are direct causes of the adoption of online activities that require the total involvement of online users, such as betting on sports events, gambling (Hsu & Lu, 2004), and shopping online.

Blogging is another prevalent online activity. The clustering of demographics (age, geography, ethnics, and lifestyle) and common interests (MTV, sports, gardening, traveling) into a network of virtual communities resulted in the mass adoption of blogging applications (Kumar, Novak, Raghavan, & Tomkins, 2004). When entertainment and fun are the goals of EC applications, the TAM alone is inadequate to predict and explain their adoption. Extending TAM by incorporating hedonic factors in different contexts can better explain the adoption behavior of hedonic EC applications.

EC applications at the business level differ from those at the individual level in the difficulty of measuring benefits, unselective release of confidential information to competitors (trust) and insufficient time to develop internal new skills (Teo & Ranganathan, 2004). Hence, there are additional factors leading to the adoption of EC applications beyond the utilitarian elements of PEOU and PU (Igbaria, Parasuraman, & Baroudi, 1996). Other corporate factors maybe as important as utilitarian factors, including industry pressure, organizational readiness, perceived strategic value (Grandon & Pearson, 2004), perceived cost, and trust.

Industry pressure originates from inter- and intra-industry competition, business partners, standards organizations, regulatory bodies, and government. These environmental factors can influence the adoption of B2B EC applications. RosettaNet (EDI for computer industry), UN/EDIFACT (EDI for commerce and transportation industry), and other XML-based EDI e-marketplaces are products of industry pressure. Industry-level compliance can lower the degree of asset specificity and uncertainty (imperfect information) but increase the number of input resources (Williamson, 1981). From the comparative institutional perspective, B2B e-marketplaces can potentially achieve three cooperative and exchange gains: (1) creating awareness of gains through joint efforts, (2) discouraging parties from bargaining their own gains, and (3) enforcing agreed-upon agreements (Hennart, 1994). Industry pressure increases existing network size and increases perceived benefits of adopting B2B EC applications. Hence, industry pressure is a direct determinant for the adoption of B2B EC applications.

The organizational readiness factor is concerned with the availability of financial and technological resources and alignment of B2B EC applications with a company's vision, values, culture, and preferred work practices (Grandon & Pearson, 2004). The varying degree of organizational readiness among business partners contribute to their difference in PEOU and PU (Iacovou, Benbasat, & Dexter, 1995).This contextual variable influences the successful adoption of B2B EC applications.

Many B2B EC applications fail to help companies realize their benefits primarily because sellers and buyers misjudge their perceived scope of benefits (Pandya & Dholakia, 2005). Primary benefits of B2B EC applications for buy-side marketplaces (e.g., GE's Global Exchange Services) include lowering purchasing price, streamlining the bidding process, and reducing requisition cycle time. Benefits of B2B EC applications for sell-side marketplaces (e.g., Intel, Cisco and Dell) range from the reduction of operation costs and cycle time, to the improvement of inventory control. Adoption of a particular B2B EC application depends on whether the application can deliver specific perceived benefits for different users of the e-marketplace.

EC applications applied to many-to-many marketplaces have different adoption issues because they requires companies to collaboratively plan, transact, design, and develop products and services. Unreliable and insecure B2B EC applications can have profound impacts on a company's operation. Trust in B2B EC can be improved from (1) organizational and economic, (2) technological, and (3) behavior perspectives (Ratnasingam & Phan, 2003). Issues about the adoption of B2B EC applications implicitly incorporate the perspective of technological trust (Ratnasingam & Pavlou, 2003). Therefore, when considering whether to adopt a B2B EC application the trust of business partners in B2B EC applications must be ensured.

Mobile Commerce Adoption

Mobile commerce (MC) is the process of buying, selling, or exchanging products and services wirelessly over mobile communication networks. MC is conducted on the Internet via mobile devices that are able to connect to the Internet via wireless application protocol (WAP) or conventional hyper-text transfer protocol (HTTP). Although most of the MC transactions take place on the Internet, MC can occur over any public or private network. The most important characteristic of MC is that products and services are made available to the customer independent of the customer's location (Turban & King, 2003). B2B MC applications include different classes, such as financial applications, inventory management, service management, product locating, business process reengineering, and data retrieval. On the other hand, B2C MC applications include classes such as financial applications, advertising, inventory and service management, product locating and shopping, auction or reverse auction, entertainment, mobile office, distance education, and data retrieval (Varshney & Vetter, 2002).

Similar to factors driving the adoption of EC, utilitarian factors heavily influence the decision to adopt EC at the business level; at the individual level, both utilitarian and hedonic factors contribute to the adoption (Coursaris & Hassanein, 2002; Haque, 2004). Note that since a wireless laptop computer essentially emulates the experience of a networked desktop computer, we will instead focus our attention on MC over handheld devices. In addition, we will place our emphasis on the consumer in our consideration of hedonic factors in adopting MC.

Utilitarian and Hedonic Perspectives of Adopting MC Applications

At the business level, one important factor is critical mass (Carroll, Howard, Peck, & Murphy, 2002), or the increased externalities of mobile devices ranging from Internet-enabled cellular phones and personal digital assistants (PDAs) to networked laptop computers. In 2002, the number of cellular phones exceeded that of fixed wireline phones on a global scale (International Telecommunication Union, 2003). In the U.S., over half of the population already carries a cellular phone. The number of network-capable mobile devices is also increasing rapidly. The growing number of MC-capable devices indicates that more service providers will be willing to develop and deploy new MC applications.

Another factor is the demonstrable benefit of adopting MC applications for businesses. With the increased diversity of data services and contents that can be delivered over wireless networks, organizations are beginning to adopt more MC applications. Many of the MC application deployments are vertical applications and aim to serve a specific company or industry need. Examples are fleet tracking, field sales force, and education. These applications typically have clearly defined goals (e.g., to streamline a specific process) and have well-defined net present value (NPV) justifications. Businesses typically develop these applications in-house or utilize content enablers and middleware.

At the individual level, both utilitarian and hedonic factors are important (Coursaris & Hassanein, 2002; Haque, 2004). Mobile voice communication is still the most successful mobile wireless application. Mobile voice is a focused application in that it concentrates a user's attention on one thing—conversation, and it is easy to use. Time and attention are more critical for mobile applications because users have a limited time span and may be distracted by their environment (Turban & King, 2003). It is clear now that PEOU is a factor that made mobile voice communication successful. PEOU is also an important factor in users' adoption of MC on modern networked handheld devices (Pagani, 2004). Another factor contributing to adoption is PU (Pagani, 2004). MC can be beneficial to the user, the benefit being that the user is able to carry out business activities, and conduct business transactions any where, any time. In addition, users are able to leverage unproductive time (e.g., during commute and travel) for productive tasks (Perry, O'Hara, Sellen, Brown, & Harper, 2001).

The third factor is the cost of using mobile devices (Haque, 2004). Accessing the Internet and checking e-mails using network-capable devices represent a lower-cost and higher-accessibility alternative to using a traditional personal computer (PC). The fourth factor is perceived system quality (Kleijnen, Wetzels, & Ruyter, 2004). Mobile devices have more limited bandwidth than their fixed counterparts, so it is important to ration the amount of information to be downloaded to the device (Treese & Stewart, 2003). In addition, network quality (e.g., unnoticed latency, jitters control and high resilience) has to be excellent so that problems arising from weak signal strength do not frustrate the users and distract them from their tasks.

Other hedonic factors such as culture, fun, hype, and lifestyle are also important to a user's decision to adopt. The widespread use of mobile devices is becoming a social phenomenon, especially among high-school and college age students. These users have grown up in a time when mobile devices are already popular. Many users in this age group will consume more MC services once they start working and will already be comfortable with making purchases and transacting via mobile devices (Turban & King, 2003). Kleijnen, Wetzels, and Ruyter (2004) cite social influence as an antecedent in adopting mobile financial applications, and Lu, Yu, Liu and Yao (2003) also suggest social influence in their proposed theoretical model as an antecedent in adopting wireless Internet.

Recent research has begun to suggest fun and hype as emerging factors in adoption. Pagani (2004) cites enjoyment as a factor after conducting an exploratory study with focus groups in six countries (i.e., Brazil, Germany, Italy, Singapore, United Kingdom, and U.S.) and a survey study of 1,000 mobile users in Italy. Haque (2004) also cites entertainment as an antecedent as a result of his survey in Malaysia. In terms of hype, consumers are constantly bombarded with images such as "…executives reclining on sun drenched beaches, cheerfully pecking away at their laptops, or strutting, like alpha males through airports checking their stock portfolios on PDAs and mobile phones" (Sherry & Salvador, 2001, p. 108). In spending millions on advertising, companies expect to have a positive impact on their sales. In fact, Pagani (2004) cites perceived innovation as a factor in the adoption of 3G mobile multimedia services, the perception of which is also affected by various innovations.

Carroll, Howard, Peck, and Murphy (2002) identified lifestyle as an antecedent in the continued use of SMS in their survey of 16 to 22 year-old mobile device users in Australia. Lifestyle is often defined as a way of life or style of living that reflects the attitudes and values of a person. It is reasonable to treat lifestyle as an important factor leading to continued use; if device use is part of a user's way of life already (e.g., communicating with friends via SMS instead of face-to-face), its continued use is facilitated.

Overall, from a hedonic perspective, "killing time" may be the "killer application." Even for mobile users that use mobile devices for utilitarian reasons (e.g., work productivity), it is reasonable to suggest they would turn to their mobile devices for entertainment when they have a few minutes in between tasks or meetings. In addition, in those parts of the world where owning a mobile device costs less than owning a desktop PC, mobile devices may be the primary source of electronic entertainment (Coursaris & Hassanein, 2002).

FUTURE TRENDS OF E-COMMERCE AND MOBILE COMMERCE APPLICATIONS

As far as EC applications are concerned, EC applications have become diversified and more sophisticated after many years of development. In the future, however, EC applications need to overcome a variety of problems which Dekleva (2000) grouped into four themes: (1) trust, (2) legal framework, (3) information infrastructure, and (4) benefits maximization. Different issues exist in each of these themes. Regarding the trust theme, privacy, security, as well as PEOU and PU of EC applications will remain to be important issues. Regarding legal framework, laws related to taxation, intellectual property protection, and payment systems will continue to evolve. Regarding information infrastructure, reliable Internet infrastructure, effective systems integration, and common industry standards will continue to be needed to support future EC applications. Lastly, regarding benefits maximization, organizations will continue to institute systems to measure benefits and costs of adopting EC applications. In addition, new EC applications will emerge to address issues present in each one of these four themes. For example, digital rights management (DRM) applications have already emerged to address the issues of trust and legal framework related to the transmission and consumption of entertainment-related contents (e.g., music and movies).

As far as MC applications are concerned, several trends are emerging in MC which can be examined in terms of the (1) mobile device, (2) network, and (3) application. Regarding the mobile device, there is clearly a trend toward the convergence of several functions into one physical device (Turban & King, 2003). For instance, the PDA/phone combination allows users to not only look up a phone number directly in the PDA and dial it, but also avoid carrying multiple devices while traveling. Furthermore, mobile devices now possess more hedonic features such as still-image camera, camcorder, and music player.

Regarding the network, wireless networks will continue to offer higher data-rate services. In wireless wide-area networks (WWANs), network operators have continued to deploy next-generation systems, such as General Packet Radio Service (GPRS) and Universal Mobile Telephone Service (UMTS). GPRS, which is based on a packet-switched core network, offers data rates of between 50 and 60 kbps. UMTS, which has both a packet-switched core network and an enhanced air interface, provides a higher data rate of at least 384 kbps. In wireless local-area networks (WLANs), wireless hot spots have continued to proliferate, covering hotels, airports, convention centers, and coffee shops. These networks, although nowhere near ubiquitous, offer stationary users much higher data rates ranging from 11 Mbps (peak for 802.11b) to 54 Mbps (peak for 802.11g and 802.11a). These higher-speed mobile networks can enable those applications that traditionally have been run on desktop PCs, such as e-mailing large attachments and distance learning (Varshney & Vetter, 2002).

Regarding the application, the increased data rates and more coverage areas will enable new kinds of MC applications to emerge. Many of these applications will target the hedonic elements of MC. We have already seen that mobile entertainment is one factor contributing to the success of I-Mode service in Japan. In the U.S., consumers can download full-length music titles to their phones and store them locally on the phones. In video services, mobile users in Korea routinely watch live television broadcasts streamed to their cell phones. With the advent of 3G networks, higher data rates will help improve the mobile user's gaming experience (Coursaris & Hassanein, 2002; Harmer, 2001). Furthermore, with the popularization of online blogging, many mobile users are now engaged in mobile image blogging (i.e., recording their daily activities in pictures taken by cellular phones and uploading them to a Web site).

CONCLUSION

Tim Berners-Lee, the inventor of the World Wide Web (WWW) and the director of WWW Consortium (W3C), foresees the emergence of a more open "resource description framework" (Klyne, Carroll & McBride 2004, p. 1) that can draw connections between all sorts of objects and information via wired and wireless devices. The first step towards the realization of this vision depends upon the adoption of EC and MC applications. A framework for including utilitarian and hedonic considerations to clarify reasons for the adoption of EC and MC applications by individuals and businesses is proposed in this article. EC applications at the individual level need to address both utilitarian factors of perceived usefulness and perceived ease of use, and hedonic factors of perceived enjoyment in different contexts. Immediate utilitarian determinants to the adoption of EC applications at the business level include industry pressure, organizational readiness, perceived benefits and trust. MC applications have different adoption issues to resolve. These issues can also be grouped into utilitarian and hedonic categories. Utilitarian determinants include the perceived ease of use and perceived usefulness. Hedonic determinants range from culture, fun, and hype to lifestyle.

KEY TERMS

E-Commerce: The process of transacting, transferring, or exchanging products and services over communication networks, including the Internet.

Electronic Data Interchange (EDI): The transfer of data between different companies using value-added networks, including the Internet.

M-Commerce: The process of buying, selling, or exchanging products and services wirelessly over mobile communication networks.

Perceived Ease of Use (PEOU): The degree to which a person believes that using a particular system would be free of effort (Davis, 1989, p. 320).

Perceived Enjoyment: The extent to which the activity of using the computer is perceived to be enjoyable in its own right, apart from any performance consequences that may be anticipated (Davis, Bagozzi, & Warshaw, 1992, p. 1113).

Perceived Usefulness (PU): The degree to which a person believes that using a particular system would enhance his or her job performance.

Short Message Service (SMS): The transmission of short text messages to and from mobile devices, including cellular phones and PDAs.

Technology Acceptance Model (TAM): A user-behavior theory which states that user acceptance of information technology can be explained by two beliefs: perceived usefulness and perceived ease of use.

E-Commerce Challenges and Policy Considerations in Nigeria

INTRODUCTION

Electronic commerce (or *e-commerce*) is the popular term for doing business electronically. According to Haag, Cummings, and McCubbrey (1998), for businesses, electronic commerce includes performing transactions with customers over the Internet for purposes such as home shopping, home banking, and electronic cash use; performing transactions with other organizations through the use of electronic data interchange (EDI); gathering information relating to consumer market research and competitors; and distributing information to prospective customers through interactive advertising, sales, and marketing efforts. Benefits of e-commerce to companies include a wider potential market (i.e., global access); lowering of transaction costs; increase in the speed of transactions; improved economies of scale; minimization of human intervention in business processes; and unlimited access to product information for customers (Sesan, 2000; Wood, 2003).

While a few developing countries such as Costa Rica are making inroads into electronic commerce (Travica, 2002), many others are slow in its adoption. For example, a study, which rated 42 developing countries on their "e-readiness," found that Taiwan and Estonia had emerged as leaders among developing countries in the ability to conduct e-commerce, whereas Russia, much of the Middle East, and Africa were lagging behind (Anonymous, 2000). One of the countries included in the study but that rated poorly in its e-commerce efforts is Nigeria. In this articl, we shall be discussing the challenges being faced by the country as it grapples with the adoption of e-commerce.

BACKGROUND

Electronic commerce developed as a result of synergism between two industries, namely business and information technology. In the business industry, e-commerce is viewed as a buying and selling process that is supported by electronic means (Wood, 2003) whereas in the information technology industry, it is viewed as an electronic business application aimed at commercial transactions systems. In general, there are four types of e-commerce (Rayport & Jaworski, 2001):

1. **Business to Business (B2B):** B2B refers to e-commerce that takes place between business organizations. The foundation of B2B e-commerce, according to Haag et al. (2002), is electronic data interchange (EDI). EDI is the direct computer-to-computer transfer of transactions information contained in standard business documents such as invoices and purchase orders, in a standard format. EDI replaces paper documents with digital records exchanged between trading partners' computers.
2. **Business to Consumer (B2C):** B2C involves e-commerce sites that sell products and services, or provide information services directly to consumers. B2C (or retail) e-commerce has spawned many new businesses that have no physical stores but can deliver a wide variety of goods on request (National Science Board, 2002). B2C also includes services such as banking, education, consulting, retailing, gambling, and governance (Iyer, Taube, & Raquet, 2002).
3. **Consumer to Business (C2B):** C2B is e-commerce in which the Internet makes it possible for many consumers who want to buy the same or similar products to band together in order to obtain volume discounts from a business.
4. **Consumer to Consumer (C2C):** C2C involves consumers dealing with each other, either through an auction site or directly in one of the peer to peer networking applications.

In terms of product suitability, certain products/services appear more suitable for e-commerce while others remain more suitable for offline sales. The most successful purely virtual companies deal with digital products, including information storage, retrieval, and modification, music, movies, education, communication, software, photography, and financial transactions. Virtual marketers can sell some nondigital products/services successfully. Such products have a high value-to-weight ratio, are embarrassing purchases, typically go to people in remote locations, or are typically purchased by shut-ins (Wikipedia, 2004). Purchases of pornography and of other sex-related products and services fulfill the requirements of being virtual (or if nonvirtual, generally high value) and of potential embarrassment; unsurprisingly, provision of such services has become the most profitable segment of e-commerce.

Products such as spare parts, both for consumer items like washing machines and industrial equipment like centrifugal pumps, also seem good candidates for selling online. Retailers often need to order spare parts specially, since they typically do not stock them at consumer outlets –this means that e-commerce solutions in this area do not compete with retail stores, only with other ordering systems. Products unsuitable for e-commerce include products that have a low value-to-weight ratio, products that have a smell, taste, or touch component, products that need trial fittings, and products where color integrity appears important (Wikipedia, 2004).

Globally, consumers have accepted the e-commerce business model more slowly than its proponents originally expected (Humphrey, Mansell, Paré, & Schmitz, 2004). Even in product categories suitable for e-commerce, electronic shopping has developed only slowly. Several reasons have been adduced for the slow uptake, including:

1. Concerns about security. Many people will not use credit cards over the Internet due to concerns about theft and fraud. This is in addition to the lack of credit card culture in many developing countries (Travica, 2002).
2. Lack of instant gratification with most e-purchases (nondigital purchases). Much of a consumer's reward for purchasing a product lies in the instant gratification of using, and being seen to use the product. This reward does not exist when one's purchase does not arrive for days or weeks.
3. The problem of Internet access, particularly for developing countries. Low penetration rates of Internet access (see Table 1) greatly reduce the potential for e-commerce in developing countries, especially in Africa, Asia, the Middle East, and Latin America.
4. The social aspect of shopping. Some people enjoy talking to sales staff, to other shoppers, or to their cohorts: this social reward does not exist in online shopping.

CURRENT STATUS OF E-COMMERCE IN NIGERIA

Nigeria—which has been long locked and dragged back by brick-and-mortar methods in governance, education, and business—is at last taking steps to cross the digital divide. With the ongoing revolution in technology and the realization that no country can move forward without first advancing technologically, Nigeria has joined the countries currently reveling the online bug. In the educational sector, seven examination bodies, including the Joint Admissions and Matriculation Board (JAMB) and West African Examinations Council (WAEC) now allow students to register for examinations and to check and to print out their results online. Also, through the initiatives of AfriHub Inc., of the United States, the first phase of electronic learning facilities were recently launched at the two campuses of the University of Nigeria (UNN) at Nsukka and Enugu (Akpore, 2005). The facilities, which are meant to provide real time online training to university students, will be extended to 38 other tertiary institutions across the six geopolitical zones in Nigeria. Access to the Internet in almost all parts of Nigeria has also made it easier for Nigerians to acquire international information technology certifications such as Microsoft, Linux, and Sun certifications.

Table 1. World Internet usage and population statistics (From InternetWorldStats.com, September 30, 2004)

World Regions	**Population (2004 Est.)**	Internet Usage, Latest Data	Usage Growth 2000-2004	Penetration (% Pop.)
Africa	893,197,200	12,937,100	186.6 %	1.4 %
Asia	3,607,499,800	257,898,314	125.6 %	7.1 %
Europe	730,894,078	230,886,424	124.0 %	31.6 %
Middle East	258,993,600	17,325,900	227.8 %	6.7 %
North America	325,246,100	222,165,659	105.5 %	68.3 %
Latin America/Caribbean	541,775,800	55,930,974	209.5 %	10.3 %
Oceania	32,540,909	15,787,221	107.2 %	48.5 %
WORLD TOTAL	6,390,147,487	812,931,592	125.2 %	12.7 %

Banks and financial institutions have also made progress in providing online services starting with First Atlantic Bank of Nigeria's introduction of electronic banking service in November 2001 (Huang, Makoju, Newell, & Galliers, 2003) to the recent commencement of on-line banking in 106 branches of the Union Bank of Nigeria (Anonymous, 2004). Banks now offer services ranging from daily fund transfer to access to account information.

In the area of governance, the federal government and some state governments have launched their e-government programs. A typical state program involves the floating of a Web site for disseminating information about government activities to its citizens as well as the provision of e-mail addresses for sending comments to various officials in the legislative and executive branches of government. Useful application forms, along with their necessary instructions, are also made available for the citizens to download and use.

Despite these various e-commerce efforts, there are still major constraints slowing down the growth and use of e-commerce in Nigeria. According to Ilori (2001), some of these constraints are poor or obsolete communication facilities; erratic and unreliable electricity supply; poor implementation of computerization; computer phobia, which has led to inadequate use of the computer among the citizenry; and absence of secure, online payment methods. Although Dungor (2001); Amosa, Adenawo, and Adekigbe (2001); and Adibe (2001) agree with Ilori that the inefficient communication system in Nigeria is the greatest drawback in implementing e-commerce in the country, they also believe that lack of awareness in the business communities is equally inhibiting its growth. Furthermore, Amosa et al. (2001) view the negative attitude of government agencies through inadequate funding, low-income level, and inadequate sustainability of manpower as additional constraints to the effective practice of e-commerce in Nigeria. They submitted further that, although the question of insecurity in e-commerce transactions is a global phenomenon, Nigeria's peculiar situation rather disturbingly reflects that while other countries are taking proactive measures in their local environments to minimize or eliminate risks that are associated with e-commerce transactions, Nigeria has yet to evolve a coordinated survival *policy* as a credible playing nation in the emerging commercial terrain.

THE WAY FORWARD FOR E-COMMERCE IN NIGERIA

In support of the growth of e-commerce, there are some promising signals in the Nigeria's national information technology (IT) policy that was approved in March 2001. The IT Policy sets out certain objectives concerning some of the country's economic sectors, including agriculture, arts, culture and tourism, and the nascent e-commerce sector. In broad terms, the objectives in the e-commerce sector include the creation of an enabling environment for e-commerce to improve productivity and the nation's global competitiveness; the development of information infrastructure; and creating an e-commerce culture for easy, quick, and cost-effective national and international transactions. In order to achieve these lofty objectives, the following strategies should be adopted:

- **Infrastructure Development:** There should be the establishment of National Information Infrastructure (NII) as a fundamental national mission, and involving the planning, designing and configuring of a scalable National Information Infrastructure Backbone to achieve a minimum capacity of 2.5 gigabytes per second, using combination of optical fibres, satellite communications, and wireless technology. In the creation of the NII backbone, nodes should be set up in each state and local government for easy and effective implementation. Existing facilities such as power grids and railways infrastructure should be used to enhance the creation of the NII Backbone, encouraging the private sector, through relevant incentives to build interfacing NII of fibre transmission systems designed strictly to provide transmission capabilities on lease basis to service providers essentially for data transmission and not for telephony.
- **Human Resource Development:** There is a need for an appropriate IT education philosophy for sustained human expertise at all the levels (primary, secondary, and tertiary) of the Nigerian educational system. According to the African Information Society Initiative framework drawn up by the United Nations Economic Commission for Africa, the focus on capacity building is important since the adoption of appropriate information and communication policies would be futile if a country's institutions do not have the capacity and the incentives to ensure effective policy implementation.
- **Appropriate Legislation:** The National Information Technology Development Agency (NITDA) should ensure that the government forwards all relevant bills that will facilitate electronic commerce to the National Assembly to be passed into law and to remove existing legal impediments as contained, for example, in existing legislation and legal principles that are predicated on the presumption of paper-based transactions. According to Bamodu (2004), there is undoubted need for legislative provisions concerning the legal recognition

of the use of electronic signatures, as these are important to the conduct of e-commerce. It is suggested however that a single consistent comprehensive e-commerce legislation covering various relevant aspects (e.g., the role and liability of service providers, private international law considerations, online dispute resolution, formation of contracts) is preferable to piecemeal legislations. A basic model or framework for e-commerce legislation of some international recognition is the amendments to the Model Law on Electronic Commerce (1996), which was drafted by the United Nations Commission on International Trade Law. It has influenced e-commerce legislation in a number of countries and regions, including the United States, the European Union, and Singapore.

- **Institutional Framework:** There is also a need for a body overseeing the development of e-commerce. Already, Nigeria's national IT policy provides for the establishment of a National Electronic Commerce Council (NECC). In this connection, NITDA should ensure that NECC is inaugurated and be made to start to function without any delay. Also, the Council's functions and operations should be made clearly facilitative of e-commerce rather than being of a heavy-handed regulatory nature that might end up perversely being an impediment to the growth of e-commerce.

CONCLUSION

In this article, we have reviewed the current state of e-commerce in a developing country, Nigeria. We also discussed the models for the diffusion of e-commerce growth and the constraints inhibiting the growth of e-commerce in the country. Also, we proposed strategies that could be used in eliminating these constraints, especially in the areas of infrastructure and human resource development, appropriate legislation and strengthening of the existing institutional framework. We believe that if these strategies are followed, then Nigeria should be reaping the benefits of e-commerce in the very near future.

KEY TERMS

Developing Country: A country with a relatively low per capita gross national product (GNP).

Electronic Commerce: Commerce accelerated and enhanced by information technology.

Electronic Data Interchange: The direct computer-to-computer transfer of transaction information contained in standard business documents.

Information Technology: Information technology encompasses all forms of technology used in the processing and disseminating information.

Internet: A vast network of computers that connects millions of people worldwide.

Mobile Commerce: Electronic commerce conducted over a wireless device such as a cell phone or PDA.

Policy: A public statement of intentions and behavioral norms that is usually formalized and made explicit by a sovereign government, institution, corporation or other organizational entity.

E-Commerce Consumer and Product Characteristics

Daniele Scarpi

Francesca Dall'Olmo-Riley
University of Kingston upon Thames, UK

INTRODUCTION

Retailers having an online selling facility, or considering doing so, would benefit from a better understanding of the factors that influence consumers' willingness to purchase online. This understanding would help them to plan their Internet strategies better, to design Web sites more effectively, to select the assortment of goods more likely to sell online, and to convert mere browsers into actual buyers. In fact, despite the worldwide diffusion and ever-increasing use of the Internet, e-commerce remains a limited phenomenon compared with the sales figures of traditional retailing: while an ever-increasing number of people use the Internet for gathering information, comparatively few buy online (Citrin, Stern, Spangenberg, & Clark, 2003; Dall'Olmo-Riley & Scarpi, 2005).

This article aims at providing Internet marketing academics and practitioners with an account of the drivers and barriers to e-commerce, identified from a state-of-the-art literature review. The review is structured around the two main factors that appear to influence behavior on the Internet: consumer and product characteristics. Researchers agree that, although product characteristics play a role in e-commerce, the effects of attitudes, risk perception, and expertise are dominant. Hence, we first consider consumer characteristics.

BACKGROUND

Numerous Internet users appear reluctant to shop online and use the Internet only as a means of gathering information, before purchasing in traditional brick-and-mortar environments. For instance, Dieringer Research Group (cited in Mazur, 2003) report that in the past year $138bn were spent by U.S. consumers for purchasing products off-line after seeking information online, compared with $95bn spent for shopping directly online.

According to the literature there are two key factors influencing purchase behavior on the Internet: consumer-related factors and product-related factors. Although the literature considers these two factors from numerous different perspectives, there is shared agreement about their importance for understanding (and directing) consumers' behavior online. Appropriate retailer factors (i.e., retailers' Internet strategies and tactics) are further key elements influencing how the Internet is used (e.g., for buying rather than browsing), and how the overall online shopping experience is evaluated (see Cowles, Kiecker, & Little, 2002). Conversely, while new technologies can enhance the shopping experience, their application "must be tailored to the unique requirements of consumer segments and product categories" (Burke, 2002, p. 411). Thus, consumer- and product-related factors must be taken into account for providing useful managerial implications in the online medium.

From an extensive review of the existing literature, we identify four main consumer-related dimensions relevant to the understanding of the adoption of e-commerce:

1. **Consumers' Attitudes** (Helander & Khalid, 2000; Goldsmith & Bridges, 2000; Venkatesh, 2000; Childers, Carr, Peck, & Carson, 2001; Goldsmith & Goldsmith, 2002; Hoffman, Novak, & Duhachek, 2002; Sénécal, Gharbi & Nantel, 2002; Citrin et al., 2003; Joines, Scherer, & Scheufele, 2003; Lee & Tan, 2003; Meuter, Ostrom, Bitner, & Roundtree, 2003; O'Cass & Fenech, 2003)
2. **Risk Perception** (Wee & Ramachandra, 2000; Forsythe & Shi, 2003; Kau, Tang, & Ghose, 2003; Lee & Tan, 2003)
3. **Previous Experience** (Goldsmith & Goldsmith, 2002; Forsythe & Shi, 2003; O'Cass & Fenech, 2003; Dall'Olmo-Riley & Scarpi, 2005)
4. **Price Consciousness** (Goldsmith & Newell, 1997; Degeratu, Rangaswamy, & Wu, 2000; Fenech & O'Cass, 2001; Joines et al., 2003; O'Cass & Fenech, 2003; Shankar, Smith, & Rangaswamy, 2003)

On the other hand, there is no doubt that also products play a key role. First of all, not all products are equally suited to be sold online; for instance, products whose core essence is of an intangible and informative nature are more suited to be distributed through the Internet than others (Girard, Silverblatt, & Korgaonkar, 2002; Kau et al., 2003). Similarly, products can be categorized on the basis of the balance between "search" and "experience" attributes they possess (Klein, 1998; Citrin, 2003). For "search products", full information on the most important attributes can be obtained prior to purchase, while for "experience" products, it cannot, or is more costly/difficult than direct experience. Thus, by facilitating the acquisition of information and by lowering the cost of searching, the Internet not only suits search products, but may also enable the transformation of "experience" products into "search". For instance, the attributes of clothes (fit, quality of material, feel, etc.) can be assessed before purchase when bought in a traditional brick-and-mortar environment, but shift towards becoming 'experiential' when sold online. Furthermore, most researchers agree that consumers are more likely to shop online for goods with well-known brands and from well-known retailers, and it has been postulated that brand equity could have higher impact online than off-line.

Basing on these considerations, we identify and focus upon two product-related dimensions:

1. **Products and Services Typology** (Bowen, 1990; Van den Poel & Leunis, 1999; Fenech & O'Cass, 2001; Girard et al., 2002; Lee & Johnson, 2002; Citrin et al., 2003; Forsythe & Shi, 2003; Kau et al., 2003; Lee & Tan, 2003; Marzocchi, Misso, & Bononcini, 2003; Dall'Olmo-Riley & Scarpi, 2005)
2. **Brand Names** (Klein, 1998; Degeratu et al., 2000; Harvin, 2000; Balabanis & Reynolds, 2001; Citrin et al., 2003; Kau et al., 2003; Lee & Tan, 2003)

Indeed, the characteristics of the good/service have to be considered in conjunction with the peculiarities of the Internet if one wants to gain a deeper insight and derive useful implications for practice. The next paragraphs address these topics in more detail.

CONSUMER AND PRODUCT CHARACTERISTICS

Attitudes

Consumers' attitudes towards e-commerce have a significant influence upon the usage of online retailers, and could even discriminate between e-buyers and non-e-buyers (Helander & Khalid, 2000; Goldsmith & Bridges, 2000; Goldsmith & Goldsmith, 2002); for instance, consumers' likelihood of buying online is found to depend on their expectations of the benefits to be obtained from doing so (Lee & Tan, 2003).

Enjoyment and ease of use were identified as a strong predictor of attitude toward Internet shopping in a study by Childers et al. (2001), but O'Cass and Fenech (2003) also found that pleasure-driven "recreational" shoppers have a more positive attitude towards e-commerce than goal-oriented "economic" shoppers, who see shopping as a duty or a task. Consistently, a positive relationship has been suggested between the experience of "flow" and the hedonic value of consumers' online experiences (Hoffman et al., 2002; Sénécal et al., 2002).

Attitudes toward the use of technology also influence the perceived value of e-commerce (e.g., Venkatesh, 2000). Just like Massara and Scarpi (2004), who suggest that attitudes could discriminate between buyers and non-buyers better than demographic variables, Meuter et al. (2003) suggest that "technology anxiety" is a better predictor of using the Internet than demographic variables. Indeed, the level of technology anxiety was found to be inversely related to the use of the Internet and to the likelihood of engaging in positive word of mouth.

Hence, managers should keep their Web sites easy to use and avoid the use of non-essential technological complexity, in order to minimize the technology anxiety of some users (Meuter et al., 2003; O'Cass & Fenech, 2003). At the same time, similarly to atmospheric variables in off-line retailing, the use of colors, music, and other sensory features of the Web site should be carefully considered and selected to provide a "pleasurable" shopping experience to hedonic consumers (Citrin et al., 2003; Joines et al., 2003). This will not only prevent the "abandoned chart" syndrome, but also increase consumers' perceptions that the Web is a valuable way of shopping.

Risk Perception

As risk perceptions appear to affect Internet browsers much more than shoppers (Forsythe & Shi, 2003), this may help differentiate between the two groups of consumers. Lee and Tan (2003, p. 879) state:

Since Internet shopping is a high technology form of non-store shopping, consumers will tend to perceive a higher level of risk when purchasing products…the perceived product and service failure rates will be higher under online shopping than under in-store shopping.

Specifically, four types of perceived risk may prevent browsers from becoming shoppers: financial risk, time/convenience risk, product performance risk, and privacy concerns.

Other risks frequently associated with e-commerce include credit card fraud, inability to touch the product, and problems of returning unsatisfactory goods (e.g., Wee & Ramachandra, 2000; Kau et al., 2003). As difficulties in building trust in an online site may affect customers' willingness to purchase and to return to the site (e.g., Lynch, Kent, & Srinivasan, 2001), managers should consider offering a money-back guarantee, price reductions, clear explanations of the return and billing processes (e.g., amazon.com, paypal.com), possibly alongside third-party reviews and endorsement. Furthermore, a tracking system should be used to keep the purchaser up to date (by e-mail) with the status of the order, again helping to overcome possible risk perceptions.

Previous Experience

Researchers agree that expertise with the Internet has a positive influence on the frequency and number of online purchases, no matter what the product is (e.g., Goldsmith & Goldsmith, 2002; Forsythe & Shi, 2003; O'Cass & Fenech, 2003). Heavy users of the Internet evaluate the Internet more favorably than light users (O'Cass & Fenech, 2003); expert online buyers have more positive attitudes toward the Internet in general (Goldsmith & Goldsmith, 2002) and feel less technological anxiety toward than novices (O'Cass & Fenech, 2003). All in all, expertise emerges in the recent literature as one of the key predictors of online buying and overall evaluation of the online shopping experience (Dall'Olmo-Riley & Scarpi, 2005). Hence, managers should consider providing incentives to attract first-time buyers and to encourage customers' trial of the site. Vouchers, discounts, free gifts, and special offers (e.g., free delivery and returns) are possible incentives, alongside quick registration processes, free trials, and toll-free complaint hotlines.

Price Consciousness

In contrast with common belief, price sensitivity or price consciousness has not been found to be a strong discriminator between Internet shoppers and non-shoppers (Fenech & O'Cass, 2001; O'Cass & Fenech, 2003). Goldsmith and Newell in 1997 noted that shopping innovators were on average less price sensitive than later buyers. Furthermore, since innovators usually have high income, they tend to value reliability and quality of information more than price (Shankar et al., 2003). Consistently, researchers tend to agree that price sensitivity may be lower online than off-line (Degeratu et al., 2000; Shankar et al., 2003).

Nonetheless, the success of low-cost airlines in using the Internet as a distribution channel suggests that price *can* indeed be effectively used as an incentive to overcome the fears and the reluctance of consumers to purchase online. Indeed, Joines et al. (2003) found that economic motivations were positively related *both* to the percentage of time spent looking for information online *and* to the amount of online shopping undertaken.

However, the extent to which consumer-related factors facilitate (or hamper) Internet purchase probability is often dependent upon the interaction with product-related factors. This leads us to examine product characteristics as possible facilitators and barriers to e-commerce.

Products and Services Typology

It has been suggested that: (1) cost, (2) frequency of purchase, (3) value proposition, (4) degree of differentiation, (5) degree of tangibility, and (6) informational nature of the goods determine whether the Internet is a suitable distribution channel (e.g., Girard et al., 2002). For instance, tangible goods purchased frequently, low in cost, and with low potential for differentiation (e.g., milk and eggs) are less likely to be sold online, unless they can be bundled with other goods, like in online grocery shopping. In contrast, intangible and informational goods can be easily sold online. Furthermore, the Internet should not alter significantly the core essence of services purchasing, since they are by definition rich in experience attributes and are therefore hard to evaluate prior to use also off-line. Indeed, since services do not require a "tactile input" prior to buying, consumers might find it easier to purchase services rather than products online.

However, two considerations need to be made. First, typical high contact, customized, personal services in the off-line world (Bowen, 1990) may be very hard to deliver online, since they rely to a great extent on personal requirements (Dall'Olmo-Riley & Scarpi, 2005); thus customers are reluctant to forfeit any kind of face-to-face interaction with the provider. Instead, typically moderate contact, standardized off-line services such as booking of airline tickets (Lovelock, 1984) appear perfectly suited to online delivery, since for this kind of service customers value speed, consistency, and price saving the most (Kau et al., 2003; Dall'Olmo-Riley & Scarpi, 2005). This may explain the high acceptance of the Internet more as an information source and reservation device (e.g., Lee & Tan, 2003).

Second, the propensity to purchase a good via the Internet decreases as one moves from lower priced items to higher priced ones, since the risk associated with making the wrong purchase increases (Van den Poel & Leunis, 1999; Citrin et al., 2003), although experience with e-purchases acts as a moderating factor (Fenech & O'Cass, 2001; Forsythe & Shi, 2003).

Hence, it would be a mistake for sellers to stop offering the opportunity to engage in a face-to-face interaction experience in favor of a purely Web-based distribution. For some goods at least, the complete lack of tangible cues in buying straight from the Internet could make consumers feel uneasy and uncertain (Girard et al., 2002). At the same time, search goods such as books, CDs, and software not only score high in consumers' declared purchase preference from an Internet retailer (e.g., Girard et al., 2002), but also top most of the online sales statistics (e.g., Lee & Johnson, 2002).

These findings have relevant practical implications, and suggest that technology should be a fundamental consideration of online managers. In fact, technological solutions (e.g., the 'virtual model' available at www.landsend.com) can provide customers with cues overcoming the need of touching the product or of interacting face to face, and also illustrate more effectively product characteristics through a combination of video images and text, rather than by text only or by still pictures alone (Marzocchi et al., 2003). Moreover, video streams and music can also enhance the perceived hedonic value of the site.

Brand Names

Brands may have an important role in shifting consumers' perceptions away from experience attributes such as tactility, to search attributes such as reputation, and a well-known brand is an important risk reliever for consumers shopping online (e.g., Citrin et al., 2003). Indeed, most researchers agree that consumers are more likely to shop online for goods with well-known brands and are more likely to shop from well-known retailers (Kau et al., 2003; Lee & Tan, 2003). As Klein (1998) remarks, the brand's name is an important extrinsic cue, facilitating consumers' choices whenever it is difficult or costly to collect and examine intrinsic product attributes such as flavor, color, size, and texture. Hence, for all goods that either cannot be properly evaluated prior to online purchase or involve a high degree of purchase risk, brands fulfill a key role (e.g., Harvin, 2000; Balabanis & Reynolds, 2001).

Thus, brand equity could have higher impact online than off-line (Degeratu et al., 2000). Well-established retailers have an advantage over new start-ups in electronic retailing, since they can capitalize on their reputation and brands to reduce the risk-aversion of consumers (Lee & Tan, 2003). Managers operating online should therefore particularly invest into building the reputation of their own brands, while firms new to e-commerce could try to target the less risk-averse consumers as their initial segment, or they should carry well-known third-part brands.

FUTURE TRENDS

Practitioners and researchers should keep in mind that, although consumers are going to move a portion of their purchases online, they will still have relationships with regular stores. The dynamics and the advantages of managing multiple channels of distribution are still far from being completely understood, yet they are extremely important. Firstly, regular brick-and-mortar stores allow prospective Web shoppers to interact directly with the products or with the service provider before online purchase. Secondly, there are implications for branding, since a failed attempt to purchase from a retailer online is likely to have a negative effect on purchases from the same retailer off-line. Furthermore, the issues of satisfaction and word-of-mouth need to be further investigated with regards to the multi-channel retailing context.

Finally, there are many possible ways of reducing or even overcoming the barriers preventing consumers from increasing the proportion of purchases they do online. Conversely, firms may decide to focus more on providing information and better services over the Internet, rather than on selling (Bradford, 2001).[1] These barriers, strategies, and solutions need a systematic analysis and comparison, for a better understanding of the dynamics underlying e-commerce and its future development.

CONCLUSION

Through a review of the literature, this analysis has focused on two key features of e-commerce, namely consumer and product characteristics. It has examined the role that attitudes, risk perception, past experience, and price consciousness play in consumers' adoption of e-commerce, as well as how brand names and the type of product can affect online purchasing and retailers' strategies.

Without forgetting the perspective of practitioners, this article has discussed how e-retailers' marketing efforts can be used to overcome the barriers to e-commerce resulting from specific product- and consumer-related characteristics. The intent has been to provide a sound analysis of the extant literature, as well as clear and easy-to-implement recommendations to managers.

KEY TERMS

E-Retailer: A collective term applied to any Web site that sells a product or service, accepts payments, and fulfills orders; a retailer who has an online storefront.

Flow: Holistic sensation that people feel when they act in total involvement.

Hedonic/Recreational Consumers: Consumers who enjoy shopping for its own sake, not just for the items they purchase; they are driven by fun, pleasure, curiosity, and exploration.

Perceived Risk: The uncertainty that consumers face when they cannot foresee the consequences of their purchase decisions.

Technology Anxiety: A state of apprehension, uncertainty, and fear relative to implementing technology (*here*: in the buying/shopping process).

Utilitarian/Economic Consumers: Consumer who consider the shopping expedition as a task to be fulfilled; they are goal oriented, do not derive pleasure from the act of shopping, and value quick shopping expeditions.

Virtual Experience: A psychological and emotional state consumers undergo when interacting with visual products; an indirect experience in which the product affordances do not originate from the sensory and motor systems, but are provided by interactive virtual images/simulations.

ENDNOTE

1 This is, for instance, the strategy of insurance companies in the U.S., where online sales make up only 1% of the insurance market, but the large majority of firms provides consumers with the ability to do self-service online.

E-Commerce in a Digital Economy

Sushil K. Sharma
Ball State University, USA

INTRODUCTION

A digital economy is a convergence of communications, computing, and information. The essential in the new economy is a structural shift from the industrial economy toward an economy characterized by information, intangibles, and services, and a parallel change toward new work organizations and institutional forms (Gronstedt, 2001; Harreld, 1998; Sharma, Wickramasinghe & Gupta, 2004; Woodall, 2000). The new economy or digital economy is based more in the form of intangibles, information, innovation, and creativity, to expand economic potential (Sharma, 2004; Tapscott, 1996, 1998) and is based on the exploitation of ideas rather than material things. The essential elements of the digital economy are:

- Digitalization and intensive use of information and communication technologies (ICT);
- Codification of knowledge;
- Transformation of information into commodities; and
- New ways of organizing work and production.

This implies that extensive information and many services are available online. A widely distributed access to the networks, the intranet and Internet, and of skills to live and work in the Information Society, is the basis for the digital economy. In a digital environment, the Internet's growth and e-commerce begins to create fundamental change to government, societies, and economies with social, economic and political implications (Boulton, Libert, & Samek, 2000; McGarvey, 2001). E-commerce has already improved business value by fundamentally changing the ways products are conceived, marketed, delivered, and supported. The relationship and interaction of various stakeholders such as customers, suppliers, strategic partners, agents, or distributors is noticeably changed. The real impact of e-commerce is its ability to reduce costs and prices and make doing business more efficient (Zwass, 1998). These savings permeate the entire value chain and impact significantly in business interactions with other businesses (Bernardes, 2000; Sharma, 2004; Sharma & Gupta, 2003a).

BACKGROUND

As e-commerce continues to grow rapidly, it could have significant effects on the social and economic structures. The impacts of these changes are diverse and may even widen the digital divide among nations, alter the composition of trade, disrupt labor markets, and change taxation (Anonymous, 2000). Widespread use of the Internet for e-commerce may have ramifications for intellectual property rights, privacy protection, and data filtering etc. Therefore, in the digital economy, it is becoming imperative to know how e-commerce affects organizations and society for economic and social concerns. Some of these effects of e-commerce are unintentional and create adverse business and personal conditions that could have societal consequences. Social and economic aspects of information and communication technologies (ICTs) have been studied by a wide variety of researchers and practitioners for over fifty years (Dutton, 1999). However, the influences of e-commerce are far bigger than previously imagined (Sharma & Gupta, 2003b; Sharma & Gupta, 2001).

E-commerce continues to show strong growth and has been influencing the social and economic growth of nations. While e-commerce technologies have helped nations to accelerate their economic growth and to provide more opportunities for businesses to grow, but it has also created many challenges and effects across numerous domains of society, and policy makers. These unintended consequences of e-commerce have raised concerns about whether e-commerce benefits only the privileged few. This article describes the various unintended socioeconomic impacts and influences that have been created by the e-commerce in a digital economy.

UNINTENDED CONSEQUENCES OF E-COMMERCE

As the digital economy expands, we are beginning to see the effects at both the individual and aggregate levels (Granovetter, 1985; Sharma, Wickramasinghe, & Gupta, 2004). Some unintended consequences are discussed in the next paragraph.

Increasing the Digital Divide

The use of ICTs for e-commerce deepens and intensifies the socioeconomic divisions among people, businesses, and nations. On one hand, e-commerce has provided new opportunities for economic growth; on the other hand, it has created a social problem of digital divide. Digital divide refers to the disparity between those who have use of and access to ICT, and those who do not. More than two-thirds of the world population is still deprived of access to ICTs. There is a complicated patchwork of varying levels of ICT access, basic ICT usage, and ICT applications among socioeconomic groups; many disparities are getting even larger (Sharma, 2004). Hindered by poverty and a poor telecommunications infrastructure, the gap between developing nations and developed nations is widening further and therefore, those nations who are not able to join the e-commerce bandwagon and have poor access to the Internet, suffer from great disparity in wealth (Rombel, 2000; Sharma, 2004).

E-Commerce and Marginalization

The use of ICT for e-commerce has brought greater than the existing marginalization. These sentiments are echoed by the World Employment Report (2001), which says that the use of technologies such as e-commerce is positively correlated with economic growth—both on a national and organizational level. It also states that in countries where ICTs are relatively expensive, many people (particularly previously marginalized, e.g., rural people) are further marginalized. These persons are marginalized to a greater degree than before (i.e., they are being excluded from the electronic market place and are simply ignored by "electronic players"). Those organizations or business people who do not have access to such facilities are unable to respond. Again, they are left out of the mainstream of activities (Sharma, 2004).

Social Isolation

E-commerce has been an important facilitator of new flexible work forms. Types of flexible work refer to; the location of work, with a flexible location (e.g., working on the move, working from home, and working from telecentres or satellite offices). E-commerce has far reaching implications in a social context. On one hand, it provides all the comfort of shopping from home, on the other side, it removes old-fashioned human interactions for social needs (Gershuny, 2000). E-commerce makes it possible for consumers to purchase almost all their needs from home and have those items delivered, but this phenomenon leads to social isolation. Due to such phenomenon, there are fewer people active in their neighborhoods than in the 1960s.

Privacy

The emergence of ever pervasive and intrusive technologies is representing a threat not only to privacy, but to fundamental freedoms as citizens (Ambrose & Gelb, 2001). Computers can monitor every aspect of our online activities. In the work place, electronic monitoring of employees is not unusual. The threats to our freedoms are even wider than ever imagined (Gupta & Sharma, 2001; Miyazaki & Fernandez, 2000; Zaret & Sawyer, 2000).

Privacy remains an important issue while doing e-commerce. Two-thirds of Internet users are concerned with the confidentiality of the Internet (Cranor, Reagle, & Ackerman, 1999; Hoffman, Novak, & Peralta, 1999; Pew Research Center, 2000) and an equal number see the Internet as a threat to their privacy (Cole, 2001). Privacy threats may lower participation in commercial and social activities online (Pew Research Center, 2000) and are of particular concern to new users (Pew Research Center, 2000). A content analysis of leading e-commerce sites by the Federal Trade Commission found that only 20% met the agency's standards (FTC, 2000). These guidelines entail disclosure of privacy policies, providing consumers choice and consent, access to their data, and security of the data that is collected. Independent studies have revealed continuing gaps in online privacy practices (Culnan, 1999, 2000; Miyazaki & Fernandez, 2000; Miyazaki & Krishnamurthy, 2002).

Survival of Local Businesses

Whitten and Steinfield show that as electronic commerce grows, it will create an important socioeconomic side effect which will increase competition with the traditional businesses in any given local community (Steinfield, Mahler, & Bauer, 1999a, 1999b). Their study indicates local merchants are ill-prepared to take full advantage of electronic commerce due to various reasons, and thus are unlikely to see gains from it. Distant Web-based businesses have several advantages over their local physical businesses. Using transaction cost theory, one can conclude that electronic commerce implies new competition for local retailers, particularly those offering products that are readily obtainable from other sources, and that are easily transported (Steinfield & Whitten, 1999; Steinfield, Mahler, & Bauer, 1999, Uzzi, 1997).

Community Level Impacts of Electronic Commerce

E-commerce has many positive influences at the individual level whereby local buyers gain more value and greater access to suppliers, however, the results at the aggregate community level may be undesirable for local residents. Some of the community level social costs of electronic commerce are; job losses, particularly in relatively unskilled areas already quickly disappearing in the digital economy. However, not all communities will be affected equally, and some may even find that electronic commerce leads to significant growth in jobs, tax revenues and service levels (Steinfield & Whitten, 1999; Steinfield et al, 1999).

Impact on Tax, Trade, and Regulatory Policies

E-commerce has a strong impact on taxation and tax policy. Concerns have been expressed that e-commerce could result in the erosion of tax bases. Consumption taxes are levied on the principle of taxation at the place of consumption and according to rates set in individual countries, or in individual states in the case of federal nations. Tax planning for an e-business differs from tax planning for a traditional bricks-and-mortar company. Historically, the generation of income depended on the physical presence of assets and activities. This physical presence, or permanent establishment, generally determined which jurisdiction had the primary right to tax the income generated. Because of the growth of electronic commerce, new e-business models (including digital marketplaces, online catalogs, virtual communities, subscription-based information services, online auctions, and portals) have emerged. Each allows taxpayers to conduct business and generate income in a country with little or no physical presence in that country. The separation of assets and activities from the source of the income represents a significant departure from historic business models. This change creates new tax planning, challenges, and opportunities (Anonymous, 2000; Olin, 2001; Penbera, 1999; Sharma, 2004).

Impact on Employment and Labor Policy

Since e-commerce may create more knowledge-based products, it is likely to drive widespread changes in the labor market, shifting the composition of workers required to produce and deliver a product or service (Anonymous, 2000). There will be shifts in the kind of skills needed. Faster rates of innovation and diffusion may also be associated with a higher turnover of jobs. This may create more turbulence as workers will need to enhance their skills from time to time. This may result in reallocation of labor to the changing needs of the economy (Sharma & Gupta, 2003b; Anonymous, 2000). Businesses will incur ICT costs including cost of new applications, developer time, software licenses, any hardware or software, support and maintenance costs, and business costs associated with making the transition to the new system. (Penbera, 1999).

Competitive Environment-Influence on Monopolistic Trends

Since e-commerce would transcend geographical boundaries, many big firms of known brands may not only expand their markets, but also may enter into new business activities across the broad spectrum of business activities. E-commerce, especially, facilitates enterprises whose success depends on network effects—“winner-takes-all” situations for companies with significant market share—which further facilitate their growth and market dominance. This effect may create problems for competition and antitrust policy. Certain players may become monopoly holders which will have greater consequences for competition. The recent evidence from a Microsoft case has shown that there is considerable potential for weakening the competitive process (Bakos, 1997; Sharma, 2004; Sharma & Gupta, 2003b; Uzzi, 1997).

The Threat to SMEs

From a theoretical perspective, small business and rural enterprises can benefit greatly with e-commerce as they gain access to more customers (even globally) and can even compete with large businesses since e-commerce is a “level playing field”. But in reality, this may not be true. As indicated in the previous paragraph, many big firms of known brands may not only expand their markets but also may enter into new business activities across the broad spectrum of business activities and thus may kill many SMEs (Auger & Gallaugher, 1997; Sharma, 2004).

FUTURE TRENDS

The Internet provides considerable opportunities for firms to streamline their business operations, as well as offering greater choices and lower prices to customers shopping online or alternatively obtaining product information before making a store or catalogue purchase. A large number of enterprises have migrated to Internet-based systems for increased efficiencies, lower costs, and the ability to operate in real time across different platforms. E-commerce is changing business economics and as a result, many firms are reengineering their core business processes. Suppliers and retailers are able to collaborate on product forecasts, product flow, and inventory management decisions using the collaborative Internet-based networks between suppliers and retailers. Retailers are able to allow customers to mass customize orders based on virtually thousands of choices. The entire value chain makes better decisions collaboratively with the end result being vastly improved performance throughout the entire chain. The digital economy will result in lower prices for consumers, better information access and increased competitiveness of small and midsize businesses. It will also pave the way for a true global trading community.

CONCLUSION

As electronic commerce grows, there will be many unintended effects. Although, e-commerce technologies are helping organizations, societies and nations to accelerate their socioeconomic growth and to provide more opportunities for businesses to grow, but it has also created many challenges and effects across numerous domains of society. In this article, we have identified a comprehensive set of many of those unintended socioeconomic effects that are influenced by e-commerce. Further empirical validation could be done for these variables in different countries.

KEY TERMS

Digital Divide: The digital divide is the disparity in access to technology that exists across certain demographic groups. A term used to describe the discrepancy between people who have access to and the resources to use new information and communication tools, such as the Internet, and people who do not have the resources and access to the technology. The term also describes the discrepancy between those who have the skills, knowledge and abilities to use the technologies and those who do not.

Digital Economy: Digital economy is defined as the economy that is based more in the form of intangibles, information, innovation, and creativity, to expand economic potential and is based on the exploitation of ideas rather than material things using digital infrastructure.

E-Commerce: Electronic commerce means doing business online or selling and buying products and services through Web storefronts. E simply means anything done electronically, usually via the Internet. E-commerce is the means of selling goods on the Internet, using Web pages.

Internet Economy: Internet economy is defined as that part of the economy that deals with information goods such as software, online contents, knowledge-based goods, the new media, and supporting technology industries using the Internet.

Knowledge Economy: The knowledge-based economy is all about adding ideas to products and turning new ideas into new products. Relationships with trading partners, customers and suppliers, distribution networks, intellectual property, patents, image, etc., are all elements of a knowledge economy. These elements represent intellectual capital.

Network Infrastructure: This comprises the Internet as well as all forms of telecommunications and broadcasting infrastructure including television, cable TV, wireless, and satellite networks.

Privacy: Privacy is the interest that individuals have in sustaining a "personal space", free from interference by other people and organizations. It is the interest an individual has in controlling, or at least significantly influencing, the handling of data about themselves.

E-Commerce in Developing Countries

Janet Toland
Victoria University of Wellington, New Zealand

INTRODUCTION

Internet access in *developing countries* is growing rapidly. Developing countries accounted for one-third of Internet users worldwide by the end of 2003, and the catch up rate is getting faster. Between 2000 and 2003, developing countries increased their share of the Internet population of the world by nearly 50%. This has led some commentators, such as World Bank to claim that initiatives to close the *digital divide* are no longer relevant (Atkins, 2005). However, most residents of these countries still have no access to the Internet. For example, Internet access in Africa is less than two percent in a population of more than 900 million; the lowest rate of access in the world (Dunphy, 2000, UNCTAD 2004). *E-commerce*, *e-government*, and *mobile commerce* provide significant opportunities for developing countries, but their adoption will be slowed by technological, cultural, economic, political, and legal problems (Davis, 1999; Enns & Huff, 1999). Differences in e-readiness and related barriers to e-commerce will sustain substantial differences between regions of the world, between countries within regions, between urban and rural areas within countries, and between the genders and age groups.

Different opinions exist as to what benefits the use of information and communication technologies (ICTs) can offer developing countries. Do they provide developing countries with the opportunity to "leapfrog" ahead, skipping over certain stages of infrastructure development? Or do ICTs simply widen the gulf between the developed and the developing world even further (Economist, 2005)? The World Summit on the Information Society (WSIS) views ICTs as enabling technologies that can improve the quality of life for citizens of developing countries. Whereas Bill Gates view is that ICTs can provide little benefit to developing countries until more basic needs like clean water, health, and education have been met. In spite of this lack of agreement the reality is that if a basic communications infrastructure is available, options do exist to utilize e-commerce in developing countries. This article explores the potential opportunities that these technologies offer, and considers the barriers to uptake.

E-commerce involves buying and selling goods and services within an electronic marketplace, and also servicing customers, collaborating with business partners, and conducting electronic transactions within an organization (Turban, McLean, & Wetherbe, 2004). E-commerce can take place between one business and another (Business-to-business), and between a business and its customers (business-to-consumer).

E-government is the application of e-commerce technologies to the public sector. Developments in e-government have opened up the potential for governments worldwide to improve the services they offer to their citizens. A move towards e-government offers particular advantages to developing countries that may have difficulties interacting with their citizens through more traditional communication channels. E-government consists of two separate areas. First, it is concerned with changing internal government operations, inasmuch as information technology is used to support cooperation among government agencies (government-to-government). Second, it is used to support external government operations, in particular the interactions between citizens and companies, and the public sector, on a self-service basis (government-to-citizen) (Howle, 2003).

Mobile commerce offers the potential to bypass inadequate landline telecommunications infrastructure. Growth in the number of mobile telephone users worldwide has expanded from 50 million in 1998 to over 1.3 billion by 2004 (Turban et al., 2004). *Wireless technologies* have taken off even in relatively low-income areas of the world, where prepaid cards allow access without having to pass a creditworthiness check. At the end of 2003, Africa had more than 50 million mobile device users, whilst the number of fixed line telephone subscribers stood at only 25.1 million (ITU, 2004). Similar trends have been observed in Latin America and Asia, where handheld devices enable users to overcome the difficulties caused by low fixed line penetrations.

BACKGROUND OF E-COMMERCE WORLDWIDE

Table 1 shows the number of Internet users in the major regions of the world, reflecting vast differences in e-readiness. Less than 11% of the population in the developing regions of Africa, Middle East, Latin America and the Caribbean, and Asia were using the Internet in 2005 as compared to regions such as North America, Europe, and

Table 1. World Internet usage (Adapted from http://www.internetworldstats.com/stats.htm)

REGION	POPULATION (2005 Est.)	INTERNET USAGE (2005)	USAGE GROWTH 2000-2005	% IN REGION
Africa	900,465,500	12,937,100	187%	1.4%
Asia	3,612.363,200	266,742,420	133%	7.4%
Europe	730,991,100	230,923,400	124%	31.6%
Middle East	259,499,800	17,325,900	228%	6.7%
North America	328,387,000	218,400,400	102%	66.5%
Latin America/ Caribbean	546,917,200	55,279,800	206%	10.1%
Oceania / Australia	33,443,500	15,838,200	108%	47.4%
WORLD	**6,412,067,200**	**888,681,100**	**126%**	**12.7%**

Australasia where at least 30% of the population used the Internet.

Africa

The digital divide is largest in Africa, with only 1.4% of the population having access to the Internet, as compared to 50% in most advanced countries. However, local Internet connection is now available in all African capital cities. Business-to-business e-commerce is growing in South Africa, but there have been limited developments in the rest of the continent. There are some success stories in the business-to-consumer area, mostly in the traditional handicrafts area, where the Internet offers the opportunity for a niche player to access the global market of Africans living abroad.

Asia

Asia leads in the adoption of e-commerce among developing countries. This is partly due to demographics, but also because organizations tend to be more integrated into global trade flows than in other developing countries. Manufacturing enterprises in particular face pressure from their customers in developed countries to adopt e-commerce. China offers the greatest potential e-commerce market, and is now considered one of the top five nations in the world in terms of Internet use. While many Chinese are going online for the first time, less than 20% have done any online shopping (Hsu, 2003).

Latin America

Four countries, Argentina, Brazil, Chile, and Mexico, account for two-thirds of Internet users in the region. Most business use involves searching for contacts, and gathering information with limited use of transactions. However, business-to-consumer e-commerce is growing, with online car sales, consumer auctions, travel, computer hardware and software, and banking responsible for the highest revenue. Business-to-business e-commerce is being used mainly by large transnational corporations in the automotive sector.

Middle East

The number of Internet users is growing rapidly, with the two main drivers of demand being the Internet and e-mail. Only a handful of large companies have adopted business-to-business e-commerce. The development of business-to-consumer e-commerce is hindered by high communication costs, and the fact that many Arab consumers are more comfortable with cash than credit card payments. This has led to some companies, such as Lebanon's GetForLess convenience store, implementing a hybrid e-commerce system that enables customers to order online, yet pay by cash (Gibeily, 2001).

North America/ Europe/ Oceania

In the developed world the growth in e-commerce continues. The business-to-business area is growing faster than business-to-consumer, with Forrester Research Inc. (2001) forecasting that 26% of business-to-business sales in the United States will be traded online by 2006, business-to-consumer has progressed significantly in some sectors, such as software, music, and travel services.

OPPORTUNITIES AND BARRIERS

A number of organizations have frameworks that can be used to track developments in e-commerce and e-government (Jupp, 2003). The UN/ASPA five-stage model, shown as Table 2, is particularly appropriate for developing

Table 2. UN-ASPA five stages of e-government (Adapted from UN & ASPA, 2002)

STAGE	DESCRIPTION	SPECIFIC FEATURES
Stage One	**Emerging Web Presence** Static information on the government or organisation is provided	Postal Address Email Address FAQs
Stage Two	**Enhanced Web Presence** Information is kept up to date, official forms and documents can be downloaded	Updated regularly Search function Newsletters
Stage Three	**Interactive Web Presence** Citizens or consumers can search databases, and submit online forms	Downloadable forms Specialised databases Discussion Forum
Stage Four	**Transactional Web Presence** Transactions can be completed online, and sites are fully secure	Public user log on Online Payment Security Policy
Stage Five	**Fully Integrated Web Presence** A single customisable portal provides all services and links	Portal Complete information

countries. Though this model was specifically developed for e-government it can also be applied to e-commerce.

The model tracks a country's e-government progress. A stage one e-government presence (Web site) will be a basic public information source, often developed by employees of the agency rather than professional Web developers. At stage two the Web site will be regularly updated, some documents will be available for download, and e-mail will be available for queries and comments. Once stage three is reached, the government Web site begins to act as a portal with links to related sites, both government and non-government. At stage four, citizens will be able to complete transactions online, and Web sites will be secure. Stage five occurs when there is an integrated countrywide portal where all services offered by government can be offered through one integrated "one stop shop" site (Lallana, Pascual, & Soriano, 2002).

The UN-ASPA model can also be used to monitor the development of e-commerce in the private sector. At stage one for example a traveller may be provided with a Web site that gives the contact details for the local tourist office. At stage two they will be provided with information about local accommodation, and possibly download a brochure. Stage three is reached when the potential customer is able to search for different types of accommodation, and make a booking online. By stage four the Web site is fully secure, and the customer is able to use a credit card to pay for their accommodation online. The final portal stage is more relevant to larger companies that may want to set up such sites to link more closely with their major suppliers and trading partners.

In both the private and public sectors the use of Web sites and e-mail is widespread, though there is little transactive use. Larger multinational companies have well developed business-to-business systems. However for smaller organizations the main use of the Internet is for email; there is relatively little business-to-consumer e-commerce. Lack of e-readiness, or what might be called barriers to e-commerce, such as low credit card use, and poor logistics and fulfilment, inhibit fully developed e-commerce (UNCTAD, 2002).

Governments can develop *e-procurement* systems to purchase goods and services online from the private sector. As the government is usually the largest purchaser in an economy, this provides an incentive for local businesses to adopt ICTs. Although this does raise the danger that some small businesses may be left behind. One of the risks of e-procurement is that, smaller firms

Table 3. Barriers to e-commerce in developing countries

Unstable power supplies
Poor telecommunications service
Limited penetration and/or high cost of Internet connections
Lack of competition in international telephone traffic
Lack of suitable regulatory environment
Illiteracy
Low incomes
No tradition of mail order type shopping
Inadequate payment systems and low credit card usage
Fulfilment problems occasioned by poor physical infrastructure (road, rail, air)
Poor customer service
Shortage of technical skills
A preponderance of small and medium size enterprises that lack capital for development of e-commerce
Lack of critical mass

without online capability may find themselves excluded from the market. High population countries, such as Malaysia and Brazil, have introduced extensive e-procurement systems, but for smaller countries benefits can be gained from even minor changes such as posting information about current tenders online (UNCTAD, 2004).

