We assume that providers in general have sufficient resources to generate their privacy policies. Certainly, the literature is full of works relating to enterprise privacy policies and models (e.g., Barth & Mitchell, 2005; Karjoth & Schunter 2002). Consumers, on the other hand, need help in formulating machine-processable privacy policies. In addition, the creation of such policies needs to be as easy as possible or consumers would simply avoid using them. Existing privacy specification languages such as P3P, APPEL (W3C; W3C, 2002), and EPAL (IBM) are far too complicated for the average internet user to understand. Understanding or changing a privacy policy expressed in these languages effectively requires knowing how to program. Moreover, most of these languages suffer from inadequate expressiveness (Stufflebeam, Anton, He, & Jain, 2004). What is needed is an easy, semi-automated way of seeding a personal privacy policy with a consumer's privacy preferences. In this work, we present two semi-automated approaches for obtaining consumer personal privacy policies for e-services through seeding. This article is based on our work in Yee and Korba (2004).

The section "Background" examines related work and the content of personal privacy policies. The section "Semi-Automated Seeding of Personal Privacy Policies" shows how personal privacy policies can be semi-automatically seeded or generated. The section "Future Trends" identifies some of the developments we see in this area over the next few years. We end with "Conclusion".

BACKGROUND

We have been able to find only two other authors who have written on the derivation of personal privacy policies. Dreyer and Olivier (1998) describe a tool called the "Privacy Workbench" for creating and analyzing privacy policies. However, it is not clear from their article how one comes up with the privacy policy in the first place, as it seems to just appear followed by a description of how the tool can perform conflict analysis. It is a model-based rules inference approach for validating an existing privacy policy. More importantly, Privacy Workbench is a tool for a programmer, as it is far too complex for the average consumer to understand and use. Snekkenes (Snekkenes, 2001) wrote about the derivation of personal location privacy policies for use with a location-based service, (e.g., E911 emergency location service in the United States). Snekkenes' view is that "individuals should be equipped with tools to become in the position to formulate their own personal location privacy policies". This author provided concepts as well as fragments of a language for formulating personal location privacy policies. Unfortunately, the language presented can only be understood by programmers and not the average consumer. Our approaches for generating personal privacy policies are not model-driven or service specific and have been designed for ease-of-use by the average consumer.

Privacy Legislation and Directives

Before we can consider how to seed a personal privacy policy, we need to know what such a policy should contain in terms of privacy provisions. We use privacy legislation to obtain what must be specified in a personal privacy policy. Therefore, this gives a minimum policy in the sense that all elements required by law have been specified, but additional provisions can be included at the discretion of the consumer.

In Canada, privacy legislation is enacted in the *Personal Information Protection and Electronic Documents Act* (Department of Justice, 2005; Government of Canada) and is based on the Canadian Standards Association's Model Code for the Protection of Personal Information *(Canadian Standards Association)* recognized as a national standard in 1996. This Code consists of ten Privacy Principles *(Canadian Standards Association)* that for convenience, we label as CSAPP. Data privacy in the European Union is governed by a comprehensive set of regulations called the Data Protection Directive (Euro-

pean Union). In the United States, privacy protection is achieved through a patchwork of legislation at the federal and state levels. However, privacy has been recognized as a constitutional right and there exists a highly developed system of privacy protection under tort law for the past century (Industry Canada).

We seek attributes of private information collection using CSAPP as a guide. We use CSAPP because it is representative of privacy legislation in other countries and has withstood the test of time, originating from 1996. We will then apply these attributes to the specification of privacy policy contents.

Personal Privacy Policy Content Based on Legislation

Based on an exploration of CSAPP (Yee & Korba, 2004, 2005), the contents of a privacy policy should, for each item of PII, identify (a) collector—who wishes to collect the information (for consumer policies only), (b) what—the nature of the information, (c) purposes—the purposes for which the information is being collected, (d) retention time—the amount of time for the provider to keep the information, and (e) disclose-to—the parties to whom the information will be disclosed. Figure 1 gives 3 examples of consumer personal privacy policies for use with an e-learning provider, an online bookseller, and an online medical help clinic. The first item in a policy indicates the type of online service for which the policy will be used. Since a privacy policy may change over time, we have a *valid* field to hold the time period during which the policy is valid. For a consumer policy, the proxy field holds the name of the proxy if a proxy is employed to provide the information. Otherwise, this field has the default value of "no". For a provider policy, the proxy field has a default value of "yes" indicating that the consumer can use a proxy to provide the information. Otherwise, this field has the value "no".

A personal privacy policy thus consists of "header" information (policy use, owner, proxy, valid) together with 5-tuples or privacy rules

<collector, what, purposes, retention time, disclose-to>

where each 5-tuple or rule represents an item of private information and the conditions under which the information may be shared. A personal privacy policy therefore consists of a header plus one or more privacy rules.

SEMI-AUTOMATED SEEDING OF PERSONAL PRIVACY POLICIES

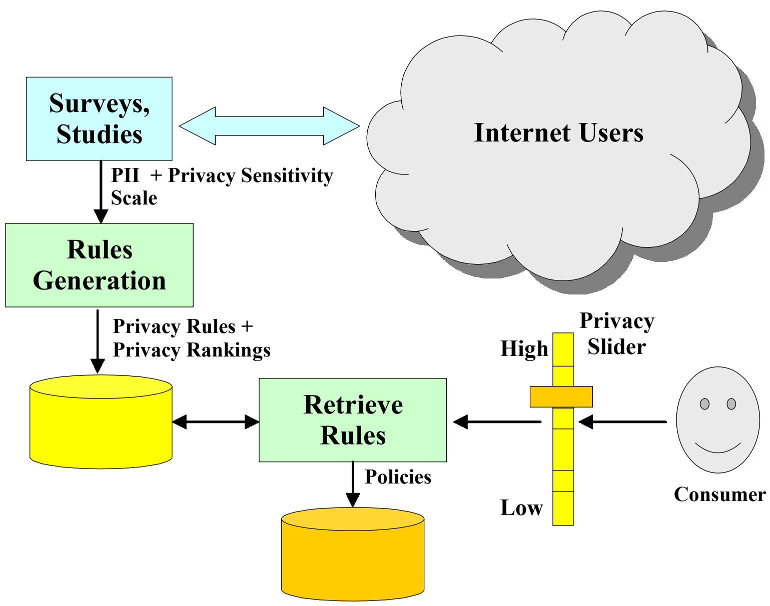
A semi-automated seeding (or derivation) of a personal privacy policy is the use of mechanisms (described in the following paragraph) that may be semi-automated to obtain a set of privacy rules for a particular use (see previous paragraph). We present two approaches for such derivations. The first approach relies on third party surveys of user perceptions of data privacy. The second approach is based on retrieval from a community of peers.

Seeding through Third Party Surveys

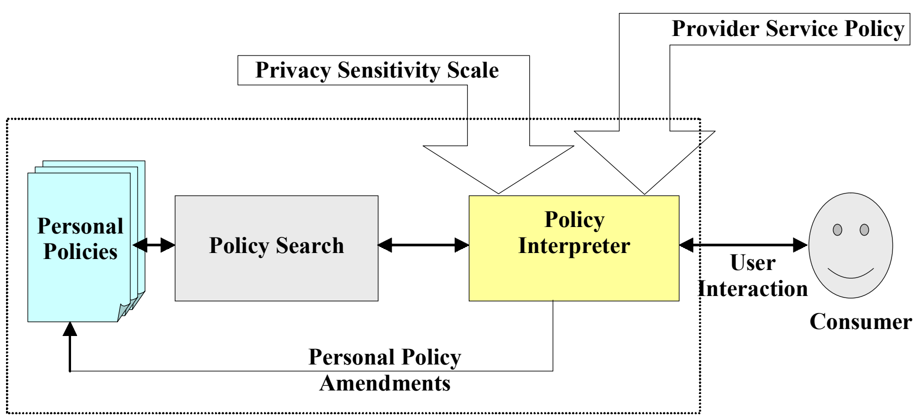
1. A policy provider makes use of third party surveys performed on a regular basis as well as those published in research literature to obtain user perceptions of the level of privacy for various sets of PII separated according to their uses. This gives a sensitivity or range of privacy levels for different PII in different situations.
2. Corresponding to a provider's privacy policy (which specifies what PII is required), the policy provider or a software application constructs and ranks the privacy rules for each use using the PII in number 1 above, according to their sensitivity levels, such that the rules are selectable by a single value privacy level from a "privacy slider". The outcome of this process is a set of consumer privacy rules, ranked by PII sensitivity, for different providers. The policy provider would express the resulting privacy rules in a policy language such as APPEL. There are different ways to do this ranking. One way is to assign a privacy rule the median of its sensitivity range as its privacy level (illustrated below).
3. Consumers obtain online from the policy provider the privacy rules that make up whole policies. They do this by specifying the use for the rules, the provider for which a consumer privacy policy is required, and the level of privacy required using the privacy slider. The consumer then completes each privacy policy by adding the rest of the header information. This can be done through a human computer interface that shelters the user from the complexity of the policy language. In this way, large populations of consumers may quickly obtain privacy policies for many service providers

Figure 2. Derivation of personal privacy policies through surveys

(a) Derivation of personal privacy policies from surveys



(b) Adapting personal privacy policies to the service provider



that reflect the privacy sensitivities of the communities surveyed.

4. Consumers may interactively adapt their privacy policies for different service providers based on their current policies, the sensitivities of the privacy rules, and the policy of the service provider. This assumes the availability of an easy to understand interface for the interaction as well as software to reflect the changes back into the policy language.

This approach requires trust in the policy provider. Effectively the policy provider becomes a trusted third party. A certification process for the policy provider is probably required. For instance, in Canada, the offices for the provincial and federal privacy commissioners could be this certification body. They could also provide this policy creation service.

A notification process should be used during the policy exchange phase between a consumer and a service provider to let the consumer know when "sensitive data" is exchanged. The degree of consumer sensitivity to different PII for different situations would also be available from the policy provider. This information could be updated regularly by the policy provider, or updated through a short online survey. The sensitivities would either modulate the base policy or set a trigger level for user warnings during policy exchange. During the warning, the user is presented with options that may allow the "degradation" or shoring up of the privacy policy. Figure 2 illustrates this approach.

Example

Suppose the item of PII for which we wish to derive a privacy rule is "course marks retention time" from the e-learning privacy policy in Figure 1.

Then the previous steps are implemented as follows:

1. The third party survey generates the following results for course marks retention time (the higher the privacy level, the higher the privacy; the highest level is 5, the lowest level is 1). Note that CMRT stands for "Course Marks Retention Time".

PII	Privacy Level
CMRT: 6 months	3
CMRT: 6 months	4
CMRT: 6 months	4
CMRT: 6 months	5
CMRT: 12 months	1
CMRT: 12 months	1
CMRT: 12 months	2
CMRT: 12 months	3

CMRT = Course Marks Retention Time

Note that the other parameters in a privacy rule may change too, not just retention time. We change retention time only to keep the example simple. Actually, each different combination of parameters represents a different privacy level. The privacy level is inversely proportional to the retention time of the marks. The different privacy levels obtained for the same PII constitute one part of the privacy sensitivity scale.

2. In this step, the policy provider constructs privacy rules from the PII in number 1 and ranks them using the median value from the corresponding sensitivity range. Thus for the 4 course mark retention times of 6 months, the lowest value is 3, the highest value is 5, and the median is 4. Therefore the rule < any, course marks, records, 6 months, none > is ranked with privacy level 4. Similarly, the rule < any, course marks, records, 12 months, none > is ranked with privacy level 2.
3. To obtain his or her privacy rules, the consumer specifies the use as e-learning and a privacy slider value of four (for example). He or she then obtains the rule

   < any, course marks, records, 6 months, none >

   and proceeds to complete the policy by adding header values for *owner*, *proxy*, and *valid*.

Retrieval from a Community of Peers

This approach assumes an existing community of peers already possessing specific use privacy policies with rules according to desired levels of privacy. A new consumer joining the community searches for personal privacy rules or whole personal privacy policies (sets of rules). The existing personal privacy policies may have been derived using the third party surveys as above. The privacy policy rules are each stored along with its privacy level so that it may be selected according to this level. Where a rule has been adapted or modified by the owner, it is the owner's responsibility to ensure that the slider privacy value of the modified rule is consistent with the privacy sensitivity scale from surveys.

1. All online users are peers and everyone has a privacy slider. The new consumer broadcasts a request for privacy rules to the community, specifying use and slider value. This is essentially a peer-to-peer search over all peers.

2. The community responds by forwarding matching (in terms of use and slider value) rules to the consumer. This match may be a fuzzy match as well.
3. The consumer compares the rules and selects them according to use, popularity (those that are from the greater number of peers), and best fit in terms of privacy. After obtaining the rules, the consumer completes the privacy policies by completing the headers as in the above derivation from surveys approach.
4. Consumers may adapt their privacy policies for different service providers as in the derivation by surveys approach.

There is a challenge here regarding how to carry out this approach in a timely fashion. Efficient peer-to-peer search techniques will collect the policies in a timely manner, but the amount of information collected by the requester may be quite large. As well, since the various policies collected will probably differ from each other, the requestor will have to compare them to determine which one to select. Quick comparison so as to reduce the amount of data collected would be through a peer-to-peer policy search that employs a policy hash array, containing hashed values for different portions of the policy for more rapid comparison.

FUTURE TRENDS

We expect that over the next few years, consumers will become increasingly aware of their privacy rights. This is already happening as consumers are faced with the practical implications of privacy legislation. In Canada, this has meant that consumers are being asked for permission before their private data is collected every time they walk into a dentist's office or visit an optician for glasses. To ensure that their privacy rights are respected, consumers will need to express their privacy preferences in personal privacy policies. Hence the need for consumers to be able to create their personal privacy policies easily will grow. In response to this need, researchers will discover more ways for them to do so easily. In addition, there will be a need for technologies that are associated with personal privacy policies, such as policy negotiation, policy compliance, and trustable interfaces for interfacing the consumer to the provider for the purpose of privacy policy management (see "Introduction" for policy negotiation and compliance). Consumer privacy will only be truly protected once these technologies are available and used.

CONCLUSION

The protection of personal privacy is paramount if e-services are to be successful. A privacy policy approach to privacy protection seems best for e-services. However, for this approach to work, consumers must be able to seed their personal privacy policies easily. We have presented two semi-automated approaches for seeding the policies: one based on third party surveys of consumer perceptions of privacy, the other based on retrieval from a peer community. Both approaches reflect the privacy sensitivities of the community, giving the consumer confidence that his/her privacy preferences are interpreted with the best information available. As well, they might be effectively combined.

Clearly, the notion of a trusted third party as a personal policy provider may be controversial to some. Any error made by the policy provider could affect PII for many hundreds or thousands of people. Having privacy commissioners' offices take responsibility for this process seems to be a natural fit, given their mandate as privacy watchdog for the consumer. However, the process would have a cost. Costs might be recovered via micro-charges to the consumer, or the service provider for the policies provided. Aggregated information from the PII surveys might be sold to service providers.

KEY TERMS

Community of Peers: A grouping of peers having something in common or considered grouped for a specific purpose, (e.g., having particular types of privacy policies as discussed above).

Consumer: Of an e-service is a user of the service, possibly by paying a fee.

E-Service: An electronic service accessed via a network such as the internet. Example e-services include online banking, online stock broker, online tax information, and online learning.

Peer: Another node in a network that is like every other node in the network.

Personal Information or Personally Identifiable Information (PII): Information that is personal about an individual that may be linked with the individual or identify the individual, (eg. credit card number, birth date, home address, social security number).

Personal Privacy Policy: A description of personal privacy preferences, stating what personal information or PII may be communicated to others, to whom such information may be communicated, and under what conditions the communications may occur.

Privacy: The right of an individual to determine when, how, and to what extent his or her personal information is communicated to others.

Provider: Of an e-service is a business that operates the e-service and offers it to consumers, possibly earning fees for the use of the service by consumers.

Provider Privacy Policy: A description of provider privacy preferences, stating what personal information or PII the provider requires from the consumer, and the conditions under which the information is required, in order for the provider to carry out its service.

Sensis Search

Fang Zhao
Royal Melbourne Institute of Technology University, Australia

BACKGROUND OF THE BUSINESS

In 2002, Sensis Pty. Ltd. was launched as a new corporate brand and company name to replace the Pacific Access Pty. Ltd., a wholly owned subsidiary of Telstra Corporation, Australia's largest telecommunication company. According to the CEO of Sensis, the name of the company, Sensis, reflects the essence of today's business—keeping people in touch through appealing to the key human senses of sight, sound, and touch, using different media—print, voice, online, and wireless (Sensis, 2002). To strengthen the strategic position of Sensis in online advertising business, the company acquired CitySearch Online and BMC Media Ad Sales, adding new lines of advertising business to Sensis. After 2 years' operation driven by an aggressive-growth strategy, Sensis has developed into one of Australia's leading advertising and search companies, offering a suite of print, online, voice and wireless products designed to bring buyers and sellers together any time, anywhere. Sensis Pty. Ltd. has a team of over 3,100 employees, among which 2,300 people are directly employed by Sensis and 800 by its wholly owned subsidiary, the Trading Post Group of companies.

Sensis' products and solutions include:

- **Sensis Search (www.sensis.com.au):** An Internet search engine that utilises some of the most comprehensive and up-to-date product and service listings in Australia, with a much greater emphasis on local and national businesses. The Web site was launched in July 2004 and used by 59% of Australians with over 5 million visitors every month according to a recent Neilsen/NetRatings (Sensis, 2004a).
- **Yellow Pages®:** With over 14 million copies in circulation, the Yellow Pages® print directories are found in virtually every home and business in Australia.
- **White Pages®:** Print and online business directories.
- **City Search®:** Australia's leading online culture and lifestyle guide, offers tailored Internet solutions.
- **Whereis®:** Whereis® products and services are the location (digital mapping) and navigation brand of Sensis Search.
- **Sensis1234:** With sensis®1234, callers can find a business (and residential listings) through a single number, whether they know the business name or not.
- **MediaSmart®:** Providing consulting services on the best sites and advertising formats to reach your target market.
- **Trading Post®:** A print and online private and classified advertisements directory for goods and services.
- **JustListed.com.au:** A new commercial and residential online real estate portal currently based in Sydney, where its inventory includes over 42,000 rental and sale properties and 1,670 real estate agents. Due to the very successful performance of the portal, Sensis plans to develop it into a national, online real estate portal.

As shown above, Sensis Search (sensis.com.au) is a key component of Sensis multiple dimensions of business and plays a central hub role in the interfaces between online and print searches of information. This article focuses on exploring the experiences of sensis.com.au and identifying key issues of its operation. Data for this qualitative case study was collected mainly from two primary sources: (a) a documentary research into Sensis's business reports, online newsletters, memos, agenda, and other official publications; and (b) an in-depth interviews with a senior manager of Sensis.com.au. The case study focuses on how Sensis has been managed, how it has succeeded, and what lessons can be learned from its experience.

Description of the Business

Sensis Pty. Ltd. launched its search engine Sensis Search (sensis.com.au) in July 2004, which constitutes all the online/electronic portfolio of Sensis Pty. Ltd. including www.whitepages.com.au, www.yellowpages.com.au, www.whereis.com, and www.CitySearch.com.au (Sensis, 2004c). By doing so, Sensis Search is able to provide Australians with fully blended search results across local proprietary and global Internet content. For example, Australians can use sensis.com.au to find a local florist anywhere in Australia and can also locate and purchase a pair of shoes in New York. The search engine provides local, commercial and global searches from which customers can get blended results from local Yellow Pages®, White Pages®, CitySearch® and Whereis® data combined with global Web content. Sensis Search is the first mover in redefining Australian search market and creates a new paradigm for Internet search that delivers relevant, quality local and global results. Sensis Search represents a "world first" amongst search engines as it integrates Internet Web page content and structured content (e.g., the Yellow Pages directory) into a "one-stop shop" for searches, unlike other search engines such as Google, where these services are available, but under different URLs. As such, searches can be performed locally, nationally, globally, and throughout the Sensis sites. The strategy to develop synergies among Sensis's businesses contributes to the success of Sensis and Sensis Search. The focus on, and pursuit of Sensis Search for, relevant, local, and quality return results herald the maturity of online search services. The success of online search is no longer measured by the volume or the size of the Internet index but by the extent of meeting specific user's search needs. Moreover, Sensis Search provides Australian users with very easy access to commercial content through Internet access. Commercial content is classified under nine categories; products, services, people, places, events, jobs, cars, houses and consumer classifieds, which might include searches of Sensis directories such as the Trading Post.

Due to the initial success of Sensis Search in managing to provide the most innovative and comprehensive online search engine in Australia, Sensis management decided to expand the business further. In December 2004, Sensis acquired one of Australia's most successful mapping and street directory businesses, Universal Publishers Pty. Ltd. The acquisition has significantly strengthened the market share and position of Sensis Search which now boasts the largest and most up-to-date database of navigable mapping content in Australia. Unlike its competitors, as one line of its business, Sensis Search provides nearly 100% geographic coverage of Australia and "its contents covers everything from urban streets, to points of interest, four-wheel drive tracks in the remote outback and smaller roads you'd never see on a normal map" (Sensis, 2004a, p. 1) said, the CEO of Sensis Pty. Ltd.. This aggressive growth strategy of Sensis through acquisition aims to accommodate the increasing demand of Australia's local consumers for localised advertising and map-based search to find local businesses, products and services. Sensis Search's digital mapping business now serves more than 18 million digital maps online every month through its Whereis® brand on the www.sensis.com.au site (Sensis, 2004a).

To survive and succeed in today's fierce competition in the search engine industry, Sensis Search pursues two complementary lines of businesses—online advertising and online search. The market share of Sensis Search online advertising has now exceeded 23% of online advertising in Australia, and meanwhile, it has seized approximately 70% of the combined search and directories market in Australia (Sensis, 2004b). In the light of the Online Advertising Expenditure Report issued by the Audit Bureau of Verification Services, the revenues from online advertising grew by 58% to AU$300 million in the 2003/2004 financial year in Australia. The stellar growth in online advertising is both an opportunity and a challenge to Sensis Search. The company develops its corporate strategy and direction focusing on local online search within Australia, thus becoming the major player in local Australia's search through providing relevant and complete, localised business information. The success in providing relevant and quality search results to meet specific user searches helps boost the online advertising business of Sensis Search as well as the entire business of Sensis Pty. Ltd.

Sensis Search, the online/electronic portfolio of Sensis Pty. Ltd., recorded a 40.7 growth for the year 2004 and 34% online usage growth for the same year (Sensis, 2004b), although Sensis's print business grew by 5.6% only compared with the previous financial year (Sensis, 2004d).

Lessons Learned

Sensis Search's experience presents several fundamental management lessons for the business operations and development of today's dot-coms and e-businesses. This section examines and explores these lessons.

First, the success of Sensis Search is one of combined innovation and entrepreneurship in the e-business world (thus called *e-innovation* and *e-entrepreneurship*). Today's e-business operates in a highly competitive marketplace where sustainable competitive advantage is almost impossible as there are minimal barriers to new entrants and competitors in the marketplace. Innovation faces constant challenges of imitation and erosion. There have been different views in the literature about the benefits of first movers in e-business marketplace. Mellahi and Johnson (2000, p. 445) asked the question "does it pay to be first to market or should e-commerce firms wait for first movers to make an investment and then cannibalize the idea with lower entry cost?" The cause of the concerns are raised by a general belief that it is safer and less expensive to imitate the first mover in the e-business environment, where there is a higher level of technical uncertainties and rapid rate of technological innovation. For instance, many new dotcoms rushed to build an e-marketplace and chose imitation as a business strategy rather than innovation. This author argues that it is the lack of a combination of innovation and entrepreneurship capacity that has caused the demise of many imitators in the dot-com industry. The essence of innovation and entrepreneurship is taking a new idea to market, not imitating a new idea without taking into account the special needs of local markets, and being innovatively and proactively responsive to environmental changes by introducing a new product, process, service or implementing a distinctive business model. Sense Search's success has clearly been contributed by the first mover advantage (being the first company in the world that took its directory products online).

Both empirical and theoretical studies show that innovation interacts with entrepreneurship to achieve business success (Kanungo, 1999; Drucker, 1994; Zhao, 2005). The key elements of entrepreneurship include risk-taking, proactivity, and innovation (Miller, 1983). However, Slevin and Covin (1990) argued that the three elements are not sufficient to ensure organisational success. They maintained that "a successful firm not only engages in entrepreneurial managerial behaviour, but also has the appropriate culture and organisational structure to support such behaviour" (p. 43). Thus, there is clearly overlapping and interdependence between entrepreneurship and innovation. Both are needed for firms to be successful and sustainable. Furthermore, entrepreneurship is related to the development of new products and services. Innovation is sometimes not necessarily related to new products but concerns doing something differently and better. Although entrepreneurship is related to working with new products and services, it is not necessarily about doing things better. Innovation however, is about doing something better by doing it differently. As such, entrepreneurship carries extra financial and risk issues because of the newness of the venture. According to the experience of the company's senior manager interviewed for the present study, there are no conceptual and/or practical differences in terms of online and offline entrepreneurship and innovation. The approach is the same, regardless of the online or offline environment, although the skill set required is obviously different. The company believes that entrepreneurship and innovation are crucial to their success and innovation should be inculcated into the organisational culture, and is developed internally. It includes encouraging staff to interact with customers, and undertake research and development. Sensis Search is not only an entrepreneurial company in terms of its aggressive growth strategy but also a pioneer of innovation. Sensis has claimed to be the first company in the world that took its directory products online. Sensis Search has identified seven factors, which it believes drive innovation, and which it has subsequently applied to all new product areas:

1. clear vision communicated throughout the company;
2. development of a culture of innovation—through rewarding people and taking calculated risks;
3. an organic organisational structure—rather than having a central group of IT managers, producers and product managers, each product unit employs their own staff with their own responsibilities and P&L statements;
4. job role clarity;
5. accountability and responsibility;
6. clear key performance indicators (KPIs); and
7. sufficient funding, realistic revenue expectations and people positively motivated.

The entrepreneurship strategy that Sensis Pty. has taken is actually that of an intrapreneurship, that is, entrepreneurship within an organization. Sensis's story indicates that development of entrepreneurship and innovation should be dependent on the size of the company. For instance, the Sensis group includes large, established companies such as Yellow Pages®, and the much younger and relatively smaller Sensis Search. Yellow Pages® is built on an established, traditional business model, whereas the Sensis Search approach is entirely different. As such, there is a need to separate the companies, and to allow new business units within the group to "quarantine space," where they can grow (within set timeframes), using different people, with different rewards, finances etc., rather than trying to fit in with the old models.

Second, Sensis Search can be viewed as a successful start up of a new generation of dot-coms that are more mature in terms of business models and information technologies, focusing more on justification and accountability of business processes and outcomes than on a "can-do" mentality only. The post-2000 e-business successes generally tended to be those that were first to market, and which were sufficiently funded to weather the crash. These companies also managed to maintain their people and stay sufficiently focused on their core strategies, rather than diversifying too greatly. Therefore, they have distinctive features from their counterparts in the earlier days of e-commerce. In hindsight, e-commerce failures tended to be the Me2 brands, which were merely copying existing, successful e-commerce models under the premise of "build it and customers will come," wholly failing to recognise the power of established branding.

Sensis Search is Australian-based, but competes against global giants such as Microsoft, Yahoo, and Google. As such, they have identified two ways by which they can be competitive. The first is by providing a higher amount of business and commercial content and the second is by having good relationships with global partners in order to deliver their solutions in the most efficient and cost effective manner. For instance, Sensis Search has partnered with Fast, a Norwegian company specialising in algorithmic search technology which powers the Sensis Search engine. It has continued to achieve strong growth and to develop leading edge online search solutions for Australians. It offers its advertisers the opportunity to put their companies' existing print content online at little or no additional cost. For example, businesses do not need to have a Web site to be found on sensis.com.au but simply be listed on the Sensis's Yellow Pages® Online site.

Third, successful dotcoms require sufficient funds and people skills, as well as adherence to the seven-step innovation model cited above. Sensis Pty has made significant investment in developing its online/electronic dimension of its business as a long-term corporate strategy. Generally speaking, there appears to be a shortfall in people with specific expertise in e-commerce in Australia. This may be because international demand is high and it takes time for the right skills to be taught in universities. The shortage in human resources and skills remains a significant barrier to online entrepreneurship and innovation in Australia. Sensis believes that retention of staff is a very significant driver of innovation and as such they have developed reward systems which will commit their people to the company, and offer them recognition, training and opportunities. The company has also developed relationships with universities, and regularly engages speakers to address staff.

Other lessons learned from Sensis Search are also fundamental. According to the Sensis's CEO, the key factors contributing to the company's success are Sensis's continued focus and commitment to its people and customers. Survey data showed that its customer satisfaction improved 10% in 2004 and its employee satisfaction has continued to rate up to 10% higher than the Australian average with regard to key satisfaction measures (Sensis, 2004d). In addition, there is a need to be realistic (particularly if the company is competing against established players), and to identify what differentiates the company from its competitors, and the sustainability of that differentiation. Further, companies should also have firm milestones, which can be derived from a user point of view, customers, brand recognition or advertising, with which to gauge the progress of their investment. Finally, a calculated risk assessment is crucial to an online business. Companies should know when to let go, or substantially change their model or sell it to others in order to go to the next level.

The overall improvement of economic conditions worldwide in 2003 and 2004, and the recovery of investors' confidence in high-tech and e-business industries have refuelled the growth of e-businesses. Indeed, the public interest in Google's IPO launched in August 2004 is an indicator of the recovery. After two days trading, Google's share price jumped 27% and the company's value (around US$29 billion) equalled that of the Ford Motor Company (Wood, 2004). According to the projection made by Forrester Research, online sales will grow at a year-over-year pace of 19% to US$225.9 billion in 2008 in the United States. Further, the number of online shoppers will also increase significantly and nearly 5 million new United States households will shop online every year (*TechWeb News*, 2003). The mega economic environment entails a positive and promising future for e-business although there are many challenges and hurdles that need to be surmounted. There is clear evidence as provided by companies like Google, Yahoo, and Amazon as well as the case company of this study that e-innovation is alive and well. Consumer behaviour has changed, and people are more likely to accept new Internet technology than 5 years ago. E-entrepreneurship and e-innovation will help an e-business get to the stage where they are profitable and sustainable.

However, dotcoms are also facing greater challenges than ever. First, dot-com industries need to achieve sustainability, due to a more uncertain economic environment and the increasing complexities of new technologies and a more globalised economy. Second, the business success and fast expansion of Amazon.com, Dell, travel.com and the like through e-business partnerships reinforce the value of strategic alliances. Corporate e-partnerships will be a crucial factor and play a key role in the future development of e-business activities. In the frenetically changing competitive landscape of today's business world, few organizations can rely only on their internal strengths to gain a competitive advantage in national and/or international markets. Continued expansion to global markets will push more international dotcoms to form strategic alliances in e-business. Yahoo!, Google, eBay, and E*trade provide good examples of global expansion using alliances with local e-businesses worldwide for smaller players who will follow the trend to go global. Finally, the key principles of total quality management will be the fundamental cornerstone to e-business success, which include customer focus; and continuous improvement and measurement to achieve customer satisfaction. The failure of many e-businesses and the dotcom crash have on the whole been caused by poor quality customer services and support, problems with Web site security and technologies, and weaker change management (Janenko, 2003).

Future research could focus on

- the complex, dynamic, and sophisticated structures under which e-business can operate;

- identification of the e-business networks and relationships that are most likely to succeed, and how they succeed;
- the specific nature and characteristics of the operations of dotcoms in different industry sectors and in different country settings;
- the impact of specific e-business technological innovations on specific functional areas of e-businesses; and
- the effectiveness of the current technological trend of "one size fits all" e-business solutions built on 'industry best practices' for e-business.

INTRODUCTION

The established global business environment is under intense pressure from Asian countries such as Korea, China, and India. This forces businesses to concentrate on their core competencies and adopt leaner management structures. The coordination of activities both within companies and with suppliers and customers has become a crucial competitive advantage. At the same time, the Internet has transformed the way in which businesses run. As the Internet becomes a cheap and effective communication channel, businesses are quick to adopt the Web for integrating their systems together and linking them with their suppliers and customers. Current enterprise computing using J2EE (Java 2 Platform, Enterprise Edition) has yielded systems in which the coupling between various components in them are too tight to be effective for ubiquitous B2B (business-to-business) and B2C (business-to-consumer) e-business over the Internet. This approach requires too much agreement and shared context between business systems from different organizations. There is a need to move away from tightly coupled, monolithic systems and toward systems of loosely coupled, dynamically bound components. The emerging technology, Web services, provides the tools to accomplish this integration, but this approach presents many new challenges and problems that must be overcome. In this article, we will discuss the current approaches in enterprise application integration (EAI) and the limitations. There is also a need for service-oriented applications, that is, Web services. Finally, the challenges in implementing Web services are outlined.

BACKGROUND

The advancement of computing in the past decade results in enterprise computing being distributed in a heterogeneous environment: computers ranging from mainframes to PCs (personal computers; including top-of-the-line 64-bit processors and outdated 386s) and running two or three different operating systems, database software from different vendors, and a variety of servers. On the other hand, the Internet changes the way that businesses run. The converging mobile and wireless technologies enable mobile users to access the Internet anywhere with broadband. The Internet becomes an indispensable and cheap communication medium and the backbone for enterprise application integration.

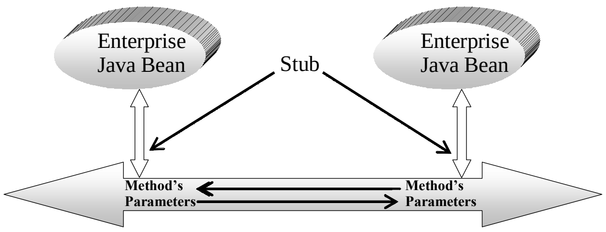
Developers have to put a lot of effort and resources in integrating new applications with existing ones, as well as getting existing applications to communicate with one another while keeping the number of changes to these applications to a minimum. Typically, this kind of integration is called EAI. The Java 2 Platform, Enterprise Edition and Microsoft .NET both address the need for making existing applications and business processes available on the Web in a robust, secure, and distributed transactional way. J2EE is platform independent while .NET is limited to Windows-based platforms. In addition, J2EE provides a connector, Java 2 Connector, to integrate with legacy systems such as IBM CICS (Customer Information Control System) for mission-critical applications. However, the choice really depends on the existing infrastructure of a company: Windows-based or multiple platforms. Here, J2EE is used to illustrate the operations and the limitations.

J2EE has a number of applications models (Graham et al., 2005).

- Thin client-browser-based applications use servlets and Java server pages in the Internet environment.
- Thick managed application clients use RMI-IIOP (remote method invocation run over Internet inter-orb protocol) to communicate with server-based

S

Figure 1. Java RMI architecture



EJBs (Enterprise Java Beans) components. This is applied in the intranet, which provides the extra infrastructure that allows Java programs to directly access EJBs within the intranet domain.

- Messaging applications use the Java message services to act on messages in queues or from subscriptions.

The first two models require a tight coupling between applications. Coupling is the strength of interconnection between two software modules: The higher the strength of interconnection, the higher the coupling (Wijegunaratne & Fernandez, 1998). Loosely coupled systems make it easier for the developer to modify as he or she can maintain one module without having to know very much about any other module in the system. If two modules are highly coupled, then there is a high probability that a programmer trying to modify one of them will have to change the other. The tight coupling in J2EE is due to the stubs. Figure 1 shows the Java RMI middleware. A Java application is composed of a number of components, called Java Beans, distributed across a network. The stub is used to connect to the middleware and transfer activation parameters from the component to the network. In such a way, components can be exchanged for other components, and this allows code mobility. However, any change in the application will be done in the stub in each component due to the tight coupling.

The third model is based on messaging called message-oriented middleware (MOM) and is asynchronous by nature (Serian, 2002). MOM sends messages from one application to another using a queue as a temporary storage area. The queues reside in the middleware layer and do not require a direct connection to the retrieving applications. Furthermore, applications can retrieve the message from the message queue at anytime and in any order. Figure 2 shows message-oriented middleware's architecture. The implementation involves the communication code only and reduces the involvement with the *complexity* of the distributed mechanism. Since the application code is not involved, each application code is independent of each other; that is, there is a decoupling. Conclusively, J2EE is not applicable for dynamic e-business environments where services are called on demand.

THE NEED FOR A SERVICE-ORIENTED ARCHITECTURE

Businesses are under intense pressure. First, customers are like butterflies. As they are well informed in the digital era, they are smart in shopping around and their preferences are changing. Customers are no longer loyal to the same business. Second, the emerging industrial nations in Asia such as Korea, China, and India are posing a threat.

Figure 2. The message-oriented middleware's architecture

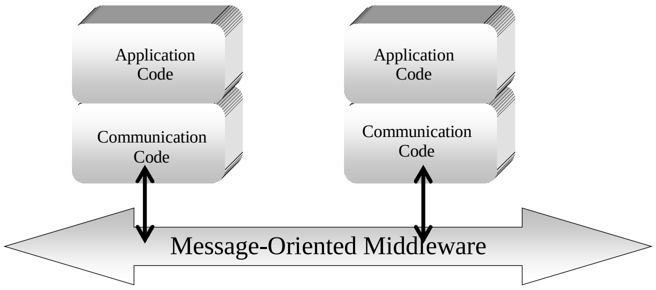


Figure 3. The coordination activities of business

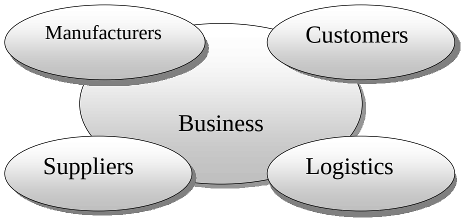

Figure 4. Service-oriented architecture

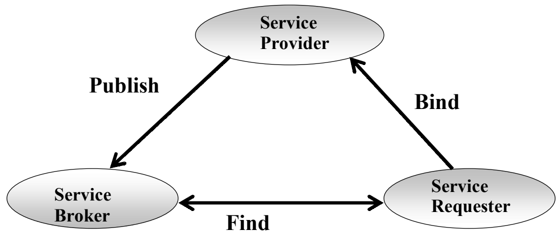


Businesses have to compete dynamically. This forces businesses to concentrate on their core competencies and adopt leaner management structures. Businesses have to coordinate the activities of suppliers, manufacturers, and customers in a global environment (Figure 3). Partners come and go dynamically. From the discovery of new partners to the integration of other entities, dynamic e-business has evolved from human-to-application (H2A) to application-to-application (A2A) exchanges (Zimmermann, Tomlinson, & Peuser, 2003) in which there is no human involvement. A service-oriented architecture (SOA) provides the framework for dynamic e-business with the following characteristics:

- Quick response time to customers, suppliers, and business partners;
- Redefinition of operations dynamically according to the changing business environment; and
- Automatic discovery of service interfaces and implementations.

To achieve SOA, the integration layer must be independent of any specific implementation languages, the transport protocol, the operating system, and the platform, and has to be supported by open standards. Furthermore, no human is involved at run time. It is programmed automatically, not manually. The current approaches in EAI using J2EE and .NET are made up of tightly coupled applications and subsystems. A change to any one subsystem can cause breakage in a variety of dependent applications.

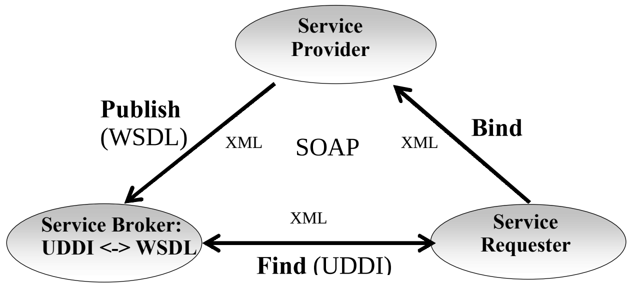
SOA is based on the assumption that an application can be partitioned into fragments of business processes, called services. Each service exposes a well-defined interface, which is accessible over the network (Figure 4). Hence, SOA applications are much more flexible, easier to integrate with, and simpler to maintain than classic monolithic applications such as EAI using J2EE or .NET. Web services provide a simple interoperability platform for SOA and a formal way to describe service interfaces (Pezzini, 2004). The Web-services technology meets the overall requirements.

A Web service is a software system designed to support interoperable machine-to-machine interaction over a network. It has an interface described in a machine-processable format (specifically, WSDL [Web services description language]). Other systems interact with the Web service in a manner prescribed by its description using SOAP (simple object access protocol) messages, typically conveyed using HTTP (hypertext transfer protocol) with an XML (extensible markup language) serialization in conjunction with other Web-related standards (Booth et al., 2003). Hence, Web services are architectural and a technology solution for connecting distributed applications in SOA. Web services make use of several standards such as the following (Gisolfi, 2001).

- **XML:** The extensible markup language is used as a language for defining data-descriptive languages, such as markup grammars or vocabularies, and interchange formats and messaging protocols.
- **SOAP:** The simple object access protocol is an XML-based lightweight protocol for the exchange of information in a decentralized, distributed environment.
- **WSDL:** The Web services description language defines the characteristics of the service including the location of the service and how to access it. The service provider publishes its interface contract in the form of a WSDL document.
- **UDDI:** The universal description, discovery, and integration specification provides a common set of SOAP APIs that enable the implementation of a service broker.

Figure 5 shows the implementation of SOA with Web services. The service provider publishes its interface contract in the form of a WSDL document. Service requestors locate services by using a service registry, UDDI. The UDDI server contains the database of service descriptions and provides them to the service requestor's application. The requestor uses the WSDL document to

Figure 5. The implementation of SOA with Web services



understand the interface contract with the Web service. Using the information in the WSDL document, the requestor will understand how to access the service, what methods it has, and what parameters need to be sent, among other things. Web services simplify the business process without the involvement of humans. For example, when an employee books a flight, he or she fills in the desired flight time. Then a personnel staff will surf the airline-flight Web server and book the ticket as there is no integration between the company's travel request and the airline's flight reservation. Through the Web service, the two services are integrated and the process is automated.

THE CHALLENGES OF WEB SERVICES

Web services are a simple, programming-language-neutral, and interoperable communication technology. Web services are available today at low initial costs and minimal risk. Many business scenarios such as EAI, B2B, and common services can be supported as comprehensive and mature tool support is available; huge productivity gains can be realized (Zimmermann et al., 2003). However, since the introduction of Web services in 2001, the deployment rate is poor. First, security is a critical issue. In transforming EAI built by J2EE to Web services, a developer has to move the stubs written in Java, which act as glue among applications to XML. XML forms the basis for distributed system protocols to integrate applications across the Internet. XML languages are text based and provide a structured way to add context to data so that they can be shared among different applications. XML is primarily for Internet-based communications; thus, it provides the opportunity for others to sniff or spoof information. Integrating more applications and resources implies an increased degree of exposure to access that has not been possible (Brose, 2003). Furthermore, standard security functionalities such as authentication, authorization, privacy, and nonrepudiation are mostly incomplete.

Second, the interaction among applications in Web services is automatically generated. If things go wrong, it is hard to debug. Third, Web services are emerging standards that are still under development. The specifications are being developed by different standards bodies without a unifying authority. While there was a good deal of agreement in the first phase of basic Web-services protocols, there is a significant rift between backers of different reliable messaging proposals, pitting IBM, Microsoft, BEA Systems, and their technical partners against Oracle, Sun Microsystems, Hitachi, and others. Tim Bray, coinventor of XML and director of Web technologies at Sun Microsystems, said recently that Web-services standards have become bloated, opaque, and insanely complex (LaMonica, 2004). Businesses have to be cautious when embracing Web-services technology and the standardization process. IT industries must reconcile their differences to achieve unified standards in Web services.

KEY TERMS

Coupling: Used to measure the extent to which interdependencies exist between software modules: The higher the interdependencies, the higher the coupling. It implies that if you want to reuse one component, you will also have to import all the ones with which it is coupled.

Enterprise Java Beans (EJBs): Components of distributed transaction-oriented enterprise applications. EJBs execute within an *EJB container,* which in turn executes within an *EJB server.* The EJB container is where the EJB component resides. The EJB container provides services such as transaction and resource management, versioning, scalability, mobility, persistence, and security to the EJB components it contains. Since the EJB container handles all of these functions, the EJB-component developer can concentrate on business rules, and leave database manipulation and other such fine details to the container. It automatically stores the contexts of the calls made by the user and can make the connection between several calls coming from the same user (Johnson, 1998).

Extensible Markup Language (XML): Describes a class of data objects called XML documents and partially describes the behavior of computer programs that process them (Bray et al., 2004).

Message-Oriented Middleware (MOM): Asynchronous by nature. MOM sends messages from one application to another using a queue as a temporary storage area, like e-mail.

Middleware: The wide range of services layered between the applications and operating systems that provide specialized services and interoperability between distributed applications. The services consist of transaction-processing monitors, remote procedure calls, message-oriented middleware, and object request brokers.

Remote Method Invocation run over Internet Inter-Orb Protocol (RMI-IIOP): Like CORBA (common object request broker architecture), RMI over IIOP is based on open standards defined by the Object Management Group and uses IIOP as its communication protocol. IIOP eases legacy application and platform integration by allowing application components written in C++, Smalltalk, and other CORBA-supported languages to communicate with components running on the Java platform (Sun Microsystems, 2004).

Service-Oriented Architecture: Essentially a collection of services. These services communicate with each other. The communication can involve either simple data passing or it could involve two or more services coordinating some activity. Some means of connecting services to each other is needed.

Stub: Used to connect to the middleware and transfer activation parameters from the component to the network. For instance, the client stub marshals the parameters and packs them up with the procedure identifier to a message, sends the message to the server, and then awaits the reply message, unmarshals it, and returns the results (Coulouris, Dollimore, & Kindberg, 1999).

Web Services: Web-based enterprise applications that use open, XML-based standards and transport protocols to exchange data with calling clients.

Service–Oriented Architectures and Virtual Enterprises

Nicolaos Protogeros
University of Macedonia, Greece

INTRODUCTION

This article presents some trends in e-commerce technology and more specifically the service-oriented architectures (SOA) and its interoperability promise applied to innovative organization schemes such as virtual enterprises (VE). The evolution of software architectures from traditional to SOA is presented through comparison of characteristics, advantages and disadvantages, and problems and difficulties in applying the SOA, while also focusing on the compatibility between SOA and modern organizational structures. The main focus is on the SOA technology trends of modern organizational structures with regards their formation and integration. The comparison between SOA and traditional Architectures provides a clear path to their adoption in various cases.

BACKGROUND

Service-oriented architecture was first introduced by Gartner, Inc. (1996) as:

> *...a software architecture that starts with an interface definition and builds the entire application topology as a topology of interfaces, interface implementations and interface calls. SOA would be better named* interface-oriented architecture*. SOA is a relationship of services and service consumers, both software modules large enough to represent a complete business function. Services are software modules that are accessed by name via an interface typically in a request-reply mode. Service consumers are software that embeds a service interface proxy (the client representation of the interface).*

SOA has since excited many software architects and developers but only recently with the advent of Web services, SOA has found its route to real applications. Other technologies have been tried in the mean time but undoubtedly Web services is the most prominent technology that forms a solid base to develop robust SOA applications. Web services are defined by Gartner (Plummer, Blosch, & Woolfe, 2002) as: "modular business services with each module fully implemented in software and delivered over the Internet. The modules can be combined, can come from any source, and can eventually be acquired dynamically and without human intervention when needed."

Web services and SOA are complimentary technologies that represent the most recent step in the evolution scale, which started with distributed programming and object distribution technologies like CORBA, COM/DCOM, DCE and more recently J2EE. Web services represent a technology specification—meaning that an application must use its standards like Web services description language (WSDL), simple object access protocol (SOAP) or Universal Description, Discovery and Integration (UDDI) to be considered as Web services. SOA on the other hand is more considered as a design principle (Natis, 2005) meaning that Web services interfaces like WSDL (WSDL) and SOAP are suitable interface definition standards (UDDI, 2001; WSDL, 2001; SOAP, 2001; Atkinson, 2002; IBM, 2001).

SOA has an inherent ability to apply itself efficiently across enterprises, being the most promising technology to form and operate virtual enterprises where different economic organizations are combining their strengths (and thus minimizing their weaknesses) to provide a specific service traditionally provided by a single enterprise. Such a development will offer, in the long term, immense influence on the economy and enterprise development strategies. The availability, through SOA on the Internet, of standardized SME information, relevant for participating in virtual enterprises, will dramatically multiply the number of business opportunities transformed into successful business ventures. The most important requirements for virtuality in virtual enterprises are (Protogeros, 2005):

1. **Visibility Across the Virtual Enterprise:** There is a need to have an overall visibility on the entire life cycle of the products and/or services produced, starting from its development to its launch into the market. Such a visibility must be permitted to all the companies' personnel involved in the virtual enterprise operation and in particular to the Project Managers that often, in the traditional supply chain, cannot adequately follow the development of im-

portant sub-systems, which are supplied by a sub contractor.

2. **Consistent and Uniform Business Model:** Gou, Huang, Liu, and Xiu (2003) define a business process of a virtual enterprise as a set of linked activities that are distributed at member enterprises of the virtual enterprise and collectively realize its common business goal. A uniform business model is very important for the viability of the virtual enterprise. It should support the evolution of the product, process and organization according to the increasing detail of the attributes representing the same concept (e.g., the status of an order, the categorization of the order, the customer contact information, the customer account representation, etc.) in a consistent manner.
3. **Consistent Co-Operative Process and Data Model:** The data model of the companies can capture various behavioral semantics of the business entities. Thus it is not sufficient to have just a consistent conceptual business model of the business entities for smooth operation (Setrag, 2002). Data semantics and operational behavior must also be represented and applied consistently.
4. **Uniform Organizational Model:** The organizational view of enterprises captures information about departments, roles, employees, partners and entire organizations. The organizational model of the virtual enterprise should encompass ownership, privileges and responsibility of messages, documents, and activities that are involved in the processes of the virtual enterprise. It also has to involve extensive security as well as personalization requirements. Virtual enterprises can be thought of as an aggregation of processes. Thus processes use information, operations, roles, and sequencing of tasks to carry out specific objectives in the virtual enterprise.
5. The large diversity in business practices reflected in the plethora of monolithic and legacy applications, along with the huge gaps in business scope and differences in working standards between the large enterprises and the SMEs make the integration process for virtual enterprises a real headache for analysts and developers. SMEs significantly contribute to the value chain by supplying to large enterprises the equipment and subsystems required. In Europe, for example, where a large number of SMEs exist, the need for harmonizing the large and small/medium enterprises business approach and practices has been pointed out several times at European Community level. Technology should support the four main phases of a virtual enterprise life cycle [200], which are: creation/configuration, operation, evolution and dissolution. By now a large number of projects are addressing various aspects of infrastructures for virtual enterprises including NIIIP (NIIIP), PRODNET II (Camarinha-Matos & Cardoso, 1999), VIRTEC (Bremer, 1999), Co-OPERATE (Azevedo, Torscano, & Sousa, 2002), and BIDSAVER (Protogeros, 2005). Some of them are developing Service based reference architectures for example the NIIIP.

SOA TECHNOLOGY AND STANDARDS

In recent years a new trend has appeared related to the reuse of old applications in new type user-transactions. This style, being an alternative to the development of purely new applications, is known as composite development. In 2003 the majority of new business applications developed were composite applications (Natis, 2005). In taking that approach, wrappers are developed around legacy or other functionality that assemble those components into heterogeneous composite transactions. SOA is the natural place were these types of composite components fit together. From an industry and standards perspective, SOA technologies are quite advanced. All major software vendors have at least some level of support for Web services in their products, providing Web service technologies broad industry support. On the other hand, the baseline standards underlying Web services—XML, SOAP, and WSDL—are stable and mature since they have been used for many years now (since 1998, 2000, and 2001 respectively). According to Gartner Group, these standards have reached the “plateau of productivity,” a term Gartner applies to technologies whose value is demonstrated and accepted.