Developing countries lack the well-developed commercial and logistics infrastructures of developed countries, which support the development of e-commerce. In order for goods ordered online to be delivered safely, there has to be a good quality transport system, and a reliable postal service. Table 3 lists the main *inhibitors of e-commerce* in developing countries.

As a result of the barriers, most e-commerce in developing countries takes place between organizations. Business-to-business e-commerce accounts for 95% of all e-commerce in developing countries. Much of this is driven by large multinational organizations. Business-to-business e-commerce applications have the potential to enable producer firms in developing countries to gain better information about global markets. E-marketplaces which link together many different producers and buyers can be a means of obtaining new customers. However the main effect of business-to-business e-commerce to date has been to reinforce relationships between existing trading partners; little business is generated with new firms (Humphrey, Mansell, Paré, & Schmidtz, 2003). Developing countries need to be aware that business-to-business e-commerce may favor multinationals at the expense of local businesses. Indigenous business-to-consumer e-commerce is usually small by comparison with business-to-business, the buyers are often offshore customers in the developed world, as is the case for the tourism, art, and handicrafts markets.

In order for e-commerce to take off the number of users needs to reach a critical mass. More businesses and more customers will be online if they know they can do transactions efficiently by e-commerce. In addition, more businesses in developing countries will be online if they know they can reach customers across the globe efficiently. With sufficient demand from businesses and customers, the level of *infrastructure* represented by Internet service providers and facilities for Web site development and hosting and processing if electronic payments will also become available. These developments are interrelated and self-reinforcing.

Most payments for online purchases are still accomplished by *credit card* in the developed world, an option that exists for a much smaller percentage of customers in developing countries. However, where there is sufficient population density, fulfilment of physical goods purchased through online stores can include payment at the time of delivery, as happens in a significant portion of such purchases in China.

On the demand or customer side, access is growing through shared facilities like Internet cafes and through growing individual and family computer ownership. These options are still only available to higher income individuals living in cities in the developing world. Nonetheless, the number of customers and the number of online businesses is expanding rapidly.

FUTURE TRENDS

The rapid uptake of mobile telephony in the developing world, particularly in Africa brings the opportunity to overcome the problem of an inadequate telecommunications infrastructure. Mobile phones can provide an "Internet in your pocket". Is this the technology that will allow developing countries to "leapfrog"? Illiteracy is no barrier when operating a mobile phone, neither is lack of English. The availability of prepaid cards means that no credit checks are necessary. Access to mobile phones is a lot more widespread than ownership numbers suggest. A telephone may be owned by one person in a village who runs a small business taking and receiving calls for the other inhabitants. Mobile phones are also being used to make payments for items as diverse as petrol, laundry and deliveries of Coca-cola. This is a significant advantage as in many developing countries the lack of a reliable credit card system is a real inhibitor of e-commerce. There are many ways that mobile phones can used to assist a business. One example is that of the Tanzanian fishermen who use mobile phones to check the price of fish in different ports before deciding where to land their boats (*Economist Editorial*, 2005; Coyle, 2005).

Many ICT projects in developing countries have focussed on rural *telecentres*, which offer Internet access, and training for local people. Telecentres also offer access to the same information about weather patterns, crop prices, and market trends that are offered by mobile phones. A 2005 Economist editorial argued that the publicly owned telecentre model was outdated, and that private ownership of mobile phones was the way to overcome the digital divide. However as the editorial was based on research carried out by Vodafone, questions have to be raised about the impartiality of the findings. What is clear is that the increasing use of mobile phones in the developing world will have an impact on the development of e-commerce.

CONCLUSION

Patterns of Internet use and e-commerce are likely to remain skewed for some time. Communication, in particular email, will continue to be the first priority of users.

Searching for information will also be important in the future. Business-to-business e-commerce will remain more significant than business-to-consumer. Growth in entertainment and online purchases will lag. Business-to-consumer e-commerce growth will be largely an urban phenomenon, and rural areas will participate at much lower rates. The gaps between young and old and males and females, which have narrowed in the developed world, will persist much longer for people in developing countries.

Infrastructural issues are bound up with politics in many developing countries. The future will see wide variation as some countries move forward and others do not. The development of e-commerce may be encouraged by government interventions such as deregulating the telecommunications sector, and promoting competition among players to bring prices down. This is likely to be successful in high population countries whose large potential markets make them attractive to private investors. In countries with lower populations the government may need to retain responsibility for telecommunications.

There is a substantial body of research demonstrating significant improvements in the economies of countries, resulting from investment in telecommunications infrastructure (Parker, 2000). The more remote the location, the greater the benefits will be. A good telecommunications infrastructure can overcome the barriers to growth caused by distance, and lack of economies of scale. These benefits can also be gained through the use of mobile computing. Research carried out by Leonard Waverman has demonstrated that investment in mobile telecommunications has a positive impact on economic growth, and that this impact is stronger in developing countries. In a typical developing country an increase of ten mobile phones per 100 people boosts GDP by 0.6% (Economist, 2005).

The barriers to the development of business-to-consumer e-commerce all have a common source in the conditions that create and sustain differences between the developed and developing world. Until these conditions change, Developing countries will continually lag the developed world in e-commerce, as they do in many, more important indicators of well-being such as health and education.

KEY TERMS

Business-to-Business (B2B): A business selling goods and/or services online to another business.

Business-to-Consumer (B2C): A business selling goods and/or services online to private customers.

Digital Divide: The gap in ICT usage between different sections of the world population. It can be used with reference to the developed and developing world, or within one country to describe the difference in ICT take up between rural and urban areas, or between different ethnic groups.

E-Marketplace: An online marketplace where many buyers and sellers barter and conduct transactions. They are frequently owned and operated by a third party.

E-Procurement: The use of the Internet by government to procure or purchase goods and services, advertise their needs, select vendors, manage services, organize fulfilment of contracts and effect payments.

E-Readiness: A measurement of how ready a society is to benefit from recent developments in ICT. An e-readiness assessment normally takes into account education levels, infrastructure, the accessibility of ICT, and legal and regulatory issues.

Government to Citizen (G2C): Governments offering services to citizens online.

Government to Government (G2G): Online interactions between different government agencies.

Wireless Technologies: Technologies that communicate without landlines e.g. satellite, microwave, cellular radio, infrared. Common uses are pagers, cellular telephones, personal digital assistants, mobile data communications, and personal communications services.

E-Commerce in Enron

BACKGROUND OF THE BUSINESS

Enron was formed in 1985 when a Houston natural gas company merged with InterNorth, a gas provider in Nebraska to operate an interstate natural gas pipeline that linked the Great Lakes with Texas. Kenneth Lay, a former Exxon executive, became chief executive officer (CEO) of Enron in 1986. Enron began trading gas commodities in 1989 and soon became the largest supplier in the USA. The business activities of Enron spread all around the world and included activities in countries like Argentina, Bolivia, Brazil, China India, Indonesia, Mozambique, and the Philippines (Chatterjee, 2000). Enron also diversified its product range and expanded on to the Internet trading in a wide range of products from pulp and paper to petrochemicals and plastics. It also traded in esoteric products such as airport landing rights, railroad hauling capacity, and clean air credits.

In less than two decades, Enron grew from a small gas pipe line company into the world's leading energy trading company with $100 billion in revenue, $60 billion market value and 21,000 employees in 40 countries. In 2000 the Fortune magazine named Enron as the most innovative company in the USA for the fifth year in succession. In the same year Energy Financial Group ranked Enron as the sixth largest energy company worldwide.

Enron's mergers brought the company much success, but Enron wanted more. Enron wanted growth which eventually led to its demise. This phenomenal growth was made possible by the use of new market strategies that tilted towards knowledge and innovation in place of traditional ownership of physical assets. The central strategy at Enron was to totally use the financial derivatives in the market to acquire commodities that anybody wanted to sell and dispose it at a profit to anyone who required it. This started with oil and natural gas and then just expanded into electric power generation and pipeline capacity, broadband communication, and freight capacity of modular containers. All these were the factors that were responsible for Enron's growth and corporate greed led to its downfall (Ekbia, 2004).

DESCRIPTION OF THE BUSINESS

Prior to the Internet, the tools of trade were regular phones and fax machines. Computers were used but the Internet was still an untapped resource. With the new technology, information that took days to spread by newsletter and fax became available instantly. E-mail and instant messaging then made online trading the logical next step. Charles Moore, president of PetroVantage, said, "Rather than a threat to market stability, online services have made the industry more efficient by allowing companies to quickly analyze an offer and instantly run the decision tools to make a profitable transaction" (Jones, 2001, p. 3).

Meteoric Rise and Sudden Fall

Enron was a product of the information age. The basic premise behind Enron's strategy was to create markets for goods and services that were traditionally transacted through legacy distribution channels. Enron played three different roles at the same time as a broker, a trader, and a market maker. E-commerce provides numerous opportunities in increasing networking efforts, increasing efficiency, hence decreasing costs. Enron launched EnronOnline (EOL) in November 1999, the first ever-global Web-based online commodity trading site. EOL was a principal-based online trading system. All transactions were directly with an Enron company. Customers could view real-time prices and accept full contractual terms online, such as Argentine natural gas, Japanese weather, Dutch aluminum, Spanish electricity, and U.S.

lumber. Enron had an edge over its competitors in that there was no commission and no subscription fee charged to the customer. The key factor that separated Enron from its competition was the way it interacted with its buyers and sellers. In addition, Enron offered risk management product to these buyers and sellers to make them comfortable with this new marketing exploit by hedging their financial exposures.

The introduction of EOL facilitated gas trading and operations. Enron was a large market participant, as both a buyer and seller of spot, fixed, and futures contracts. "Its launch quickly changed not just the firm but markets around the world", EOL was acclaimed by BBC News (2001). "Two years after its launch, the platform was averaging 6,000 transactions a day worth an average $2.5 billion. Twenty-one hundred different financial products were on offer to traders, across four continents in 15 different currencies." Before the collapse of Enron the company was most certainly a success story. From 1985 to 1999 Enron's net income rose from $125 million to $893 million; its market value grew from 2 billion to $50.5 billion (Enron, 2002).

Even though Enron had an advantage being a global market, offering customers an electronic option was not easy. They had to deal with a host of regulatory issues from one country to another. Data-protection laws as well as regulations vary from one country to another. Consequently, Enron had to develop different registration forms and to some degrees take a lowest-common-denominator approach. Also its competitors, like Aquila, Duke Energy, Dynegy, and The Williams Cos. wanted a share of the commodity trading market. The main problem now, given all Enron's challenges, was making success last.

Enron launched the New Power Company (NPC), the first national energy service in May 2000 along with its new strategic investors IBM and America Online. The NPC was created to provide energy services for residential and small businesses in the U.S., where deregulations in the energy market were introduced. In early 2001, Jeff Skilling took over as Enron's CEO from Ken Lay. In October 2001, the tables were turned again and Ken Lay returned as CEO with Jeff Skilling having resigned in August. Then hints of overstated earnings began to circulate, along with nose-dived share prices—employees were terminated and their life savings emptied. Investigations into corporate crimes and accountancy fraud were initiated on Enron leading to the collapse of the Enron empire (Siylak, 2002). Enron declared bankruptcy in December 2001. Quite a few of its executives reaped large benefits by disposing their stock options for cash when the share prices were high. The employees were the losers as they put all their pension money in Enron shares and lost it all when the firm went bankrupt.

Certainly, Enron exploited new areas of business in dynamic and innovative ways. Enron has had a major impact on the Internet trading industry. A competitor of Enron—Atlanta, Georgia-based IntercontinentalExchange—began discussing an IPO after seeing a surge of new business since Enron's collapse. And Enron's model, in which the company essentially served as the medium that backed every trade with a money-back guarantee—likely will live on as well, according to Forrester Research analyst James Walker. In a report, Forrester's Walker explained the somewhat ironic reason for Enron's previous success in this way: "Enron exploded online by managing risk better than others" (Regan, 2002).

How the Company was Directed

Virtually every company, including those that plunder, has a policy with the proper lofty language about their commitment to integrity. But there is a difference between words and deeds (Wright, 2003). It is an irony that at the time these companies were engaged in wrongdoing, they were never more eager to present themselves as good citizens.

Enron's token commitment to its code of ethics was famed "RICE" (respect, integrity, communication, and excellence). However, The RICE values were neither modeled by leaders nor integrated into operations. Enron was obsessed with values relating to business success and profitability. Risk taking and "do deals" had become the dominant value in the company. Enron adopted an aggressive employee review system—a semiannual weeding out known as the "rank and yank". In the performance review committee (PRC), which became known as the harshest employee ranking system in the country, every six months 15% of employees were to be given unsatisfactory ratings that largely doomed their careers at Enron. Fierce internal competition prevailed. Paranoia flourished and contracts began to contain highly restrictive confidentiality clauses.

Hypothetically, the introduction of EOL could have increased the competitive functioning of the gas markets, or instead it could become a vehicle for increasing the concentration of market information in the hands of the Enron traders. Aided by the information available through EOL, Enron could emerge as a dominant firm exerting influence on the market to its own advantage (Murry & Zhu, 2004).

With the use of e-commerce and the acceptance of its countless benefits come responsibilities and risks if not met. Enron began diversifying its portfolio through the use of thousands of special purpose entities (SPEs) which allowed the company to embark upon less conventional ventures without necessarily reflecting their cost on its balance sheets. The pushing of boundaries was most likely encouraged throughout the company. They were pioneering business methods, of the entrepreneurial culture, of innovation and deal-making. Finally they pushed too hard; they "crossed a line and strayed into illegal behavior" (Zellner, 2003, p. 16).

For the fact that activities that eventually resulted in the collapse of Enron did not occur over night, nor conducted by one person many people are responsible for what has occurred inside of Enron. CEO Jeff Skilling and Chairman Ken Lay, also former CEO of Enron, the ex-CFO Andrew Fastow played major roles in the way Enron's future turned out. Board of Directors supported the CEO and the Chairman and they were further supported by an intelligent staff of accountants, auditors, and lawyers.

The only positive outcome of the Enron failure was the revision of accounting principles and retirement plan regulations. Legislative remedies were immediately sought, culminating in the Sarbanes-Oxley Act (SOX) of 2002. SOX included a number of provisions designed to strengthen both public and private oversight of corporate behavior, and subject violators to harsher penalties (Leeds, 2003).

Saunders (2003) emphasized that "as a result of Enron there have been the biggest changes to company rules in the U.S. since the 1929 crash. CEOs must now testify to the accuracy of the accounts and auditors are effectively banned from consulting to clients." But Stanford (2004) noticed that ethical behavior cannot be legislated: it has to come from within the individual and within an organization's culture. Research suggests that to the extent organizational structure can promote ethical behavior, a decentralized structure is best. When decisions reflect consensus, and accountability is shared, self-dealing should be curtailed if not eliminated.

The Main Reasons for the Company's Failure

It's been a tremendous success during Enron's ill-fated bull run. Even nowadays, many analysts wonder what could have been if Enron was still around. "It is impossible to know how much of its potential, real or imagined, Enron's Web effort might have achieved" (Regan, 2002). In retrospect, maybe Enron had "too much, too soon."

The collapse of Enron has been explained in a range of ways. Enron's downfall is considered by many to be a classic accounting failure characterized by the inappropriate use of generally accepted accounting principles (GAAP), off-balance-sheet schemes, and questionable independent auditor performance. It was a failure brought about by loose practices and a betrayal of trust.

Kreitner and Kinicki (2004, p. 107) blamed "the damage to the culture by the unscrupulous demands and practices of the CEO 'to make the numbers' at whatever cost necessary, which contributed significantly to the company's financial and legal problems."

The Washington Post described Enron as "a fundamentally self-destructive institution, a house of cards, where human error and a culture of ambition, secrecy, and greed made collapse inevitable" (Behr & Witt, 2002, p. A1). Zellner (2003, p. 16) mentioned "the unbridled greed, the Byzantine financial deals, and the toothless watchdogs at Arthur Andersen." In Awe's (2003, p. 63) point of view, "dubious financial maneuvers, excessive spending, and intricate and questionable accounting practices", as well as "political assistance" from the big man contributed to Enron's rise and fall.

On the other hand, the demise of Enron is not only the result of ethically challenged corporate managers but also a tale of fatal near-sightedness on the part of directors, auditors, bankers, lawyers, and analysts (Martorelli, 2004). Enron dealt in commodities and derivative structures and deal terms that were far too unusual to have an established price. The both hard pressure from the "rank and yank" and soft supervision from the non-standard measurements were Enron's unprecedented environment.

Also, Prentice (2003) argued that behavioral decision theory has substantial explanatory power in the Enron debacle. Because of subgoal pursuit, individual units of Enron tackled huge, risky projects and a number of them helping drag Enron down. The self-serving bias worked particular evil at Enron. Trades were often recorded at full value as revenue rather than according to the simple profit that was made. Energy was sometimes bought, sold, and then bought back in order to inflate revenues. Emphasis was placed on stock values almost to the exclusion of all else. Enron was an organization where money was the only yardstick and where the code of ethics was only window dressing.

LESSONS LEARNED

In accordance with Seeger and Ulmer (2003), the Enron case cost investors billions of dollars in equity, dealt a fatal blow to the accounting giant Arthur Andersen, generated a dizzying array of lawsuits, and prompted serious rethinking of SEC regulations.

Enron was not in isolation of being the only company to have conducted such illegal activities when dealing with e-commerce. Other companies include but are not limited to WorldCom, Adelphia Communications, Global Crossing, and Tyco International. Over the last five years over 700 companies have been forced to re-state their earnings in the U.S. Each and every one can be accused of contributing to the damaged credibility of today's businesses (Awe, 2003).

Why "good" people make "bad" moral choices? How can long-term social acceptance be achieved in parallel with short-term maximization of returns? Does SOX, that makes structures governing the conduct of the corporation a matter of federal law, offer a panacea? Several questions remain.

Among the embers of what remains of Enron and the people who ran it there are some fundamental lessons to be learned in order to ensure that nothing of this magnitude is allowed to happen again. Three of the most important areas for corporate reform include: (1) Independent auditors are a must, (2) Redefine duties of loyalty, (3) Shake up the boardroom (Anonymous, 2003). Duska's (2004) six simple rules that simply restate old virtues that were eroded in the single-minded pursuit of profit are: (1) Constrain self-interest, (2) Don't be greedy, (3) Keep worthwhile goals in mind, (4) Avoid hubris, (5) Don't misplace loyalty, (6) Be professional.

Recently, Maccoby (2005) assets that to make both companies and government organizations behave morally, the focus should be on organizational values and leadership. What needs to be done to raise the moral level? One key factor is whether employees feel it's safe to tell the truth, argue minority views and deliver bad news, especially when telling the truth may be essential to the well-being of others. Of course, leaders must articulate and model organizational values. If leaders are serious about raising the moral level, they need to actively engage the organization.

Common sense and research show that:

- Without solid ethical foundations any company will falter.
- If you persistently try to push boundaries and attempt to get around the rules, you will eventually break them.
- The pursuit of shareholder gain should not take place at the expense of the wider community.
- Never let the inner workings of a company become so complex that the managers don't even understand what is going on.
- Substantial amount of innovative and rapid growth, if not controlled, can become unsustainable in the long run.
- If you don't understand it, don't do it!

In many ways Enron is a quintessential example of the irrational exuberance of the dot-com bubble. The negative issues and problems that came about since the unraveling of Enron are quite obvious, but America is certainly using it, to its advantage, as a learning experience for everyone involved. As a nation we are gaining from our experiences and even though many of the new challenges probably have not come to light yet, there is no doubt that as they continue to come out we will continue to use it to learn from it and not let history repeat itself.

KEY TERMS

Centralized Structure: In contrast with decentralization, the centralized structure is sometimes referred to as vertical, bureaucratic, mechanistic, rigid, or inflexible.

Decentralization: Also as participative or democratic management, employee involvement (EI), and team-based practices to denote governance philosophies, while the flat or horizontal organization represents the type of structural design. Other terms referring to the decentralized structure as organic or flexible (Thomas, 2004).

Ethics: A set of principles of right conduct. The rules or standards governing the conduct of a person or the members of a profession.

Generally Accepted Accounting Principles (GAAP): A widely accepted set of rules, conventions, standards, and procedures for reporting financial information, as established by the Financial Accounting Standards Board.

Integrity: The character traits of honesty, candor, and protection of confidentiality (AICPA—American Institute of Certified Public Accountants).

Mark-to-Market Accounting: Whenever companies have outstanding or other derivative contracts (either assets or liabilities) on their balance sheets at the end of a particular quarter, they must adjust them to fair market value, booking unrealized gains or losses to the income statement of the period.

Morality: It has to do with reasoning and behaving according to values that go beyond narrow self-interest.

Organizational Responsibility: It refers to obligations to operate regularly according to accepted social norms and standards. Those organizations that comply with basic standards are able to argue that their behavior is ethical and that their operations are normative and legitimate.

Special Purposes Entities (SPE): An SPE, dubbed the Raptors, is a trust, corporation, limited partnership, or other legal vehicle authorized to carry out specific activities as enumerated in its establishing legal document.

E-Commerce Services Based on Mobile Agents

INTRODUCTION

The Internet offers a unique opportunity for e-commerce to take central stage in the rapidly growing online economy. With the advent of the Web, the first generation of business-to-consumer (B2C) applications was developed and deployed. Classical examples include virtual shops, on-demand delivery of contents, and e-travel agency. Another facet of e-commerce is represented by business-to-business (B2B), which can have even more dramatic economic implications since it far exceeds B2C in both the volume of transactions and rate of growth. Examples of B2B applications include procurement, customer relationship management (CRM), billing, accounting, human resources, supply chain, and manufacturing (Medjahed, Benatallah, Bouguettaya, Ngu, & Elmagarmid, 2003).

Although the currently available Web-based and object-oriented technologies are well-suited for developing and supporting e-commerce services, new infrastructures are needed to achieve a higher degree of intelligence and automation of e-commerce services. Such a new generation of e-commerce services can be effectively developed and provided by combining the emerging agent paradigm and technology with new Web-based standards such as ebXML (2005).

Agents have already been demonstrated to retain the potential for fully supporting the development lifecycle of large-scale software systems which require complex interactions between autonomous distributed components (Luck, McBurney, & Preist, 2004). In particular, e-commerce has been one of the traditional arenas for agent technology (Sierra & Dignum, 2001). Agent-mediated e-commerce (AMEC) is concerned with providing agent-based solutions which support different stages of the trading processes in e-commerce, including needs identification, product brokering, merchant brokering, contract negotiation and agreement, payment and delivery, and service and evaluation. In addition, the mobility characteristic of peculiar agents (a.k.a. *mobile agents*), which allows them to move across the nodes of a networked environment, can further extend the support offered by the agents by featuring advanced e-commerce solutions such as location-aware shopping, mobile and networked comparison shopping, mobile auction bidding, and mobile contract negotiation (Kowalczyk, Ulieru, & Unland, 2003; Maes, Guttman, & Moukas, 1999).

To date, several agent- and mobile agent-based e-commerce applications and systems have been developed which allow for the creation of complex e-marketplaces—that is, e-commerce environments which offer buyers and sellers new channels and business models for trading goods and services over the Internet.

However, the growing complexity of agent-based marketplaces demands for proper methodologies and tools supporting the validation, evaluation, and comparison of: (1) models, mechanisms, policies, and protocols of the agents involved in such e-marketplaces; and (2) aspects concerned with the overall complex dynamics of the e-marketplaces.

The use of such methodologies and tools can actually provide the twofold advantage of:

1. analyzing existing e-marketplaces to identify the best reusable solutions and/or identify hidden pitfalls for reverse engineering purposes; and
2. analyzing new models of e-marketplaces before their actual implementation and deployment to identify, *a priori*, the best solutions, thus saving reverse engineering efforts.

This article presents an overview of an approach to the modeling and analysis of agent-based e-marketplaces (Fortino, Garro, & Russo, 2004a, 2005). The approach centers on a Statecharts-based development process for agent-based applications and systems (Fortino, Russo, & Zimeo, 2004b) and on a discrete event simulation framework for mobile and multi-agent systems (MAS) (Fortino et al, 2004a). A case study modeling and analyzing a real consumer-driven e-commerce service system based on mobile agents within an agent-based e-marketplace on the

Internet (Bredin, Kotz, & Rus, 1998; Wang, Tan, & Ren, 2002) is also described to demonstrate the effectiveness of the proposed approach.

BACKGROUND

In a broad sense, an agent is any program that acts on behalf of a (human) user (Karnik & Triphati, 1998). An agent can just sit there and interact with its environment and with other agents through conventional means, such as local/remote procedure calls and asynchronous messaging, or through more advanced coordination infrastructures such as *tuple* spaces and *event*-based systems. Agents that do not or cannot move are called "stationary agents." Conversely, a mobile agent is a program that represents a user in a computer network and can migrate autonomously from node to node to perform some computation on behalf of the user. Thus mobility is an orthogonal property of agents—that is, not all agents are mobile. Also mobile agents can interact with their environment and, notably, with other agents through mobility-aware and mobility-unaware infrastructures (Fortino & Russo, 2005). Indeed, the emergence of mobile agents was motivated by the benefits they provide for creating distributed systems. In fact, as Lange and Oshima (1999) pointed out in their seminal paper, there are at least seven good reasons to employ mobile agents: reduction of network load, overcoming of network latency, encapsulation of protocols, asynchronous and autonomous execution ("dispatch your agents, shut off your machine"), dynamic adaptation, seamless system integration, and robustness and fault-tolerance.

An agent-based e-marketplace (AEM) is a distributed multi-agent system formed by both stationary and mobile agents which provide e-commerce services to end-users within a business context. AEMs are, as previously pointed out, distributed large-scale complex systems which require tools which are able to analyze not only the AEM at the *micro* level (i.e., behaviors and interactions of their constituting agents), but also the AEM at the *macro* level (i.e., the overall AEM dynamics).

In Griss and Letsinger (2000), an agent-based framework for e-commerce simulation games has been developed by using *Zeus*, a Java-based multi-agent system developed at the British Telecom Lab. Its goal is to evaluate the potential consequences of novel combinations of market models, business strategies, and new e-services through multi-player shopping games, in which agents represent various typologies of sellers, buyers, brokers, and services.

In Wang et al. (2002), an infrastructure for Internet e-marketplaces based on the *Aglets* mobile agents that enables real commercial activities by consumers, agents, and merchants, has been proposed. Its goal is not only to provide an advanced e-commerce service, but also to evaluate several dispatching models for mobile agents.

Bredin et al. (1998) describe a simulated environment for mobile agents which allows analyzing the market-based resource control system of the *D'Agents* mobile agent system and, in particular, the resource allocation mechanism of its resource manager using a sealed-bid, second-price auction policy.

Although useful insights about AEM micro and macro levels can be acquired by playing e-commerce simulation games and, then, analyzing the obtained results, or by evaluating real e-commerce applications, discrete event simulators are essential for evaluating how AEMs work on scales much larger than that achievable in games or in applications which involve humans. In fact, discrete event simulation is currently extensively exploited as a strategic tool in most research and application areas which are directly or indirectly related to computer science. In this context, the article proposes an approach based on discrete event simulation and shows its application to the analysis of micro-level issues of a consumer-driven AEM: validation and evaluation of services based on mobile agents for product searching and buying.

MODELING AND ANALYSIS OF MOBILE AGENT-BASED SYSTEMS

The StateCharts-Based Approach for Modeling and Analysis

The proposed approach (Fortino, Garro & Russo, 2005) consists of the following phases: high-level modeling, detailed design, and coding and simulation (see Figure 1).

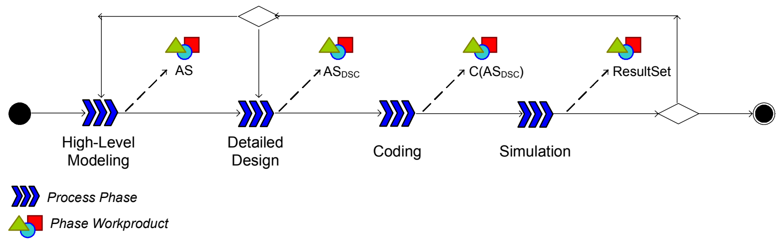
The *High-Level Modeling* of an agent-based system can be supported through well-established agent-oriented methodologies (such as the Gaia methodology; Wooldridge, Jennings, & Kinny, 2000) which cover the phases of requirements capture, analysis, and high-level design. An agent-based system (AS) can be modeled as follows:

AS = <AT, LCL, act, ser, pro>,

where:

- AT (Agent Types) is the set of types of agents embodying activity, offering services, and interacting with each other.
- LCL (Logical CommunicationLinks) is the set of logical communication channels among agent types which embody interaction protocols.

Figure 1. Phases and work products of the proposed approach



act: $AT \rightarrow$ *activity description* is the activity relation which associates one or more activities to an agent type.
ser: $AT \rightarrow$ *service description* is the service relation which associates one or more services to an agent type.
pro: $LCL \rightarrow$ *interaction description* is the protocol relation which associates an interaction protocol to a logical communication channel.

The *Detailed Design* of an AS is achieved through a Statecharts-based formalism, namely Distilled StateCharts (DSC) (Fortino et al., 2004b), which allows for the specification of the behavior of the agent types and the interaction protocols among the agent types. In fact, a Statecharts-based specification of an entity describes both internal behavior and coordination through the reception and generation of events (Harel & Gery, 1997). DSC allow for the specification of the behavior of lightweight agents which have the following features: event-driven, single-threaded, capable of transparent migration, and executing chains of atomic actions. The DSC-based specification of an AS (AS_{DSC}) can be expressed as follows:

$AS_{DSC} = \{Beh(AT_1), \ldots, Beh(AT_n)\}$,
where:
$Beh(AT_i)$ is the DSC-based specification of the behavior of the i-th agent type.
$Beh(AT_i) = <S_{Beh}(AT_i), E_{Beh}(AT_i)>$, where $S_{Beh}(AT_i)$ is a hierarchical state machine incorporating the activity and interaction handling of the i-th agent type and $E_{Beh}(AT_i)$ is the related set of events to be handled triggering state transitions in $S_{Beh}(AT_i)$.

The *Coding* of an AS_{DSC}, $C(AS_{DSC})$, is carried out through the Java-based Mobile Active Object (MAO) Framework (Fortino et al., 2004b). In particular, $Beh(AT_i)$ can be seamlessly translated into a composite object (called MAOBehavior object), which is the object-based representation of $S_{Beh}(AT_i)$, and into a set of related event objects representing $E_{Beh}(AT_i)$.

Finally, the *Simulation* phase of AS_{DSC} is supported by a Java-based discrete event simulation framework for distributed agent systems. The framework provides:

1. *Basic Simulation Objects*:
- **Agent (Ag):** Represents a stationary or a mobile agent and includes a pair of objects: <MAOId, MAOBehavior>, where MAOId is the unique agent identifier and MAOBehavior is an agent behavior object.
- **Event (Evt):** Represents the event for intra- and inter-Ags interactions.
- **AgentServer (AgS):** Represents the agent server hosting **Ag**s.
- **VirtualNetwork (VN):** Represents the logical network of hosts on which **AgS** are mapped.
- **UserAgent (UA):** Represents a user, directly connected to an **AgS**, who can create, launch, and interact with **Ag**s.

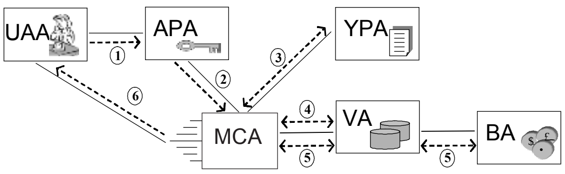
2. A *Simulation Engine* Enabling:
- execution of **Ag**s by interleaving their **Evt**s processing;
- transmission of **Evts** among **Ag**s; and
- migration of **Ag**s.

On the basis of the framework, a simulator program can be implemented and executed to obtain a ResultSet containing validation traces and performance parameter values. While the validation of agent behaviors and interactions is carried out on execution traces automatically generated, the performance evaluation relies on the specific agent-based system to be analyzed; the performance evaluation parameters are therefore set ad-hoc. The ResultSet can also be used to feed back the high-level modeling and detailed design phases.

A Consumer-Driven Agent-Based E-Marketplace

A consumer-driven e-marketplace is an e-marketplace in which the exchange of goods is driven by the consumers

Figure 2. The reference consumer-driven agent-based e-marketplace model: the types of agents, the logical communication links among them, and the sequence of agent interactions



that wish to buy a product. The modeled AEM, inspired by the systems presented in Bredin et al. (1998) and Wang et al. (2002) consists of a set of stationary and mobile agents (see Figure 2) which provides basic services for the searching, buying, selling, and payment of goods.

The identified types of agents are:

- **User Assistant Agent (UAA):** Associated with users and assists them in: (1) looking for a specific product that meets their needs; and (2) buying the product according to a specific buying policy.
- **Access Point Agent (APA):** Represents the entry point of the e-marketplace. It accepts requests for buying a product from a registered UUA.
- **Mobile Consumer Agent (MCA):** Represents an autonomous mobile agent dealing with the searching, contracting, evaluation, and payment of goods.
- **Vendor Agent (VA):** Represents the vendor of specific goods.
- **Yellow Pages Agent (YPA):** Represents the contact point of the distributed Yellow Pages Service (YPS) providing the location of agents selling a given product. The organization of the YPS can be: (1) *Centralized* (C), where each YPA stores a complete list of Vendor Agents; (2) *One Neighbor Federated* (1NF), where each YPA stores a list of VAs and keeps a reference to only another YPA; or (3) *M-Neighbors Federated* (MNF), where each YPA stores a list of VAs and keeps a list of at most M YPAs.
- **Bank Agent (BA):** Represents a reference bank supervising money transactions between MCAs and VAs

The identified types of interactions between the agent types are described below by relating them to the system workflow triggered by a user's request (see Figure 2):

1. **Request Input (UAA $\rightarrow$ APA):** The UAA sends a request to the APA containing a set of parameters selected by the user for searching and buying the desired product—that is, the product description (*Prod_Desc*), the maximum product price (P_{MAX}) the user is willing to pay, and the type of buying policy (*BP*).
2. **Service Instantiation (APA$\rightarrow$ MCA):** The APA creates a specific MCA and provides it with the set of user parameters, the type of searching policy (*SP*), and the location of the initial YPA to be contacted. Upon creation, the MCA moves to the initial YPA location.
3. **Searching (MCA$\rightarrow$YPA):** The MCA requests a list of locations of VAs selling the desired product to the YPA. The YPA replies with a list of VA locations and, possibly, with a list of linked YPA locations.
4. **Contracting & Evaluation (MCA$\rightarrow$VA):** The MCA interacts with the found VAs to request an offer (P_{offer}) for the desired product, evaluates the received offers, and selects an offer, if any, for which the price is acceptable (i.e., P_{offer}<=P_{MAX}) according to the type of *BP*.
5. **Buying (MCA $\rightarrow$ VA $\rightarrow$ BA):** The MCA moves to the location of the selected VA and pays for the desired product using a given amount of e-cash (or bills) triggering the following money transaction: (a) the MCA gives the bills to the VA; (b) the VA sends the bills to a BA; (c) the BA validates the authenticity of the bills, disables them for re-use, and, finally, issues an amount of bills equal to that previously received to the VA; and (d) the VA notifies the MCA.
6. **Result Report (MCA $\rightarrow$ UAA):** The MCA reports the buying result to the UUA.

Analysis of Mobile Agent-Based Services

A model of MCA is defined on the basis of the tuple:

<*SP*, *BP*, *TEM*>,

where:

- *SP* is a searching policy in {ALL, PA, OS}:
  (a) ALL: All YPAs are contacted.
  (b) *Partial* (PA): A subset of YPAs are contacted.

(c) *One-Shot* (OS): Only one YPA is contacted.

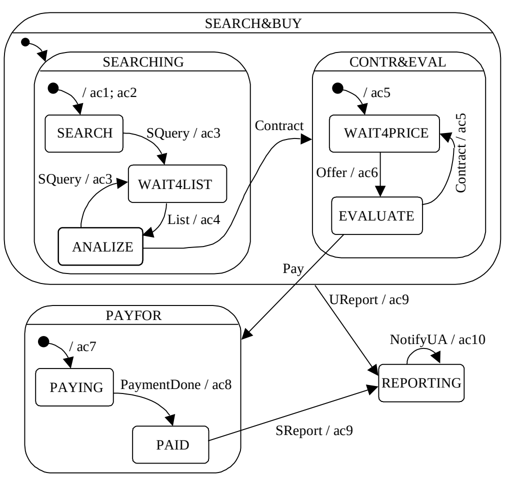
- *BP* is a buying policy in {MP, FS, FT, RT}:
  (a) *Minimum Price* (MP): The MCA first interacts with all the VAs to look for the best price of the desired product; then, it buys the product from the VA offering the best acceptable price.
  (b) *First Shot* (FS): The MCA interacts with the VAs until it obtains an offer for the product at an acceptable price; then, it buys the product.
  (c) *Fixed Trials* (FT): The MCA interacts with a given number of VAs and buys the product from the VA which offers the best acceptable price.
  (d) *Random Trials* (RT): The MCA interacts with a random number of VAs and buys the product from the VA which offers the best acceptable price.
- *TEM* is a task execution model in {ITIN, PAR}:
  (a) *Itinerary* (ITIN): The *Searching* and *Contracting & Evaluation* phases are performed by a single MCA which fulfils its task by sequentially moving from one location to another.
  (b) *Parallel* (PAR): The *Searching* and *Contracting & Evaluation* phases are performed by a set of mobile agents in a parallel mode. In particular, the MCA is able to generate a set of children (generically called workers) and to dispatch them to different locations; the workers can, in turn, spawn other workers.

Thus, each one of the defined models implements the product buying service differently. Figure 3 shows the generic DSC-based behavior of the MCA models <*,*,ITIN>. For the sake of brevity, the explanation is not given here, but readers unfamiliar with DSC-based programming can refer to Fortino et al. (2004b).

In order to analyze and compare the MCA models, the Task Completion Time (T_{TC}) parameter was defined as follows: $T_{TC} = T_{CREATION} - T_{REPORT}$ where, $T_{CREATION}$ is the creation time of the MCA and T_{REPORT} is the reception time of the MCA report. Accordingly, a simulator program was implemented which allows for computation of T_{TC} for each MCA model by varying the *Yellow Pages* organization, the number of YPAs (N_{YPA}), and the number of VAs (N_{VA}). In particular, the simulation scenario was set up as follows:

- Each stationary agent (UAA, APA, YPA, VA, BA) executes in a different agent server.
- Agent servers are mapped onto different network nodes which are completely connected through links having the same characteristics. The communication delay (δ) on a network link is modeled as a lognormally distributed random variable with a mean, μ, and a standard deviation, σ (Floyd & Paxson, 2001).
- Each UAA is connected to only one APA.
- The price of a product, which is uniformly distributed between a minimum (PP_{MIN}) and a maximum (PP_{MAX}) price, is set in each VA at initialization time and is never changed; thus the VAs adopt a fixed-pricing policy to sell products.

Figure 3. DSC-based behavior of the MCA models <,*,ITIN>*



```
ac1  :nextYP=0;
ac2  :YPATarget=(MAOId)yp.elementAt(nextYP++);
      generate(new Move(self(), YPATarget.getCurrLocation()));
      generate(new SQuery(self()));
ac3  :generate(new VAListQuery(self(), YPATarget, vaListQuery));
ac4  :List reply = (List)mevent;
      Proc proc = processYPAReply(reply);
      if (proc.continueSearching()) ac2();
      else if (proc.noVendors()) sa2();
      else { nextVA=0; sa1(); }
sa1  :VATarget=(MAOId)va.elementAt(nextVA++);
      generate(new Move(self(), VATarget.getCurrLocation()));
      generate(new Contract(self()));
sa2  :generate(new UReport(self()));
ac5  :generate(new PriceQuery (self(), VATarget, priceQuery));
ac6  :Offer offer = (Offer)mevent;
      Eval eval = evaluateVAOffer(offer);
      if (eval.buySoon()) generate(new Pay(self()));
      else if (eval.moveAndBuy()){
       generate(new MAOMove(self(), VATarget.getCurrLocation()));
       generate(new Pay(self()));
      }
      else if (eval.noBuy()) sa2();
      else sa1();
ac7  :bills = prepareBills(price);
      generate(new PayFor(self(), VATarget, bills);
ac8  :nbills = nbills - eval.price();
      generate(new SReport(self()));
ac9  :generate(new Move(self(), self().getHomeLocation()));
      generate(new NotifyUA(self()));
ac10:reportTR();
```

Figure 4. Task completion time of the MCA models in an e-marketplace with N_{YPA}=10, N_{VA}=80, and YPS=2NFBT

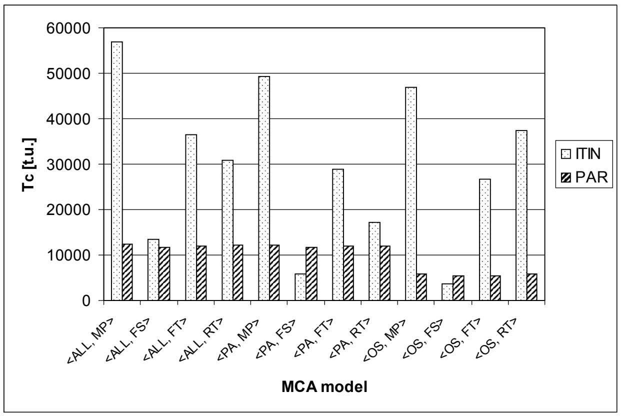


*Figure 5. Performance evaluation of the <ALL, MP, * > models for an e-marketplace with YPS=2NFBT, N_{YPA} ={10, 100}, and variable N_{VA}*

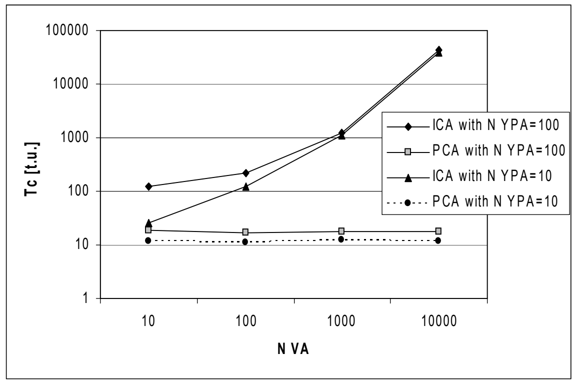

- Each YPA manages a list of locations of VAs selling available products.
- An UAA searches for a desired product, which always exists in the e-marketplace, and is willing to pay a price P_{MAX} for the desired product which can be any value uniformly distributed between PP_{MAX} and $(PP_{MAX}+PP_{MIN})/2$.

Simulations were run by varying (1) the organization of the Yellow Pages (C, 1NF and 2NF organized as a binary tree or 2NFBT), (2) the number of YPA agents in the range [10..1000], and (3) the number of VA agents in the range [10..10000]. These ranges were chosen for accommodating small as well as large e-marketplaces. The duration of the performed simulations were set so to allow for the completion of the buying task carried out by the MCA.

Figure 4 shows the T_{TC} of the <*,*,ITIN> and <*,*,PAR> models in a *medium-sized* e-marketplace with N_{YPA}=10, N_{VA}=80, and YPS=2NFBT. The lowest-performance model is the <ALL,MP,ITIN> model. The <ALL,MP,*> models are the only models guaranteeing both a successful purchase and the best purchase since they are able to find the VA offering the minimum price. The <*,*,PAR> models always outperform the <*,*,ITIN> models, but the <*,FS,*> models where the <*,FS,ITIN> models perform similarly or slightly better than the <*,FS,PAR> models. However, in the latter case, purchase of the desired product at the best price is not guaranteed.

In order to compare the performances of PCA (Parallel Consumer Agent) and ICA (Itinerary Consumer Agent) models, the results obtained for the <ALL, MP, *> MCA models adopting a YPA organization of the 2NFBT type are reported in Figure 5, where results were obtained setting N_{YPA} ={10, 100} and varying N_{VA}. In agreement with the analytical model reported in Wang et al. (2002), the PCA, due to its parallel dispatching mechanism, outperforms the ICA when N_{VA} and N_{YPA} are increased.

FUTURE TRENDS

To date, *Agents* have been employed primarily for product and merchant discovery and brokering (Sierra & Dignum, 2001). The next stage will involve moving into real trading, which will require considerable research and development efforts, including the definition, implementation, and notably, analysis of new products and services such as market-specific shells, payment and contracting methods, risk assessment and coverage, quality and performance certification, security, and trust management.

Moreover, in the very near future, a rapid growth in agent-mediated auctions is expected. Auction is a long-established and well-understood trading mechanism, and the agent technology can be used to develop and support agent-mediated auction houses (Luck et al., 2004).

In order to test these new trading and auction services within large-scale MAS, discrete-event simulation seems to be the most appropriate and reliable tool. Therefore, flexible and robust agent-oriented, discrete-event simulation frameworks must be carefully designed and developed to support analysis of MAS at different levels of granularity: from agent behaviors, protocols, and services (*micro-level*) to global MAS behavior (*macro-level*).

CONCLUSION

Using *agents* to support e-commerce (both B2C and B2B) is considered a key challenge for the agent community. This article has presented an integrated approach which effectively models and analyzes e-commerce services based on *agents*. In particular, a consumer-driven AEM was modeled, and the product searching and buying strategies carried out by the mobile consumer agents in this AEM were analyzed. The consumer-driven AEM model used here was derived from real systems using agent-based e-marketplaces on the Internet (Bredin et al., 1998; Wang et al., 2002). In line with the *future trends* which have been delineated, the proposed approach is being applied to the modeling and analysis of more complex AEMs and related services, and also enhanced by exploiting game theory and economics models.

KEY TERMS

AEM: An agent-based e-marketplace is a distributed multi-agent system formed by stationary and mobile agents which provide e-commerce services to end-users within a business context.

Agent: In a broad sense, any program that acts on behalf of a (human) user.

AMEC: Agent-mediated e-commerce is concerned with providing agent-based solutions which support different stages of the trading processes in e-commerce, including needs identification, product brokering, merchant brokering, contract negotiation and agreement, payment and delivery, and service and evaluation.

Distilled StateCharts: A statecharts-based formalism for lightweight mobile agents.

ebXML: Electronic business XML is an XML-based language and infrastructure which aims at enabling B2B interactions among companies of any size.

E-Marketplace: An electronic marketplace is an e-commerce environment which offers new channels and business models for buyers and sellers to trade goods and services over the Internet.

Mobile Agent: A program that represents a user in a computer network and can migrate autonomously from node to node, to perform a computation on behalf of the user.

E-Commerce Use by Chinese Consumers

University of San Francisco, USA

INTRODUCTION

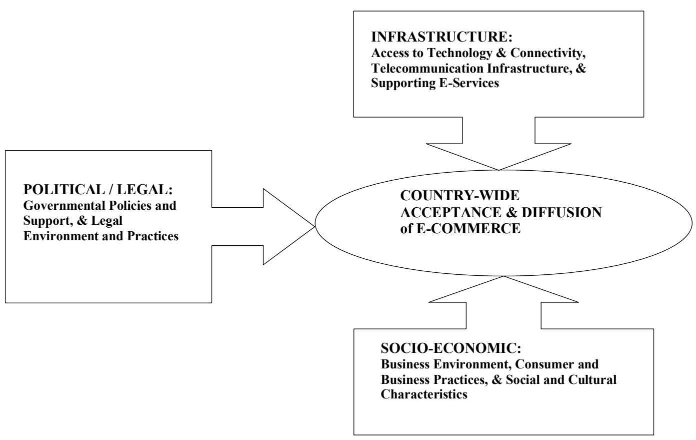
The number of Internet users around the world has steadily grown, and this growth has provided the impetus and the opportunities for global and regional e-commerce. However with the Internet, different characteristics of the local environment, both infrastructural and socioeconomic, have created a significant level of variation in the acceptance and growth of e-commerce in different regions of the world. Over time, various studies have been conducted and models have been developed to identify diffusion of e-commerce in different environments (Hasan & Ditsa, 1999; Travica, 2002; Wolcott, Press, McHenry, Goodman, & Foster, 2001; Zwass, 1999). These models have looked at "infrastructure" (e.g., connectivity hardware and software, telecommunications, product delivery and transportation systems) and "services" (e.g., e-payment systems, secure messaging, electronic markets) as the primary diffusion factors. Furthermore, Travica's (2002) study focused on Costa Rica and its culture, and Hasan and Ditsa (1999) tried to identify and present possible cultural factors that may impact broad-based adoption of information technology.

Industry-based organizations have also been interested in diffusion of e-commerce in different countries and have also identified similar factors, and have rated these countries on their readiness for e-commerce using those factors. Most widely cited of these ratings are presented by IBM and the intelligence unit of *The Economist,* which define e-readiness by measurement in six distinct categories: (a) connectivity and technology infrastructure, (b) business environment, (c) consumer and business adoption, (d) social and cultural environment, (e) legal and policy environment, and (f) supporting e-services. Based on these characteristics, *The Economist* rated China (the country that is the focus of our research) as number 51 for year 2000, number 52 (a tie with Sri Lanka) for year 2004, and number 12 out of 16 nations included in the Asia-Pacific Region. (Economist Intelligence Unit, 2004).

BACKGROUND

In addition to infrastructural and business system issues, trust (termed *transactional trust* in this article) has been identified as one of the critical issues that confront new businesses or businesses that utilize new business models like e-commerce. One of the most widely studied cultural classifications was originally proposed by Hofstede (1980). His cultural framework consists of four dimensions identified as individualism-collectivism, uncertainty avoidance, power distance, and masculinity-femininity. Even though Hofstede's framework was originally developed for national-level analyses, Oyserman, Coon, and Kemmelmeir (2002) have shown that it can also

Figure 1. Influences on diffusion of e-commerce



be applied at individual levels. Further research by Doney, Cannon, and Mullen (1998) and Jarvenpaa, Tractinsky, Saarinen, and Vitale (1999) have suggested that individualism-collectivism effects the ways people form trust and may affect the users' willingness to trust online vendors. Other studies have also tried to find correlations between trust and experience with a new system, concept, or relationships, including a correlation to frequency of e-commerce activity, and other researchers have noted that trust may be significantly influenced by culture of a given society (Lee & Turban, 2001; McKnight & Chervany, 2001; McKnight, Cummings, & Chervany, 1998). Grabner-Kraeuter (2002) observed and stated that trust is "the most significant long-term barrier for realizing the potential of e-commerce to consumers" (p. 49), and others state that trust will be a "key differentiator that will determine the success of failure of many Web companies" (Urban, Sultan, & Qualls, 2000). Other studies by Park (1993) and Keil, Tan, Wei, and Saarinen (2000) focused on the impact of uncertainty avoidance on people's willingness to accept uncertainty, which is an unavoidable foundation of e-commerce.

As my colleagues and I planned our research study, we knew from first-hand experience (I have traveled in China for extended time periods and have experienced local life, customs, culture, and have used the infrastructure) that, in spite of recently increased governmental efforts and investments, the telecommunication and e-commerce infrastructure was not as developed in China as they were in United States or Europe, and we accepted technical and infrastructural limitations to be significant current impediments for broad diffusion of e-commerce in China. We also accepted that, given the accelerated changes that are taking place in China and the continuous investments in e-commerce-related infrastructure, most of the current technical problems and issues will cease to be major impediments. Therefore, we focused on the societal issues and specifically wanted to identify and explore the influence of culture on acceptance and use e-commerce in this developing country (Bond, 1986; Chen, 1993; Moore, 1967). In the following sections, the research and its findings are presented and discussed, the changes that will be required for broader acceptance and diffusion and use of e-commerce by Chinese consumers are identified, and approaches that businesses may use to enhance this development are proposed

RESEARCH STUDY

Our objectives were to find answers to a primary research question and present some possible solutions. Furthermore, by identifying consumers with technological and financial capabilities, we wanted to minimize the impact of technological impediments on usage patterns and frequency and focus primarily on cultural and societal issues and impediments.

1. If the negative impact of technological and transactional impediments can be minimized, what are some of the prevailing attitudes and cultural issues associated with individuals' use of e-commerce in China (identify and test the influence and impact of prominent Chinese cultural characteristics on e-commerce)?
2. What can domestic and foreign businesses do to facilitate e-commerce in China (present some short- and long-run recommendations and approaches to e-commerce development in China)?

To address our research objectives, a 20-item questionnaire was created, developed in English and translated to and administered in Chinese. It contained questions designed to collect information on demographics, Internet usage, and e-commerce activities (frequency of commerce and type of purchase, means used for purchase, transaction experience, and perceptions of e-commerce in China). The questionnaire was administered on site and in groups, and the results were tabulated using the frequency of responses. The results, presented below, are based on the responses received from the study group (some comparative data, from other studies, is also provided and included in the discussion). Some of these responses were provided through the questionnaire and others through follow-up discussions with some members of the study group.

The study group consisted of selected 252 individuals that would be considered to be a close match to e-commerce users in developed countries and were considered to be "early adopters." Because the primary focus was on the "impact of culture." we wanted to get the opinions of actual participants and users of e-commerce and wanted to eliminate the infrastructure problems as much as possible. The study participants resided and worked in different regions and for different types of organizations and had different educational levels, professions, and genders. They held professional supervisory positions in their organizations and had much higher economic means than the average income levels for the local population.

The study participants were asked about their Internet usage to identify their familiarity with technology and their access to Internet, and their e-commerce participation to determine their ability (access to type of medium used for payment) to pay (possession of credit cards) for e-commerce and whether they purchased any goods or services using e-commerce within the previous 12-month period. The respondents (166 out of 252) who indicated

Table 1. Study demographics (n = 252)

GENDER		EDUCATION		AGE		ORGANIZATION		
Male	Female	BS Degree	Graduate	25-40 years	Over 40 years	MNC	DE*	JV
59.92%	40.08%	75.40%	13.49%	75.40%	7.54%	21.03%	63.49%	15.48%
* DOMESTIC ENTERPRISES including Private Enterprises, State Owned Enterprises (SOE), and University; MNC = Multinational Corporation; JV = Joint Venture								

Table 2. Sample population (n = 252) vs. e-commerce participants (n = 166)

	Male*	Age < 36 years*	Education (BS-GRAD)	Have Credit Card	Purchase in 12-mo	Purchase in 6-mo
Total Population (%)	59.92%	79.37%	88.89%	86.51%	64.29%	65.88%
E-Commerce Participants (%)	55.42%	88.55%	88.55%	86.75%	97.59%	100.00%

*Differences not statistically significant.

Bank Transfer	Cash/Check	COD	Credit Card
8.43%	33.13%	39.16%	19.28%

they had purchased goods or services were further asked about the frequency of their transactions during the previous 12- and 6-month time periods, the products or services they purchased, the highest total value of their single purchase, and their payment method (credit cards and other commonly used methods of payment in China) for these purchases. They were also asked to list their primary reasons for utilizing e-commerce and rate their overall satisfaction with the activity, and to provide unstructured comments on what they consider to be impediments to the development of e-commerce in China and Chinese attitudes towards use technology as a means for commerce.

The unstructured section of the questionnaire and the follow-up unstructured interviews were used to further explore and to identify perceptions on positive and negative aspects of e-commerce in China as it currently exits, the future of e-commerce in China, and any other issues that might have been neglected and not categorized and included in the questionnaire. These comments sometimes provided additional information and at other times reinforced the previous responses and strengthened the data collected through other questions.

RESEARCH FINDINGS

The 252 study participants had complete and fairly easy access to Internet enabling technology (e.g., access to a PC and telecommunication connection to an ISP) and used Internet regularly for multiple purposes or activities (e.g., e-mail, search), with 65.88% of the study group participating in e-commerce activities.

As was expected, for the research participants, ability to pay (access to credit cards) was not an impediment to e-commerce (86.51% had credit cards, with 69.84% having two or more credit cards), and there was no correlation between having increased number of credit cards and higher frequency of purchases. Respondents with four or more credit cards constituted 21.03% of total respondents and 21.69% of e-commerce participants. Other credit card ownership ranges also had similar distributions between the study participants vs. e-commerce participants.

The respondents paid for their purchases in four ways: cash or check (travel related purchases were paid at the time of use, e.g., hotel stay), COD, credit card, and bank transfer. As can be seen in Table 3, contrary to purchases made by U.S. consumers, in our study group, credit card purchases were not the most common payment method. This finding is also supported by the latest China Internet Network Information Center (CNNIC) survey, which identifies the top three payment methods as cash and carry (33.1%), online payment (30.7%), and post office transfer (30.0%; CNNIC, 2002; CNNIC, 2003).

With an estimated RMB 410 billion (U.S. $50 billion) in savings stashed away (most of it at homes), China still exhibits the characteristics of a cash society. According to Economist Intelligence Unit (2004), Global Insights and McKinsey China's saving rate for the years 1997 through 2005 is 40.3% (Pitsilis, Woetzel, Woetzel, & Wong, 2004). Our findings support this cultural characteristic. Even though 86.51% of our study group (218 respondents) had credit cards, only 19.28% of the e-commerce participants (32 out of 166 respondents) paid for their purchases using a credit card.

The overall results of our study clearly show that both the economic and infrastructural issues (which we had anticipated and assumed to exist but for which we tested, nevertheless) and culture continue to impede and constrain the development of e-commerce in China. Our findings also reinforced our initial premise that our study group participants were not negatively impacted by technical and infrastructure impediments, and they were much more concerned with and influenced by their culture, while deciding to participate in e-commerce.

Infrastructure and E-Support Impediments to E-Commerce

Even though they were not impacted by it, our study participants nevertheless identified specific infrastructure related impediments that will restrain and be obstacles to full development of e-commerce in China in the near future. Among the most repeatedly mentioned issues were a lack of credit cards (wide availability of them for the general public in China) and convenient payment means; poor distribution logistics; a lack of specialized, trustworthy online merchants of reasonable size (too many small players facing many bottlenecks and without necessary resources to set up e-commerce systems); an imperfect legal system; and a lack of large-scale telecommunication transmission capability (broadband). As users of e-commerce, the primary obstacles for our study group, in the order of importance, were (a) Internet security, (b) lack of feel-and-touch associated with online purchases, (c) problems in returning products, and (d) selection (product availability and breadth).

In spite of the aforementioned concerns, the respondents were reasonably positive about the availability of hardware or software and government and industry support for IT in China, and there is significant other data that support this optimism. The China Center of Information Industry Development (CCID) estimated that desktop PC sales in China would reach 17.4 million units in 2003 and projected an annual growth rate of 18.8% over the next 5 years. If these growth rates are realized, China will become the second largest PC market in the world, surpassing Japan by 2007 (Magee, 2002) These projections were supported by April 2002 Nielsen/NetRatings ranking China at second place with 57 million people having Web access at home, following the United States (166 million), and followed by Japan (51 million), Germany (32 million) and the United Kingdom (29 million). They further projected a 5% to 6% growth rate per month and expected 25% of the population (approximately 250 million people) to have Internet access in just 3 or 4 years (Juliussen, 2002; Rose & Rosin, 2002) Finally, CNNIC (official data collector for the Chinese government) 2003 figures show that 2.1% of China's Web users had bought online (CNNIC, 2002; CNNIC, 2003).

Sociological and Cultural Impediments to E-Commerce

Our study participants were slightly less positive when asked if the Chinese culture "supports" the propagation of IT and e-commerce. The group thought the Chinese consumer society was not quite ready for e-commerce and the conditions were not "ripe" (lack of confidence in technology and off-site transactions, online culture, and overall sophistication of the general public). They were especially concerned with issues related to "trust." The study participants were in agreement when it came to the potential for e-commerce but stated that the industry needs time to realize its potential in China.

Doney et al. (1998) argued that people in collectivist cultures (China is classified as a collectivist culture in Hofstede, 1991 are more likely to form trust based on prior experiences or opinions of their in-group members. According to Wong and Tam (2000), in societies with little history of formal legal contracts, trust-based relationships are the only way of doing business and strangers are not to be trusted. For the Chinese, a strong individual relationship and long-term association between the parties, *guanxi*, provide a sense of community and enhances social bonding. (Davies & Lsung, 1995) and this "social bonding" acts as the foundation of trust between the sellers of products and services and the consumers of such. It is very hard to develop a similar socioeconomic entity using e-commerce, which is primarily based on a business model and a process that brings anonymity and distances the vendor from the customer and depersonalizes the relationship between the sellers and the buyers of the product or service. Our research findings also show that "transactional trust" and related issues are major concerns for Chinese consumers conducting online transactions. Our respondents complained about existence of trust-worthy online merchants, and Internet security and credit card security. They were as wary of counterfeit products as western consumers are. As one Chinese gentleman put it "History and reality told us not to trust the system or the people's honor! E-commerce is a radical behavior that goes contrary to experience and culture. There is no 'western honor system' in China."

FUTURE TRENDS

The state of infrastructure and the unique cultural characteristics of a given country can and will act as major impediments to full-scale consumer participation in e-commerce in that country. In China, among the most pressing infrastructure limitations were broad access to technology (computers, connectivity, and gateway to the Internet), payment systems for enabling transfer of funds (wide availability of credit cards), and distribution systems for physical transfer of goods, and cultural impediments as attitudes towards off-site or depersonalized transaction systems, and level of trust in public institutions and commercial activity.

In my opinion, the unique social and cultural characteristics of China and the concepts associated with off-site exchange systems, as compared to infrastructure related limitations, pose a much greater challenge and act as the major impediments to diffusion and broad acceptance of e-commerce in China. Even though off-site exchange systems that are precursors to e-commerce, such as catalog and telephone sales, have existed in developed countries and have been used by the public for an extended time period, such systems are new and novel approaches in China, in many other developing countries, and may not be as suitable to its culture and way of doing business. Since the business foundation of e-commerce is based on such a methodology, some of these local cultural characteristics do pose significant challenges for the e-commerce industry in China. This study was an attempt to identify and to understand the possible influences of unique cultural characteristics of e-commerce in one developing country. The findings show that, even though a developing country government may make the necessary investments in infrastructure (as China has done to a significant degree), unless the e-commerce industry participants understand and address the cultural issues that are unique to that country and relate to off-site transactional process, the large scale diffusion and success of such endeavors will be greatly impeded.

CONCLUSION

Businesses, to overcome these infrastructure and cultural impediments, should take a more active role to bring about a broad-based consumer society, encourage the Chinese government to institute reforms that enhance the economic system (legal changes that support business contracts, discourage counterfeiting, and encourage consumer credit and servicing by the banking industry, built telecommunication and transportation infrastructure, etc.). However, they might not have much choice but to wait for more profound cultural changes to take hold (with the help of governmental actions and increasingly higher living standards) and, as they do, can utilize business processes that will enable and encourage e-commerce. Given the current stage of China's socioeconomic state and prevailing governmental processes, a combination business model (virtual and physical presence) may be the only way for businesses to participate in e-commerce in China.

A virtual storefront supported by a local distribution center will overcome the "touch-and-feel" concern and the lack of "transactional trust" (Zhao, 2004, personal communicatin). It will also help develop a physical relationship between the two parties (buyer and the virtual seller) involved in the transaction, addressing and taking advantage of another additional unique characteristic of Chinese business and transaction culture, *guanxi*, development of long-lasting business relationship. The face-to-face relationship, made possible by utilizing the local distribution center, will enable the economic enterprises to develop new or even deeper relationships between the various parties involved in the exchange.

Chinese people place a great deal of emphasis on uncertainty avoidance (Hofstede's 1991 classification) and spend a great deal of time planning in order to reduce even the smallest risk. This desire for stability also means Chinese consumers tend to prefer to deal with older, more well-established firms than newer ones. Chinese view age as valuable and (Schutte & Ciarlante, 1998) older firms and businesses tend to be viewed as having proved themselves over a period of time, and since they have survived, they have obviously delivered on their promises to customers. It is very hard for new companies or new exchange models to gain foothold and sustainability in local communities. Therefore, I suggest that the companies that never have had any local physical presence, new entrants, employ a "third party certification" or a "guarantee system supported by local government or business" to overcome the major transactional trust issue that is a profound characteristic of this culture.

KEY TERMS

Cultural Dimensions: Identifying and classifying social foundations of a country using Hofstede's (1980) model.

Digital Economy: Economic system using Internet and technology for business transactions.

Electronic Commerce: Business-to-consumer exchange systems using virtual storefronts.

Online Shopping: Consumers using virtual storefronts and Internet to buy goods and services.

Technology Diffusion: Pervasive application and use of technology in everyday life.

Transaction Trust: Trust-based exchanges between buyers and sellers of products and services. "Relational trust" as defined by Rousseau, Sitkin, Burt, and Camerer (1998) applied to commerce.

Virtual Storefront: A commercial enterprise using Internet and web servers to sell products or services.

E-Customer Loyalty

Alvin Y. C. Yeo
University of Western Australia, Australia

Michael K. M. Chiam
Ngee Ann Polytechnic, Singapore

INTRODUCTION

Increasingly, businesses are beginning to understand the profit potential of loyal customers (Oliver, 1999). Marketers endowed with such consumers can expect repeat patronage to remain high until competitors can find a way to: (1) close the gap in attitude among brands, (2) increase the differentiation of their own brand, or (3) encourage spurious loyalty from consumers (Dick & Basu, 1994). Loyalty leads to higher retention. According to one study, a 5% increase in customer retention rates increases profits by 25% to 95% (Reicheld & Schefter, 2000).