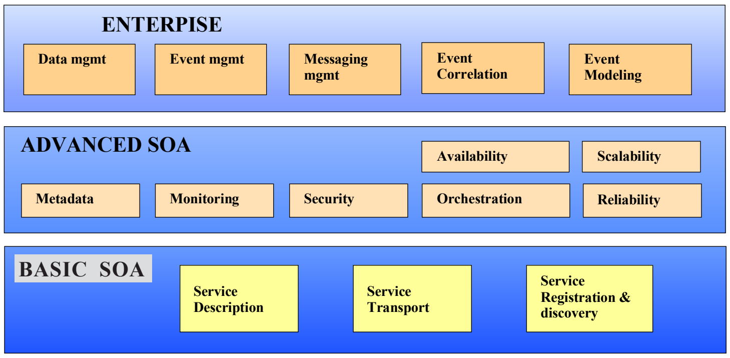
An important step towards interoperability in SOA is the formation of the WS-I—the Web Services Interoperability Organization—an organization driven by vendors. This organization’s role is to assure that the “common language” of Web services (and the entire supporting infrastructure around it) is interoperable among implementations.

The WS-I has published a “basic profile” which describes how to build and use the base Web services standards to ensure interoperability. In addition, a version of the “security profile” has also been published.

Can SOA Be the Key Driver of Virtual Enterprise Integration?

Ashkenas, Ulrich, Jick, and Kerr (2002) described the emergence of the “Boundaryless Organization” that in-

Figure 1. Functional elements of service-oriented architecture



creasingly requires organizations to consider four boundaries; vertical, horizontal, external, and geographic, in determining the shape of their enterprise. Web service environments can support horizontal integration by delivering the standardized technological infrastructure that will enable organizations to more effectively share knowledge and collaborate within and beyond organizational boundaries (Estrem, 2003). Typical benefits that SOA brings to virtual enterprise IT are:

1. **Interoperability:** Through the addition of a thin and transparent layer to existing software, Web service–enabled components can communicate with each other via a platform-independent messaging protocol. This ability completed by a semantic interoperability, will enable two Web services to interact with each other despite their semantic differences. Only with semantic interoperability could different applications in members of a virtual enterprise build a composite application that exchanges data with each other's business systems.
2. Web services can provide the infrastructure that would support virtual enterprise relationships (Estrem, 2003). This would provide the flexibility and agility that could support manufacturing approaches by reducing the complexity and driving down the transaction costs associated with outsourcing and extended value chain operations between principals and their agents. The ability to dynamically integrate functions that are spread across the value chain would reduce the time, cost, and complexity associated with establishing the relationships needed to support virtual business processes.
3. **Incremental and Flexible Development and Deployment:** Conventional monolithic IT systems apply many technologies and exchange data and requests via multiple connections. The resulting dependencies between systems are so numerous that system reconfigurations—for example, to support a new business requirement—are often extremely time consuming. Tight coupling between applications may render conventional architectures so fragile that changes become prohibitively complex. SOA, in contrast, is much more flexible. Web services present many new potential opportunities to significantly reduce the complexity and costs of enterprise computing for developing and maintaining e-business applications (Huang & Chung 2003)
4. **Low-Cost Development of New Business Processes:** In the traditional software development process, translating requirements into working distributed systems is both time-consuming and difficult, requiring several stages of manual development and deployment. This complex, error-prone task can be effectively streamlined using a higher-level, component-based SOA architecture. SOA's components ease of development considerably lowers total development costs. Development of new business solutions for the virtual enterprise is reduced to an assembly of service components that do not require the in-depth technical skills when coding solutions from scratch.
5. **Easier Version Control and Dynamic Configuration Management:** SOA permits fine-grained control over deployments across the virtual enterprise. Components within a process can be easily replaced by new or updated components, further reducing the time taken to modify or change an existing process in response to business requirements.
6. **Clarity of Application Alignment:** Traditional application design bound by conventional architectures has pursued a technology-driven approach to the automation of the enterprise's business

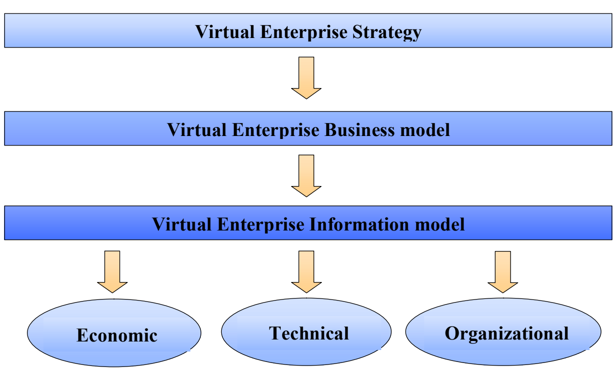
processes. Under SOA the emphasis is given to a business solution–driven approach where created services are more meaningful and hence more accessible to business users. This approach shifts effort to a much closer alignment between the IT function and virtual enterprise member companies' business units.

Interoperability is the key issue for virtual enterprise operation but the use of Web services is not a panacea. A lot of management and security challenges come up when dividing up monolithic applications into collections of distributed services. As many early adopters have discovered (Actional Corporation, 2004), XML firewalls and Web services management products are necessary to preserve anticipated return of investment (ROI) and resolve the many infrastructure issues appearing such as security, routing, versioning, provisioning, and transformation of Web services. The most important challenges fit into three contexts which are: economic, technological, and organizational (Estrem, 2003) Figure 2.

Standards do not guarantee interoperability. This is particularly true in software development and SOA where standards are designed to support many different uses across many different types of organizations. In the security standards for example, many different types of credentials are allowed related to the way a user is identified (e-mail, username, digital certificate, etc.) If both the sender and receiver do not understand the same types of credentials then they cannot communicate. Thus there is an obvious need to agree on specific subsets of standards narrowing down the available options via policies and procedures.

SOA components can be developed by different teams of developers, each of which focus only on their specific functions. In such a development model none has visibility into all of the moving parts that make up their overall application. This scenario is even worse in virtual enterprise integration development where services are owned by different companies. This has a number of implications. For example, how does an application team ensure visibility across the services owned by various enterprises across a virtual enterprise and how in that case can they ensure that their overall application is secure? If their application will be exposed to partners and customers via the internet, how do they ensure that the services they use are not vulnerable to malicious attacks aimed at stealing or corrupting information? Further, who has a truly global view of all the interrelated services that are driving the member's applications overall? Who dictates security and business policy as it relates to shared services?

Figure 2. Virtual enterprise framework



Economical Context

The valuation of Web services in the virtual environment is a multidimensional problem. While the analysis must include economic and financial factors, other factors must be considered as well. In recent years, strategic cost management methods such as total cost of ownership (TCO) have been employed as a means of evaluating information technology investment alternatives (Ellram & Siferd, 1998). However, Daghfous and White (1994) have showed that making decisions solely based on narrow differences in financial measures such as ROI, TCO, or payback period, could result in erroneous decisions. Instead, they suggested that an innovative technological concept, such as Web services, be evaluated in four dimensions: inventive concept, embodiment merit, operational practice, and market dynamics.

With traditional business applications or SOA development for internal use to the organization, it is easy to estimate the initial implementation cost and ongoing operational and maintenance costs and thus the pricing policy. However, who pays for a service shared by many applications in various organizations participating in a virtual enterprise? A possible payment scheme would be that each line of business pay proportional to their use—those who use it most should pay the most. Essentially this is a transfer pricing model. However the problem in such a case is how to track usage by each line of business—if you cannot measure usage, how can you charge for it!

Organizational Context

Web services are easier than previous generations of distributed computing innovations (Estrem, 2003). However, the dimensions of transformation and exploitation will be more challenging. According to Zahra and George (2002), transformation relates to the organization's capability to harvest and incorporate knowledge into its operations, combining the newly acquired and assimilated innovation with existing organizational knowledge. Organizations that can successfully exploit Web services to transform their business processes could achieve significant competitive advantage. However, this process will require significant organizational learning and change. In order to provide more functional frameworks, researchers have found that Web services can be combined with agent technology. Hao, Shen, and Wang, (2005) propose a virtual enterprise framework which permits VE operation in a more flexible, scalable, and interoperable way. This framework is based on Web services and agent technologies which are combined to provide an integrative solution for enterprise collaboration.

FUTURE TRENDS

Virtual enterprise integration and operation will greatly depend on Web services and SOA standards adoption from a corporate perspective. How is corporate adoption progressing? An IDC's study from 2003 (just a few years after the SOA standards appeared) shows that among large organizations (those with more than 1000 employees), 96% were actively pursuing Web services technologies. Of these organizations, 50% already had at least one Web service project in production, while the remaining 50% were either evaluating or running pilots with the technologies. Of the organizations with Web services in production, 81% had more than one Web service project in production.

Given that trend, it is safe to assume that the adoption of Web services and SOA has progressed even further than these figures indicate. Organizations are embracing these standards (Ziff Davis Media Custom Publishing, 2004) and deploying Web services for many internal projects and sometimes modern organisation schemes like virtual enterprises. However, most organizations and specifically SMEs have yet to fully capture the value available to them through a strategic use and reuse of services through a service-oriented architecture. SOA's true value escalates when organizations harness the economies of scale of consolidation and reuse. When an organization moves from ad hoc use of collections of Web services to a more formalized SOA, the value of those services rises dramatically (Actional Corporation, 2004).

CONCLUSION

Clearly, projects deployed with Web services and SOA can achieve an important level of business process abstraction. The interoperability and integration issues can successfully be addressed through SOA. The experience on projects addressing the interoperability issue between organizations is very positive according to Gartner and IDC research.

However, there is work to do, specifically to the wider standards adoptions between medium and small enterprises. The lack of custom tools drives developers to manually recode services or provide "glue code" so that they can interconnect with one another. Such painstaking labor deprives SOAs of much of their virtue—namely, rapid integration and composite application.

Wider virtual enterprise models acceptance tightly connects with the ease of integration at the business process level, and this in turn relates closely with SOA acceptance and adoption. This cohesion makes us more optimistic about the future of virtual enterprises.

KEY TERMS

Business Process (of a Virtual Enterprise): A set of linked activities that are distributed at member enterprises of the virtual enterprise and collectively realize its common business goal.

Service-Oriented Architecture: A software architecture that starts with an interface definition and builds the entire application topology as a topology of interfaces, interface implementations and interface calls

Service Consumers: Software that embeds a service interface proxy (the client representation of the interface).

Services: Software modules that are accessed by name via an interface typically in a request-reply mode.

Software Agents: Pieces of code that present some unique characteristics like autonomy, collaboration and learning.

Virtual Enterprise: Set of economic actors, mainly enterprises, that combine their strengths to provide a specific service traditionally provided by a single enterprise.

Web Services: Modular business services with each module fully implemented in software and delivered over the Internet. The modules can be combined, can come from any source, and can eventually be acquired dynamically and without human intervention when needed.

Simulation Technologies for Enhancing Citizen Participation

John O'Looney
University of Georgia, USA

INTRODUCTION

In the first decade of the 21st century, citizenship is increasingly channeled into and organized through digital communications and experiences (Center for Technology in Government, 1999; Fountain, 2001; Larsen & Rainie, 2002). This article presents an overview of a set of new information technologies—online modeling, simulation, and decision-support technologies that have the potential to transform the way citizens understand complex issues and communicate that understanding to fellow citizens and governmental decision makers.

Those who have thought deeply about democracy and technology tend to understand that new technologies often possess both beneficial and detrimental traits. These traits are also likely to occur with respect to simulation technologies for citizen participation (Shapiro, 1999; Sunstein, 2000). Whether simulation technologies will ultimately be more beneficial than detrimental will ultimately be determined by how the next generation of simulation designers do their jobs. One purpose of this article is to identify factors that these designers should consider.

What defines and makes simulation technologies unique is their ability to act as a new mode of communication. Models, simulations, and decision-support technologies communicate as much through experience as they do through any direct effort to convey a specific message. As Marshall McLuhan (1967) suggested, things are different when the medium becomes a major part of the message. In the case of models, simulations, and decision-support technologies, the medium can be much more than the video presentations that McLuhan identified as having such an impact on our culture. Specifically, these technologies can exist as entire miniature worlds of experience and can possess features that address multiple senses at one time. Moreover, simulations can be designed to specifically stimulate higher cognitive functions as well as our sense of discovery and history.

Although the terms *model, simulation,* and *decision support* are similar (see Key Terms) in that all of them involve some use of representations to help human beings understand processes, each term possesses some connotations that can be useful in different circumstances. For example, *simulations* seems to imply a greater level of experience on the part of the user when compared to models and decision-support technologies. Similarly, the term *decision-support technologies* (or *expert systems*) tend to imply a more *goal-oriented representation* of a problem. Although it is important to understand the subtle differences among these terms, for the purposes of this article I will use the term *simulation* to refer to the entire spectrum of these technologies.

Scientists and engineers have long used computer modeling, simulation, and decision support, but only recently have these technologies been employed in support of citizen participation in policy development. This article describes the uses of, the rationales for, and the trends behind the employment of these simulation technologies in this manner. Specifically, I examine three major factors that are driving the trend toward the use of simulations to promote citizen participation as well as to identify factors that will enable citizens and public managers to make better use these technologies.

BACKGROUND: INCREASING CITIZEN UNDERSTANDING OF AND ENGAGEMENT IN GOVERNMENT

Effective citizen participation is often affected by the citizens' understanding of how their dreams of the future can be realized through public-policy choices. Although many public policy choices are made based on the application of existing knowledge, some policies can only be evaluated based on how different sets of assumptions would affect the future. Specifically, simulations can be very valuable when

- *feedback loops* are too long;
- there are complicated interactions among numerous variables (Brown & Jones, 1998);
- the real-world equivalent of the simulated world is inaccessible;
- exploring numerous "what-if" scenarios in the real world would be too expensive; and
- observations are too rare in the real world.

One can observe many of the circumstances that support the use of simulations in helping citizens and public employees to better understand their world. Examples include understanding

- complex *ecological systems*;
- how different transportation policies impact different values (e.g., travel time, pollution, accessibility, beauty, etc.);
- how to respond in an emergency; and
- the complex trade-offs involved in a budget process.

In addition to overcoming limitations to using the real world as a policy test bed, simulations can also be used to help

- stakeholders recognize problems (e.g., that the flow of pollution will threaten an important water source in 15 years);
- solve computationally difficult problems faster and/or more reliably;
- stimulate new ideas (e.g., what would the neighborhood look like were the city to allow higher density development?);
- develop evidence to justify a position or to provide explanations (Kidd, 1985);
- provide advice or shape the discussion of an issue (Carroll & McKendree, 1987);
- provide a kind of accountability (e.g., experiencing a simulation prevents one from being seduced by someone's overly optimistic vision; Teicholz, 1999); and
- citizens examine trade offs (e.g., between cost and value; Jones, 1997).

There is not enough space to list the extended catalogof simulations that are being used to inform citizens about public policy. O'Looney (2003) provided descriptions of simulations that span numerous areas of public policy and civic knowledge. The number and variety of simulations being used in the planning process has, for example, become so great as to lead the Environmental Protection Agency to commission a study of strengths and weakness of various planning-support software (U.S. Environmental Protection Agency, 2000).

UNDERSTANDING AND ENGAGEMENT

If increasing citizens' *understanding* of government is the first step in enhancing citizens' participation, increasing the capacity to *engage* government officials, programs, and policy-making processes represents the next step. *Engagement-supporting technologies* tend to include communications and data aggregation capacities that help people communicate more about what they know. An engagement simulation might be one that links a simulation experience with online opportunities for communications (e.g., the city council of Kalix, Sweden, facilitated online deliberation by citizens in the redesign of the town center. After looking at renovation plans and options, citizens could give their opinions and vote online; HM Government/UK Online, 2002, p. 26).

Whereas increased understanding is an individual goal, engagement involves a group. Also, engagement tends to occur around more concrete or situation-specific events or challenges such as

- identifying the likely impacts of a land-use plan over a set period of years, and
- identifying areas that should be targeted with public funds for redevelopment.

Because engagement-focused simulations tend to address a more specific domain or problem, they are often more complex and more difficult for citizens to use in comparison to simulations for increasing understanding, which can work as simplified or "teaching model" simulations.

FACTORS LEADING TO AN ENHANCED ROLE FOR SIMULATION TECHNOLOGY IN CITIZEN PARTICIPATION

Factor 1: Citizens Demanding More Participation

As levels of education have risen, so has the desire to participate more actively in government policy making. Similarly, legislative requirements, changing professional norms, and recognition of the value of social capital are legitimizing an enhanced role for citizens in numerous areas of pubic affairs and management (Thomas, 1995). Governmental advantages of citizen involvement include increased problem-solving ability, better channels for communication, improved program implementation, and a more streamlined budget process (Norris, 2002; Thomas, 1995).

Although the benefits of citizen participation are well recognized, the actual promotion and acceptance of online technologies that enhance citizen involvement and participation has been less prevalent (O'Looney, 2000b, 2001). For citizens, online technologies that allow for more efficient participation would seem to be an ideal solution.[1] However, public managers and officials have often shown only lukewarm support for these technologies for a number of reasons, including

- their negative experiences with online technology such as e-mail (e.g., officials are often flooded with messages, leading some to stop accepting e-mail from constituents; Congress Online Project, 2004);
- the lack of experience with and substantial additional work involved in managing citizen participation;
- the uncertainty of the legal foundation for using or not using certain technologies; and
- the increased technical complexity of public policy issues that makes it more difficult to include lay citizens as equal participants and more likely that managers will depend on the advice of experts (Jasanoff, 1990).

The use of simulation technology in the general culture, the creation of a more stable legal foundation for online transactions, and increasingly positive experiences with online public technologies should help a new generation of managers become more comfortable with using technology in citizen-participation efforts. However, the lack of policy expertise (or access to or ability to purchase expertise) among ordinary citizens may be the most difficult barrier to overcome. Fortunately, simulation technology can play an important role in addressing this deficiency.

The online simulations help overcome the cost and access to expertise problems by incorporating much of the knowledge of experts into the application. This is particularly the case in decision-support technologies. Well-designed simulations can also act as jargon-free teaching tools that can begin to educate citizens so that they are more capable of participating in public decision making processes.

Simulations may also be able to help address another problem that has been noted with much of the online communications related to civic issues—its failure to promote deliberation. That is, instantly available online communications can prompt knee-jerk rather than deliberative responses (Pethokoukis, 1995). It tends to work against the slowness that is characteristic of *deliberative processes* (Barber, cited in Doheny-Farina, 1994, p. 79). Simulations can work to promote deliberation by structuring the pace at which participants to go through certain steps to match the deliberative demand of the issues (O'Looney, 2003).

Factor 2: Changes in the Way the Next Generation is Learning or Could Learn

A cursory look at the growth of simulation- or game-based learning suggests that the next generation of citizens may come to expect simulations as part of citizen outreach efforts. Schools in the last 10 years have purchased educational games and simulations by the thousands (O'Looney, 2003). Moreover, sales of commercial simulation and computer games estimated at $14 billion certainly support the idea that game-based or experiential learning is the preferred way for the next generation of citizens to learn. Moreover, whereas some computer gaming has been criticized for leading to social isolation and violence, new research indicates that moderate computer game play (e.g., 18 hours a week) is associated with higher levels of concentration and coordination, particularly in the visual mode (Subrahmanyam, Kraut, Greenfield, & Gross, 2000).

The potential for building a new learning paradigm around simulations has not been lost on the educational-technology community. Development of sophisticated simulations that are better adapted to the higher learning needs of students has occurred in areas such as consumer research, business, crisis management, science, social science, civic education, *international relations,* organizational operations, and urban and regional planning (O'Looney, 2003). Schank (2000) and other educators are calling for a major restructuring of academic courses into goal-based scenarios or simulations that get children excited about learning.

Factor 3: Building on the Science of Learning and Decision Making

Ultimately, simulations are be more likely to be adopted for citizen outreach if they can actually improve their ability to learn. Findings suggest that simulations may have a role to play in this regard . Specifically, simulations may be useful in helping to address important preconceptions, to deepen and organize knowledge, and to improve reasoning and learning strategies. For example, educational simulation can be designed to insure that students are tested for common preconceptions that could impede (or facilitate) learning. Based on efficient diagnosis of this type, the simulation can more effectively move students from their initial understanding to a grasp of new concepts (Bransford, Brown, & Cocking, 1999; Donovan, Bransford, & Pellegrino, 1999).

Bias represents a particular type of preconception. It is particularly problematic in deliberations over complex public issues. Participants may experience perceptual, social, and organizational factors that can distort their decision making. New knowledge about these decision-distorting factors suggests that simulations and decision-support technologies may have a role to play in reducing bias. O'Looney (2003) described in detail exactly how simulations can be designed to help overcome bias. For example simulations can be designed to emphasize objective quantity values rather than more subjective perceptions; for example, by more prominently displaying certain utility measures (e.g., *net benefits*) that are considered to be more relevant to good policy decisions (Kemp & Willetts, 1995; Wilkenfeld, Kraus, & Holley, 1998). Similarly, based on research on learning attitudes (Dweck & Bempechat, 1983), educational simulation designers are building learning environments that force impulsive students to work through problems step by step rather than to simply recall an answer (Hickey, 1999; Hickey, Wolfe, & Kindfield, 2001).

Simulations can also help people to deepen and organize their knowledge by making learning more meaningful from the very beginning. In traditional classrooms, students typically learn in two distinct phases. In the first phase, they learn hundreds of facts, names, and concepts. In the second phase they are challenged to wrestle with relationships and meaning. Because simulations typically allow people to observe, experience, or even manipulate complex objects and to point to or demonstrate what they mean *before* they have learned the technical names for these objects, it becomes possible for students earlier to grasp larger meanings.,Well-designed simulations can therefore help reestablish the appropriate sequencing of the "romantic" (or motivational) and "technical" phases of learning (Russell, 1961). For example, in a water management policy simulation developed at the Carl Vinson Institute of Government, players can place various types of buildings or foliage in various locations with different soil types and slopes, and they can also implement various policies (e.g., related to septic systems). Using different models of the interaction between buildings, connecting highways, soil type, slope, and impervious surface, the simulation calculates run-off coefficients and identifies the resulting levels of water pollutants. Players do not need to know the technical specifications for all the factors in order to begin to see that certain policies will have specific impacts on water quality and quantity. Simulations can also help to teach new reasoning skills such as cause–effect reasoning that are important in a number of policy areas, such as climate change, risk analysis, and health policy. Simulations accomplish this by sequencing events and tasks so as to force people to think about effects of their causes.

Finally, simulation technologies can help make people aware of their current learning strategies and to improve upon them. For example, it is common for educational simulations to track learners' responses, interpret what these mean in terms of a learning strategy, and provide relevant feedback and suggestions. This process by which learners are gradually guided from less effective to more effective learning strategies is known as *scafolding*.

FUTURE TRENDS

The prospects for using simulations effectively to address citizen engagement and understanding will depend on software creators overcoming three key barriers to development, outlined in Table 1.

CONCLUSION

How far governments are willing to support the development of simulations for citizen participation will depend on factors such as (a) whether the results are worth the resources spent on development or the time needed for a simulation player to reach exemplary performance and (b) whether simulation participants are challenged to think at a higher cognitive level (Miller & Singleton, 1997).

Similarly, the worth and effectiveness of simulations will involve the following factors:

- Fitting simulations within the larger array of techniques such as media campaigns for enhancing citizen understanding (City of Denton, 2000; Davis, 1997; McKeever, Hanson, Thomas, & Snyder, 1999).
- Correctly orienting simulation experiences within the spectrum from gamelike to serious experiences. Although "gamers" may increase tacit knowledge (e.g., of how a simulated world works), they may not necessarily gain in conscious understanding or an ability to apply knowledge to other fields (Rieber, 1996; Rieber & Noah, 1997; Rieber et al., 1996).
- Ensuring that the context for use is appropriate (e.g., will not result in detachment or act as a substitute for needed face-to-face interactions; Turkle, 1997).
- Ensuring that the simulation offers opportunities to explore different perspectives and deliberation (Judge, 1997).
- Identifying the appropriate role of government in developing simulations. Software such as SimCity is frequently criticized for policy biases (e.g., "tax too much and you lose") and the lack of transparency. Government may need to play a role in supporting development of unbiased and transparent simulations (Turkle, 1997).

S

Table 1.

Barrier	Possible Response
Simulations not designed with citizens in mind	Design simulations that build on the user's prior knowledge and are attentive to individual needs and learning styles. Design simulations that are specialized enough to help citizens understand a specific set of public policy tools, but general enough to allow a layperson to approach the subject without undue trepidation Create user-friendly interfaces to existing complex simulations, (e.g., PriceWaterhouseCoopers new interface to Transims built by Los Alamos National Labs (Kulisch, 2001)
Lack of Effective Funding Strategies	Support initiatives such as the Digital Promise project of the Century Foundation designed to create new training materials for civic engagement by using techniques such as modeling, simulation, and advanced information visualization techniques. (Weber, 2001). Follow the European Commission's Information Society Technologies (IST) Program funding model in which funded programs must be both commercially viable and provide a means for citizen access to products, information, and services. (European Commission, 2001).
Lack of support from Public Managers with concerns about cost or accuracy	Provide funding to off-set the cost of transforming a simulation developed for a policy study into a more generalized simulation for use by citizens and other governments. Insure that designers put time limits or warnings on their applications when there is a potential for inaccuracy in the simulations due to time-sensitive data (O'Donoghue , 1998). Include disclaimers related to use of simulations to demonstrate the advantages of policies different from current government policy.

Finally, although one can and should ask for transparency in simulations for civic education, one may also need to recognize that people regularly use computers in the real world to perform tasks where the underlying workings of the computer remain obscure. As the sociologist Paul Starr (1994) pointed out, "policymaking inevitably relies on imperfect models and simplifying assumptions that the media, the public and even policymakers themselves do not understand." Obviously, the development of simulations for citizen use will involve similar trade-offs.

S

KEY TERMS

Decision-Support (or Expert) System: A type of application program that makes decisions or solves problems in a particular field by using knowledge and analytical rules defined by experts in the field (PC AI, 2005).

Deliberative Processes: A careful discussion, pondering, and weighing of facts.

Ecological Systems: The organization and interactions of communities of living things, together with the chemical and physical factors in their environment.

Engagement-Supporting Technologies: Technologies that enable people to learn and communicate with fellow citizens about a specific policy-related event or challenge.

Feedback Loops: A self-perpetuating mechanism of change.