It is thus heartening to note that "one of the most exciting and successful uses of [the Internet] … may be the Internet's role in building customer loyalty and maximizing sales to your existing customers" (Griffin, 1996, p. 50). Given its relative importance in cyberspace, it is surprising that relatively little has been done in conceptualizing and validating e-loyalty models (Luarn & Lin, 2003).

Parasuraman and Grewal (2000) argue for more research pertaining to the influence of technology on customer responses, such as perceived value and customer loyalty. Besides customer trust, our study also incorporates two constructs—corporate image and perceived value—that have been poorly explored in online environments despite their recognized importance in off-line contexts.

Consequently, a primary objective of this article is to discuss the impact of three constructs (i.e., customer trust, corporate image, and perceived value) on e-loyalty in a business-to-consumer (B2C) e-commerce context. In doing so, our model is expected to offer useful suggestions on how to manage customer trust, corporate image, and perceived value as online loyalty management tools.

This article is generally divided into three sections. The first section will discuss the constructs of interest and clarify what they mean. In the second section, we will propose hypotheses explaining these relationships. And in the final section, we introduce actionable strategies for online loyalty management based on the proposed framework.

BACKGROUND

Customer Loyalty

In research conducted in the 1960s and 1970s, customer loyalty was interpreted as a form of customer behavior (i.e., repeat purchasing) directed toward a particular brand over time. However, Day (1969) criticizes behavioral conceptualizations and argues that loyalty has an attitudinal component.

More recently, Morgan and Hunt (1994) defined loyalty as an ongoing relationship with another that is so important as to warrant maximum efforts at maintaining it which implies strong affective and behavioral commitment to the company. In this chapter, consistent with Oliver (1999), e-loyalty herein is defined as a deeply held intention to repurchase a preferred product/service consistently from a particular e-vendor in the future, despite the presence of factors or circumstances that may induce switching behavior.

Customer Trust

Online markets are different from the traditional brick-and-mortar marketplaces, owing to the lack of face-to-face personal contact and the opportunity for buyers to see products physically. There are inherent risks in trading online because of information asymmetry. All these factors make trust crucial to e-commerce because it lowers transactions risks. As a result, it puts pressure on online marketers to nurture stronger feelings of trust than is required in off-line environments (Keen, 1997).

In this study, we adopted a parsimonious definition, in tandem with Gefen, Karahanna, and Straub (2003). E-trust is defined herein as a set of specific beliefs dealing primarily with integrity (trustee and honesty and promise keeping), benevolence (trustee caring and motivation to act in the truster's interest), competence (ability of trustee to do what truster needs), and predictability (trustee's behavioral consistency of a particular e-vendor).

Corporate Image

A growing number of companies have tried to position themselves through the communication channel with the objective of building strong corporate images in order to create relative attractiveness (Andreassen & Lindestad, 1998). A favorable image is a powerful tool not only for encouraging customers to choose the company's products and services, but also for improving their attitudes and levels of satisfaction toward the company (Aaker, 1992, p. 16).

A review of the literature, however, reveals scant research on the concept of corporate image in online environments. Much of the traditional research, however, focuses on products (e.g., Darden & Schwinghammer, 1985) or services (Gronroos, 1990) in off-line environments. There is an urgent need for more of such research that explores this concept better as it applies to online environments. Customers are often overwhelmed with a variety of offerings on the Internet; as a result they base their decision on global judgments, such as store image and reputation (Teas & Agarwal, 2000).

In consonance with definitions by Barich and Kotler (1991), corporate e-image is defined in this article as an overall impression held of an e-vendor by its customers at a particular point in time. This, in turn, is the net result of consumers' experiences with an organization, both online and off-line, and from the processing of information on the attributes that constitute functional indicators of image.

Customer Value

The inclusion of the value construct in our model is important for several reasons. First, recent research revealed that more that 70% of customers feel they gain nothing by being loyal to a company (Gillespie, 1999) and, therefore, would move if perceived benefits were greater elsewhere. This makes understanding what buyers value within a given offering, creating value for them, and then managing it over time, essential elements of every market-oriented firm's core business strategy (Slater & Narver, 1998).

Second, Helm and Sinha (2001) argue for the importance of delivering customer value in electronic B2C operations. However, there has been little empirical research to develop an in-depth understanding of the concept (Sweeney & Soutar, 2001). Fewer studies still (e.g., Chen & Dubinsky, 2003) have examined this construct in the context of online environments. Finally, to the best of our knowledge, there seems to be no research that has captured the relationships between corporate image, customer trust, and perceived value in a single integrative framework.

Based on a synthesis of previous definitions (Chen & Dubinsky, 2003; Woodruff, 1997), perceived customer value is defined here as a consumer's perception of the benefits gained in exchange for the costs incurred to attain his/her goals at a particular point in time.

A PROPOSED MODEL FOR BUSINESS-TO-CONSUMER E-COMMERCE

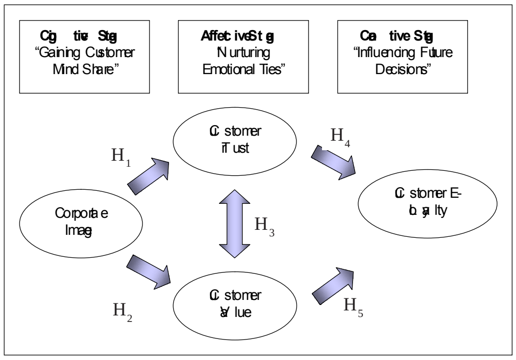
Consumers rely heavily on the online vendor's image as a proxy for trustworthiness (Lee & Turban, 2001). This is because of the lack of intrinsic product cues that are generally used to evaluate quality. Indeed, Yoon (2002) found that Web site trust is significantly related to corporate awareness and image. We thus posit that: *Corporate image leads to customer trust (H_1).*

Chen and Dubinsky (2003) reported that online retailer image is a forward indicator of value in the online context. This is corroborated by Strader and Shaw (1999) who found that in e-marketing, unless a seller's price is significantly lower than prices of a trusted seller, switching costs will inhibit the consumer from buying from the unknown e-seller. Thus, we argue that: *Corporate image leads to perceived value (H_2).*

Meanwhile, Sirdeshmukh, Singh, and Sabol (2002) suggested that perceived value is an important partial mediator of the trust-loyalty relationship. Customer relationship value may only develop when the customer has "confidence in an exchange partner's reliability and integrity" (Morgan & Hunt, 1994, p. 23). Safety, credibility, and security are important to reduce the sacrifice for the customer in a relationship and therefore lead to higher e-relationship value. Hence, we postulate that: *Customer trust leads to perceived value (H_3).*

Finally, Hoffman and Novak (1996) argued that the likelihood of Internet product purchase is influenced by the amount of consumer trust regarding the delivery of goods and use of personal information. Trust influences loyalty by affecting the consumer's perception of congruence in values with the good/service provider (Gwinner, Gremler, & Bitner, 1998). Also, when there is perceived similarity in values between the firm and the consumer, the consumer is more entrenched in a relationship. This is also evidenced in research by Gefen (2000) which showed that customer trust has a positive effect on e-adoption intention. We thus propose that: *Customer trust leads to e-customer loyalty (H_4)* and *Perceived value leads to e-customer loyalty (H_5).*

Figure 1. An integrative framework for understanding e-customer loyalty



These relationships are captured in a conceptual model in Figure 1.

REALIZING E-CUSTOMER LOYALTY: RECOMMENDATIONS

This next section suggests three strategies to attain the "Tao of Loyalty" through effective management of each of the three constructs of interest:

1. Build Trust
2. Realize Corporate Image Equity
3. Provide Customer Value

Build Trust

We argue that efforts to build trust should focus on three areas—transactional security trust, information privacy trust, and exchange trust—each with its own function in motivating consumer participation in exchange.

Transactional security trust refers to: (1) the customers' belief about the e-tailer's expertise in providing a secure shopping environment, and (2) the consumer's expectation about an e-tailer's ability to protect his/her information from unauthorized access by third parties (i.e., hackers). To assuage customers on this aspect, firms should put in place reliable control systems that can be easily understood by customers. Expedia.com, an online travel agency, explains to its customers that when personal information is sent over the Internet, their data is protected by Secure Socket Layer (SSL) technology to ensure safe transmission.

Like transactional security trust, *information privacy trust* is conceptualized in terms of two dimensions—unauthorized tracking and unauthorized information dissemination—that refer to an e-tailer's privacy protection responsibilities. Research has shown that fairness of a company's Web site with respect to information privacy is a significant factor in building trust and in ensuring the continuation of the relationship with the e-retailer (Culnan & Armstrong, 1999). For example, Expedia has an extensive privacy policy that is audited by an external audit firm, PricewaterhouseCoopers LLP.

Exchange trust is defined in terms of competence and benevolence as they apply to an e-tailer's promise fulfillment function (Sirdeshmukh et al., 2002). Specifically, exchange trust is customer confidence that the e-tailer: (a) will fulfill its transaction-specific obligations consistent with the terms of the purchase agreement or other internally held reference standards developed as a result of interaction with other e-tailers or non-store retailers (competence), and (b) will not engage in opportunistic behavior at any time in the process of product or service delivery (benevolence). A type of services, online virtual community is emerging to mitigate exchange risks. One of the better-known ones, eBay's Feedback Forum, provides information on sellers' reputations, based on feedback from previous trades. Traders having high reputation may enjoy price premiums in online market competitions.

Realize Corporate Image Equity

Having a Web site is important for brand building and creating a favorable corporate image (Farr, 1999). However, that alone is not sufficient.

First, firms should strive to create a strong Internet identity through a distinctive personality, recognizing that a company's name identifies it to outside observers (Aaker, 1992). For example, Tiffany, the well-known jewelry retailer, invested substantially in digital imaging technology to ensure that all images of jewelry on its Web site are presented using high-quality graphics. The overall impact of the Web site reinforces Tiffany's reputation as a prestigious, high-quality retailer.

Second, firms should ensure there is sustained buzz about the firm's presence. Many online firms use banner advertisements, pop-up windows, and mass e-mails to promote their products. Advertising directly confers brand and product information to consumers, and it serves to increase consumers' awareness and knowledge of a particular brand (Vakratsas & Ambler, 1999). High levels of advertising expenditures send a strong signal about a firm's commitment to quality (Shapiro, 1983). For example, Amazon.com invests more than 23% of its revenues in advertising, thus making it one of the most well-known companies in the online book retail business. However, marketers should be careful that the buzz does not degenerate into advertising clutter (i.e., excessive advertising) which erodes the overall effectiveness of advertising.

Finally, firms should strive to earn a reputation for being innovative. Generally, research has found that early movers enjoy initial and sustain continuous market share advantages. For example, Robinson and Fornell (1985) suggested that being a pioneer or product leader gives consumers a favorable image and higher familiarity on the firm's products. Examples of online firms that attain such leadership include Priceline.com, which pioneered the "name your own price" practice in its travel booking service, and eBay, which introduced the proxy bidding technology and feedback mechanism in its Internet auction business.

Create Value Experiences Online

In this section, actionable strategies relating to two important areas—target marketing and enriching the customers' online experience—will be discussed.

Target Marketing

A thorough understanding of one's target audience is critical. With a better understanding of the target market, businesses will be able to better design their Web sites to match preferences of their target groups. Two crucial areas need to be addressed: (1) How do customers make purchasing decisions?, and (2) "What information do they need in making that decision?" Wine.com, a leading purveyor of wine and gourmet products, originally believed that its core customers were wine connoisseurs. A careful assessment of online data revealed that its best customers were wine novices. With this knowledge, Wine.com significantly modified its Web site to deliver the features these less-experienced consumers wanted—recommendations and educational content.

Enriching the Customers' Online Experience

The natural question, once marketing managers know who their best customers are, is how to enrich these customers' overall experience. One suggestion marketing managers may want to focus their efforts on is customization. Customization increases the probability that customers will find something that they wish to buy, creates the perception of increased choice by enabling a quick focus on what the customer really wants (Shostak, 1987), signals high quality (Ostrom & Iacobucci, 1995), and drives customers to use simplistic decision rules to narrow down the alternatives (Kahn, 1998). In this respect, customization has often been regarded as one of the essential determinants of customer loyalty (Reynolds & Beatty, 1999).

FUTURE TRENDS

To enable more compelling value propositions to be crafted, future research could examine the moderating effects of consumer attributes like involvement and affect on the model. For example, depending on the level of involvement, consumers may be passive or active when receiving advertising communication, which in turn could moderate their perceptions of value and trust levels. Empirical comparison between different cultures could also be collated for greater generalizations of the proposed model.

CONCLUSION

Marketers are perpetually seeking to increase customer loyalty, which perhaps is the only source of sustainable competitive advantage in the coming decade for many a firm. This article suggests strategies for firms to develop an e-customer relationship orientation and improve e-customer loyalty. In this aspect, corporate image, customer trust, and customer value were found to be important drivers of e-customer loyalty. It is hoped that the accompanying suggested strategies would enable marketing managers to craft even more compelling value propositions and effective marketing-mix strategies.

KEY TERMS

Corporate E-Image: An overall impression held of an e-vendor by its customers at a particular point in time. This, in turn, is the net result of consumers' experiences with an organization, both online and off-line, and from the processing of information on the attributes that constitute functional indicators of image.

E-Loyalty: A deeply held intention to repurchase a preferred product/service consistently from a particular e-vendor in the future, despite the presence of factors or circumstances that may induce switching behavior.

E-Trust: A set of specific beliefs dealing primarily with integrity (trustee and honesty and promise keeping), benevolence (trustee caring and motivation to act in the truster's interest), competence (ability of trustee to do what truster needs), and predictability (trustee's behavioral consistency of a particular e-vendor).

Exchange Trust: Customer confidence that the e-tailer: (a) will fulfill its transaction-specific obligations consistent with the terms of the purchase agreement or other internally held reference standards developed as a result of interaction with other e-tailers or non-store retailers (competence), and (b) will not engage in opportunistic behavior at any time in the process of product or service delivery (benevolence).

Information Privacy Trust: Unauthorized tracking and unauthorized information dissemination—that refer to an e-tailer's privacy protection responsibilities.

Perceived Customer Value: A consumer's perception of the benefits gained in exchange for the costs incurred to attain his/her goals at a particular point in time.

Transactional Security Trust: The customers' belief about the e-tailer's expertise in providing a secure shopping environment; also, the consumer's expectation about an e-tailer's ability to protect his/her information from unauthorized access by third parties (i.e., hackers).

INTRODUCTION

Technology increasingly pervades the business world and society generally. According to Walters (2004, p. 219) "markets have globalized, technology has become all embracing, and relationships with suppliers, customers, and competitors are undergoing constant change." These developments potentially raise considerable opportunities for small and medium enterprises (SMEs)[1] to enter into the global marketplace and form "partnerships" including alliances, networks, and collaborative commerce (c-commerce) (Jarrett, 1998). Though exemplars of c-commerce exist in Australia, it has not been widely adopted by SME's.

Generally, Australian SMEs have been slow to adopt any form of electronic commerce. The primary reason given for lack of adoption amongst many small businesses is that they see no real benefit in having a Web presence, that is they perceive their businesses to be too small, or they had not factored in the on going maintenance of Web pages (ABS, 2003; van Beveren & Thomson, 2002). Fear of the unknown and lack of skills have also been suggested as reasons why the uptake of technology is less for small businesses (Barry & Milner, 2002; Darch & Lucas, 2002).

If firms have been slow to embrace e-commerce, then it could explain the slow uptake of c-commerce. This article looks beyond e-commerce and suggests framework to explain c-commerce adoption.

BACKGROUND

C-commerce consists of all of an organization's information technologies (IT) bases, knowledge management, and business interactions with its customers, suppliers, and partners in the business communities in which it interacts (McCarthy, 1999; GartnerGroup, 1999; Burdick, 1999) and can be horizontal competitive cooperation or co-opetition (Levy, Loebbecke, & Powell, 2003), as well as vertical collaboration along a supply chain. Essentially this means that firms, including competitors, come together to exploit an opportunity that arises, as and when appropriate.

C-commerce signifies an organizational shift in focus from transactions and exchange, characteristic of e-commerce, to one of relationships between firms (Sheth, 1996). As global competition intensifies many organizations are forming partnerships as an expeditious way to keep up or to access unique or "pioneering" resources (Ring & Van de Ven, 1992, 1994).

Benefits of C-Commerce for SMEs

C-commerce is concerned with obtaining sustainable competitive advantage from the maximization of value adding benefits obtained by working collaboratively with others via IT. The adoption of IT has been identified as a possible source of strategic competitive advantage for SMEs (Yetton, Johnston, & Craig, 1994), collaboration using IT can generated innovation resulting in further competitive advantage (Ryssel, Ritter, & Germunden, 2004).

SMEs are better able to compete in an increasingly dynamic marketplace via the exploitation of the advantages of the Web (Grover, Teng, & Fiedler, 2002). C-commerce enables small firms to "grow" their assets, which is important for Australian SMEs due to their size and access markets not previously possible (Holsapple & Singh, 2000; Ring & Van der Ven, 1994; Tetteh, 1999;). C-commerce also facilitates innovation and information, knowledge, and systems sharing and exchange (Holsapple & Singh, 2000). Internal efficiencies can be generated by the sharing of information via IT within interorganizational relationships (IORs) (Ryssel, et al., (2004). Bitici, Martinez, Albores, & Parung (2004, p. 266) concluded that collaborative enterprises or networks "create new and unique value propositions by complementing, integrating, and leveraging each other's capabilities and competencies."

To enable SMEs to make the most of the opportunities afforded by c-commerce, SMEs need to "adopt an entirely different approach to strategic planning and management which can enable them to deploy an extensive infrastructure network based on shared resources with other firms" (Tetteh & Burn 2001, p. 171). This requires strategic thinking, trust, and a realization of the importance of co-opting rather than competition which typically exists amongst individual firms. Therefore, c-commerce requires firms to develop a strategy, both short and long term, adopt appropriate business models, develop and sustain appropriate collaborative cultures engendering trust, invest in ICT to facilitate information and knowledge sharing, and set in place appropriate organizational structures to enable collaboration (Kalakota & Robinson, 1999).

Interorganizational systems (IOS), which include c-commerce, represent one use of IT and allow the transfer of information across organization boundaries. SMEs in Australia have tended not to adopt these systems due to the previously mentioned barriers. In the past electronic data interchange (EDI) and electronic funds transfer (EFT) have been the technologies to enter into IOS. The standards required for EDI and the high set up costs have tended to act as a barrier for SMEs to enter into IOS. This is potentially overcome by the Internet which facilitates participation by SMEs in c-commerce.

It can be argued that c-commerce is the next step following adoption of the full functionality of e-commerce and e-business. Whether there is a linear progression from e- to c-commerce is debatable given the differing antecedents. A number of models have been developed that depict a progression of the application of e-commerce such as the DTI Model (Martin & Matlay, 2001).

Adoption of e-commerce or e-business cannot be said to be a direct precursor to c-commerce. However the "technology" required in these preceding stages needs to be in place for c-commerce to occur. The technology required to enter into c-commerce is more complex and involves other hardware and software in addition to the internet, as well as other factors.

THREE DIMENSIONS FOR THE ADOPTION OF C-COMMERCE

The literature reveals that three major areas are important to c-commerce adoption by SME's. The factors identified are IORs, resources, and the degree of IT integration within business strategy and will be discussed.

Depth of Interorganizational Relationships (IORs)

Global competition is increasingly occurring between networks of firms (Morgan & Hunt, 1994), and so partnerships, including c-commerce, are being established. This requires firms to choose appropriate partners and determine and agree upon the management of relationships (Ring & Van der Ven, 1992; 1994; Ritter, Wilkinson, & Johnston, 2002).

In the context of this article, IORs refers to cooperative IOR's that include strategic alliances, partnerships, coalitions, joint ventures, franchises, and network organizations. This article has adopted the framework developed by Holmlund and Tornroos (1997) that describes a number of dimensions of IOR's; Structural (the resource links, connections with other organizations through the IOR, and the institutional bonds such as contractual agreements); Economic (financial investment made in the relationship and expected economic returns form the relationship); and Social (relational concepts including characteristics such as trust, commitment, attractions, atmosphere, and social bonds).

The authors have added the dimension of "Organizational" to encompass characteristics that relate to how the organization interacts with others. Table 1 builds on these dimensions and summarizes factors deemed to be critical, to collaborative IORs and so c-commerce. The extent to which these factors explain the adoption of c-commerce or antecedents to its adoption need to be considered in subsequent research.

A coming together around IT is secondary to the formation and existence of relationships between firms since they underpin collaborative relationships (O'Keefe, 2001). Without the cultivation of relationships, firms are not able to capture the full value of technology (O'Keefe, 2001). Such a coming together will only occur if the shared benefits are acknowledged and are deemed to be worth-

Table 1. Four dimensions/factors critical to IORs (Grieger, 2004; Holmlund & Strandvik, 1999; Holmlund & Tornroos, 1997; Humphreys, Shiu, & Chan, 2001; Kauser & Shaw, 2003; Lawton, Smith, & Dickson, 2003; Marshall, 2004; Pearce, 2001; Ritter, Wilkinson, & Johnston 2002; Ryssel, Ritter, & Gemunden, 2004; Sherer, 2003; Vyas, Shelburn, & Rogers, 1995; Walter & Ritter, 2003)

Dimensions	Category
Structural/Infrastructure	Information Technology

	Communication
	Organisational Interconnectedness
	Relationship Management
Social	Commitment to the Relationship
	Trust
	Organisational Culture
	Individual Interaction

while. Perceptions of these benefits and a willingness to engage in c-commerce are influenced by attitudes to and experience of IT as well as the availability of resources able to be dedicated to c-commerce.

Degree of Integration of IT within Organizational Strategy

Gaddea, Huemerb, and Hakansson (2003) define strategy as an organization's direction, purpose, strategic leadership, and organizational and competitive performance. IT potentially plays a significant role in enabling a firm to achieve its strategic objectives. Levy, Powell, and Yetton (2001) argue that as well as being a major driver of strategic change, IT facilitates the exploitation of information by firms to achieve value added benefits.

In contrast, SMEs tend to adopt IT to reduce costs (Hagmann & McCahon, 1993) rather than as a way to add value. Previous research indicates that there is a limited use of management information systems (IS) amongst SMEs (Premkumar & Roberts, 1999). Consequently few benefits have flowed to SMEs from IS (Cragg & King, 1992), which reflects SMEs limited knowledge of IS which precludes them from taking advantage of the strategic information available from IT systems (Levy et al., 2001).

SMEs that make strategic IT investments often fail to obtain strategic benefits unless the IS is integral to the overall strategy of the firm (King, Cragg, & Hussein, 2000; Lesjak & Lynn, 2000). Firms that are driven by cost and efficiency are less likely to take a strategic view of IS (Lesjak & Lynn, 2000). Organizations involved in c-commerce are concerned with maximizing the benefits from value adding through IT having taken a strategic view of investment in IT.

In addition to interorganizational relationships and organizational strategy, c-commerce requires dedicated resources directed to the outcomes of partnerships.

Organizational Resources

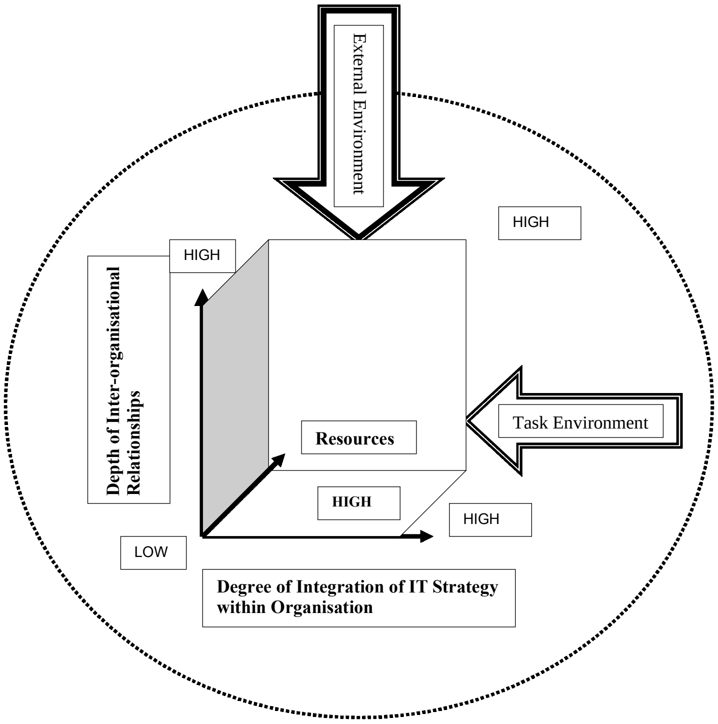
One way of looking at IT adoption and implementation amongst small business is via the resource-based theory (RBT) of the firm (Caldeira & Ward, 2003, Feeny & Willcocks, 1998). Firms are characterized by a set of competencies or skills and capabilities that are important to enable it to achieve a sustainable competitive advantage. IT expertise is part of this resource set with synergies to other resources.

Size is important as it has a bearing on resources available to the firm. SMEs tend to be resource poor—time, financial, and expertise, such as IT expertise, which limits their ability to be involved in other than day to day operations (Thong, 2001). In part, this is a function of the size of the business and often results in limited IT capabilities of the firm. This resource poverty has implications for growth and planning for the future, including investment in IT, and poses a critical difficulty for small business. On the other hand, c-commerce is one avenue for SME's to overcome resource limitations.

Resources necessary for c-commerce adoption are also relational. C-commerce requires that partners are flexible, able to provide a strategic advantage to collaborators, and have interoperable platforms that facilitate information and knowledge sharing. This presupposes a willingness to share and the existence of trust amongst "partners". Robbins (2003) argued that the key to success is to develop a knowledge sharing culture. Trust, which requires a collaborative organizational culture, is critical to encouraging the sharing of information (Ring & Van de Ven, 1992, 1994; Morgan & Hunt, 1994) using the internet, and within organizations, the intranet.

The sharing of resources and information among firms (Lee & Lau, 1999) is critical to the success of emerging business partnerships. Information needs to be communicated efficiently and effectively both within the organization and between partners in a collaborative arrangement. This is made possible via IT and requires integration of systems within the organization (Enterprise Application Integration), as well as between organizations. This necessitates interoperable platforms and systems that participants put in place (Holsapple & Singh, 2000; Badii & Shariff, 2003) which require re-

Figure 1. Framework depicting factors influential to the adoption of c-commerce



sources and potentially adaptation of systems to achieve interoperability.

FUTURE TRENDS

New business patterns are characterized by inter alia, diminishing geographical and time boundaries, globalization of the labor market, increased connectivity, and extended or virtual companies. Successful businesses are forming alliances and partnerships to enable them to more effectively compete given markets are globalized. C-commerce is the coming together of firms, including competitors, to exploit opportunities that arise and one example of this response and is seen by some as the next stage in e-business.

C-commerce is an example of collaborative networks which arise as knowledge management becomes more widespread. With the concept of knowledge networks, we enter a new era in that firms looking to be involved in collaborative networks need to "develop a new knowledge management process" (European Community, 2000, p. 3) and new business models, such as c-commerce.

Collaborative networks, including c-commerce, demand a new approach by firms incorporating new relationships, new assumptions, trust, and a shift in culture that values partnerships. Without adopting these factors it is not likely that SMEs will consider these options.

From the foregoing discussion, a proposed framework is put forward. It argues that organizations must possess certain characteristics for effective c-commerce adoption. The lack of these characteristics and low level of awareness of the benefits of c-commerce is believed to partly explain the low rate of adoption by SMEs in Australia.

The three dimensions set out in Figure 1 over plot the nature and quality of the relationships between collaborators, the extent of resources available to support the relationship, and the extent to which IT is part of the strategy, vision, and direction of the organization. Aside from the three dimensions which are internal to the organization and collaboration, Storey (1994) argues other external factors may influence c-commerce adoption. The immediate task environment such as the industry sector as well as the broader external environment may impact the organization and so are included in the proposed framework. The proposed framework acknowledges the part these factors play with regard to c-commerce adoption.

This framework enables the position of individual SMEs to be plotted in relation to these three variables should they be validated. By applying this framework to SMEs and plotting their position against the three axis, areas in which they are deficient can be readily identified. This will assist them to become c-commerce ready, should this be an appropriate strategy.

CONCLUSION

Firms engaged in c-commerce do so because they recognize the strategic benefits, however c-commerce demands significant investments in IOS. A commitment to the relationship requiring investment in IT from a long term perspective then is critical. Efficiency no longer is the sole motivation for IT adoption (Levy et al., 2002).

Yet to be identified is the relationship between the three dimensions and their relative importance to c-commerce adoption. Research is required to "test" whether these factors are critical antecedents to c-commerce adoption, as well as the interdependence between these and/or other factors identified by subsequent research. The proposed model indicates a positive relationship between these dimensions, however this requires validation. Since the development of a checklist depicting c-commerce readiness is an expected outcome of the research, the point at which an organization is "ready" to consider c-commerce needs to be mapped.

Investigation of the external and task environments are also important especially comparing the Australian context with environments where c-commerce is more entrenched in order to identify significant differences. Given that the majority of research regarding collaborative IOR's and c-commerce has taken place in Europe, the impact of the cultural and institutional settings needs to be acknowledged.

In conclusion, c-commerce is an emerging phenomenon in Australia. This article seeks to identify the antecedents required to facilitate c-commerce adoption for SMEs operating in the Australian environment. The model proposed in this article will require "testing" in different national and industry contexts so that validation or refinement can occur.

KEY TERMS

Collaborative Commerce: The processes, technologies, and the supporting standards that allow continuous and automated exchange of information between trading partners and can be horizontal competitive cooperation or co-opetition as well as vertical collaboration along a supply chain.

Electronic Commerce: Business to business electronic commerce includes supply chain management, virtual alliances, virtual trading partners, disintermediation, and reintermediation. It is the use of IT, particularly the Internet, to facilitate trading between two or more firms.

External Environment: The conditions, trends, and forces essentially those outside the control of organizational members.

Interorganizational Relationships: Cooperative IOR's that include strategic alliances, partnerships, coalitions, joint ventures, franchises, and network organizations.

Interorganizational Systems (IOS): Are defined as "a computer and communication infrastructure that permits the sharing of an application" across organizational boundaries. The aim of an IOS is to create and exploit interorganizational efficiencies.

Organizational Resources: Include financial, physical, human, and organizational assets used to produce goods and services. Also included are competencies or skills and capabilities which are the firm's ability to put its resources to use to achieve a desired end.

Organizational Strategy: Is an organization's direction, purpose, strategic leadership, organizational, and competitive performance.

Small and Medium Enterprises: In Australia there are several size definitions for SMEs—micro-businesses employ less than five employees; small businesses employ less than 20; and medium less than 200 employees. Definitions of what constitutes an SME by the Australian Bureau of Statistics exclude agriculture since the number of employees tend to be small, however turnover may be significant. Variation in definitions needs to be borne in mind when reviewing literature from around the world given the different size classifications.

Task Environment: Includes those sectors that have a direct working relationship with the organisation. It includes customers, competitors, suppliers, and the labor market. Effectively it is the industry in which the firm operates, which is a subset of the wider environment.

ENDNOTE

1 The way in which SME's are defined varies according to country however the definitions used in this paper are the standard Australian Bureau of Statistics classifications, which are micro business being 0-4 persons, small business being 5-19 persons and medium being 20-200 persons (ABS, 2002).

E-Government and the Construction Industry

O. K. B. Barima
University of Hong Kong, Hong Kong

INTRODUCTION

Recent trends indicate drives by various governments to adopt electronic means to handle their affairs and also provide value to their citizens irrespective of time and space via so-called electronic governments (see, e.g., Mathews, 2001; Tillett, 2000). Although the construction industry is part of the clientele which e-government seeks to serve, traditionally many governments are often the major clients for the supplied services of the industry. This scenario appears to re-shape the traditional customer-supplier relations into that of evolving roles, as for example in the digital environment both parties may find themselves in the roles of supplier or customers at varied times. This article seeks to explore the nature of the exchange interactions which may evolve between e-governments and the construction industry in the digital environment in value delivery. First, perspectives on the key concepts in this article are offered, then relevant literature on the subject is examined, before conceptual models to explain potential evolving roles of the two entities in the delivery of value in the digital/virtual realms is given. An outlook on future trends on the topic is then proposed before the conclusions.

BACKGROUND

Perspective on Key Concepts

Prior to the review of other relevant literature this section first examines three major concepts: electronic government, customer-supplier relationship, and digital value delivery.

Electronic Government

Electronic government also referred to as e-government, digital government or e-gov, government online, etc., made its debut in 1998 in the U.S. (Bose, 2004; Mathews, 2001). There are indications to however suggest that conditions which led to this phenomenon were at least identified about 30 years ago (see, e.g., Relyea, 2001). There appears not to be any consistent definition for the electronic government concept (see, e.g., Fang, 2002; Relyea, 2001; Seifert, 2003). As a dynamic concept it has evolved through varied perceptions. Initial perceptions of this concept concerned the use and application of information technology (IT) by government bodies, and later perceptions relate it to the ambiguous symbolic perceived use of IT to the operations of government, as well as the attainment of the goals of performance efficiency and economy (Relyea, 2001).

Three stakeholders which appear to be commonly identified within electronic government relationships are the government, citizens and business (Fang, 2002; Nikolopoulos, Patrikakis, & Lin, 2004; Seifert, 2003; The World Bank Group, n.d.). This may provide three clusters of operational interest as follows: government to government (G2G), government to citizens (G2C); government to business (G2B) (see, e.g., Fang, 2002; Nikolopoulos, Patrikakis, & Lin, 2004; Seifert, 2003; The World Bank Group, n.d.). These broad areas may also be subject to variations relative to one's intentions. For example within the G2G cluster one could refer to inter or intra government operations, and in the latter case one may for example identify government to employee (G2E) (see, e.g., Bose, 2004; Liu & Lai, 2004). The interest of this article is in the G2B cluster with specific reference to the exchange interactions (customer-supplier relations) between e-government and the construction industry. This interaction may concern the delivery of services, goods and allied items which may provide business efficacy. The next section discusses customer-supplier link in value delivery.

Customer-Supplier Exchange Relationship

Potential procurers (customers) of goods and services may directly or indirectly require exchange interactions with potential suppliers to fulfill (to a relative degree) their needs or wants. This appears to make the customer-supplier link important in fulfilling requirements. The term customer-supplier has been directly or indirectly used across varied disciplines (see, e.g., Ellegaard, Johansen, & Drejer, 2003). In marketing for example, the concept of "exchange" between potential customers and suppliers has been a recognized central model for many decades (Blois, 2004). The customer-supplier link is stressed in marketing exchange concept via emphasizing (among others) what both potential customers and suppliers have to offer and benefit from an exchange (Blois, 2004). One other prominent area in literature (of relevance to this article) which has heralded the importance of the customer-supplier link has been that of quality and its related fields. Most of these literature emphasize (among others) the need to: involve customers in value delivery processes so as to understand their requirements well in order to fulfill or exceed their expectations; continuously improve the suppliers' transformation processes and other value delivery systems (see, e.g., Huang & Lin, 2002; Ousthuizen, Koster, & Rey, 1998). The seemingly increased attention to include the customer in recent times contrast previous management orientation where transformation processes for example tended to focus on the suppliers' internal activities and were indifferent to the customer (see, e.g., Ousthuizen, Koster, & Rey, 1998). Thus arguably a shift to a relatively much broader and beneficial way in dealing with exchange interactions between customers and suppliers in delivering value. The next section discusses digital value delivery.

Digital Value Delivery

One of the aims in customer-supplier interactions concerns that of the delivery of value. One influential work on value delivery (in the business sector) was the work of Porter (1985). He defined value as the amount buyers are willing to pay for what a firm delivers to them. This work perceives value delivery via the analogy of a chain, whereby the processes for delivering value are seen as linked value adding processes. Although this work has been criticized as linear, and other conceptions like value constellations, nets, etc., proposed (see, e.g., Kippenberger, 1997a, 1997b; Parolini, 1999) it made significant impact on the conception of value delivery in the business sector (see, e.g., Kippenberger, 1997a). As value delivery within the digital environment evolved, Rayport and Sviokla (1999) also offered another seminal conception of value delivery within the digital environment, which they called virtual value chain. In their article they argued that although the processes for delivering value in the physical and virtual worlds are mutually dependent they are however not the same. They asserted that unlike the traditional value chain model which perceives information as a supporting element, the digital environment enables the use of information as a primary source of value creation (Rayport & Sviokla, 1999). They defined the virtual value chain to involve the processes of creating visibility, mirroring, and establishing new customer relationships. Visibility involves the ability of companies to use information to see their physical operations more effectively; mirroring involves the substitution of physical activities with virtual activities; then new customer relations can be created via the use of information (Rayport & Sviokla, 1999).

Although value delivery may require consideration of many other relevant things (e.g., dynamic turbulent business environment, etc.), the seminal models explained above, as well as those based on the supplier-customer delivery perspective could provide meaningful reference point, and hence basis for more complex and varied conceptions.

Trends in E-Government and Construction Industry and the Importance of a Focused Structured Link Between the Two Entities

Since the debut of e-government, various research has been done to assist in the comprehension, improvement or impact of e-government concept (see, e.g., Buckley, 2003; Fang, 2002; Hazlett & Hill, 2003; Mathews, 2001; Nikolopoulos, Patrikakis, & Lin, 2004; Teicher, Hughes, & Dow, 2002). A sample of the research findings however provide mixed results of either spectacular failure in some cases (see, e.g., Hazlett & Hill, 2003); modest or disproportionate impact (see e.g., Teicher, Hughes, & Dow, 2002); or success and a positive correlation between e-government adoption and economic competitiveness (see, e.g., Deloitte Touche Tohmatsu, 2003). Other researchers have also highlighted some of the potential opportunities for e-government leverage via enhanced forecasting, information provision, transactions, etc. (see, e.g., Nikolopoulos, Patrikakis, & Lin, 2004); whilst others have cautioned on the need to perceive e-government as both an opportunity (e.g., improvements in government services) as well as challenge (e.g., Internet security, privacy, etc. (see, e.g., Seifert, 2003).

Although the theme of most of this research is on improvements and related issues, little focus has been accorded the link between e-government and a specific sector like the construction industry. Certain governments however commissioned studies which were aimed at improving traditional construction delivery (see, e.g., CIRC, 2001). The focused study of the interaction between e-government and the construction industry could aid improve or transform: the traditional relationship between the two which often involves huge monetary exchange transactions; the role of the industry (just like other sectors) in contributing to employment, taxes, etc. For example, e-government initiatives on building permits approvals accrued 100 million dollars savings to the construction industry in the State of Oregon, USA (see e.g., Deloitte Touche Tohmatsu, 2003) This savings may also aid improve on reciprocal tax receipts to government, etc. E-governments could also offer many other things to the construction industry through say providing better: information on existing infrastructure via geographic information systems (GIS); customer input on proposed product definition and development at the construction conception/development phases via improved 3D or 4D digital visualization. Such intangible things could all have substantial impact on the success of the final delivered product.

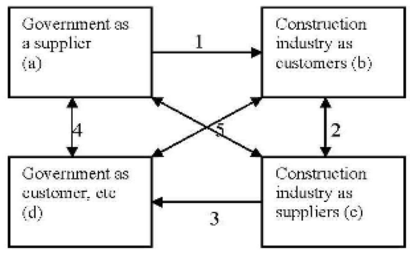
However, in spite of the potential mutual direct and indirect benefits which could be gained from the structured focused link between e-government and the construction industry, there appears to be a general lack of studies in fitting structure on the leverage of e-commerce in construction (see e.g., Ruikar, Anumba, & Carrillo, 2003). Focused structural emphasis like e-government link to construction industry could offer potential to aid study improvements, opportunities, and challenges from both macro and micro perspectives. The parties' core value delivery issues could be aligned across both entities in a linked manner to mutually satisfy their core needs at varied operational levels and capabilities. Thus, this will provide the advantage of studying the phenomena from inter-relationships rather than standalone entities. The next section presents models to highlight the evolving roles of e-government and the construction industry from a customer-supplier perspective for mutual benefit. It also builds on Rayport and Sviokla's (1999) work on virtual value delivery to support the proposed macro-perspective of construction product value delivery exchange. In addition to the explained use of the models (in the text in this subsection), other potential uses may be for the focused studies in other sectors of the economy at the macro or micro levels.

CONCEPTUAL MODELS ON THE EXCHANGE INTERACTIONS BETWEEN GOVERNMENTS AND THE CONSTRUCTION INDUSTRY

E-government and the construction industry may be usefully perceived from the evolving roles of customer-supplier relationship in a reciprocal exchange interaction. The shifting roles between government and the industry's services provision from a macro perspective is shown in Figure 1.

The role of government (a) in relationship 1 is that of a supplier of service to the construction industry through for example the approval of building permits. This role changes in relationship 3, where the government becomes the customer for the services of the construction industry. The shifting roles of both parties are shown in relation-

Figure 1. Shifting customer-supplier roles of e-governments and construction service provision



ships 2 and 4, while interactions 5 a-c and 5 b-d relates to supplier-supplier and customer-customer iterations respectively. Relationship 5 a-c could be used to study what, how, where and when e-government service delivery (e.g., time for permit delivery) impacts on the supply of services by the construction industry (e.g., delays, costs, etc.). Iteration 5c-a relates for instance to what feedback information could be collated from the construction industry to aid the e-governments deliver better services continuously. For example benchmark metrics (i.e., intra-government, comparative international, etc.) and collective strategies evolved between industry and e-government relationships to monitor this on say year on year basis. Varied routes within the model could also be leveraged and explored for studies. Latent in the model may (for example) be indirect losses in taxes from the construction industry to government as a result of consequential losses resulting from poor service delivery (e.g., due to e-government inaction, etc.) to the construction industry. Figure 2 expands this value exchange model shown in Figure 1. This may indicate a product perspective of what must be delivered via the virtual means.

Figure 2. Macro-perspective of e-government—construction industry service/product value delivery exchange

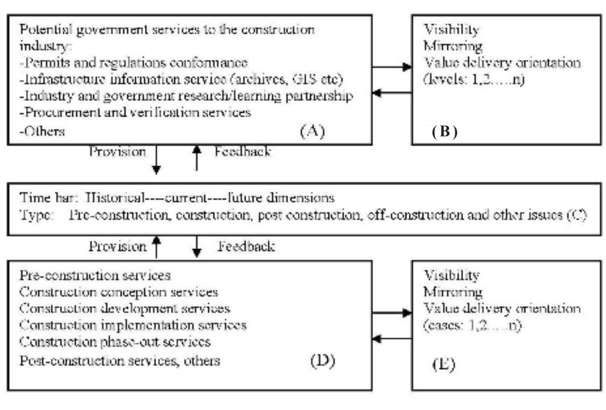


Figure 3. Cross-sectional service delivery perspective of e-government

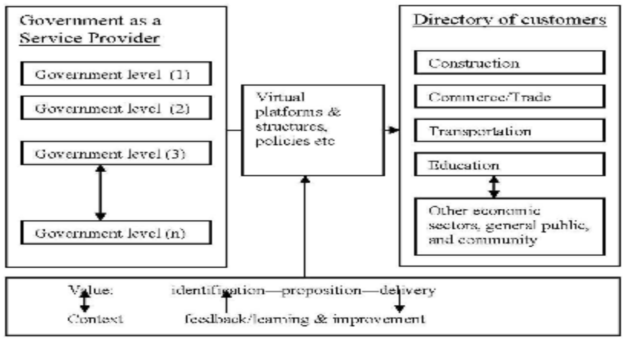

Figure 4. Cross-sectional perspective of value delivery from the construction industry

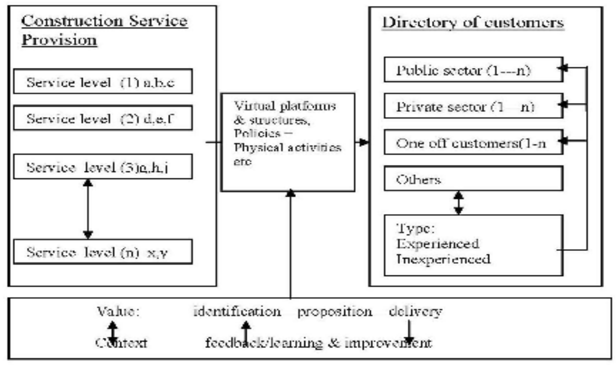

Certain categories of services from both e-government and construction industry are indicated in items A and D respectively, whilst items B and E show the packaged delivery from e-government by levels and construction service delivery by cases. Items A and D feed and receive feedback from item C, which offers time-based perspectives on the different lifecycle phases of construction. Item C also acts as the link between items A,B (via e-government) and D,E (construction industry) for linked collaborative learning, improvements, etc. The time-based perspective of the types of service delivery (i.e., pre-construction, construction, etc) in item C could be seen (relative to any strategically defined periods) from historical, current and future perspective. Feedback information from item C could be used to aid say: collaborative historical analysis for planning, current monitoring and control, and future improvement or fundamental innovation per each given context. Service delivery (see items B and E) may be packaged via decomposition into the elements of visibility, mirroring and new customer relations (see, e.g., Rayport & Sviokla, 1999). Visibility could be created for all intended processes and their delivery; mirroring may involve importing physical activities into the digital environment with say the aim of transforming existing processes in the physical realms; relations with the customer could be transformed via value delivery orientation which offers customer-centered approach and intimacy to deliver varied offerings relative to need (and this may also be supported by feedback metrics and communication mechanisms). The model in Figure 2 may also be used for improvement studies at the micro-level between specific e-government and construction project micro-cases relative to a given context.

Figures 3 and 4 provide the cross-sectional value delivery perspectives form both the e-government and the construction industry as service providers to the indicated respective categories of customers. Value delivery in each case (i.e., Figures 3 and 4) may involve tailoring delivery to each specific context relative to evolving roles as client or supplier of services, and this may involve the processes of value identification, proposition, delivery and feedback for say improvement. Tailoring in say the case of e-government (see Figure 3) may be to each specific context and customer directory orientation, as for example the needs for transportation sector may differ from the construction industry. The levels of government say levels 1 and 2, etc., may refer to the central and local government, etc. which are linked in a given context to the virtual platforms, structures, policies, etc.

Relative to the construction service delivery (see Figure 4), levels 1, 2, etc. may indicate the various levels of service in the industry, which may be categorized via types like heavy engineering, maintenance and repairs, etc. At each level (i.e., 1, 2, etc.) there may be many providers. For example at level 1 there may be providers a, b, c, etc. for any corresponding customer (which may also vary relative the nature of customers). Delivery to say the public sector may for example include customers (1, 2, 3, etc.) which may refer to specific central, local government, etc. The virtual platforms, structures and policies may aid as a collaborative framework in delivering any mutually defined value.

FUTURE TRENDS

Studies have shown that even the most mature e-governments have attained less than 20% of their full potential (see, e.g., The World Bank Group, n.d.). The feasibility of use of the models in Figures 1, 2 and 3 in this article could also be linked to e-government value delivery maturity progression levels (see e.g., The World Bank Group, n.d.) as template to study the context for further improvement and progression, to provide linked value delivery for specific industries (like construction, commerce, etc). Such an approach could provide the benefit of a focused link between e-government progression which also takes account of a value delivery orientation tailored to the specific needs of particular industries like construction, commerce, transportation, etc via linked value delivery exchange interactions for their mutual benefits.

CONCLUSION

This article explored the exchange interactions which may evolve between the construction industry and e-governments in delivering mutually beneficial value. The adoption of e-government by many governments have much implications for the construction industry, and also offers new perspective in the traditional customer-supplier relations, as both entities may play different evolving roles as customers or suppliers in the digital environment. This article offered models which structurally link the customer-supplier evolving roles of both entities to aid study relational improvements/transformations for mutual benefits. These may assist in focusing attention for the improvement or transformation of the interaction between e-government and the construction industry and other sectors of the economy.

KEY TERMS

Construction Project Life-Cycle: This is analogous to comparing construction projects to real life. Thus projects may be assumed to evolve through the life phases of conception; development; implementation and phase-out. Post delivery involves the facilities operation/maintenance phase till asset disposal.

Customer: Refers to the entity which procures goods and services.

Customer-Supplier Perspective: Refers to the linked interrelation between the requirements (needs, wants, etc.) of the customer to the provision of these by the supplier to their mutual benefit.

Exchange Interaction: Involves the interactive relationship between e-government and the construction industry for potential mutual gains.

Supplier: refers to the entity which provides wanted or needed goods and services.

Value Delivery: This term (although variable) may generally refer to the delivery of tangible or intangible things of worth or importance. In a product transformation process this term may refer to efficient processes, and the effectiveness in attaining the right inputs, results, impacts, goals, etc. and in managing any relative context.

Value Delivery Orientation: Refers to positioning to deliver value to fit or exceed expectations of any relatively defined value. This positioning may entail both cognitive and behavioral aspects.

Virtual Value: Is the value created via the virtual media, thus with the use of information (see Rayport & Sviokla,1999). This may be extended to include value created via the integrated leverage of the physical activities and ICT based information.

E-Government and the Digital Divide

Tan Yigitcanlar

Scott Baum
Griffith University, Australia

INTRODUCTION

Many governments world wide are attempting to increase accountability, transparency, and the quality of services by adopting information and communications technologies (ICTs) to modernize and change the way their administrations work. Meanwhile e-government is becoming a significant decision-making and service tool at local, regional and national government levels. The vast majority of users of these government online services see significant benefits from being able to access services online.

The rapid pace of technological development has created increasingly more powerful ICTs that are capable of radically transforming public institutions and private organizations alike. These technologies have proven to be extraordinarily useful instruments in enabling governments to enhance the quality, speed of delivery and reliability of services to citizens and to business (VanderMeer & VanWinden, 2003).

However, just because the technology is available does not mean it is accessible to all. The term digital divide has been used since the 1990s to describe patterns of unequal access to ICTs—primarily computers and the Internet—based on income, ethnicity, geography, age, and other factors. Over time it has evolved to more broadly define disparities in technology usage, resulting from a lack of access, skills, or interest in using technology.

This article provides an overview of recent literature on e-government and the digital divide, and includes a discussion on the potential of e-government in addressing the digital divide.

BACKGROUND

The adoption of highly intensive and complex systems of ICT networks to establish e-government are radically changing how national, state, and local administrations deliver services, collect, integrate, and share information, and communicate with one another and citizens. A growing number of professionals see the Internet as a transformative technology, and they regard e-government as part of a new vision of government for the 21st century (Jones & Crowe 2001; Kearns, Bend, & Stern, 2002; OECD 2001; Pardo 2000; Socitim & Idea, 2002). The use of ICTs to support public participatory decision-making via e-government triggers information technology to make government operate more efficiently (Griffiths, 2002; Lenihan, 2002; Lenk & Traunmuller, 2002; Macintosh, Malina, & Whyte, 2002). E-government focuses on the actions and innovations enabled by ICTs combined with higher levels of speed, scalability, and accuracy.

For the past two decades, the debate about the ways technology can aid democratic governance has been continuing especially in the developed (Arterton, 1987; Mclean, 1989) and has continued to accelerate with the proliferation of the Internet as an information and communication medium (Karakaya, 2003). The interactive nature of Internet in e-government allows contributions from the user instead of broadcasting data from one centre to many users (Hewitt, 2000; Yigitcanlar, 2003). For example in the local governance context, citizens can obtain information about their council through the council's Web site, can contact their representatives easily via e-mail and state their own views through online consultations and discussion forums.

ICT is not a solution to all concerns about e-government, but it can start to close the gap between what governments do and people's everyday lives. For that reason e-government means more than just a Web site, it has the power to transform citizens' lives. Socitim and Idea (2002) state that the overwhelming majority—up to 80%—of citizen-government transactions takes place at the local level. In this way the applications of e-government are affecting people's daily lives. That is to say applications of e-government are actually affecting—easing—people's daily lives. However without giving equal opportunity and accessibility to the public, e-government is nothing more that an elitist tool. Therefore, as e-government is becoming wide spread all around the world, governments have realized the importance of developing policies and programs to address the inequalities that are becoming evident in access to ICTs and the usage of these technologies.

E-GOVERNMENT AND THE DIGITAL DIVIDE

In e-government discussions, the term digital divide has quickly become popular. It is used to explain any and every disparity within the online community. At its basic level the digital divide is about the difference between those with access and those without access to ICTs. It is also used as a term to indicate social exclusion in the online world as we move to the knowledge economy, or the knowledge society (Graham, 2002; Stimson, 2002; Woodbury & Thompson, 1999). Most of the available literature suggests that socioeconomic status and demographic characteristics determine the frequency of use of ICTs (Hoffman & Novak, 2000; NITA, 1999). In particular, issues of income and education are often seen as being important, while age and ethnic background may also be an issue (NOIE, 2002; VanderMeer & VanWinden, 2003). There may also be a geographic component.

The concept of the digital divide is generally understood as a multidimensional phenomenon encompassing three distinct aspects. The "global divide" refers to the divergence of Internet access between industrialized and developing societies. The "social divide" concerns the gap between information rich and poor in each nation. And lastly within the online community, the "democratic divide" signifies the difference between those who do, and do not, use the panoply of digital resources to engage, mobilize and participate in public life (Norris, 2001).

It is clear that technology will continue to evolve rapidly, along with its social uses. Yet despite the need for considerable caution in weighing the available evidence, if we can establish the main drivers behind the diffusion of the Internet, and if these prove similar to the reasons behind the adoption of older forms of information technologies, then we are in a much better position to understand and predict the probable pattern of future developments, the potential consequences of the rise of the Internet age, and also the policy initiatives most likely to overcome the digital—global, social and democratic—divide.

Research into global internet trends by Neilsen Netratings (2001) suggested that at the beginning of the current decade there were an estimated 429 million people online globally. Neilsen Netratings (2003) reports that at the end of 2002 with a 35% increase Internet was being used by 580 million people. However the global divide still remained the same. For example, of those 580 million, 29% were in the U.S., while 23% of the online population lived in Europe, 13% of the online population logged on from Asia Pacific, and only 2% of the world's online population was in South America.

The digital divide is becoming more of a recognized reality as technology makes phenomenal progress and e-government applications become widespread in the new information age. The United Nations Human Development Report demonstrates that high income OECD countries, with only 14% of the world's population, were home to 79% of all Internet users, and only 0.4% of people in South Asia were online although the region is home to one-fifth of the world's population (UNDP, 2001). More than ever, unequal adoption of technology is excluding many people from reaping the fruits of the e-government and global economy.

> *... Even in advanced industrial nations with rapid maturing Internet markets, whole sections of the urban population fail to benefit from the skills, education, equipment, infrastructure, capital, finance and support necessary to go and remain 'online'. This is so at precisely the time when being online is becoming ever-more critical to access key resources, information, public services and employment opportunities.* (Graham, 2002, p. 37)

The digital divide is a complex issue with no singular cause or effect. Unfortunately, new technologies alone will not suffice to close the digital divide, since they are heavily dependent on physical capital (for infrastructure, hardware and software), human capital (for installation, maintenance, updates and efficient usage of the computers) and the general economic policy environment (for functioning payment systems, stability) (DDN, 2003). Whilst e-government provides many opportunities for local authorities to serve citizens more effectively, it also runs the risk of widening existing inequalities and making non-IT users second-class citizens.

The Digital Divide Network (2003) underlines that addressing the digital divide requires a multi-faceted approach involving: (a) affordable access to information tools for the elderly, the poor, the disabled, and those living in rural areas; (b) economic development of communities developing an infrastructure of telecommunications facilities and cultivating a well-trained workforce so that communities can remain competitive in attracting and retaining businesses; (c) Internet content that is relevant to and produced by communities addressing the availability of community-relevant information, overcoming language and literacy barriers, and promoting the diversity of cultural voices; and (d) a society devoted to lifelong learning developing the learning skills which will enable all generations to adapt to constantly changing times.

The OECD (2001) stresses apart from general approaches in reducing the digital divide like extending the infrastructure, skills, and information, it will be especially important to offer low costs access. With computers and Internet available at public institutions like libraries, post offices, local and regional government facilities, schools, etc., individuals can build up familiarity with the information technology and develop important relevant skills. The provision of low-cost and subsidized access in schools for example will help to establish sound fundament for computer literacy of the future workforce and will improve the diffusion of decisive knowledge for the new economy. This diffusion of knowledge is an important aspect of developing successful e-government programs.

E-DEMOCRACY AND THE DIGITAL DIVIDE

Griffiths (2002) characterize e-democracy as referring to relations of two-way and horizontal power—using technologies to enhance democratic practice. She also identifies e-government as referring to relations of top/down power—governing populations through use of online information services, and it is often thought to be a political or more "uninvolved" than e-democracy. E-democracy focuses more on the use of ICTs in support of citizen-centered democratic processes and uses them to make elected officials more accountable to the public (Snider, 2001). It involves a shift from a more closed to a more open e-government system. Conventional e-government is, relatively speaking, a one way system where by information flow and decision-making are hierarchically controlled and community involvement is limited. By contrast, e-democracy seems likely to produce a wide range of new connections to support two-way communication and collaboration that will involve government officials in relationships with organizations and individuals (Lenihan, 2002).

E-democracy provides ways to educate and empower communities. In an e-democracy project education is one of the most important issues to address the digital divide. Education in remote areas could be supported by a number of technology-enabled applications, including a mobile teaching assistant to provide teachers with curriculum information, as well as class materials. Virtual universities and education portals could also be supported with the proper application of ICTs. Another key issue is empowerment. Empowerment and participation in government could be enabled by such applications as an m-government assistant, a mobile terminal that a rural government employee could use to provide government information and services in remote areas.

At present e-democracy and e-participation hold great promise for enhancing citizen involvement in the political process. That includes finding ways to narrow the digital divide. International experience and major international programs—to identify ways of ensuring that the digital revolution will benefit the population of the whole world—have demonstrated that e-government and e-democracy can make an invaluable contribution to helping to create digital opportunities for all by enhancing citizen involvement (i.e., Singapore and Minnesota e-government services).

Atlanta, Cleveland, Durham, and Seattle are among the U.S. cities that developed e-government initiatives to bridge the digital divide to make e-government accessible to all. European Union's e-Europe project can also be mentioned as a good practice. This e-government project includes numerous "social inclusion" initiatives. Another good practice is the Australian Capital Territory's Community IT Access Plan. It sets out the strategic approach being taken to bridge the digital divide.

FUTURE TRENDS

The digital divide is one manifestation of the unequal distribution of power. The various demographic dimensions, along which the digital divide runs, represent a map of how that social power is distributed. No matter where they are located, those who have higher incomes have greater access to, and are more likely to use the Internet. Urban dwellers are usually better connected to electronic media than rural dwellers. Those with more education often have both higher incomes, and better connectivity. Trying to close the digital divide can be interpreted as one form of economic redistribution. Riley (2004, p. 18) argues narrowing the digital dived is a matter of time and states that:

... Prior programs of a Keynesian type have successfully extended other forms of infrastructure (electricity distribution, sewage treatment, public education, telephone service, etc.) from the upper classes to the entire population. Are there some significant differences between Internet connectivity and these prior forms of infrastructure extension that precludes the digital divide from being treated in the same way as the provision of roads or sewers?

Similarly NIC (2000, p. 32) points out that "…wide range of ICT developments is leading to the rapid diffusion of Internet… by 2015, information technology will make major inroads in remote rural areas as well as urban areas around the globe."

In many countries, governments, and NGOs are already developing various initiatives to close the digital divide including: (a) providing public ICT access through libraries and community centers; (b) offering ICT training programs; (c) providing ICT access and training to disadvantaged target groups including people with a disability and their caretakers; (d) distributing a free computer training resource through libraries, shop fronts and community centers; and (e) establishing a PC Reuse Scheme to provide affordable refurbished computers to people on a low income and not-for-profit community groups. In the near future, the continuum of these policies will help in narrowing the divide, and increasing the accessibility of e-government services.

As Loader and Keeble (2004:43) note future research agenda needs to focus on the following issues: (a) economic, social and cultural characteristics of the public; (b) sustainable strategies for challenging the digital divide; (c) community intermediaries to stimulate computer literacy; and (d) economically and socially sustaining the digital divide initiatives.

CONCLUSION

The first step in handling the widening digital gap is, understanding the breadth and depth of any cultural, racial, education, knowledge or literary divide that exists in any given jurisdiction. It is incumbent on governments to bridge these divides and ensure that there are no inequities between those who have the capacity to engage in online transactions with governments and those who do not have access or do not wish to participate in the online world. Many federal, state and local governments are seeking to find solutions. This is the next challenge in ensuring successful e-government and the delivery of e-services (Riley, 2004).

E-government is an exciting frontier, but technology (e.g., bigger and faster servers, more powerful search engines) alone is not going to get governments there. What it is going to take to move to the kind of government that uses technology as a tool to provide greater accountability, transparency and collective decision making through better and more meaningful public access to government information (Hewitt, 2000). Therefore online services and activities should not be focused solely on technology but be supported by it.

International practices have shown that there are many citizens who currently can not participate in the information society, and as e-government becomes more pervasive they will increasingly be left behind and become disenfranchised. Consequently, for any e-government project to be successful there needs to be some degree of e-participation and community development. Only by understanding and addressing the digital divide, and the needs of the citizens will local governments be able to realize the vision of true e-government.

The real success of e-government comes from developing policies and programs for: (a) understanding the differences among citizens; (b) taking various public opinions and needs into consideration; (c) adding them into decision making processes; and (d) fine tuning e-government for a wider individual and community participation. In conclusion, many authors (Mossberger, Tolbert, & Stansbury, 2003; Norris, 2001; Servon, 2002; Warschauer, 2003) acknowledge that e-government is not a panacea to solve the whole digital divide problem, but when used correctly it has the potential to bridge the divide.

KEY TERMS

Digital Divide: Is the gap in opportunities experienced by those with limited accessibility to technology especially, computers and the Internet.

E-Democracy: Refers to relations of two-way and horizontal power—using technologies to enhance democratic practice.

E-Government: Refers to relations of top/down power—governing populations through use of online information and services.

E-Participation: Is the engagement of an individual or a group in specific decision-making and action by using ICT means. It aims to encourage of those not normally involved in a particular process or decision-making system to be involved.

Information and Communication Technology: Is a term created to refer to the amalgam of computing and telecommunications technologies, including the Internet, which are the matrix within which information and digital media are created, distributed and accessed.

Local E-Government: Refers to information, services or transactions that local governments provide online to citizens using the Internet and Web sites.

M-Government: Is a subset of e-government and it utilizes mobile and wireless technologies like mobile phones, and laptops and PDAs (personal digital assistants) connected to wireless local area networks. It makes public information and government services available "anytime, anywhere" to citizens and officials.

E-Government Development and Implementation

INTRODUCTION

This article intends to review important research issues in e-government and aims to shed light on future studies on e-government in a global setting. Specifically, this article: (1) reviews the background and development of e-government in developed and developing countries; and (2) identifies and discusses key issues and future trends/ challenges in e-government research, which provides some insights and directions for future studies in e-government.

BACKGROUND

E-government is a cost-effective solution that improves communication between government agencies and their constituents by providing access to information and services online. *The Economist* magazine estimates that the potential savings of implementing e-government could be as much as $110 billion and £144 billion in the U.S. and Europe, respectively (Symonds, 2000). Narrowly defined, e-government is the production and delivery of government services through IT applications, used to simplify and improve transactions between governments and citizens (G2C), businesses (G2B), and other government agencies (G2G) (Sprecher, 2000). Unlike the traditional bureaucratic model where information flows only vertically and rarely between departments, e-government links new technology with legacy systems internally and in turn links government information infrastructures externally with everything digital (Tapscott, 1995). Table 1 summarizes the characteristic differences between the traditional government and e-government organizations.

Though a new subject, e-government has attracted more and more research interest and focus from industries, national governments, and universities, such as IBM's Institute for Electronic Government and various "e-government task forces" in different countries around the world (Huang, D'Ambra, & Bhalla, 2002). E-government implementation has become a very important global issue faced by many countries of the world. So far, most, if not all, published IS papers discuss e-government implementation issues and problems based on the experience of developed countries, not on developing coun-

Table 1. Main differences between traditional and e-government organizations

Traditional Government	E-Government
Bureaucratic controls, clear authority hierarchy	Client service and community empowerment, leveled/blurred hierarchy
Process centricity	Customer centricity
Isolated administrative functions and data collection	Integrated resource service and knowledge focus
Functional specialization of units or geographic bias	Breakdown of unit barrier, government integration
Decision based on uniform rules and awkward reporting approvals	Decision based on negotiation and implicit controls and approvals
Isolated administrative functions	Integrated resource services
Disjointed information technologies	Integrated network solutions
Time-consuming process	Rapid streamlined responses

Table 2. Main differences between developed and developing countries

	Developed Countries	Developing Countries
History and Culture	• Government and economy developed early, immediately after independence • Economy growing at a constant rate, productivity increasing, high standard of living	• Government usually not specifically defined; economy not increasing in productivity • Economy not growing or increasing productivity; low standard of living
Technical Staff (Ledford, 2002)	• Has a current staff, needs to increase technical abilities and hire younger professionals • Has outsourcing abilities and financial resources to outsource; current staff would be able to define requirements for development	• Does not have a staff, or has very limited in-house staff • Does not have local outsourcing abilities and rarely has the financial ability to outsource; current staff may be unable to define specific requirements
Infrastructure (Dooley, 2002)	• Good current infrastructure • High Internet access for employees and citizens	• Bad current infrastructure • Low Internet access for employees and citizens
Citizens (ICeGD, 2002)	• High Internet access and computer literacy; still has digital divide and privacy issues	• Low Internet access and citizens are reluctant to trust online services; few citizens know how to operate computers
Government Officers	• Decent computer literacy and dedication of resources; many do not place e-government at a high priority	• Low computer literacy and dedication of resources; many do not place e-government at a high priority due to lack of knowledge on the issue

tries (Huang, Siau, & Wei, 2004). Can successful experience of e-government implementation in developed countries be directly applicable to developing countries? If not, why not? How can a country learn from other countries' experiences in e-government implementation? What are key issues and future trends of e-government development and implementation from a global perspective? These important questions have not had satisfactory answers yet.