Goal-Oriented Representation: An application designed to solve rather than simply describe a problem or process.

Model: A representation of reality used to simulate a process, understand a situation, predict an outcome, or analyze a problem. A model is structured as a set of rules and procedures (U.S. Environmental Protection Agency, 2005).

Net Benefit: Benefits that remain after costs are subtracted.

Scaffolding: The process by which learners are gradually guided from less-effective to more-effective learning strategies.

Simulation: A software package that recreates or simulates, albeit in a simplified manner, a complex phenomena, environment, or experience (Schumaker, 1999).

Small Business and Regional Portals in Australia

Arthur Tatnall
Victoria University, Australia

Stephen Burgess
Victoria University, Australia

Mohini Singh
RMIT University, Australia

BACKGROUND

A portal is a special Web site designed to act as a *gateway* to give access to other related sites (Tatnall 2005b). It is often used as a base site that users will keep returning to after accessing other sites, and is often seen as a starting point for specific groups of users when they access the Web. What is unique about Web portals is the way that these special sites are now being used to facilitate access to other sites that may be closely related, in the case of special purpose portals, or quite diverse in the case of general portals (Internet.com, 1999).

There are many differences in the ways in that small businesses adopt and use information technology (IT) by comparison with larger businesses. Small businesses are constrained by a lack of resources (time, money and expertise) and the strategic, longer-term focus necessary to plan effective use of IT. These differences extend to the adoption and use of the Internet and electronic commerce. This article considers the still evolving concept of *portals* and the potential use of community and regional portals by small businesses. Benefits that portals can provide to small businesses are discussed here, and two Australian regional portals are contrasted against the more generic e-mall to illustrate the benefits that portals can provide for small businesses.

The term *Web portal* is overused and difficult to define precisely. There is no definitive categorisation of the types of portal, but Tatnall (2005a) offers the following:

1. **General Portals:** Portals can aim to provide links to sites that can be either closely related or quite diverse. General portals provide links to all sorts of different sites of the user's choosing, many having developed from being simple search tools (such as Yahoo), Internet service providers (such as AOL), and e-mail services (such as Hotmail).
2. **Vertical Industry Portals:** Usually based around specific industries and aggregate information relevant to particular groups, or 'on-line trade communities' of closely related industries. They aim to facilitate the exchange of goods and services in a particular market as part of a value chain.
3. **Horizontal Industry Portals:** A portal is described as *horizontal* when it is utilised by a broad base of users across a horizontal market. Horizontal industry portals are typically based around a group of industries, or a local area.
4. **Community Portals:** Often set up by community groups, or are sometimes based around special group interests. They attempt to foster virtual communities where users share a common location or interest, and provide many different services. Sometimes community portals represent specific regional areas (and are thus called *regional portals*).
5. **Enterprise Information Portal:** The term enterprise (or corporate) information portal is often applied to the gateways to the corporate intranets that are used to manage the knowledge within an organisation.
6. **E-Marketplace Portals:** These extended enterprise portals often offer access to a company's extranet services and are useful for business-to-business processes such as ordering, tendering and supply of goods.
7. **Personal/Mobile Portals:** Following the trends towards mobile (or pervasive) computing personal/mobile portals are increasingly being embedded into mobile phones wireless PDAs and similar devices.
8. **Information Portals:** These can be viewed as a category in their own right as portals whose *prime* aim is to provide a specific type of information.
9. **Specialised/Niche Portals** are portals designed *primarily* to satisfy specific niche markets, but often could also be classified as Information Portals.

Eduard (2001) refered to portal Web sites as being the *fourth* stage of development of a business Web sites. The earlier stages are:

1. Dumb Web site,
2. Simple interactive Web site, and
3. Transactional interactive Web site.

The fourth stage of Web sites development, according to Eisenmann (2002), is where the business attempts to become a focus of attention for customers (and perhaps suppliers). It becomes the first "port of call" for that group for many of their needs, perhaps linking through to other businesses. This opens up options for other forms of revenue, such as advertising or sales commissions.

PORTALS AND SMALL BUSINESS IN AUSTRALIA

Internet business use is well known for new, evolving, and interchangeable terminologies. A few years ago what we now know as portals were generally known as e-malls, either generic or specialised, especially in the retail industry. More recently, portals also include a very narrow vertical structure such as www.rmit.edu.au/ebusiness/, which is aimed at a small community with specific information. Many small businesses involved with portals usually do so as a *user* rather than setting up the portal themselves (Eduard, 2001). One of the best mechanisms by which small businesses can become involved is through regional and community portals.

A number of regional and community portals, whose primary function is to service the needs of small businesses, exist in Australia. In the remainder of this article two typical small business regional portals are contrasted against the more generic e-mall. In each instance, the portals are examined to see whether they provide the benefits indicated. For the first regional portal and the e-malls, the authors gathered details via observation of the actual portals themselves. For the second regional portal, details were gained from a series of interviews with various stakeholders. While not atypical, the authors do not claim that these portals are representative of all portals in Australia.

THE EBIZNET PORTAL

Background of Organisation

Ebiznet (www.ebiznet.com.au) was set up in 1997 by a number of regional development boards in South Australia for the purpose of increasing awareness and use of communication technologies in the regions to boost economic development and employment growth (Ebiznet, 1999a). A number of separate Web sites were set up within the project, including the Adelaide Hills Regional Portal (www.adelaide-hills.com.au), Information about the operation of the Web sites was extracted from the Web sites by the authors in October 2002. The Adelaide Hills Regional Portal offers a number of services (Ebiznet, 2000):

- **Come Visit:** Links to accommodation, dining, events and shopping information, as well as details about local attractions and location maps.
- **Go Shopping:** Links to regional businesses that have successfully taken their business online and are utilising e-commerce.
- **Do Business:** Links to information Web sites on government and other business services.
- **Live Here:** This section is more for individuals and families.

Description of E-Commerce Using the Portal

Small businesses were primarily interested in the Go Shopping and Do Business links. To set up the project, IT personnel in the regions formed part of a project team that went through a series of interrelated development stages aimed at providing awareness of the Internet and its business applications. The main emphasis was on e-commerce. Work began with the development of cost effective e-commerce applications and establishment of a range of demonstration Web sites with e-commerce capacities, including shopping carts. Training in IT business applications and use of the Internet was also provided. The project was specifically targeted to regional small businesses. In particular it aimed to facilitate e-commerce solutions for small businesses that were judged unlikely to otherwise acquire the necessary skills (Ebiznet, 1999a).

Functions provided by local Web service providers were project management, strategic planning, Web design, hosting, e-commerce, Web marketing, Web maintenance, and training (Ebiznet 1999b). Initially, information seminars were run for small businesses, but these were not well attended. It was felt that this was because of a lack of advertising dollars and effort. Those that did attend found the seminars to be very useful and were particularly interested in the e-commerce applications. Training courses were subsidised and were oversubscribed, with extra courses being run. It was felt that *local* examples were most important to the success of the courses (Ebiznet, 1999a).

Impact of the Portal on Small Business

A number of the businesses operated using secure online payments on the Adelaide Hills Web site. These ranged from accommodation to provision of food and wine, a general store and an online recruitment agency. Other community portal sites within Ebiznet offered a similar structure to Adelaide Hills. A total of 26 businesses were part of the secure online shopping area of the Ebiznet sites.

The benefits to small businesses that became involved in Ebiznet (2000) were the opportunity to receive subsidised training, the technology itself and secure payment processes set up and available to use. They also had the chance of traffic heading to their own Web sites through the portal and there was the opportunity to support the local region. Unfortunately this portal recently ceased operation.

THE BIZEWEST PORTAL

Background of Organisation

In June 2000, the Western Region Economic Development Organisation (WREDO), a not-for-profit organisation sponsored by the six municipalities that make up the western region of Melbourne, Australia, received a government grant for a project to set up a business-to-business portal. The project was to create a horizontal portal—*Bizewest*, that would enable small businesses in Melbourne's west to engage in an increased number of e-commerce transactions with each other. In setting up the Bizewest Portal it was noted that the majority of e-commerce activity currently occurs on a business-to-business level (Department of Industry Science and Tourism, 1998). It is estimated that transactions of this type comprises 80% of all electronic commerce (Conhaim, 1999) and that this is likely to remain the case in the near future (Straub, 1998).

Description of E-Commerce Using the Portal

The main objective of the Bizewest Portal project, in its initial stages, was to encourage small to medium enterprises in Melbourne's west to be more aggressive in their up-take of e-commerce business opportunities, and to encourage them to work with other local enterprises in the region also using the Portal (Pliaskin & Tatnall, 2005; Tatnall & Burgess, 2002). The project was to create a true business-to-business portal on which online trading was to occur. The initial plan was to gain the participation of about three hundred SMEs from the local region in the use of the portal to facilitate their business-to-business and business to local government interactions. Another important project goal was youth involvement and students from the local high schools and colleges who were studying IT-related subjects, were to be given the opportunity to 'consult' with SMEs on a one-to-one basis in the development of their Web pages for the portal. When the Portal was launched, a payment gateway was not initially included, meaning that orders could be placed but that full transaction processing functionality was not initially available. It was always intended that a payment gateway be added to the Portal as soon as this was possible. After some initial delays the Bizewest Portal went online in June 2001.

Once the portal was operational, getting local business online was the next step and this involved two parts: convincing regional SMEs to adopt the portal, and providing them with suitable Web sites to link to the portal.

Impact of the Portal on Small Business

An important group in local adoption of the portal were the five companies designated by WREDO as business champions for this project. One of the business champions was a medium-sized Melbourne company, with about 100 employees, that stores frozen food and transports it to supermarkets and other locations around the country. A major reason that this company adopted the portal was the hope that it would provide a better opportunity to deal with people in the local region (Tatnall & Burgess, 2004). A firm of solicitors had also just started making use of the portal and were trying to work out the best ways to utilise it to advantage. Their primary goal was to use the portal to increase their visibility. Another business champion was a small printer with 15 employees that had just begun using the portal. They saw the portal as having "fantastic possibilities," but there were some problems in difficulty with customers being able to contact them via the portal. Finally, a textile company just outside the metropolitan area were using the portal mainly for promoting their image but did intend to move to B-B operations in the future. One of the problems that this company faced was lack of computing expertise, which is a common problem in small business (Burgess, 2002). Despite some successes, however, in early 2003 the WREDO Board decided that Bizewest was costing too much in relation to the benefits it was providing, and reluctantly closed the portal down.

There is a distinct contrast between the 'usefulness' to small business as reported on the Web site of Ebiznet and that resulting from actual interviews with small businesses participating in Bizewest. The interviews indicated that there were some less obvious reasons for linking with the community portal – such as "it seemed like a good idea" and "we didn't want to be left behind."

E-MALLS

Background

An e-mall consists of a number of e-shops, and serves as a gateway through which a visitor can access other e-shops. An e-mall may be generalised or specialised depending on the products offered by the e-shops it hosts. Revenues for e-mall operators include membership fees from participating e-shops and customers, advertising, and possibly a fee on each transaction if the e-mall operator also processes payments. E-shops, on the other hand, benefit from brand reinforcement and increased traffic as visiting one shop on the e-mall often leads to visits to neighbouring shops.

Description of E-Commerce Using the E-Mall

Visitors to e-malls benefit from the convenience of easy access to other e-shops and ease of use through a common interface (Farhoomand & Lovelock, 2001).One example is Internet Marketing (http://www.e-mall.com.au/index.htm), which is a community directory that lists local businesses and community services in the area of Sydney's west. The e-mall Web site promotes itself as offering solutions from Web site development to listings in local business directories, allowing the move to a Web presence to be "cheap and easy." The Australian Internet Shopping Mall (http://dkd.net/mall/holesale.html) offers a range of services, including a national presence and regional divisions. Both of these enterprises have therefore recognised the value of regional or local influences on their participants.

Impact of the E-Mall on Small Business

E-malls enable small businesses to promote their business, tap into infrastructure for online business already set up for transactions, expand market reach by acquiring new users and to be listed on search engines. They also allow these businesses to participate in community building, supplement their hardware sales with revenues from online services, partner with other providers and increase the value of their products and services, retain traffic to their Web sites, invest in marketing activities at reduced costs, and remain innovative. Where they have differed from regional portals is that, although there are benefits in relation to cost efficiencies and possible market expansion, they have not tapped into community relations, but this may be changing.

DISCUSSION

Do the portals examined provide significant benefits to small businesses? Table 1 summarises the findings of the authors in this respect.

The two regional portals investigated here offer services, a consistent infrastructure and search and directory services to allow businesses and consumers to find the products and services they are after. E-malls offer some of these services (depending upon the mall), with the added advantage of having access to a wider market—*if* that is what the small business desires. In the end, the small business must balance the benefits of regionality against what an e-mall may offer. It still seems, however, that there is potential for the regional portals we have examined to develop further, especially in the areas of

Figure 1. Australian Internet shopping mall

Figure 2. E-mall Internet marketing

Table 1. Benefits of example portals

Potential Benefits	Ebiznet	Bizewest	E-Malls
A Secure Environment	Secure catalogue, order and payment facility provided.	Secure environment developed after initial launch.	Not all e-malls offer ordering and purchasing. Some just offer links to business Web sites (cheapest solution). Others offer full service.
Search and Directory Services	Directory, but no search provided.	Search and Directory options are provided.	Search and Directory options are provided.
New Partnerships	No service for 'bidding' for business; but training was provided.	No service for "bidding" for business; links to providers of training are provided.	Will sometimes link to printed directories.
Community Building and Regional Relationships	Community news; community notice boards; community contact details.	"Regional" services include maps; government services; youth services.	Starting to introduce "regional" categories for their services.
Strategy, Management and Business Trust	Infrastructure is identical for all participants.	Infrastructure will be identical for all participants.	Again, it depends upon the e-mall. Those that only offer links to business websites do not offer identical infrastructure for all participants.
Improved Customer Management	No "special deals" in relation to attracting customers are apparent.	No "special deals" in relation to attracting customers are apparent.	Some can provide cross-promotional opportunities.

fostering new partnerships and improving customer relationships.

CONCLUSION

With developments in the Internet, and its increased application to business in the last 10 years, portals have developed, largely from being directories and search engines to new e-business model selling and advertising goods and services. Within the e-business model, portals are generic, specific to an industry, vertical or community based. There has been considerable growth in community portals in recent years and more small businesses have capitalised on this and achieved revenue growth. Small business benefits anticipated from community portals include: increased customer loyalty, improved business relationships, enhanced trust in e-business, lower infrastructure costs, easy access to expert advice, increased market share and expanded business. Regional portals add the benefit of community participation, a very strong part of many small businesses, to the list of portal strengths (although e-malls are beginning to address this). Our investigation of portals indicates that there is scope to increase the level of benefits that they can provide to small businesses.

KEY TERMS

Community Portals: often set up by community groups or based around special group interests, they attempt to foster the concept of a virtual community where all users share a common location or interest, and provide many different services.

Electronic Commerce: Computers, communications technologies and information systems used by people to improve the ways in which they do business.

E-Mall: A number of e-shops that serve as a gateway through which a visitor can access other e-shops.

Horizontal Industry Portals: Portals utilised by a broad base of users across a horizontal market.

Small Business: Those businesses with 1-20 employees.

Vertical Industry Portals: Usually based around specific industries, they aim to aggregate information relevant to these groups of closely related industries to facilitate the exchange of goods and services in a particular market as part of a value chain.

Web Portal: A special Internet (or intranet) site designed to act as a gateway to give access to other sites.

SME's Perceptions of B2B E-Commerce

Assion Lawson-Body

Eastern Illinois University, USA

INTRODUCTION: BACKGROUND OF ORGANIZATIONS

The primary objective of this study is to examine the effects of the Internet's Web tools (the level of Web content and the level of security on the Internet) on the interorganizational relationships (IOR) between small and medium-sized enterprises (SMEs) and their loyal customers.

This article focuses on B2B electronic commerce because according to a recent report, the value of goods and services sold via B2B electronic markets will reach $2.7 trillion by the year 2004 (Gartner Group, 2000). While these figures give the impression that B2B electronic commerce is expanding fast, the fact remains that many SMEs are still sitting on the sidelines (Caldeira & Ward, 2002; Lam, Shankar, Erramilli, & Murthy, 2004; Teo, Wei, & Benbasat, 2003). Many SMEs that maintain IOR with their customers have difficulties achieving the benefits as suggested by media and early research (Lituchy & Rail, 2000; Poon, 2000; Tagliavini, Ravarini, & Antonelli, 2001). In addition, there is little existing research that has empirically tested the impact of the Internet's Web tools on IOR which lead to customer loyalty.

The Study Sample

The sample consists of 1700 SMEs in the USA and Canada, each having a Web site and an e-mail address. Company size is measured by number of employees (Chow and Holden, 1997). In this study, an SME is one with less than 500 employees. The senior sales representative, company executive, or president of each of the above companies was sent a cover letter through the Internet (by e-mail) along with the URL of the Web site containing the research instrument (questionnaire). As an incentive, respondents were told that a summary of the results would be sent at their request. A total of 386 SMEs responded, producing a 22.7% response rate. The response rate achieved is acceptable, given the length of the research instrument, the technical and confidential nature of the information requested and the nature of the respondents.

Characteristics of Participating SMEs

The respondents were spread across 10 different industry sectors. Seventy-four percent (74%) of the respondents were primarily involved in Manufacturing, Information Technologies Hardware/Software, and others sectors. In terms of annual sales volume, 40% of the sample had annual sales of less than $1 million, while 42% had annual sales between $1 and $10 million and 18% don't want to share that information. About 40% of the SMEs had less than 10 employees, while roughly 42% had less than 50 employees. Approximately 14% of the SMEs possess between 50 and 500 employees. Only 4% possess more than 500 employees.

Most of the participating SMEs (about 64%) have been in business for more than 10 years, while 32% have been in business between 1 and 9 years. A total of 75% of the respondents claimed to have had a company Web site in existence for 1 to 6 years, while 18% of SMEs claimed to have been online for less than one year. A total of 81% of the SMEs have 10% of their budget invested in Web site development and/or maintenance, while 7% of SMEs invested between 11 and 30% of their budget in online resources. Only 2% of SMEs invested more than 50% of their annual budget in Web site development and/or maintenance. In terms of location, 18% of SMEs are located in the western part of North America; the same percentage is located in the eastern part; while 9% does business in the southern part, and 43% in the northern part of North America. The rest of SMEs (12%) is spread across other regions.

THE THEORETICAL RESEARCH MODEL AND HYPOTHESES/ DESCRIPTION OF E-COMMERCE

The use of Internet technology to link SMEs to their customers can be demonstrated to have an effect on their loyal customer base. The Internet's Web tools, such as the level of Web content and the level of security on the internet, can support the formation and maintenance of

IOR because they facilitate the way organizations cooperate with, depend upon, and trust each other. The quality of a Web site can directly influence the type of relationships developed between SMEs and their loyal customers.

The key constructs of the research model, identified through the objective of this article, are as follows: the dependent variable will be drawn from customer loyalty construct, the independent variables will be drawn from the IOR construct and the moderating variables will be drawn from the Internet's Web tools construct.

Customer Loyalty

In this article, loyalty is defined as building and sustaining a trusted relationship with customers that leads to the customers' repeated purchases of products or services over a given period of time (Gefen, 2002; Lam et al., 2004). Customer loyalty, in general, increases profit and growth in many ways to the extent that increasing the percentage of loyal customers by as little as 5% can increase profitability by as much as 30% to 85%, depending upon the industry involved (Gefen, 2002).

IOR from SMEs Perspectives

In this study, an IOR is defined as the process whereby an SME builds long-term relationships with current customers so that both seller and buyer work toward a common set of specified goals (Evans & Laskin, 1994).

Trust is a critical factor in any IOR in which the trustor does not have direct control over the actions of a trustee, and there are possible negative consequences of one party not fulfilling its obligations (Jarvenpaa & Tractinski, 1999). IOR are built around interactions and can be characterized by a tension between autonomy and interdependence, between team loyalty and individuality, and between competition and cooperation (Nouwens & Bouwman, 1995). The primary goal of an IOR is to achieve a competitive advantage via mutual loyalty in relation to companies outside their network. Therefore an IOR is heavily dependent upon relationships based on cooperation, interdependence and trust. They are discussed in the following:

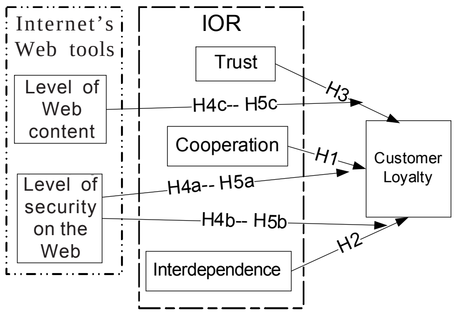
1. **Cooperation:** It is defined in this study as coordinated actions taken by parties to achieve mutual outcomes (Lewin & Johnston, 1997). Cooperation promotes effective relationship success. Cooperation is proactive because it suggests actively agreeing to advertise a partner's products.
2. **Interdependence:** Parties involved in an IOR become interdependent when there are significant switching costs associated with replacing the incumbent suppliers (Lewin & Johnston, 1997). Interdependence is an important relationship variable (Reichheld & Schefter, 2000). A loyal customer will remain with a vendor because the cost of switching to another vendor is too high (Reichheld & Schefter, 2000).
3. **Trust:** Trust is a willingness to rely on an exchange partner in whom one has confidence (Berry, 1995). Becoming a trusted partner of a customer is a key to maintaining IOR. Trust can be achieved by providing the customer with valuable information using a high quality Web site.

Internet's Web Tools

There is an existing need to investigate the tools that make a Web site effective for B2B electronic commerce. According to Dholakia and Rego (1998), the Web possesses several tools that effect the electronic commerce system, including: (1) the Web is an easy and inexpensive way to advertise, lowering the barriers to entry for SMEs; (2) the Web overturns the traditional hierarchical system of distribution channels, that is, former channel partners become competitors in the global marketplace; (3) unlike traditional means of communication, such as newspapers or television, the Web gives the customer control of choosing and processing information about the firm; (4) the breadth of the medium allows wider availability, accessibility, and selection of hard-to-find products/services (Dholakia & Rego, 1998). The Internet's Web tools range from simple associatively linked collections of static hypertext documents to interactive, integrated, customizable solutions and agent-based negotiation support (Gefen, 2002); and since the Internet's Web tools were initially developed to address the development of B2C transactions, they can also be effectively applied in B2B settings as well (Gebauer and Scharl, 1999). There are essentially two variables that encompass the construct of the Internet's Web tools: the level of Web content and the level of security on the Internet.

1. **The Level of Web Content:** The level of Web content is defined as the new Internet-based channels through which SMEs can display information about themselves and the products and services they offer or, better yet, as a dynamic interactive portal (Joseph, Cook, & Javalgi, 2001).
2. **The Level of Security on the Internet:** The level of security on the Web is defined as the risks associated with Web technology assets such as loss, disruption, and unauthorized access of information, data, and Internet resources (Cavusoglu,

Figure 1. Theoretical research model



Raghunathan, & Mishra, 2002). One of the greatest concerns about doing business on the Internet is the level of security in transactions (Cavusoglu et al., 2002). The perception of unsatisfactory security on the Internet is one of the primary hindrances of IOR. Despite advances and endeavors in Internet security mechanisms, companies are still concerned about using an impersonal transaction medium like the Internet for secure transactions (Cavusoglu et al., 2002). Although organizational acceptance of the risk of conducting transactions over the Internet is growing, it is still wavering.

The Research Model

This research model enables us to test the following hypotheses.

- **H1:** Cooperation will have a positive effect on customer loyalty.
- **H2:** Interdependence will have a positive effect on customer loyalty.
- **H3:** Trust will have a positive effect on customer loyalty.
- **H4:** The level of Web content will have a positive effect on the relation between IOR and customer loyalty.
- **H4a:** The level of Web content will have a positive effect on the relation between cooperation and customer loyalty.
- **H4b:** The level of Web content will have a positive effect on the relation between interdependence and customer loyalty.
- **H4c:** The level of Web content will have a positive effect on the relation between trust and customer loyalty.
- **H5:** The level of security on the Internet will have a positive effect on the relation between IOR and customer loyalty.

Table 1. Reliability coefficient rho

Variables	Coefficients Rho
Interdependence	0.869
Cooperation	0.754
Trust	0.726
Loyalty	0.735

- **H5a:** The level of security on the Internet will have a positive effect on the relation between cooperation and customer loyalty.
- **H5b:** The level of security on the Internet will have a positive effect on the relation between interdependence and customer loyalty.
- **H5c:** The level of security on the Internet will have a positive effect on the relation between trust and customer loyalty.

ANALYSIS AND RESULTS/IMPACT OF E-COMMERCE ON THE ORGANIZATIONS

Measures

All of the measures were selected from the survey instrument used by Lawson-Body (2003) in his study. After slight modification, the questions measuring all of the variables, except loyalty, used a scale of 1 (never) to 5 (always). The questions measuring Interdependence used a scale of 1 (disagree very strongly) to 6 (agree very strongly). The scale used to measure Loyalty was 1 (decreasing sharply) to 5 (Increasing sharply). Since the instruments have been slightly revised from the original ones, reliability coefficients have been obtained.

The test of reliability on the sample of the 386 respondents was carried out with a statistical tool named PLS-GRAPH. Table 1 presents the reliability coefficients Rho. Its first column presents the independent and dependent variables of the research model. The second column of table 1 presents the indicator of the reliability of a measure which is the Rho coefficient. Aubert, Rivard, and Patry, (1994) report that the guidelines established by Nunnally (1978) for the interpretation of Cronbach's alpha also apply to the Rho coefficient. These guidelines estimate that acceptable reliability coefficients must be higher than 0.6. It can be seen that all Rho coefficients are ranged between 0.735 and 0.869. This is considered very satisfactory.

To measure the Internet Web tools variables, the evaluation grid, mounted according to the guidelines offered by Kassarjian (1977) and found in the study of

Lawson-Body (2003) was used. Internet's Web tools such as the level of Web content and the level of security on the Internet were evaluated by two judges: the researcher and a graduate student. The inter-judges reliability coefficient is 81%. Berelson (1952; cited in Kassarjian, 1977) claimed a range located between 66% and 95% for acceptable inter-judges reliability coefficients. The ratio of 81% appeared to be satisfactory.