Research literature shows that although e-government has become a hot research topic and there have been many prior studies on e-government, most of them are published based on experience of developed country's e-government development and implementation, such as in Britain (Irani, Love, Elliman, Jones, & Themistocleous, 2005), Australia (Huang et al., 2002), the European Union as a whole (Heinderyckx, 2002; Lassnig & Markus, 2003; Lowe, 2003; Schweighofer, 2003), Finland (Kampen, Snijkers, & Bouckaert, 2005), France (Benamou, Busson, & Keravel, 2004), Spain (Latre, 2003; Pasic, Sassen, & Garcia, 2004; Sabucedo & Anido, 2004), Italy (Ferro, Cantanmessa, & Paolucci, 2004), The Netherlands (Arendsen & van Engers, 2004), Germany (Bartels & Steimke, 2004), Switzerland (Chappelet, 2004), Belgium (Rotthier, 2004), Japan (Omura, 2000; Thompson, 2002), Canada (Marche & McNiven, 2003), and the United States (Ni & Ho, 2005; Reddick, 2005).

Although e-government technologies have a potential to improve the lives of the 80% of the world's population that lives in developing countries, so far developed countries such as the United States, Canada, Britain, and Australia are leaders in e-government (Accenture, 2002), reaping the vast majority of initial gains of e-government implementation. More than 75% of Australians file income taxes online, while the mayor of Minnesota receives about 13,000 e-mails from the public each week (Palmer, 2002). The gap between developed and developing countries in Internet technological infrastructures, practices, and usage has been wider rather than narrower over recent years. Besides the lack of sufficient capital to build up expensive national information infrastructure (NII) on which e-government is based, developing countries also lack sufficient knowledge and skills to develop suitable and effective strategies for establishing and promoting e-government.

Prior study provides some empirical evidence to show that e-government development and implementation differ in different countries in terms of income level, development status (developed vs. developing countries), and geographical regions. To examine those underlying reasons resulting in different e-government development strategies and outcomes between developing and developed countries, it is important to examine the main differences between developing and developed countries in terms of governments' characteristics. Drawn upon literature search and research, Table 2 summarizes differences between developed and developing countries in various aspects of government.

KEY ISSUES

Various stages of e-government development reflect the degree of technical sophistication and interaction with users (Hiller & Belanger, 2001), as shown in Table 3.

With the world economy going towards more and more regional and global, e-government research and implementation from a global perspective has become more and more important. Some key issues, future development trends and/or challenges that are important to both developed and developing countries are summarized as follows.

- **Accessibility issue for individuals with disabilities when accessing e-government Web sites**. For example, there are more than 54 million individuals with disabilities in the United States (Jaeger, 2004), and other countries (either developed or developing countries) have significant numbers of citizens with disabilities as well. In many developed countries, governments have invested a lot to improve hardware facilities specifically for those with disabilities. However, so far, to our knowledge, there is no single e-government Web site specifically designed for those with disabilities. What are the accessibility requirements of these people that are different from normal citizens when they are accessing and using e-government services? How can we design e-government Web sites specifically for those with disabilities? These are very important research issues, even though little empirical research has been done in the research literature.
- **Interoperability Issue** (Benamou et al., 2004; Cava & Guijarro, 2003; Guijarro, 2004). E-government includes G2C, G2G, and G2B, which requires restructuring working processes of governmental agencies as well as better coordination among citizens, businesses, and governmental agencies. To this end, e-government systems must be interoperable at different levels (federal, state, and local governments), considering different dimensions (political, organizational, human, and technical).
  To deal with this important issue, one has to deal with the existing problems that current legislatures miss components that specifically encourage and promote coordination among governmental agencies for e-government implementation (Strejcek & Theil, 2003). Further, an increasing number of governments worldwide recognize the role of establishing a metadata standard as an integral ingredient of their interoperability framework towards realizing their e-government strategy. Metadata are "data about data" or "information about information." In the public sector, metadata may be used among others for the discovery and retrieval of governmental information (Tambouris & Tarabanis, 2004).
- **Security Issue** (Kalloniatis, Kavakli, & Gritzalis, 2004). The need for keeping information secure is increasingly important in modern e-government environments. This holds because personally identifiable information can be electronically transmitted and disseminated over insecure open networks and the Internet. Some key issues include: how to develop quality requirements engineering (RE) framework for eliciting and managing security requirements (SRs), and then how to develop an effective security system for e-government services? What are key restrictions and difficulties while building up a secure e-government system (Hof & Reichstadter, 2004)?
- **Anti-Corruption Information Systems and E-Government Development** (Costake, 2003)**.** Corruption exists in almost every country, both in developed and developing countries, but it seems to be more important for developing countries than developed countries. While e-government development and implementation require restructuring of cur-

Table 3. Five stages of e-government implementation

Stage 1	The most basic form of e-government; uses IT for disseminating information by posting data on the Web sites that are viewable
Stage 2	Two-way communication between government and constituents; e-mail systems are incorporated as well as data-transfer technologies
Stage 3	Web-based self-services where online service and financial transactions are available
Stage 4	Various government services are connected internally and externally for enhanced efficiency, user friendliness, and effectiveness
Stage 5	The promotion of Web-based political participation, including online voting; highlights Web-based political activities by citizens

rent working processes and ways of doing things in governments, they provide a good chance to reexamine the issue of how to use e-government development and implementation as a catalyst to identify and formulate general informational requirements to support anti-corruption actions, which can form part of the infrastructure of e-government.

- **Cross-Cultural Issues in Global E-Government Development and Implementation** (Denman-Maier & Parycek, 2003). As shown in the proposed framework presented in this article, large differences exist between developed and developing countries in terms of national cultures. Even developed countries where most e-government initiatives are being launched tend to be far from culturally homogeneous political entities. Most of them have large minorities that may not only speak different languages, but also have different religions, use different scripts, and differ in their cultural values, traditions, and attitudes. How do these factors influence those peoples' understanding of information distributed by public authorities, and their cognitive approach to knowledge representation, so that they can also use e-government services more effectively in a more satisfactory way?
- **Best Practice in E-Government** (Makolm, 2002; Millard, 2002). How do we examine the best of e-government experience across developed and developing countries in relation to technology, organizational change, and meeting the needs of the user (citizens and business)? How do we address different needs and requirements when building up best practice solutions in the fields of G2C, G2B, and G2G?

Table 4 summarizes other key issues and trends faced by e-government development and implementation in the near future.

Table 4. Key issues and trends of e-government development and implementation

No.	Key Issues and Trends	References
1	Although there is a growing body of eGovernment literature, relatively little of it is empirical. More empirical investigation on eGovernment development and implementation will be needed in the future.	(Norris and Moon, 2005)
2	More research on privacy issue in eGovernment. The Central Intelligence Agency came under public criticism when it was discovered that their Web site used persistent "cookies" to track Web visits in violation of federal privacy policy.	(Stratford, 2004)
3	eGovernment adoption and diffusion in public sector, especially in local governments. Prior study in US shows that eGovernment has been penetrating state government much more rapidly than local government. Future research should study effects of factors such as proper marketing, privacy issues, equity, and financing on full penetration of eGovernment in public sector.	(Edmiston, 2003)
4	Information technology provides some powerful supporting tools for eGovernment, which may empower government to provide additional and/or new services to the public, which otherwise may not be possible to do so. Future study can look into the research issue on how to provide new and value-added services through integrated eGovernment.	(Pfaff and Simon, 2002)
5	Very little has been known about eGovernment usability issue for old citizens who don't have skills in computer usage.	(Becker, 2005)
6	Future research should study the relationship between eGovernment and eGovernance, and how one issue influences another in eGovernment development and implementation.	(Marche and McNiven, 2003)
7	eGovernment and accountability. Will eGovernment lead to a more transparent, interactive, open and hence, accountable, government? If not, what should we do to make it happen in developing eGovernment strategies?	(Wong and Welch, 2004)
8	Qualification issue and training issue in eGovernment. While eGovernment has a potential to substantially change the current way public section is operating and functioning, new qualification requirements arise for users, managers, decision makers in public administration. As a result, effective training programs should be worked out to meet this potentially big demand from public sector. However, little research has been done in this area.	(Kaiser, 2004)
9	Risk issue in eGovernment. Electronic government transaction services may offer a potential of increased efficiency and quality with the minim cost in the way the public administration deals with its customers. Recent reports show that this is far from reality, as eGovernment projects seem to be failing to deliver. Future study should look into this important issue on identifying key risk factors and how those risk factors influence the success or failure of eGovernment project.	(Evangelidis, Macintosh and Davenport, 2004)

FUTURE TRENDS

Due to the substantial differences discussed in Table 2, developing countries cannot and should not directly adopt developed countries' successful e-government implementation strategies. Developing countries should consider their own positions and learn from other countries' successful e-government implementation experience, and then work out their e-government implementation strategies that fit with their countries' characteristics and conditions.

A useful conceptual framework was proposed recently, which incorporates critical success factors (CSFs) influencing e-government development and implementation (Huang, Chen, & Ching, 2005). The framework includes the national e-government infrastructure (NeI) factors such as network access, networked learning, networked economy, and network policy, as well as other critical success factors such as society factors like national history and citizens (Huang et al., 2002); government staff and governance (Wimmer, Traunmuller, & Lenk, 2001); organizational structure (Baligh, 1994); and cultural factors like national culture (Hoftstede, 1980, 1991), organizational culture (Hoftstede, 1980; Schein, 1993), and social norms (Ajzen, 1988). Using a comprehensive framework, one can compare e-government development and implementation experience in different cultures and countries, understand the specific conditions and contextual factors that are related to the success of e-government development and implementation in developed or developing countries, and thus better learn from the success and/or failure of other countries' experience.

Moreover, with some emerging technologies, future studies can look into some important research issues in e-government implementation, such as how mobile technologies can be used in supporting and enhancing e-government functions and development. While e-government technologies give developing countries a chance for "leap frog" development, how do developing countries use Internet technologies to establish e-government services that may never have existed in their countries before? Further, it would be interesting and important to examine whether the five stages of e-government development are linear or discontinuous based on the experience of developed and developing countries.

CONCLUSION

Due to the considerable differences between developed and developing countries, successful e-government development and implementation experience from developed countries may not be directly applied to developing countries. On the other hand, little research has been done on exploring why and how different countries, such as developed and developing counties, adopted different e-government development and implementation strategies in the research literature. Further, less has been known about e-government development and implementation in developing countries (Huang et al., 2004).

The current study intends to do some initial work to bridge the gap by comparing specific conditions and contextual factors that are related to the success of e-government development and implementation in developed or developing countries. In addition, this article compares strategic issues and implementations of e-government between developed and developing countries. It identifies and discusses key future trends and/or challenges of e-government development in both developed and developing countries, and provides some insights for future research and practice in global e-government development and implementation.

KEY TERMS

E-Government: The production and delivery of government services through IT applications; used to simplify and improve transactions between governments and citizens (G2C), businesses (G2B), and other government agencies (G2G) (Sprecher, 2000).

Metadata: "Data about data" or "information about information." In the public sector, metadata may be used among others for the discovery and retrieval of governmental information (Tambouris & Tarabanis, 2004).

National E-Government Infrastructure (NeI): Refers to the basic foundation, in both hardware and software, on which an e-government system can be built and developed. It generally consists of "4N factors": network access, network learning, network economy, and network policy.

Network Access: Refers to the availability, cost, and quality of information and communication technology networks, services, and equipment (Kirkman, Osorio, & Sachs, 2002).

Networked Economy: Refers to a new form of economy where businesses and governments use information and communication technologies to interact with the public and with each other to get business transactions done (Kirkman et al., 2002).

Networked Learning: Refers to an educational system that integrates information and communication technologies into its processes to improve learning? Communities of a society should have effective technical training programs that can train and prepare an ICT workforce (Kirkman et al., 2002).

Network Policy: Refers to the policy environment that promotes or hinders the growth of information and communication technology adoption and use in government agencies. Some related key issues include legislations, laws, strategies (visions and missions), and accountability (Kirkman et al., 2002).

E-Government Portals in Mexico[1]

Rodrigo Sandoval Almazán
Instituto Tecnológico de Estudios Superiores de Monterrey (ITESM), Mexico

University at Albany, SUNY & Harvard University, USA

INTRODUCTION

Electronic government has become a powerful administrative tool for governments around the world (Dawes & Pardo, 2002; Fountain, 2001; UN & ASPA, 2002). Governments at all levels are attempting to improve services and increase their interactions with citizens using information and communication technologies (ICTs). In Mexico, state and local governments are expending large amounts of money to introduce ICTs in operational tasks, as well as in the provision of public services. Many of these governments have created Web pages, which provide information about government agencies and, in some cases, allow transactions. Unfortunately, in Mexico, there is no systematic or rigorous research program that measures and assesses the evolution and impact of e-government.

As an initial step of a broader research effort, this study focuses on the functionality of state portals, looking at technical aspects, as well as their potential to improve the quality of the services provided by states. Gant and Gant (2002) state, "A Web portal serves as the integrated gateway into the state government Web site and provides visitors with a single point of contact for online service delivery within the state." Therefore, these portals contain an interesting mixture of applications and are good examples of current e-government efforts. Accordingly, taking an evolutionary approach, this study provides an initial assessment of e-government at the state level in Mexico. This article is organized into six sections including these introductory comments. In the second section, three approaches to e-government assessment are described briefly. The third section explains our method of analysis. In the fourth section, we present some preliminary results. The fifth section includes some future trends and areas for research. Finally, section six provides some concluding remarks.

BACKGROUND: APPROACHES TO E-GOVERNMENT ASSESSMENT

There is a current debate about the concept and characteristics of electronic government (Prins, 2001; Gil-García & Luna-Reyes, 2003; Schelin, 2003). This debate can be interpreted through (1) managerial, (2) citizen-centered, and (3) evolutionary perspectives, among others. This section very briefly describes these three perspectives and attempts to highlight their advantages and limitations as approaches to e-government assessment. This article takes the evolutionary perspective to preliminary evaluate state portals in Mexico.

Managerial Perspective

According to the managerial perspective, electronic government must focus on managerial processes. Similar to the concept of e-management (Gil-García & Luna-Reyes, 2003), this perspective establishes that the main objective of e-government is to improve managerial effectiveness and efficiency. For example, Wescott (2002) states, "e-government is the use of information and communication technology (ICT) to promote more efficient and cost-effective government, facilitate more convenient government services, allow greater public access to information, and make government more accountable to citizens" (p. 1).

West (2001) and Toral (2000) also pay attention to managerial processes but in their relationships to services and citizens. West states that e-government refers to the delivery of information and services online through the Internet. Similarly, Toral says, "electronic government is the future government, which offers and performs services to the population in the way they need" (p. 6A). Finally, Holmes (2001) states, "Electronic government or e-government is the use of information technology, in particular the internet, to deliver public services in a much more convenient, customer-oriented, cost-effective, and altogether different and a better way" (p. 2).

Citizen-Centered Perspective

The citizen-centered approach to electronic government emphasizes the predominant role of citizens as drivers of e-government. This perspective also offers a critical lens to evaluate the influence of e-government initiatives on individuals and societies. Pipa Norris (2000) says that the influence of the Internet on societies, especially on the poor ones, can change their life by improving education and access to government decisions. It should be clear that the nature of e-government is different from how businesses use the Internet to interact with customers. For example, Naief Yehya (2002) mentions, "Substantially, the egov idea is radically different to the e-commerce idea" (p. 31). This technology can make life simpler for people and their real objective is to promote, protect and make strong the democratic values (p. 32).

In summary, the managerial perspective is mainly oriented to processes, methods, information, and government legitimacy, excludes any links with citizens and avoids the opportunity to make interactions the strongest part of the process. In contrast, the citizen-centered perspective focuses on people's needs and takes into consideration important transformations in government procedures to make services and information more accessible to citizens.

Evolutionary Perspective

This kind of vision maintains the assumption that electronic government is evolutionary. Some authors contend that each one of the stages is already electronic government. Others delimit from which of the phases a government can be considered electronic. After reviewing different ways to present the stages of e-government, the following model was integrated as the synthesis of previous theoretical developments (see Table 1).

Three hypotheses frame this research. First, Mexican state portals provide valuable information but few online services. Accordingly, the majority of the state portals are in the first stages of e-government (e.g., initial presence, extended presence). Second, state governments are mainly using old and less sophisticated Web technologies for their portals. With existing technologies, it is much more difficult to communicate complex information and provide transactional services. Third, there are sizable differences among state portals. Those differences may be related to economic and political factors, as well as to specific state e-government initiatives.

RESEARCH METHOD

In order to answer our hypotheses, we conducted a systematic analysis of the 32 state portals between January and February of 2005. The questionnaire includes 58

Table 1. Evolutionary approaches to e-government assessment: An overview

E-Government Stage	Additional Technological and Organizational Sophistication	References
Presence	▪ Limited government information ▪ Few Web pages developed by single agencies ▪ Static information about government structure and services	UN & ASPA, 2002
Information	▪ More dynamic information (frequent updates) ▪ Greater number of Web pages ▪ Statewide portal as the entry point with links to most of the state pages	Hiller & Bélanger, 2001; Layne & Lee, 2001; Moon, 2002; UN & ASPA, 2002; Holden, Norris & Fletcher, 2003
Interaction	▪ Forms that can be downloaded ▪ Two-way communication through electronic mail ▪ Use of search engines ▪ Use of chats, forums or other forms of interactive communication (service related) ▪ Some customization (citizen's profiles, use of passwords)	Hiller & Bélanger, 2001; Moon, 2002; UN & ASPA, 2002
Transaction	▪ Online services (secure and completely online), including accepting electronic payments (e.g., credit cards) ▪ More customization (use of passwords, citizen's profiles, etc.) ▪ Portal organized according to people's needs instead of government structures	Hiller & Bélanger, 2001; Layne & Lee, 2001; Moon, 2002; UN & ASPA, 2002; Holden, Norris & Fletcher, 2003

Integration	▪ Service portal with a single checkout point
	  ▪ Multiple agencies, *same* function, *different* levels of government
	  ▪ Multiple agencies, *different* functions, *same* level of government
	  ▪ Multiple agencies, *different* functions, *different* levels of government
		Hiller & Bélanger, 2001; Moon, 2002; UN & ASPA, 2002; Layne & Lee, 2001; Holden, Norris & Fletcher, 2003

Political Participation	▪ Political participation ▪ Online public forums/Opinion surveys ▪ Online voting	Hiller & Bélanger, 2001; Moon, 2002

Table 2. The evolution of Mexican portals (Source: Original research by the authors)

E-Government Stage	Number of Portals with Characteristics of this Stage	Percentage of Portals with Characteristics of this Stage
Presence	10	31.25
Information	15	46.88
Interaction	3	9.37
Transaction	8	25.00
Integration	5	15.62
Political Participation	5	15.62

Note: Columns 2 and 3 add up to more than 32 and 100% respectively, because some state portals have characteristics of different stages.

quantitative and qualitative items. It looks at several dimensions of portal functionality such as information provision, services provision, privacy and security aspects, accessibility, and target audiences. We will also partially assess the technological sophistication of the portal by looking at aspects such as Web development languages/programs (e.g., HTML, Dreamweaver, XML, etc.), its need of specific plug-ins (e.g., Acrobat Reader, Flash, Java, etc.), and its architectural design.

MAIN THRUST: A PRELIMINARY ASSESSMENT OF STATE PORTALS IN MEXICO

Table 3 shows results that support our first hypothesis. Forty seven percent (47%) of the Mexican state portals show characteristics associated with the information stage and many of them (31%) have characteristics of the presence stage. Therefore, our conclusion is that many of the Mexican state portals are in early stages of e-government. However, eight portals are currently providing online transactions. It is important to clarify that for this research we do not assume necessarily that there is a linear progression in the stages or that their characteristics are cumulative. For instance, Sinaloa is aligned most closely with characteristics in the presence stage, but this portal contains a link to participate politically. State portals with the highest grades are Estado de México, Sonora, and Yucatán. Generally, the more points they get, the more technically sophisticated their portals are. It is clear that Mexican state portals vary with respect to quality of services, organization, purpose and technology.

We also evaluate other variables such as openness, customization, usability, transparency, electronic services, privacy, security, broken links, search problems, design problems, readability, and the use of user fees. Twenty-five percent (25%) of the portals include the ability to review information related to taxes and government services. Twenty-one percent (21%) of the sites allowed downloading forms and other documents (mostly in PDF format). Six states (18%) have at least one complete transaction (e.g., allowing payment and delivery of the product/service online). Regarding portal organization, 34% of the Web pages have links to inside pages, mostly sites related to government. Thirty-one percent (31%) of the portals serve only as a main index. Twenty-five percent (25%) included an online catalogue of government services and procedures. Nine percent (9%) required passwords for users and registration was needed for accessing most of the portal services.

Openness can be thought of as a way to reduce corruption and was evaluated in this study. Fifty percent (50%) of the state portals do not have adequate information, but most of them include laws, regulations, and services. Important information like payment roles or directories was not available. Only seven states (22%) have a directory and five of them (15%) provide information that is more complete. Some examples of states with better information related to openness and transparency are Guanajuato, Sonora, and the Federal District. Customization is another interesting factor. Sixty-nine percent (69%) of the Mexican state Web sites do not have any way to be personalized. Only four states (12%) have the capability to select a view according to different audiences (e.g., senior citizens, business, etc.). Veracruz is the only state that provides the possibility of changing the color of the Web pages.

Regarding design, 50% of the sites are well-designed and relatively easy to use. The best example of this is the portal of Sonora. Twenty-nine percent (29%) of the sites have a very complicated, and in some cases, chaotic structure and are very hard to navigate. One example of this situation is the state portal of Oaxaca with extraordinary pictures and excellent use of Flash technology, but relatively little information and a non-systematic structure. Seventy-two percent (72%) of the portals use

Table 3. Evolutionary approaches to e-government assessment: An overview of the states in Mexico (Source: Original Research by authors [January-February 2005])

E-Government Stage	Mexican State	Comments
Presence	**High Level** Oaxaca & Yucatan (6 points) **Medium Level**: Nayarit, Zacatecas **Low Level**: Quintana Roo, San Luis Potosí y Sinaloa, Coahuila, Guerrero y Veracruz.	▪ Limited government information ▪ Few Web pages developed by single agencies ▪ Static information about government structure and services
Information	**High Level** (6 points) Baja California , Colima, Estado de México, Hidalgo, Jalisco, Michoacán, Morelos, Nuevo León, Sonora, Tabasco, Tamaulipas **Medium Level** (5p): Chiapas; Distrito Federal (DF) ; Puebla & Tlaxcala	▪ Greater number of Web pages ▪ Statewide portal as the entry point with links to most of the state pages ▪ More dynamic information (frequent updates).
Interaction	**High Level** 6 points: Sonora **Medium Level** 4 points: Chiapas & Estado de México	▪ Forms that can be downloaded ▪ Two-way communication through electronic mail ▪ Use of search engines ▪ Use of chats, forums or other forms of interactive communication (service related) ▪ Some customization (citizen's profiles, use of passwords)
Transaction	**Medium Level** (4 points) Baja California Estado de México; Nuevo León; Querétaro; Sonora; Tabasco; Tamaulipas & Yucatán	▪ On-line services (secure and completely online), including electronic payments (e.g., credit cards). ▪ More customization (use of passwords, citizen's profiles, etc.) ▪ Portal organized according to people's needs instead of government structures.
Integration	**High Level** 6 points: Estado de México. **Medium Level** 4-5 points: Chiapas, Chihuahua, Durango and Michoacan	▪ Services portal with a single point of checkout (multiple agencies, same function, and different levels of government). ▪ Services portal with a single point of checkout (multiple agencies, different functions, same level of government). ▪ Services portal with a single point of checkout (multiple agencies, different functions, different levels of government).
Political Participation	**Low Level** (1 point) Chiapas; Estado de México; Querétaro; Sinaloa; Sonora.	▪ Online opinion about new bills or laws ▪ Online Public debate with ministers ▪ Electronic vote for or against bills ▪ Electronic vote for promoting public ideas

only HTML and flash presentations. Only one state uses window server, PHP, and HTML. Three states use windows server or a combination of PHP and Apache servers. Two good examples are Sonora and Nuevo Leon. Finally, eighty-four percent (84%) are focused on the public, and 12% on government personnel.

Table 3 shows the correspondence between state portals and characteristics of different evolutionary stages. Results are divided into three categories: (1) high level, these are states that receive the highest possible score (6 points) in a category; (2) medium level, are states that received a medium score (5-4 points) in a category; and (3) low level, includes states that received 3 points or less. From this table, it is evident that characteristics of different stages can be present in a single state portal. The assumption that evolutionary stages are progressive and mutually exclusive seems not to be true empirically, at least for the case of Mexico.

Regarding the stage of political participation, no state portal received more than one point in our scale. It seems that states in Mexico are not trying to engage citizens politically through their official Web sites. Again, there is no evidence for a truly stage-oriented e-government. In fact, there are some states that combine characteristics of early and advanced stages. This is not consistent with the evolutionary stance. For the evolutionary perspective, each stage is represented by certain characteristics and these characteristics are expected to be found together. In this way, researchers can assess in which stage an e-government initiative (e.g., a state portal) currently falls. As mentioned early, this is not necessarily evident for the case of Mexican state portals.

According to the measures used in this study, the state portals that received the greatest scores (19-21 points) are Estado de México, Sonora, and Yucatán. Chiapas, Querétaro, Tabasco, Tamaulipas, and Nuevo León followed with a score between 15 and 16 points. Campeche, Colima, Hidalgo, Sinaloa, Veracruz, Coahuila, Michoacán, Puebla, Baja California, Chihuahua, Jalisco, and Tlaxcala received between 11 and 14 points. The rest of the state portals have scores below 11 points. The more points they get means that they are in a more advanced stage within the evolution of e-government. However, as mentioned before, the evolutionary approach has several limitations and should be complemented with other perspectives.

FUTURE TRENDS

There are three main trends in the Mexican government portals. First, there is a trend toward the improvement of online services. Currently, the great majority of state portals do not offer complete services and credit card transactions online, but they are increasingly adding these features. In the near future, these services will be completed entirely over the Internet and without any type of human support. The second trend is related to the first one and refers to the increasing improvement of security. Enhanced security will ensure citizens' privacy and confidentiality. One way to start improving security is the use of passwords and vertical systems to integrate one ID number for multiple transactions by the same citizen.

The third trend is to expand government openness and citizens' ability to search for a variety of information—taxes, government payroll, investments—that promotes freedom and avoids corruption inside government agencies. Openness should not be considered a fashion, but a technological and managerial need to guarantee government efficiency and effectiveness. In the end, another trend could be a highly functional e-democracy that is considered the final outcome of a democratic electronic government. In this scenario, citizens should not only be able to search information or perform transactional services, but also give opinions about public affairs, vote online, and democratically participate in government decision-making.

CONCLUSION

This article provides a useful way to assess e-government portals. This assessment is sensitive to differences in context and rich in quantitative and qualitative information. This methodology recognizes that what is considered a stage does not necessarily follow a linear progression (Moon, 2002). In addition, a state portal is not a homogeneous entity and can have characteristics of several stages. The purpose of this type of research should not only be to classify Web sites in different stages; but also to provide a better understanding of the quality and functionality of the state portals, as well as some practical suggestions about how to improve the current situation.

Mexican state portals are in the initial stages of electronic government. They provide information online but very few offer complete services. In addition, there is not enough information available for citizens. Information is mostly about government structures and services, and there is little information related to accountability. Very few state portals allow customization or have versions in other languages. The differences between states are enormous. Some are attempting to have a better presence and more current information, while others are providing several transactions or even integrating some of their services. Political, institutional, organizational, and economic factors may explain a proportion of these differences (Gil-Garcia, 2005), and future studies must build causal models to understand the relative impact of different factors.

KEY TERMS

Citizen-Centered Approach to E-Government: A way to study e-government that emphasizes the social and political nature of the relationships between citizens and government and conceptualizes citizens as the most important stakeholder of e-government initiatives.

Customization: Fundamental characteristic of a Web site regarding personalization of information or tailoring special requirements from a specific user.

E-Government: Electronic government is the use of information technologies (IT) to improve and facilitate citizens' relationships with government through democratic procedures, cost-effective transactions, and efficient regulations, all of which enhance these relationships.

Evolutionary Approach to E-Government: A way to study e-government that identifies different stages as the right path for e-government evolution.

Managerial Approach to E-Government: A way to study e-government that emphasizes administrative processes, efficiency and effectiveness as the most important goals of e-government initiatives.

Openness: A measure of the freedom to search, collect, and exchange governmental information related to public services or to the bureaucratic structure.

State Portal: Vertical Web site where information refers mostly to the information of a national, state or local entity.

E-Government Services Framework

Sushil K. Sharma
Ball State University, USA

INTRODUCTION

E-government generally refers to the delivery of national or local government information and services via the Internet or other digital means (Relyea, 2002). E-government refers to the ability of government to interact electronically with citizens, businesses, and other governmental entities. The interaction may be in the form of obtaining information, filings, or making payments, and a host of other activities via the World Wide Web (Abramson & Means, 2001; Bertucci, 2003; Sharma, 2004; Sharma & Gupta, 2002).

The benefits of e-government usually include improved: quality of citizen services, internal efficiencies, law enforcement, education and information, promotion and outreach activities, safety and security, health care services and management, and involvement of citizens in the democratic process. Many believe that e-government can provide seamless services to draw agencies together, leading to more citizen-centric services (Grönlund, 2002; Gurstein, 2000; Venkatachalam, Shore, & Sharma, 2003). Many countries have decided to employ information and communication technologies (ICTs) to enhance delivery of government services to their citizens, and are thus at various stages of e-government implementation (Ho, 2002; Holliday, 2002; Layne & Lee, 2001; Netchaeva, 2002; United Nations & American Society for Public Administration, 2002; Sharma, 2004; Sharma & Gupta, 2002, 2003; Taylor, 2002). After examining studies conducted by various researchers on e-government models and frameworks, this article presents a holistic approach to create an e-government framework.

BACKGROUND

Virtually all developed and other OECD nations have launched comprehensive and challenging e-government initiatives and all levels of governments are increasingly using the Internet as another way to deliver information and services to citizens (Fletcher, 2002). E-government constitutes the way public sector institutions use technology to apply public administration principles and conduct the business of government (Riley, 2003a, 2003b; Riley & Riley, 2003). There are several models that attempt to explain the way in which e-government has evolved or is evolving. The first step into the e-government (or online government) world is a basic Web presence. Accenture (2003) describes three levels of online delivery capability before the final stage of service transformation (Ho, 2002; Sharma, 2004; Sharma & Gupta, 2003; UN, 2002; UNDESA, 2003).

Various authors have described four to six stages of e-government implementation (Layne & Lee 2001; Moon, 2002; Netchaeva, 2002; Sharma & Gupta, 2003; Silcock, 2001: United Nations & American Society for Public Administration, 2002) but all of them show the development of e-government services as an evolutionary process. For example, Silcock (2001) describes six stages which she characterizes as dynamic; these include: information publishing/dissemination, official two-way transaction, multipurpose portals, portal personalization, clustering of common services, and full integration and enterprise transformation. Netchaeva (2002) describes more or less similar stages without giving them specific terms, but she condenses them to five stages, whereas the UN (2002) categorizes five stages as: emerging, enhanced, interactive, transactional, and seamless (fully integrated). Layne and Lee (2001) proposed a four-stage growth model for e-government development: cataloguing, transaction, vertical integration, and horizontal integration. The cataloguing stage is the one in which governments establish an online presence. The Web site is usually one in which government information is made available. In the second stage, transaction, government customers are permitted to enter into transactions online, such as paying license fees and fines. The third stage, vertical integration, is one in which local, state, and federal agencies engaged in fulfilling the same customer need, or function, are linked together so as to form a seamless service. In the final stage of their model, horizontal integration is applied to break down the boundaries between functional silos within government.

Moon proposed a five-stage model, with stages named: information dissemination/cataloguing, two-way communication, service and financial transactions, vertical and horizontal integration, and political participation. Moon's stages one and two are extensions of Layne and Lee's stage one. His stage three is Layne and Lee's transaction stage. The two stages of vertical integration and horizontal integration that Layne and Lee had in their model have been concatenated into one stage by Moon. Moon has a fifth stage that recognizes the political dimension of e-government.

Sharma and Gupta's e-government framework not only includes the stages of growth model like Layne and Lee, but also contains supporting structures that are needed to achieve e-government stages and the delivery channels of e-government (Sharma & Gupta, 2003).

AN E-GOVERNMENT FRAMEWORK

Implementing a comprehensive e-government framework is a challenging task, as it requires many agencies, departments, and policy makers to coordinate their efforts, in addition to preparing the technology and support infrastructure; the soft infrastructure which includes the laws, rules, and regulations that must be changed in order to facilitate the development of both the new infrastructure and information services (Detlor & Finn, 2002; Kaaya, 2003). The previously described e-government's frameworks or models only describe the "supply side" of an e-government framework. These frameworks could be helpful to measure the presence and delivery of government service through the Internet or other digital means, however, these frameworks do not provide any indicator to measure the quality of service, the amount of citizens' engagement and participation, and use of service (West, 2001; Economic and Social Commission for Western Asia (ESCWA), 2003; European Commission/CGE&Y Study, 2002; United Nations & American Society for Public Administration, 2001). The philosophy of e-government should result in citizen-cantered and demand-oriented online service delivery (La Porte, Demchak, & de Jong, 2002; LaVigne, Simon, Dawes, Pardo, & Berlin, 2002; Zweers, & Planqué, 2001). Our proposed framework, as shown in Figure 1, is more holistic in nature and addresses both the demand and supply side of e-government implementation.

Back End Systems

Back end systems consisting of legacy data applications, ERP, workflow system, document management systems, and other data management systems. This part of the framework suggests that whatever the stage of e-government, it requires a massive integration of data that is spread across many government agencies. Many document technologies like imaging document management and workflow technologies, ERP systems, e-mail, and groupware systems are integrated to achieve structure and efficiency for data management (Dawes & Pardo, 2002; Knapp & Sanders, 2000). It also suggests that the integration of data may also result in much reengineering of various government processes (Sharma, 2004; Sharma & Gupta, 2003).

The Supply Side

The supply side stages of e-government evolution are well addressed by most of the researchers whereby the evolution is usually depicted as a four-stage process. These stages are: presence, interaction, transaction, and transformation as illustrated in Figure 1 (Sharma, 2004; Sharma & Gupta, 2003).

The Demand Side

The demand side of the framework describes customers' (including citizens, businesses, government, and employees) access to online government services through multiple channels. Including this in the framework ensures that e-government addresses the need for a critical mass of manpower, knowledge, and skills sufficient to support an e-governance strategy. Unless citizens are trained and have requisite skills to participate in e-governance, citizens' participation, and engagement would be a difficult task for evolving electronic democracy (O'Siochru & Constanza-hock, 2003; Sharma & Gupta, 2003; Surman & Reilly, 2003; Watson & Mundy, 2001).

The framework for e-government is incomplete if it is not supported with a required legal and regulatory infrastructure. The support infrastructure includes an integrated network of banks and financial institutions to serve as an automatic clearing house and a legal and regulatory structure to support payments online and protect privacy. Security must be a top priority during the creation of a support infrastructure for an e-government (Cresswell & Pardo, 2001).

FUTURE TRENDS

The contemporary literature on e-government shows that while most governments worldwide have a presence on the Web and are at least at the beginning stages of e-government development, few of them offer sophisticated online services involving interactive transactions (Gant, 2004; Garson, 2004; Sharma, 2004). E-government is rapidly moving to its full potential of e-governance and e-democracy (United Nations & American Society for Public Administration, 2002; UNPAN, 2002). E-government will ultimately lead towards direct democracy. Direct democracy means direct vote of all (interested) citizens on all important issues. Each vote should be preceded by a wide discussion and self-education of the citizens on the issue(s) to be decided. This would require unrestricted access of all citizens to information (Stowers, 2004). This form of democracy is going to be different from the present form of representative democracy. This would create a tremendous challenge to upkeep technological infrastructure, as well as to develop real time based response systems. Government needs to prepare a plan how businesses of government at every level, from parish to Parliament, will be announced in a way that makes it accessible to anyone interested (Rocheleau, 2003). Voter education and campaign information are therefore significant issues in relation to direct democracy. Presently, there is a lack of diverse and effective tools for building awareness and advocacy efforts around e-government development and specifically around the use of e-government for deepening democracy in the world (LaVigne, 2002). Government also needs to devise systems for handling privacy concerns (Hiller & Bélanger, 2001).

CONCLUSION

The current research on e-government briefly outlined above, shows that ICT and Internet technologies are increasingly moving into a civil societal domain which is multidimensional and requires new forms of research, management, and learning. Since the mid 1990s, governments around the world have made extraordinary efforts to provide services and information over the Web. E-government implementations have improved service delivery and offer greater transparency and accountability in governance systems (Fletcher, 2004).

The first wave of e-government implementation has focused primarily on the supply side. However, e-government frameworks should consider both demand and supply side to understand the requirements for total e-government implementation. Essentially, e-government implementation should simplify service delivery to citizens; eliminate layers of government management; create easier access to information and services for citizens, businesses and government employees. E-government must establish a new decision-making mechanism that involves all of the stakeholders (Holden, Norris, & Fletcher, 2003; Pavlichev & Garson, 2003).

KEY TERMS

Digital Government: Digital government has different possible definitions, from online services to any use of ICTs in the public. In general terms, digital government refers to the use of ICTs in government for at least three purposes: providing public services, improving managerial effectiveness, and promoting democracy.

E-Democracy: E-democracy is whereby e-government is involved in the development of direct forms of political deliberation and decision-making through electronic referendums and similar devices.

E-Governance: E-governance refers to a much broader range of issues and relationships around the impact of the Internet on political life at all levels, not just the level of states and their bureaucracies. E-governance is a broader concept, which includes the use of ICT by government and civil society to promote greater participation of citizens in the governance of political institutions.

E-Government: E-government refers to any government functions or processes that are carried out in digital form over the Internet. E-government refers to the use by government agencies of information technologies (such as Wide Area Networks, the Internet, and mobile computing) that have the ability to transform relations with citizens, businesses, and other arms of government.

E-Policy: E-policy represents the policy formulation and legal function of government. E-policy does not refer only to the use of ICTs in government settings, but also to the leading role of government in promoting the information society through an adequate regulatory framework.

E-Services: E-services refer to the provision of services using ICTs, especially the Internet and the World Wide Web.

Information Privacy: Is the interest an individual has in controlling, or at least significantly influencing, the handling of data about themselves.

Privacy: Privacy is the interest that individuals have in sustaining a "personal space", free from interference by other people and organizations.

E-Health Dot-Coms' Critical Success Factors

Abrams A. O'Buyonge

Leida Chen
Creighton University, USA

BACKGROUND OF THE BUSINESSES

The increasing use of the Internet by consumers gave rise to an information boom to health-care consumers. Not only could the Internet be used as a communication tool to provide information that would allow patients to make informed decisions, but it could also be used to generate revenue for investors. The dot-com boom of the late 1990s exploited this opportunity, targeting the health-care system, a $1.7 trillion market in the United States alone. Overall, the health-care system is wasteful and costly (Itagaki, Berlin, & Schatz, 2002), and as a result, health-care IT was touted as the magic pill for cutting costs. The Internet boom of the late 1990s saw the emergence of e-health: the delivery of health services and health information through the Internet and Internet-related technologies (Eysenbach, 2001). Leading the many entrepreneurs and venture capitalists who stepped in to seize a piece of the health-care industry cake were WebMD Corp., an online provider of medical information for doctors and consumers in Elmwood Park, New Jersey, and DrKoop.com, an Austin, Texas-born company that later moved to Santa Monica, California, and began doing business as Dr. Koop LifeCare Corp.

Dr. C. Everett Koop, the former U.S. surgeon general, had spent over 6 decades in the medical profession. He envisioned the Internet as an opportunity to change the health-care delivery system in order to empower individuals to take charge of their own health care (Musselwhite, 2002). With this vision and his reputation as an advocate for health-care reform, along with the help of two budding entrepreneurs, Don Hackett and John Zacarro, the trio opened a business-to-consumer Internet portal: DrKoop.com. The portal was designed to provide health information to consumers in areas such as chronic illness, food and nutrition, fitness, and medical breakthroughs. At the beginning, the Web site was an overwhelming success, receiving a million hits per month after 2 years of operation, and about 4 million unique visitors per month at its peak. The portal included a personal medical-records system that facilitated the cross-referencing of medications for interactions, as well as the storage of medical reports that could then be accessed by both patients and physicians.

DrKoop.com's public woes began in February 2000 when its auditor, PricewaterhouseCoopers, issued a "going concern qualification," an ominous warning that highlighted the precarious financial situation the Internet-based health service was in Cleary (2000). By the end of 2000, DrKoop.com was still struggling, and in the first 9 months of 2001 alone, the company's losses were nearly 3 times its revenue. According to the Securities and Exchange Commision (SEC) filings, from January 1999 until the service's liquidation in September 2001, DrKoop.com's losses stood at $193.6 million, dwarfing the $41 million revenue generated during the period. At the site's peak in July 1999, DrKoop.com's stock rose to $45.75 per share on the NASDAQ, but was worth $0.12 at the time of bankruptcy filing. In July 2002, Vitacost.com, a privately held online seller of nutritional supplements, paid a paltry $186,000 in cash for DrKoop.com's assets, which included the brand name, trademarks, domain names, the Web site, and the e-mail addresses of its registered users.

WebMD, originally called Healtheon/WebMD, was founded by Jim Clark, who also founded Silicon Graphics and Netscape. Clark's vision was to connect insurance companies, doctors, and patients over the Internet in order to lower costs and reduce paper trails. Rather than building its own products and services, Healtheon used its highly valued stock to finance acquisitions of leading companies in the industries it targeted. In 1999, it acquired WebMD.com and OnHealth, both leading health portals, giving it access to the consumer health market (Salkever, 2000). Though WebMD lost $6.5 billion on revenue of $530.2 million in the first 9 months of 2001, it still continued to expand long after DrKoop.com had dropped off the radar screen. For the fiscal year ending in December 2003, WebMD reported revenues of $964 million, an increase of 10.6% on the previous year's revenues, which totaled $871.7 million. Of the 11 health-care mergers and acquisition deals in the first 7 months of 2004, valued at $900 million, WebMD was the leading acquirer (Abrams, 2004). Two of WebMD's high-profile acquisitions in 2004 were the $160 million cash purchase of ViPS, a privately held provider in Baltimore, Maryland, of information technology to the government, Blue Cross-Blue Shield, and other health-care insurers; and the $40 million acquisition of Dakota Imaging Inc., a private company in Columbia, Maryland, that offered automated health-care claims processing technology.

As industry leaders, WebMD and DrKoop.com faced competition from both health-care information portals (such as HealthGrades.com, MDConsult, ZoeMed.com) and online pharmacies that provided consumers with one-stop shopping for medications and medical information (Walgreens.com, drugstore.com, Webvan.com). The threat from the health-care information portals, nevertheless, was minimal due to their limited brand recognition and information coverage. In the online pharmacy sector, however, Walgreens.com gained a substantial market share by combining the best of both worlds: complementing its physical stores located throughout the country by offering online customer service, convenience, and real-time access to a health library that provided comprehensive information on prescription drugs, insurance, and health issues.

DESCRIPTION OF THE BUSINESSES

Products and Services

DrKoop.com's vision for its online venture was a Web-based health-care information portal on which individuals and their doctors could have one-stop access to personal medical records, prescription history, medical exam results, and general health-care information (Itagaki et al., 2002; Musselwhite, 2002). According to Musselwhite, the venture's marketing strategy was to differentiate itself as "the premier healthcare information website," and would accomplish this via the four *C*s: content (which would be the driver), community (bringing people together to discuss issues pertaining to health), cool tools (such as Drug Checker), and commerce (enabling people to purchase drugs online from strategic e-commerce partners such as Drug Emporium) (p. 6). In order to generate revenue, DrKoop.com sold advertising rights to health-care-related companies that would pitch sales and promote their products to the portal's users and communities. Unfortunately, DrKoop.com failed to implement checks and controls on advertising, and some of the companies began making promotional claims that were not always substantiated.

WebMD's products and services, on the other hand, were more diversified with the overall objective of facilitating information exchange, communication, and transactions between consumers, physicians, and health-care institutions. Through a series of mergers and acquisitions, WebMD was able to offer a wide variety of health-related products and services, including health-care information to consumers and physicians, billing and transaction processing for physician practices and hospitals, and handheld services (Itagaki et al., 2002).

Management and Business Models

DrKoop.com was plagued with management problems from the start. None of the founders had business experience, but with less than $1 million of lifetime revenue, DrKoop.com still raised $84.4 million in its initial public offering (IPO). The company swelled from a handful of employees to 200 after the IPO, and an 80,000-square-foot office was acquired in a long-term lease. At a time when competition was fierce, advertising revenue alone could not support operational expenses, but the corporation continued its free-spending practices. Employees' in-house massages cost $9,000 per month, and free, catered Friday lunches cost $15,000 each week, contributing to a monthly burn rate of $7 million (Hawkins, 2001). The company signed a 3-year, $58 million agreement with Disney's Go Network to be the exclusive provider of health-care information on that network (Musselwhite, 2002). This was later followed by a 4-year agreement with AOL for a whopping $89 million to be featured on the AOL Web site, a sum that surpassed the IPO capitalization. Such evidence of capital mismanagement sent the wrong signals to investors, who began to question the viability of DrKoop.com. The business model envisioned by the company—a health-care information portal whose content would attract users, and in which advertisers would be attracted to the users—soon began to crack. By April of 2000, DrKoop.com was trailing its two major rivals in visitors per month and was spiraling into the dot-com abyss. In July, two class-action lawsuits were filed against management alleging the withholding of financial information for the purpose of inflating its stock price. The lawsuit was bolstered by other questionable actions by executives, including the selling of shares before the end of a 6-month holding period, which gave the impression of insider profiteering. Subsequently, two top executives, the chief operations officer and the chief financial officer, were forced to resign. In August, the stock fell below $1 a share and the downward trend never reversed. Public trust and investor goodwill on DrKoop.com were dealt a final blow with more reports of unethical practices. The company had received revenue from a pharmaceutical firm for referring patients for clinical trials, undisclosed commissions were received on health products and services sold through the Web site, and companies had paid money to be listed exclusively in some sections of the Web site, thus misleading customers (Noble, 1999).

Unlike DrKoop.com, WebMD adopted a comprehensive business model, targeting both consumers and providers across multiple industry segments. WebMD began a multibillion-dollar shopping binge from the start, acquiring several firms specializing in medical-related ventures such as electronic medical-claims processing, medical software, medical information, charge capture, physician practice management, and so forth. As the company's financial report shows (see Table 1), revenues from all areas were growing at a healthy pace. WebMD's revenues were expected to top $1 billion in 2004, and after several years of systematic cost cutting, operating earnings were expected to rise to at least $150 million (Tsao, 2004). The strength, weakness, opportunigy, threat (SWOT) analysis from Datamonitor (WebMD Corporation, 2004; see Table 2) indicates a favorable competitive environment for WebMD's continued growth. Using the value proposition framework (Crossan, Fry, & Killing, 2002), the goals, product market focus, core activities, and value propositions of both WebMD and DrKoop.com are compared in Figure 1. Compared to Dr.Koop.com, WebMD has more diversified product market focus and core activities. As a result, WebMD has been able to achieve more enhanced and sustainable value propositions.

LESSONS LEARNED

Apart from the irrational exuberance exhibited by investors, the success or failure of dot-coms can be attributed to other factors. Itagaki et al. (2002) identified four critical factors that predict the success or failure of e-health companies: a compelling value, an unambiguous revenue model, competitive barriers to entry, and the organizational structure for cost control. These factors can be matched to the traits described by Walters (2002): the "lots of money, but no vision" dilemma; the "business-as-a-website" approach; the burn rate; and the speed trap. The following sections discuss how these critical factors played out in the cases of WebMD and DrKoop.com, and the lessons that can be learned.

A Compelling Value or Vision: In the end, both WebMD and DrKoop.com succeeded in providing valuable, easy-to-understand, and useful health-care information to patients and physicians. However, DrKoop.com began to deviate from the original vision and mission, focusing on internal growth and fast-tracking to the IPO without adequate planning for the aftermath, a trap that befell many of the dot-coms that are now virtually extinct. WebMD developed a clear vision (to be a comprehensive e-health provider) and stuck to it, focusing on diversifying assets in order to augment its value. As of July 2004, WebMD Health provided the content for two of DrKoop.com's high-profile customers, the health channels for MSN and America Online, and had teamed up with the federal government to make consumer health information more widely available via the Department of Health and Human Services (HHS) channel on the WebMD Health portal (Henkel, 2004).

Table 1. Financial overview of WebMD (Source: Company Reports)

Financial Overview, WebMD
2003 vs. 2002
(in millions of $ dollars)

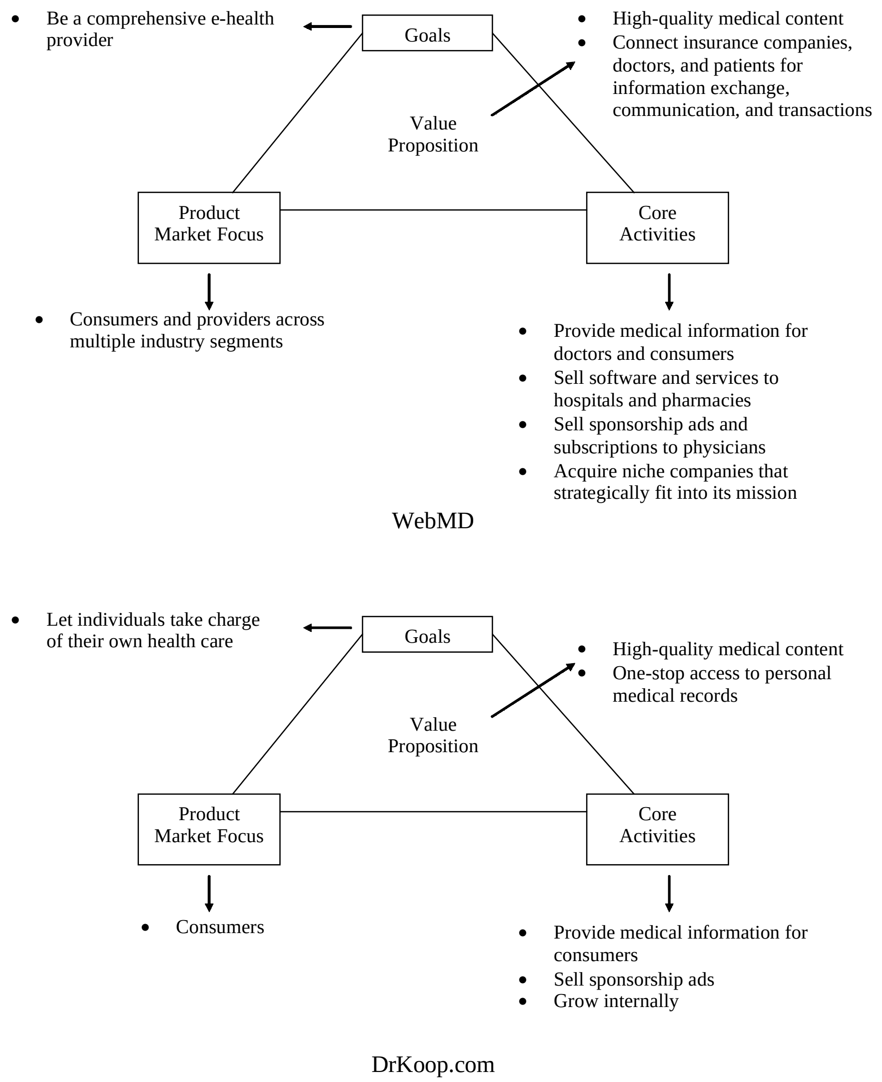
	2003	2002	Change
Transaction services	$505.7	$466.8	8.3%
Physician services	302.6	275.3	9.9%
Portal services	110.7	84.3	31.3%
Plastic Technologies	71.9	65.8	9.3%
Adjustment	-27.0	-20.5	31.5%
Revenues	$963.9	$871.7	10.6%
Net Income	$17.0	$49.7	NA

Source: Company Reports

Table 2. SWOT analysis of WebMD (Source: WebMD Corporation, 2004)

Strengths	Weaknesses
• Large footfall • Growing financial strength • Aggressive acquisition strategy	• Large restructuring charges • Acquisition-driven strategy • Investors unsure of strategy
Opportunities	**Threats**
• Shed unprofitable alliances • Drive core strength and diversify • Excess cash to pursue acquisition • Self-directed health-plan market	• Low demand from practitioners • Increasingly innovative competitors • Power shift in the market

Figure 1. Value proposition frameworks for WebMD and DrKoop.com



The lesson here is that instead of quickly rushing to the IPO, companies should first have a clear vision of where they want to be, a long-term strategy on how to get there, and the realization that agility is the key to survival in the fluid e-commerce marketplace. DrKoop.com lacked a long-term strategy and was forced to take poorly calculated risks. As a result, the stock price plummeted, massive layoffs soon followed, and in a desperate move to save the sinking ship, the company began engaging in questionable practices.

An Unambiguous Revenue Model and Avoiding the Business-as-Web-Site Approach: DrKoop.com built a technology infrastructure that relied heavily on an unproven revenue model and did not have alternative strategies for generating revenue. As a result, expenses soared and, with increased competition, Web-site traffic declined. WebMD, on the other hand, aggressively diversified its revenue sources via strategic mergers and acquisitions of firms in health-related industries. Consequently, WebMD began generating most of its revenue from the sale of software and services to hospitals and pharmacies (Bulkeley, 2003).

The lesson here is that companies should have a viable plan and alternative sources of revenue instead of putting all their eggs in one basket. WebMD's growth from a health-information portal to a comprehensive e-health site enabled the company to effectively deter the threat from substitute products and services. By expanding its offerings to both patients and physicians, and aggressively seeking business opportunities that are in sync with its corporate strategy, WebMD continues to thrive in the volatile e-commerce marketplace.

Competitive Barriers to Entry and Avoiding the Speed Trap: Both WebMD and DrKoop.com were able to create high-quality medical content, utilizing experts to ensure that the information was accurate. DrKoop.com went a step further by branding itself using the identity of a prominent physician. However, by aggressively pursuing a getting-to-market-first approach, DrKoop.com was lean on contingency planning and was thus not able to deal with the shocks that soon followed, such as the droughts of funding and declining customer demand fueled by competition. WebMD, however, was favored by economies of scale: Its large size and comprehensive services made it a dominant force and, in essence, was an entry barrier to competitors. By focusing on expansion, capturing new markets, and buying niche companies that strategically fit into its mission, the company was able to shield itself from competition and market downturns.

The lesson from this is that companies should be alert and ready to adapt to change, or perish. WebMD expanded its base by building relationships with its customers (physicians and general-health-information consumers), industry partners, and the government. Even though fast market penetration has competitive advantages, companies should also exercise patience, ensuring they have a solid and well-tested business model and contingency plan before they set sail into the expanse of the e-commerce market. Competitors who wait and take advantage of the new and improved technologies and business processes often surpass first movers in this dynamic technical and business environment. Marketing gurus emphasize the importance of capitalizing on the first-to-market advantage, but the history of e-commerce has taught us that competitive advantages created by IT were often unsustainable and could be easily duplicated by competitors (Porter, 2001).

Organizational Structure for Cost Control and Controlling the Burn Rate: Cost control was the nemesis of many dot-coms, including WebMD and DrKoop.com. The pay-per-click revenue model was fragile and unpredictable. Companies that did not have alternative revenue sources soon realized that their expenses could not be met. Within the first 6 months following the IPO, DrKoop.com spent $50 million while raising revenues of only $8 million. DrKoop.com's extravagance, with little consideration for earning a profit, further contributed to its demise. WebMD's struggle with cost control was complicated by the arduous task of harmonizing operations among the many business units it owns, but it had accumulated cash reserves that have enabled it to grow.

The lesson here is that management should not abuse its investors' trust by spending irresponsibly. Costs should be controlled and, in essence, aligned to revenues so that expenses do not spiral out of control. The surviving e-businesses spent funds wisely because they recognized that in the e-marketplace, the bargaining power of customers is very strong and demand is ever changing.

The dot-com boom was short lived, and following the bubble burst, many of the dot-coms never recovered. For a time, DrKoop.com seemed to defy the odds, but eventually it succumbed as well. WebMD managed to ride the tide and is now on its way to profitability. In this article, we have explored the factors that were critical to the failure and success of DrKoop.com and WebMD, respectively, and discussed some of the lessons learned. As can be gleaned from the demise of DrKoop.com and the continuing growth of WebMD, success in Internet commerce cannot be realized without a compelling value and vision, a clear-cut and effective revenue-generating strategy, cohesive and effective organization, and a cost-control system. Profit is not the goal but the requisite for any business, thus any dollars spent for creating and keeping customers should be measured and tracked against incremental revenue. Executives must watch the cash flow, income, and loss statements closely, and make changes where necessary to ensure that unnecessary expenses are curbed.

KEY TERMS

Business-to-Consumer (B2C): An e-commerce business model that facilitates transactions between a company and a consumer, as opposed to a transaction between companies (called B2B) or a transaction between consumers (C2C).

E-Business: Any financial or non-financial transaction involving an electronic process using the Internet or Internet technologies e.g. creating a map with directions on Mapquest.com.

E-Commerce (electronic commerce): The buying and selling of products and services by businesses and consumers over the Internet. E-commerce involves a direct financial transaction in the electronic process using Internet technologies. E-commerce encompasses business-to-business or B2B (Cisco), business-to-consumer or B2C (Amazon.com), and consumer-to-consumer or C2C (eBay).

E-Health: The use of emerging technologies, especially the Internet, to improve or enable health and healthcare-related services. The Journal of Medical Internet Research defines e-health as "an emerging field in the intersection of medical informatics, public health and business, referring to health services and information delivered or enhanced through the Internet and related technologies" (Eysenbach, 2001).

Handheld Services: The use of hand-held devices, such as Personal Digital Assistants (PDAs) and Pocket PCs, as an extension of workstation resources through the use of client/server based software for access and synchronization in conjunction with wireless access service provider. Handheld services are used for electronic prescribing, real-time drug references, scheduling, charge capture, etc.

Pay-per-Click: A search engine advertising strategy that allows for companies to bid for a website ranking based on the price they are willing to pay per click-through (when a visitor clicks on a Web ad as a result of keywords used when performing the search, e.g. on Google.com). The client chooses the keywords to appear on his website when a search is performed.

Portal: An electronic environment that provides a secure, single point of interaction with diverse information, business processes, and people, personalized to a user's needs and responsibilities. Examples of web portals include About.com, MSN, and Yahoo.

INTRODUCTION

The widespread and fast-developing information technologies, especially wireless communications and the Internet, have allowed for the realization of greater automation systems than ever in health-care industries: E-health has become an apparent trend, and having a clinic at home or even anywhere at anytime is no longer a dream.

E-health, including telemedicine featured by conducting health-care transactions over the Internet, has been revolutionizing the well-being of human society. Traditionally, common practices in the health-care industry place tremendous burdens on both patients and health-care providers, with heavy loads of paper-based documents and inefficient communications through mail or phone calls. The transmission of medical data is even messy for cases in which patients have to transfer between different health providers. In addition, the medical documents prepared manually are prone to errors and delays, which may lead to serious consequences. The time, energy, and resources wasted in such processes are intolerable and unimaginable in any fast-paced society. For these problems, e-health provides powerful solutions to share and exchange information over the Internet in a timely, easy, and safe manner (Balas et al., 1997).

Incorporating fast and cost-efficient Internet and wireless communication techniques has enabled the substantial development of e-health. The use of the Internet to transmit sensitive medical data, however, leaves the door open to the threats of information misuse either accidentally or maliciously. Health-care industries need be extremely cautious in handling and delivering electronic patient records using computer networks due to the high vulnerabilities of such information. To this extent, security and privacy issues become two of the biggest concerns in developing e-health infrastructures.

BACKGROUND

As early as 1987, Dr. Thomas Ferguson proposed online health care for consumers. In 1993, Dr. Ferguson, together with several other pioneers, initiated the first national conference on e-health (Nelson & Ball, 2004). The efforts laid the very foundation for the early development of e-health. However, e-health did not make a big step until the late 1990s, mainly due to the technical difficulties and high infrastructure cost. The striking development of information technology, particularly that of the computer, Internet, and wireless communications, dramatizes the reemergence of e-business and e-health (Collen, 1999). Thus, significant improvements to a new health-care infrastructure are anticipated so that health care can take place in a ubiquitous and security-assured manner.

The Internet as a fast, open, and cost-efficient way of exchanging information still faces the big challenge of protecting medical information security and privacy. The information transmitted through the Internet could be accessed, altered, deleted, or copied illegally, jeopardizing the patients' security and privacy. The security issues of e-health, in general, represented by all the precautions taken when safely accessing, collecting, and transferring the health information, must be addressed. In fact, the exchange of health information can be made more secure than in a paper-based system when carefully designed with proper security technologies. Information privacy is controlling whether and how personal data can be gathered, stored, processed, or selectively disseminated (Fischer-Hubner, 2001). Medical information may contain some of the most sensitive information about topics such as one's HIV (human immunodeficiency virus) status, emotional and psychiatric care, and abortions. Thus, the privacy of medical information needs to be especially safeguarded.

Ensuring security and privacy in e-health while preserving the fast transaction of medical data is, however, not an easy task. Security by itself is a complicated and tough task to accomplish in every sense, and there seems to be always a balance between the optimum efficiency and cost vs. maximized security (Fischer-Hubner, 2001). Security in e-business has being studied extensively, yet not a single system has been found to meet the requirements of all levels of protection. Healthcare systems need a higher level of protection because medical data are more sensitive and vulnerable to various misuses or attacks (Mac McMillan, 2002). When accessing medical data, possible errors and attacks could occur during the identification, authentication, and authorization processes. Potential threats and dangers incurred by the transmission of e-health data may come from computer viruses such as Trojan horses and droppers, and from intercepting threats such as masquerading, IP (Internet protocol) spoofing, misrouting, information modifying, and packet sniffing. General security mechanisms, which have been widely used at present, consist of the protection of individual servers and applications, firewalls, and secure data channels during transmission.

An early work conducted by the University of California, San Diego, and others in 1996, titled Patient Centered Access to Secure Systems Online (PCASSO), successfully developed a robust security architecture for Internet access (Baker & Masys, 1999). Since then, more efforts have been directed toward developing e-health security measures for virus protection, firewalls, authentication and access control, encryption, and so forth. Many businesses and research organizations have been developing and marketing their techniques and products, for example, ActiveCard Inc., MediTrust, National Health Key Corroborative, and so forth. Current technologies exploit smart cards, digital signatures, biometric devices, digital watermarking, public-key repository infrastructures, privacy-enhancing techniques, and so on (Ball, Chadwick, & Mundy, 2003; Cheng, Wang, & Tan, 2004). We believe that effective solutions to security and privacy in e-health must rely on a unified framework, with the deployment of wide-range security and privacy technologies from various vendors.

E-health security and privacy are challenging not only due to the difficulties of developing an error-free, complex framework, but also because of the complications of various moral and legal issues among all the stakeholders in the e-health industry such as the consumers, vendors, and health providers. To protect security and privacy in health care, governments around the world need to establish necessary regulatory standards. The Health Insurance Portability and Accountability Act (HIPPA) created in 1996 is a standard made by the U.S. federal government to provide the guidelines and policies that protect medical records. HIPAA presents both challenges and opportunities to improve the way in which medical data are acquired, exchanged, and distributed (Hippaadvisory, 2004). Meeting the challenges of HIPAA legislation requires a careful study of the legal infrastructure and a thorough understanding of the HIPAA evaluation process.

CONCEPTS AND REQUIREMENTS

Security in e-health is an integrated concept requiring the confidentiality, accountability, integrity, and availability of medical data. Confidentiality is ensuring that the data are inaccessible to unauthorized users. Accountability is the ability to trace back all the actions and changes made to the data, for example, through security logs used for recording log-ins, dates, accessed content, and changes. Integrity is preventing information from being modified by unauthorized users. Availability is ensuring the readiness of the information when needed. These four features are equally important and need to be satisfied simultaneously, and by working all together, they encompass the concept of security (Schneier, 2000; Stajano, 2002).

Security issues, in general, cover strategies in four different areas: (a) access security including user-authorization identification and management, (b) communication security related to the secure communication of messages, (c) content security including the protection of content such as data confidentiality, integrity, and availability, and (d) security management including security and vulnerability assessments, the implementation of policies, and guidance (Stajano, 2002; Van de Velde & Degoulet, 2003). To address the above issues, a solution to protecting the privacy and security of e-health needs to accomplish at least the following functions.

- Authentication, the process to validate the identity of the user
- Access control, the process to ensure that only authorized users see the authorized content or information
- Encryption, the process to prevent illegal access or use during data communication
- Intrusion detection and theft termination, the process to automatically detect and disable the devices if they are being accessed or attacked illegally

Privacy is the right of an individual to determine the disclosure and use of this personal data on principle at his or her discretion (Fischer-Hubner, 2001). In e-health applications over the open Internet, privacy may be seriously endangered without sufficient protection by privacy legislation and privacy-enhancing technologies

(PETs; Goldberg, Wagner, & Brewer, 1997). Besides the confidentiality and integrity of personal data considered by data security techniques, PETs need to protect user identities in terms of anonymity, pseudonymity, unlinkability, and unobservability, and also user identities in terms of the anonymity and pseudonymity of data subjects (Fischer-Hubner, 2001). PETs usually exploit encryption tools and access control, and can be enforced with security policies.

TECHNOLOGIES AND CHALLENGES

Security and privacy issues arise when accessing and communicating the health data. Basically, there are three steps for security after logging into the computerized healthcare system (Van de Velde & Degoulet, 2003).

- Identification to check who the end user is
- Authentication to check whether the information provided during the identification step is correct or not
- Authorization to check whether the user is authorized to perform certain tasks

Authentication and access control are required for security when accessing medical data through an e-health infrastructure. Many techniques have been applied for such proposes, for example, smart cards, firewalls, digital certification, biometric devices, password and PIN (personal identification number) generators, and others (Ferrara, 1998). Encryption can be incorporated into different protocols such as NCSA's Secure HTTP (hypertext transfer protocol; SHTTP) and Microsoft's Private Communications Technology (PCT; Goldman & Rawles, 2004). Theft termination is an effective and active protection strategy (Goldberg et al., 1997), and more studies are needed in developing such functionalities in e-health. In the following, we shall briefly discuss several technologies for e-health security and privacy.

Firewalls

Firewalls are a common practice set on the Internet for a business' Web site to prevent unauthorized access to confidential data. A firewall can act as an isolating layer between the inside and outside networks: All information entering the firewall is filtered or examined to determine whether the users have the rights to access the network, and whether the information entered meets the requirements of the inside network for further dissemination over the network (Gollmann, 1999).

The architecture of the firewall consists of packet filters, proxies, and internal firewalls. Packet filters are programs designed at the port level that determine access by checking the source and destination addresses of the incoming data. Proxies, also known as application-level filters or application gateways, take a step further to exam the validity of the request for the entire set of data. Proxies are also entitled the right of refusing connections based on traffic directions; for example, certain files can be uploaded but not downloaded. To prevent internal attacks from insiders, internal firewalls emerged as an access control mechanism inside the network (Stajano, 2002).

Firewalls have found widespread applications in e-health (and other industries). Some popular products include the Firewall-1 from Checkpoint, Alta Vista Firewall from Compaq, and Gauntlet from Network Associates. However, there are certain limitations to this technique. First, designing firewalls often assumes the threats or attacks are from the outside network, which is not always true in reality. Second, the firewalls cannot resist outside threats at all if we are not able to control or monitor the outside connections. Third, the packet filters cannot prevent hackers from IP spoofing, and the proxies are unable to detect many computer viruses such as Trojan horses or macro viruses. Last but not the least, there is no standard established for firewall architectures, functionalities, or interoperability (Schneier, 2000, Stajano, 2002).

Smart Card

Smart cards are actually one form of token-authentication technology, and they generate the session password that can be authenticated by the server. The whole authentication process involves one or more of the following.

1. The client software, to enter the password and communicate with the server software
2. The server software, to verify the password and record the card history
3. The application software, to integrate the token-authentication technology with other technologies (Fischer-Hubner, 2001)

In general, there are two approaches in token-authentication technology: challenge-response and time-synchronous token authentication. The former works in the following way.

- The server software generates a challenge based on the ID and password that a user entered.

- The smart card generates a response number based on the challenge number and user ID.
- The server checks the response from the smart card. The log-in session is enabled if it matches the correct one.

Time-synchronous token authentication simplifies the challenge-response authentication in that there is no server-to-client step. The user can directly enter the access code from the display of the smart card, which can be matched by the server software since every 60 seconds the smart card and the server software will generate a new access code (Goldman & Rawles, 2004). ActiveCard is an example of using smart cards in e-health services. Its one-time password method is similar to the time-synchronous token-authentication approach, while its device-PIN method incorporates digital certificates or biometric information stored on the card. Graded authentication controls different levels of access rights and needs of the confidential medical data. For example, the users are entitled different levels of rights based on their roles as physicians, clinicians, nurses, technicians, administrators, insurers, and patients. The shortcomings for using smart cards include the fact that the authentication may fail when the physical device degenerates over time, and they are easy to get lost or stolen.

Biometrics

Biometric authentication is the authentication process using the unique physiological and behavioral characteristics of a user such as fingerprints, palm prints, retinal patterns, hand geometry, facial images, voice, or others. This process requires establishing a large database for the user's biometric features as the reference during validation (Jain, Bolle, & Pankanti, 1999). Accuracy and sensitivity are important issues. Usually, a good trade-off between them needs to be achieved because accuracy depends on the ability of the equipment to detect despite small variations between biometric characteristics. Though perfect biometric devices have not yet been developed, adding biometric features to smart cards provides an improved way to achieve security and key management. Such commercial products are gradually replacing the old smart cards in e-health applications. Biometric techniques for security are an active research area, and their applications to e-health industries appear rosy.

An important challenge is how to protect privacy while exploiting biometrics. It is often possible to obtain someone's biometric sample without that person's knowledge, thus, those who desire to remain anonymous in any particular situation can be denied their privacy by biometric recognition. This covert recognition of previously enrolled people may raise privacy concerns over unintended application scopes. Besides this, unintended functional scopes also pose a privacy concern. For example, collectors may obtain or infer additional personal information from biological measurements. Such derived information could lead to discrimination against segments of the population perceived as risky. An effective way to enhance privacy while permitting all the advantages of biometric-based recognition is to decentralize the biometric system. The biometric information is stored in decentralized, encrypted databases over which the individual has complete control. To enhance privacy in using biometric information, legislation by government is necessary. The European Union has legislated against sharing biometric identifiers and personal information. Another solution to the privacy problem includes building autonomous enforcement by independent regulatory organizations like a central biometric authority.

Data Encryption of Health Data

During transmission over the Web, medical data could be intercepted and manipulated maliciously with the information confidentiality and integrity compromised. A common data-protection technique uses data encryption with either symmetric or asymmetric algorithms (Stinson, 2000). The conventional encryption algorithms include Blowfish, CAST-128, IDEA (International Data Encryption Algorithm), Data Encryption Standard (DES), and so forth. Concurrent algorithms include AES (Rijndael), Serpent, RC6, Twofish, and so on (Stinson). For symmetric encryption, the same key is used during both encryption and decryption such as DES developed by IBM. The problem for symmetric encryption lies in the difficulty of key management, where the security process will fail if the third party obtains the key.

For asymmetric encryption, a pair of keys is used including the private key that is only known to the owners, and the public key that others can process. The private key has the highest security level, which cannot be inferred from the public key though they are mathematically related. When the public key decrypts the messages encrypted with the private key, the identity of the sender can be authenticated. This technique is also known as digital signature. When the private key decrypts the messages enciphered with the corresponding public key, the identity of the receiver can be authenticated. Commonly used asymmetric algorithms include RSA (Rivest, Shamir, & Adleman, 1978), elliptic curve cryptosystems (Koblitz, 1997), and so forth. Digital signature is a common technology using asymmetric cryptography to authenticate the author of electronic transmitted documents. The biggest problem with asymmetric encryption is its high computing cost and slow process (Van de Velde & Degoulet, 2003). Thus, asymmetric cryptosystems are usually used for transmitting symmetric keys as it is inefficient for large amounts of data such as medial images.

COMPLIANCE WITH HIPPA

HIPPA has been the standard in the United States for health-care industries, with the guidelines and policies to protect the privacy and security of medical records since it was created in 1996. It includes more than 68 information security conditions in three areas that must be satisfied to ensure compliance with HIPAA. These areas include the following:

1. technical security services such as user authorization and authentication, access control, and encryption;
2. administrative procedures such as formal security planning, record maintenance, and audits; and
3. physical safeguards such as the security of buildings, and the privacy of offices and workstations that handle patient information.

The standard provides a uniform level of protection for all health information, and safeguards physical storage and maintenance, transmission, and access to individual health information. It does not require specific technologies to be used, and solutions will vary from business to business depending on the needs and technologies in place. However, all stakeholders in healthcare systems including health plans, healthcare providers, and clearinghouses are required to comply with HIPPA. Such compliance ensures the protection of patient privacy and data security through e-health, and will ultimately increase public confidence in using e-health as their preferred means for healthcare. How can the e-health strategies, technologies, services, and management be deployed to ensure HIPPA compliance? Such questions are faced by the health-care industries in promoting e-health. In sum, HIPAA has a far-reaching effect on the health-care industry, presenting health-care organizations with numerous planning, operational, technical, and financial challenges.

TRENDS

Security mechanisms are usually regarded as technical means to protect privacy. However, they can also contradict privacy. Oftentimes required is the collection of sensitive personal information from the users to better protect security. The user must trust the security system and provide such private information. The government needs to enforce the laws and keep the e-health system running healthily. Technically, one global trend in e-health is the development of privacy-protection mechanisms in e-prescription systems, patient record databases, and medical information systems. The development of security business management also represents an important trend. A healthy security system requires not only the measures to prevent current threats, risks, and attacks, but also reasonable protections against future generations of attacks and misuses. With the rapid evolvement of cyberattacks, excellent security business management skills and strategies are necessary in providing visionary preparation for future threats beforehand, and in designing and managing smart security systems. Because each security technique has its own strengths and weaknesses, an important development is to build a holistic framework, taking advantage of various techniques while compensating for their drawbacks. An industrial standard is lacking but urgently needs to integrate various security techniques so that maximum efficiency can be achieved.

CONCLUSION

E-health, a fast-developing area in healthcare industries, faces the challenges of privacy and security issues. Only with high confidence in security and privacy can both patients and health providers greatly benefit from the high efficiency and quality of service of e-health systems. We discuss relevant concepts, technologies, limitations, challenges, and trends in e-health security and privacy. Also discussed are strategies and standards such as HIPAA. We conclude our article by emphasizing that only through the collective efforts of technologies, businesses, management, and legislative regulation can the security and privacy of e-health be safeguarded.

KEY TERMS

Cryptography: The conversion of data into secret codes for transmission over a public network to prevent unauthorized use.

Data Accountability: The ability to trace back all the actions and changes made to the information.

Data Availability: The ability to ensure the readiness of the information when needed.

Data Confidentiality: The ability to ensure the data is inaccessible to unauthorized users.

Data Encryption: The process of "scrambling" the data for transmission to ensure that it is not intercepted along the way.

Data Integrity: The ability to prevent the information from being modified by unauthorized users.

E-Health: Refers to the market, companies, and initiatives for conducting healthcare-related transactions electronically using the Internet and/or wireless communications.

Firewall: Special software used to prevent unauthorized access to a company's confidential data from the Internet through filtering all network packets entering the firewall at one or more levels of network protocols.

HIPAA (Health Insurance Portability and Accountability Act): Standard guidelines and policies enforced by the U.S. federal government to protect confidential medical records.

Privacy: The right of individuals to control or influence what information related to them can be disclosed, by whom it can be disclosed, and to whom it can be disclosed.

Security: Defined as the combination of processes, procedures, and systems used to attain the confidentiality, accountability, integrity, and availability of the needed information.

Smart Cards: Used in token-authentication systems. It can be either a hardware-based card or smart IDs the size of about a credit card with or without a numeric keypad.

Telemedicine: Refers to the delivery of health care at a distance using telecommunications or the Internet.

E-Learning Concepts and Development

Fung Fai Ng
The University of Hong Kong, Hong Kong

INTRODUCTION

Our society is gradually changing from information-based to knowledge-based. The Internet is transforming our workplace and the ways we work and learn. Wallace (2004) calls it a netcentric workplace, and the netcentric technologies bring a host of new tools and capabilities to workers, especially in the areas of information access, communication, and collaboration.

In recent years, we have seen an explosion of interest in e-learning, not only from the academic institutions but also from the commercial organizations. There are many activities, research, and development related to e-learning such as lifelong learning, self-directed learning, organizational learning, and virtual learning environment and virtual universities. The market for educational products and services is expanding rapidly especially in a global context.

The aim of this article is to explain the various concepts associated with e-learning: the stakeholders involved, the technology and related standards, and the products and services provided. The issues, challenges, and trends will also be explored and discussed.

BACKGROUND

The introduction of new technology changes the ways that teaching and learning can be conducted and affects the effectiveness of the process. There are four aspects related to the effectiveness of teaching and learning. They are time, place, delivery process, and the learning process.

From interactive video disc to computer-based training (CBT), the history of technology-based training is well over 30 years. With the introduction of the computer, traditional paper-based training materials became digitized. Packaged with other multimedia materials such as graphics and video, a CBT module can be produced, stored, and delivered as a CD-ROM to the desktop of the learner. However, CBT materials distributed on CD-ROMs cannot easily be updated and can quickly become out of date.

With the Internet, a new channel for delivery of content and communication is available for teaching and learning. Web-based training (WBT) starts to replace CBT. With Web-based learning materials, information can be updated on the server and made immediately available to every learner regardless of time and location (Khan, 2001). E-learning, online learning, e-content, mobile learning (m-learning), and learning management systems become popular terms.

Fallon and Brown (2003, p. 4) define e-learning as “any learning, training or education that is facilitated by the use of well-known and proven computer technologies, specifically networks based on Internet technology.” Piskurich (2003b, p. 8) defines e-learning as: “Learning that uses computer networks or webs as the delivery or mediation mechanism. By this definition neither CD-ROM-based nor satellite-based delivery would be considered as e-learning.” Rather, at the core of the e-learning evolution is the Internet.

From a technological perspective, the Internet serves two specific purposes: delivery and communication. In terms of delivery, instructional and learning materials can be packaged into learning content. Content providers such as publishers, universities, and knowledge institutes deliver the learning content to their learners via the Internet. Digital goods such as e-books and courseware can be delivered to learners regardless of time and location. Hence, just-in-time and on-demand learning are feasible. In terms of communication, instructors and learners using the Internet are able to communicate among themselves by means of e-mail, discussion forums, chat rooms, video conferences, instant messages, and so forth.

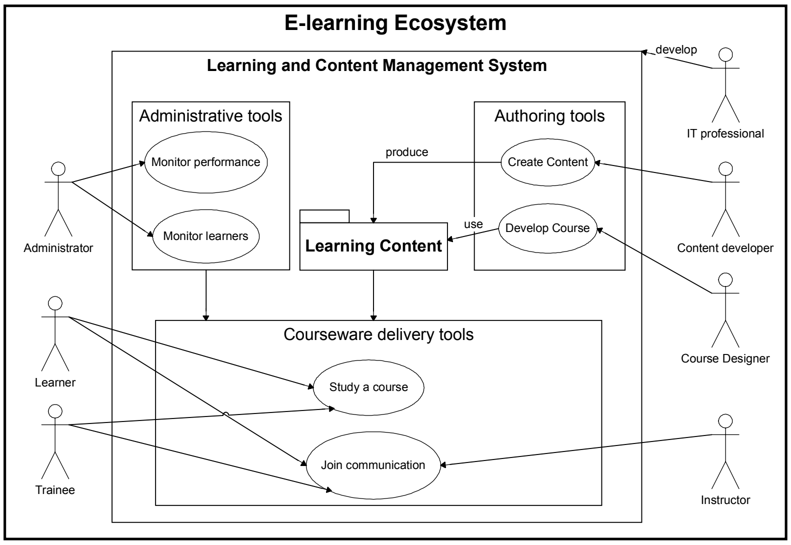
E-LEARNING CONCEPTS AND DEVELOPMENT

The E-Learning Ecosystem

E-learning is a complex field involving institutional, individual, technical, and social components. The e-learning ecosystem refers to the environment and the stakeholders involved in e-learning. Figure 1 shows an overview of the e-learning ecosystem and its components.

Within the e-learning ecosystem, there are infrastructures and platforms to support stakeholders in performing their roles required for teaching and learning such as administrator, learner, instructor, course designer, and

Figure 1. The e-learning ecosystem



content developer. There are learners and trainees who are the primary consumers. There are instructors to help and guide the learners. There are experts and content providers to create and produce contents. There are educational specialists and course designers that develop courses and learning activities. There are administrators to track enrollments and success rates, and to assess and monitor the performance of the courses and the learners. There are IT professionals to develop and create applications to support content creation, delivery, administration, and management of the courses.

The state of the e-learning ecosystem is changing dynamically. The associated technologies are evolving rapidly. The demand for quality training and learning is increasing globally both in the commercial and educational sectors. The market for more digital learning content is expanding, and hence the business of content provider or publisher is growing. At the same time, there is another market for software developers to create authoring tools for content providers, as well as administrative and management tools for administrators and managers.

The primary goal is to enhance the effectiveness of e-learning. However, different stakeholders within the e-learning ecosystem have different perspectives and definitions of e-learning which emphasize different characteristics of e-learning. Different content providers produce and store digital learning content in a different format. Different vendors are developing different applications running on different platforms. Different learners have different personal experiences and learning styles in participating e-learning courses. So, achieving effective e-learning is not a simple matter.

From a technological perspective, the main issues affecting effectiveness are reusability and interoperability of various components in different e-learning platforms. From the mangers' and administrators' perspective, the criteria for measuring effectiveness are cost, profit, enrollment, and success rate. From the learners' and educators' perspective, effective e-learning actually depends on how to achieve the desired learning goals.

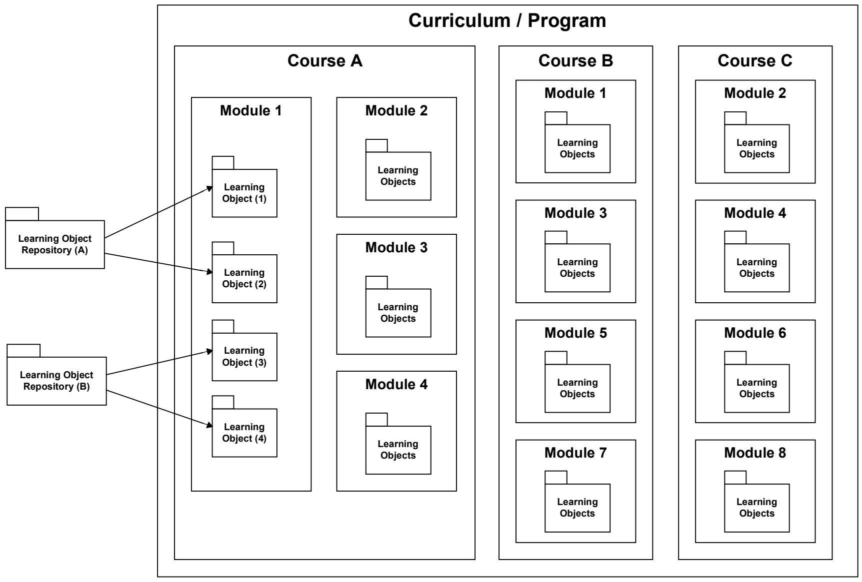
Learning Object Standards

The core of the e-learning environment is the learning content. Creating educational materials to be used in e-learning courses requires considerable investment, as they are expensive to develop. Therefore, reuse of the educational materials is necessary to gain economic benefit (Littlejohn, 2003).

In software engineering, the object-oriented approach emphasizes creating program codes that are encapsulated in objects, which are reused by different computer programs. The term "learning object" reflects the reusability feature of objects. The idea is to split educational materials into small, independent, reusable learning objects. A learning object can be used in more than one educational activity. A learning object can be aggregated from other learning objects. Reusability of learning objects is the availability of learning objects for others to use (McGreal, 2004). Learning objects created by teachers, educators, and publishers would be stored in digital repositories. A course

E

Figure 2. Aggregating learning objects into modules and courses



designer would access the learning object repositories to select, recombine, and reuse those learning objects in creating a new online course as shown in Figure 2.

The idea of reusing learning objects in different contexts implies the need for some degree of standardization. At very least, learning objects have to be categorized for easy identification and access. Combining different learning objects from different authors requires further information and functions. Learning objects are reusable but not necessarily interoperable without standardization. Standardization includes two basic standards. Interoperability standards define how lessons communicate with the administrative tools to exchange data about learners and their progress. Content-packaging standards define how learning objects should be categorized, stored, searched, accessed, packaged, and reused.

The first standard related to e-learning is the computer-managed instruction (CMI) specification developed by the Aviation Industry CBT Committee (AICC) in 1993. Another key development in e-learning standards was carried out by the Advanced Distributed Learning Initiative (ADL), which published the first version of its e-learning specification, the sharable content object reference model (SCORM), in 1999. SCORM is becoming a recognized standard in the e-learning market. E-learning application vendors are eager to meet SCORM conformance to maintain a share in the huge e-learning market. SCORM is still evolving and is revised on a regular basis to add new specifications. Many learning management systems (LMSs) and learning content management systems (LCMSs) on the market today are tested for SCORM conformance. Features of LMS vary from one system to another, but generally they include a learner interface and some administrative functions such as course setup, learner registration, course assignment, and reporting of learner's progress. Features of LCMS emphasize content creation. They usually include authoring tools for producing learning objects, a repository for storing learning objects, a framework and structure for content aggregation, and a course delivery module (Horton & Horton, 2003).

Learning Object Repositories

Reusing educational materials is a common practice in teaching and learning. As shown in Figure 2, learning object repositories are places to store digital objects or links pointing to the storage location of the objects. A key function of learning object repositories is to provide an indexing system or catalogue that enables efficient search, discovery, and sharing of learning objects. Examples of learning object repositories are: Campus Alberta Repository of Educational Objects (CAREO) at www.careo.org and Multimedia Educational Resource for Learning and Online Teaching (MERLOT) at www.merlot.org. MERLOT holds a large collection of links to learning objects, together with descriptions, peer reviews, lesson plans, or assignments.

Educators in the E-Learning Ecosystem

Reusing and combining learning objects into courseware emphasizes the approach of packaging learning materials into self-study modules. Current e-learning standards focus more on solving the technological problems related to compatibility and interoperability. However, educators care more about the quality of the learning objects, the performance of the learners, and the outcomes of the learning process—that is, the effectiveness of learning. Educators design the courses including not only the content, but also the learning activities. In the constructivist view of learning, learners use their own process to acquire and construct knowledge rather than passively receiving knowledge from external sources (Kafai & Resnik, 1996). In the view of collaborative learning, learners work in groups or communities to share and construct knowledge. Effective knowledge sharing requires the support of efficient communication services. Therefore, another important feature of learning management systems is to provide communication tools for both synchronous and asynchronous e-learning. Chat rooms, discussion forums, e-mail, video conferences, and instant messages could be incorporated into learning activities. Design of the learning activities could be stored as a template and packed together with the educational materials into learning objects. However, learning activities are usually designed for a specific context, especially in situated learning. To capture the learning activities into a learning object that can be shared and applied in another context, educators have to take an additional step to separate contextual information from learning activities, which is not common practice (Jochems, Merrienboer, & Koper, 2004).

Learners in the E-Learning Ecosystem

An important aspect of e-learning is to put the control of the learning process in the hand of the learners. It is the interaction between the learners and the e-learning environment that determines the quality and effectiveness of learning. Other factors include the prior knowledge and the learning style and attitude of the learners. If the learners are ready for e-learning, it is an efficient, effective, and economical approach. However, if the learners are not, their e-learning experience may be a failure, incomplete, and frustrated. As e-learning is based on technology, the technical readiness of the learners is critical. Technical readiness includes the technical knowledge and skills required to operate the system used to deliver e-learning courseware. Moreover, the technical attitudes and habits of the learners would help to eliminate any technical barriers or roadblocks (Piskurich, 2004). In terms of learning style, successful e-learners share the same characteristics as successful self-directed learners. Those characteristics include creativity and independence in learning, willingness to seek help, and acceptance of responsibility for one's own learning. E-learners can perform better if they understand their learning styles and preferences. Hence, the first step of an e-learning program is to assess the learners' readiness for e-learning. New e-learners or learners with lower levels of readiness might need additional support in their first encounter with the e-learning program (Piskurich, 2003a).

FUTURE TRENDS

Learning object repositories are developed to support sharing and reuse of learning objects. Copyright is an issue, as the law has not been able to keep up with the development of e-learning. New laws are emerging and new technologies are developed to make learning objects sharable and reusable while still protecting intellectual property rights. Digital rights management (DRM) technology is developed for vendors and publishers to protect their intellectual property (Barlas, Cunard & Hill, 2003). Another technological challenge for e-learning will be to develop strategies and standards for digital repositories of courseware and online course management systems, to make it easier to catalog, share, and reuse valuable content.

For the learners, there is an increasing demand for lifelong learning that is timely, personalized, and targeted. Individuals want learning tailored to their particular needs and context. They want flexibility of access and just-in-time content, for example, accessing courseware using mobile devices—that is, m-learning (Lundin & Magnusson, 2003). More learner control would be available in the next generation of e-learning. Instead of a course designed to fit all learners, each learner could select and aggregate learning objects and modules to create a customized course for achieving specific learning goals (Garrison & Anderson, 2003).

Computer-assisted assessment is an important element in e-learning. Similar to learning objects, a test and its questions can also be shared and reused. There are vendors marketing standard tests to assess people's level of skill and competence in specific areas. To facilitate effective e-learning, the purposes of assessment are:

- to verify learner's prior knowledge and skills before taking an e-learning course,
- to test the learner's understanding of the content during the course, and

- to identify knowledge gaps of the learner and to select appropriate e-learning content for the learner.

Incorporation of technology into assessment is inevitable. The challenge is to develop cost-effective systems of assessment that have both summative and formative components (Bennett, 2002). Better facilities to evaluate and provide feedback on a learner's performance, weaknesses, and strategies to improve are essential.

Research and development are carried out in the areas of intelligent software agents and computer-supported collaborative learning. Intelligent agents have been incorporated into a wide range of educational systems, from intelligent tutoring systems to computer-supported collaborative learning systems. The goal is to create a smart learning environment where intelligent agents support and enhance interaction among learners, facilitators, and active contents of the courseware. A learner's agents could also customize courses dynamically according to the learner's profile, learning style, and preferences (Lin, 2005).

CONCLUSION

E-learning is characterized by its independence of time and place, its integrated presentation and communication facilities, and its opportunities for reuse of instructional materials in the form of learning objects. It offers advantages over earlier computer-based training programs because of the way materials are developed, updated, and distributed.

In the e-learning market, learning management systems, learning content management systems, and authoring tools are available as commercial products. Digital repositories and portals of learning objects are developed in both public domain and private organizations. Online education in both academic institutes and commercial organizations is growing rapidly and globally. The value added by e-learning to organizational learning is critical to the competitive advantages of organizations.

E-learning has been driven by the advanced information and communication technologies. Infrastructures, supporting tools, and applications have been established in the e-learning ecosystem. As an ecosystem, the stakeholders involved are facing problems arising from the action and demand of other stakeholders. Demands from educators, trainers, and learners are setting new requirements for e-learning. The objective of e-learning remains the same: to support effective learning. However, the demand for effectiveness of learning is increasing. New principles and new applications are being developed to fulfill the new demands. Feedback and collaboration drives continuous improvement and development of the e-learning ecosystem.

KEY TERMS

Computer-Based Training (CBT): Training materials and programs usually delivered on a CD-ROM or via an organization's local area network.

Digital Right Management (DRM): Technology used to control or restrict the use of digital media content on electronic devices, in order to protect intellectual property and to combat piracy.

E-Learning: An approach to facilitate and enhance learning through the use of devices based on information communication technologies and the Internet.

Learning Content Management Systems (LCMSs): Designed for the design, delivery, and management of educational materials and e-learning courses. They usually include authoring tools for producing learning objects, a repository for storing learning objects, a framework and structure for content aggregation, and a course delivery module with administrative functions.

Learning Management Systems (LMSs): Designed for the delivery and management of e-learning courses. They generally include a learner interface and some administrative functions such as course setup, learner registration, course assignment, and reporting of learner's progress.

Learning Object (LO): A reusable unit of educational materials. It is the basic building block for e-learning content. A learning object can be aggregated from other learning objects and can be used in more than one educational activity.

Sharable Content Object Reference Model (SCORM): A standard for categorizing and assembling learning objects to create e-learning courses. By specifying key information in a standardized way, SCORM makes learning objects sharable and reusable in different courses that are interoperable and compatible with different learning content management systems.

Electronic Data Interchange

David Whiteley
Manchester Metropolitan University, UK

INTRODUCTION

The popular notion of e-commerce is a consumer interacting with a Web page to buy a book from Amazon or a ticket from Expedia. This is an important aspect of e-commerce, but the applications and technologies used in e-commerce are much wider than business-to-consumer e-commerce facilitated by the Internet and the World Wide Web.

E-commerce is summarized by the phrase "doing business electronically," and to that we should add the qualification that the business is conducted between the organization and some external party. E-commerce is defined by Wigland (1997, p. 5) as "…the seamless application of information and communications technology from its point of origin to its endpoint along the entire value chain of business processes conducted electronically and designed to enable the accomplishment of business goals."

This includes business-to-business transactions as well as business-to-consumer transactions, and does not presume the type of technology that is used to facilitate these transactions. There are authors that seek to define e-commerce in a way that limits the term to business transacted over the Internet, but this seems to be without merit: Did not transactions conducted using Minitel or Prodigy serve the same purpose as today's Web-based transactions, and does not the development of m-commerce still come within the more general classifications of e-commerce and e-business?

Whiteley (2000) suggests that e-commerce was facilitated by three technologies: electronic data interchange (EDI), electronic markets, and the Internet- (or e-shop) type facilities. EDI and electronic markets predate the e-shop model and, for the *Encyclopedia of E-Commerce, E-Government, and Mobile Commerce*, this article will concentrate on EDI.

What is EDI?

EDI is an e-technology that supports business-to-business transactions and is principally used by large organizations that have a large volume of standardized transactions. There are a number of definitions around, but (unlike definitions of e-commerce and e-business) they are all different ways of saying the same thing. The definition adopted by the UK National Computing Centre (Parfett, 1992, p. 7) is the "transfer of structured data, by agreed message standards, from one computer system to another, by electronic means."

The first phrase of the definition, "structured data," brings most trade exchanges within the potential scope of EDI. A simple business-to-business trade exchange consists of an order, delivery note, invoice, and payment, and these are all structured data. The utility and preciseness of the trade exchange data is enhanced by the use of codes in place of addresses and product descriptions. The Article Numbering Associations (ANA) is one set of organizations that have devised appropriate coding systems; EAN (European Article Number) and UPC (Universal Product Code) are examples of this. The scope of EDI has also been extended from basic trade documents to requirements such as customs clearance, container information, and continuous replenishment (Lauden & Traver, 2004). EDI is also used for other applications, for example, in banking (electronic funds transfer, EFT), education, medicine, and weather forecasting.

The phrase "agreed message standards" implies a message coding system that has wider application than just the two (or a small group of) organizations involved in trade exchanges. EDI standards were initially devised by industry-sector organizations and often on a national basis. Examples of early EDI standards include Tradacoms, devised by the UK ANA for general merchandise, Odette, used by automobile assemblers, and UCS, used in the grocery trade in the United States. A difficulty with the early message standards was that they were trade-sector or nationally based. As the use of electronic trade exchanges expanded to a wider range of products and across international borders, suppliers were increasingly being asked to implement more than one standard. The answer to this problem was to devise a standard that was more widely accepted and catered for a greater range of requirements. This resulted in the ANSI X12 standard in the United States, and EDIFACT (EDI for Administration, Commerce and Transport) in Europe. EDIFACT was developed under the auspices of the United Nations (UN) Economic Commission for Europe but was subsequently adopted as the international standard at a meeting of the International Organization for Standards in September 1987. Since that date, the EDIFACT standard has continued to develop and now includes in excess of 190 messages (trade documents). The full standard is available on the UN Web site (2004). The standard is vast, but that does not mean that an individual transaction has to be complex.

It is the phrase "from one computer system to another" that distinguishes the application of EDI from most other e-technologies. The concept is of an exchange that directly links the computer application of the customer to that of the supplier. This can be, for example, the stock-control or replenishment system of a supermarket chain "talking" to the order-processing system of the supplier of breakfast cereals, or the material and requirements planning system of an automobile assembler issuing just-in-time orders for the delivery of components and subassemblies by the supplier of those products. EDI is used for business-to-business transactions that are computer generated, frequently repeated, and computer processed. To gain the full benefit of EDI, there should be no requirement for manual (administrative) intervention at either end. EDI is the e-technology that most effectively automates and integrates the logistics supply chain. It facilitates the creation of an interorganization information system (IOS) integrating the business systems of customers and suppliers, and it can include other players such as shippers, customs authorities, and banks.

Finally, "by electronic means" implies the transaction takes place over a network. Traditionally, the network has been a commercial value-added data service (VADS), also known as a value-added network (VAN). These networks, marketed and managed by companies such as AT&T and GE, provide high-quality network services. A feature common to all these networks is the provision of post-and-forward facility so senders can transmit their EDI exchanges at times that suit them, and the addressees can pick them up in accordance with their own operating schedules. The VADS operator can also provide other services such as consultancy and trusted third-party services. In recent years, the Internet has been used as an alternative EDI network. The use of the Internet can be substantially cheaper than a VADS (savings of up to 90% are reported; Chaffey, 2002), but there are, or have been, concerns about reliability and security. AS2 is a recently introduced transport standard for transmitting EDI over the Internet (Adshead & Thomas, 2003)

The EDIFACT Standard

To understand EDI, it is useful to have an idea of what an EDI message would look like. As already stated, the EDIFACT standard is vast, but any specific requirement will only utilize a small subset of that standard (although agreeing on the exact subset that is to be used can be a problem). To illustrate the standard, let us consider the order shown in Figure 1.

The customer and the supplier will have already agreed on the terms of the trade. The address and product codes are standard for the trade sector, and thus names, addresses, and product descriptions are not needed in the electronic transaction. This order can then be coded into EDIFACT giving the short message shown in Figure 2. Note that the codes not in Figure 1 are qualifiers specified by EDIFACT; for instance, the DTM (date-time) data segment includes a *4*, which specifies it is the order date, and *102*, specifying the date is in century date format.

The customer and supplier will have EDI software integrated in their stock-control and order-processing application, and thus the EDIFACT message can be automatically coded and sent from the customer and will be automatically received and decoded at the supplier's end.

EDI Trading

Once the e-technology for EDI trading is installed, then the organizations involved can trade very efficiently. The impetus for EDI trading normally comes from a large customer organization that is sending out many orders on a daily or weekly basis to a large number of suppliers. A supermarket chain typically has in excess of 1,000 suppliers (and many of them will be common to several or all the major supermarket chains). The major motor manufactur-

Figure 1. Example order

```
Customer:        Johnson Wholesale
                 address code: 6261601
Supplier:        Mary's Preserves
                 address code: 3231301
Order No.:       929190
Order Date:      30 Sept 2004 (20040930)
Product 1:       Organic English Mustard
                 quantity: 200 (300 gm) pots
                 product code: 3231604
Product 2:       Yorkshire Piccalilli
                 quantity: 180 (500 gm) pots
                 product code: 3231627
```

ers will typically have fewer suppliers, but for some items the orders will be more frequent. Sequenced delivery is a term that is used for components that have to be delivered at "track side" at a specific time with variants of the components loaded in the sequence. They are needed for the cars that are coming down the assembly line (thus obviating the need for storage and double handling of those items).

The large customer organization can gain greatly from the use of EDI, and it will also be appropriate for the large supplier with automated order-processing and production planning systems. EDI can be less suited to a small supplier for which the volume of transactions would not necessarily justify the investment (of time as well as money) that would be required to set up the appropriate systems.

The sending of the EDI order will typically be responded to by a delivery note when the goods are dispatched and an invoice when payment is due, and eventually the payment will be sent to settle the account. These further exchanges can also be electronic. The use of EDI for these exchanges can obviously help with the volume, but it also speeds up the matching process and cuts down on errors. The delivery note, when it is received by the customer, should be matched to the corresponding order. The invoice similarly needs to be matched against the order, and a check is made that the goods have been delivered. Finally, the payment, sent to the supplier, needs to be matched against the invoice so it can be marked as paid. The payment can be in two parts with an EFT to the supplier's bank and an EDI payment advice to the supplier.

Alternatives to EDI

EDI has been having bad press (see, for example, Deitel, Deitel, & Steinbuhler, 2001; Kay, 2000; Turban, King, Lee, Warkentin, & Chung, 2002). The criticisms of EDI include the following.

- It is expensive to set up (commercial EDI software are reasonably priced, but integrating and interfacing them to applications can be both time consuming and expensive).
- The charges for commercial VADS systems are expensive (but then, as already noted, EDI exchanges can be sent over the Internet if the parties agree).
- The standards are complex.
- The standard-forming process is both long winded and time consuming.

All of these criticisms are true, but any commercial business information system is expensive and all standards processes are time consuming (also, the EDIFACT standard is in existence, and changes to the established messages are normally relatively minor). The alternative that is proposed is the use of XML (extensible markup language) for business-to-business electronic data exchanges. The advantages claimed for XML are the following.

- The standards are simple; you can devise your own (and so can everyone else).
- XML software are readily available and in many cases they are free (although there will still be the need to integrate the XML processing software with the business application).
- EDI is old and, in comparison, XML is new, versatile, and exciting.

XML messaging has been included as an option along with EDI in many of the new Internet-enabled electronic markets such as Commerce One, Biznet, and Aribia. XML has also been used to create message standards in new areas of electronic data interchange, with the European Bioinformatics Institute (http://www.ebi.ac.uk), used by colleagues at Manchester University, being an example.

The use of XML messaging allows us to convey much the same information as we can with EDI but in a different type of coding system. Taking the order that was used in

Figure 3. Example XML order

```
<? xml version="1.0" standalone="yes" ?>
<purchase-order order-no="929190">
<order-header>
    <reference-no>929190</reference-no>
    <date>20040930</date>
</order-header>
<company>
    <company-no>6261601</company-no>
</company>
<supplier>
    <supplier-no>3232301</supplier-no>
</supplier>
<order-item>
    <item-no>3231604</item-no>
    <quantity>200</quantity>
</order-item>
<order-item>
    <item-no>3231627</item-no>
    <quantity>180</quantity>
</order-item>
</purchase-order>
```

Figure 2 to illustrate EDIFACT, we can devise an equivalent XML message (see Figure 3). The XML message can be supplemented by an XML schema, defining the rules, elements, and data types, and a style sheet that governs how the data is displayed (if that is required).

XML is now included in many EDI software packages; for example, Perwill's EDI software also processes XML messages (see, for example, the case of Arla Foods; Perwill & IBM, 2004). There is the drawback that XML standards for trade exchanges do not have the acceptance and maturity of the EDIFACT EDI standard (see, for example, Kay, 2000; UN & CEFACT, 1999 for a detailed assessment of the use of XML). Some IT industry leaders have developed their own XML interchange standards (Chaffey, 2002), and in some cases, the tags used are their own internal database definitions (UN & CEFACT). In addition, there are more general standards being developed, for instance, the EANCOM standard (the European standard for retail and manufacturing), and these tend to draw heavily on EDI experience.

There is the possible advantage that by using XML, a trading partner, that is too small to be able to afford an integrated IS infrastructure, could use an XML style sheet and free XML software to print the transaction (but that makes a rather large assumption that a small organization would have the expertise to undertake the task).

BACKGROUND OF ORGANIZATION

An example of an organization that uses EDI is Automotive Products (AP) Driveline Technology. AP is based in Leamington in the British Midlands and also has a factory in Spain. AP Driveline manufactures clutches. Their claim is, "From a family hatchback to a Ferrari and from a tractor to a static land or water based industrial plant, Automotive Products Driveline Technologies has the expertise, ability and experience to provide a total driveline solution" (http://www.apdriveline.com). The company has been based in Leamington for more than 70 years, with its driveline products originally marketed under the Borg and Beck name. The company was, until about 7 years ago, part of the AP Group, which manufactured a range of other vehicle components (including Lockheed brake systems). The company supplies original equipment (OE) to manufacturers such as Rover, Jaguar, Honda, and Aston Martin. The company also supplies the aftermarket (replacement parts).

DESCRIPTION OF E-COMMERCE

The AP Group used to have a large IT department and EDI arrangements with a number of customers. AP Driveline, when it separated from the AP Group, had to set up its own smaller, leaner IT infrastructure. The current technology is an IBM AS400 running a BPIX ERP system. BPIX includes e-commerce facilities.

Currently, AP Driveline has a single EDI link with its largest aftermarket customer and receives about 600 order lines a week. A number of other customers want AP Driveline to trade electronically, but the company has not had the resources to implement the interfaces, and these customers seem to have put their long-standing supply relationship before their normal requirement for electronic trading. For OE customers, the quantities can be quite large but the range of part numbers will be limited, making the ordering process more manageable (at least for AP Driveline). Currently, there is a project to establish EDI links with five more customers using the Odette and EDIFACT standards and probably AT&T as the VADS (seen as a more appropriate, but more expensive, solution than the current VADS supplier).

In the absence of EDI links, AP Driveline takes forecasts and orders from a variety of media. For a number of customers, including large OE customers, forecasts are downloaded from the customer's Web site and keyed into the system. Some customers will also take advice (delivery notes) electronically through their Web site. One customer was insisting on the use of Covisant (a motor-industry portal), but that requirement was dropped. Customers are also contemplating the use of XML messaging, but as yet there seems to be no clear standard and no firm requirement.

AP Driveline does not use EDI for trade with its suppliers (and the understanding is that very few organizations in the motor industry use EDI with second-tier suppliers). For most supplies, the schedules from the BPIX system are converted to a spreadsheet format and then sent by e-mail.

IMPACT OF E-COMMERCE ON THE ORGANIZATION

The restructuring of the AP Group set back the use of EDI in AP Driveline by about 10 years. AP Driveline's order-taking and trade-transaction systems are a mixed bag, and arguably they have been lucky that their customers have tolerated the situation (this would not have been the case for larger components, fitted on the assembly line, where just-in-time sequenced delivery would be required). AP Driveline would like to increase its use of EDI (and electronic trading systems—EDI is seen as a legacy technology), but it has been hard to justify the investment (particularly when the volume of lines is small and the various customers have different interpretations and subsets of the EDI standards).

CONCLUSION

EDI has, over the years, been supplemented and complemented by e-technologies such as Web-based e-shops, Internet-enabled e-markets (including Web services), and m-computing. These enable business-to-consumer and business-to-administration e-commerce and are also applicable to aspects of business-to-business e-commerce. These technologies supplement rather than replace EDI e-commerce. EDI, whether it uses a traditional EDI standard or an XML-derived convention, and whether it uses a VADS or the Internet for its network connection, is still the appropriate e-technology for high-volume, repeated business-system-to-business-system exchanges. The case study of AP Driveline shows it is still relevant, but that the picture is rather more complex and untidy than we may suppose.

EDI standards have been developed over the years and are a mature technology. There is a move to substitute XML-derived messages for their EDIFACT equivalents. The rationale for this move is unclear (and the justifications that have been put forward are, in general, readily refuted). It would be unfortunate if the standardization that has been achieved over the years in ANSI X12 and EDIFACT is discarded and replaced by a miscellaneous set of bilateral and sector-based standards—that is where EDI was 30 years ago.

KEY TERMS

ANSI X12: The predominate American EDI messaging standard.

Business-to-Administration (B2A): Data interchange between commercial organizations and government bodies using e-technologies such as EDI or an Internet Web site. It is a component of e-government.

Business-to-Business (B2B): Commercial transactions between commercial trading partners using e-technologies such as EDI or an Internet e-shop.

Business-to-Consumer (B2C): Commercial transactions between commercial organizations and members of the public, typically using an Internet e-shop.

Consumer-to-Administration (C2A): Data interchange between citizens and government bodies, typically using an Internet Web site. It is a component of e-government.

EDIFACT: The worldwide EDI messaging standard, administered and maintained by the UN.

Electronic Data Interchange (EDI): "The transfer of structured data, by agreed message standards, from one computer system to another, by electronic means" (Parfett, 1992, p. 7).

XML (Extensible Markup Language): A markup-language standard for the Web. It can be used as an alternative to traditional EDI messaging standards for the transfer of structured data.

Electronic Voting as the Key to Ballot Reform

Rick Gibson
American University, USA

Christopher Brown
American University, USA

BACKGROUND

The emergence of online markets and e-business was expected to revolutionize market structures, supply chains, and consumer behavior. The technological potential led to hasty forecasts that predicted extremely low costs for information. Corresponding communications advances suggested increased transparency and response speeds. Nowhere have these expectations been shown to be more flawed than in the attempted application of electronic voting in the United States. Following the controversy of voting fraud accusations, such as the narrow margin in the Florida election counts in 2000, traditional voting methods have suffered a general loss of trust in the public perception (Dill et al., 2003). These methods, which include but are not limited to optical readers and punch-card ballots, have been heavily scrutinized by critics in the wake of reports of widespread malfunctions, which suggest that the primary attributes of a successful e-vote scheme: anonymity, scalability, speed, audit, and accuracy. It also brings much criticism into the picture in regard to the reliability of direct recording electronic (DRE) voting machines.

Cranor (2001) reported that, in Florida, esoteric terms for voting mishaps (e.g., the "hanging chad") became the focus of many postelection jokes due to faulty punch-card machinery. Moreover, she reported that some local polling sites in New York with ancient voting mechanisms were missing levers. These machines had been manufactured so long ago that the necessary maintenance could no longer be performed. Such technical problems present huge obstacles for vote integrity.

Weiss (2001) provided explanations of the many ways in which votes are recorded and how effective (or ineffective) these methods have been in elections. The author provides a general overview of the possibilities for Internet voting in addition to drawing a parallel between it and ATM transactions, noting the importance of setting up an e-vote system, which takes advantage of the same kind of transaction-based technology as ATMs, which do not use the Internet per se—thus dealing with the social issues that often go hand-in-hand with a fundamentally new advance in voting procedure, such as the conveto the aforementioned faulty voting machines, there is a real concern regarding ballot design in light of "butterfly ballot" confusion made notorious during the Florida national election. Such odd designs are the result of election officials putting the function of the voting machine ahead of voter readability and understanding. Thus, even voters with 20/20 vision and great hand-eye coordination may not be able to vote properly with poor ballot layouts, contrary to the popular belief that such voting errors resulted from those voters of old age with visual handicaps. Mercuri (2002) reported on the defects of DREs brought into Florida poll sites after the election fiasco of 2000. New technologies should be studied further until real implementation can be brought into the polling sites.

If U.S. citizens look beyond their own national issues with voting failure, they find themselves behind the times when they glance at other democratic countries such as Brazil and Costa Rica (Weiss, 2001). Such systems involving secure electronic implementations force voters to consider the benefits of electronic over paper systems in terms of voter fraud, cost, accessibility, and usability.

One pertinent question becomes obvious at this point: Why are poll sites continuing to use voting equipment that does not meet the needs of its voters? If the mechanisms for voting are compromised, the very nature of our democracy is threatened. Undoubtedly, as with any information system, the success of the electronic voting process critically depends on voters' beliefs and feelings about the electronic voting process. The more voters, become aware of the system's failure and lack of credibility, there will be less trust in the efficacy of the voting procedures and in those who oversee elections.

As a response to the degeneration of traditional voting methods and spurred by technological paradigms, *e-voting* has become a new catch-phrase in ballot reform. This new term, however, is shrouded in ambiguity. On one side of the debate we have those that talk about e-voting in terms of the Internet and the ability to cast votes from a great number of different locations (Weiss, 2001). The other camp of e-voting still thinks of the process in the traditional sense of conducting elections at local polling sites, but instead polling sites would be virtually, if not entirely, paperless. Both camps, however, agree that e-voting has the potential for solving the problems of traditional voting techniques but must first be approached with cautious planning.

DESCRIPTION OF E-VOTING ISSUES AND ALTERNATIVES

Internet voting takes advantage of remote access to increase voter participation. This follows from the logic that most people are familiar with browsing the Web from their personal computers and will more readily be able to participate in an election where both physical and scheduling obstacles do not interfere. Mohen and Glidden (2001) described how the 2000 Democratic primary in the state of Arizona utilized the power of Internet voting in conjunction with mail-in and poll-site options. The voting process, run through election.com, enabled Democrats from all locations within the state to vote on their personal computers with Internet access. Voter identity and authentication were successfully dealt with in a secure operating environment. Internet voting advocates in the state claim that polling site locations were increased in those areas that had limited access. They present the Arizona Democratic primaries as a success in e-voting and a fundamental reason for encouraging states to adopt such e-vote measures and also show the decryption technologies available for use and the effectiveness of these techniques for combating hackers.

Although groups like the Voting Integrity project have taken issue with Arizona's implementation of Internet voting in regard to its exclusion of those minority voters without Internet access (Craft, 2000). In addition to the Arizona primary in 2000, the Alaskan Republican Party's presidential straw poll utilized the Internet for voting in January of the same year. In this example, geographically inaccessible polling sites and other physical limitations could only be overcome by using a quick and easy remote access method. Craft (2000) also provides an overview of some case-studies in Internet voting and the pitfalls that it might succumb in terms of security. Specifically, the voices of the California Internet Voting Initiative are heard in regard to what we would need to do in order to preserve the integrity of elections.

Following from this, we also see the benefits for U.S. citizens currently involved in overseas military action or for a number of personal reasons, as opposed to mail-in ballots. To support this move, researchers have discovered that mail-in fraud had been on the rise since states have become less strict with the procedural rules (Phillips & von Spakovsky, 2001).

Rubin (2002) asserted that the major concern of such remote voting techniques lies within the realm of security, especially when one considers the possible manipulation of votes by hackers or denial-of-service attacks on Web servers hosting these election sites. Such a large-scale implementation of Internet-based voting could seriously compromise the nature of an election by a concerted effort by malicious online entities. He delves into the concerns over security breaches to a communications infrastructure supporting an online election system. Thus, social engineering, in addition to technical hacker attacks, is a threat lurking beneath the obvious ways of manipulation. For example, pseudoelection servers could be set up on the Internet to trick those unfamiliar with e-voting into believing they have actually cast a vote when they have not. There must be secure voting in order to ensure votes are not "stolen" by malicious hackers.

E-voting advocates, however, do not always support the Internet voting method. On the other hand, some advocates say traditional polling sites should convert the mix of old voting methods (such as paper ballots, punch-card ballots, optical-reader ballots, and lever ballots) to an electronic medium. A private network, as opposed to the public Internet voting framework, provides a safer, more secure transmission of ballot choices. Such a network depends on direct recording electronic systems (DREs) to present information to each voter in a way that is easy to read and understand and capable of accurately and reliably recording voter choices to a back-end database server.

Proponents of these machines often refer back to the not-so-distant past with regard to the butterfly ballot scandal in Florida. Better prepared visual layouts are promised through the use of electronic interfaces, in which the function of the device does not determine the layout. Whether or not this actually occurs in practice within the DRE market is questioned by analysts, such as Bederson et al. (2003), who further consider how malicious coding by private e-vote companies (unregulated) can corrupt election results. This leads to the question of the design of e-voting systems, such as Diebold AccuVote, and their accessibility, including ballot layout issues and their impact on elections, in addition to the problem of training requirements for both election site officials and voters.

In both forms of e-voting there is the primary concern of being able to recount votes and analyze the paper trail for corruption. Whether this serves merely the losing candidate's political vested interests or the will of the people, however, is questionable. It is clear, however, that some alternative auditing techniques must exist for the voting system to have validity within the eyes of the voters involved in the entire process. Zetter (2004) illustrated the ineffectiveness of one e-voting company's security and of a disturbing trend in how such systems can be easily exploited by simple malicious code. It also presents an interesting critique of systems which are or can be given to a single person who has the ability to manipulate the way in which votes are counted or recorded.

As explained by Saltman (1998), voting, as it is carried out in the United States today, consists of four distinct administrative steps: (a) voter authorization: the determination of whether the prospective voter is entitled to vote at a particular place, and for what set of offices and issues; (b) secret choice: provision of the opportunity for the voter to express his or her choices without intimidation; (c) precise recording of the expression of each voter's choices in a voter-disconnected and easily countable format; and (d) accurate summarization of all voters' choices by candidate and issue alternative.

Paper Ballots

Paper ballots remain in use today in small communities and rural areas by a small percent of U.S. registered voters. Saltman (1998) described the vulnerabilities of paper ballots as subject to possible fraud and error in their distribution, in their use at polling places, and in counting.

Lever Machines

As Saltman (1998) explained, the vulnerabilities lever machines center on the fact that there is no ballot (i.e., no independent verification of each machine's recorded result). Although the lack of ballots eliminates the possibility of chain voting, counterfeit ballots, and spoiling of the opponent's ballots, there are other possibilities for fraud or error, some available because there are no ballots including vote count frauds, no audit trail of voter intent, no true recount capability, write-in difficulty, mislabeling, storage and transport.

Punch-Card Voting

Saltman (1998) asserted that punch card ballots have all of the vulnerabilities of paper ballots that are related to distribution, precinct use, and collection. Administrative controls may be implemented to prevent the typical paper ballot frauds.

Voting with a Mark-Sense Ballot

Saltman (1998) explained that, with this type of ballot, the voter makes a mark in a small rectangle or circle on a ballot to indicate a vote, and after the ballot is handed in, it is automatically read. Mark-sense technology is widely used also in standardized testing, for example for college entrance, and in statewide lotteries. Vulnerabilities include: ballot-reader and ballot requirements and treatment of reader-rejected ballots.

Direct Recording Electronic (DRE) Machines

This type of machine, the newest entry in applying computer techniques to voting, is an electronic implementation of the lever-machine concept. As with a lever machine, there is no ballot; the possible choices are visible to the voter on the front of the machine. The voter directly enters choices into electronic storage in the machine with the use of a touchscreen, or pushbuttons, or similar devices. If an alphabetic keyboard is provided with the voter-choice entry device, write-in possibilities are significantly eased. Saltman (1998) noted that the DRE machine is an electronic implementation of the lever machine concept, with significant distinctions regarding set-up and risks.

According to Zetter (2005), one of the big debates over how to handle the problem of source code manipulation in skewing election results is whether proprietary code should be made open source or not. Proprietary DRE makers are often criticized for keeping the black box closed in order to make profits for their secrecy at the expense of transparent and honest code evaluation. This is not entirely true, however, because independent testing authorities (ITAs) referenced by HAVA are allowed to view proprietary code in order to conduct evaluations of software robustness. Furthermore, following an Election Assistance Commission strategic plan announcement in June 2004, five major proprietary software vendors of DREs (Election Systems and Software, Diebold Election Systems, Sequoia Voting Systems, and Hart InterCivice) have voluntary released their source code to the federal government for safekeeping in the National Software Reference Library

IMPACT OF FIXING AMERICA'S VOTING SYSTEM

The disputed American presidential election of 2000 has made it clear that we can no longer take our election procedures for granted. This election was ultimately decided by a margin of 537 votes, an insignificant sum when one considers that as many as 6 million ballots throughout the United States either were not counted or were prevented from being cast in the first place (Selker, 2004). In order to prevent a recurrence of the voting problems Americans experienced in 2000, Congress in

2002 passed the Help America Vote Act (HAVA). Under the auspices of this act, $3.6 billion dollars was distributed to local jurisdictions in an effort to improve voting procedures. Yet despite this massive effort, many contests in the 2004 election below the presidential level continued to be plagued with problems similar to those we saw in 2000.

In 2002, U.S. Congress passed the Help America Vote Act (HAVA) which provided $3.9 billion in funding for states wishing to implement electronic voting systems. In addition, the HAVA outlined steps that states should take in order to fulfill voting requirements for election integrity. These recommended guidelines cannot strictly be enforced by states, as the right to choose and implement the voting process is not established by federal mandate but by the local municipalities holding the voting (Stewart, 2005).

This state of affairs is both puzzling and astonishing. The United States possesses the information technology capable of successfully tracking the transactions required to fuel an $11 trillion dollar economy (CIA, 2005). Billions of these transactions occur daily with few if any mistakes being made by the systems required to process them. Why then is it so difficult to conduct an election consisting of around 100 million votes occurring at only infrequent intervals? We expect a great many things from our voting system, some of which are mutually exclusive. To a great extent, fixing our voting system will involve finding the right balance of tradeoffs among undesirable factors rather perfect solutions.

CONCLUSION

What has been explored in this article is the feasibility of developing an e-voting system for national elections. The Internet (remotely) and DREs (polling sites) have been looked at in comparison to traditional mechanical voting methods in terms of usability, accuracy and audit. In light of the many advantages and disadvantages, it appears that our democracy has enough faith in e-voting, in whatever form it may take, for it to become common practice. Unanswered questions center on a social critique of e-voting from a digital divide perspective—whether wealthier homes are more likely to have Internet access and, hence, vote more easily than poorer homes.

Finally, a concern express by Selker et al. (2003) while addressing the problems of usability in new e-voting technologies. Of course, specialists must be involved in the process of designing systems that are voter-friendly. Perceptions of validity among voters are key factors in switching technologies. If there is no trust in an e-vote system, the entire experience will be altered in ways that extend beyond the real threats. The democratic system itself will be endangered.

KEY TERMS

Direct Recording Electronic Systems: DREs, as they are commonly abbreviated, are a new technique for collecting and counting ballots. This system utilizes, in most cases, some form of touchscreen and stores the vote results in a back-end database server.

HAVA: Help America Vote Act. This act provided funding to states to encourage the adoption of new electronic voting systems. It also provided voluntary federal guidelines to be followed in implementing these systems.

ITA: Independent Testing Authority. These companies are authorized by the government to test and certify proprietary DRE software and hardware systems.

Optical-Scan Voting Systems: Optical-scan voting systems requires voters to use a pen or pencil to fill in an oval or connect dots on a paper ballot. This is the same system used to record test scores on standardized tests like the SATs.

Paper Trail: The ability to track votes through tangible means, as opposed to electronic auditing procedures.

Punch-Card Voting Systems: Punch-card voting systems are operated by punching holes in cards that lock into holder devices. Holes in the card correspond to the appropriate candidate or issue in the device holder book.

Vote Accuracy: Conformity of the output data of a vote-tallying system with logically correct and acceptably precise treatment of all input data provided to the system.

Electronic Word-of-Mouth

Ronald E. Goldsmith
Florida State University, USA

INTRODUCTION

One of the most powerful and pervasive influences on consumer behavior is variously described as "social communication," "word-of-mouth," "opinion leadership," or "buzz." These terms all refer to the effects that consumers have on each other when they communicate. The importance of off-line social communication has long been recognized by social scientists (e.g., Lazarsfeld, Berelson, & Gaudet, 1944) and especially by marketing management (Dichter, 1966; Whyte, 1954). Good word-of-mouth (WOM), the term most often used in business, is still considered to be the most effective form of promotion, so it is highly valued by marketers (e.g., Dye, 2000; Walker, 1995). The advent of the Internet and the growth of the World Wide Web, however, have given consumers an entirely new realm in which they can communicate and thus influence each other (Negroponte & Maes, 1996). That they do so with a vengeance is evidenced by the sheer amount of social communication online, by the many forms these interactions assume, and by the grudging acknowledgment by marketers and managers that this has become a vital component of e-commerce (e.g., Kirkpatrick & Roth, 2005). This article explains some of the theoretical aspects of social influence, describes the many ways social influence operates online, and suggests methods by which marketers can manage this force to benefit their brands.

BACKGROUND

Social communication is distinguished from mass communication, the formal communications marketers and advertisers use to persuade consumers to buy their brands (see Schiffman & Kanuk, 2004). The elements of these marketer-dominated strategies consist of advertising in all its many forms, personal selling, sales promotion, public relations, and publicity, making up the Promotion component of a marketing strategy. These communications are characteristically one way or unidirectional, highly scripted, impersonal, and use media, thereby permitting few opportunities for consumers to respond. These communications take the form of "one-to-many."

In contrast, social communication (see Gladwell, 2000; Weimann, 1994) takes place when consumers talk (face to face or at a distance) or write to each other. (Some social communication is non-verbal signaling using body language or symbols ("you are what you drive") or imitation, which occurs when consumers copy other consumers' behaviors. These topics are better discussed under the rubric of "reference group theory.") Like formal marketer-dominated communications, informal, consumer-dominated communications often include two elements: information and advice. Information refers to the objective, descriptive elements of communication that are factual or presumably fact based. Information answers the questions: "who, what, why, when, where, and how?" Advice refers to the opinions of others. Advice describes a subjective evaluation part of a communication relating to whether the topic is good, bad, worthwhile, valuable, and so forth. Advice is present when one party attempts to persuade or change the mind of the other party. It is the answer to the questions: "What did you think of it?" or "Did you like it?"

Social communication stands in contrast to formal communication because it is informal, personal, unscripted, encourages feedback and exchange of information, and does not require media to take place. Social communication is usually "one to one." We distinguish two principal ways social communication takes place. It occurs first in the course of ordinary, casual conversations in which the topics of shopping, buying, owing, or consuming arise without the participants deliberately broaching them. Information thus is exchanged, and one party of the conversation might attempt to influence the other, but there is no premeditated effort to seek or give opinions.

Social scientists have not directed most of their attention to this casual form of consumption-related social communication, but instead have focused on a more deliberate, premeditated, and purposeful type of social exchange. This is usually referred to as "word-of-mouth" or "opinion leadership." In this instance, some consumers seek out others whom they view as credible (knowledgeable, trustworthy, attractive) and solicit both information and advice. Thus, social communication can be taken as the broadest descriptive term for this phenomenon, and word-of-mouth can be considered an informal, generic term for either casual conversations or opinion seeking/opinion leadership. The slang term "buzz" is currently used to refer to any type of social communication, but most often today seems to refer to these communications when they take place online (Darlin, 2003; Dye, 2000; Rosen, 2000).

Social communication is powerful because people trust others more than communications from marketers, owing to a perceived lack of vested interest. Why would someone try to persuade you to buy a product when they do not benefit; but advertisers and marketers always benefit when you buy. The aspects of attractiveness, expertise, and trustworthiness (i.e., credibility) of information sources are of prime importance in deciding whether to place credence in a message, and personal contacts frequently are perceived to be superior to impersonal marketing messages in this regard. Consequently, social communication is a powerful influence on consumer behavior. Its extension to the Web, and even to other new forms of communication such as mobile commerce, represent a challenge to marketing managers who lose their ability to influence via promotion. It also gives public policymakers new opportunities to promote social goals by enlisting the influence of consumers online to spread socially beneficial information more efficiently and effectively than limited advertising budgets ever could. Thus, it is important to understand the types and nature of eWOM.

SOCIAL COMMUNICATION ON THE INTERNET

The Internet gives consumers many opportunities to share information and to give opinions. Thus, we would expect to find consumption-related elements embedded within the context of other cyber conversations occurring in e-mail, blogs, and listservs. This is analogous to the casual, unpremeditated word-of-mouth so common offline. Because what is transmitted on the Internet can be collected and preserved, researchers can perform content analysis of these cyber conversations to determine main themes and to detect trends in consumer behavior. Moreover, the deliberate seeking and giving of information and advice featuring opinion leaders and opinion seekers online constitutes a major aspect of e-commerce, an important source of information for consumers, and an opportunity for marketers to influence consumer behavior. The ability of consumers to receive the information and advice of other consumers online is part of a general shift of marketplace power from producers to consumers (Baker & Green, 2005; Donation, 2003; Kiecker & Cowles, 2001). As markets fragment, communications media proliferate, and traditional promotion tools such as advertising lose effectiveness, marketers increasingly turn to techniques such as WOM to influence consumers.

Why do consumers give opinions online? The extensive body of research and theory on social communication provides us with several key insights. Information givers can be motivated by their interest in the product category; they enjoy talking about it with other consumers. They like to exhibit their product knowledge and expertise, thereby also gaining status and respect. Advertisements can form the stimulus and content of conversations when they are particularly memorable, entertaining, or informative. Opinion givers can be genuinely motivated by a desire to help other consumers or by the analogous desire to help a favored brand. Negative WOM is often motivated by a desire to punish firms that have offended the consumer through insensitive, incompetent, or irresponsible behaviors, strategies, or products. Revenge is sweet. Online, some additional motives for giving opinions are a desire for social interaction and for economic incentives (Hennig-Thurau, Gwinner, Wlash, & Gremler, 2004).

The motives for seeking opinions are also many and varied. As sources of information, opinion leaders are sought out because it is simpler, cheaper, and easier to consult them than it is to locate and to examine marketer-dominated advertising, promotion, and sales personnel. As noted above, personal sources of information are trusted more than impersonal sources. Other people might have more direct and specific experience with a brand than any other source of information about it. Seeking prepurchase information is an effective way to reduce the risk of buying and consuming, especially for big-ticket purchases or for “experience” products (those purchases consumers cannot evaluate prior to purchase, such as a vacation, entertainment, or restaurant) or “credence” products (purchases consumers cannot evaluate confidently even after they are consumed, such as financial products or medical/dental services). Finally, some consumers seek opinions from others because they are seeking contact with other people in addition to the information they receive, thereby satisfying some of their need for social interaction.

How do consumers share opinions online? Although it seems as if new forms of online communication continue to appear, at this point in time there are at least nine unique ways in which consumers can seek and give information and opinions online. While there is no unequivocal way to order or classify these communication modes, they are presented here roughly in order of how much they are controlled by consumers vs. how much they are controlled by marketers, recognizing that these are gray areas on the Internet and often these communication channels are integrated within each other.

The first avenue for online social communication was *e-mail*. Consumers talk about consumption online in much the same way they do via surface mail, with the added dimensions of speed and convenience that e-mail provides, becoming perhaps, "word-of-mouse". *Instant messaging* is a similar form of this social communication channel analogous to the telephone.

A related type of social communication takes place via *listservs* or *forums*. These are e-mail discussion groups with regular subscribers whose messages are forwarded to all members of the list. A listserv provides a superb way for consumers to ask about products and brands, and receive the opinions of many other consumers.

Bulletin boards or *newsgroups* are areas online where users can post messages on selected topics for others to read. Such sites yield threaded discussions that can provide detailed, authentic information if they are organized and accessed correctly. An example of a product-focused bulletin board is www.saturn.com/mysaturn, a site for Saturn owners to discuss their cars, thereby providing many opportunities for product-related social exchange. Another good example might be Rotten Tomatoes, a popular site for movie reviews submitted by ordinary consumers that are arranged and featured by the site organizers, by and for movie buffs (Grover, 2004). TripAdvisor.com also provides destination reviews by travelers.

Similar to bulletin boards are *chat rooms*. These are virtual meeting grounds where groups of regulars come to gab in real time. There are so many of these online that several sites have been created to simply list them (e.g., http://chat.yahoo.com).