Procedures for Testing the Hypothesis

Gefen et al. (2000) have used PLS method to process and analyze data because of its exploratory nature and its emphasis on explaining variance (Gefen, 2002). Gefen (2002) also used PLS method to analyze the dimensionality of SERVQUAL. Finally, Aubert et al., (1994) have used PLS method to analyze the development of measures to assess dimensions of information systems operation transactions.

In this research, Partial Least Squares (PLS), a second generation multivariate method was used to process and analyze the data. The PLS method simultaneously evaluates both the measurement model and the theoretical model. It adjusts the relationships among the variables accordingly (Aubert et al., 1994). PLS was selected in this research because it presupposes no distributional form on the data.

The test of Hypothesis H1, H2, and H3 on the sample of the 386 respondents was carried out with a statistical tool named PLS-GRAPH. Table 2 shows that Student's T (t value) of impacts of interdependence (2.2856), cooperation (2.0041), and trust (1.7780) on customer loyalty are higher than 1.65 ($P<=0.05$). This first hypothesis test shows that these three variables of the IOR have a positive and direct impact on customer loyalty. In other words, customer loyalty is increased ($R^2 = .78$) by interdependence, by cooperation, and by trust, supporting H1, H2, and H3 respectively.

The coefficient of T-statistic and the weights presented in Table 3 show that only some indicators (items) contribute to the formation or creation of the variable customer loyalty and the three variables (interdependence, cooperation and trust) which have impact on customer loyalty. The indicators with (*) asterisks in table 3 bring their contribution to the creation of the variable they are connected to. According to the values of their T-statistics, some indicators contribute more than others to the formation of their variables. The indicators presented in Table 3 which do not have (*) asterisks do not play enough role in the formation of their corresponding variables.

To test the interaction effects, analysis was pursued with the three variables (interdependence, cooperation, and trust) that have a positive and direct impact on customer loyalty. The two variables of the Internet's Web tools play a moderating role. Therefore the interaction tests of Hypotheses H4, H5, and H6 were carried out with PLS-GRAPH. Table 4 presents the results of this test of the interaction effect and the size of the interaction effect, including the statistical values of the Student (T-statistic).

The results from the survey of 386 SMEs in North America concur: because of the significant value of T-statistics in the last column of table 4, the Internet's Web tools (which include the level of Web content and the level of security on the Internet) have a positive impact on the relation between cooperation and interdependence, and customer loyalty. However, that impact is debatable for trust. The path coefficient with interaction is lower for the impact of the level of Web content on the relation between trust and customer loyalty; this indicates a lower size of the interaction effect. That impact differs from the

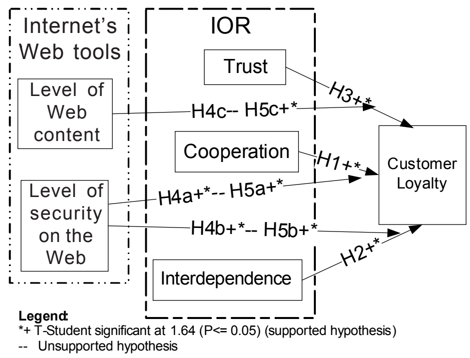
Figure 2. Results of PLS analysis



impact of the level of security on the Internet on the relation between trust and customer loyalty. For example, the beta for the impact of trust on customer loyalty is 0.3104. The interaction betas for the impact of the Internet's Web tools on the relation between trust and customer loyalty are 0.3108 and 0.2419 respectively. In consequence, the use of non-secure Web tools reduces the impact of trust on customer loyalty and the use of secure Web tools doesn't increase or decrease the impact of trust on customer loyalty. There are improvements with the interactions between the use of Web tools and interdependence, and the use of Web tools and cooperation on loyalty. The betas for the impact of interdependence on loyalty and for the impact of cooperation on loyalty are 0.2364 and 0.3331. The interaction betas for the impact of the Internet's Web tools on the relation between interdependence and loyalty are 0.2895 and 0.2960. The interaction betas for the impact of the Internet's Web tools on the relation between cooperation and loyalty are 0.3419 and 0.3459.

DISCUSSION AND CONCLUSION

We found support for eight of our nine hypotheses. More importantly, we found that the use of Web sites increases cooperation and interdependence between SMEs and their loyal customers. We also found that the impact of the use of secure Web sites on the relation between trust and customer loyalty is neutral. However, we failed to find support for the impact of the use of non-secure Web sites on the relation between trust and customer loyalty. That means, if SMEs use non secure Web sites to maintain a relationship with their customers, trust in SMEs will decrease, therefore customers will be less loyal to SMEs.

The main contribution of this study has been to provide empirical evidence on the impact of the Internet's Web tools on the relation between cooperation, interdependence, and trust and customer loyalty. In fact, business is based on trust between two parties, whether the business is conducted in person, by phone, or over a Web site. The customer can get a sense of the company and the person from face-to-face discussions or from the appearance and location of the office; but this element of trust is difficult to reconstruct in electronic transactions because all the customer knows about the supplier is what can be seen on the Web site. Therefore, creating trust via the Web depends on fostering IOR through electronic means of well-established Web tools. When SMEs treat the Web as more than just a communication tool, the trust between companies will grow, an IOR will be developed and maintained, and customer loyalty will develop.

The results of this study show that SMEs are perceived to be flexible and adaptable in terms of structure and speed of response. Therefore SMEs are perceived to promptly adopt the Internet's Web tools technologies. SMEs are set to benefit from the adoption of B2B electronic commerce because of the lower-cost Internet technologies. Some authors conclude that because the entry barriers are so low, SMEs can establish presence on the Internet, which thus helps level the playing field between small and large firms.

The findings of this research will help SMEs identify the IOR factors which they should emphasize when the Internet's Web tools are used to augment customer loyalty.

Future research is necessary because Internet technology evolves so rapidly and its evolution may likely affect in different ways the relationship between trust and customer loyalty. Additional research should also expand the range of the Internet's Web tools variables and examine their effects on the link between IOR and customer loyalty.

ENDNOTE

[1] See APPENDIX A at the end of the article for the full definition of the items.

APPENDIX A: FULL DEFINITION OF THE ITEMS

	Loyalty
Items	Questions
LOYAVE	The average number of years during which your firm maintains business relationships with its customers
LOYREGS	Your firm maintains business relationships with its customers
LOYPERP	The percentage of sales to regular customers (customers with whom your firm maintains business relationships) out of your firm's total sales
LOYPERT	The percentage of sales from regular customers instead of one time sales
LOYPERF	The frequency of sales from your firm's regular customer
LOYPERH	The total dollar value sales from your firm's regular customer
LOYEXP	The average yearly revenue per regular customer
LOYNBF	The number of your firm's regular customers
LOYGEN	In general, your firm's customers repeat purchases of products and/or services.
	Interdependence
Items	Questions
INDCOST	In your judgment, the total costs to your firm in switching to a competitor's product line would be
INDTERM	The average length of time your firm relationship lasts with your customers
INDDIFF	Differences of opinion between your firm and its customers will probably be viewed as just a part of doing business
INDBENEF	Differences of opinion between your firm and its customers will likely results in benefits to both of them
	Cooperation
Items	Questions
COOPHELP	Your firm helps out its customers in whatever ways they ask
COOPDECI	Customers have considerable latitude in deciding how much technical support they get from your firm for their products
COOPOLIC	Your firm complies with the policies that customers establish for the marketing of their products
COOPRECO	Customers follow whatever recommendations your firm makes regarding the marketing and selling of its product line
	Trust
Items	Questions
TRUSTPRO	I have found that my firm's customers can rely on it to keep the promises that it makes
TRUSTHON	My firm is basically honest toward its customers
TRUSTIME	In my firm's relationship with its customers, it cannot be trusted at times
TRUSTCOU	In my firm's relationship with its customers, it can be counted on to do what is right
TRUSTINT	In my firm's relationship with its customers, it has high integrity
TRUSTEXP	My firm enjoys a high level of trust with its customers

Software Metrics and Measurements

Michalis Xenos
Hellenic Open University, Greece

INTRODUCTION

In the past few years, a large number of e-government and e-commerce systems have been developed, thus resulting to a constantly increasing number of software developers involved in software development for such systems. To ensure the production of high quality e-government and e-commerce systems, it is important for developers to collect and analyze measurable data that guide estimation, decision making, and assessment. It is common sense that one can control and manage better what he is able to measure.

Although there are major differences between e-commerce and e-government (e.g., access, structure and accountability; Jorgenson & Cable, 2002) there are no significant differences in terms of software metrics that can be applied to both. Metrics are used in e-government and e-commerce software development to measure various factors related to software quality and can be classified as product metrics, process metrics and recourse metrics. *Product metrics* are also called software metrics. These are metrics that are directly related to the product itself, such as code statements, delivered executables, manuals, and strive to measure product quality, or attributes of the product that can be related to product quality. *Process metrics* focus on the process of software development and measure process characteristics, aiming to detect problems or to push forward successful practices. *Resource metrics* are related to the resources required for software development and their performance.

This article focuses on product metrics and on how such metrics can aid in design, prediction and assessment of the final product quality, provide data used for decision making, cost and effort estimation, fault prevention, testing time reduction, and, consequently, aid in producing better software for e-government and e-commerce systems.

BACKGROUND

Measurement is the process by which numbers or symbols are assigned to attributes of entities in the real world so as to describe such entities according to clearly defined rules (Fenton & Pfleeger, 2004). In software development, measurements are conducted by using metrics. A *metric* is an empirical assignment of a value to an entity aiming to describe a specific characteristic of this entity. Measurements have been introduced into the e-government and e-commerce software development process in order to satisfy the need to control software development and produce higher quality results.

Since the mid 1970s when the first software metrics were proposed, a large number of metrics have been proposed in the following years. The proliferation of metrics was followed by more practical proposals on how to interpret results from metrics (see Shepperd & Ince, 1990) and methods combining metrics into measurement methodologies (see Xenos, 2003).

Public or private entities involved in software development for e-gsovernment and e-commerce applications can select from a variety of applied metrics those that are more suitable to be included in the development process (e.g., see Goodman, 2004; Kan, 2003). Therefore, taking into account the volume of literature that exists about software metrics, it is no more a question of finding metrics for an e-government or e-commerce project, rather than selecting the appropriate ones and extensively training engineering teams to utilize them (Hirsh, 2005). Given the large number of metrics (measuring almost everything), any attempt to select a metric without basing the selection on a detailed breakdown of the development needs and an extensive investigation of the proposed metric's applicability would result in minor benefits from its use or no benefits at all. To benefit from the use of metrics, apart from fully understanding the various existing metrics, one should also define well *why* he wants to measure, *what* to measure and *when* is the right time to measure it.

So the first question is: *Why use metrics?* The answer to this question is that metrics are needed to provide understanding of different elements of e-government and e-commerce software projects. Because it is not always clear what causes a project to fail, it is essential to measure and record characteristics of good projects as well as bad ones. Metrics provide indicators for the developed software. As Ragland (1995) stated, indicators are metrics or combinations of metrics that provide insights of the software development process, the software project, or the product itself. Measurements aim at the assessment of the status of the development process and the developed product. Therefore, metrics can be used for performance evaluation, cost estimation as Stamelos and Angelis (2001) have proposed, effort estimation, improving productivity, selecting best practices and—in general—for improving the quality of e-government and e-commerce systems.

This discussion leads to the next question: *What to measure?* As previously mentioned, process and product are what we need to measure. One may argue that, since the result of e-government and e-commerce projects is software, what we need to measure is only software. This is not true. According to Deming (1986), if the product you have developed is erroneous, do not just fix the errors, but also fix the process that allowed the errors into the product. This way you will not have to keep fixing the error in subsequent productions. Therefore, both process and product metrics and measurements are important in e-government and e-commerce software development.

It must be noted that, before selecting the appropriate metrics, it is very important to define the desired product quality characteristics. The selection of quality characteristics aids in defining what needs to be measured and what needs not, depending on the particular needs of the e-government and e-commerce application. In the early 1970s, McCall, Richards, and Walters (1977) defined a framework for measuring such characteristics and proposed the Factors Criteria Metrics model—also known as FCM model—defining what is software quality in terms of subcharacteristics. Incorporating FCM and experience from similar proposals, years later, the ISO standard ISO/IEC 9126 (2001) standardized what product quality is in terms of subcharacteristics. Therefore the definition of product quality is important, as product metrics are used in the software development procedure to measure those product characteristics that are related to product quality.

Having defined the goals and reasons for measuring, the next question is: *When to measure?* Although measurements should be conducted throughout the entire e-government and e-commerce software development life cycle, their scope varies depending on the development phase. Different measurement goals are defined at different development phases, thus resulting into different kinds of metrics. In the early phases of e-government and e-commerce software development, metrics are used mainly for estimation purposes. It is useful to collect metrics relating to different projects as these can serve as historical data for future projects, aiding in better results.

In the intermediate phases of the e-government and e-commerce development process, metrics are used for project monitoring purposes and, in the meantime, code metrics are used to prevent errors. Furthermore, defect reports during testing are used for evaluating product quality and calibrating the measurement methods of the early phases. This purpose is also served by collecting external measurement data following project delivery, namely during the beta testing or maintenance phases of an e-government or e-commerce project. So the time to measure is determined by the requirements and the aims of the measurement program and can vary from a project to another.

Summarizing, using an oversimplifying statement, it could be said that metrics are an important instrument for the development of software to be integrated into e-government and e-commerce systems; metrics aid in making estimations in the early phases of a project, preventing problems in intermediate phases and evaluating quality in the late project phases.

USING METRICS IN SOFTWARE DEVELOPMENT FOR E-GOVERNMENT AND E-COMMERCE SYSTEMS

This section classifies product metrics in two categories—internal and external—provides a short definition and examples of each category, and discusses their advantages and disadvantages. The section concludes by presenting how these metrics can be combined and used in software development for e-government and e-commerce systems.

Product metrics can be categorized (Fenton & Pfleeger, 2004) as internal product metrics and external product metrics. *Internal product metrics* are those used to measure attributes of the product that can be measured directly by examining the product on its own irrespectively of its behavior. *External product metrics* are those used to measure attributes of the product that can be measured only with respect to how the product relates to its environment.

Internal Metrics

Internal metrics can be classified in three categories based on the product attributes they measure. These categories are size, complexity, and data metrics. As far as internal product metrics in general are concerned, it is important to mention that one of their major *advantages* is that they are easy to automate and therefore data collection can be made in an easy, automated, and cost-effective way. Furthermore, the measurement results can also be analyzed in an automated way using statistical techniques and thus conclusions can be drawn rapidly. Tools such as QSUP (Xenos, Thanos, & Christodoulakis, 1996), Emerald (Hudepohl et al., 1996), GQM automation (Lavazza, 2000), and so forth have rendered internal measurements very easy to conduct. The screenshot from the metrics results

Figure 1. The results presentation window from QSUP Internal metrics

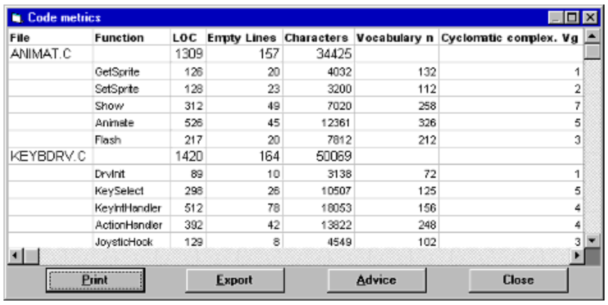

Table 1. High-level characteristics of e-commerce systems

Characteristics of e-commerce systems	Related quality factors
Easy access to the Web pages of the e-commerce system	Functionality, Usability, Efficiency
Easy navigation	Functionality, Usability
Adaptation to user profile	Functionality, Usability, Efficiency
Search engine service	Functionality, Usability, Reliability
Easy exit—undo functions	Functionality
Useful help service	Functionality, Usability, Efficiency
Electronic shopping cart	Functionality, Usability
Electronic shopping list	Functionality, Usability
Secure and reliable transactions	Functionality, Reliability
Security protocols SET, SSL	Reliability
Correct and accurate information about the products	Reliability
Direct delivery of the products	Usability, Efficiency
Indisputable financial transactions	Reliability
Recoverability of products and services	Usability, Functionality
Legitimate Web site	Reliability

of QSUP shown in Figure 1 is an example of the simple and automated way in which such measurements can be conducted. For further examples regarding metrics application, see Xenos (2003).

On the other hand, it should be mentioned that a major among the *disadvantages* of internal product measurements is the fact that they are often difficult to interpret. In other cases, the internal quantities measured are not clearly related to the external quality characteristics that one wants to assess. Such problems can only be solved in the framework of a well-defined measurement method that combines internal and external metrics, as will be discussed next.

External Metrics

Based on the ISO/IEC 9126 (2001) standard and on similar works such as Jung and Kim (2004), the *external factors* affecting software quality are Functionality, Usability, Efficiency and Reliability. For their definitions see "Key Terms," as defined by Kitchenham and Pfleeger (1996). External metrics are used to measure directly these four factors or the characteristics of which these factors are composed. For example, a set of high-level quality characteristics of e-commerce systems is presented in Table 1 (Stefani & Xenos 2001). This is important for the distinction between generic metrics and metrics defined especially for e-commerce systems.

Unlike internal metrics (measuring software internal characteristics and aiming at relating measurements of such characteristics to these factors), external metrics measure directly these factors or their characteristics. Such metrics can be based on subjective estimates. Among the means employed by external metrics are surveys on user opinion providing valuable measurements for software functionality or usability. Measures like defect reports or mean time between failures are used to determine product reliability, whereas measures like memory usage are used to determine efficiency.

As already mentioned, the application of external metrics implies that a certain extent of subjectivity is involved; even metrics that appear to be objective are often characterized by some degree of subjectivity. For example, defect reports seem to be a solid metric that can be used to objectively measure reliability. But the number of defect reports submitted by a user is influenced by issues such as the time and the extent of product usage, the user experience and even the user's motivation to edit and submit a defect report. Therefore, such metrics must be analyzed very carefully and under a framework that will take under consideration such issues.

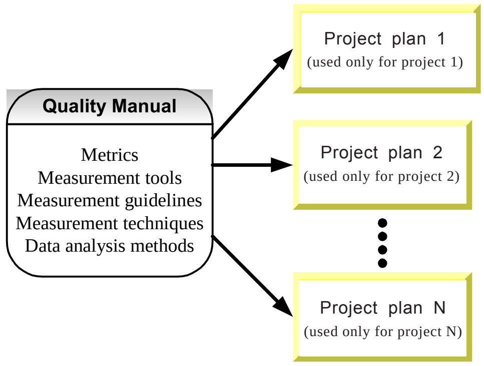
One of the major *advantages* of external metrics is that they measure directly the desired external product quality characteristics, thus no further analysis or interpretation is needed. Additionally, external metrics contribute to a great extent to what is considered to be one of the main goals of e-government and e-commerce quality: user satisfaction. On the other hand, *disadvantages* and problems should be seriously taken under consideration when deciding to use external metrics, the most important of which being that such metrics are not objective and as a result additional effort is required to ensure their objectivity. Furthermore, they are not as cost effective as internal measurements and in many cases it is difficult to conduct measurements due to high error rates especially in cases that error detection techniques have not been used during measurements.

Combining Internal and External Metrics into a Measurement Method

As already mentioned, internal and external measurements must be conducted under a well-defined framework with precise goals. Before selecting the appropriate metrics for any project, a *quality manual* should be established collecting and documenting all metrics available for use in the software developing entity. This manual is a basic component of the metrics application process and includes the metrics, the measurement techniques as well as the guidelines for the application of metrics, the data analysis and the corrective actions required for improving the developing process of e-government and e-commerce systems. It should also be mentioned that the quality manual includes all metrics that are available regardless of how many times they have been used, or the availability of measurements data from past software development projects.

Then, for each e-government or e-commerce project, a set of metrics appropriate for this particular project is selected from the quality manual. The criteria on which the selection of metrics is based are the particular quality factors that the project places emphasis on. This set of metrics is documented—using the guidelines available in the quality manual—and consists the *quality plan* of the particular project. Thus, an e-government or e-commerce project quality plan should include all the metrics, measurement guidelines and goals applicable for the project. It is self-evident that the project plan of a specific project may be entirely different from another project's plan and may use a completely different set of metrics. Figure 2 presents an illustration of the above procedure.

Figure 2. Selection of metrics for each project



The quality plan of each e-government or e-commerce project should include internal metrics so as to provide an easy and inexpensive way to detect possible causes for low product quality, as this might be perceived by the end-users, and take early corrective action. It should also include external metrics—applied during alpha or beta testing and post shipment—so as to measure external quality factors, as well as the soundness of the internal metrics and measurements results or even calibrate internal metrics.

It should be noted that the successful selection of metrics and measurement techniques to be included in an entity's quality manual is heavily dependent on the entity's maturity. The adoption of sophisticated techniques and complex metrics by a company may prove to be ineffective, if it is not supported by years of experience with metrics and measurements and large volumes of data from past project measurements. Software developing companies should always keep this fact in mind and set feasible measurement goals not aiming too high at the early stages of metrics application.

FUTURE TRENDS

For about 3 decades now, metrics have been used for the estimation of product related issues (such as product size, required effort, time required for testing, etc.) for early detection and prevention of problems during development and for product assessment after product release. Although in both cases metrics have proved to be successful in practice and have aided significantly towards developing higher quality e-government and e-commerce applications, the benefits from the use of metrics are not commonly recognized. This is partly due to the lack of awareness of metrics in small- and medium-size software developing companies. Although metrics are extensively used in large companies, in many cases, small- and medium-size enterprises are not even aware of the prospect and benefits of using metrics. However, this is constantly changing. More and more small- and medium-size e-government and e-commerce software-developing companies become aware of product metrics and measurements. Besides, the adoption of standards such as the ISO, or assessment in CMM higher levels, has contributed to this change since both standards are encouraging the use of metrics.

Another issue that is expected to change in the near future is the availability of more sophisticated tools. Although many measurement tools are available, using a number of metrics, there are not many tools available yet combining past projects' measurement data with current project data in order to aid in decision making. Combining metrics with decision support techniques, or methods for resolving uncertainty will lead to the development of valuable tools, which can aid towards higher quality software for e-government and e-commerce systems. A recent approach towards this direction (Fenton, Krause, & Neil, 2002) is using metrics and Bayesian networks for controlling software development, by automatically predicting defects in the released product.

CONCLUSION

This article introduced the reader to software metrics that are used to provide insight about different elements of e-government or e-commerce systems software. It presented internal metrics that can be applied prior to the release of the product to provide indications relating to quality characteristics, and external metrics applied after product delivery to give information about user perception of product quality.

Software metrics can be used to measure various factors related to software product development. These factors include estimation, early detection and prevention of problems, product assessment, etc. Their utilization within a measurements framework in combination to the use of automated tools can aid towards development process control and higher quality software for e-government and e-commerce systems.

Our focus was placed on the particular factors affecting the quality of e-government or e-commerce software. Such software can be measured effectively using a combination of generic internal software metrics and external metrics. The former are appropriate for most types of software, whereas the latter are designed especially for e-government or e-commerce systems.

KEY TERMS

External Metric: A metric used to measure attributes of the product that can be measured only with respect to how the product relates to its environment.

Functionality: The external quality factor that refers to a set of functions and specified properties that satisfy stated or implied needs.

Internal Metric: A metric used to measure attributes of the product that can be measured directly by examining the product on its own, irrespective of its behavior.

Measurement: A process by which numbers or symbols are assigned to attributes of entities in the real world in such a way as to describe them according to clearly defined rules.

Metric: An empirical assignment of a value in an entity aiming to describe a specific characteristic of this entity.

Quality Manual: A manual used by the software developing company that includes the metrics, the measurement techniques, the guidelines for the application of metrics data analysis, and the corrective actions required for improving the software developing process.

Quality Plan: A plan developed particularly for each software project that includes all the metrics, measurement guidelines and goals applicable for this project only.

Usability: The external quality factor that is defined as a set of attributes that bear on the effort needed for the use and on the individual assessment of such use by a stated or implied set of users.

Special Features of Mobile Advertising and Their Utilization

Jari Salo

INTRODUCTION

Mobile advertising, or m-advertising, refers to ads sent to and presented on mobile devices such as cellular phones, PDAs (personal digital assistants), and other handheld devices.[1] M-advertising can be seen as a part of m-commerce (e.g., Mennecke & Strader, 2003), which is seen as radically different from traditional commerce (e.g., Choi, Stahl, & Whinston, 1997). Thus, it can be argued that m-advertising is also different. M-advertising enables the advertiser not only to send unique, personalized, and customized ads (Turban, King, Lee, Warkentin, & Chung, 2002), but also to engage consumers in discussions and transactions with the advertiser.

Any retailer can make use of m-advertising. Thus this study focuses on the brick-and-mortar retailers' use of m-advertising in Finland. In Finland, mobile phone subscriptions reached 84% of the population at the end of the year 2002 (Ministry of Transport and Communications Finland, 2003), and more than 30% of the users under 35 years and over 20% of all users have received m-advertising in the form of SMS (www.opas.net/suora/mob%20markk%20nous.htm). However, there are no commercial solutions available for the MMS type of m-advertising. Therefore, the empirical setting of this study is a service system SmartRotuaari, which is a part of a research project (see Ojala et al., 2003; www.rotuaari.net) offering the retailers an infrastructure and a service system for context-dependent m-advertising in the city of Oulu in Northern Finland.

This study focuses on permission-based m-advertising. In Finland, that is the only form of m-advertising that is legal. Firstly, we will discuss the features of m-advertising that make it unique. Secondly, we will present some empirical results from the SmartRotuaari case. Based on the recognized features, we study which of them retailers utilized in their m-ads, as well as those remaining unused. The aim is to find out how well the uniqueness of m-advertising was portrayed in the m-ads. The study concludes by suggesting how retailers could improve the use of m-advertising in order to fully harness its power.

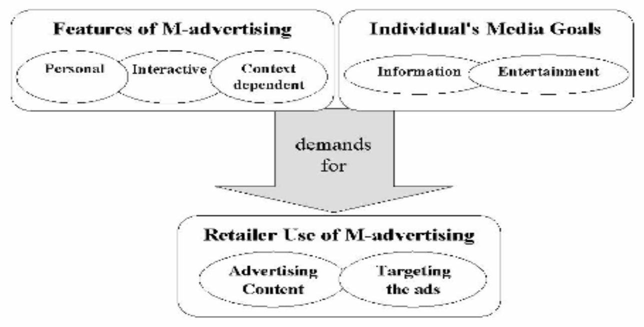
DESCRIPTION OF MOBILE COMMERCE

Based on existing research and the empirical data gathered for this study, we suggest a framework that describes the factors that influence the success of retailers' use of m-advertising. The factors are related to the media or advertising channel itself and its special features, and to the receiver of the messages—that is, the individual customer and her/his goal in using the mobile device.

Factors Influencing the Success of Permission-Based M-Advertising

Because of the special features, m-advertising can and should be used to deliver ads which are different from the traditional ones. The special features include: the personal nature of the device, the interactivity that the device enables, and the context dependency that the infrastructure enables. The features influence the type of content that permission-based m-advertising should offer to the consumer in order to be perceived as valuable and/or entertaining. The value of the content is also related to the individual's needs and reasons for using the media, such as media goals (Juntunen, 2001). A person may use a mobile device to receive information, but also for the purpose of personal entertainment. Both these goals influence the expectations she/he has for the mobile ads. Unless the consumer perceives permission-based m-advertising positively, she/he can deny the company or any company the permission to send ads to her/him. Thus it is vital for a m-advertiser to be aware of the special features and the requirements that the features set for the content of the ads, as well as for the segmentation or almost individual targeting of the ad. In the sections below we will take a closer look at each of the features depicted in Figure 1.

Figure 1. Possible features influencing the success of permission-based m-advertising



Personal Nature of M-Advertising

M-advertising is as personal as personal selling. Mobile devices, especially mobile phones, are highly personal devices, with personally selected or even self-composed ringing tones, individually tailored covers or general appearance, and additional decorations, not to mention the 'content' of the phone, including information on personal friends as well as a personal calendar. Moreover, the users wear their device almost everywhere and at all times. Thus the personal nature of the device is transferred to the information that is sent and received through the device (see also Barwise & Strong, 2002). Therefore, m-advertising is not for the masses, but for individuals.

Interactive Nature of M-Advertising

The mobile device allows m-advertising to be highly interactive—that is, the parties can act on each other, on the communication medium, and on the messages (Liu & Shrum, 2002). A customer may reply to an ad by phoning; sending an SMS, MMS, or an e-mail; or logging into the advertiser's Web page by using the mobile device. In addition, a customer may distribute the ad to her/his friends. Such viral marketing is very beneficial for the advertiser, as the customer forwarding the ad her/himself becomes the sender of the message and therefore the message gains in credibility.

Context Awareness of M-Advertising

The first context to be taken into account is the device to which the advertisement is distributed. Unless the message is tailored to the terminal, the receiver will face problems in receiving and understanding the message. Even if such problems are avoided, the devices have a relatively small screen size, limited screen colors, and limited battery time. However, the technology used in building m-advertising systems enables context awareness. The context may be location, time, and/or weather. For example, the m-advertising service is able to locate the user's mobile device and send an ad only when the customer walks by the retailer's shop.

An Individual's Media Goals

An individual's goals are often referred to as a person's cognition of what s/he is pursuing in a particular situation and to an associated inner state of arousal (e.g., Eysenck, 1982; Pervin, 1989). Thus an individual's media goal is her/his cognition of the processing goal s/he is pursuing when attending to her/his mobile device (see Juntunen, 2001), which in this case is the medium for m-ads. Depending on what type of goal the receiver is trying to achieve by using a mobile device also affects her/his processing of the ads. If the user's media goal is information, the customer will be more interested in ads that provide her/him relevant information on products/services or companies.

On the other hand, if the customer's goals are more towards entertainment, s/he will enjoy ads that are entertaining and provide experiential satisfaction through aesthetic pleasure, emotional stimulation, or social experience (see also Barwise & Strong, 2002). A consumer may wish to achieve both kinds of goals at the same time, and the relative importance of the types may change according to the situation that s/he is in.

In the above, we have discussed the features that make m-advertising a unique form of advertising, as well as the ways users are using their mobile devices. Together they place m-advertising closer to personal selling than traditional advertising—having the same message sent to many receivers with limited control over the context. Since m-advertising is so personal, it sets new kinds of demands for the advertising planning. We will now move into considering how to plan m-advertising—that is, targeting and planning the content of the ad.

Targeting the Ads

It is possible to target m-advertising if the retailer can make use of the user-specific information that is added to the m-advertising service system. This can be done through two different, but complementary ways. Firstly, each user, when granting the permission to send ads, also fills in a user profile that can include demographic details, user's current mood (e.g., is s/he hungry, looking for fun, shopping), and areas of personal interest (e.g., fashion, food, hunting). All this can be done directly form the user's mobile device. Secondly, the retailer may use existing data from the company's customer relationship management (CRM) database, which can be connected to the mobile user's personal customer number.

Moreover, the system may obtain up-to-date weather information from a local weather station via Internet. It is thus possible to send ads of sunglasses only when the sun is actually shining. In addition, time can be used in targeting. In the morning restaurants can send special breakfast offers or in the evening they can send discount coupons for a dinner if there are seats available.

A well-planned execution of m-advertising can be more effective than, for example, direct mail (which is often left unopened) or television advertising, although the number of receivers that see the ad is considerably smaller. Based on the targeting options, the retailer can send ads that match with the mobile user's personal interests and current needs, making sure that the customer will only receive ads that s/he is willing to. This is extremely important in permission-based m-advertising, since spam messages annoy the receiver (see also Barwise & Strong, 2002; Edwards, Li, & Lee, 2002). Therefore, the advertiser can reach high view-through rates by targeting the ad successfully. In SMS m-advertising, 81% of all trialists viewed all messages before deleting them and 77% did that as soon as they received the ad (Barwise & Strong, 2002). At the same time, this means that the same ad should only be sent to each customer once during a campaign. If the campaign contains repetition, the m-ads have to be different each time they are being sent to the same consumers, otherwise they can annoy the consumer.

Advertising Content

As for the content of ads, the advertiser in any type of advertising has to decide what is being said and how to say it. Both these decisions affect the success of m-advertising as well. Kalakota and Robinson (2002) suggest that m-ads work best if customers receive concrete benefits from it, such as retail alerts, coupons, special offers, and m-tickets. However, Barwise, and Strong (2002) found six types of ads used in SMS permission-based m-advertising, ranging from messages directed to long-term effects (like brand building) to messages attempting to engage the receiver in immediate interaction with the advertiser (competitions, votes). By applying the information given by the consumer and/or information retrieved from the CRM databases, the advertiser can also provide quick and timely information (i.e., news that interests the receiver). The existing research being scarce, we do not know which type of ads are the most effective ones.

The style of the ad is also an important issue to be considered. Duchnicky and Kolers (1983) suggest that reading from mobile devices may take more time and effort than reading from a desktop computer. Because of that, and also due to the space limitations, the copy should be kept short and the use of graphics or photos is encouraged (see Edens & Cormick, 2000). Humor and surprises in the design of the ad create positive feelings toward the advertisement and may lead to viral marketing, especially among the younger receivers (Barwise & Strong, 2002). Furthermore, we assume that the personal nature of the mobile devices as well as the context specificity and novelty of m-advertising will lead consumers towards high involvement. In such situations the contrast effect appears to stimulate consumers to process the advertising even more (De Pelsmacker, Geuens, & Anckaert, 2002).

IMPACT OF MOBILE COMMERCE ON THE ORGANIZATION

The empirical part of the study is derived from the SmartRotuaari service system. The system provides a functional framework for large-scale field trials for the purpose of empirical evaluation of technology, new mobile services, customer behavior, and retailers' use of the services (for more details see Ojala et al., 2003; www.rotuaari.net). The retailers use a Web portal to send ads, which are then delivered through a WLAN network to consumers' mobile devices, in this trial the PDAs.

Retailers' Use of Permission-Based M-Advertising

The data consists of 42 m-ads that were sent to trial users (186 persons) by 12 retailers (shops, bars, restaurants, cafes) during the first field trial of the SmartRotuaari.[2] Thus, the retailers had their first experiences of m-advertising during this trial, and they had not received any special training to guide their m-ad design decisions.

Thus, this data provides a great opportunity to study how retailers that are not advertising professionals apply the uniqueness of mobile channel.

The ads were analyzed using content analysis, as it is the standard analytical tool for advertising studies (e.g., Kassarjian, 1977; Kolbe & Burnett, 1991). As suggested by Kassarjian (1977), four coders (A, B, C, and D) analyzed the commercials. However, due to confidentiality of the data, the authors served as coders as well. The authors provided the coders A and C with instructions and a brief training before they commenced the task. Since the number of ads was relatively small, all disagreements between the two pairs of coders were solved through discussion (see Kassarjian, 1977). Since the coders were able to agree on all the decisions, no measure of interjudge reliability was calculated (see Perreault & Leigh, 1989)

All m-ads used the company location as the focal point from which the distance that triggered the sending of an ad was measured. However, there were huge differences in the way the retailers used the location awareness. The distance used varied from 75 meters to 3,000 meters. The diameter of the town centre in Oulu is below the 3 kilometres, so the use of the highest distance in the location awareness does not aid the targeting of the ads. The time awareness according to certain hours of the day (e.g., opening hours, lunch hours) was used in only 18 ads, although it could have been used in every ad, so that customers would receive ads only during the opening hours.

The most-used feature of the consumer that the retailers used in targeting was age. Only some clothing shops and a few restaurants did not use it. The bars and pubs especially targeted the ads towards either the younger or the more mature customers. The mood information was used in 65% of all the ads. Especially the clothing shops and cafeterias selected customers in shopping mood, and bars and restaurants people who were hungry, thirsty, seeking company, or in a mood to party. As for the consumers' interest areas, only 14 ads included certain interest areas as criteria for targeting. None of the 42 ads used the local weather as a criterion for sending the ad.

We also analysed the content of the ads. Fifty-five percent of the ads contained either photos (people, product, or the interior of a restaurant) or graphics. The copy length ranged from 0 to 31 words. As the ads were received on PDAs, even the longest copy was readable, but it did not provide an aesthetic pleasure. From the ads, there was only one that was classified as brand building, but this is easily explained by the fact that all the advertisers were retailers, and thus most of the ads concentrated on describing the shop or the restaurant (e.g., what type of food was served). Many ads (40%) included their contact address (only three with phone number), although it was possible for the consumer to use a mobile map to locate the company. Moreover, 45% of the ads contained information on opening hours, which explains the fact that many advertisers did not use the option of sending the ad during the opening hours only. One-third of the ads included price information or special offers, thus responding to the consumer's relevant information needs. Moreover, only three ads addressed the receiver in the copy by asking them a question ("Are you hungry?") or by welcoming them to the cafe.

The retailers used very traditional profiling criteria such as the age of the customer. We can also argue that although mood or interest areas are not really a criterion that can explicitly be used in, for example, magazine or newspaper advertising, it is used implicitly when choosing the magazine (e.g., interior magazines) or placing the ad under the 'entertainment' section. Also in the content of the ad, traditional newspaper advertising was clearly the point of reference when retailers designed the m-ads. How to fit the message and the format into the context of m-advertising is a question also to be solved by advertising agencies (e.g., Kiani, 1998; Kunoe, 1998).

CONCLUSION

This study on retailers' usage of permission-based mobile advertising underlines the notion that mobile advertising is different from any other form of advertising. In addition, the retailers, using m-advertising for the first time, are not able to apply the unique features of m-advertising. Thus, both the receivers and the senders of mobile advertising messages have to learn how to use this new channel and how to fully make use of the opportunities it offers for speedy, personal, and interactive advertising communication with the consumer (see also Pura, 2002). The features of m-advertising (personal, interactive, context dependent) and individual media goals (information and/or entertainment) should be the basis to start m-advertising activities and campaigns. Therefore, the m-advertising should be personal, thus requiring a certain amount of knowledge about the receivers of the m-ads. The message of the advertisement, as well as the way it is expressed, should be carefully designed to match the needs of the target person. Moreover, m-advertising should fit into the marketing communication mix, enabling interactivity. In time, we are sure that m-advertising will move more and more towards m-crm and constant interaction between buyer and seller.

KEY TERMS

Mobile Advertisement: All advertisements sent to mobile and wireless devices.

Mobile Advertising: All advertising activities conducted via mobile and wireless devices.

Mobile Commerce: All commerce conducted via mobile and wireless devices.

Mobile Marketing: All marketing activities conducted via mobile and wireless devices.

Permission-Based Mobile Marketing and Advertising: All marketing activities conducted with permission of the consumer via mobile and wireless devices.

ENDNOTES

1 Mobile advertising can be used to refer to advertisements that move from place to place, (i.e., in busses, trucks, trains, etc.) (e.g., Hume, 1988; Goldsborough, 1995).

2 The SmartRotuaari service system consists of several mobile services, which are tested and studied in field trials. So far, m-advertising service is one possessing the most commercial potential.

Spreading Use of Digital Cash

Yutaka Kurihara
Aichi University, Japan

INTRODUCTION

Approximately 10 years have passed since the words such as *digital cash, digital money, electronic money*, and *e-cash* have been introduced. Progress has increased rapidly in the fields of communication and information technology (IT) and in the field of digital cash; its use and transaction volume have been increasing. However, little analysis has been done about this phenomenon especially from the academic field. The continued increase in its use is inevitable, and it is important to investigate its influence and problems from both practical and theoretical perspectives. The spread of the use of digital cash impacts economic activity and social structure. This article considers both the merits and the problems of digital cash in the modern economy.

This article analyzes characteristics of relationships between digital money, financial institutions, and financial authorities; considers the relation between digital cash and financial institutions; and analyzes the relation between digital cash and monetary policy authorities.

BACKGROUND

Digital cash may be classified into electronic wallet and online types (Kurihara, 2000). IC-card type digital cash has value in itself; the network type is maintained on the personal computer or the host computer. Both types of digital cash have appeared recently. The distinction between the two types has begun to disappear; Internet cash is one example.

This classification permits an examination of cost reduction and price cutting from the demand factor of the former for the reason of the cause to which digital cash spread, a technology of IC card reformation and price cutting from the supply side (U.S. Department of Commerce, 1998). The availability of the personal computer and the Internet have also prevailed, as well as Internet commercial dealings from the demand factor as an online-type personal development factor. The ongoing reduction of equipment costs (typically in computers) has helped to promote online transactions from the supply side. Electronic commerce all over the world has increased greatly. Moreover, it seems that the spread of mobile telecommunications (e.g., cellular phones) has contributed to the development of digital cash. In the near future, television or mobile phones will be used to complete financial transactions (Hammersley, 2004).

The difference between closed-loop and open-loop transactions is important. In closed-loop transactions, the transfer of the value is the same as with digital cash. For instance, when the user who receives the issue from the issue subject (typically a bank) and digital cash is allotted to pay for the commodity or service, the seller (typically, a retailer or service provider) completes the transaction for the transfer of value. Value cannot be moved among users in the closed loop, which is used in both IC-card and network digital cash transactions.

On the other hand, digital cash issued once can be used for other transactions, even if the value does not return to the issuer in the open loop. Rolling liquidity exists there. The IC-card type of the closed loop is most common in the early 21st century.

Although credit cards, checks, and debit cards have become remarkably widespread for making small payments electronically, the difference between them and digital cash is important. These transaction types should not be classified as digital cash. Considering monetary policy, the distinction from digital cash is very important.

Digital cash builds information on “near cash or itself” into the card, the network, and transactions. To qualify as digital cash, five characteristics must be present: a settlement, generality (use for any purpose), the transfer of funds, circulation (i.e., free availability), and anonymity. More concretely, digital cash is a legal currency and is legal as deposit currency. Time deposits, certificates of deposit (CD), trust money, and so on must not be included as digital cash. Debit, prepaid, and credit cards and checks do not comply with to the forgoing definition and are different from digital cash in spite of being traded in electronic form.

Although the generality of digital cash is much greater than that of prepaid cards (e.g., phone cards), it is inferior to usual money, and the transfer does not exist in the closed loop compared with current cash, either. Circulation is also low, and it is doubtful whether anonymity exists with deposit currency. Moreover, digital cash does not have the same legal status as cash. However, the examples of our statement comply with the above definition and should be classified as digital cash.

THE ADVANTAGES AND PROBLEMS OF DIGITAL CASH

Advantages

Both types of digital cash reduce cost, time, and human error. These advantages accrue both to the user and the donor of the digital cash (Davis, 2002).

With IC transactions, people do not have to carry about small change and have the advantage of high privacy buying. In network-type transactions, the buyer does not have to be present at the seller's establishment to conduct business. Furthermore, security against theft or loss is high. Even small retailers or sellers can reduce handling costs and increase business opportunities. International transactions benefit in particular (Davis, 2003).

Problems

On the other hand, there are some problems in spite of having a lot of merit, with the digital cash.

Who Pays the Cost of Digital Cash?

The cost of creating digital cash is high. The technology to manufacture cards and provide infrastructure against commitment is expensive.

How are Users Protected?

This is a legal problem as well as an economic and technological problem. For instance, it is common all over the world to construe that illegal use is the user's own responsibility in the case of online transactions. In the United States, there is a rule by which the liability is limited to $50 after the consumer's loss is borne.

Problems of the Issuing Body

Emergencies on the part of the issuing body are cause for concern. For instance, the European Central Bank (ECB) assumes that the issue of digital cash is the same as the acceptance of deposits for those who issue it. The issuing body must (a) defend the settlement system, (b) protect the consumer, (c) support the execution of monetary policy, and (d) promote competition. Only financial institutions should be able to issue digital cash.

- **User Equity:** People who do not or cannot use equipment such as personal computers, for instance, are at a disadvantage relative to other consumers.
- **Questions and Standards of Taxation:** There is a possibility of avoiding taxes incurred by digital cash. The World Trade Organization (WTO) and the United States are not inclined to tax network trading. However, the stance varies worldwide.
- **Counterfeiting:** Dealing with the problem of counterfeiting with digital cash is not as easy as with the present currency. The IC type of digital money has high privacy, but it also has the disadvantage of being easy to lose and easy to steal. In addition, money laundering has been an issue. However, digital cash transactions are not large, especially for IC type (Berger, Hancock, & Marquardt, 1996). This problem may apply more to the network type with its larger average transactions.
- **Privacy:** It is difficult to solve the problem of privacy because of the consequences of interfering with the security of network-type transactions.

DIGITAL CASH AND FINANCIAL INSTITUTION MANAGEMENT

Many banks in developed countries have adopted several kinds of Internet banking services. The possibility of cost reduction of customer services, severe competition, and increases in the number of Internet users have contributed to the prevalence of Internet banking.

The spread of digital cash has upgraded consumer access to and satisfaction with transactions. First of all, consumers need not even go to a retail establishment or ATM. With digital cash, former restrictions such as the geographical location of a shop and business hours no longer hamper consumers' ability to obtain desired goods and services. Economies of scale benefit both sellers and buyers. Even if it costs more to introduce the system for financial institutions, the customer channel can be secured widely (Davidson, 1997). SET is one example.

Some big companies are announcing an interface standard to be used for bank services. The construction cost of the system is expected to decrease further as a result. Certainly, at least handling costs of money will decrease. Movement toward the standard is becoming active in the United States. There also is some possibility that some types of settlements, particularly those beyond the type generally handled by banks, will grow with the spread of digital cash. Another possibility is a decrease in the number of branches and bank clerks required by banking institutions. Cline (1998) noted that advantages accrue to banks with fewer branches (mega commercial banks and some trust banks). The spread of digital cash may further influence financial institution management by permitting decreases in commission fees if the net settlement or the settlement at the same time is arranged. For the individual, it will be possible of losing by using the HD of a computer.

Additional management considerations are (1) banks' acquisition of business information concerning commercial distribution of creating monopoly, (2) possibility of tie-ups of institutions such as credit card companies with a set infrastructure, (3) participation by institutions other than banks may cause systemic risk. Changes in this kind of risk have been widely forecast. Operations risks may outweigh those imposed by traditional interest rates, liquidity, and market risks (Basle Commitment, 1998). Reducing the cost of acquiring information and the trend toward globalization makes it difficult for banks to monopolize technology and risk management operations (Salomon, 1996).

However, it does not seem that such a movement accelerates unilaterally. There is a view that the move to help banks obtain their vested right to profit from certain types of transactions disturbs the development of electronically managed settlement. Humphrey and Pulley (1998), BIS (2000), and Weiner (2000) stated that paper-based transactions are still mainstreams.

DIGITAL CASH AND POLICY AUTHORITIES

Digital cash influences the policy authorities. However, it is thought that digital cash is debt issued (i.e., deposited) by banks. It circulates under the assumption, guarantee, or trust that 100% of it can be changed into cash (in the form of a central bank note). Digital cash itself does not have the finality of the settlement. Policy authorities will not be greatly influenced by it in the near future. Areas of influence include the following.

Management of the Money Supply

Management of the money supply becomes difficult if settlements using deposit currency decrease as settlements with digital cash increase. Some fear the effects of the decrease of the function of deposit creation. However, there is no change in the money supply if the issued digital cash is immediately converted to currency. The problem might be the amount of money involved and the length of the time that it remains in the digital state. For instance, there is no change in the multiplier of money if the digital money is issued against a bank deposit, but the multiplier increases if digital money is issued against a national bond, for example. Moreover, there is some possibility that the multiplier becomes unstable at the diffusion period of digital cash. However, in the case of increasing the substitution of digital money for paper money, authorities can manage high-powered money and even the national debt.

It is important to consider payment preparation for the deposit. The effect of the multiplier exists as long as demand for the cash (issued by the central bank) or the preparation deposit is not extinguished. However, as digital cash prevails, the ratio of the payment preparations for the deposit becomes small. Though the spread of digital cash certainly decreases a necessary payment preparation, the multiplier rises and at the same time the effect of the monetary policy may also increase.

There is some possibility, however, that the side effect of the rise of the inter-bank market interest rates may result from a lack of preparation deposit. Moreover, the confidence multiplier expands to infinity because a legal preparation does not exist now. However, the issuing body has the payment preparation, part of it is converted into cash and a deposit, and lending demand is limited. So the one-sided acceleration of such a movement may not happen.

When the digital cash of the home country is converted into the digital cash issued in the foreign country, the management of the money supply becomes difficult.

Money Demand

The function of money is as value standard, payment instrument, and stored value. Digital cash chiefly accomplishes the function of payment instrument. Tobin's stock theory is useful when considering this aspect of digital transactions. The cost of going to a bank, changing a deposit into money, and cash demand are positively correlated. Using this theory, digital cash decreases the money demand. However, use of digital cash increases liquidity, so digital money may render money demand unstable.

It is difficult to forecast accurately the shift of the multiplier and the money demand. Policy authorities must consider these factors. In a standard theory of economics, if the shock of the economic fluctuation is real, stabilizing the amount of the money supply rather than the interest rate reduces the change of real gross domestic product (GDP; Poole, 1970). Therefore, when such shocks are not anticipated in the money market, in the appearance of digital cash, comes, it becomes important for policy authorities to stabilize the interest rate.

There has been much discussion whether or not monetary authorities should set money supply (or exchange rate) as an intermediate goal in the attainment of price stability or economic growth. The typical case in which money supply has been taken as intermediate goal is Germany (Gerlach, 1999). However, if authorities took such an instrument, they could control money supply with confidence. There should be a stable relationship between money supply and inflation. So it should be better for monetary authorities to control interest rates instead of money supply when the used of digital cash is dominant. Woodford (2000) stated that macroeconomic stabilization depends only upon the ability of central banks to control the short-term nominal interest rate.

Increased Use of Foreign Currency

If a part of domestic economic activity is accomplished using foreign currency, it may decrease the "real economy," provided by the domestic currency short-term interest rate. The influence of monetary policy then decreases because it can only influence bank lending by the domestic currency. Moreover, changes in the prices of goods and services in the foreign country may also influence the domestic economy.

Taxation Issues

Reductions in taxation may decrease revenue.

Restriction and Supervisor's Problems

Use of the Internet accommodates deposits to financial institutions in foreign countries, especially those with limited restrictions and supervisions. Monetary policy must consider the possibility of the spread of corruption from the foreign country. Moreover, there is a problem of the scope of the financial institution. Financial systems are different in each country. In addition, there is a problem of the scope of deposit insurance (See, FDIC's homepage, http://www.fdic.gov/).

Money Laundering

Government intervention regarding code keys and other transactions may arise. It is natural for authorities to want to take to such measures; however, a conflict with the individual's privacy surfaces (Mester, 2000).

Finally, the authorities lose profit, because money is a debt with no interest and the authorities get interest from asset. Yet, this is not their pursuit of profit for them.

FUTURE TRENDS

The many advantages of promoting digital cash are seductive. Accessibility provided to the elderly and the handicapped by such systems are among real benefits that should be explored. IT, and in this case, the use of digital cash, may make our world a more convenient and efficient place to live. However, there are some obstacles to overcome. Fraud is the most important matter to consider (Schwartz, 2001). Systemic risk may be much larger in the future than current predictions have indicated and should be investigated carefully.

CONCLUSION

As the use of digital cash spreads, economic activity and social structure will change. The merits of digital cash balance against the potential and realized problems. Both types of digital cash have the advantage of reducing of dealing cost, time, and human error. Defense against the high potential for fraud will call upon much needed self-responsibility on the part of the user and the supplier of the digital cash.

Financial institutions should consider the trend toward greater use of digital cash as a business opportunity. Those who lag behind in this area may disappear from the market. Authorities should examine this trend carefully. They should look to mature the "sound" market and not to confuse it with too much intervention. Their primary goal must be to develop and preserve sound financial systems.

Digital cash is here to stay. This phenomenon should be analyzed not just from a practical view but also from a theoretical view.

KEY TERMS

Closed Loop: Transfer of value happens as with digital cash. For instance, when the user receives the issue from the issue subject, and the digital money is allotted to the money payment of the commodity or service, the seller will shut the settlement to the issue subject for the transfer of value.

Digital Cash: Classified into electronic wallet (IC card) or online type (network). Note that both types of digital cash have appeared recently. The distinction between the two types has been disappearing.