Encompassing some of the above channels, but more extensive and formal, are *online communities* (also called *virtual communities*). These Web sites vary in the scope of their content, from fairly simple lists of resources to complex cyber environments offering visitors information, entertainment, and opportunities to socialize with likeminded individuals. Some of these have arisen spontaneously from the efforts of dedicated individuals, while others are sponsored or managed by companies (see Flavian & Guinaliu, 2005). Examples would be communities based on interests such as virtual vineyards, communities based on relationship communities such as The Cancer Forum (Armstrong & Hagel, 1995, 1996), or communities held together by interests in products or brands such as apple.com/usergroups.

While companies may sponsor virtual communities, or they may arise spontaneously from the efforts of individual creators, *homepages* are the property of their creators, expressing their individuality and need to communicate with other interested individuals. Many homepages contain the opinions of their owners for others to read and respond to, so that homepages can contain e-mail, chat rooms, or listservs, and will certainly contain links to virtual communities and newsgroups. Homepages may also contain *blogs*, or Web logs, online diaries where writers can publicize whatever is on their minds. Increasingly, blogs are coming to exert great influence in the marketplace as they come to be consulted by more and more consumers seeking information and advice (see Baker & Green, 2005; Kirkpatrick & Roth, 2005).

Similar to homepages are product-specific *suck sites* (also called *hate sites*). These Web pages are devoted to criticism of specific firms (e.g., *Wal*MartSucks.org*; there are lots of these!), providing consumers an opportunity to air grievances and express dissatisfaction with businesses (Crush, 2000). Site visitors will certainly read stories and learn the opinions of other consumers from these sources of interpersonal information.

Finally, many sites provide opportunities for consumers to post *product reviews* that other consumers can consult (again, rottentomatoes.com does this). For example, Amazon.com encourages consumer product reviews of the books and music sold there. Reading what another consumer thought of a book is getting their opinion, and since they have the personal experience of reading the book, they act as an opinion leader for it. Often, consumers are asked to rate a product, and these ratings are summarized in a simplified form (how many stars did the product get or what percentages of buyers liked the product), giving other consumers the collective opinions of many consumers.

Given this variety of eWOM, companies can react in many ways. Although some firms choose to ignore what consumers tell each other about their brands online, this is probably not the most prudent course of action (see Baker & Green, 2005; Crush, 2000). Kirkpatrick and Roth (2005) describe the unhappy experience of the Kryptonite lock company, one of whose products was revealed to be defective. This news spread rapidly on the Internet, and instead of admitting the problem, they denied it and waited until a crisis broke, costing the company $10M to fix and hurting their reputation. Instead of ignoring eWOM, firms try to manage it to their advantage in three ways (see Goldsmith & Litvin, 2005).

First, eWOM is a useful source of information, a type of market research. Firms can learn what consumers think about them and their brands. Managers see what consumers are saying that can alert a firm to potential problems that can be fixed promptly. They gain crucial insights about competitors. New product ideas can be suggested by consumer discussions of unmet needs and wants, and unsolved problems. Second, firms that monitor and respond to eWOM can blunt criticism and quickly solve problems, thereby creating good feelings, enhancing their reputations, and stimulating positive eWOM. Third, firms can try to encourage positive eWOM using a combination of tried-and-true techniques for managing offline WOM (Dichter, 1966; Haywood, 1989), combined with newer techniques emerging from the cyber marketplace. This approach is now commonly referred to as "buzz management" and can be very effective (e.g., Darlin, 2003). Similarly, firms can try to get customers to pass along their marketing message to other consumers online. This form of managed social communication is termed "viral marketing" (Lindgreen & Vanhamme, 2005). Rewards or incentives, connecting the marketing message to some area of concern (such as the environment), and designing the viral marketing message to be amusing or entertaining are some of the ways marketers encourage customers to spread the word about the brand.

FUTURE TRENDS

The variety of ways to communicate online are not only bidirectional, they are becoming one-to-many and many-to-many, thereby increasing the opportunities consumers have to consult with other consumers, increasing the speed and power of WOM, and increasing the importance of this force to the health of brands and companies. Work by RoperASW for the last two decades has focused attention on the *Influentials*, that 10% of the general American population that exerts disproportionate influence on their fellow citizens by virtue of being sought out for their opinions (Keller & Berry, 2003). Online, there appear to be the *e-fluentials*, the 10% of Internet users who exert disproportionate influence on other users' Internet-related behavior. Because these individuals are likely to become more influential with time, mangers are likely to want to identify these consumers and market to them in much the same way they currently market to off-line opinion leaders.

As firms adjust to new realities, eWOM will be come commonplace and part of the broader system of integrated marketing communications that many firms now design as a normal part of their overall marketing strategies. Because this phenomenon is evolving over time, companies will develop new techniques to monitor, respond, and manage eWOM. Consumers will likewise learn to use eWOM more effectively and efficiently. Thus, the point/counterpoint competition between companies and their consumers will continue. As mobile commerce becomes more commonplace, consumers will seek each other's advice using this medium as well, resulting perhaps in *mWOM* as a unique extension of the basic tendency for humans to consult with each other before making decisions or just to discuss topics of interest. The understanding of eWOM and these other manifestations will be advanced as new studies are conducted.

CONCLUSION

Consumers have always talked about shopping, buying, owning, and consuming. They have always sought and given opinions. Social communication has always been powerful. The Internet provides consumers with many new opportunities to continue these behaviors. The speed, ubiquity, and freedom of the Internet magnifies them and contributes to the general transfer of power from companies to consumers that characterizes the 21st-century marketplace. Faced with this changing informational landscape, companies cannot ignore eWOM. They must come to terms with it and develop their own creative responses that minimize its harmful effects while bringing real benefit to the firm. Marketing theorists and researchers will focus on eWOM to integrate it into the panoply of marketing doctrine and education, and study it empirically to reveal how it works and how it can be managed.

KEY TERMS

Blog: A Web log. An online diary in which a Netizen or Cybercitizen records thoughts and opinions on a theme or topic of interest to its creator.

Buzz: A buzzword referring to word-of-mouth offline or on the Internet.

Chat Room: A Web site where many individuals can talk in real time via instant messaging.

E-Fluentials: The 10% of Internet users who manifest the greatest influence on other Internet users' online behaviors.

E-WOM: Electronic word-of-mouth, or social communication on the Internet. Web surfers either transmitting or receiving product-related information online.

Listserv: A collection of online users who have chosen to belong to an e-mail-based information exchange.

Suck Sites: Hate or revenge sites. Web sites that focus on consumer complaints and dissatisfaction with specific companies.

Viral Marketing: When individuals forward information online to each other so that it spreads exponentially like a virus or rumor.

E–Marketplace Regression of National Trucking Exchange

Hope Koch
Baylor University, USA

BACKGROUND OF THE BUSINESS

This article discusses a business-to-business (B2B) electronic marketplace's (e-marketplace's) turnaround. National Trucking Exchange (NTX), a pseudonym, became one of the first true B2B e-marketplaces when it transferred its dial-up exchange to the Internet in 1996 (Patsuris, 2000). For 5 years, NTX struggled to conduct transactions. When the business environment changed and NTX incorporated powerful organization's preferences, its turnaround began. NTX's experience shows how using power and overcoming competition facilitates bringing a critical mass of competitive organizations together to form an information-technology initiative benefiting the entire industry. The article discusses NTX's background, describes its business, and offers lessons from NTX's turnaround.

These insights are based on a case study (Dube' & Pare', 2003; Eisenhardt, 1989) of NTX's B2B e-marketplace. The study spanned the dot-com boom, bust, and stabilization. The research included field visits with NTX, its organizational members, and a buyer and a seller that declined NTX's membership invitations. Data collection included participant observations, system demonstrations, interviews, surveys, and internal and external document reviews. We interviewed the people in each organization responsible for the organization's NTX participation.

NTX is a B2B e-marketplace for the United States transportation industry. B2B e-marketplaces bring together businesses wishing to sell and those wishing to buy goods and services. They promise trading communities increased business purchasing efficiency and economy by replacing traditional, limited seller-buyer networks with a B2B e-marketplace with many more sellers competing on cost, quality, and service. Sellers can contact more buyers more efficiently.

NTX's founder and a venture capitalist group formed NTX in 1994 to solve the transportation industry's unused-capacity problem. Unused capacity occurs when carriers deliver products along their routes and their remaining trailer capacity is empty (Patsuris, 2000). The American Trucking Association estimates that United States carriers travel 12% of their miles without a payload (Patsuris).

DESCRIPTION OF THE BUSINESS

This section describes NTX's service offerings, management, and reasons for success.

Service Offerings

NTX developed technology bringing shippers and carriers together into an open B2B e-marketplace. NTX enables shippers to post their shipping needs on a Web site. Carriers view the Web site by geographic region and accept loads meeting their specifications. The Web site includes the load's location, pick-up time, delivery time, weight, size, refrigeration needs, and shipping price. The shipping price is the amount the shipper is willing to pay for the load's transport less NTX's fee. NTX assesses a transaction fee on loads tendered over the e-marketplace. Transaction fees vary. To increase transaction volume, NTX does not assess a transaction fee on some loads. NTX membership is free.

Shippers post loads to NTX's Web site. In most cases, a carrier's central dispatch locates loads. If an existing load does not fill a truck or if the carrier does not have a load to haul back to its origination, the central dispatch can find other loads on NTX to fill the truck. Carriers accept loads using NTX's Web site. NTX immediately notifies the shipper. The shipper then prepares the load for the carrier. NTX does not disclose shipper and carrier identities. Keeping shipper names anonymous prevents carrier salespeople from soliciting the business. Carrier anonymity prevents carriers from knowing they are participating in an e-marketplace with one another. The transportation industry is competitive and carriers do not like being compared in an open e-marketplace with one another.

NTX offers shippers and carriers value for less-than-truckload freight. Less-than-truckload freight occurs when shippers hire a carrier to transport a product that does not fill the truck. Carriers must charge for the entire truck to cover the truck and the driver miles traveled. By bringing shippers and carriers together, NTX increases the chances of consolidating loads into one truck. This lowers shipping costs and increases carrier profits. Mileage and driver costs are spread over many shipments. For carriers, once loads cover costs, additional loads become profit. Shippers in our study developed spreadsheets calculating their savings from using NTX. The spreadsheets listed by load the usual shipping cost, cost using NTX, and savings. The shippers felt that NTX use had saved their company money substantially.

NTX reduces shipper and carrier search time. Over the years, large-volume shippers and carriers have developed long-term relationships facilitated by prenegotiated contracts and electronic data interchange (EDI; Premkumar, Ramamurthy, & Crum, 1997; Williams, 1994). These relationships reduce carrier and shipper search costs. However, nonroutine shipments, either occasional shipments or shipments falling outside a carrier's routine shipping area, require soliciting bids. This process involves calling carriers, providing load information, and requesting prices. Because of quote variations and carrier availability, shippers must solicit bids from several carriers. A sales representative comments, "Finding a carrier to transport a load could take all day."

Before NTX, carriers used regional brokers like dial-a-truck to fill unused truck capacity. Shippers telephone dial-a-truck with available loads. Carriers telephone dial-a-truck to find available loads. Since time passed between calling in or accepting a load, and updating dial-a-truck's load listing, errors occurred. NTX's Internet-based model is more efficient, dynamic, accurate, and timely.

By-products of NTX's core value proposition include accounting-practice simplification and report improvement. NTX simplifies shipper and carrier accounting practices. NTX reduces the number of vendors shippers have to pay. One monthly bill detailing all NTX-tendered loads replaces bills for each carrier and each load. NTX reduces the accounts carriers have to collect. Carriers receive bimonthly checks from NTX for all NTX-tendered shipments. NTX offers improved reporting. Shipper reports show the savings from NTX use. The report compares the shipper's expected price to NTX's transacted price. The tracking reports track loads to the stock-keeping-unit level.

NTX has standards. Carriers must achieve certification. Passing certification requires maintaining insurance and current inspections. Carriers and shippers must follow NTX's business rules. Carriers must pick up and deliver loads on time and in good condition. Shippers must have loads ready for pick up at the specified time. NTX imposes a $200 fine for rule violation. If a party violates the business rules three times, NTX bans further participation.

NTX is a Web site on the Internet. Anyone with an Internet connection and computer or other Internet access device can use NTX. NTX's customer-support methods includes e-mail, Internet, fax, and telephone. NTX e-mails and faxes load confirmations. Customers frequently contact customer support using the telephone. Sales and initial training occur in person or over the Internet.

Management

While private investors and venture capitalists funded NTX, NTX struggled until the e-marketplace cultivated industry relationships. Today, NTX's management team and sales representatives are from the transportation industry. A president, chief executive officer, and board chairman; a chief financial officer and treasurer; and a technology vice president comprise NTX's management team. NTX's labor force includes sales representatives and customer-support analysts. Becoming a sales representative requires transportation-industry experience, expertise, and contacts. Sales representatives solicit shipper and carrier membership, train members, maintain customer relationships, and customize marketplace solutions to customer needs. Shippers and carriers comprise NTX's customer advisory board. The board ensures NTX's cognizance of customer needs.

Success Reasons

Innovation-diffusion theory links "an innovation being better than the ideas it supersedes to its adoption" (Rogers, 2003, p. 265). The American Trucking Association estimates that unused capacity costs the transportation industry $22 billion dollars annually (Patsuris, 2000). Even though NTX could help solve this problem, it struggled achieving use. A business environment change and e-marketplace regression contributed to NTX's success.

Environment Change

The year 2000's (Y2K's) aftermath and September 11, 2001 facilitated NTX's success. In Y2K's aftermath, NTX's membership doubled. American information-technology departments had spent unprecedented amounts making systems Y2K ready. Countries that dedicated few resources to Y2K preparation experienced minimal problems. In the aftermath, many believed information-technology departments had wasted resources preparing for Y2K. Under pressure, many information-technology departments were exploring ways to deliver savings. Many organizations adopted NTX to do so.

NTX's membership further increased after September 11, 2001, when America's economy slowed. Carriers reduced fleet sizes and a freight shortage occurred. With less freight capacity available, freight rates increased. Reflecting market prices, NTX offered better rates than carriers' long-term, fixed-price contracts. Carriers broke contracts and began using NTX. Shippers struggled finding carriers. They started using NTX to find them. NTX thought excess freight was its biggest strength, but freight shortages were it's biggest.

Environmental change stimulated other B2B e-marketplaces' formation. E-marketplaces in the London insurance market (Barrett & Walsham, 1999), the Dutch flower market (Kambil & van Heck, 1998), and the United States utility industry (Koch, 2004) formed in response to industry business-environment changes. Record numbers of B2B e-marketplaces formed in response to a business environment encouraging EC. When the boom turned to bust, B2B e-marketplaces failed in record numbers (Day & Fein, 2003). This may indicate that while business-environment change can motivate e-marketplace membership and formation, when the environment changes again, the motivation may not endure.

Regression

NTX began achieving significant volume when it regressed to support preexisting freight arrangements. In the transportation industry, prenegotiated contracts cover most loads. Shippers prefer prenegotiated contracts because they routinize load tendering and ensure products are delivered on time and in good condition. Shippers perceived that the labor costs and risks of open e-marketplace use exceeded the potential cost savings from routine, open e-marketplace carrier comparison. For carriers, prenegotiated contracts routinize the load-tendering process, enable load consolidation to fill truck capacity, increase profits, and facilitate maintaining a stable labor force and adequate fleet size. Carriers believed NTX's requirement that carriers accept shipper prices would lower freight prices. Since NTX required carriers to monitor NTX's Web site to find shipper-posted loads, carriers perceived that the labor costs would increase.

Given shippers' and carriers' preference for preexisting contracts and the fact that preexisting contracts cover most loads, large-volume shippers and carriers rarely used NTX. Without large-volume shippers' and carriers' volume, the chances of a shipper-posted load being in a carrier's geographic region were unlikely.

To survive, NTX regressed to support existing relationships. Industry relationships and customer input facilitated NTX's regression. After struggling to attract members, NTX hired sales representatives with industry experience. They presented NTX to industry contacts. The contacts recognized NTX's value for loads not covered by existing freight arrangements and recognized NTX's potential for managing their existing carrier arrangements. NTX incorporated this input and regressed the e-marketplace to support existing freight arrangements. Large-volume shippers began using NTX to electronically facilitate existing freight arrangements. When a shipper's existing carriers were not available, the shipper used NTX. They first used NTX to procure freight from second-tier, company-selected carriers. When this carrier tier was unavailable, shippers posted loads to the open marketplace for any carrier. Shippers required their carriers to join NTX. This brought the carriers to NTX and made their excess capacity available on the open e-marketplace. With large-volume shippers' and carriers' routine NTX use, small-volume shippers and carriers that do not have prenegotiated contracts increased their benefits.

Surviving B2B e-marketplaces in the utility (Koch, 2004) and health-care (White & Daniel, 2004) industries also support existing relationships. Two e-marketplace failures in the convenience-store industry did not support existing relationships (Koch, 2005). The utility industry B2B e-marketplace was founded on matching buyers and suppliers, but evolved to support relationships after struggling with the open e-marketplace model. This may indicate that facilitating existing relationships is key to e-marketplace success. However, this raises the question of whether these surviving e-marketplaces are e-marketplaces.

LESSONS LEARNED

Of 1,734 B2B e-marketplaces that formed in 2000, analysts predicted 407 would remain (Meehan, 2002). NTX is one of these. This article provides insight into NTX. NTX formed in 1994 and began operating in 1995. It executed the transportation industry's first online logistics trade in 1996. NTX struggled for 5 years to attract members and tender loads. The study tracks NTX during the dot-com boom, bust, and stabilization. Contrary to many dot-com endeavors, NTX struggled through the dot-com boom and began attracting members and achieving significant volume during the aftermath of Y2K and September 11, 2001. NTX has attracted over 2,500 shippers and carriers (NTE, 2002a, 2002b), and tenders over 10,000 transactions daily.

Developing information-technology initiatives for which benefits depend on a critical mass of self-interested organizations' participation is difficult. Unlike single-organization information-technology implementations, no organization in a B2B e-marketplace has the power to force the change. Understanding power relationships and competition can help B2B e-marketplace makers develop an e-marketplace using member critical mass. NTX's turnaround offers lessons in power and competition.

Power

Lesson 1: When powerful organizations perceive that B2B e-marketplace use offers their organizations a relative advantage, they will join the e-marketplace and encourage their business partners' membership.

NTX began achieving significant volume when they modified the e-marketplace to support powerful organizations' preferences. In the transportation industry, large-volume shippers have power. Carriers depend on shippers for revenue. When NTX modified its e-marketplace to support shippers' preferences, the shippers joined and encouraged their carriers' membership. NTX could not convince large-volume carriers to join its e-marketplace. The carriers felt NTX's price-comparison model did not emphasize their strengths. Carriers joined NTX when their shippers requested their membership. The shippers interviewed in this study indicated that their primary membership motivation was maintaining their shipper contracts. The same pattern occurred with the electronic-data-interchange adoption. Carriers did not want to adopt electronic data interchange. They adopted it at their shippers' requests (Premkumar et al., 1997; Williams, 1994).

This observation shows how power facilitates e-marketplace adoption. Power theory (Emerson, 1962) and resource-dependency theory (Pfeffer & Salancik, 1978) posit that organizations depend on other organizations to the extent that an organization needs resources or performances from the other organization, and in inverse proportion to the extent that others can provide the same resources or performances. The theory explains that powerful organizations can influence the activities of organizations that depend on them.

The interorganizational information-systems literature supports our finding that offering powerful organizations a relative advantage facilitates adoption. Many firms adopt electronic data interchange to maintain powerful trading-partner relationships (Chwelos, Benbasat, & Dexter, 2001; Iacovou, Benbasat, & Dexter, 1995). B2B e-marketplaces that do not offer powerful organizations a substantial relative advantage fail (Kambil & van Heck, 1998; Koch, 2005; Lee & Clark, 1996).

Despite evidence that power facilitates e-marketplace adoption, e-marketplace makers and powerful trading partners must be aware of power's negative effects. Using coercive power to force weaker business partners' e-marketplace adoption can degrade business-partner relationships and cause coerced parties to distrust the e-marketplace (Allen, Colligan, Finnie, & Kern, 2000). A marketplace's adoption may slow if marketplace participants perceive the e-marketplace will transfer power to the other participants (Barrett & Walsham, 1999).

Competition

Lesson 2: B2B e-marketplaces may overcome competitive organizations' resistance to participate with one another in an open e-marketplace by having trading partners solicit their membership.

The trade press (Memishi, 2001) and empirical research (Koch, 2003) show that organizations with competitive histories do not want to participate in an e-marketplace with one another and do not want to collaborate to build an e-marketplace benefiting all industry participants. Given the transportation industry's competitive nature, why did carriers join the same e-marketplace as one another? Shippers drove membership, not carriers. Since shippers come from an array of industries, they are not competitive with one another. Shippers did not mind being in the same e-marketplace as one another or sharing information to improve the e-marketplace's operations. Competitive forces actually facilitated the carriers' membership. The carriers in our study explained that they joined NTX to maintain their shipper contracts and ensure their competitors did not secure their contracts. This is a pattern in the transportation industry as these same reasons motivated carrier EDI adoption (Premkumar et al., 1997; Williams, 1994).

Empirical research shows that industry competition affects e-marketplace success. B2B e-marketplaces in the United States utility (Koch, 2005) and United Kingdom health-care (White & Daniel, 2004) industries achieved success and linked their success to the industries' non-competitive nature. Two B2B e-marketplaces in the United States convenience-store industry failed partly because of the industry's competitive nature and partly because of the industry organizations' reluctance to collaborate and participate with one another (Koch, 2003). While competition can inhibit membership, if an e-marketplace takes an approach opposite of bringing competitors together to collaborate, competition can stimulate membership.

Emergent Semantic Web

Mahesh S. Raisinghani
Texas Woman's University, USA

Tapas R. Sahoo
University of Dallas, USA

INTRODUCTION

In less than a decade, the World Wide Web has become popular because of the depth of information it provides and the simplicity of its usage by simple clicks through related and interlinked pages. However, the amount of information and the numerous formats in which it is presented are simply overwhelming, and it is not uncommon to get overloaded with irrelevant or unrelated information. For example, a simple search task of finding books written by an author named David Flower would fetch hundreds of pages that merely contain the words David and/or Flower.

The Web contains information on millions of Web pages interwoven by the use of hyperlinks and presented in rich HTML (hypertext markup language) formats, such as images, graphics, audio, and video. This rich presentation capability makes the Web highly readable for humans, but adds no meaning to the information when read by computers.

The Semantic Web, which is considered to be the next evolution of the current Web, would qualify information with well-defined meaning. This added meaning to data, called metadata, would enable computers and people to work in cooperation (Hendler, Berners-Lee, & Miller, 2002). In addition to having hyperlinked pages containing media objects, the Semantic Web will also contain resources pointing to real-world objects such as people, places, organizations, and events. These objects will be linked based on their real-world relationships.

Another goal of the Semantic Web is to develop enabling standards and technologies designed to help machines understand more information on the Web so that they can support richer discovery, data integration, navigation, and automation of tasks (Berners-Lee, Hendler, & Lassila, 2001). The current Web has the potential of becoming the largest database system, but it suffers from its foundation as a presentation media. This article addresses issues involved in effectively storing and managing data on the Web and focuses on various research activities in this direction.

The Semantic Web is a vision that will extend the current Web to give well-defined meaning to information, enabling computers and people to work in better cooperation. A collaborative effort between the World Wide Web Consortium (W3C) and a large number of researchers and industrial partners is defining standards and technologies required for building the Semantic Web. This effort will enable data to be understood by machines and will be used for effective discovery, automation, integration, and reuse across applications.

BACKGROUND

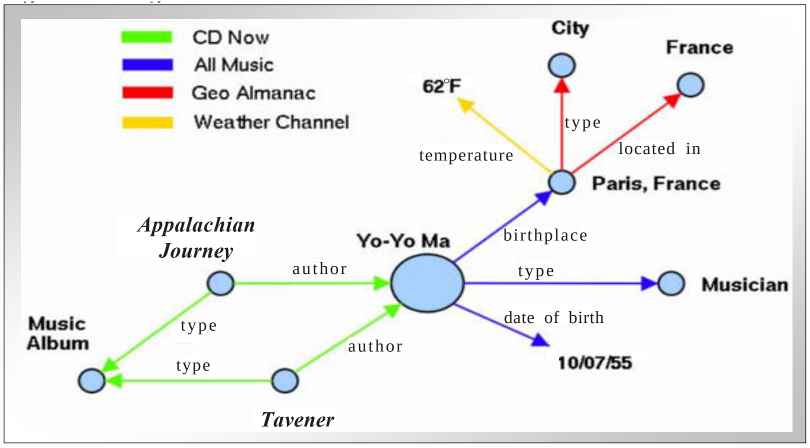
The Semantic Web is not just a web of documents; it is a web of relations between resources representing real-world objects, such as people, places, and events. It includes documents describing explicit relationships between objects and containing semantic information intended for automated processing by the machines.

Figure 1 shows a small chunk of the Semantic Web corresponding to the cellist Yo-Yo Ma (Guha, McCool, & Miller, 2003). It contains objects such as the city of Paris, the musician Yo-Yo Ma, the music album *Appalachian Journey*, and so forth. It is clear from the diagram that many different sources such as CD Now, All Music, Geo Almanac, and the Weather Channel have published different types of information about Yo-Yo Ma.

The Semantic Web extends the cumulative knowledge about any resource in a distributed fashion. This example illustrates the basic idea behind building the Semantic Web.

To transform the novel idea behind the Semantic Web into a reality, the designers of the Semantic Web are following a bottom-up approach to deal with the complexities involved in such a gigantic structure. They are building simple components for specific purposes that can be glued together in a layered structure. Figure 2 displays this layered architecture of the Semantic Web along with its various components. Some of the major components are described in the following section.

Figure 1. A segment of the Semantic Web (Source: Semantic Search)



SEMANTIC WEB ARCHITECTURE

In this section, some of important architectural components of the Semantic Web are analyzed and a proposal is derived.

Infrastructural Components

Uniform Resource Identifiers

Each item on the Web is considered a resource, and uniform resource identifiers or URIs are used to uniquely identify them (Swartz, 2002). URIs can be assigned to real-world objects like persons, places, books, and so forth. The most common form of URI is the universal resource locator (URL), which represents the address of a unique Web page on the Internet. However, the primary function of a URI is to identify a resource in lieu of providing an address of a specific file on the Web.

Resource Description Framework

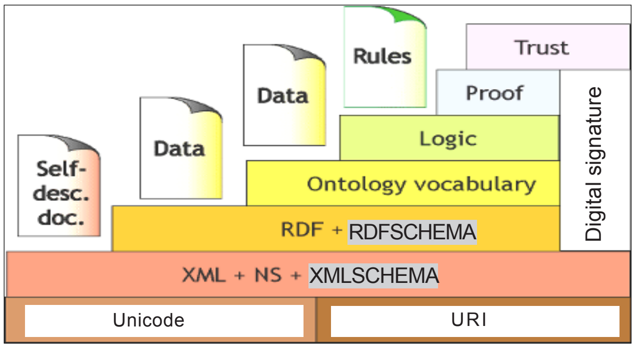
In order to automate the understanding of data by machines, metadata have to be added to describe the data contained on the Web. The resource description framework (RDF) is the standard followed by W3C to process metadata on the Semantic Web (Brickley & Guha, 2000). RDF is a framework to create statements about resources in a machine-readable format and is based on the idea of identifying things using URIs and describing resources in terms of simple properties and property values. This enables RDF to represent simple statements about resources as directed, labeled graphs of nodes and arcs representing the resources and their properties and values (Manola & Miller, 2003).

Ontologies

Ontologies are ways to describe the meaning and relationships between terms. RDF is used to create these descriptions that help computers know how to use different terms.

The ontology for a domain enumerates and gives semantic descriptions of concepts in the domain of discourse, defining domain-relevant attributes of concepts and various relationships among them. For example, an ontology that describes wines will include concepts like vintages, wine regions, wineries, and grape varieties. It will also include relations such as by whom a wine is

Figure 2: Architecture of the Semantic Web (Source: Semantic Web-XML 2000, http://www.w3.org/2000/Talks/1206-xml2k-tbl/slide10-0.html)



produced, from what it is made, its color, its year, and the body of the wine (Noy, 2003).

Logic

One of the biggest challenges in making the computers more intelligent is to enable them to apply logical principles and draw conclusions by inference. This is one of the key research areas in the field of artificial intelligence. Although it is not likely to happen in the near future, we are definitely headed in that direction.

Proof and Trust

As there is no central authority controlling the Web, it is assumed that anyone can say anything about anything. This freedom of expression is a great idea, but it can lead to misuse of this freedom and result in mistrust. If the Web has to become the single source of all information, it has to provide a mechanism of proving trustworthiness. The digital signature is the mechanism that is going to be used to provide proof that a certain person wrote (or agrees with) a document or statement. This will enable users to decide who to trust and who not to.

Inference Engines

Inference engines are one of the main components of the Semantic Web that will process the available knowledge. They will deduce new knowledge from the knowledge already specified to them. The inference engines will apply reasoning over the information that is coming in from all over the Web. They will not have control over when that information arrives, how often it is updated, or how accurate or reliable it is. The engines, therefore, will have to have built-in mechanisms for dealing with these real-time uncertainties. The standardization of the data through the markup languages should make some aspects of building these systems a little easier.

Web Services

The Web, once solely a repository for text and images, is evolving into a provider of automated services in different forms, such as flight-booking programs and a variety of e-commerce and business-to-business (B2B) applications. Web-accessible programs, databases, sensors, and a variety of other physical devices are already realizing these services (McIlraith, Son, & Zeng, 2001). A fundamental component of the Semantic Web will be the markup of Web services to make them computer interpretable, use apparent, and agent ready.

Managing Data on the Semantic Web

The Web is the largest source of data, yet is far from offering the benefits of a database-management system. Database-management systems are characterized by a structural model (the entity relationship model or the object-oriented model) as well as by efficient operations of data extraction and manipulation (the structured query language, SQL). Even though the Web uses many databases at the back end, the structure and semantics of the data is lost when it is squeezed into the Web (Marchiori, 2001). Also, the Web lacks the ability to provide a good way of querying the data. Inside a database, any piece of information has a well-defined meaning in terms of entities and relationships. Considering the example of employee and department tables in a database, the “Dept. No.” column uniquely identifies a department and also defines the relationship between the two tables. This defined relationship makes it very easy to query the employees belonging to a particular department. However, once this information is published on a Web page, both the meaning of the data and the relationship between them is lost. Only a human with the domain knowledge can infer the relationship; the computer has no way to know that the number actually represents a department and that the employees listed belong to that department.

A Proposed Model for Searching Dynamic Pages

Search engines fail to access information from dynamic pages as these pages do not contain any information as such. Their content is built dynamically based on user queries. These pages send the queries to the back-end database and retrieve the information requested by users. Even though the dynamic pages do not contain any data, they do contain the query that gets executed. In the case of relational databases, this query is written using SQL. An SQL query in its simplest form has three clauses: Select, From, and Where. The Select clause lists the data items being fetched from the database. The From clause tells which tables are the source of the information and how they are joined. The Where clause filters the information based on the user’s requirements. SQL is not limited to data-retrieval queries since it comprises a data-definition, data-manipulation, and data-control language.

The collection of dynamic Web pages, referred to as the “deep Web,” is estimated to be around 500 times the size of the “surface Web” (Bergman, 2001). As most of the existing search engines fail to index this vast portion of the Web, there arises the need for intelligent tools that can extract and integrate the results from dynamic Web pages. The key prerequisite for this kind of information integration is obtaining the schema of these Web sites. One of the recent research works in this area (Wang & Lochovsky, 2003) describes the DeLa (data extraction and label assignment) system that can capture the schema and extract data from dynamic Web pages with complex HTML search forms. This makes further manipulation and integration of the data much easier. Future research in this field is directed toward automatically locating the Web site(s) from which users want to extract data objects.

The greatest hurdle in implementing this idea is to have a global identifier for the databases. Without this identifier, it would be ambiguous to identify which database is referenced in the query. The query might be referring to a local database, but there might be many other databases with the same name. With the URI and RDF technologies used for the Semantic Web, a global identifier can be created for all databases (Laborda & Conrad, 2003).

FUTURE TRENDS

As the Semantic Web effort is gaining momentum, numerous research activities in diverse fields are bringing rapid evolution to the technologies. However, there are many challenges ahead regarding the standardization of technology and a consensus about the direction and characteristics of the Semantic Web.

Developing Ontologies

One significant area of concern in the development of ontologies is the difference between the RDF framework and the majority of existing data sources. While RDF is focused on identifying the domain structure, most of today's data sources tend to focus more on the document structure around important objects. For example, RDF would explicitly represent the relationship between a book and its author as "author writes book." However, an XML (extensible markup language) document might represent this relationship only implicitly by embedding an author object inside a book object. The Semantic Web applications need to be able to interoperate with existing data sources by mapping between different domains as well as document structures.

Many research organizations are currently working to develop systems that address the aforementioned problems. One such system, called Piazza (Halevy, Ives, Mork, & Tatarinov, 2003), provides algorithms to map the domain and document structures, as well as enabling the interoperation of XML data with RDF data. Mappings in Piazza are provided at a local scale between small sets of nodes, and its query-answering algorithm is able to chain sets of mappings together to obtain relevant data from across the Piazza network.

Constructing Thesaurus

Another area of ongoing research is the automatic construction of a thesaurus by discovering the semantic relationships between existing Web pages. A hand-coded thesaurus has been widely used in many applications, including information retrieval, natural-language processing, and question answering. Chen et al. (2003) have proposed a new technique to automatically construct a domain-specific thesaurus from the Web using link structure information. The proposed method extracts relationships between terms, and can identify new terms as the Web evolves. Their research is based on the observation that Web pages contain two types of links: navigational links for easy browsing, and semantic links for connecting related pages together.

Semantic Annotation

The vision of the Semantic Web heavily depends on metadata. Ongoing research activities are focused on two approaches to define metadata. The first approach is to create ontologies that will store metadata about entities and provide them when needed. The second approach is to annotate Web pages with semantic tags. Semantic annotation (also called semantic tagging) is the process of augmenting data to facilitate the automatic recognition of the underlying semantic structure. However, the majority of the documents on the current Web do not contain any semantic annotations. With the lack of applications for automatic annotation, it is unlikely that Web developers would add the semantic tags manually. Dill, Eiron, Gibson, Gruhl, Guha, and Jhingran (2003) have proposed an application called SemTag that performs automatic semantic tagging. They have also developed a platform called Seeker that can be shared by different tagging applications.

CONCLUSION

The Semantic Web has the potential to eliminate many of the drawbacks of the current Web by making it understandable by machines. This can be achieved by adding meaning to data by using frameworks such as URIs, RDF, and ontologies. The W3C, in collaboration with a large number of research organizations, is defining the required standards and technologies. The Semantic Web also has the potential of becoming a huge distributed database.

Various XML-based query languages are under development to effectively retrieve the data from various data sources. With the development of the right infrastructure, the inability of current search engines to retrieve dynamic Web pages can be eliminated. There is absolutely no doubt that every Web user will find more than one reason to support the grand vision of the Semantic Web. There are endless possibilities, and the journey itself is worth the effort even if all the goals are not achieved.

KEY TERMS

Metadata: Metadata are data about data. Metadata are commonly used to identify information that describes a Web asset, most typically an HTML file. Metadata refer to the use of a structured set of elements to describe an information resource and its intellectual property rights. The elements used should assist in the identification, location, and retrieval of information resources by end users.

Ontology: A systematic arrangement of all of the important categories of objects or concepts, which exist in some field of discourse, showing the relations between them. When complete, an ontology is a categorization of all of the concepts in some field of knowledge, including the objects and all of the properties, relations, and functions needed to define the objects and specify their actions.

RDF (Resource Description Framework): A specification developed in 2000 by the World Wide Web Consortium as a foundation for processing machine-understandable metadata regarding resources on the Internet, including the World Wide Web. It uses XML.

Semantic Web: The Semantic Web provides a common framework that allows data to be shared and reused across application, enterprise, and community boundaries. It is a collaborative effort led by W3C with participation from a large number of researchers and industrial partners. It is based on the Resource Description Framework, which integrates a variety of applications using XML for syntax and URIs for naming.

SQL (Structured Query Language): A language for sending queries to databases. SQL was developed by IBM in the mid-1970s as a way to get information into and out of relational database-management systems (RDBMSs). A fundamental difference between SQL and standard programming languages is that SQL is declarative. You specify what kind of data you want from the database, and the RDBMS is responsible for figuring out how to retrieve it.

URIs (Uniform Resource Identifiers): URIs are short strings that identify resources on the Web: documents, images, downloadable files, services, electronic mailboxes, and others. They make resources available under a variety of naming schemes and access methods such as HTTP, FTP, and Internet mail addressable in the same simple way.

XML (Extensible Markup Language): A specification developed by the World Wide Web Consortium. XML is a pared-down version of the standard generalized markup language (SGML), designed especially for Web documents. It allows designers to create their own customized tags, enabling the definition, transmission, validation, and interpretation of data between applications and between organizations

Engineering Adaptive Concept-Based Systems for the Web

INTRODUCTION

In recent years we have witnessed a growing interest in adaptation and personalization in numerous application domains including business, education, and so forth. Applications that offer large bodies of information have in the Web era turned into systems with a significantly different nature than two decades ago. Think of the typical book catalog database from 20 years ago and the Web site of a book seller nowadays. A characteristic aspect of the restyling is the attention paid to the individual user. Technology has evolved and now allows application designers to include adaptation and personalization in the applications. This is especially important in the field of e-commerce, where users (customers) expect personalized services similar to those they receive in a conventional store.

Typical e-commerce systems employ large bodies of information. In the case of a bookstore Web site, the designer defines an appropriate structure for the collection of books with all relevant properties. Generally, the design uses structures of concepts, where the concepts represent the actual information objects. The adaptation engineering is later performed on the level of these (abstract) concepts. We refer to these applications as *concept-based systems*.

Adaptive concept-based systems are especially accepted in areas where the main goal is to tailor large amounts of information to the individual preference and knowledge state of the user. Besides electronic commerce, other examples include online museums (the visitor wandering through the collection on an individual basis) and e-learning applications (the student being involved with learning material in a way that the teacher thinks fits the student's situation).

BACKGROUND

Concept-Based Systems

Most concept-based systems use navigation in one way or another to structure the information they present. The design of navigation is not trivial, and including adaptation in it increases the complexity quickly. A nice example for adaptation and personalization in a business context (customer management) is ATG's Dynamo Personalization Server (http://www.atg.com): explicit user data from marketing databases is combined with implicit information gathered from the user's browsing behavior to provide dynamic content adaptation. Educational applications based on the adaptive hypertext architecture AHA! (De Bra et al., 2003) show how adaptation platforms are successfully used for presenting personalized learning environments.

The typical concept-based system on the Web is a data-intensive information system that contains content retrieved dynamically from a repository and uses hypermedia to present the output:

- The system is *data intensive*. There are classes of adaptive concept-based systems where handcrafting is possible, but typically the collection of information objects is so large that designers cannot do this organization by hand and have to rely on schematic designs.
- The system holds the data elements in a *repository*. Systems differ in the way they materialize this repository. Some assume a fixed set of data elements that are all individually known to the designer. In others the properties of the data elements are known and available for the designer at schema level (like

in databases). Some systems retrieve data in the way we know from search and retrieval engines, leading to yet another engineering process.

- The system uses *hypermedia* to present the output to the user. Systems differ in how they use hyperlinks to structure the output information. Note that this structuring is crucial in communicating the semantics of the output.

Development of Adaptive Concept-Based Systems

Adding adaptation and personalization to the picture influences the three issues mentioned above. Adaptation plays a major role in the hypermedia construction. For example, one might want to look at the user's platform, such that the application presents the (conceptually) same information differently for PC, personal digital assistant (PDA), phone, or other viewer, considering screen size or bandwidth. A different kind of adjustment would be based on the user's previous actions in the application. It is obvious that with the data-intensive nature of the application, including adaptation and personalization in the requirements, immediately leads to a much more complex *development and authoring process*. This presents the need to find a systematic and application-independent approach to adaptation engineering:

- Obviously, general object-oriented software engineering approaches, such as unified process (Jacobson, Booch, & Rumbaugh, 1999), lack the specific hypermedia aspect. On the other hand, specific methodologies for hypermedia like relationship management methodology (RMM) (Isakowitz, Stohr, & Balasubramanian, 1995) or object-oriented hypermedia design methodology (OOHDM) (Schwabe & Rossi, 1998) do not cover significant aspects related to adaptation (like user modeling and personalization).
- There are efforts that systematize the engineering (lifecycle) process and offer an integrated methodology, for example, the UML-based Web Engineering (UWE) approach (Koch, 2001). We observe that UML gives only a specification of the process, but not the semantics to perform the reasoning required for adaptation: semantically richer approaches are needed and current research on Semantic Web (Berners-Lee, Hendler, & Lassila, 2001) and ontologies (Sowa, 2000) offer solutions.
- The hypermedia community has defined reference models for adaptive hypermedia systems (e.g., the AHAM model (De Bra, Houben, & Wu, 1999) and the Munich model (Koch & Wirsing, 2002)). Although the number of adaptive systems grows, their development process is still rather ad-hoc, without a lot of re-use, and therefore difficult to manage.

We observe a lack of uniform methods to describe the functionality of adaptive concept-based systems for analysis and comparison. The target is a systematic, unified, and measurable approach for engineering adaptive concept-based systems, starting from the *conceptualization* of the domain through application modeling, maintenance, and upgrade (Lowe & Hall, 1998).

ADAPTATION ENGINEERING

Principles of Adaptation Engineering

Modeling the Domain

The specification of concepts and their structure is a crucial aspect of concept-based system design. Concept-based systems, whether adaptive or not, commonly employ a well-specified subject *domain model* to define the information processed in the application. Traditionally, content descriptions are expressed in terms of concept structures, such as concept maps, semantic networks, or conceptual graphs (Sowa, 1984).

Modeling the User

The user plays a fundamental role in the system and therefore in its design. The system might want to record the user's presentation preferences (e.g., for platform, layout, font size, or other presentation aspects), as well as content preferences. Typically, the systems maintain a model of the individual user as an overlay of the domain model to record the current state of the user w.r.t. his/her preferences/knowledge of domain concepts. This *user model* is the basis for adapting the content presentation.

Modeling the Adaptation

The challenge left is to combine the information domain and user model when generating the appropriate adaptive presentation. This adaptive presentation includes individualized content selection and/or individualized navigation paths/links. Phrased differently, the main adaptation design challenge is to define *content selection* and *navigation* through adaptive methods and techniques (Brusilovsky, 2001). Typically this is done in the *adaptation model*.

Adaptive Web Information Systems

A large and general class of concept-based systems is built by the *Web Information System* (WIS) (Isakowitz, Bieber, & Vitali, 1998). WIS emerged when the Web paradigm was applied to data in databases and other structured data repositories (Gaedke & Graf, 2000). Examples are Web sites about products for sale in a store, or employees working at a large corporation. Most current Web applications are WIS and constitute the "deep Web" (opposed to the "surface Web").

Hypermedia design became a crucial challenge in WIS design. While most of the mentioned approaches like Unified Process, OOHDM, and RMM try to support the hypermedia aspect, modern WIS methodologies like WebML (Ceri et al., 2002) or Hera (Vdovjak, Frasincar, Houben, & Barna, 2003) go a step further and make the design of the content presentation the focus of WIS design.

We discuss the main principles of such methods and use Hera terminology to illustrate. Typical is the model-driven nature:

- The *conceptual (domain) model* describes the conceptual structure of the application content in terms of *concepts* and their *concept relationships*. Several data modeling formalisms are used in the different approaches (e.g., Hera uses RDF(S)).
- The *application model* specifies the abstract navigational view over the content from the conceptual model. Hera identifies *slices* as meaningful units (pages) in the navigation structure. The *slice relationships* connect slices and complete the actual navigation structure with hyperlinks.
- The *adaptation model* specifies the *adaptation*. It defines how the user is modeled, and how the content presentation depends on that.
- The *user profile* captures the user's preferences, for example, device properties. It is used to support *adaptability*: the presentation is constructed following the constraints from the user profile.
- The *user model* holds the state of the user w.r.t. the presentation content. This supports *adaptivity*: the user model changes *during* the navigational use (browsing) of the presentation. Think of the user's knowledge about application concepts—for example, has the user seen (visited) a concept before?

The focus of WIS design methodologies is on the navigational structure, but a thorough definition of the content is needed first. The methodologies therefore give a major role to the *domain model*.

The notion of *user model* is implemented in WIS design methodologies less prominently. Among the notable exceptions, Hera identifies a user profile and user model, thus influencing the availability (visibility) of content and links.

The *adaptation model* extends the application model in Hera. With conditions relating to user profile and user model, it becomes possible via adjusting content/link visibility to implement different adaptive methods and techniques.

We conclude that methods for adaptive WIS are strong in supporting adaptation in relation to *data-intensive* applications. They target the creation of *hypermedia* presentations, and in terms of *adaptation* primarily aim to support different device/user situations. The designers' main challenge concerns the large quantity of content elements fitting a given structure.

Adaptive Hypermedia Systems

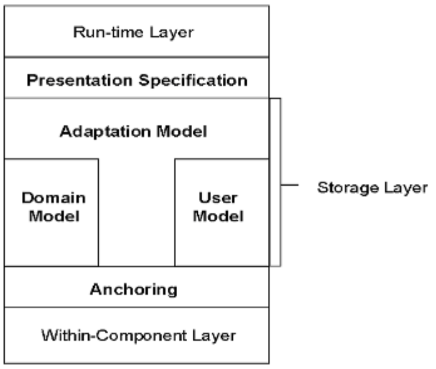
Adaptive hypermedia systems (AHS) (Brusilovsky, De Bra, & Houben, 1999; Brusilovsky, 2001) build the second class of adaptive concept-based systems.

Hypermedia designers have the difficult task of deciding on which pages to place which links. Ideally each page contains only links that are of interest for each user, independent of how the user got to the page: impossible in practice. Content and presentation of each page should fit preference, interest, and knowledge level of each user: an even harder task. *Adaptive* hypermedia offers a potential solution. It allows selecting links, content, and presentation elements that are *potentially* appropriate. Based on a *user model,* the adaptive system can decide which links and content to show, and how to present them.

The AHAM reference model (De Bra, Houben, & Wu, 1999; see Figure 1), gives the overall architecture with three main parts for adaptation in the *Storage Layer*:

- The *domain model* represents the application (subject) domain conceptually. It consists of *concepts*

Figure 1. The AHAM reference model



with *attributes* and of *concept relationships.* Concepts can represent broad topics or small concrete objects. AHAM only deals with this conceptual level, not with the actual content in the *Within-Component Layer*. A typical example of concept relationship is *prerequisite*: A is prerequisite for B, if knowledge of A is needed before the system considers B appropriate (for this user).

- The *user model* is the system's representation of the (assumed) state of mind of the user. Usually it is an *overlay model* of the domain model. In AHAM every domain model concept also appears also in the user model with an appropriate *knowledge/access* indicator.
- The *adaptation model* links the other two, using *adaptation rules*. When the user accesses a page, a rule determines how this event influences the user model. A second type of rule deduces navigation and presentation adaptation: a link to an "appropriate" page is displayed prominently while others are de-emphasized, hidden, or removed. Brusilovsky (1996, 2001) identifies possible adaptation methods and techniques.

A good illustration is the general-purpose adaptive engine AHA! (De Bra et al., 2003), which combines the *domain* and *adaptation models*. When the user accesses a page, the rules associated with the page are triggered, updating the *user model*. They also determine values for "presentation attributes" such as *suitability* and *visited*. *Suitability* influences including, hiding, or annotating links or fragments. *Visited* is similar to the blue/purple link-color change from browsers.

AHSs directly implement the domain, user, and adaptation model. Their *domain model* is a structure of concepts from the application content. Their *user model* represents the application's assumptions on the user's knowledge on these concepts. Their strongest emphasis is on the *adaptation model*, which requires *rules* for user model updates and presentation adaptation, and a rule engine.

Most adaptive hypermedia reference models like AHAM assume *handcrafting*. The author carefully selects the content, designs a hypermedia presentation out of it, and configures its adaptation. Newer approaches aim at more automated adaptation design, but require a close coupling between designers' understanding/knowledge of the content and adaptation.

Adaptive Task-Based Systems

Adaptive task-based systems are characterized by a strong task-orientation in adaptation. To efficiently implement *content selection* and *navigation,* they require domain *conceptualization*—a process of classifying subject domain knowledge and presenting it in *concept structures*. Concept-based content representations play a pivotal role not only in modeling domain content (*domain model*) and user (*user model*), but also in modeling the application-oriented problem-solving strategies (*task model*) and the employed adaptive mechanisms (*adaptation model*).

Concept structures include domain concepts and semantic relationships among them. They present a *meta-layer* over the domain, clearly separated from the content units (data), and allow dynamic linking of content units to relevant concepts. The explicit concept structure (efficiently indexing the content) supports adaptation through dynamic topical content generation.

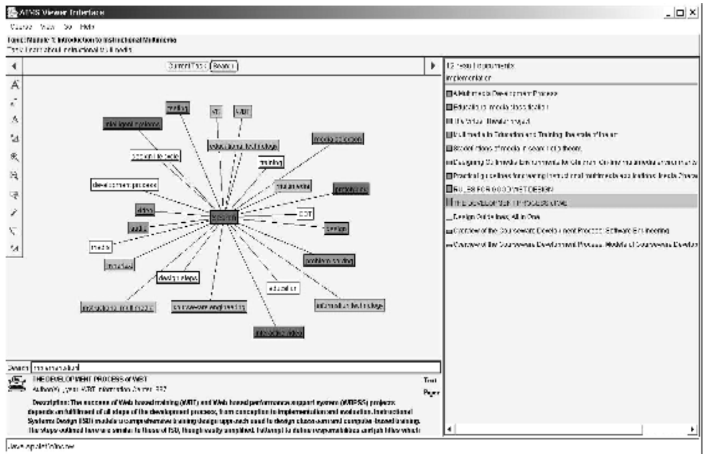
Conceptualization allows for *standardization*. The concept structure can represent a domain ontology providing a broadly agreed vocabulary for domain knowledge representation, thus making the content reusable, interchangeable, and interoperable.

As illustration we consider an *educational information support system (EISS)*—AIMS (Aroyo & Dicheva, 2001). EISS exhibits adaptation engineering in task-based systems (Magoulas, Papanikolaou, & Grigoriadou, 2003), combining ontologies with educational metadata standards to achieve openness and interoperability of intelligent instructional software. AIMS focuses on efficient information provision for *task-oriented problem solving*. The ontological structure of the subject domain acts as an index, represented graphically by a *concept map* (see Figure 2), which supports efficient search and strong visual presentation/navigation of search results.

AIMS uses four models:

- The *domain model* conceptualizes subject domain with *concept* and *link* objects. Objects have attributes to characterize behavior, used in adaptation rules to allocate the most appropriate concepts for tasks.
- The *resource library model* semantically annotates *resources* used in AIMS. Resources have metadata for educational applicability and are linked to domain concepts. Links have weights indicating the relationship strength.
- The *course tasks model* specifies course tasks and a course structure by using the domain and resource library models. Tasks have an input/output of concepts/resources and sets of pre-/post-conditions to define the start/end states of relevant user knowledge. *Adaptation rules* define navigation patterns based on user model values and concept links in the domain model. Post-conditions trigger user model updates.

Figure 2. AIMS search & browse tool



- The *user model* is a domain model overlay: domain concepts have specific *user* values indicating current user knowledge (*state* within the entire instructional cycle).

The AIMS approach separates the abstract domain concepts from the resource library items describing them. It also uses an explicit (course) tasks model to represent goals and tasks of users, and defines the adaptation on this task model. This allows designers to effectively specify paths through resources.

The authoring aspect is rather different here. The author (instructor) has a large influence on composing learning resources into personalized courses (Aroyo & Dicheva, 2003; Specht, Kravcik, Klemke, Pesin, & Huttenhain, 2002). Authoring activities include:

- **Domain-Related:** Editing and annotating the domain model concepts and links.
- **Course-Related:** Generating the course structure and sequencing course tasks, including user-related activities to define the user model and its application.
- **Resource-Related:** Defining educational resources in the library, for example, using LOM-based metadata (LOM, n.d.).

The tasks offer a significant variety in constructing adaptation through identifying tasks and subsequent content sequencing. Separating concepts from resources allows an extra adaptation dimension, as the resource-concept association can be programmed to realize personalization. Conceptual structures based on standardized metadata also allow reuse/exchange of resources.

AHA! and AIMS approach conceptual structuring differently. AHA! uses concepts to label content fragments, concept relationships to indicate dependency, and knowledge-propagation links to structure these fragments. AIMS uses conceptual structures in the more traditional ontological meaning—to represent the subject domain knowledge and allow more elaborate contextual reasoning. Whereas engineering systems like AHA! typically start from the available content and use concept structures to organize the content and its adaptation, systems like AIMS typically start from concept (ontological) structures to support more complex reasoning in the domain and only run-time associate content (resources) with the concepts.

FUTURE TRENDS

In the discussion of three large classes of adaptive concept-based systems, we have identified their strengths and weaknesses. With the current technologies these systems are primarily effective in application areas where engineering is of a more authoring nature. For an effective application in larger-scale situations, the more general WIS and the task-based systems appear more promising, since they use a more engineering approach to adaptation.

The "hottest" trend is certainly the exploitation of *ontologies* for organizing the concepts and their adaptation and facilitating interoperability. The engineering of ontologies is therefore a relevant research topic. *Interoperability* is an essential condition for success. In the world of e-commerce, nobody is waiting for isolated, unconnected solutions. While there is already some advancement in reusing and exchanging content, the reuse and exchange of adaptation mechanisms is an open problem. Application areas like education show a possible way, but also demonstrate the problems ahead for a general solution for adaptation engineering in e-commerce.

CONCLUSION

We have discussed *adaptation engineering* in the concept-based systems that play a vital role in the modern e-society. We have demonstrated how adaptive concept-based systems in general are characterized by a domain model, user model, and adaptation model. As different types of systems have different properties, we have identified three main classes of adaptive concept-based systems. We have discussed these classes on the basis of representative systems, and have identified similarities and differences.

KEY TERMS

Adaptation Engineering: The process of constructing the automatic adjustment of an application to the user; often in adaptation engineering, models are created for the domain, the user, and the adaptation.

Adaptation Model: Representation of the way in which both the selection and presentation of content are adapted to the user.

Adaptive Hypermedia System: An adaptive concept-based system that is based on applying adaptation to a hypermedia application; characteristic is the (virtual) construction of a hyperdocument.

Adaptive Task-Based System: An adaptive concept-based system that is based on organizing the conceptual structures and the adaptation on the basis of the tasks and goals of the user; characteristic is the explicit representation of tasks.

Adaptive Web-Based Information System: An adaptive concept-based system that is based on the principle of using hypermedia to present output from a structured repository or database, and that performs the adaptation on the hypermedia presentation and the content retrieval; characteristic is the role of navigation.

Concept-Based System: An information system that uses conceptual structures to organize and present the information content; typical systems are data intensive, retrieve content dynamically from a repository, and use hypermedia to present the output.

Conceptualization: The process of constructing conceptual structures—that is, structures of concepts and their relationships that represent a subject domain.

Domain Model: Representation of the subject domain at a conceptual level, often in terms of concepts and their relationships.

Ontology: An explicit specification of a shared conceptualization of a domain of interest; an ontology is a controlled vocabulary that describes objects and the relations between them in a formal way; the vocabulary is used to make queries and assertions; ontological commitments are agreements to use the vocabulary in a consistent way for knowledge sharing.

User Model: Representation of the preferences and the state of knowledge of the user (to be used as a basis for adaptation).

Enterprise Application Service Model

University of Economics, Prague, Czech Republic

INTRODUCTION

Following the recent changes in the global business environment, many organizations are reevaluating their approach to delivering enterprise applications and are looking for more effective ways to control IT costs. There is growing evidence of reluctance to fund large-scale implementation projects, and of tighter budgets forcing more careful cost-benefit analysis to justify IT investments. It is becoming increasingly clear that the traditional model for delivering enterprise applications that involves the implementation of licensed software such as ERP (enterprise resource planning) applications within end-user organizations is not suited to the fast-evolving business world of the 21st century. Almost invariably, situations in which organizations own and maintain their entire IT infrastructure lead to very high costs of ownership, and consequently high levels of IT spending, which can detract from the core business in which the organization is engaged. This has led to a situation in which some businesses doubt the benefits of IT (Carr, 2003), and some observers even contend that productivity improvements, once assumed to be the result of IT, are more likely to be the results of other factors such as longer working hours (Nevens, 2002). This backlash that followed the IT boom at the end of the last century has forced software vendors to seek more cost-effective models for the delivery of enterprise applications, and has led to the reemergence of the ASP (application service provider) model as an alternative to licensed software. Today, the ASP model (or software-as-a-service model) is a part of a more general trend toward utility computing, where the service provider delivers highly scalable application services to a large population of end-user organizations in a reliable and cost-effective manner, typically from a remote data center. Utility computing aims to supply application services on demand, similar to other utility services (e.g., gas or electricity), and relies on new technologies and architectures that enable the virtualization and sharing of resources across a large number of users in order to minimize costs and maximize utilization. The use of advanced service-oriented architectures (SOAs), grid computing, cluster technologies, and failure-resistant configurations enable the delivery of highly scalable application services in a reliable manner to a large population of users. These technological advances distinguish utility computing from the earlier ASP and outsourcing models, and will ultimately result in significant reduction in the costs of enterprise software solutions and wide adoption of the software-as-a-service model. Major IT vendors including IBM, Microsoft, Sun, Oracle, and HP are promoting utility computing, albeit under different names (e.g., on-demand computing, etc.), and are investing vast resources into the construction of data centers and related facilities (Abbas, 2003). Others, such as Salesforce.com, have been successful with providing hosted services for CRM (customer-relationship management) and other related types of applications, validating the ASP model and further confirming the trend toward utility computing.

As the enterprise application software market matures, major ERP vendors are changing their revenue model to decrease their reliance on new software licenses toward income generated from software-license upgrades and product support (Karpecki, 2004; Levy, 2004). This change combined with the fact that most organizations spend as much as 80% of software-related costs on software maintenance and related activities (Haber, 2004) creates a situation in which licensed software is de facto rented. It is precisely this high level of ongoing costs that motivate many organizations toward alternatives such as outsourcing and the ASP model.

In this article we first examine the business drivers for the ASP model and contrast the software-as-a-service model with the traditional software-as-a-license approach. We then discuss future enterprise computing trends, focusing on the reemergence of the ASP model for enterprise applications and the likely impact of the wide adoption of this model on the IT landscape. In conclusion, we summarize the main arguments in this article.

BACKGROUND

The economic downturn at the beginning of this decade resulted in organizations dramatically reducing IT budgets, leading to scaling down existing projects and in some cases discontinuing projects altogether. In this section, we consider the background of these developments and the main business drivers that are forcing the transition to a new model for the delivery of enterprise applications as services.

High Cost of IT Projects

Problems of controlling the costs associated with IT projects are well documented. Notwithstanding the long experience that the IT industry has with the implementation of enterprise applications, costs of many projects significantly exceed their original budgets. According to a study of ERP implementation projects of 117 U.S. companies, 25% exceeded their budgets, 20% were abandoned before completion, and 40% failed to achieve business objectives (Cooke, Gelman, & Peterson, 2001). There have been other studies of this type that clearly demonstrate that the traditional model that involves the in-house implementation and maintenance of enterprise applications is associated with significant risks that are not being addressed by new, improved implementation methodologies and more technologically advanced software platforms. Equally, there is ample evidence that the outsourcing of the implementation and support of enterprise applications to a third party does not always bring the anticipated benefits (i.e., cost savings, improved responsiveness to new requirements, etc.); this is most likely because the implementation methodologies and technology architectures used by outsourcing organizations are essentially the same as those used by end-user organizations.

Fast Rate of Technology Change

Another significant risk factor associated with enterprise applications is the rapid development of underlying technologies, often necessitating the time-consuming reengineering of applications and costly upgrades. There is growing evidence that end-user organizations are no longer able to keep pace with new technological developments as delivered by IT vendors. New technology platforms and new versions of enterprise applications are often mandated by vendors who are reluctant to support older versions of their products, delivering no direct business benefit to end-user organizations.

High Demand on IT Skills

The traditional licensed-software model is associated with the high demand on IT skills needed to implement enterprise applications. Many small and medium-size enterprises (SMEs) cannot justify the cost of retaining their own internal IT staff with the appropriate expertise. Another contributing factor is that the expertise of IT specialists employed by end-user organizations and third-party consulting companies is not fully up to date and often significantly lags behind the expertise available from technology vendors. This factor leads to poor implementation results and is a major cause of the high rate of failure of IT projects.

Complexity of Enterprise Applications

Enterprise applications are becoming increasingly more sophisticated and complex. This complexity is particularly evident in large (horizontal) ERP application systems that provide comprehensive functionality designed to address requirements across a range of end-user organizations irrespective of the industry and the needs of individual businesses. While providing a complex and comprehensive solution, the actual utilization of the overall functionality of an ERP system by individual end users is relatively low. Customization to suit the needs of individual client organizations requires a high level of expertise and often involves the setting up of a large number of configuration parameters. Limited knowledge of the client's business processes by third-party consultants is another key factor, according to recent studies, that inhibits the successful implementation of ERP systems (Karpecki, 2002). ERP systems are characterized by high complexity of operation, even in situations in which the corresponding business process is relatively simple, and that leads to a high cost of end-user training. Because of the increasing size and complexity of new software versions, there is a corresponding growth in the demand on hardware resources. All these factors lead to increased implementation costs of enterprise applications that the client organizations are no longer willing to accept.

Globalization of the Business Environment

Globalization impacts enterprise applications in two important ways. First, as a result of globalization and the formation of regional economic blocks with standardized business practices and regulations, ERP applications can be used across a larger (international) user base without extensive customization to suit individual countries. For example, in the European Union, with the growing number of member countries using similar business laws and regulation, enterprise applications are becoming standardized across the entire region. Second, the global deployment of enterprise applications is becoming a growing trend. Many large, multinational companies implement global applications across the entire enterprise, in some cases using a single centralized data center and centralized applications accessible via the company's intranet. This simplified environment, with standardized business practices across the entire global organization, is highly suited to implementation using the software-as-a-service model.

Increased Acceptance of Alternative Models for Enterprise Application Delivery

Over the last 5 years, there has been an increase in awareness of alternative models for the delivery of enterprise applications, in particular, the outsourcing model. Given the highly competitive global business environment, organizations are becoming aware of the need to focus on their core business and avoid devoting resources to IT-related activities. This leads to the willingness to consider outsourcing noncore business functions, including the implementation and support of ERP applications to external providers.

THE MAIN FEATURES OF THE SOFTWARE-AS-A-SERVICE MODEL

The software-as-a-service model has recently evolved into a sophisticated model for the delivery of enterprise applications that substantially differs from the traditional approach (Feuerlicht & Vorisek, 2003; Levy, 2004; McCabe, 2004; Vorisek, Pavelka, & Vít, 2003; Wainewright, 2004). Table 1 summarizes the key differentiators between the software-as-a-service and software-as-a-license models, identifying the features of the software-as-a-service model that benefit organizations in addressing today's IS and IT issues.

The comparison table includes a number of compelling arguments that are likely to make the software-as-a-service model a preferred solution for enterprise application delivery in the future. Many of the benefits listed are results of recent technological advances combined with the increasing sophistication of service providers and the ability to configure suitable architectures for the delivery of enterprise application services. There is little doubt that standardized applications such as CRM can

Table 1. Comparison of the software-as-a-service vs. software-as-a-license models

Key Differentiator	ASP Model (Software-as-a-Service Model)	Traditional Model (Software-as-a-License Model)
Design Approach	Designed for delivery as Internet-based service for a large number of customers. It includes specific HW and SW architectures, and business model.	Designed for implementation by specialists and for customers to operate and maintain.
Architecture	Multitenant service-oriented architecture enables support of thousands of users from different user organizations on a scalable basis.	Architecture suitable for deployment by individual company on a dedicated IT infrastructure.
Upgrade Cycle	Frequent (3-6 months) upgrades. The same version of the application is running for all users.	Infrequent upgrades (12-24 months). Individual clients using different versions of the software. High costs of version management.
Problem and Change Management Procedures	Short feedback cycle. Procedures enable almost immediate feedback. Support staff can directly identify and fix problems. Fixing a problem for one customer fixes it for everyone, which reduces support costs.	Problem solving is often indirect via intermediaries (VARs, SIs, etc.). Patches and upgrades are implemented at individual customer sites. Costly and unreliable, as customers often delay installation of patches and upgrades.
Start-Up Implementation	Short start-up implementation cycle.	Long start-up implementation cycle. Typically involves complex implementation of hardware and software resources and knowledge transfer.
Scalability	The volume of the service (i.e., number of users, number of transactions) can be scaled on demand.	Configuration needs to support peak requirements and cannot be scaled down.
Customization	Typically limited.	Extensive customization possible, but expensive.
Functionality	Often limited functionality. Application typically designed for narrow vertical market.	Can provide extensive functionality. Often only small part of the available functions is used.
Required Resources	Only limited client resources are needed. Most of the company resources are dedicated to core business.	Extensive internal resources used for IT support.
Resource Utilization	IT resources (hardware, software, IT specialists, etc.) are shared across all clients. Provider has advantages of economies of scale.	IT resources are dedicated to a single organization.
Cost	Predictable ongoing operating costs. Typically no initial investments required. Costs correlate with the volume of services.	Both investments and operating costs involved. The costs generally do not correlate with the volume of service.
Service Agreement	SLAs are widely used.	SLAs used occasionally.
Required Expertise	Only minimal IT expertise needed.	Wide spectrum of IT knowledge and expertise needed.

be delivered more effectively using the software-as-a-service model than by using the traditional approach. While such applications are good candidates for delivery as services, it is doubtful that the benefits extend to all application types and scenarios, necessitating the careful evaluation of candidate applications. For example, the software-as-a-service model may not be suitable for the following.