IC-Card Type Digital Cash: Has the value in itself. Money is stored in it.

Internet Cash: Users are digitally signed but are not stored in the database. It is a kind of debit card.

Network-Type Digital Cash: Maintained on the personal computer or the host computer.

Open Loop: Digital cash issued once can be used for the additional transactions, even if the value does not return to the issuer. The open loop provides rolling liquidity.

SET: Secure electronic transaction (SET) is a system for ensuring the security of financial transactions. Secure socket layer (SSL) is used more than SET. It is a simpler standard than SET.

Category: Concepts, Trends, and Challenges

Straight-Through Processing Adoption

Pallab Saha
National University of Singapore, Singapore

INTRODUCTION

Free trading has been instrumental in the enormous growth of the number and volume of cross-border trading transactions across all industries. In 2000, volume at the National Securities Clearing Corporation (NSCC) reached 18.1 million securities transactions, with actual daily share volumes regularly exceeding 5 billion shares in major financial markets (Depository Trust and Clearing Corporation [DTCC], 2000).

Securities trading starts with either an individual or a business institution expressing desire to purchase securities. While the process is deceptively simple, approximately $1.8 trillion of securities trades remain unsettled and outstanding every business day (David & Kumar, 2000), which poses significant risks to all participants and players in the securities trading cycle. A shorter settlement cycle is seen as an approach to reduce both nonpayment and nondelivery risks to all stakeholders in the trading cycle (Toppen, Smits, & Ribbers, 1998). Compressing settlement cycles needs the redesign and management of securities business processes with significant IT support and involvement. Recent advances in information technology provide ample opportunities for various stakeholders to communicate seamlessly through electronic communication networks (ECNs), enabling both speedier and richer information exchange (Dale, 1996; Venkataraman & Zaheer, 1990).

Currently, settlement times largely vary between 2 and 5 days. Constant push from governmental regulatory bodies is expected to reduce this to 1 or less than 1 day, popularly known as T+1/T+0 settlement times (Freund, 1991; Group of Thirty, 1993). While it is possible to achieve straight-through processing (STP) without targeting for T+1/T+0, it is almost impossible to attain T+1/T+0 without STP (Leman, 2003). There is a dearth of empirical research with emphasis on financial securities operations. This article attempts to address an existing void in this area.

The first part of this article examines current securities trading operations and STP, and discusses the business drivers of STP. The second part of the article elaborates the factors influencing the adoption of STP by various participants. Finally, the article discusses areas that are amenable to future exploration and empirical research with the aim of ultimately increasing the adoption of STP globally.

BACKGROUND

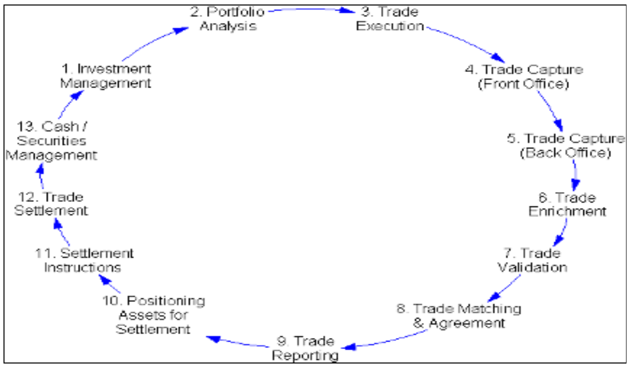
Securities Trading Process (Trading Cycle)

The steps involved in a trade, from the point of order receipt and trade execution through trade settlement, are commonly referred to as the securities trading life cycle (STLC). Basically, the STLC is a combination of the investment and portfolio analysis process, the trading process, and the settlement process comprising major phases like execution, confirmation, settling, and clearance (Toppen et al., 1998). Figure 1 depicts the STLC.

The STLC is usually initiated by an investor or an investment management organization deciding to either buy or sell securities. The preferred approach is the delivery-vs.-payment (DVP) approach in which the transfer of securities and payment takes place simultaneously to reduce nonpayment and nondelivery risks. Following the trade settlement, the investment manager ensures that cash and/or securities positions are updated to reflect the actual situation. The stakeholders involved in the STLC include the following:

- **Investor:** An entity (an individual or a business organization) initiating the STLC by buying and/or selling securities.
- **Investment Manager/Advisor:** A professional providing support to the investor in the decision to invest capital with the ultimate objective of maximiz-

Figure 1. Steps in securities trading life cycle



ing returns for the investor. Usually, investment managers also liaise with securities trading organizations and brokers as needed.

- **Securities Trading Organization (STO):** An organization involved in the buying, selling, and holding of securities for its own purpose
- **Broker/Dealer:** A broker or dealer places orders on behalf of the investor or STO for execution at the appropriate venue, like a stock exchange, which is based on the type of securities to be executed. A broker's primary objective is to match sellers and buyers.
- **Regulatory Authority:** Usually a government entity that sets rules for the functioning of the securities marketplace, and subsequently monitors and controls the activities of the marketplace to ensure compliance to rules and regulations.
- **Stock Exchange:** A government-recognized entity where securities can initially be issued and subsequently be bought and sold by investors
- **Custodian:** An organization that provides services to its clients including the holding of securities, holding of cash, settlement of trades, and collection of corporate actions.
- **Registrar:** An organization appointed by the issuer of a registered security to maintain a register of holders of that security. It is also known as a transfer agent.
- **Clearing Firm:** Central receiving and distribution centers that provide clearing facilities to entities involved in the trade.
- **Depository and Settlement Facility:** A central entity that holds all securities and usually facilitates the clearing, comparing, and settlement of trades.

Table 1 summarizes the primary involvement of various stakeholders along the STLC phases. With such a complex set of processes distributed across multiple participants, the smooth execution and practice of the STLC presents numerous challenges, including the following:

- Transmission of information among various stakeholders
- Multiple points of data entry
- Multiple interaction points between trading partners
- Definitive shift to cross-border trading practice with divergent rules and regulations
- Increased trading volumes
- Potentially long trade-execution time with high failure rates and increasing costs
- Nonstandard trading business processes among stakeholders
- High exposure to different operations and credit-risk profiles

What is Straight-Through Processing?

With the intention of addressing the challenges identified earlier, the Securities Industry Association (SIA) and the DTCC recommended a complete transformation of securities operations. This industry-wide initiative, called straight-through processing, encompasses all stakeholders participating in the STLC. STP increasingly is coming to represent a continually evolving set of aspirations rather than an existing reality (Douthitt, 2000; McIntyre, 2004). In its current (and still evolving) form, STP means the complete transformation and management of all aspects of investment operations (Douthitt, 2000). Straight-through processing is the capability of financial services companies to process cross-border trade execution, clearance, payments, settlement, custody, reporting, and accounting with minimal human intervention (David & Kumar, 2000). STP applies to all major trading areas including foreign exchanges, equities (including corporate actions), bonds, treasuries, money markets, commodities and futures, mutual funds, unit trusts, derivatives, and futures and options.

Table 1. Stakeholders in the STLC (Adapted from Toppen et al., 1998)

Stakeholders	Securities Trading Life-Cycle Processes												
	1	2	3	4	5	6	7	8	9	10	11	12	13
Investor	X	X						X					X
Investment Manager/Advisor	X	X						X					X
Securities Trading Organization			X	X	X	X	X	X	X	X	X	X	X
Broker/Dealer/Agent			X	X	X	X	X	X	X	X	X	X	
Custodian										X	X	X	X
Clearing Firm			X								X	X	X
Securities Depository			X							X	X	X	X
Regulatory Authority			X								X	X	
Stock Exchange			X								X	X	
Registrar			X	X	X				X				X

According to Tower Group (1999), "STP is much easier to conceptualize than to accomplish." STP implementations are complex because of vastly different requirements of different stakeholders (Douthitt, 2000). The processes and activities within STP differ vastly with participants in the STLC depending on their respective roles. Furthermore, increasing the complexities is a continually evolving set of financial products that STP is expected to support. Against this backdrop, the critical areas that STP focuses on are (a) the capabilities required by buy-side financial institutions to accomplish STP, (b) the elements in the flow within the STLC, and (c) the value various entities add to the execution of the STLC.

Business Drivers of STP

Analysis of the challenges inherent in the STLC and the STP vision leads us to factors that drive the accomplishment of STP among STLC participants, which are the following:

- **Potential to Reduce the Cost of Trade Execution and Operational Inefficiencies:** In a completely automated STP environment, the cost of settling a trade is $10 (Society for Worldwide Interbank Financial Telecommunications [SWIFT], 2001). A manual or semiautomatic STLC is wrought with do-undo-redo cycles due to various reasons. It usually costs about $6 to correct a trade during the trade instruction step, but this increases to $16 if the mistake is identified during trade matching. Subsequently, according to SWIFT, this shoots up to $50 per trade if the mistake is identified and corrected during trade settlement. Currently, approximately 60% of all trades need correction during the instruction phase, about 10% need correction during trade matching, and about 15% of all trades fail to settle on time (SWIFT).
- **Increasing Risk Potential of Trading Operations:** The STLC presents several risk factors (McIntyre, 2004; Toppen et al., 1998). An analysis of financial disasters that have occurred in the recent past reveals the need for efficient processes, tighter process integration across trading partners, and lower throughput time to address risks like systemic risks, settlement risks, liquidity risks, custody risks, and legal risks.
- **High Error Rates and Complexities Leading to Delays in Trade Settlement:** The involvement of multiple participants, use of nonstandard procedures, and multiple points of data entry lead to nearly 20% of all trades needing manual intervention or exception processing (SWIFT, 2001).
- **Recognition of the Desire to Move to Real-Time Settlement (T+1/T+0):** Business needs and regulatory requirements are forcing STLC stakeholders to move to real-time (T+0) or near-real-time settlement (T+1). Achieving this is possible only if the complete STLC is subjected to business-process reengineering and transformation. Major benefits of shorter settlement cycles include the following (Frimmel, 2000).
  - Risk-exposure reduction by 67% of $750 billion by 2004
  - Possible reduction in the size of current clearing funds by one third
  - Approximated annual savings of $2.7 billion
  - Faster payments and better asset allocation and utilization due to synchronized trading cycles
- **Growth in Cross-Border Trading System:** The increasing globalization of businesses and financial markets is pushing up cross-border trading volumes 44.2% annually, increasing cross-border trades from 36 million in 1999 to 108 million globally in 2002 (Tower Group, 1999).
- **Technological Advancements Striving for Disintermediation:** One of the critical benefits of information technology is the ability to reduce and eliminate intermediaries from a process (Davenport, 1992). Advances in information and communication technologies are facilitating the integration of business processes between trading partners. Protocols like the Financial Information Exchange (FIX) and the Society for Worldwide Interbank Financial Telecommunications facilitate information exchange, which is a critical requirement to accomplish STP.
- **Mergers and Acquisitions:** Mergers and acquisitions (M&As) are an important business characteristic in large economies. The reasons for M&As are primarily linked to consolidation, economies of scale, market expansion, market share, and talent retention and acquisition. Financial organizations that are unable or unwilling to commit investment into the infrastructure to support STP are considering mergers or acquisitions.
- **Trading Operations Extending to 24/7:** With cross-border trading and globalization, securities trading needs to operate without breaks, stops, or disruptions. STOs, brokers, dealers, and agents who deal with multiple markets have to operate 24 hours (David & Kumar, 2000). Supporting this calls for a high degree of liquidity in the system so that, for instance, a trader can settle out of a trade in Tokyo and successfully trade in London without interruptions.

- **Global Aspiration to Move to Electronic Certificates from Physical Certificates:** Most securities presently exist in standard certified form. Trading involves the transfer of the ownership of securities, leading to the physical movement of certificates, which introduces risks of theft or loss (McIntyre, 2004; Simmons, 2002). There is a global shift toward electronic certificates in dematerialized form (demat form) for which securities holdings are represented by electronic records. The increased use of the demat form is heralding the move to STP.

FACTORS INFLUENCING STP ADOPTION

An analysis of the business drivers of STP reveals the compelling benefits of embracing STP for all stakeholders. The decision to embrace STP presents specific characteristics unique to the securities industry and stakeholders in the STLC. It is critical for stakeholders to understand these specific factors that influence the adoption of STP. Adding to the complexity are the business implications of STP that vary depending on stakeholders and the roles they play in the STLC. Current STP adoption rates range between 60 and 80% in developed economies (*Straight Through Processing Magazine*, 2000), and lower in other countries (David & Kumar, 2000). There are many factors that influence its adoption. Factors that positively influence and facilitate STP adoption (facilitators) and factors that negatively influence and obstruct STP adoption (obstructers) are identified and used to develop hypotheses to understand their significance in STP adoption.

Trading costs are cited in the literature as a major factor positively influencing STP adoption (David & Kumar, 2000; Frimmel, 2000). With the increasing complexities of the trading process and the involvement of multiple trading partners who have different expectations and success criteria, the cost of securities trading is not low and increases at a steady rate along the STLC (Frimmel). Stakeholders view trading-cost control and its minimization as a direct benefit of adopting STP. Therefore the following hypothesis:

- **H1: The securities trading cost positively influences the adoption of STP.** Trading error rates and complexities pose significant challenges as the steps of STP are distributed across various participants. The successful execution of the STLC necessitates a high degree of coordination and rich communication among partners. Inherently, this provides numerous opportunities to introduce errors during the trading cycle (David & Kumar, 2000; McIntyre, 2004). Reducing errors and simplifying the STLC is a major goal of STP. Therefore, the related hypothesis is as follows:
- **H2: The level of error rates in the STLC execution positively influences the adoption of STP.** Credit and operational risks are a big issue in the securities industry. Perhaps the most widely covered was the Barings Futures Singapore case in February 1995 with an estimated loss of $1.5 billion (Toppen et al., 1998). Longer settlement cycles introduce nondelivery and nonpayment risks, and absorb liquidity from the system. Therefore, the following hypothesis applies:
- **H3: The level of credit and operational risk positively influences the adoption of STP.** Trading volumes in the past few years have ballooned as businesses are going global. Also, many public-sector organizations in emerging economies like India and China are facing reduced government holdings as a result of market deregulation. This is inducing such companies to go public and offer its government-held shares to individuals and institutional investors, including foreign institutional investors. The increase in trading volumes is also being fueled by sharp increases in cross-border trading. According to Global Straight-Through Process Association (GSTPA) in 1999, cross-border trading is currently clocking an average annual growth rate of 44.2%. Therefore, the related hypotheses are the following:
- **H4: Trading volumes positively influence the adoption of STP.**
- **H5: The level of cross-border trading positively influences the adoption of STP.** The STLC is a complex business process governed by several business rules and regulatory requirements. The STLC presents several sources that introduce errors in the process, ranging from trade capture to trade enrichment, static data, trade validation, settlement instructions, and trade matching, among others. According to SWIFT (2001), currently, about 20% of cross-border trades fail to settle on time. Lowering settlements times to T+1/T+0 is the primary catalyst for adopting STP (Frimmel, 2000). According to SIA, the guiding principles for the T+1 vision are (a) seamless communication among parties, (b) concurrent exchange of information, (c) significant real-time processing, and (d) virtual, not physical, processing. Therefore the following hypothesis exists:
- **H6: Reduction in settlement times will positively influence adoption of STP.** Information and communication technologies are natural enablers in securities operations. On one hand, participants are

taking advantage of information technologies to realize securities business processes, and on the other hand, advances in communication technologies are paving the way for tighter integration and richer collaboration between trading partners. Therefore, the related hypothesis follows:

- **H7: The extent of advancements in information and communication technologies positively influences the degree of STP adoption.** The STLC is a classic end-to-end business process with sufficient ingredients to implement all aspects of business-process management (BPM; Smith & Fingar, 2003). Major guiding principles for business process management (BPM) within the STLC are (a) real-time automated business processes with no manual handoffs, (b) performance management and benchmarking, (c) automated exception handling, (d) business-driven process reengineering, (e) process integration across trading partners, (f) facilitating the deployment of standards like the financial products markup language (FpML), FIX, SWIFT, and ISO 15002 XML (extensible markup language), (g) Web-service enabling (Samtani & Sadhwani, 2002), (h) business-rules-driven approach, and (i) support for dynamic process topologies. Therefore, the BPM hypothesis is as follows:
- **H8: Business-process management will positively influence STP adoption.** Regulations, practices, and legal issues (http://www.stpinfo.com/supplements) play a very critical role in the adoption of STP. As more and more trades are characterized by their cross-border nature, issues pertaining to the conflict of laws, enforceability of rights, business practices, compliance requirements, and nonstandard operational procedures come into play. Many laws and regulations adopted by countries may serve national interests, but they create barriers to cross-border trading. These have the potential to create hindrances in seamless global securities operations. Therefore, the hypotheses follow:
- **H9: The governance of the STLC through national laws and regulations negatively influences the adoption of STP.**
- **H10: National interests negatively influence STP adoption.** Standards and protocols in communication technologies enabling STP adoption (Douthitt, 2000) include (a) FpML, which aims to standardize e-commerce activities for derivatives, swaps, and structured products, (b) FIX, which is a standard for sending and receiving messages on expressions of interests, orders, order acknowledgments, fills, and account allocations between financial institutions, brokers and dealers, and stock exchanges via ECNs, (c) SWIFT, which is a bank-owned consortium to create and transmit settlement messages and other aspects of trading, and (d) ISO 15002 XML, which is a convergence of FIX, FpML, and SWIFT. These standards and protocols work together with Web services. Therefore, standards and protocols lead to the following hypothesis:
- **H11: Standards and protocols positively influence the adoption of STP.** The STLC is characterized by the back-office nature of many of its steps, making them prime candidates for business-process outsourcing. With the rise in trading volumes and stagnant margins, many organizations in the securities industry are beginning to take advantage of labor arbitrage and lower costs by outsourcing part of or the entire back-office operations to countries such as India, the Philippines, and Malaysia (David & Kumar, 2000). Therefore the following hypothesis exists:
- **H12: Business-process outsourcing negatively influences STP adoption.** Fundamental changes in the securities marketplace are ushering in a slew of regulations and requirements. In the United States, the Securities and Exchange Commission (SEC) has identified three critical issues, namely, (a) price transparency, (b) intermarket linkages to displayed prices, and (c) the duty of best execution owed by brokers to customers (SEC, 2000). These moves by regulatory bodies like SEC are fueling the shift to STP. Therefore, the related hypothesis is as follows.
- **H13: Market changes positively influence adoption of STP.**

FUTURE TRENDS

STP is emerging as a mainstream e-commerce initiative in the securities industry. However, in order for STP to be adopted, certain issues need to be addressed. First, while the goals of STP are clear, these need to be extended, and specific measures and targets need to be developed. Communicating performance against measures and targets provides direction and motivation to STLC participants. Second, the business implications of adopting STP and targeting T+1/T+0 should be made explicit to all participants up front before any STP initiatives are started. This is critical as increased STP adoption potentially might lead to the disappearance (or reduced involvement) of certain participants from the STLC. STP adoption can be staggered with internal STP happening prior to external STP. Finally, prioritized services in the STLC that could be automated ahead of others need to be clearly identified and unambiguously justified in terms of overall business impact.

CONCLUSION

The phenomenal growth of automated trading and settlement, and advancements in information and telecommunication technologies provide STOs with ample scope to embrace STP. STOs can benefit significantly by reducing trading and settlement times, increasing liquidity in the trading system, and increasing operational efficiencies. Secondary data used to develop conjectures in this article, proposed in the form of hypotheses, provide a foundation for rigorous empirical research to (a) understand the importance of each facilitator and obstructer to STP adoption, (b) analyze interrelationships between influencing factors, leading to deeper understanding of the underlying systemic complexity, (c) uncover the strengths of these influences, and (d) develop an STP adoption road map that enhances the probability of accomplishing STP goals and objectives. The results can provide significant inputs to develop an implementation framework that addresses issues concerning the adoption of STP.

KEY TERMS

Delivery-vs.-Payment (DVP): A securities-industry procedure in which the buyer's payment for securities is due at the time of delivery; that is, security delivery and payment are simultaneous.

Demat Form: The move from physical certificates to electronic bookkeeping. Actual stock certificates are slowly being removed and retired from circulation in exchange for electronic recording.

Electronic Communication Network (ECN): An electronic system that brings buyers and sellers together for the electronic execution of trades. ECNs represent orders in NASDAQ stocks; they internally match buy and sell orders, or represent the highest bid prices and lowest ask prices on the open market.

Financial Information Exchange (FIX): A vendor-neutral standard-message-format protocol for describing real-time security transactions. FIX is a public-domain specification owned and maintained by FIX Protocol, Ltd. The protocol supports all electronic conversations between brokers and other financial institutions.

Securities and Exchange Commission (SEC): The primary federal regulatory agency for the securities industry, whose responsibility is to promote full disclosure and to protect investors against fraudulent and manipulative practices in the securities markets.

Security: An investment instrument, other than an insurance policy or fixed annuity, issued by an enterprise, government, or other organization that offers evidence of debt or equity.

Settlement: The finalizing of the sale of securities as the title is transferred from the seller to the buyer (also called closing). A settlement marks the completion of all aspects of the trading instance. The average price at which a contract trades, calculated at both the open and close of each trading day, is called the settlement price.

Society for Worldwide Interbank Financial Telecommunications (SWIFT): An international body that sets protocols and standards for international payment systems, such as electronic money transfers.

Strategic Planning for Distance Training

Todd Brace
Provident Bank, USA

Zane Berge
UMBC, USA

INTRODUCTION

As pressure increases for training to justify itself as an activity with a return on investment (ROI), it needs to align its activities with the strategic objectives of the organization. More importantly, it must position itself in the minds of the organization's decision makers as a necessary component in the strategic-planning process.

In most instances, training is seen as an on-call resource, basically given marching orders after the strategic direction is set. It might occupy a similar position in the process as the purchasing department—that is to say, none. After the strategic plan is set, orders for training are placed with the training function to be filled and delivered as ordered.

This article looks at the issue of training, specifically distance training and education (DT&E), as a factor in the business unit's strategic-planning process. The training function's historical place in the typical organization will be reviewed briefly, as well as a few of the unique dynamics introduced by the emergence of DT&E. To provide adequate background, a discussion of the strategic-planning process will be presented. Included will be a review of factors contributing to effective strategic planning that moves an organization forward. Additionally, common pitfalls of strategic planning will be discussed. The discussion will then move to training's role in strategic planning or, too often, the lack of training's role. The article concludes with a specific look at how distance training and learning is being addressed in the strategic-planning process.

BACKGROUND

In the past, governments ignored DT&E, and higher education only begrudgingly came kicking and sneering to e-learning. Training is undergoing increased scrutiny for its relevance in terms of the value it represents within the organization. Pepitone (1995) cited four key factors driving the evaluation of training. First, how does training assist the organization in responding to increasing competitive pressures? Second, how does it contribute to meeting the challenge of remaining profitable and developing a strategic competitive advantage? Third, to what extent is the aforementioned negative image of training accurate, particularly as a dark hole into which resources pour? Fourth, management often has a concern that the practitioners in training lack business acumen and may even hold disrespect for management. Training's value is made even more complex when one looks at distance training and education. DT&E has caused the training function to rethink everything from the fundamentals of instructional design to computing ROI.

The bottom line regarding training is changing completely, and that change is being driven by the growth of DT&E initiatives. The very competencies required of trainers have changed (Berge, de Verneil, Berge, Davis, & Smith, 2002). The up-front costs of DT&E are largely seen to be higher than traditional classroom training, with capital investments higher, and more common, complex, and extensive partnering with vendors and others (Kruse, 2000). This has been a catalyst for many changes, one of which is that training must explain and justify itself in terms of ROI. It is this focus on ROI that will help ease the training function's access to the strategic-planning table. Complicating this partnership, however, is the role strategic planning often plays in an organization. In truth, few organizations do it well.

WHAT IS STRATEGIC PLANNING AND WHY DO IT?

The strategic-planning process generally results in a visionary statement. Unfortunately, the vision is often unclear and fails to communicate the big picture that drives an organization's direction. Typically the process involves the preparation of a massive document, itself often a roll-up of disjointed data supplied by various parts of the organization. Discussions of the industry, competition, market share, cost cutting, and obligatory goals and objectives are the core of the document. Almost without exception, budgets, spreadsheets, and graphs are added to support the narrative (Kim & Mauborgne, 2002).

How Training Fits in the Planning Process

Where does training fit into the strategic-planning process? Does it fit in at all? Specifically, where does the application of DT&E fit in? In the model above, the role of training would be articulated in the environment-assessment stage. Training resources should be seen as those that need to be deployed to accomplish the strategic objectives. The usual approach, however, is for the various areas of an organization to approach the training function after the goals, objectives, and plans are in place. Essentially, departments place their orders for training. This approach often leaves the training function caught short—scrambling for time and resources. This situation almost always results in a function that cannot possibly provide all the services asked of it. Moreover, training must provide its support with the constraints of a budget that has little relationship to need.

Training is Out of the Information Loop

Many organizations persist in treating employees more as an expense requiring control than an asset to be both used and protected (Landes, 2000). It follows that within those organizations, support systems, such as training, are seen as an expense to be controlled.

Although that way of thinking is still common, or even predominant, in the workplace more companies are realizing that shortchanging employee development has a direct impact on the bottom line (Simpson, 2001). Strategic planning's increasing importance is largely a function of a business climate where rapid change is the norm. The changes that companies face are driven by technology, competition, societal trends, and people (Zuber, 1999).

LEARNING ORGANIZATIONS

A sign that training, or more precisely, staff development, is being seen as a strategic process is the emergence of the concept of learning organizations. A learning organization is one in which learning processes are developed and fully aligned with an organization's improvement and strategic goals. Learning organizations are those that recognize that learning is not confined to the training function, but that there are multiple channels for ongoing learning for the employees. In this case, training becomes one of several learning modes in the company (Gephart, & Marsick, 1996).

Training's role in an organization has been concretely defined over the years. Historically, training is the logical place where trainers should be expected to be working (Main, 2000). Companies that succeed in breaking out of the mold are taking a first step in becoming learning organizations. Because of the rapidly changing dynamics in the business world, survival for organizations requires that there be a change from a training to a performance focus in terms of staff development. Main suggested that this change in focus can take a committed organization 2 to 5 years.