- Mission-critical core business applications: These types of applications are typically not available from external providers, and the critical nature of these applications dictates in-house implementation and control.
- Highly customized and specialized applications: Providers cannot achieve economies of scale as the number of clients using such applications is relatively small.
- Applications with extensive integration requirements: Such applications have close dependencies on other enterprise applications and cannot be effectively managed externally.

FUTURE TRENDS

The ASP model emerged toward the end of the 1990s with often-exaggerated claims of advantages for client organizations, in particular for SMEs. Notwithstanding many perceived advantages, the ASP approach did not gain wide acceptance as the new model for the delivery of enterprise applications. Many of the early ASP providers have not been able to establish a viable business model and have discontinued ASP services or went out of business altogether. Perhaps the most important factor contributing to the demise of early ASP providers was the lack of a suitable technological infrastructure for hosting a large number of complex enterprise applications in a scalable and secure manner. Customization capabilities and support for integration with other enterprise applications were also lacking. As a result of these shortcomings, early ASP providers failed to deliver cost savings to their customers, resulting in poor acceptance of the ASP model by the marketplace.

Recently, however, a number of important IT vendors have reconfirmed their commitment to the ASP model in the context of the new utility-computing approach, and have made significant investments in infrastructure for the delivery of application services (Dubie, 2004). The main idea of utility computing is that IT services are supplied on demand (i.e., as required by the end-user organization) via a grid of interconnected, dynamically configurable, highly reliable and scalable computing resources (i.e., servers, data storage, and application resources). Enterprise computing grids are widely regarded as providing a suitable architecture for application services with the ability to host a large number of enterprise applications in a scalable and reliable manner. Resource sharing, resulting in improved utilization of hardware and software associated with grid-computing architectures, provides a more cost-effective solution for hosting enterprise applications than a set of independent servers each dedicated to a specific application. The availability of low-cost commodity components such as storage devices and CPUs enable the construction of large clusters of servers, storage arrays, and other resources, and create virtual resources on demand as required by enterprise applications. A number of infrastructure-technology vendors (IBM, HP, Oracle) are in the process of building large data centers with the view of moving toward the utility-computing model (Eriksen, 2003). Investment in infrastructure on this scale clearly demonstrates a strategic commitment to utility computing and more specifically to the software-as-a-service model as the new outsourcing model for enterprise applications.

Another key trend favoring the software-as-a-service model over the traditional software-licensing model is the emergence of service computing. In addition to supporting business processes within a given organization, most enterprise applications today have a requirement to interoperate across enterprise boundaries to support electronic business (e-business). Service-oriented computing and more specifically Web-services standards and technologies are playing a key role in the implementation of e-business applications and are likely to become the dominant enterprise computing approach in the future. There is a close relationship between the ASP model and service-oriented computing. The wide adoption of Web-services standards across various computing environments (i.e., .Net, J2EE) makes Web services an ideal solution for application integration, and for externalizing business functions of complex enterprise applications. Web services can be regarded as the enabling technology for the integration of ASP applications, and for the delivery of low-granularity application services (Ferguson, 2004).

The emergence of the software-as-a-service model as the new paradigm for the delivery of enterprise applications will have a major impact on the IT landscape, creating new opportunities and challenges for both the providers and client organizations. The reduction in the size of the traditional software-license market, reduced demand for on-site implementation, and the corresponding increase in demand for application services will lead to further rationalization of the IT vendor market (Cohen, 2004). The shift toward the software-as-a-service model is likely to take several years to be fully realized, but the impact on the IT industry as a whole, and the software vendors and third-party consulting organizations in particular, is likely to be dramatic, leading to the restructuring and realignment of the major industry players that will favor large software vendors that already have significant penetration in the ASP market and proven track records in successfully delivering application services to end-user organizations. Consulting organizations whose main activity is implementing ERP systems and similar applications for client organizations will need to refocus their business activities as there are not likely to be very many large-scale implementation projects of this type in the future. The software-as-a-service model will be associated with new business and pricing models that are likely to dramatically reduce the cost of ownership of enterprise applications. The reduction of demand for in-house IT specialists will lead to the restructuring of the IT labor market, and will demand important changes from user organizations that will need to implement a suitable management structure and an IT architecture that enable effective participation in the world of service-oriented computing. Adoption of the software-as-a-service model will also demand a change in the culture of client organizations, including the redistribution of responsibilities for IT costs and benefits to ensure the successful introduction of this new model of enterprise computing.

CONCLUSION

The business and technological factors discussed in this article have created a situation in which the delivery of enterprise applications in the form of services becomes both technically possible and economically desirable. The software-as-a-service model provides a viable alternative to software licensing for many application types today, and it is likely to become the dominant method for the delivery of enterprise applications in the future. This will have a major impact on enterprise computing over the next 5 years, finally tipping the balance from licensed software toward software delivered as a service.

KEY TERMS

ASP (Application Service Provider): A provider of application services over the Internet or an intranet.

CRM (Customer Relationship Management): Application system that allows a company to manage its relationship with a customer, including sales, marketing, customer service, and support.

ERP (Enterprise Resource Planning): System designed to support and automate business processes for manufacturing, distribution, payroll, and finances for an enterprise.

Grid Computing: Grid (network) of computing resources designed to provide computing and storage to applications in a scalable and reliable manner, ensuring high levels of utilization.

Outsourcing: IT resources are managed by an external provider who delivers IT services to the end-user organization.

Utility Computing: Computing services are provided on demand by a provider organization that uses its computers and facilities. Customers access the computers via a private network or over the Internet and are charged according to resource usage.

Web Services: Web-based application that uses standard Internet protocols and languages (SOAP, XML [extensible markup language]) to interact with other applications.

Entrepreneur Behaviors on E-Commerce Security

Michael Kyobe
University of the Free State, South Africa

INTRODUCTION

Electronic communication developments have always been associated with many security *risks* since the ARPANET implementation in 1960s. In 1972, John Draper (Captain Crunch) unlocked the AT&T phone network marking the beginning of the modern technology of hacking. Later in the 1980s, the seminal developments in the U.S. laid the conceptual and practical foundation for future electronic crime tools such as trapdoors, trojans, and viruses. More recently in the Internet environment, *electronic attacks* have reached an epidemic level (US-CERT, 2004). In South Africa alone, over 500 Web sites were defaced in January 2005 and e-crime losses are estimated at around 40 billion a year.

BACKGROUND

While electronic attacks present serious social and economic implications for small organizations engaged in e-commerce, these organizations are complacent about these attacks and continue to ignore *good security practices* (Jacque, 2003). One possible explanation for this *low regard for security* and subsequent attacks could be found in the examination of the *decision-making behaviors* of entrepreneurs during the e-commerce adoption process. While researchers have looked at *entrepreneurial traits* to explain the adoption process of e-commerce and many agree that personal characteristics of individual actors modulate the adoption of innovations (Wejnert, 2002), the potential impact of these traits on the adopted systems has not been examined. It is the view of the researcher that the decision-making behaviors of entrepreneurs at the time of e-commerce adoption affect the security of their information systems (IS). Entrepreneurs are mainly business owners who operate in uncertain environment and make all of the business decisions. They use intuition rather than data analysis and are often perceived to be somewhat irrational (Olson, 1985). *IS security* is the protection of information and the systems that use, store, and transmit that information.

This study examines the influence of entrepreneur decision-making behaviors on the quality of IS security. It explains why entrepreneurs ignore security, creates awareness of the dire consequences of *mistaken perceptions of security*, and emphasizes the importance of proper analysis of business and technological implications before the implementation of e-commerce. In the following sections, the decision-making behaviors of entrepreneurs, their potential influence on IS security, and the research propositions are presented. The research methodology is presented first. This is followed by the data analysis, the results of the survey, and finally the conclusion.

ENTREPRENEUR BEHAVIOR AND IS SECURITY

Two influential concepts in the field of entrepreneurship are used to examine this relationship. These are: entrepreneurial orientation (Miller, 1983) and entrepreneurial management (Stevenson, 1983). Entrepreneurship may be defined as the art of finding profitable solutions to problems.

Entrepreneurial Orientation

Entrepreneurship researchers have used the term entrepreneurial orientation to describe the methods, practices, and decision-making styles managers use to keep the firms competitive. Several researchers (Grundy & Kickul, 2001; Miller, 1983; Miller & Friesen, 1978) emphasize the need for risk-taking, innovativeness, and proactiveness. Risk-taking refers to taking chances in a decision-making situation. Innovation refers to doing new things by recombining parts of what is already being done, and proactiveness is the ability to take the initiative whenever the situation arises (Jun & Deschoomeester, 2004).

However, entrepreneurs take risks because they are unaware of risk implications or sometimes simply ignore them. They tend to have low-risk perception (defined as the subjective assessment of the probability of a risk (Sjöberg, Moen, & Rundmo, 2004)) and consequently implement risk prevention measures as a hurried reaction to a bad experience. Jun and Deschomester (2004) argue that *proactive risk-handling* is an important dimension of entrepreneurial orientation which has unfortunately received limited consideration. They contend that successful entrepreneurs do not only take risks, but also possess the propensity to handle them proactively. They define risk-handling as the process in which potential risks to a business are identified in advance, analyzed, mitigated, and prevented, and the cost of protection is balanced with the cost of exposure to the risk. In an electronic environment where market needs, technology requirements, and security challenges change very rapidly, proactive risk-handling is essential.

Entrepreneurial Management

Stevenson (1983) views entrepreneurship as a management approach of pursuing opportunity without regard to resources currently used. He categorizes management behavior into the following dimensions. These behaviors and their influence on IS security are discussed as follows. The research propositions are also named.

Strategic Orientation

Strategic orientation describes what factors drive the creation of strategy. For an entrepreneur, strategy is driven solely by the opportunity, not the resources needed to exploit the opportunity. Resources are defined here as assets, capabilities, routines, and knowledge used by an organization.

As entrepreneurs seek new opportunities, they give limited attention to resources and some organizational activities. Gifford (1998) contends that limited entrepreneurial attention explains many issues relating to entrepreneurial activities (e.g., limited firm size growth and innovation, the choice of resource procurement and relationship between managers and employees). Evidence shows that limited attention is often paid to the resources and system requirements needed to support e-commerce activities (Hoffman, 2003; Jain, 2003). Literature on the evolution of e-business (Earl, 2000) also confirms that in the early stages of e-commerce, there is limited use of IT by small organizations and systems security measures are usually basic. The adoption of technologies such as firewall and authentication systems is not extensive (Allan, Annear, Beck, & Beveren, 2003) and managers often shun good security practices (Jacque, 2003). Jensen (2004) found that security only became of much greater concern for the entrepreneurs once they had adopted e-commerce and for non-adopters, this was a matter of least concern. Katsikas and Gritzalis (2002) warn that if security is applied as an add-on or patch to existing e-commerce solutions, degraded services will be provided since existing e-commerce functional requirements cannot easily be altered a posteriori. By placing limited attention to resources and security requirements, entrepreneurs fail to handle security risks proactively. It is therefore hypothesized that:

H1: Entrepreneur's lack of propensity for systems risk-handling will negatively influence the quality of IS security.

Lack of propensity for systems risk-handling is the inability to proactively identify, analyze and prevent systems and e-commerce security risks. *Quality of IS security* refers to the degree to which the information system is protected from e-crime or cyber attacks.

The Commitment to Opportunity

According to Stevenson, entrepreneurs are ready to commit to action rapidly. Many writers report that key decision-makers in small organizations haven't the time to devote adequate attention to the appropriateness of their decisions. They instead rely mostly upon their intuition and feelings (Miller & Friesen, 1978). Studies by (Jensen, 2004) reveal that many entrepreneurs adopted e-commerce before fully examining the resource, financial & risk implications. Exploiting e-commerce opportunities irrationally may result into the failure to engage the right players; improper evaluation of the systems and resources; and failure to examine potential vulnerabilities, the regulatory environment and legal issues. It is hypothesized that:

H2: Entrepreneur's irrational commitment to opportunities will negatively affect the quality of IS security.

Irrational commitment to opportunities refers to the tendency to seize opportunities without proper consideration given to potential implications.

Commitment of Resources

Stevenson maintains that entrepreneurs will commit as few resources as possible at each stage of the project and may even try to pursue opportunities without the proper resources. Jain (2003) found that many small business owners are reluctant to purchase up-to-date hardware/software and argues that piracy is one extreme option available to them. They also approach novelty with caution due to the fear of loss and related cost implications (Wejnert, 2002). In their national study, Daniel and Myer (2001) found that the majority of entrepreneurs in the UK used a staged approach to e-commerce adoption due to limited resources. While this approach allowed entrepreneurs to gain some experience through trial and error, a number of costly, disintegrated and incomplete e-commerce applications were developed. By using immature, disintegrated, poorly tested or pirate systems the organization and its business partners are exposed to severe security attacks. It is therefore hypothesized that:

H3: Entrepreneur's propensity for resource minimization will negatively affect the quality of IS security.

Propensity for resource minimization refers to the orientation towards utilizing very limited resources.

Control Over Resources

Stevenson maintains that entrepreneurs will reduce as much as possible the amount of resources they own and use. Small organisations are poor in resources, which causes them to rely on external assistance. Overreliance on outsourced services can lead to loss of flexibility and control. In addition, some vendors usually parade the positive features of their wares and down-play issues such as compatibility, maintenance, training and security. Outsourcing services such as intrusion detection, e-mail and firewall systems may also lead to security problems since service providers often abide by their own policies rather than those of their clients. Furthermore, since providers offer customized services to several service receivers including competitors, concern arises over data confidentiality and reliability issues and the amount of assistance extended to each customer's problems. It is therefore hypothesized that:

H4: Entrepreneur's overreliance on external resources will negatively affect the quality of IS security.

Overreliance on external resources refers to the over-dependence on other organisations for human, technical and financial assistance.

Management Structure

The management structure of the entrepreneur organization is flat without clearly defined lines of authority or routine tasks. Entrepreneurs tend to have a strong desire for autonomy and control which could easily hamper the success of the organization (Curtis, 1983). They tend to be rigid, traditional and sometimes outdated in their business practices. In many such organizations there are no definitive duties or responsibilities drawn up for subordinates and the high degree of generality resulting from undertaking heterogeneous work prevent employees from developing expertise in areas such as IT security. Fear of loss of control and lack of trust also make delegation difficult (Kyobe, 2004). It is therefore hypothesized that:

H5: Entrepreneur's desire for control and autonomy will negatively influence the quality of IS security.

Desire for control and autonomy refers to the orientation toward retaining much control over the business activities. The research model for this research is presented in Figure 1. Quality of IS security is the dependent variable and the characteristics of the entrepreneur are the independent variables.

Research Methodology

Most of the measures used were adopted from previous studies, but modified to capture data relevant to the current study (see Table 1). A five-point Likert scale was used in which 1 indicated "strong disagreement" and 5 "strong agreement".

Data Collection and Sample

Based on a previously compiled list of Internet users in the Free-State and Kwazulu-Natal provinces, entrepre-

Figure 1. Research model

Construct	Ref.	Measure	Adapted from
Lack of propensity for systems risk handling	RH1 RH2 RH3 RH4	Lack of : • Maintenance arrangements • Hardware/software guarantees • Insurance coverage • A security plan.	Jun and Deschoomester (2004).
Irrational commitment to opportunities	IC1 IC2 IC3 IC4	Failure to : • Consult with vendors, IT consultants and partners • Analyze e-commerce risks • Evaluate resources • Analyze costs & benefits.	Dean and Sharfman (1993).
Propensity for resource minimization	RM1 RM2 RM3	Approach used to engage resources. Type and quality of hardware/software used. Category & expertise of people involved.	Gable (1991); Croteau and Bergeron (2001); Thong (1999).
Over-reliance on external resources	OR1 OR2	Amount spent on outsourced resources. Number of applications and services outsourced.	Grover, Cheon and Teng (1994).
Desire for control & autonomy	MS1 MS2 MS3	Lack of : • Delegation of control • Allocation of tasks • Openness of communication.	Watson (1990).
Quality of IS security	QIS1 QIS2 QIS3	Number of attack incidents in past 12 months. Number of security measures implemented. Level of awareness of security risks and standards.	Straub (1990); Internet Security Alliance (2004).

neurs engaged in e-commerce were selected at random. 150 questionnaires were mailed of which 60 were returned. Five incomplete responses were, however, dropped. Follow-up letters and phone calls were made to encourage other respondents to participate. Fifteen additional responses were obtained after 3 weeks. The response rate was 47%.

Sample Characteristics

Respondents came from the manufacturing, retail, finance, construction, marketing, transport, training, entertainment, and agricultural industries. The majority were from the retail sector. The respondents' age ranged between 20-55 years and their computer and e-commerce experience ranged between 1-9 years. Most of these respondents were in business for less than 10 years.

Tests for Non-Response Bias

A test for non-response bias was done by comparing responses obtained in time with those obtained 3 weeks after follow-up letters were sent. It has been found that late respondents are likely to have similar characteristics to non-respondents (Thong, 1999). The T-test results show no significant difference between the two groups (T = 1.24; p = 0.185) at the 5% significant level, suggesting that non-response bias did not exist.

Data Analysis

Assessment of Validity and Reliability

Content validity was established by ensuring that most items used for measuring the constructs were obtained from prior studies. The reliability or internal consistency of each variable was assessed by calculating the Cronbach alpha coefficient. Table 2 shows that none of the Cronbach alpha was below 0.70 (Nunnally, 1978).

Factor analysis was also conducted to analyze interrelationships among the variables. Five factors were extracted as presented in Table 3 below. RH4 (0.812), ICI (0.838), RM2 (0.816), MS2 (0.803) had particularly high factor loadings.

The possibility of multicolinearity was examined using Person Correlation (see Table 4). None of the squared correlations was close to 0.80 to suggest possibility of this problem (Hair, Anderson, Tatham, & Black, 1995).

We also conducted correlation analysis to determine the relationship between the characteristics of the entrepreneur and the quality of IS security. Results are presented in Table 5. Except for *Propensity for resource minimization*, all other characteristics were both negatively correlated with the quality of IS security and statistically significant thereby supporting hypotheses H1, H2, H4, and H5.

Discussion

Correlation analysis revealed that there was a significant correlation between all entrepreneur characteristics. Except for *Propensity to minimize resources*, all other characteristics were significantly correlated with the quality of information systems security. *Irrational commitment to opportunities* had the highest mean (mean = 4.85, Std. = .61), indicating that entrepreneurs rapidly adopt e-commerce before analyzing its security implications. Table 3 shows that IC1 had the highest influence on factor 1 (0.838), emphasizing the importance of consultation in order to minimize potential security risks. Previous studies show however that IT service providers in the region charge high consultation fees and sometimes lack commitment (Kyobe, 2004). This perhaps discourages entrepreneurs from seeking such assistance. Table 3 shows that IC4 (failure to analyze costs/benefits) also loaded

highly on factor 1 (0.831). Entrepreneurs don't maintain formal records necessary for planning and lack the necessary skills to conduct financial and risk evaluations (Kyobe, 2004).

The failure of entrepreneurs to consult experts and to maintain formal records might have also influenced their ability to prepare security plans and arrangements for handling risks (factor 2, Table 3). This confirms earlier findings that small firms often fail to plan and to protect their resources (Kyobe, 2004). *Propensity for resource minimization* was surprisingly statistically insignificant, suggesting that it does not influence IS security. Analysis of factor 3 indicates however that RM1 and RM2 loaded highly on this factor (0.777 and 0.816 respectively). Most entrepreneurs adopted the ad hoc approach and used existing hardware and software to implement their systems. They relied on cheaper and somehow inexperienced resources (e.g., friends, children, and local firms) to implement their systems. This relationship should be invested further.

Items that measured the *quality of IS security* revealed that outdated and risk-prone hardware and software such as Windows98 and PentiumII computers were still used by many entrepreneurs. In most organizations anti-virus software and passwords were the only protection measures. Encryption and authentication technologies were not commonly used, there was a general lack of awareness of security standards and many suffered electronic attacks. Systems in these organizations were therefore not adequately protected.

The mean scores for *desire for control and autonomy* (mean = 3.95, Std. = 0.57 in Table 2) indicates that tasks were not allocated, authority was not delegated, and communication was not open. MS2 loading on factor 5 (Table 3) was particularly high (0.803) confirming the common problem of lack of task allocation which doesn't encourage IT skills development in many small organizations. Grundy and Kickul (2001) report that managers that helped employees feel connected to their vision and values were growing at a rate of 141% compared with 10% for those that did not. Our findings, therefore, suggest that entrepreneurs will continue to depend on external rather than internal resources for systems support and maintenance (see OR2 (0.591), OR1 (0.641) in factor 4).

FUTURE TRENDS

Emerging trends in e-commerce and security provide both promises and pitfalls for small organizations. While cheaper and secure solutions for SMEs are now provided by IBM, Microsoft, HP, and Cisco, security still remains a major problem. Organizations are, therefore, encouraged to adopt a holistic approach to e-commerce security, whereby individuals, businesses, vendors, and government work in partnership to address this problem (EURIM, 2003; US-CERT, 2004). Several other initiatives, such as improvements in reporting methods (EURIM, 2003), research into "trust" (Clarke, 2002) and emerging practices, and Netpreneur challenges (Grundy & Kickul, 2001), are already underway.

CONCLUSION

Our findings confirm that due to their decision-making behaviors, entrepreneurs do not implement e-commerce with security in mind. There is a need for careful evaluation of business and technological implications beforehand. In addition, entrepreneurs need to involve experts, invest in up-to-date resources, and ensure better work relations with employees. This study was only conducted in regional areas. An extension into urban areas where the profile of entrepreneurship differs may provide useful information for policy advisors.

KEY TERMS

E-Crime: Is the illegal exploitation of computer technologies, such as the Internet.

Electronic Commerce: Use of electronic means to exchange information and to carry out transactions.

Entrepreneur: A business owner who takes all decisions and operates in uncertain environment.

Entrepreneurial Orientation: The practices and decision making styles managers use to keep the firms competitive.

Information Systems Security: The protection of information and systems that use, store, and transmit information.

Irrational Commitment to Opportunities: The tendency to seize opportunities without proper consideration given to potential implications.

Low-Risk Perception: Refers to the subjective assessment of the probability of a risk.

Risk-Handling: The process in which potential risks to a business are identified in advance, analyzed, mitigated, prevented, and the cost of protection is balanced with the cost of exposure to the risk.

SMEs: According to the South African Small Business Act (Act 102 of 1996), SMEs are businesses with up to one hundred employees.

E-Questionnaire for Innovative Adaptive-Learning Scheme

Tzouveli Paraskevi
National Technical University of Athens, Greece

Stefanos Kollias
National Technical University of Athens, Greece

INTRODUCTION AND BACKGROUND

As broadband connectivity to the Internet becomes faster, Web-based learning systems have appeared and play an important role for self-learning, especially for working people. Most of the systems are not adapting to the learner, so the learner has to spend a lot of time before reaching the learning goal that is suitable for him or her (Solomos & Avouris, 1999). This procedure may discourage the learner from continuing his or her studies (Bixler & Spotts, 2000; Fitzelle & Trochim, 2000).

To overcome these difficulties, we have to design an e-learning system that will be adapted to the learner's ICT level and knowledge. In our proposal, we introduce an e-learning schema that has these characteristics. Specifically, we consider the IEEE reference model (WG) of the Learning Technology Standards Committee and use it to model the architecture of an e-learning system. Our approach is based on the usage of electronic questionnaires (e-questionnaires) that are designed by experts and aim to detect the learner's ICT level and learning preferences prior to the learning experience as well as after its completion. Through the analysis of learner responses to questionnaires, learners may be assigned to their corresponding learner profiles so that they are served with learning material that best matches their needs.

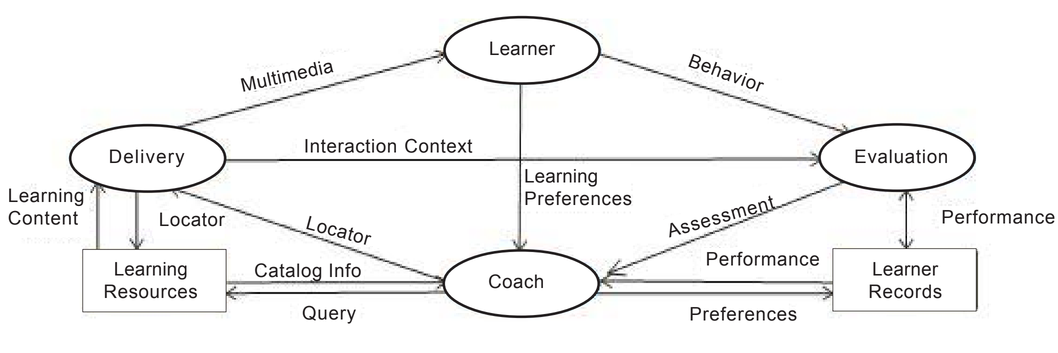
The structure of the article is the following. In the first section "Description of the E-Technology Application," we briefly present the generic structure of the e-learning system, as specified in the IEEE reference model (WG) of the Learning Technology Standards Committee, and then we present our approach to this model. Continuing, we outline the profile adaptation method that is used in our schema. Finally, in the section "Impact of the E-Technology Application," we refer to the SPERO project, in the framework in which the proposed system is being applied, and finally we list our concluding remarks.

DESCRIPTION OF THE E-TECHNOLOGY APPLICATION

Learning Technology Systems Architecture by IEEE

The proposed system is based on IEEE P1484.1/D9, the draft standard for a learning-technology system architecture (LTSA; IEEE P1484.1, n.d., http://jtc1sc36.org). This standard identifies a high-level architecture for e-learning systems that includes processes, stores, and flows as is depicted in Figure 1, and describes the interaction between these modules.

Figure 1. IEEE 1484.1 LTSA system components



This system, which could be adaptive for any educational course, contains two stores: learning resources and learner records. The learning resources store is invoked using a database that represents knowledge, information, and other resources that are used in the learning experiences. It may be represented as a collection of presentations, tutorials, experiments, or lessons. The other store of the IEEE LTSA system, the learner records, contains information about the learner as assessment information and certifications that the evaluation and coach processes have derived.

The learner entity, coach, evaluation, and delivery processes each have a main role in the system.

The main entity of the system is the learner entity, which represents a single learner or a group of learners with different needs. The learner process receives a multimedia presentation via the multimedia flow, which has been retrieved from the learning resources by the delivery process.

While the multimedia presentation is shown to the learner, his or her behavior and reactions are observed via the behavior flow, which provides information about the learner's activities. Information as keyboard clicks or mouse clicks is recorded in real time by the behavior flow and is used to evaluate the results of the learning.

The learning preferences flow is negotiated with the coach process based on language and cultural adaptation, as well as accessibility for people with physical limitations. The learner entity's observable behavior flow is an input to the evaluation process. The interaction context flow is a data flow from the delivery process to the evaluation process that may provide the necessary information for interpreting the information contained in the behavior data flow.

On the one hand, the evaluation process produces assessment information, which is sent to the coach process. On the other hand, the evaluation process creates performance information that is stored in the learner records. Performance information may come from both the evaluation process (e.g., grades on lessons) and the coach process (e.g., certifications). The coach may receive performance information from the learner records at any time. Performance information, such as assessment information and certifications, and preferences may be stored in the learner records by the coach process.

Based on this information, the coach process may generate queries and forward them to the learning resources store in order to request learning materials that are appropriate for each learner. The learning resources store replies to the coach process with catalog info flow, that is, with a list of locators that match the search query. The delivery process to retrieve learning content may use these.

Finally, the delivery process transforms information obtained, using the learning content store, into a presentation, which may be transferred to the learner entity, passing through the multimedia stream. The evaluation process that is described in the LTSA draft standard is not apparently adaptive to the learner as there is no mechanism that could provide this adaptation. In the proposed schema, we attempt to outline the procedure through which the LTSA draft standard may be applied with the direction of learner-centered content delivery. Our approach to understanding the learner's needs is outlined in the following section.

A NEW APPROACH TO LEARNING TECHNOLOGY SYSTEMS DESIGN

The presented procedure evolves around the notion of the e-questionnaire with the aim of the detection of the learner's learning preferences and ICT level, with respect to a specific learning topic. Through this procedure, learner adaptation to the proper learning topic and course can be achieved using an e-questionnaire. Our proposal could be considered as an extension of the IEEE LTSA draft, adding two stores, the questionnaire and learner profiles, and two processes, the e-survey and the experts' group, and enriching all modules that the IEEE LTSA contains with new functionalities with the purpose of effective collaboration between them (Figure 2).

In our case, the learner entity represents a teacher who works in the special educational needs sector (http://www.image.ntua.gr/questspero; Tzouveli, Tsapatsoulis, Kollias, & Michaelidou, 2003). The expert-group process is represented by a variety of people, such as teachers, teachers of the special-education sector, experts in e-learning, data analysts, psychologists, and software engineers. In our case study, the experts' group has designed and illustrated e-questionnaires, which are addressed to the teachers in the special educational needs sector and are intended to collect information for teachers' educational background, as well as their background in ICT. In addition, information concerning teachers' opinions about the pedagogical utilization of ICT and the amount of ICT they use in the teaching procedure are also extracted from these questionnaires.

It is noticeable that the experts' group is responsible for determining the learning issue that the e-learning schema can provide and for the learners' group in which this learning subject is addressed.

The questionnaire store is a database that contains various questionnaires designed for diverse educational needs and types of learners. Each of these questionnaires has a limited number of questions; these may be of various types, such as multiple choice, which include the appropriate values for the answers of each question. The questionnaire texts are defined and stored in the questionnaire store by the experts' group that has decided the learning subject, which the questionnaire will negotiate.

The layout of the questionnaire is automatically illustrated (by software that has been produced by the experts' group; Skordalakis, 1991; http://www.image.ntua.gr/questspero) through the delivery process, taking as input the questionnaire texts that are stored in the questionnaire store; they are provided to the learner though the multimedia flow (Figure 2) as hypertext that contains a form schema.

Likewise, statistic experts who belong to the experts' group assign the values of the answers of each question that the e-questionnaire contains. The emphasis is on the questionnaire, the answers to which can be processed in an automated manner and can be lead to the learner's classification and also to an e-survey.

In this way, the delivery process sends the values of the questions from this questionnaire to the evaluation process via the interaction-context flow. So, the interaction–context flow has been assigned with this function.

Once a learner replies to the e-questionnaire, his or her reply is submitted to the evaluation process via the behavior flow. This is necessary for the computation of the values that each learner has given taking under consideration the learners' profile store. The proposed schema needs this computation in order to find out the learner's level of knowledge in a specific subject and to classify the learner's profile, which is then stored in the learner records.

The new store, learner profiles, contains the current profiles that the e-learning system provides. The way in which these profiles are accumulated in the store will be analyzed in the following section (http://www.image.ntua.gr/statspero/profiles).

In the proposed scheme, the coach process of the IEEE LTSA draft has been improved so as to select the proper learner resources for learners according to their profiles; these are stored in the leaner records. If the learners have already accessed the specific e-learning system, they will not be asked to answer the questionnaire but will receive the proper learning material according to their profiles, stored in the learner records. Otherwise, if the learners access the specific e-learning system for the first time, they will receive the questionnaire that is proper for the learning topic that they will take.

The e-survey process can provide statistics over the learners' answers, taking as input the learner's records where the learner's answers to the e-questionnaire are stored, as well as providing a statistical analysis on these records. The e-survey process is added for statistical reasons, and the results of this procedure can be useful for the scientific section that the questionnaire has as a subject (http://www.image.ntua.gr/statsspero).

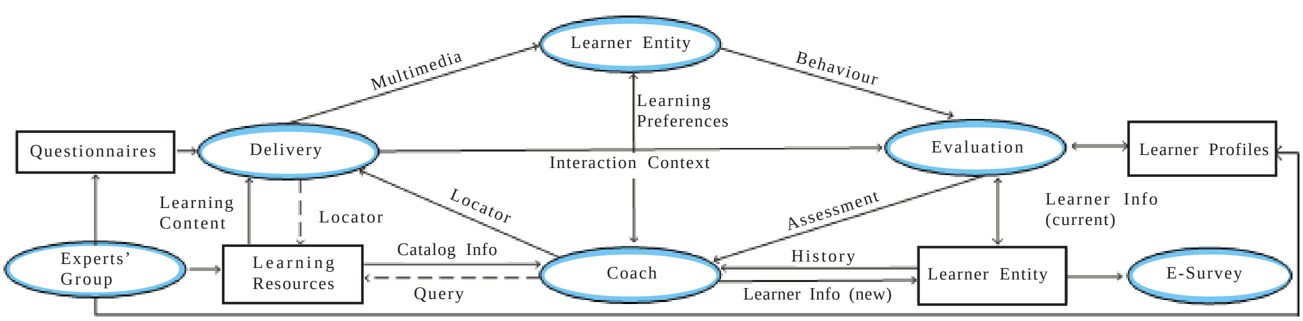
For example, if the questionnaire includes questions about computers and the Internet, as it happens in our case study, a statistical analysis for the learner's familiarity with ICT can be carried out (Papoulis, 1984).

PROFILE ADAPTATION

Among the research community dealing with personalized learning and intelligent learning applications, it becomes clear that the results to be achieved from any kind of electronic questionnaires or surveys will not have the desired effectiveness unless major focus is given to individual learner profiling and the corresponding learner behavior. Such functionalities define learners' capabilities and also to some extent define learners' future choices. Additionally, major profits evolve from learner profiling, especially when used in interactive learning systems and information-retrieval methods for learning (Mylonas, Tzouveli, & Kollias, 2004).

However, automated learner-profile extraction from several sources of knowledge is, in general, a complex task (Wallace et al., 2004). It is expected that it can be tackled when dealing with specific application domains.

Figure 2. Proposed system components



Herein, we focus on any information bit that may be utilized in order to either enhance the learning experience that will be offered to the specific learner in the future, or enhance the system's interaction with other learners as well, applying the principles of collaborative learning. The term collaborative learning refers to the hypothesis that similar learners will act in a similar manner when faced with similar situations, which allows for a group of learners to be handled by a system through a single learner profile.

This section describes the algorithms that may be utilized for the analysis of feedback collected from the learner in the form of replies to e-questionnaires, as well as the way to utilize the mined information in order to enhance the learning experience provided by the system.

The adaptive operation of the proposed system relies on the principles of collaborative learning (Solomos & Avouris, 1999); thus, a small set of predefined, static profiles needs to be included in the profile database before learners can be efficiently served. The population of the database with the initial profiles is achieved with the aid of a group of experts. In order to acquire the necessary input for the generation of the initial learner profiles, the experts' team designs an e-questionnaire that is forwarded to a characteristic sample of learners.

The initial e-questionnaire is specially designed to detect the learners' ICT levels concerning the topic of the instruction, their learning preferences, any learning or accessibility difficulties they may have, their approach toward the topic of instruction as well as toward e-learning tools, and their interfaces and their preferred language of instruction. The primary aim of this questionnaire is to allow for the learners of the characteristic sample to be divided into groups of learners, with learners of each group displaying similar learning behaviors.

When designing the questionnaire, together with the questions and the sets of corresponding answers, the experts also indicate the way to interpret each answer according to the value of the question. Using this information, the questions are divided into groups depending on the type of information that they provide about the learner. Moreover, distance metrics among answers corresponding to questions of the same group are defined, indicating the degree to which the answers are incompatible.

The learner profiles that have been defined by the experts' team are stored in the learner-profile store. Each one of them describes, in addition to the characteristics of the learner it describes, the learner's needs and preferences. Thus, once a learner is assigned to a learner profile, the coach may use this information in order to locate in the learning-resources store the learning materials that best match his or her learning needs and preferences.

As a first step of processing, learners' replies are checked for consistency. Specifically, the average sum of distances between answers (for questions of the same group) is used as an indicator of the consistency of the replies. A large percentage of incompatibilities in learner answers corresponds to either a poorly designed set of questions or to a poorly designed answer-interpretation scheme. In either case, this is a strong indication that the e-questionnaire needs to be reconsidered, and possibly reanswered by learners, before the process of data analysis proceeds.

Once this step is over and the learner replies have been verified as consistent, the process of the detection of typical learner behaviors starts. This is undertaken through the clustering of learner replies.

In the beginning, the group of experts calibrates the possible answers of each question, and these values are stored in the e-questionnaire store. Afterward, initial static profiles are defined by the group of experts according to possible combinations between answers of the questionnaire, and these profiles are stored in the learner profiles. The categories of these static profiles are three now: beginner, intermediate, and expert learners.

Next, the evaluation process (Figure 2), whose functionality has been extended in the proposed schema, collaborates with the learner entity with the aim of retrieving each answer that the learner has chosen. Having these values, the evaluation process applies the k-means algorithm (Duda, Hart, & Stork, 2000), computing the distance between each answer and the centres of each category stored in the learner-profiles store. Selecting the nearest centre defines the profile in each question that the learner has indicated, and the average of the questions' profiles defines the learner profile, which is stored in the learner records.

The experts use average learner replies from each learner group in order to define the corresponding collaborative learner profile. Specifically, the experts have to specify

- which learning resources are suitable for learners in each profile and
- what the characteristics of each collaborative profile are.

The latter is needed in order for a new e-questionnaire to be designed with the aim to quickly, that is, using a much shorter e-questionnaire, classify new learners to the collaborative profile that best matches them. All new learners are required to reply to the questions of this e-questionnaire before the system can serve them with learning material that suits them.

Learners are also required to provide answers to questionnaires after completing an e-course. Answers to these e-questionnaires are used by the system to adapt its operation to the changing needs and ICT levels of the learners. Specifically, learners are classified, based on their answers, to the collaborative learner profiles of the profile database. In this process, it is possible for a learner to be assigned to a different profile than the one he or she originally belonged to; in this way, the system's future interaction is adapted to the new learner characteristics.

IMPACT OF THE E-TECHNOLOGY APPLICATION

The proposed schema has been developed under the European project SPERO: TeleInformatics System for Continuous Collection, Processing, Diffusion of Material for Teacher Training in Special Education (Leonardo da Vinci program, Theme 5: E-Learning, 2001-2004).

The overall objective of the SPERO project has been to provide data concerning the field of special educational needs in order to identify the meaning of exclusion and to introduce policies and strategies for social inclusion. For this reason, SPERO has collected and processed material for training teachers mainly in special education that offer valuable information in the area of training. Data have been collected by the "clever" questionnaire, which is developed based on the proposed schema. Automatic statistic analysis is used to analyze factors and variables that may lead to unemployment and social exclusion. Emerging issues can lead to proposed actions that may be adopted in order to prevent the risk of unemployment.

CONCLUSION

In the era of the information society, surveys should not only be used to record information about a particular subject in particular time instances. Their main conclusions need to be usable in a dynamic manner. In this article, we have presented how an e-questionnaire, designed for conducting a survey about the ICT level of knowledge of teachers working in the special education sector, can be used in the framework of a dynamic distance learning scheme so as to achieve user adaptive-learning facilities. Work is continuing in this area through the collection of large numbers of teacher responses from many European countries, aimed at attempting to apply the proposed schema to large multinational populations.

KEY TERMS

Distance Education: Distance education takes place when an instructor and student are separated by physical distance, and various technologies (e.g., the Internet, videoconferencing, etc.) are used to bridge the distance. These types of instructional delivery systems can provide nontraditional students with a second chance at a college education, and reach those disadvantaged by time constraints, physical disability, or remote geographical locations. It is sometimes called distance learning.

E-Course: An online educational program that introduces and explains a specific educational subject

E-Learning: Technologically mediated learning using computers whether from a distance or in a face-to-face classroom setting (computer-assisted learning).

E-Questionnaire: A questionnaire in an electronic form that can be completed via the Internet.

E-Survey: A survey that is based on answers of an e-questionnaire.

ICT Level of Knowledge: The level of knowledge in the field of information and communication technologies that someone has.

User Profile: The user profile specifies what data and network resources a user can access and the type of access.

E-Shoppers' Perception of Web-Based Decision Aid

Fen Wang
University of Maryland, Baltimore County, USA

INTRODUCTION

The WWW, for better or worse, has forever changed the way retailers do business nowadays. E-shoppers, who become more sophisticated and mature nowadays, are demanding increased flexibility and intelligent aids in accessing product information, making purchasing decisions, and obtaining e-services (Anupam, Hull, & Kumar, 2001; Chen, Gillenson, & Sherrell, 2004). The Internet facilitates interactive selling approaches, whereby product offerings can be tailored to individual preferences. It allows e-shoppers to easily gather, retrieve, and analyze product information. Ultimately, the Web offers the ideal vehicle for delivering intelligent online support tools directly to customers (Grenci & Todd, 2002).

Unfortunately, most e-commerce sites are rarely aware of taking advantage of such Internet-driven customer aid. Rapid advancements in Internet technology have offered a solution of Web-based customer decision support system (WCDSS) that can improve transactional efficiency by providing tailored merchandising information, offering sales support and consultation, facilitating sales promotion and advertising, and enhancing the consistency, availability and quality of online support to e-shoppers (O'Keefe & Mceachern, 1998). As the WCDSS aims to empower e-shoppers by enabling them to make informed decisions online, the question of how they would perceive such support arises.

In this article, we aim to establish a theory-founded framework to understand and explain e-shoppers' perceptions of the proposed WCDSS functions. We look at the key features of WCDSS functions that may have impact on e-shopper's perceptions, and how to scale and analyze e-shoppers' perceptions regarding specific functions. The specific objectives are threefold. We aim (a) to verify the role WCDSS can play in facilitating e-shoppers, (b) to identify the key issues that impact e-shoppers' perceptions of WCDSS, and (c) to suggest ways in designing and improving WCDSS functions and interfaces.

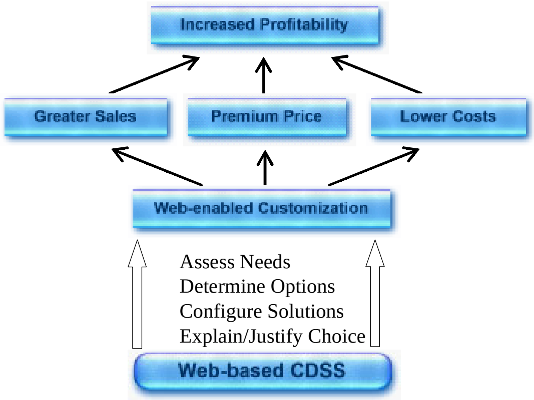
BACKGROUND OVERVIEW

Throughout the e-commerce literature, customer-side researches have repeatedly stated that customers are at the core of all businesses no matter they are brick-and-motor or virtually online (Hughes, 2002; Rodgers, Yen, & Chou, 2002). E-commerce success depends on effectively managing relationships with the customers and understanding their online behavior and preference in a comprehensive and interactive way (Rowley, 2002). With the advent of the Internet, customers have realized the benefits of shopping online including convenience, broader selection, and competitive pricing, but on the other hand, their involvement in online retailing is impeded by factors such as information overload and other technology barriers or unfamiliarity (Chen et al., 2004).

Taking advantage of the Internet-driven technology, WCDSS, a Web-based customer decision support system, offers an ideal vehicle that provides customized and intelligent real-time assistance for e-shoppers in overcoming substantial impediments to participation and satisfaction online. Starting more than 40 years ago, long before the Web and notions of e-commerce access, there has been great interest in the human decision making process (Forgionne, 2000). In Gregg, Goul, and Philippakis (2002), work on decision support development, they proffered that "it is now possible to access these DSS using the Internet" (p. 233). A WCDSS is thus defined as a Web-based system that connects a company to its existing or potential customers, providing support for the customers' online decision-making process (O'Keefe & McEachern, 1998).

A WCDSS is believed to have the ability to offer significant value to the entire customer decision-making process, especially in the Internet era of self-service, configure-to-order buying (Grenci & Todd, 2002). The complexity of configuring and selecting the customizable goods and services sold on the Web suggests there is particular value in an interface that guides and directs customer choices and markets complex and customizable products (Grenci & Todd, 2002). Such WCDSS-enabled

Figure 1. WCDSS in support of e-commerce activities



personalization and customization will then lead to lower transaction cost, premium product pricing, and greater promotional sales which all together will result in increased profitability. Figure 1 depicts the aforesaid functions and features of a WCDSS and its impact on the e-commerce performance.

Although the WCDSS is gaining momentum in facilitating online shopping, much work has been done on the algorithms of the proposed approach with little consideration of the interaction with the potential customers (Anupam et al., 2001). One exception is a simple framework proposed by Chiasson and Lovato (2001) to understand the factors that influence the formation of a user's perceptions of a DSS innovation. Those factors include subjective norms, adoption stage, user competence, implementation processes, and organizational factors. However, e-commerce introduces new business objectives, enables new business activities, and creates new channels in which the service experience and data gathering about the customer are closely coupled (Rowley, 2002). As a result, the old measures of customers' perceptions of general DSS functions may no longer apply in the context of e-commerce. To fill the gap, this study offers such an exploratory investigation on e-shoppers' perceptions of the specific WCDSS functions. The framework proposed in this study links the WCDSS features and functions to each e-shoppers' decision-making step, and helps WCDSS designers and implementers in their development, implementation, evaluation, and ongoing utilization of the system.

FRAMEWORK TO UNDERSTAND E-SHOPPERS' PERCEPTION

To explore e-shoppers' perceptions of the WCDSS functions, we first look at the specific steps involved in the customer shopping process, what parts of the process can be supported by the WCDSS, and how the customers would perceive such Web-based support. From a decision-making perspective, the customer shopping process breaks down into five stages of decision-making steps (see Table 1).

Throughout the process, WCDSS could provide proper decision aids to facilitate certain tasks within each stage. Based on an early work on the impact of design elements and policies on customer attitudes (Hahn, 2001), we identify two dimensions of e-commerce system, which reflect the proposed WCDSS functions: Market Site-Structure and Market Techno-Structure. We define EC Site-Structure as related to the presentation and navigation of items or instructions. EC Techno-Structure refers

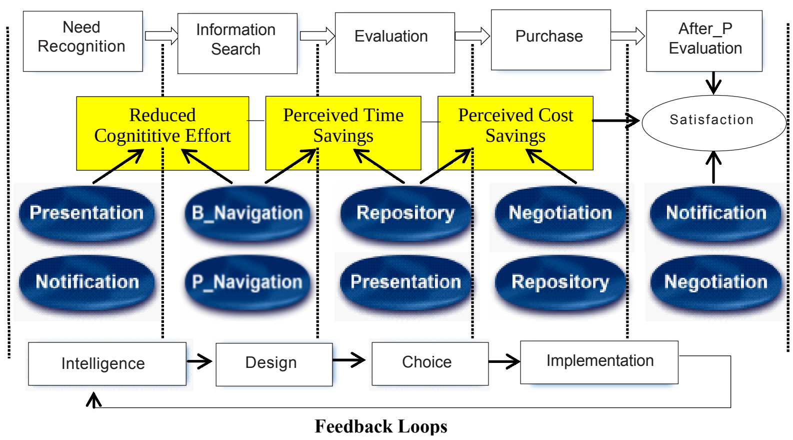
Table 1. Overview of e-shoppers' decision making stages

E-Commerce Shopping Stages	E-Shoppers' Decision-Making Steps (O'Keefe & McEachern, 1998)	General Decision-Making Steps (Forgionne, 2000)
Need recognition	E-shoppers must recognize they have a need that can be satisfied through a purchase online.	Intelligence—Observe reality and gain problem or opportunity understanding.
Information search	E-shoppers then search for a product or service that satisfies this need, along with outlets that can provide it.	Intelligence—acquire needed information; design—develop decision alternatives.
Evaluation	E-shoppers use decision heuristics to evaluate and compare goods, often using surrogate measures where limited information is available.	Choice—logically evaluate the decision alternatives and develop recommended actions that best meet the criteria.
Purchase	E-shoppers place an order, pay for it (or arrange payment), and possibly arrange for collection, delivery, or maybe installation.	Implementation—gain confidence in the decision, develop an implementation plan, and put into action.
After purchase evaluation	E-shoppers evaluate purchases with a view to future decision making.	Feedback loops—utilize the outputs to guide further decision-making process.

Table 2. WCDSS facilities in the context of e-commerce

EC-Dimensions	WCDSS Facilities
EC Site-Structure	Basic navigation support, Personalized navigation aids, Item presentation
EC Techno-Structure	Negotiation mechanism, Notification mechanism, Rules repository

Figure 2. Influence of WCDSS on e-shoppers' perceptions in e-commerce



to formalized institutional procedures that govern trade execution between market participants. Within each dimension, we identified a set of features to address the major WCDSS functions (see Table 2).

In the current context, our metrics for customer attitudes and perceptions concentrated heavily on satisfaction with the proposed WCDSS functions. Specifically, reduced cognitive decision effort and perceived time and cost savings have been identified to be associated with an e-shopper's satisfaction with the online purchase making process (Pereira, 1999; Todd & Benbasat, 1991). We then establish a comprehensive framework that facilitates a better understanding of e-shoppers' perceptions of specific WCDSS functions (see Figure 2).

- **Basic Navigation Support:** WCDSS offers basic navigation tools such as the internal search on the Web site and links to (and guidance on) external sources which provide browsing aids for searching (O'Keefe & McEachern, 1998). Such basic navigation support can facilitate the e-shoppers' Information Search phase and result in perceived time savings and reduced cognitive search effort. Reduced cognitive search effort refers to the expectation that the goal-directed search for specific information is expected to be much more effective if the e-shoppers have the navigation support delivered through a WCDSS.
- **Personalized Navigation Aids:** Assisted by IT-enabled technologies, WCDSS can effectively mass customize and market product information to meet individual customer needs (Grenci & Todd, 2002). Such facilities include but are not limited to structural interaction and question/answer sessions and customer profile where information will be captured and customized to the customer's personal tastes and needs automatically (Claypool, Le, Wased, & Brown, 2001). Similar to the basic navigation support, such personalized navigation aids also enables e-shoppers search for product related information more efficiently and effectively.
- **Item Presentation:** How items are presented is important in that this affects the buyers' information seeking and item comparison/evaluation behaviors (Hahn, 2001). WDMSS presents virtual catalogs, 3D picture display, and samples and trials (e.g., customized virtual model in Apparel e-commerce sites) that assist product presentation and promotion (Need Recognition phase) and help customers better evaluate and compare the products (Evaluation phase). Therefore, effective item presentation facilities will lead to reduced decision effort and perceived time and cost savings in online purchases.

- **Negotiation Mechanism:** WCDSS enables certain negotiation facilities such as pointers to (and information on) the product providers as well as other existing customers, structural interactions, and question/answer sessions (O'Keefe & McEachern, 1998). E-shoppers' sensitivity or preference data can be captured and stored at the same time. Accordingly, such negotiation capabilities will guide e-shoppers through the Purchase and After Purchase Evaluation phases and eventually enhance the e-shoppers' trust on the site and ensure their satisfaction with the purchase.
- **Notification Mechanism:** WCDSS can utilize unique Web features to allow customer information captured to change dynamically for flexible decision making aids. Interactive notification, such as customer support via e-mail and a newsgroup, may increase customer engagement and satisfaction and help them identify product/service that match their needs (Need Recognition) and evaluate the purchase afterwards (After Purchase Evaluation) more effectively.
- **Rules Repository:** FAQs and other summaries as well as evaluative models can be delivered through a WCDSS to help e-shoppers make informed decisions online. Specifically, when evaluating a candidate product, the e-shopper can interact with the WCDSS and experiment on different choices or matches by specifying his or her preferences and corresponding weights. When check out, the e-shopper can always refer to the WCDSS rules repository for needed information to accomplish tasks in an error-free manner.

In summary, as illustrated in Figure 2, the proposed WCDSS functions facilitate e-shoppers' purchase making process in an integrated and continuous way. E-shoppers who have access to the WCDSS are kept updated with new product information and sales or promotions that would stimulate their shopping needs and help them specify the requirements (Need Recognition). With WCDSS, e-shoppers would easily be able to locate product candidates, which closely match the preferences they specify in their initial searches (Information Search). The use of the WCDSS will then provide e-shoppers with the capability to screen information efficiently so that s/he can focus on alternatives that best match his or her preferences (Evaluation). The embedded rules repository supports the e-shoppers' order process, ranging from adding products to their shopping basket to entering the credit card information for completion (Purchase). Finally, the WCDSS presents a structural evaluation form that could help the e-shoppers review their purchase experience in a systematic way (After Purchase Evaluation). As a result, the use of WCDSS throughout the five online purchase stages will result in reduced cognitive decision effort, perceived time savings, and perceived cost savings that will eventually lead to the e-shoppers' satisfaction with the purchase.

Accordingly, such influences, either positive or negative, of the WCDSS on e-shoppers' perceptions need to be incorporated into future WCDSS design and development. Firstly, in order to reduce the e-shoppers' cognitive decision effort, the provision of models, including evaluation models in Evaluation phase and preference models in Information Search phase, in a WCDSS should be straightforward (O'Keefe & McEachern, 1998). Otherwise, data entry and the time to execute the model are both burdens to e-shoppers. Therefore, sufficient care should be taken to ensure that e-shoppers understand the assumptions and limits of any model in a WCDSS.

Secondly, the WDSS interface can be very problematic. As Grenci and Todd (2002) proffered, the degree of online support for a custom purchase is reflected in the interface design of a Web-based decision support. Effective WCDSS interface design, with respect to reduced cognitive decision effort and perceived time savings, should consider product complexity and the e-shoppers' expertise in question. For instance, a passive interface that offers minimal guidance or advice may be ineffective for a novice e-shopper, and an active interface that offers a lot of assistance may be annoying and inefficient for an expert e-shopper. Similarly, complex products with a large number of configurable components may require expert-driven decision support techniques that use e-shoppers' preferences to filter out irrelevant or undesirable choice options (Grenci & Todd, 2002).

Last but not the least, the WCDSS should be structured in a way that strengthens the bond of the e-shoppers' trust of the e-commerce site. Trust, especially in the depersonalized setting of the Internet, is very fragile. Trust builds with transactions and interactions, but a key element of trust relates to how the system uses customer information and knowledge (Rowley, 2002). Personalized decision support should not interfere with e-shoppers' security and privacy concerns. Irrelevant, inaccurate or inappropriate decision support customization may weaken e-shoppers' trust and eventually result in dissatisfaction with the purchase. Therefore, to deliver reliable and accurate support is more effective in building e-commerce trust than just present seemingly enticing advertisements.

FUTURE TRENDS AND DIRECTIONS

So far, we have established a conceptual framework to explore e-shoppers' perceptions of the WCDSS functions. This exploratory investigation offers opportunities

Table 3. An illustration of the theoretical framework operationalization

WCDSS Site-Structure Perception		
Variable	*Description*	Reference
Basic navigation support	I think the internal search saves me time finding useful product information.	*Chen (2000);*
	I desire the browsing capability that could help me identify product more effectively.	
Personalized navigation aids	I'd like to be identified and welcomed once I revisit the e-commerce site.	*Hahn (2001);*
	I'd like to make my own search criteria and get personalized navigation support.	*Kumar & Feldman (2000);*
Item Presentation	I'd like to see the 3D pictures before making final purchasing decisions.	
	I desire to get price and other feature comparison report of the items I feel interested.	
Notification mechanism	I want to be informed timely about the sale and promotion information.	*Reck (1997);*
	I'd like to get immediate responses to my questions when shopping online.	
Negotiation mechanism	I think real time guide would be useful while searching or buying products online.	*Hahn, (2001);*
	I desire to ask the seller questions interactively about the item of interest.	
Rules repository	I would trust the site more if it allows interactive evaluation of the items I feel interested.	*Rowley (2002)*
	Complete FAQs and other tips would make it easier for me to accomplish a purchase.	
WCDSS Techno-Structure Perception		

for future endeavor on this interesting topic. For instance, the "satisfaction with the proposed WCDSS functions" construct is based on validated theories from the literature. To further broaden the application base and offer specific empirical experience, the framework proposed in this study can be implemented and evaluated in a field setting. This effort could possibly involve an operationalization of the conceptual framework to construct perception and attitude scales for a survey study and a structured experimental study in which, ideally, potential e-shoppers are revealed to a specific type of WCDSS or prototype illustration. Such endeavor could possibly generate more empirical evidence on the topic and offer more concrete guidelines in WCDSS design and development.

As an illustration of the framework operationalization, we draw a list of 25 sample survey statements addressing e-shoppers' perceptions of the WCDSS. Table 3 shows a sample operationalization of each feature and the corresponding survey statements.

CONCLUSION

People who are affected by a decision should have an opportunity to influence it. Since WCDSS affects e-shoppers' purchasing activities, we believe they should have the right to speak out their opinions, and their feedbacks will enlighten the WCDSS interface and functionality design in turn. In this study, we identified five phases involved in e-shoppers' decision making process, including Need Recognition, Information Search, Evaluation, Purchase, and After Purchase Evaluation. We also specified Site-Structure features and Techno-Structure features of a WCDSS in e-commerce applications and examined their respective impact on e-shoppers' perceptions in each phase of the purchase decision making process. Then we elicited important WCDSS design implications with respect to enhancing e-shoppers' engagement and satisfaction with a purchase.

As an exploratory study on e-shoppers' perception of WCDSS functions, this study offers both theoretical contributions and practical implication. In theory, the framework helps in understanding WCDSS key features and their corresponding impact on e-shoppers' perceptions in each decision making stage. In practice, the findings assist WCDSS designers and developers in identifying the key factors that influence the adoption of WCDSS in e-commerce applications.

KEY TERMS

Basic Navigation Support: Basic WCDSS navigation structures such as the categories of offerings that provide browsing aids for searching.

Customer Shopping Process: The entire process that an e-shopper completes a purchase, which involves five stages: Need Recognition, Information Search, Evaluation, Purchase, and After Purchase Evaluation (O'Keefe & McEachern, 1998).

EC Site-Structure: An e-commerce system dimension that is related to the presentation and navigation of items or instructions (Hahn, 2001).

EC Techno-Structure: An e-commerce system dimension that is related to the formalized institutional procedures that govern online trade execution between e-market participants (Hahn, 2001).

Item Presentation: WCDSS product display and promotion formats such as virtual catalogs, 3D picture display, and samples and trials.

Negotiation Mechanism: The means of a WCDSS to enable e-shoppers to interact directly and interactively with representatives or other parties and adjust their shopping actions before they have committed to an erroneous result.

Notification Mechanism: The means of a WCDSS to provide e-shoppers immediate and continuous alerts to tailored merchandising information, sales promotions and advertising, and other purchase related information.

Personalized Navigation Aids: Customized WCDSS navigation structures such as the personal shopping gallery that meets individual customer needs or desires.

Rules Repository: WCDSS information and knowledge base that contains directions and instruction to help e-shoppers make informed decisions online.

WCDSS: Web-based customer decision support system that connects e-commerce companies to their existing or potential customers and provides online support for the customer decision-making process (O'Keefe & McEachern, 1998).

E-Supply Chain Orchestration

INTRODUCTION

The world today is witnessing a growing interest in conducting supply chain business processes electronically. Different supporting technologies are emerging, and many are already available on the market. The adoption of these technologies is hampered by the fact that organizations constantly face new requirements, constraints and demands. Recent research has shown that service-oriented architectures and its supporting technology, Web services, can address many major issues encountered in complex supply chains. However, one of the largely unsolved issues is the orchestration of the variety of Web services in the supply chain. This chapter presents an investigation on orchestration of supply chain business processes using portals and Web service technologies. The portal-based orchestration concepts were carried out in a project for supporting end-to-end supply chain logistics in the United States Department of Defense. A second supply chain study looked at the added value of Web service orchestration.

BACKGROUND

Cheap transportation options and advanced use of information and communication technologies enable organizations to source and to sell globally, and to host their supporting services in any place of the world. As a result, organizations in the current business era create alliances with partners so as to form business networks (Bradley, Hausman, & Nolan, 1993; Nohria & Eccles, 1992). As a result, operational business processes tend not to be self-contained within an organization. When products or services are followed through the network, the successive steps of value addition in the network are often described with the term "supply chain" (Simchi-Levi, Kaminsky, & Simchi-Levi, 2003). The choice for the term supply chain is unfortunately because it leads to confusion. "Chains" evoke linear, unchanging, and powerless images. "Supply" feels pushy and savors of mass production rather than mass customization. Better names like "demand network" or "customer driven Webs" have been proposed. Yet, the name "supply chain" seems to have stuck (Johnson & Pyke, 2000). Strictly speaking, the supply chain is a network of multiple businesses and relationships (Lambert, Cooper, & Pagh, 1998). Because of globalization and short-term contracts, modern supply chains include external partner processes that have a limited visibility. This increases the difficulty for decision makers to understand and redesign the process orchestration in the business network. In addition, the dynamic nature of the business network, for instance changing numbers and types of partners, and an involvement in several networks, increases the difficulty and complexity to manage supply chain processes. Information and communication technologies that can help organizations to design, manage, and maintain these complex inter-organizational processes are urgently required.

In a pilot project for the U.S. Department of Defense (DoD), the authors were part of a large, multidisciplinary team that designed and tested prototype solutions for supply chain integration. The project showed the feasibility of portaled solutions for real-time support for end-to-end supply chain management in a complex organization. The next section illustrates how portaling technologies can be seen as a first step towards solving the management problems of DoD's complex supply chains (Boyson, Corsi, & Verbraeck, 2003; Boyson, Harrington, & Corsi, 2004).

SOLUTIONS FOR E-SUPPLY CHAIN ORCHESTRATION

Portaling Technologies as the First Solution Step

In the project, a first version of a supply chain orchestration portal was built to provide Web-based business functionality, asset visibility, and total system intelligence to the supply chain managers of the U.S. Air Force (Boyson et al., 2003). A portal is an infrastructure providing secure, customizable, personalizable, integrated access to dynamic content from a variety of sources, in a variety of source formats, wherever it is needed (Smith, 2004). The study focused on providing timely information on spare parts for one of the engines used in the Air Force. Currently, mechanics who work on the engines use a paper-based system for requesting parts needed for maintenance. Once the mechanic has completed the assessment of the engine, he or she prepares a hard copy paper parts list of items needed to complete work on the engine. This article parts list is subsequently entered into a database, which is then processed by a parts manager, who searches existing inventory to determine availability. Based on the result of that search, a decision is made about how to transfer the part from one base to another or even from one location on a base to another location on that same base. If the part or parts are not available from existing bases, then a requisition process is initiated (Boyson et al., 2003).

As one can imagine, this sequential process is very inefficient. There are significant delays as one action must be completed before another one can be started. Furthermore, there is no central place for information about the mechanic's order once he or she completes the parts request list. Often, the mechanic has no further information about the order until the parts actually are delivered. There is no visibility to the mechanic about the status of the order as it moves from one step to another. Often, one organization is waiting for information from the other, and the phone is used often to clarify why delays occur. Consequently, planning and anticipation in both organizations is difficult, and most business process activities wait till a previous activity has been completed. When activities would have been carried out in parallel, and real-time information would have been used, much time and effort could have been saved. The main idea of the portal project for the U.S. Air Force supply chain has been to implement these ideas.

Using the U.S. Air Force spare parts supply chain as a reference model, a comprehensive electronic platform was built that combined real-time data from the field, ERP systems, advanced planning systems, and collaborative planning and forecasting systems in both organizations. A test portal was built for evaluation by participants in the supply chain in order to experiment with these kinds of online functionality.

The prototype showed how the current stovepiped decision-making and orchestration in the spare parts supply chain could be transformed into an integrated high-performance process (Boyson et al., 2004). Supporting benefits include improved financial performance, inventory availability and reduced life cycle costs by providing the right information to the right people to make the best decisions in near real time. The portal solution uses middleware to link systems and orchestrate processes, and to create a seamless supply chain for system users while hiding the transactional level processing complexity. The system integration relied on the Tibco message bus that made it possible for the diverse systems to talk to one another.

Linking the databases and information systems of the different organizations to the message bus took a lot of effort. Furthermore, the message bus in itself did not help much in streamlining the inter-organizational processes. The business processes of the participating organizations were analyzed by hand, and the Java-based software to link the different business processes was specifically written for this project. In order to carry out projects like this more effective and more efficient, the standardization of the middleware should take place on a higher level than the message bus. Ideally, the description of the business processes would take place on such a level that it could be used to automatically generate parts of the solution applications. The next three sections describe service-oriented architectures, and so-called orchestration standards that can help to overcome the labor-intensive activities to streamline inter-organizational business processes.

Service-Oriented Architectures and Web Services

Service-oriented architectures (SOA) based on Web services technology facilitates interactions and sharing of information in a heterogeneous environment, as it is based on the exchange of messages in XML. Supply chain process partners need to share and access information like stock levels and inventory. Web services can "glue together" applications running on two different platforms, enable database information to be accessible to others, and enable internal applications to be made available over the Internet (Kreger, 2003).

A Service-oriented architecture (SOA) is essentially an architecture that describes the communication pattern between services communicating with each other, functions and their operations (Papazoglou & Georgakopoulos, 2003). These architectures provide the ability to register, discover, and use services.

In the perspective of SOA a service is a function that is well defined, self-contained, and does not depend on the context or state of other services. An SOA defines how two computing entities interact in such a way that it enables one entity to perform a unit of work on behalf of another entity. The unit of work is referred to as a service, and the service interactions are defined using a description language. Each interaction is self-contained and loosely coupled, so that each interaction is independent of any other interaction.

Web services technology facilitates collaboration between services and their orchestration and in addition defines how to describe these services, the operations and their flows. It uses a loosely coupled integration model that allows flexible integration of heterogeneous systems in a variety of domains including business-to-business, business to customer and enterprise application integration (IBM, 2001). As an Internet-based technology, Web services technology includes all network layers, but on top of it, various authors have added specific layers that make uniquely suitable for facilitating business processes. These layers include for instance a process layer, a description layer, and a messages layer (Curbera, Khalaf, Mukhi, Tai, & Weerawarana, 2003). Martin (2003) describes additional layers relating to the technology components and functions, such as presentation, process flow, transaction, discovery, description, messaging and transport. Furthermore, Kreger (2003) adds business- and service-level agreements as technology components. When we are able to provide service levels for the interaction between different business processes, we can describe the actual and needed coordination or orchestration of the business processes.

Orchestration is especially interesting in a supply chain context, as was explained for the DoD case. The lack of services and tools for orchestration provided the biggest problem for the U.S. Air Force e-supply chain portal. Orchestration describes how Web services can interact with each other at the message level, including the business logic and execution order of the interactions (Peltz, 2003). These interactions may span both applications and organizations, and result in a long lived, transactional, multi-step process model. Another aspect is choreography which tracks the sequence of messages that may involve multiple parties and multiple sources, including customers, suppliers, and partners (Peltz, 2003). Choreography is typically associated with the public message exchanges that occur between multiple Web services. In this article orchestration refers to both aspects.

Web Service-Based E-Supply Chain Orchestration

In a modern supply chain, there are many interactions between the partners that might benefit from well-orchestrated Web services interactions. In order to access and use the Web services, the service description need to be formalized and clear, and process orchestration needs to be taken care of to be able to effectively use the service. In line with the DoD case, we carried out a case study, called the Faplin case, to assess the added value of Web Service orchestration. The Faplin case is based on the Web Services-Interoperability Organization's supply chain case from www.ws-i.org. In the case, we considered three main business processes that are also relevant for the DoD case, namely: "catalog access", "purchase goods" and "replenish stock". Figure 1 shows part of the interaction diagram for the "purchase goods" business process. To describe the interfaces of the services, we used the Web service description language (WSDL). For the whole supply chain, 19 services were defined using WSDL.

The business processes that make use of these Web services were described and implemented in business process execution language for Web services (BPEL4WS, or BPEL for short). Each business process flow was formally described using BPEL. BPEL was mainly selected because it is the de facto standard that is widely accepted by major software vendors and businesses. BPEL4WS addresses many current business process challenges such as coordinating asynchronous communication between services, correlating message exchanges between parties, implementing parallel processing of activities, manipulating data between partner interaction, supporting long running business transactions and activities, and providing consistent exception handling mechanisms. It also supports the modeling of numerous process patterns (van der Aalst, Hofstede, Kiepuszewski, & Barros, 2003).

The specific tool used was Collaxa orchestrator, now called Oracle Process Manager. Instead of centralized orchestration, as in the case of the DoD portaling project, here the orchestration is federated, which means that each partner designs its own orchestration using internal and external services. The architecture behind the implementation is shown in Figure 2. For example, the customer sending an order from the Faplin Web site, initiates the interaction of the "purchase good" process. The order is received at Faplin and the orchestration continues further to the warehouses, using the various Web services, until the order is fulfilled or a failure response is returned.

Figure 1. Interaction diagram for the "purchase goods" business process

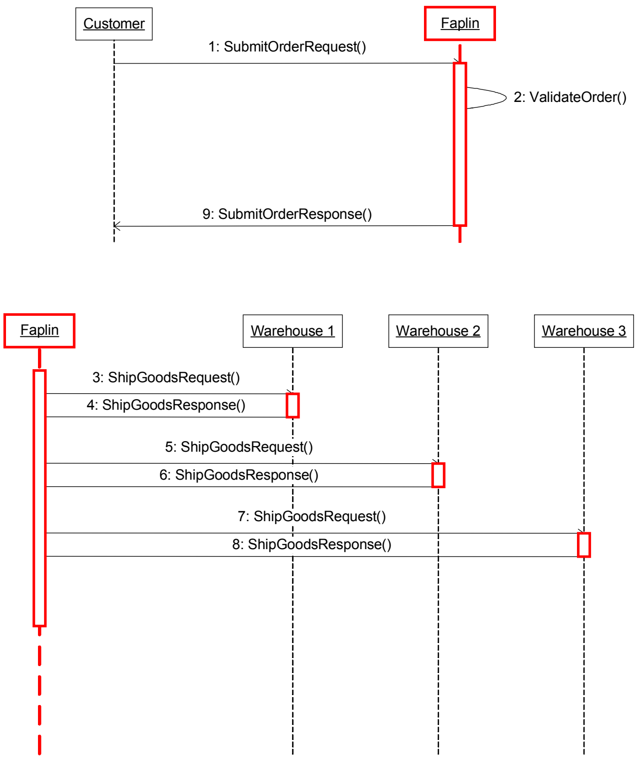

Figure 2. The architecture of the system

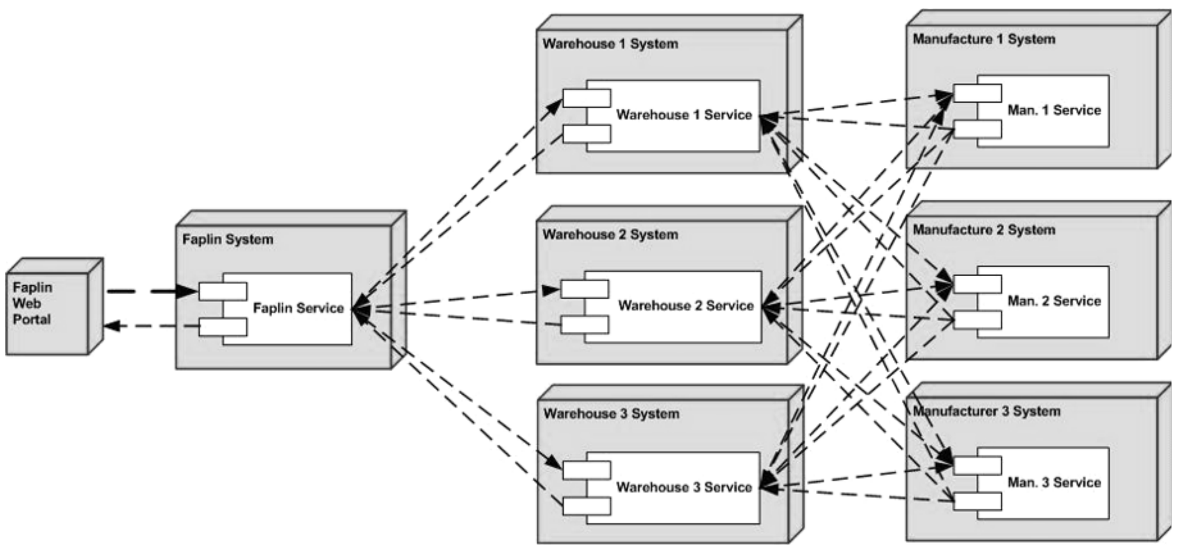

BPEL is an XML based language. XML can only support data transfer in the network environment but it cannot store data or handle variables. The facts that the business partners need to store data and even handle changing data such as stock levels and inventory levels were therefore handled by developing a database system. Web services technology provides an interface that can be used to access information from applications developed with different technologies and platforms. Therefore, we implemented a database using MySQL to enable handling such variables. Figure 3 shows as an example the implementation layout for the Replenish stock business

Figure 3. Replenish stock business process

process that involved access to various services from different partners, as well as databases.

Because BPEL4WS is built on top of the interoperable infrastructure of Web service, it uses XML to describe and specify processes. It depends on WSDL (Web service description language) and WSDL extensions. BPEL4WS can be seen as a layer on top of WSDL not only because the later is needed to invoke other Web services and to offer the process as a Web Service, but also because the data types in the WSDL documents are used to describe the exchanged information inside the process. A typical BPEL4WS scenario structure is shown in Figure 4.

The deployment of the services for accessing on the Web uses Collaxa BPEL server software. However, the user interface provided by this software gives right to any user to access all files. Enhancing system security, we developed separate user interfaces. The user interfaces were required to be dynamic so as to enable users to send information or data to the system or in real business to the dealer. Due to the dynamic nature of the Web pages, a programming language was required that allows part of the page contents to be dynamic, while the other part remains static. Also the platform independency was another criterion to choose the programming language. Servlets and Java server pages (JSP) were the options that could be used to develop such user interface. However, most of the contents of the Web site were static and very few were changing; only the data input fields. JSP is more suitable when most of the content on the page is static and few are dynamic, as opposite to the servlets. JSP was selected since the most of the content on the Web pages were required to be static. Several user interfaces were implemented in the portal to test the correct handling of a chain of business processes and exceptions. Several demonstrations to experts in the field have shown the practical applicability of the concepts.

FUTURE TRENDS

Service oriented architecture addresses important supply chain orchestration issues such as interoperability, flexibility and adaptability. It is expected that SOA to be used in standardizing process orchestration in supply chain, and BPEL as the de facto standard for implementing process orchestration. Papazoglou and Georgakopoulos (2003) stress the importance of SOA and Web services with regards to business processes in supply chains. They covered the issue of coordination, monitoring, conformance, and quality of service compositions. Meredith and Bjorg (2003) point out how contracts and trust can be reached between partners using Web services for their business processes.

The basic idea of SOA is to real-time create new business processes using readily available Web services. Management-oriented issues are not dealt with in the Web services protocol stack. It is expected that mechanisms ensuring the reliability, availability security, the automatic generation of service level agreements and payment mechanisms enabling payment per use will arise. This will make the vision of the real-time creation and management of business processes feasible.

CONCLUSION

In this article we presented two e-supply chain process orchestration cases using portaling technologies and the emerging Web services technologies. The DoD case showed that portal technology can support and simplify business process orchestration in a real-time setting. However, one of the important missing parts turned out to be the standardized orchestration of inter-organizational business processes. The second case study showed the potential benefits of using Web services and the BPEL standard for orchestration of processes in supply chains. The well-established XML, SOAP, WSDL and the de facto BPEL standards enable not only cross-platform information system integration but also the inclusion of supply chain business logic. We found the technology relatively easy-to-use and the models are human readable. A disadvantage is that theories and methods are still lacking for measuring or evaluating the performance of processes facilitated with Web services. Additionally, commercial cases and experiments that focus on real orchestration of processes are still lacking. Given the first successes, it is to be expected that industry implementations will be carried out, which will provide ample results to analyze further.

KEY TERMS

Middleware: Technology enabling the exchange of information between information systems and encapsulating implementation details.

Portals: An infrastructure providing secure, customizable, personalizable, integrated access to dynamic content from a variety of sources, in a variety of source formats, wherever it is needed.

Service-Oriented Architecture (SOA): A service-oriented architecture is an architectural style, according to which application functionality is not provided by one large monolithic application, but is provided by services that can be combined to get the required functionality.

Supply Chain: A distribution channel of a product, from its sourcing, to its delivery to the end consumer (also known as the value chain).

Web Service Choreography: Web service choreography defines the sequence and conditions of public message exchanges between multiple Web services (www.w3c.org).

Web Service Orchestration: Web service orchestration is the process of invoking internal and external Web services from a predefined process flow that is executed by an orchestration engine (www.w3c.org).

Web Services: Web services is a technology that enables the provisioning of functionality, on an application level or on a business level, by means of a standardized interface in a way that they are easily invoked via Internet-protocols.

EU SMEs and E-Business Innovation

Anne Wiggins
The London School of Economics and Political Science, UK

INTRODUCTION

Although motivating electronic business (e-business) adoption and implemention by small- and medium-sized enterprises (SMEs) is endorsed by policies and initiatives introduced by the European Union (EU), a number of challenges arise as the result of a limited conceptual understanding of the relationship between SMEs and information and communication technologies (ICTs). Relatively little is known about how SMEs respond to the opportunities provided by ICTs, and even less is known about why and how small businesses use ICTs (Dixon, Thompson, & McAllister, 2002).

In the first section of this critical review of the academic and government bodies of literature related to EU SMEs, e-business and policy initiatives and definitions of SMEs are explained, the unique characteristics of SMEs and entrepreneurial characteristics are outlined, and the case is made that there is a clear need for more comprehensive research on SMEs in the European Union.

The second section concentrates on e-business. Many of the factors that compel organisations to adopt and implement innovation are pertinent to the adoption and implementation of e-business. These have hitherto largely been treated as separate bodies of literature, however. In this section, the benefits of e-business are explored, the factors that motivate or act as barriers to e-business adoption and implemention are outlined, and the organisational and management attributes that would seem to ensure the success of the innovation of adopting and implementing e-business are discussed.

The third and penultimate section explores EU policy initiatives relevant to SMEs and to the promotion of e-business. The most wide-ranging and prominent initiatives directed at SMEs are examined here. The final section of the paper concludes with suggestions for further research.

BACKGROUND

There is no single definition of an SME, but schemes that are targeted at SMEs usually adopt a variety of working definitions depending on their particular objectives. The importance of the SME sector as the cornerstone of a country's economic prosperity is widely recognised: SMEs comprise approximately 95% of the enterprises in most nations, and are responsible for employing between 60-70% of a nation's workforce (OECD, 2002). Consequently, the SME sector is crucial to the EU's competitive development, collectively and for each individual member nation (Mulhern, 1995). SMEs contribute to local economic growth by providing local services, employment opportunities, and by enabling participation in the economic development of their own communities. They also play a vital role in innovation, as the intermediaries between the public research infrastructure and large organisations, as developers of new ideas, and as adopters of new technologies. SMEs have the potential to act as vehicles for the industrial and economic change of entire regions, as entrepreneurship attracts many who would otherwise withdraw from the labour market. Entrepreneurship can provide a positive way out of unemployment, particularly in disadvantaged communities, where the potential wider benefits of enterprise can be even more significant. Small businesses often stimulate productivity growth amongst rival businesses (BarNir & Smith, 2002; Jeffcoate, Chappell, & Feindt, 2002, 2004; Small Business Service, 2004), and their dynamism can stimulate competition and innovation throughout the economy as a whole.

The unique characteristics of SMEs that set them apart from larger organisations create particular issues, because in day-to-day business operations the organisational, entrepreneurial, familial, and social structures in SMEs differ from those of larger organisations. An understanding of the constitution and circumstances of SMEs is essential in order to be able to identify the fundamental differences between large and small organisations and the effects of these differences on innovation—especially e-business innovation—adoption and implementation (Cheney, Mann, & Amoroso, 1986). SMEs face both economic and organisational constraints, a lack of access to capital, cash-flow difficulties, limited ICT skills, a chaotic organisational structure, and heavy workloads—all factors that may impede innovation (Small Enterprise Telecommunications Centre, 2002). SMEs also have their own unique qualities in terms of their environment, structure, psycho-sociological climate, management, and technology usage and adoption (Castleman, Coulthard, & Hewett, 2000; Smallbone, North, Vickers, & McCarthy, 2000; Thong, 2001). SMEs tend not to have the resources available to large organisations, and this lack of resources creates time, financial and expertise constraints. Facing these constraints, SMEs are likely to be more cautious than large organisations to adopt new technologies (Huang, Hart, & Wiley, 2004).

Entrepreneurial attributes such as creativity, flexibility, and dynamism are associated with the SME sector. The importance of creating an environment rich with opportunities through the support of entrepreneurial characteristics cannot be overstressed. Entrepreneurship relies not only on individuals or groups possessing the skills to recognise and harness potential, but also on conditions that permit, encourage and sustain them in their endeavours. Governments can create the economic, fiscal and regulatory framework, infrastructure and environment in which entrepreneurs and the organisations they found and run are able to recognise, realise and maximise potential competitive advantage. Although few government policies are specifically directed at creating an entrepreneurial culture, cumulatively all government policies affect the long-term factors that create conditions that (can) foster entrepreneurs (HM Treasury, 2001). A stable and transparent economic and fiscal environment with steady economic growth can not only provide entrepreneurs with appropriate opportunities to foster entrepreneurial experiments, but also with a chance to convince the market of their potential contribution.

Entrepreneurship is closely liked to the psychological and behavioural aspects of individuals, and it would seem that an entrepreneur's personal initiative therefore dominates the potential for the success of many SMEs (Howarth, 2002; Kuemmerle, 2002; Quayle, 2002a, 2002b; Vrazalic, Bunker, MacGregor, Carlsson, & Magnusson, 2002). Entrepreneurs share a commitment to the consistent and methodological exploration of possibilities to improve a business's potential (Drucker, 1998). Entrepreneurs also share the distinctive characteristics of feeling comfortable skirting the boundaries of propriety, assuming enormous personal risk, being willing to shift strategies quickly, being profoundly opportunistic, and doing whatever it takes to close a deal (Kuemmerle, 2002).

Having examined not only a number of the characteristics of SMEs but also the issues pertaining to their operations, we turn now to examine e-business in more detail, as it is a form of technological innovation that can profoundly impact SMEs.

EU SMEs AND E-BUSINESS INNOVATION

E-business presents significant challenges to academic research. These challenges arise from its recent emergence, the rapid change that characterises the domain, the variation in behaviour in (apparently) similar contexts, the enormous media attention it has generated (with its resultant distortion of terminology and data), the lack of familiarity with e-business technologies by many management scholars, and the lack of established research approaches (Drew, 2002). It has been difficult for researchers to isolate trends in the separate innovation, ICT, and e-business canons from more general economic and organisational change drivers. Moreover, research has often failed to examine the roles of size, age, sector experience of ICTs and management support within single integrated studies, types of exporting activities, awareness of benefits, types of customer and imposition by larger trading partners. These factors have served to exacerbate the "patchy" nature of much research (Dixon et al., 2002).

Nonetheless, e-business has profound beneficial consequences for business practice and research. Technology-driven change is revolutionising business, requiring companies to redefine their strategies, products and processes in a business-operating climate that has become increasingly competitive, turbulent, and uncertain (Goldman, Nagel, & Preiss, 1995). Organisations that have adopted e-business believe that it contributes to improved performance in four main ways:

- The development of new products and services;
- The generation of new customers and business channels;
- A reduction in costs; and
- Improved productivity (HM Treasury, 2001).

E-business is a resource that is rapidly innovating not only traditional business processes but also the very nature of competition, as e-business enables market fragmentation, with its ability to treat mass clients as individuals, convergence between products and services, generation of global production networks, and simultaneous cooperation and competition between organisations. As e-business facilitates this radical transformation of both technical and business operations, it is truly innovative. Innovation is an important engine of long-term competitiveness, growth and employment. The OECD estimated that between 1970 and 1995, more than half of the total growth in output of the developed world resulted from innovation, and that this proportion is increasing as economies become more knowledge-intensive (Irwin, 2000). The cross-functional nature of innovation management requires strong leadership in managing through turbulence (Tushman, 2002).

The *Innovation Scoreboard* (which analyses statistical data in the areas of human resources, knowledge creation and the transmission and application of new knowledge, and innovation finance output and markets) found that sales of innovative products as a proportion of total turnover increases with organisation size: 15% for small, 21% for medium-sized, and 38% for large organisations. The *Innovation Scoreboard* (European Commission, 2000a) also found that large organisations spend nearly twice the proportion of their turnover (4.2%) on innovation activities as do SMEs. Similarly, the *Statistics on Innovation in Europe, 2000* (European Commission, 2000a) also found that the larger the organisation, the more likely it is to be an innovator (36% of small, 49% of medium and 71% of large firms are innovators) and that SMEs account for only 18% of Europe's innovation productions. *Building an Innovation Economy in Europe, 2001* (European Commission, 2000b) was the first in a series of Innovation Policy Studies undertaken for the European Commission's Enterprise Directorate-General to promote the message that not only is innovation important, as competitiveness increasingly depends on the ability of industry sectors to meet turbulent market needs quickly and efficiently, that innovation is pervasive and diverse, taking place in firms of all sizes, across all regions and all sectors, and that innovation is unevenly distributed, but also that innovation is systemic rather than linear, with multidimensional processes.

In order to develop these ideas, we must draw further upon the literature to explore and extend questions concerning the motivation(s) for, and genesis of, innovation. There is no single reason for an organisation to innovate: In some cases, innovation is triggered by new knowledge, in others by the opportunity to fulfil a market need (Mahdjoubi, 1997). Multiple forces inhibit change and maintain the status quo. Some of these forces are group performance norms, fear of change, member complacency, and a lack of skills (Bergquist, 1993). For lasting change to occur, new behaviours must be learned so that attitudes and routines can be replaced (Senge, 1990). Although the implementation of innovative ideas is an organisational change process (Hoffer, George, & Valacich, 1996), lasting competitive change takes application, time, and involves individual and organisational learning and adjustment. An organisation must possess (and be willing to commit) the resources needed to implement a new technology for innovation adoption and implementation to be successful (Amidon & Mahdjoubi, 1999). An organisation's size, financial resources and technical know-how all influence the adoption of technological innovation. Customer and competitive pressures, along with support from business partners, can also be strong influencing forces in the adoption decision (Iacovou, Benbasat, & Dexter, 1995; Premkumar & Roberts, 1997).

The 1999 KITE project's *Analysis of E-Business Practice in SMEs* reported that SMEs typically have more difficulty in achieving e-business success because of these characteristic SME attributes (Chappell & Feindt, 1999). The KITE project also found that SME e-business adoption and implementation success is dependent on the following factors:

- Having an original idea and/or targeting a unique market niche;
- Developing a business case for e-business;
- Finding sufficient funding to carry out e-business properly, without being dependent on third parties, or having to update sites out of hours, etc;
- Finding the right business, technology and promotional partners;
- Ensuring the right "fit" between the company's product or service and internet demographics;
- Being flexible enough to be able to respond to competition and changing technological conditions; and
- Being able to manage and scale the growth that may result (Chappell & Feindt, 1999).

Having examined the concepts of e-business and innovation, we turn now to examine EU policy initiatives directed at promoting e-business innovation amongst SMEs.

FUTURE TRENDS

A series of EU SME policies have been introduced to create a favourable competitive business environment in which SMEs can flourish. However, relevant technological innovation policy promoting e-business adoption and implementation depends on an understanding of what "really" drives adoption and implementation, of the external barriers that prevent or delay it, and of how it impacts on competitiveness and employment. Incentive schemes and policies intended to benefit the SME sector need, therefore, to take into account the culture, performance, and abilities of SMEs. Although an evolution towards more interactive support is visible, there is a high degree of heterogeneity in policy instruments aiming to foster innovation in SMEs throughout the European Union (HM Treasury, 2001). Current EU government-funded projects designed to assist SMEs to adopt e-business include the promotion of online trading and the creation of virtual business networks to promote technology diffusion (Papazafeiropoulou, Pouloudi, & Doukidis, 2002).

A number of EU policies have been formulated and introduced to facilitate the creation of a business environment in which SMEs can innovate and flourish. Most EU member state governments recognise that SMEs often have difficulty finding appropriate independent sources of business advice and information, and face skills shortages. Accordingly, they have launched national and regional initiatives to assist SMEs to acquire or adapt e-business skills (Mulhern, 1995). Many of these policies, schemes and programmes are interlinked. For example, the European Union's 1994 *Regional Technology Plan* (RTP), which was inspired by the 1993 *White Paper on Growth, Competitiveness and Employment*, was in turn instrumental to the development of the 1996 *Green Paper on Innovation*, which was created to develop an EU-wide strategy for the promotion of innovation. The 1996 *Action Plan for Innovation in Europe* paved the way for a common European analytical and political framework for innovation policy. Building on this framework, the *Trend Chart on Innovation in Europe* was introduced as a tool for policy makers. Formulated along the lines of the 2001 *Community Innovation Survey* (CIS), which is jointly implemented by Eurostat and DG Enterprise under the aegis of the European Innovation Monetory System (EIMS), *The Trend Chart* updates and analyses information on innovation policies EU-wide and at national level, and provides a forum for benchmarking and for the exchange of "good practices" in innovation and technological policy development.

The 2001 *Innovation and SME Programme* promotes innovation and supports SME participation in the *Fifth Framework Programme* (FP5) in order to optimise their potential advantages from such participation. FP5 aims to diffuse good practices and to encourage interregional cooperation in innovation by improving support infrastructures, in addition to introducing complementary policies for innovation and technology transfer through a set of interrelated projects: the *Regional Innovation Strategy* (RIS), the *Regional Innovation and Technology Transfer Infrastructures and Strategies* (RITTS) and the *Regional Technology Transfer Projects* (RTT). The RIS and RITTS projects share the same methodology and philosophy as well as many objectives in common. Both are based on building regional consensus and agreement, referenced to the same core specifications, and are able to give access to international experience. Twenty-eight European regions have been participating on RIS and RITTS projects since they were launched in 1994, and an additional forty regions have enlisted for similar initiatives. This calculates to approximately one region in four across the European Union participating in projects concentrating on enhancing local innovation capabilities, providing the most comprehensive structure for the development of regional systems of innovation in the world, by far (European Commission, 2000e).

The DEEDS Forum generated from the G7 Policy Group project *A Global Marketplace for SMEs* (1996-1999), and seeks to provide an open forum of EU policy makers to stimulate, discuss, exchange, and monitor national policies. The project has a particular focus on the uptake of e-business practices by SMEs, as did *The Bologna Charter on SME Policies*. Held in 2000, it was the first conference of EU ministers responsible specifically for SMEs. The subsequent European Council Summit in Lisbon, 2000, announced the EU's goal of becoming the "most competitive and dynamic knowledge-based economy in the world" by 2010. This objective necessitated the creation of innovation policy initiatives at EU national and regional levels (many of these initiatives were still being framed in mid-2005). The Summit called for a series of benchmarking exercises to monitor progress by member states towards the implementation of effective policies in support of innovation. The European Union responded in 2000 to this request with *The Integrated Programme for SMEs: A General Framework for all Community Actions in Favour of SMEs*, which, combined with *Innovation in a Knowledge-Driven Economy, 2001*, has contributed to an improved coherence in technological innovation policy in Europe, and also to the development of a framework for dialogue on innovation policy making and policy coordination. *eEurope 2005 - An information society for all: An Action Plan*, endorsed by the Feira European Council in June 2000, also forms part of the overriding Lisbon strategy. *Europe 2005* addresses issues relevant to internet and e-business adoption and use, consisting of national and multinational actions on e-government, e-health, e-learning, and e-business, generated with the aim to improve participation, to open up opportunities, and to enhance skills.

The European Union has devised a number of broad umbrella policies to promote the benefits of e-business and other technological innovations, not least for SMEs. Such framework policies often set clear and ambitious targets, and coordinate with other policies to ensure that the various components serve common goals. They cover a broad spectrum of initiatives, from awareness actions, to establishing SME support networks, to providing consultancy and customised services to SMEs. These initiatives aim to influence policy across the economies of countries or regions, and are often both horizontal and vertical in concept: horizontal in that they cover most business sectors and act as a bridge between education, business and the citizen; and vertical in that they can impact upon primary, secondary and higher education (in the form of training and up-skilling initiatives).

In 2002, the *Go Digital* (European Commission, 2002) initiative administered by the e-Business Policy Group (EBPG), was launched as a collaboration of representatives of the EU member states and the European Commission services. *The Third Multiannual Programme for SMEs in the European Union* (European Commission, 1996) was also adopted as the cornerstone of the European Union's actions aimed at improving the conditions in which SMEs operate. Under the *Fifth Framework*

Programme (FP5) (European Commission, 1998), it supported European SMEs to participate in FP5 actions and to optimise their advantages—especially in relation to technology—from such participation. The outcomes are still being formulated. FP5's successor, the *Sixth Framework Programme* (FP6) (European Commission, 2003), was formally launched in November 2003 (Keown, 2002).

The SMESPRIT project aims to develop a knowledge-based system that will provide support to SMEs introducing and managing e-business adoption and implementation. This is interlinked with the *COMPETE* and Brite-Euram programmes, both of which fall under the umbrella of the *Esprit* research programme (Chappell & Feindt, 1999). *COMPETE* aimed to strengthen European SME competitiveness through technology. Running from 1997 to 2002, *COMPETE* brought together more than 45 companies delegating 70 specialists and representing more than 50 EU-funded projects. Encouraging and facilitating collaboration and joint ventures for SMEs were also key aims of Brite-Euram, which enabled groups of SMEs with insufficient resources to commission university laboratories and research centres to carry out research and development (R&D) activities for them, and encourage them to pool resources with other SMEs. Thematic networks brought together various individually run projects that shared similar technological or industrial objectives, with the intention of bringing greater coherence to research activities and encouraging the exchange of knowledge and technologies. The outcome of the projects has been shared by all participants, and has also served to inform the decision-making process on future EU-funded R&D (Chappell & Feindt, 1999).

CONCLUSION

Many organisations recognize the potential strategic opportunities offered by e-business, and seek to realize them. However, other than the need to adhere to legalities (such as tax and VAT requirements) most SMEs seem to be unaware of projects, policies or initiatives intended specifically to benefit them. This strongly indicates that such projects, policies and initiatives could be better targeted to their intended audience. The overall take-up rate of e-business amongst SMEs also indicates a lack of success for these initiatives. It would seem that crucial changes could be made to policy formulation, in order to render the outcome more relevant, coherent and accessible to SMEs.

Through presenting an outline of the various domains and approaches that are present within the literature relating to SMEs, e-business and policy initiatives, the implicit aim of this article is to indicate gaps in the literature. A transdisciplinary approach such as information systems (IS) offers considerable scope for moving between these theoretical and empirical parameters. The IS perspective also creates an opportunity to study relationships that have not as yet received adequate attention between SMEs, e-business, and policy initiatives. These include the relationship between SMEs and their government(s), the organisational implications of integrating e-business into a small organisation's business, and the implications of governments adopting a more inclusive approach to creating a dialogue with SMEs. By adding texture to the study of these subjects, the opportunities that e-business affords SMEs can be opened up to scrutiny, with the potential to gain a more nuanced understanding of how governments can contribute to SMEs successfully adopting and implementing e-business.

KEY TERMS

EBPG (E-Business Policy Group): A collaboration of representatives of the EU member states and the European Commission services.

E-Business (Electronic Business): Those business activities related to the business operations of an organisation online. E-business encompasses all commercial activities. The definition of e-business that was agreed by the Organisation for Economic Co-operation and Development (OECD) and the European Union is the method by which the order is placed, which determines whether a transaction is e-business, not the payment or delivery channels. Shifting business activities from paper-based, local, face-to-face and manual processes to electronic, dispersed, mediated, and automatic processes is the essence of e-business, whether in dealing with customers or suppliers (Wilkins et al., 1999). E-business activities include, but are not limited to:

- Web sites;
- E-mail order confirmation;
- Intranet;
- E-mail;
- E-procurement;
- Web catalogues;
- Staff remote online ERP via Web;
- Trading exchanges;
- Internet auctions;
- B2C;
- Online ordering on our ERP; and
- View orders on ERP online.

E-Government: The use by government agencies of ICTs that have the ability to transform relations with citizens, businesses and other arms of government. These technologies can serve a variety of different ends: better delivery of government services to citizens, improved interactions with business and industry, citizen empowerment through access to information, or more efficient government management. The resulting benefits can be less corruption, increased transparency, greater convenience, revenue growth, and/or cost reductions (World Bank, 2002).

Innovation: The process of innovation is divided into the following broad activities:

- **Agenda setting:** general organisational problems create a perceived need for change;
- **Matching:** an organisational problem is fitted with an innovation;
- **Redefining/Restructuring:** the innovation is modified to fit the organisation, and it alters the organisational structure(s);
- **Clarifying:** the relationship between the organisation and the innovation is clearly defined; and
- **Routinising:** the innovation loses its identity as it becomes an ongoing element in the organisation's activities (Rogers, 1995).

EU: European Union.

ICT: Information and Communication Technologies.

IS (Information Systems): An information system has been described as "a system to collect, process, store, transmit, and display information" (Avison & Wood-Harper, 1990, p. 3).

SMEs (Small- and Medium-Sized Enterprises): In February 1996, the European Union adopted a single definition of SMEs to be applied across all EU programmes and proposals dating from December 31, 1997. The communication recommended that member states, the European Investment Bank and the European Investment Fund adopt the definitions. However, the communication permits the use of lower threshold figures, if desired. The European Union recommended definition for a "micro" business is that it must have a maximum of nine employees. A "small" business must satisfy the following criteria:

- A maximum number of 49 employees;
- A maximum annual turnover of 7 million euros;
- A maximum annual balance sheet total of 5 million euros; and
- The maximum of 25% owned by one, or jointly by several, enterprise(s) not satisfying the same criteria.

The EU recommendation states that a "medium-sized" business must satisfy the following criteria:

- A maximum number of 249 employees;
- A maximum annual turnover of 40 million euros;
- A maximum annual balance sheet total of 27 million euros; and
- The maximum of 25% owned by one, or jointly by several, enterprise(s) not satisfying the same criteria.

Evolution of Computer-Based Distance Learning

Sorel Reisman
MERLOT.ORG, USA & California State University, Fullteron, USA

INTRODUCTION

Distance learning (DL), distance education, remote education, online learning, e-learning, learning at a distance, and distributed learning are all synonyms for *electronic learning*, a phenomenon that over 80 years has evolved into the delivery of instruction via the Internet. The legacy of those years has provided a theoretical foundation and a history of best practices that can offer today's distance learning practitioners a sound basis for exploring new instructional models utilizing technologies of the 21st century. This article describes some of the major milestones and accomplishments upon which today's computer-based distance learning tools and practices are based.

BACKGROUND

The First Half of the 20th Century

The theoretical foundations of electronic learning are rooted in seminal works on self-instruction pioneered in the 1920s by Edward Lee Thorndike and later by Frederic Burk and Mary Ward (Foreman & Turner, 2000). The first manifestation of technology in instruction was the teaching machine invented in 1924 by Sydney L. Pressey used for rudimentary drill and practice (Pressey, 1926). In the 1950s, the behaviorist B. F. Skinner invented the *Skinner box*, a small chamber used to conduct research on operant conditioning with animals. With the introduction of programmed instruction (PI), Skinner extended his theories of operant conditioning to teaching and learning. Skinner's methodology was the basis for *linear PI*, first demonstrated in the format of paper-and-pencil self-instructional manuals. Skinnerian PI was characterized by clearly stated behavioral objectives, small frames of instruction, self-pacing, active learner responses to inserted questions, and immediate feedback regarding the correctness of a response (Clark, 2000).

The Turning Point

Despite Pressey's 1924 invention of the teaching machine and the 700 related patents taken out in the 1930s, Skinner, in the 1950s, introduced a "new" technology that he too called teaching machines; these were based on linear PI (Benjamin, 1988). Norman Crowder in 1958 extended Skinner's work and developed *branching PI*, which was characterized by, among other things, multiple-choice, response-directed instructional branches in PI manuals (Crowder, 1960), a technology that would later evolve into computer-assisted instruction (CAI). For more than 10 years, teaching-machine technologies and methodologies were prominent and controversial topics in both the academic and popular press.

Lumsdaine (1959) noted three distinguishing characteristics of the Skinner and Crowder teaching machines that were being marketed at that time. These were the following.

1. Continuous active student response was required, providing explicit practice and testing of each step of what was to be learned.
2. A basis was provided to inform the learner, with minimal delay, whether each response was correct, leading directly or indirectly to the correction of the learner's errors.
3. Learners proceeded on an individual basis at their own rates—faster ones completing an instructional sequence before slower ones—all machine tutored with patience customized to the learner's needs.

In 1962, at the height of the teaching-machine movement, Crowder, who like Skinner pursued entrepreneurial ventures related to teaching machines, predicted that by 1965 half of all American students would be using teaching machines for one or more courses (Gilmore, 1962). And while his time frame and technology forecast were wildly wrong, due mainly to IBM's introduction of the revolutionary IBM System 360, the "third generation" of digital computers in the 1960s (Campbell-Kelly & Aspray, 1996), Crowder's forecast would prove to be more or less accurate—but almost 40 years later!

Rooted in Instructional Theory

With teaching machines as a basis, in the 1950s through the 1960s the development of instructional theories and methodologies provided a foundation for future educational technology-based instructional and learning practices. Four of these are behaviorism, constructivism, cooperative learning, and individual learning. These can be described in terms of the theoreticians that have contributed to them, and the contribution of each to the technology that succeeded teaching machines: computer-assisted instruction. Appendix A provides a summary of these four theories and key theoreticians that have contributed to them. Appendix B provides a summary of contributions that each of the theories has made to the development of computer-assisted instruction (Scheepers, 2001).

These appendices clearly reflect a decades-long development of instructional theory based on technologies that are more than 50 years old, and a body of knowledge that provides a solid foundation of theory, research, and practice, one that remains valid even today.

Computer-Assisted Instruction

Beginning in the late 1950s, CAI was introduced as a mode of instructional delivery in which a learner accessed mainframe-computer-based lesson material (courseware) developed and programmed by teams of instructional designers and computer programmers. It is worth noting that over the years, there has been much debate concerning the appropriate label to assign to activities related to the delivery of instruction via the computer. Terms such as CBE (computer-based education), CBT (computer-based training), and CBI (computer-based instruction) are only a few that may be found in the literature, each focusing on different and sometimes only nuanced aspects of the technology. This article uses the term CAI to encompass all of these.

The first CAI system was the IBM 650 Inquiry Station interfaced to a text-based typewriter used to teach binary arithmetic. The IBM 650 was the first mass-produced digital computer and the very first computer acquired by many universities. Tannenbaum (1999) describes the next major instructional technology initiative and the context in which it was introduced:

During the early 1960s, IBM researchers had experimented with computer-based instruction, using earlier computers and an assembler-level language they called Coursewriter. The success of these experiments, together with the demand for better education fueled by the Russian Sputnik successes and the programmed learning research of such psychologists as B. F. Skinner, led IBM to develop the IBM 1500 system. The system was purchased by about a dozen other educational institutions (including school districts in Montgomery County, Maryland, and Kansas City, the Ohio State University and the University of Alberta in Canada).

The hardware cost more than $250,000 (the equivalent of more than $1.25 million today) for a system that could accommodate a maximum of 16…simultaneous users, about $16,000 ($80,000 today) per user. ... In the early days of developing routine courseware for the 1500 system, we estimated 100 to 300 hours of development time for each hour of learner time.

The IBM 1500 was unique. It delivered online, individualized instruction in a (proprietary local-area) networked environment, driven by a multiuser operating system. It allowed course authors to integrate (character) graphics, audio, and still images into their courseware (Buck & Hunka, 1995); it was the first computer-based, multimedia, distance learning platform.

Multimedia

The mid-1960s through late 1980s was characterized by the improvement of CAI and CBT with enhanced multimedia. During that time, debates raged regarding the definition of multimedia. A somewhat later publication offered a definition that reflected the eventual resolution of some of those debates:

The term multi-media [sic] originated with the audio-visual industry, to describe a computer-controlled, multiple-projector slide show with a sound track. In computer terms, multi-media [sic] is viewed as a blending of media types: text, audio, visual, and computer data in one convenient delivery system. (Philips International, Inc., 1988, p. 3)

Two of the dominant multimedia CAI systems of the 1960s were PLATO (Programmed Logic for Automatic Teaching Operations) and TICCIT (Time-Shared Interactive Computer Controlled Information Television).

PLATO was produced under a partnership of the University of Illinois' Computer Education Research Laboratory (CERL), the Control Data Corporation, and the National Science Foundation (NSF). PLATO courses were developed with the course-authoring (scripting) language TUTOR (later to evolve into Macromedia Authorware). Courses were run on a time-shared mainframe computer that serviced hundreds of concurrent users. In addition to the pioneering hardware development of the plasma display integrating graphical images into the courseware, PLATO system developers created user-to-user communications tools that were the predecessors to the synchronous communications tools prevalent in today's learning management systems (LMSs; Woolley, 1994).

MITRE's TICCIT, funded by the NSF in 1968, was based on television technology products controlled by a time-shared computer system, and was designed to provide individualized instruction to large numbers of students. TICCIT's TV-based audio and color video delivered a full multimedia learning experience based on the concepts of learner control (a concept underlying today's learning management system usage) and component design theory (Allessi & Trollip, 1991). For a number of reasons, however, the system, which was eventually turned over to Hazeltine Corporation for commercialization in the mid-1970s, failed to deliver on its promise.

It is interesting to note that PLATO still exists today, but as a commercial venture. While the company's pioneering multimedia and communications systems have long been made obsolete by newer technologies, PLATO Learning, Inc. markets assessment and courseware, and states that it is "the original education software company, with a history of successful student outcomes" (http://www.plato.com/aboutus/index.asp).

Personal Computers

Few would argue that the 1981 announcement of the IBM PC (personal computer) was the impetus for the computerized society in which we live today, but the real revolution began in about 1974 when Intel introduced the i8080, the first true general-purpose microprocessor. During those 7 years, affordable microcomputers from Tandy, Commodore, Atari, and Apple enabled a new generation of hardware and software hobbyists to experiment with technologies that had previously been the purview only of corporate development groups. Easy-to-use programming tools (particularly the language BASIC, developed more than 10 years earlier at Dartmouth College) enabled novice programmers, unencumbered by corporate standards and practices, to experiment with color, graphics, and sound to produce a wide array of new and exciting multimedia computer applications.

In about 1980, as a result of 10 years of research, another technology, derived from what then had been the completely separate industry of consumer electronics, made its first appearance: the analog, laser, optical videodisc. In 1979 to 1980, IBM and MCA (the media and entertainment company) formed a joint venture, DiscoVision Associates (DVA), and together with the Japanese company Pioneer Electronics began manufacturing laser discs and players, primarily as a distribution medium for motion pictures. Within only a few months of the creation of the joint venture, personal-computer hobbyists had connected stand-alone DVA videodisc players to Apple II microcomputers to produce innovative dual-screen multimedia applications controlled by Apple II software.

By 1985, recognizing the potential of multimedia computer applications, IBM introduced the IBM InfoWindow System, a professional and expensive integrated videodisc and PC touch-screen-controlled system targeted primarily for education and training (Reisman & Carr, 1991). InfoWindow System applications, authored in a revised form of the 20-year-old CAI language Coursewriter, were difficult, time consuming, and expensive to create. To produce high-quality audio and video (A/V) content required expertise unique to the film industry. At the same time, to develop courseware required computer expertise with significant input from instructional designers. Although integrated multimedia courseware was exciting for learners, the cost of hybrid analog and digital products, and the complexity of course development made the applications inaccessible to most education institutions.

A cost-effective alternative to a totally integrated, computer-controlled multimedia experience emerged as early as the middle 1970s. Computer-managed instruction (CMI) systems used the computer as an instructional supervisor and media guide for learners. For example, a CMI system might direct students to read off-line text, view off-line movies, listen to off-line audio, and also deliver scripted CAI instruction. The system administered pre- and posttests, collected and analyzed performance data, and guided learners from instructional module to module. In many ways, CMI was a precursor to today's learning-management systems that present and display learning objects in supervised learning environments.

Digitizing Multimedia

Optical storage technology continued to evolve through the 1980s, not because of the high costs and complexity of the applications described above, but to develop inexpensive, high-volume digital data-storage products for the computer and entertainment industries. Through the 1980s, Philips and Sony standardized the compact disc (CD), resulting in a two-decade-long evolution of new optical storage devices, from CD read-only memory (CD-ROM), to CD-recordable (CD-R), and more recently to the CD-rewritable (CD-RW) format (Khurshudov, 2001).

As these technologies were being developed, new, affordable, and easy-to-use personal computer-based or -related A/V digital capture, edit, and production hardware and software products were being developed and acquired by a new generation of innovative personal computer users. By the middle of the 1990s, it was common for digitally produced A/V to be integrated into personal computer applications. While more instructional applications using CD technology controlled by PC-resident courseware could access and play digitized CD-ROM-based A/V segments, there were still significant deterrents to the extensive use of computer-based instruction.

CURRENT AND FUTURE TRENDS

The Internet and the World Wide Web

Until the mid-1990s, enterprises wishing to support networked learning stations had to be concerned about network configurations and support, server compatibility, network operating systems, and workstation compatibility. The Internet, for the first time in the almost half century of commercial computing, leveled the playing field for computers users. The nonproprietary Internet communications protocol TCP/IP (transmission-control protocol/Internet protocol) could be deployed on virtually any workstation using any operating system, facilitating cost-effective communication among all nodes on a network.

Prior to the Internet, distance learning was CAI. Learners worked independently at stand-alone workstations; the networking of workstations was typically not a part of the delivery of instruction, due mainly to the complexities and costs of network technologies. Learners had to be physically present where the hardware resided in order to access courseware. Even though local workstations had become sufficiently powerful to deliver multimedia CAI, learners were not able to effectively share learning materials or to communicate electronically with one another or with the instructor as an integral part of the learning experience.

Through Web browser software technologies, learners can now access courseware locally or remotely, execute multimedia vignettes that are either resident on their local workstations or accessible remotely, and communicate synchronously or asynchronously with instructors and other students on the Internet network, regardless of the kinds of workstations they use: PC, Mac, Sun, and so forth. The ubiquity and relatively low cost of all this technology for home use has generally raised the computer literacy level of virtually all students at all levels of education. Unlike in the past, when novice students had to overcome difficult technology barriers and learning curves to even begin to use CAI courseware, today, those barriers and that learning curve are practically nonexistent. And into this environment a new technology has appeared: learning-management systems.

Learning Management Systems

Today, the application of computers to technology to instruction focuses on Internet-enabled student access to learning objects (LOs) via LMSs. Today's model resembles CMI, but with a few minor exceptions. In CMI, scripting-language-based computer programs (a) directed learners mainly to off-line learning materials, (b) administered pre- and posttests, and (c) permitted or prevented learners from moving on to other sets of learning materials. LMSs are environments within which students, in a TICCIT-like learner-control fashion, access learning objects available within the LMS. LMSs do not use directed learning; hence, there is no need for scripting-like programming languages such as Coursewriter or TUTOR. An LMS-based course is a framework and structure that contains LOs and directions to students from the instructor regarding how and when they should be accessed. With LMSs, instructors can focus their energy and expertise on the creation or utilization of LOs and the day-to-day management of their courses.

Probably the most prevalent LMSs in use today in education are Blackboard and WebCT. Blackboard, which was developed at Cornell University, was founded in 1997; in 2004, more than 2,000 schools, of which more than half are U.S. colleges and universities, used Blackboard ("Big Program on Campus," 2004). WebCT, which originated in 1995 at the University of British Columbia, claims on its Web site (http://webct.com) to be installed in "thousands of colleges and universities in more than 70 countries."

Blackboard, WebCT, and a host of other LMSs have much in common; all offer instructors an LO presentation platform, communication tools for students and instructors (e-mail, videoconferencing, telephone-like voice over Internet protocol (VOIP), chat, instant messaging, bulletin boards, etc.), and a variety of course-management utilities. Currently, issues and debates about these systems center around such matters as (a) the relatively high cost to license them, (b) their complexity, from an IT standpoint, to maintain, (c) how best to integrate them with an institution's enterprise applications, (d) LO incompatibility, (e) the difficulty of importing LOs developed on one system into another, and (f) best practices regarding the design, implementation, and management of LMS instruction.

Some solutions to these issues include (a) cost sharing through system-wide or consortium licensing, and the creation of new open-source LMSs such as Sakai (see http://sakaiproject.org/press/sakai-rc1.html), (b) local vs. commercial application service provider (ASP) hosting, (c) application integration via enterprise portals, (d) the definition and deployment of LO standards (National Information Standards Organization [NISO], 2004), (e) the use of libraries of shareable and open-source digital LOs (see http://merlot.org) and courseware (see MIT's OpenCourseWare initiative at http://ocw.mit.edu/index.html), and (f) the design of innovative hybrid courses (Swenson & Evans, 2003) as well as the formation of professional societies with journals and meetings that encourage discussion and debate regarding these and other issues.

The steady growth of distance learning has been and continues to be remarkable. Reisman (2003) reported that the market for fully online degree programs is growing at an annual rate of 40%, and in 2001 and 2002, more than 350,000 students were enrolled in fully online degree-granting programs generating $1.75 billion in tuition. He goes on to state that U.S. spending on online training is expected to skyrocket during the next 8 years, from less than $10 billion in 2002 to projected spending of more than $210 billion in 2010. From a new business standpoint, these statistics are truly remarkable. But from an eight-decade-long educational-technology perspective, we can finally state, "It's about time!"

CONCLUSION

This article chronicles 80 years of technology milestones that have contributed toward the development of the methods and practices of distance learning. All these milestones have been building blocks for a new kind of learning environment different from any other that has ever existed. Learners can be physically remote from one another and from their instructor; learners can learn at their own pace; learners and instructors need rarely, if ever, to meet in person; learners and instructors can communicate on a very regular basis using a whole host of Internet-enabling technologies; through Internet search engines, learners have immediate access to a worldwide collection of online materials; and instructors have immediate availability to shareable learning objects that they can reuse to create new online curricula. If Socrates could see all this, he would be dumbfounded.

KEY TERMS

Computer-Assisted Instruction (CAI): An extension of the branching model of teaching machines in which a learner accesses computer-based lesson material (courseware) developed and programmed by teams of instructional designers and computer programmers.

Computer-Managed Instruction (CMI): A form of CAI in which a computer serves the role of an instructional supervisor and media guide for learners, directing them to different curricular materials and/or media based on their performance in computer-administered pre- and posttests.

Laser Discs (Videodiscs): Analog optical storage devices first commercialized as a distribution medium for motion pictures in a 1980 joint venture, DiscoVision Associates, between IBM and MCA. Laser discs provided the foundational technologies for Philips' and Sony's CD formats that have evolved into CD-ROMs, CD-Rs, CD-RWs, and DVDs (digital videodiscs).

Learning-Management Systems (LMS): Software environments within which students access learning objects provided by an instructor. An LMS-based course is a framework and structure that contains LOs and directions to students from the instructor regarding how and when they should be accessed. With LMSs, instructors focus their energy and expertise on the creation or utilization of LOs and the day-to-day management of their courses.

Learning Object (LO): Reusable digital learning material.

Multimedia: A term that originated in the audiovisual industry to describe a computer-controlled, multiple-projector slide show with a sound track. Multimedia is now viewed in computer terms as a blending of media types: text, audio, visual, and data in one convenient computer-based delivery system.

PLATO (Programmed Logic for Automatic Teaching Operations): A CAI system produced by the University of Illinois, the Control Data Corporation, and the National Science Foundation. Courses authored in the TUTOR scripting language ran on a time-shared mainframe servicing hundreds of concurrent plasma-display-based terminals. PLATO's user-to-user communications tools were predecessors to synchronous communications tools prevalent in today's LMSs.

Teaching Machines: Invented in 1924 by Sydney L. Pressey to administer rudimentary drill and practice. They were also manufactured in the 1950s as programmed instruction devices based on either B. F. Skinner's linear curriculum-delivery model or Norman Crowder's branching model.

TICCIT (Time-Shared Interactive Computer Controlled Information Television): A CAI system developed by the MITRE Corp. and funded by the NSF in 1968, based on television technology products controlled by a time-shared computer system, designed to provide TV-based individualized instruction.

APPENDIX A

Theoretical Foundations to Computer-Assisted Instruction

Behaviorism	Constructivism	Cooperative Learning	Individualization
John B. Watson - Founder of behaviorism, laws of frequency, recency	M. Wertheimer - Gestalt psychology, emphasis on insight, laws of proximity and closure	L. Vygotsky - Social development	H. Gardner - Multiple intelligences
Edwin R. Guthrie - Contiguity theory, maintaining stimuli	J. Piaget - Development of schemata, accommodation and assimilation, four stages of intellectual development, conservation	A. Bandura - Social learning theory, imitation, modeling, self-efficacy	J. Piaget - Genetic epistemology
Edward L. Thorndike - Law of effect, satisfiers and annoyers	L. Vygotsky - Social development	J. Lave - Situated learning	J. P. Guilford - Structure of intellect
Clark L. Hull - Postulates and theorems, oscillations	J. Bruner - Constructivist theory	J. Dewey - Learning a result of disequilibrium	D. Rumelhart & D. Norman - Modes of learning
Robert M. Gagne - Development of hierarchical organization	A. Bandura - Social learning theory, imitation, modeling, self-efficacy	G. Pask - Conversation theory	F. Marton & N. Entwistle - Phenomenonography
B. F. Skinner - Rejection of intervening variables, reinforcement, operant behavior, shaping, behavior modifications	E. Ernst Von Glaserfeld - Radical constructivism		G. Salomon - Symbol systems
G. Miller - Information processing theory	J. Lave - Situated learning		R. Sternberg - Triarchic theory
I. Maltzman - Originality	J. Bransford - Anchored instruction		L. Cronbach & R. Snow - Aptitude-treatment interaction
E. Tolman - Sign learning	C. Rogers - Experiential learning		P. Cross - Adult learning
	J. Dewey - Learning a result of disequilibrium		M. Knowles - Andragongy
	R. Spiro - Cognitive flexibility theory		J. Dewey - Learning a result of disequilibrium
	C. Reigeluth - Elaboration theory		L. Festinger - Cognitive dissonance
	T. Sticht - Functional context		

E

APPENDIX B

Positive Aspects of Theories of Instruction to Computer-Assisted Instruction

Behaviorism	Constructivism	Cooperative Learning	Individual Learning
Stating the objectives of the software	Learner uses active mental processes to develop meaning and knowledge	Develops interdependence	Good for introverts and shy learners
Applying appropriate reinforcers, be it text, visual, or audio	Cross-field/cross-curricular integration	Students develop prosocial behavior	Builds self-confidence
Provides repetition and immediate feedback to learner	Learning occurs in lifelike situations	Improved self-esteem and appreciation of school	Safe, free from peer pressure
Shaping, chaining, modeling, punishment, and award principles are used	Learner develops holistic problem-solving skills that can be transferred to other situations	Greater psychological health	Intrinsic motivation: Challenged by competing with oneself (doing better next time), curiosity (can explore new, interesting facts without justifying it to the group), control (use own time and sequence, do not need to report to others), and fantasy (allowing oneself to daydream on certain aspects of the work)
A scoring system is very often present	Reflective and metacognitive abilities of learner are developed	Students develop positive peer relationships	Develops self-discipline
The software provides the status of progress of the learner	Learner is internally motivated to solve problems through discovery and experience	Social and communication skills are developed	Can accommodate own learning style, cognitive style, and learning approach
By using these packages, individual learners can master the subject matter on their own time and at their own pace, which addresses Blooms mastery learning principle	Internal motivation leads to development of long-term memory	Improved intrinsic motivation	Can work on own time and at own pace
Motivation is also enhanced as the student continually is kept on track of his or her performance	Learner is in control of own learning; learns to organize and manage himself or herself	Groups provide an academic and personal support system	Repetition of work as many times as necessary to master it
In contrast to being a mere receiver of information, the learner now actively participates	Social and communication skills are developed	Reflective and metacognitive abilities of learner are developed as students seek to clarify, explain, and justify their stand	Develops personal gratification
The learner's concentration is improved by the use of these packages addressing the environmental factors that should induce learning	Requires teamwork/cooperation among learners and educator	Promotes greater competencies in critical thinking	
Presents user with multiple realities	Learner learns to accommodate various perspectives on an issue	Cognitive rehearsal results in enhanced short- and long-term memory	
Frees educator of rote work	Higher cognitive levels, like analysis, synthesis, and evaluation, are developed	Learner learns to accommodate various perspectives on an issue	
Has good record-keeping facilities of students' progress		Positive attitudes toward the subject areas studied	
These packages come in various forms: drill and practice, simulations, and tutorials		Higher achievement and greater productivity

Evolution of Information-Hiding Technology

Der-Chyuan Lou

National Defense University, Taiwan

INTRODUCTION

Information-hiding technology is an ancient art and has existed for several centuries. In the past, messages could easily be intercepted because there was no technology of secret communication. Hence, a third party was able to read the message easily. This was all changed during 440 B.C., that is, the Greek Herod's era. The Greek historian Herodotus in his writing of histories stated that Demaratus was the first person who used the technique of information hiding. Demaratus, a Greek who lived in Persia, smuggled a secret message to Sparta under the cover of wax. The main intent was to warn Sparta that Xerxes, king of Persia, was planning an invasion on Greece by using his great naval fleet. He knew it would be very difficult to send the message to Sparta without it being intercepted. Hence, he came up with the idea of using a wax tablet to hide the secret message. In order to hide the secret message, he removed all the wax from the tablet, leaving only the wood underneath. He then wrote the secret message into the wood and recovered the tablet with the wax. The wax covered his message to make the wax tablet look like a blank one. Demaratus' message was hidden and never discovered by the Persians. Hence, the secret message was sent to Sparta successfully. Greece was able to defeat the invading Persians by using the secret message.

Another example of information hiding was employed by another Greek named Histaiaeus. Histaiaeus wanted to instigate a revolt against the Persian king and had to deliver a secret message about the revolt to Persia. He came up with the shaved-head technique. Histaiaeus decided to shave the head of his most trusted slave and then tattooed the secret message on his bald scalp. When the hair grew back, the secret message was covered, and then Histaiaeus ordered the slave to leave for Persia. When the slave reached his destination, his head was shaved, showing the secret message to the intended recipient.

Around 100 A.D., transparent inks made it into the secret field of information hiding. Pliny discovered that the milk of the thithymallus plant could easily be used as transparent ink. If a message was written with the milk, it would soon evaporate and left no residue. It seemed that the message was completely erased. But once the completely dried milk was heated, it would begin to char and turned to a brown color. Hence, the secret message could be written on anything that was not too flammable. The reason it turned brown was because the milk was loaded with carbon, and when carbon was heated, it tended to char.

Information hiding became downfallen and won no respect until World Wars I and II. Invisible inks, such as milk, vinegar, fruit juices, and urine, were extensively used during the wars. All of them would darken when they were heated. The technology was quite simple and noticeable. Furthermore, World War II also brought about two inventions of new technologies. The first one was the invention of the microdot technology. The microdot technology was invented by the Germans to convey secret messages to their allies. The microdot was basically a highly detailed picture shrunk to about the size of a period or dot, which permitted hiding large amounts of data into the little microdot. By using a microscope, the hidden message would be revealed. The Germans would put their dots into their letters, and they were almost undetectable to the naked eye.

The other technology was the use of open-coded messages. For open-coded messages, certain letters of each word were used to spell out the secret message. Open-coded messages used normal words and messages to write the buffer text that hid the message. Because they seemed normal, they often passed the check of security. For example, the following message was a common example of open-coded messages and was actually sent by a German spy during World War II.

Apparently neutral's protest is thoroughly discounted and ignored. Isman hard hit. Blockade issue affects pretext for embargo on by-products, ejecting suets and vegetable oils.

By extracting the second letter in each word, the secret message was revealed:

Pershing sails from NY June 1.
This technique was effective because it could pass through the check of security and was easy for someone to decode (Johnson, Duric, & Jajodia, 2001; Katzenbeisser & Petitcolas, 2000; Schaefer, 2001).

The technologies mentioned here are different ways of information hiding in different eras. With the development of computer technology, it is becoming hard for the third party to discover the secret message.

BACKGROUND

In recent years, information-hiding technology has become the glittering palace in multidisciplinary fields, including image and signal processing, compression, cryptography, communication and coding theory, and so forth. The characteristics of information-hiding systems also have been widely discussed, including imperceptibility, robustness, tampering resistance, low computation cost, and false-positive rate (Cox, Miller, & Bloom, 2000; Lou, Liu, & Li, 2004; Lou & Sung, 2004). Table 1 summarizes some characteristics of information-hiding technology (Lee & Chen, 2002; Lou & Liu, 2000). However, a scheme that meets all these requirements is not an easy work. Take embedding messages as an example. Such a scheme may not cause noticeable artifacts, but may be too weak to stand the attacks of signal processing. Moreover, if we want to hide a massive message in an image, the problem of low robustness will appear. Hence, it is an important issue to develop a good scheme of information hiding with a better trade-off between these characteristics.

Information-hiding technology became a remarkable field after the 9/11 attack in the United States by terrorists. U.S. officials said that Osama Bin Laden's followers downloaded easy-to-use encryption programs from the Web, then Bin Laden posted instructions for terrorist activities in chat rooms, pornographic bulletin boards, and other Web sites. The Internet has proven to be a boon for terrorists.

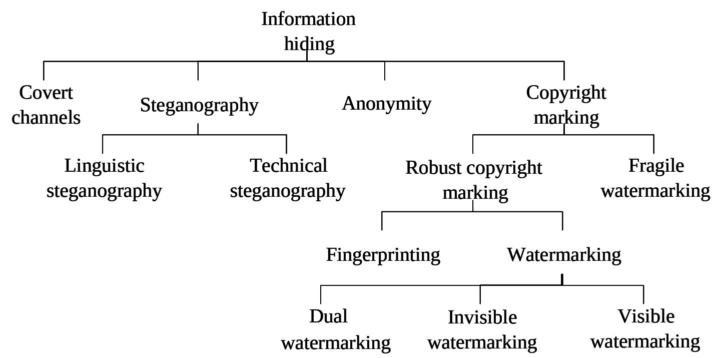
Table 1. A summary of characteristics of information-hiding technologies

- Imperceptibility
- Robustness
- Security
- Capacity
- Unambiguous
- Undetectable
- Blind detection
- Low computation cost
- False-positive rate
- Tamper resistance
- Multiple watermark

In general, information-hiding technology has several applications as given in Figure 1 (Petitcolas, Anderson, & Kuhn, 1999). Other applications (Anderson & Petitcolas, 1998; Cox & Miller, 2002; Katzenbeisser & Petitcolas, 2000; Maadonks, 2004) include the following.

1. **Automatic Monitoring of Copyrighted Material on the Web:** There are two technologies that can trace the use of copyrighted material. One is verifying the copyrighted material by comparing the digests of the images that are downloaded from the Internet with the ones that are registered in the database. The other is to identify illegal usage by using a robot to search the Web.
2. **Automatic Audit of Radio Transmission:** This involves using a computer to listen to a radio station and search for a special piece of advertisement or music that has been broadcast.
3. **Data Augmentation:** Information is added for the benefit of the public. This can be details about the work, annotation, other channels, or buying information so that someone listening to the radio in a car can simply press a button to order the goods that he or she wants. Moreover, in order to cause more retrieval from the database, the information can also be hidden to find pictures or music tracks.
4. **Authentication and Recovery:** A digest can be hidden into digital media to prevent or detect unauthorized tampering or destruction, and even to recover the media.
5. **Indexing for Archive:** Metadata (e.g., data about the owner, title, scene, director, cameraman, location, etc.) are added to the material for an indexing archive.
6. **Transaction Tracking:** This involves adding copyright notices, identifying recipients, and tracing the source of illegal copies.
7. **Proof of Ownership:** Copyright notices are added as proof of original ownership.
8. **Remote Control:** Information is added that will allow the triggering or control of devices in a broadcast chain.
9. **Copy Control:** Some message is added to prevent the copying of copyrighted material.
10. **Medical Safety:** The date and the patient's name are embedded in a medical image as a useful safety measure.

Figure 1. The classification of information-hiding technology



The applications mentioned above were discussed in various conferences. The first academic conference on information hiding was held in Cambridge, England, in 1996. Several following conferences also focused on the protection of intellectual property and some other applications. The sixth international conference on information hiding was held in Toronto, Canada, in 2004.

There are two popular researchable areas called steganography and digital watermarking, shown in Figure 1, that are generally referred to as information hiding. There are different applications for the two areas depending on the intent of use. Steganography comes from the Greek words steganos and graphein (steganos means covered, hidden, or secret; graphein means writing or drawing), and literally means "covered writing," which in turn means hiding messages in carriers such as image, audio, and video files. The main intent of steganography is to conceal a message and prevent the detection of it. The research of the subject in the scientific literature may be traced to the prisoners' problem (Simmons, 1984). There were two prisoners, Alice and Bob, who were arrested and shut in two separated cells. They wished to hatch an escape plan secretly, but all communication between each other is controlled by the warden named Wendy. If Wendy found any encrypted message, she would frustrate their plan and place them in solitary confinement. Hence, Alice hid a message in a cover-medium to produce the stego-medium, where the cover-medium could be an image, audio, or video.

Steganography and cryptography are cousins in the spy-craft family. However, steganography must not be confused with cryptography. Steganography is concealing the existence of a message so it cannot be seen. However, cryptography is concealing the content of a message by scrambling a message so it cannot be understood. The latter protection is often not enough. For example, an encrypted message delivered over the Internet may cause suspicion, while an invisible message will reduce the chance of it being suspected (Anderson & Pelitcolas, 1998).

On the other hand, digital watermarking can be thought of as commercial applications of steganography. The main intent of digital watermarking is establishing the identity of media to prevent unauthorized usage. A digital watermark is a message, such as a copyright logo or data about the authorship, that is secretly embedded into multimedia and still remains detectable or extractable after suffering from attacks. Hence, it can be used to identify the legal owner for the protection of intellectual property. Due to the distribution and duplication of digital multimedia, digital multimedia is easy to duplicated, but it is difficult to distinguish between the original and the duplicated one. Hence, the copyright protection of digital multimedia has become a severe problem. Digital watermarking may be an effective solution and may play an important role in copyright protection.

Steganalysis is another art of detecting, extracting, confusing, and disabling hidden information (Johnson & Jajodia, 1998). The major intent of steganalysis, just like cryptanalysis, is to discover hidden information and even to make the hidden information invalid. There are several types of attacks, described as follows.

1. **Stego-Only Attack:** Only a stego-object is available for analysis.
2. **Known-Cover Attack:** Both the cover and stego are known.
3. **Known-Message Attack:** In some cases, the message is known. Analyzing the stego-object pattern for this embedded message may help to attack similar systems.

4. **Chosen-Stego Attack:** The steganographic algorithm and stego-object are known.
5. **Chosen-Message Attack:** Here, the steg-analyst implements many steganographic tools for a chosen message and compares the stego-objects with the one to be analyzed, trying to find the algorithm used in the process.
6. **Known-Stego Attack:** The cover, object, and steganographic tool used are known.

Moreover, there are different existing methods for steganalysis, including the following.

1. **Statistical Steganalysis:** This involves comparing the original image to the tampered one for differences by mathematical computation.
2. **Visual Comparison:** The original image is compared to the tampered one by human eye. This method is quite simple but ineffective because it requires much time and cannot even enable one to find out where the picture has been tampered.