This change in focus supports two critical signs that the learning-organization and human-performance models are moving closer to the strategic-planning process. It must be planned for over a multiyear period. Traditional training models rarely look beyond the current annual budget, let alone map out a long-range strategy that makes sense to the organization. Additionally, the second sign is that the change requires a champion to drive the change. That champion invariably must be someone placed high within the organization. That person, in championing the change in focus of employee learning, must also do so within the context of the organization's wider vision, known as its strategic plan.

The emergence of learning organizations has given a name to that champion: the chief learning officer (CLO). The CLO's primary responsibility is to foster a culture in which a significant emphasis is placed on learning. At first blush, this may sound a great deal like the role of the traditional training manager. However, in learning organizations, the CLO is often either the organization's CEO, or someone who has the full support of the CEO in developing a learning environment. In turn, the learning environment fully supports the strategic objectives of the organization (Simpson, 2001).

DISTANCE TRAINING AND EDUCATION

Distance training is perhaps the hottest topic in the training realm today. Distance training is actually nothing new. Step-by-step procedure manuals and correspondence education, around for decades, were the early forms of distance training. As personal computers became common workplace tools, training content was delivered digitally (Alessi & Trollip, 2001). Today, DT&E can take a lot of forms, from asynchronous self-based training tutorials to instructor-led synchronous and asynchronous learning activities. Organizations have an interest in DT&E for its apparent strategic advantages. These include the potential for lower overall cost, reduced learning times, increased retention through learner-directed review, consistent delivery of content, the ability to track participation and outcomes more efficiently, and anytime, anyplace availability (Kruse, 2000).

DISTANCE TRAINING AS A STRATEGIC PARTNER

As a subset of the training function, DT&E's contribution in the strategic-planning process is closely aligned with training's contribution in general. However, there are some things that indicate that the unique aspects of DT&E make it more of a player in strategic planning.

First, the up-front costs of implementing DT&E initiatives can be staggering (Segers, 2002). The hardware, software, licensing, consulting fees, development costs, maintenance costs, outsourcing, and unique training-staff competencies needed for varying levels of distance training can add up to a significant amount—so much so as to be on the radar screen of the executives who keep an eye on the bottom line.

The end result is that initial forays into distance learning do not just require the sign-off of upper level management. Required is the intense attention of upper level management. This is not like traditional training burying Proxima projectors, overhead projectors, poster printers, or other training materials in an otherwise lightly scrutinized budget roll-up. The investment in distance training requires sign-off at the very highest level of the process. This means that it must make sense from a strategic perspective. ROI, always the elephant in the china shop from training's perspective, is not simply a goal to work toward, but must be fully articulated at the outset. Some organizations factoring distance training into their strategic plans are using a 1- to 3-year payback period, in terms of cost reductions or productivity improvements, as a yardstick with which to approve distance training's use or to measure its impact (Martin, 2001).

ROI measurements as a part of distance training means that a training manager implementing such a strategy must align with the strategic-planning process if the initiative is to be approved and sustained (Berge & Kearsley, 2003). DT&E's up-front costs, accounting, and cultural impact is such that they require attention and sign-off at the very highest level of the business unit. At that level, decisions are made on expenditures according to their relative merit for accomplishing the organization's business objectives. This indeed is a function of strategic planning.

REALITY, DISTANCE TRAINING, AND STRATEGIC PLANNING

In August 1997, Boeing Co. merged with two of its biggest competitors, and in so doing, doubled its workforce from 110,000 to 248,000 (Benini, 1999). Boeing knew, before it moved on the merger, that it could not follow traditional classroom-based instruction models to merge the learning dynamics of the new organization. Indeed, it calculated that it would take years before all staffers were adequately trained. Distance training was a part of the strategic plan for this merger from the very beginning. It might not be an exaggeration to say that without distance training, and its careful consideration in the early stages of the planning process, this strategic direction might not have even been a possibility.

In September of 2000, CTC Communications Group announced that it had just implemented an online, Web-based distance learning program for its sales and service personnel. Designed to replicate the instructor-led classroom environment as much as possible, its intent was to maintain the skill sets of its widely dispersed 450-person sales and service team ("CTC Communication," 2000).

If the deployment was simply to make training more accessible, then it may have been considered a success the moment the system was turned on. It became a strategic initiative, however, when specific business-related goals and objectives were tied to its deployment. CTC had a growth plan that included doubling its business market and doing so within an environment of cost containment ("CTC Communication," 2000).

The skill development of the workforce, done economically, efficiently, and effectively, was considered to be a critical component of accomplishing the business objective. The company realized $200,000 in savings based on training-related travel and other expenses. It was training's clearly defined role in the strategic objectives, and the plan for measuring the attainment of those objectives, that put distance training in the mix of strategic planning as opposed to traditional training models.

DT&E is seen as a cornerstone of strategic business strategies for many retail banks. Retail banks have grown in the last 10 years largely through acquisitions. Very few are opening many new branches. From a straight balance-sheet perspective, this is an easy way to acquire deposit bases, loans, mortgages, physical locations, and even market share. Most importantly, it provides market penetration as a bank moves into an area in which it previously had little or no presence.

What is difficult about this process is that each acquisition also requires the assimilation of workforces, cultures, policies, procedures, systems, products, services, and knowledge inventories. The problem is not unlike Boeing's in those respects. Where it does differ, however, is that when a bank acquires another bank, it is acquiring retail outlets with perhaps dozens of locations spread out over thousands of square miles.

Following the instructor-led model makes this process extremely difficult and expensive. Training centers must either be set up in the remote locations, or the individuals must travel to existing training locations. Either way, the costs and logistics can be considerable.

Factor in that the workers are retail workers, and leaving retail establishments to attend training creates severe coverage and customer-service challenges. It is no wonder that financial-services industries are among those who are in a position to best exploit the strategic advantages of distance learning (Martin, 2001).

FUTURE TRENDS

As globalized business moves from e-commerce to m-commerce (mobile commerce), the demand and needs for learning and performance improvement will continue to expand rapidly. Innovation by an enterprise cannot happen unless something new is learned first (O'Driscoll & Briki, 2004). The companies and industries that are truly exploiting distance training for its potential strategic payback are looking at it from the top down, not the bottom up. Bottom-up distance training is driven by the training department, and while DT&E initiatives may impress executive management, the decision makers may or may not actually see the business potential beyond some obvious efficiencies gained.

In the examples shared here, representative of countless others, we see businesses and industries that view DT&E as actually being a component that truly expands the enterprise's capacity and therefore its growth potential. If strategic planning is the tangible mapping of an organization's growth, in the previous examples DT&E has truly integrated itself in strategic planning.

Perhaps an announcement in 2000 by eYak, a provider of carrier-class voice and data application servers, is an early sign of things to come. The announcement was that eYak was adding two recognized distance learning experts to its Strategic Advisory Board. Indeed, in this example, DT&E is literally at the strategic-planning table ("Dr. John Flores," 2000).

CONCLUSION

Effective strategic planning is becoming more of an imperative for competitive organizations today. Organizations that do a good job with the process realize that factoring in the human-performance variable is more critical than ever. The workforce is required to better acquire and apply knowledge, and the organization must find ways to exploit that knowledge more effectively.

DT&E contributes greatly to an organization's ability to maintain a current knowledge base within the workforce. However, deploying DT&E requires cultural change, different types of capital investments, and different ways of measuring the performance and efficacy of training programs. It is not something that can be entered into lightly or without serious analysis on the part of upper management. It can dramatically stretch the capacity of an organization. Conversely, it can be an expensive party favor if not carefully incorporated into the company's strategic direction.

Because the use of DT&E requires that it is tied to the strategic plans for a company, one might conclude that DT&E has served as a catalyst that brought the training function closer to the strategic-planning table. Without the advantages and related considerations that accompany DT&E, the traditional training function might still be languishing far from the strategic-planning process, continuing to dutifully fill orders for training, and being seen as the first expense cut when an organization fails to accomplish its objectives.

KEY TERMS

Assessment: Used here as the process of gathering, describing, or quantifying information about performance.

Distance Training and Education (DT&E): The process of delivering instructional resources for the purposes of training and education to a location (or to locations) away from a classroom, building, or site to another classroom, building, or site by using video, audio, computer, multimedia communications, or some combination of these with other traditional delivery methods.

Learning Organization: An enterprise that facilitates the learning of all its members and continuously transforms itself.

M-Commerce (Mobile Commerce): Using wireless technology such as telephony and computing for commerce.

ROI (Return on Investment): Traditionally defined as the increase in financial value provided by a new investment. However, this definition does not work well for intangibles, such as e-learning and the effective management of human capital.

Strategic Planning: Defined as the process of developing and maintaining a strategic fit between the organization's goals and capabilities, and its changing marketing opportunities.

Synchronous and Asynchronous Learning Activities: Events, either in real time or delayed time, in which a learner increases his or her skills and knowledge.

INTRODUCTION

A successful e-commerce venture requires a viable business model and a long-term sustainable strategy. When planning and implementing e-commerce ventures, business executives must address several strategic questions, such as: What are the functions and components of a viable business model? How does one capture and capitalize on the unique features of the Internet and e-commerce to achieve sustainable competitive advantage and profits? How are values being created in the Digital Economy? How can network effects and scope economies change a company's competitive position in e-commerce? How can cost, revenue, and growth models in e-commerce differ from the traditional businesses? This article extends Lee (2001) and Lee and Vonortas' (2004) works on business model and strategy to discuss the structure, components, and key issues of a viable e-commerce business model.

BACKGROUND

A business model describes the basic framework of a business. It is the method of doing business by which a company can generate revenue to sustain itself (Rappa, 2003; Turban, King, Lee, & Viehland, 2004). It also tells what market segment is being served (who), the service that is being provided (what), and the means by which the service is produced (how) (Chaudhury & Kuilboer, 2002), and how it plans to make money long term using the Internet (Afuah & Tucci, 2003, p. 51). A firm's business model should also describe how the organization is positioned in the industry value chain. Timmers (1998) defines business model as an architecture for the product, service, and information flows, including a description of the various business actors and their roles; a description of the potential benefits for the various business actors; and a description of the sources of revenues. Weill and Vitale (2001) define an e-business model as a description of the roles and relationships among a firm's consumers, customers, allies, and suppliers that identifies the major flows of product, information, and money, and the major benefits to participants.

In terms of business areas, Rappa (2003) identifies nine basic Internet business models. They are: brokerage, advertising, infomediary (e.g., recommender system, registration model), merchant, manufacturer (direct marketing), affiliate (provide commission for online referrals), community (voluntary contributor model or knowledge networks), subscription, and utility (e.g., pay by the byte). In addition, Turban et al. (2004) also identify several types of Internet business models including: name your price, find the best price, dynamic brokering, affiliate marketing, group purchasing, electronic tendering systems, online auctions, customization and personalization, electronic marketplaces and exchanges, supply chain improvers, and collaborative commerce.

As for the specific components, an e-commerce business model should consist of multiple components and perform different functions. Rayport and Jaworski (2001) argue that a "new economy" business model requires four choices on the part of senior management. They include the specification of a value proposition or a value cluster for targeted customers; a scope of marketspace offering, which could be a product, service, information, or all three; a unique, defendable resource system—that is, the associated resource system to deliver the benefits; and a financial model, which includes a firm's revenue models, shareholder value models, and future growth models. To study the role of the business model in capturing value from innovation, Chesbrough and Rosenbloom (2002) identify the functions of a business model, which include: (1) to articulate the value proposition; (2) to identify a market segment; (3) to define the structure of the firm's value chain; (4) to specify the revenue generation mechanism(s) for the firm; (5) to describe the position of the firm within the value network; and (6) to formulate the competitive strategy to gain advantage over rivals. Other scholars, such as Dubosson-Torbay, Osterwalder, and Pigneur (2002) and Alt and Zimmermann (2001), also made significant contributions to the theoretical discussions and business practices of e-commerce business models.

MAJOR COMPONENTS AND KEY ISSUES OF AN E-COMMERCE BUSINESS MODEL

In order to sustain a successful business venture, a viable business model should address a number of issues and the dynamics of the respective elements which include: what value to offer customers (strategic goals and value proposition), which customers to provide the value to (scope of offerings), what capabilities are needed to build a successful and unique resource system, how to price the products or services and generate streams of revenues, how to increase the scale and the scope of the venture, and what strategies and processes are needed to build and sustain a successful e-commerce business model.

Structure and Components of a Viable E-Commerce Business Model

Table 1 lists and discusses major components and several key issues of a viable e-commerce business model. It can be used to assist business executives and entrepreneurs in planning and implementing e-commerce business ventures. It also serves as a basic framework for further study of the e-commerce business model and strategy.

Table 1. Components and key issues of the e-commerce business model

Component	Element	Key Issue
Value propositions	**Choice of focal customer benefits**	**Core products/services:** • What kinds of value or benefit do we provide for our customers? • How uniqueness is the value or benefit? • Do those values satisfy customer's demand? • Does the products or services have strong network effects? • Are there substitutes for our products or services? **Supplement products/services:** • How important are the supplement products or services? • How to increase customer value by improving or redesigning business processes? • How important do we need to provide product instructions, user training, and customer services?
	Target segment	**Market attractiveness** • How substantial is the market segment? • Whether the market is underserved or over-served? • What is the growth rate of the market segment? • Which stage is the product in the product lifecycle? **Intensity of market competition** • What is the market or industry structure? • How intensity is the competition? • How large is the entry and exit barriers?
Scope of offerings	**Customer decision process**	**Pre-purchase** • How to make easy for customers to obtain and compare product- or service-related information? • How importance is the advertising to inform or persuade customers to make the purchase? • Do we need to obtain a 3rd-party certificate or verification (e.g., VeriSign) in order to build a trust relationship with our customers? **Purchase** • When, where, and how do customers make the purchase? • What kinds of service are required to assist customer in purchasing the product or service? • Whether the delivery of products or services is efficient? **Post purchase** • Do we understand customer's evaluation and satisfaction of the products or service? • Do the majority of the customer make repeat purchase? **Purchasing process** • How important is to offer customer assistance in the whole process of purchasing a product? • Can we identify customer decision process and be able to provide effective assistance? • Do we have an effective e-commerce site that is user friendly? • How to lower the "transaction costs" to make easy for customer to do business with you?

Table 1. Components and key issues of the e-commerce business model (cont.)

	Product or service contents	**Core product or service** • Do we understand which business we are in? • Do our products or services solve the customer's problems? **Supplementary product or service** • Do we build and maintain a set of "digital assets" in order to know our customers better? • How to leverage on a single set of digital assets to provide value across many different and disparate markets? • How to increase customer's "switching costs" of using your company's products or services? **Core delivery process** • Do we understand and take advantage of the economies of scope in production and distribution of the product or service? • What kinds of channel (digital and/or physical) do we need to deliver our products or services? • How efficient and effective the products or services being delivered?
Unique resource system	**Resources and capabilities**	**Specifying a resource system** • Do we identify the resources (e.g., labor, capital, assets) needed to build our core competencies or capabilities? • Do we have all the necessary core capabilities to support our scope of product or service offerings? • Do we need to outsource and/or partner with others to gain missing capabilities? • Can we identify key players who can fill out the missing capabilities? • How important is the role of intellectual property rights (e.g., patents and trademarks) in building capabilities? **Assessing the quality of the resource system** • How uniqueness of our resource system? • How difficult is for competitors to imitate our system? • Do each of the capabilities support the delivery of a customer benefit? • How well do the capabilities complement and support each other? • Are the specific resources mutually reinforcing? Are they complementary? • Does the online resource system support the offline system?
	Logistics and delivery systems	**Integration** • Can we deliver a unique customer experience through e-commerce? • Are we able to achieve supply chain integration and synchronization (e.g., applying Internet-based collaborative planning, forecasting, and replenishment)? • Are we able to collaborate with business partners across a common technical platform using common e-business applications? **Fulfillment** • Can we match the performance of the physical activities to the virtual world? • Can we develop a flexible and reliable channel to reach the end customers? • Can we radically reduce the order-to-delivery time to customers?
Revenue and growth models	**Revenue models**	**Product/service sales** • Are our revenues primarily deriving from product sales or from complementary products or services? • Can we generate revenues from utilizing intellectual properties? **E-Commerce related revenues** • How to identify new sources of revenues from e-commerce (e.g., advertising, referrals, subscription, membership, commissions, transactions, etc.)? • How to use information to create value in both online and offline (e.g., FedEx's packaging tracking system)? • How to develop cross-selling opportunities to achieve synergy? • Do our customers value the benefit of one-stop shopping? **Pricing** • How to test prices, segment customers, and adjust to changes in supply and demand in real time? • How to analyze digital assets and experiment new way of pricing? • Are we able to implement innovative e-commerce pricing methods (e.g., reverse auction, one-to-one bargaining)? • How to build online brand equity to enhance loyalty and to reduce price sensitivity?

Table 1. Components and key issues of the e-commerce business model (cont.)

	Financial growth models	**Growth strategy** • How should we develop new revenue growth? (e.g., deeper penetration into the current market, new product development, new market development, and/or completely new products and markets) **Growth model** • Do we need to spin off online division to establish a new company? • Do we need to establish strategic alliances or merge with other online/offline companies?
Competitive strategy	**Value chain positioning**	**Value system or network** • Where do we position our products or services in an industry value chain? Can we integrate or move upstream or downstream to increase added values? • How do we create value? Do we create customer value as a partner in a supply chain (e.g., manufacturer or retailer), as a value shop (e.g., professional service), or as a central player of a network (e.g., intermediary service)? • Can we join a "business ecosystem" (Gossain and Kandiah, 1998) (e.g., online mega sites such as Amazon.com) as a member to provide products or services to the final customers?
	Generic Strategy	**Competitive advantage** • Do we have advantages over our competitors, in terms of marketing, cost structure, and product or service differentiation? • Do e-commerce and the Internet redefine the competitive advantage in the market or industry we are in? **Generic strategy** • Which strategy should we pursue in order to sustain our competitive advantages? (e.g., increase entry barrier or block strategy, innovation or run strategy, and/or alliance or team-up strategy)

Value Creation in E-Commerce

In the physical or traditional industrial economy, inputs to a value creation process are raw materials or all of the necessary physical inputs that are required to produce the finished products or services. Outputs are finished goods or intermediate goods used as inputs to the subsequent downstream value creation processes. In the value creation process, information serves as a supporting element. Information, such as design and engineering know-how as well as production methods and procedures, is applied to facilitate the "physical" transformation process which involves one or more of the four value-adding activities describe in Meredith and Schaffer (1999): inspect, alter, transport, and store. Under this paradigm, general management's main focus is to make the transformation process more efficient.

In contrast, input to the value creation process in the digital economy (Tapscott, 1996) is information (e.g., customer information or digital assets, and the status of production and distribution process) that firms gather, organize, select, synthesize, and distribute (Rayport & Sviokla, 1995) in the transformation process to provide individual customers a customized solution. In the digital economy, information is a source of value, and every business is an information business (Earl, 1999). Organizations in the Digital Economy should understand and be able to apply the concept and practice of virtual value chain (Rayport & Sviokla, 1995) to create value and to generate new business opportunities. Since physical and digital economies coexist within a firm and across industry supply chain, business executives must go beyond focusing on improving the transformation process itself to concentrate on leveraging information assets and capitalizing on the unique features of e-commerce and the Internet to create more value for the customers.

Five Steps toward E-Commerce Success

Lee (2001) proposes that there are five essential steps toward e-commerce success. First, companies must redefine their competitive advantage in the Digital Economy because e-commerce is changing the basis of competition. Business executives must redefine their competitive advantages in terms of cost, differentiation, marketing, and distribution. For example, Compaq built the best retail-distribution network in the computer industry in the 1990s, but cannot compete with Dell's "fast and light" direct-sales approach enabled by the Internet technology (Browning & Reiss, 1999). Second, companies must rethink the traditional ways of formulating business strategy. Executives must generalize thinking beyond building must re-engineer the organization structures and processes to capitalize on the benefits of e-commerce. For example, to implement a customer-centered e-commerce model, a company needs to integrate its suppliers, back-office functions, and front-office functions in order to achieve the organizational flexibility necessary to move at Internet speed and to satisfy customer demand. Finally, companies must be able to reinvent customer services by building cost-effective total experience and loyalty-enhancing relationships with the most profitable customers. Companies can involve customers in the product development process through initiating technology-facilitated dialogue. In addition, companies can gather knowledge about its customers by building and controlling a comprehensive customer database (i.e., digital assets). For example, mega retailing sites such as Amazon, Yahoo!, and eBay are able to redefine economies of scope by drawing on a single set of digital assets to provide value across many different and disparate markets to maximize customer value.

FUTURE TRENDS

Business models are largely believed to determine the success of an e-commerce venture. Alt and Zimmermann (2001) argue that business models are perhaps the most discussed and least understood terms in the areas of e-business. Business scholars have been conducting research in the e-commerce business model for more than a decade to assist business executives and entrepreneurs in formulating and implementing innovative business models. We now have a much better understanding of the taxonomy, components, and architecture of business models. Future research on the analysis, design, development, implementation, and controlling of the e-commerce business model include, but are not limited to the following areas:

- Innovation in the e-commerce business model and the continuing business model innovation process to achieve competitive advantage
- Convergence of strategy and business model
- Models and modeling techniques of e-commerce business models
- Trust building in the e-commerce business model
- Sustainable business models for services, digital contents, mobile commerce, collaborative commerce, and peer-to-peer architecture
- Other specific industry perspectives on implementing e-business models

CONCLUSION

The article discusses major components and addresses several key issues of designing and implementing e-commerce business models. A viable business model in the digital economy must transform value propositions and organizational structures and systems to enhance value creation. It must be able to take advantage of the Internet network effects and other unique attributes to achieve and sustain a critical mass of installed base of customer. Companies must also build and maintain a large set of digital assets and leverage them to provide a scope of offerings or value across many different and disparate markets to satisfy customers' demands. That is, companies must identify customers' latent needs and transform their business models from a product- or component-based model to a knowledge- or solution-based model. To achieve those goals, companies must be able to build a unique resource system that supports their value propositions and product or service offerings. Companies should also be able to use the Internet to make pricing more precise, to be more adaptable in responding to fluctuations in supply and demand, and to segment customers more effectively (Baker, Marn, & Zawada, 2001). In addition, companies need to understand the impact of e-commerce that has redefined a company or industry's competitive advantages, and be able to formulate and implement competitive strategies to gain and sustain new competitive advantages in the digital economy. Finally, this article discusses the five essential steps for companies building a successful e-commerce model in order to transform their business practices in the digital economy.

KEY TERMS

Business Ecosystem: A system in which companies work cooperatively and competitively to support new products, satisfy customers, and create the next round of innovation in key market segments.

Business Model: The method of doing business by which a company can generate revenue to sustain itself.

Digital Assets: The information (in digital form) a company collected about its customers. Companies that create value with digital assets may be able to reharvest them through a potentially infinite number of transactions.

Digital Economy: The economy for the age of networked intelligence. The digital economy is also a knowledge economy. Information, in all forms digital, is the input of an organizational transformation or value creation process.

Economies of Scope: *Supply-Side Economies of Scope*—Cost of the joint production of two or more products can be less than the cost of producing them separately. *Demand-Side Economies of Scope*—A single set of digital assets can provide value for customers across many different and disparate markets.

Network Effects: Products or services whose value to an individual buyer increases when many other people also consume the same products or services.

Switching Costs: Refers to costs incurred by buyers when they switch to a different supplier.

Transaction Costs: Costs associated with contractual relationships in a market economy—that is, costs that the consumer or the producer pays to make the market transaction happen.

INTRODUCTION

Real-world information, knowledge, and procedures after which information systems are modeled are generally of dynamic nature and subject to changes, due to the emergence of new requirements or revisions to initial specifications. E-government information systems (eGIS) present a higher degree of volatility in their environment, since requirement changes may stem from multiple sources, including legislation changes, organizational reforms, end-user needs, interoperability, and distribution concerns, etc. (Jansen, 2004; Prisma Project, 2002; Scholl, Klischewski, & Moon, 2005. To this end, the design and implementation of eGIS must adhere to paradigms and practices that facilitate the accommodation of changes to the eGIS as they occur in the real world. Object-oriented technologies have been extensively used to encapsulate reusable, tailorable software architectures as a collection of collaborating, extensible object classes; however the inherent conflict between software reuse and tailorability has inhibited the development of frameworks and models that would effectively support all requirements exposed by eGIS (Demeyer, Meijler, Nierstrasz, & Steyaert, 1997). The lack of such frameworks has lead to eGIS that cannot easily be adapted to the new requirements, mainly because only the predetermined specifications are taken into account and design decisions are fixed during the implementation phase (Stamoulis, Theotokis, Martakos, & Gyftodimos, 2003).

A key issue to a viable solution eGIS modeling is the provision of the ability to multiple public authorities (PAs) to represent different aspects of the same real-world entity, while maintaining at the same time information consistency. Aspect representation is not only limited to data elements that describe the particular entity, but may extend to behavior alterations, when the entity is examined in different contexts. For example, an entity representing the citizen is expected to assume the behavior of *beneficiary*, when used in the context of the Ministry of Social Security, and the behavior of *taxpayer*, when accessed from the Ministry of Finance's eGIS. Distinct behaviors may rely on different data representations and/or respond differently in requests. In this work we present a role-based modeling and implementation framework, which can be used for building eGIS and we argue that this model promotes the tailorability and maintainability of eGIS.

BACKGROUND

Currently, the representation of different real-world entity aspects is mainly achieved through the use of multiple, totally independent representations of the real-world entities, one per PA eGIS. Each representation encompasses the data elements, and models the behavior pertinent to the specific organization. Note that these data and behavior may include portions administratively regulated by other PAs, (e.g., the Ministry of Transport is administratively responsible for defining vehicle ownership-related data), however the Ministry of Finance eGIS should include such data, for taxation purposes.

At the other extreme of each eGIS having its own real-world entity representations, a single, centralized repository can be employed. According to this approach, some PA develops and maintains an eGIS, which is the authoritative source for both defining the schema and storing all data values for real-world entities. The schema must consolidate all data-related requirements of all PAs, while security rules can limit the access of any PA to the schema elements pertinent to its task(s).

Between the fully replicated and the fully centralized approach, a federated database approach (Chorafas & Steinmann, 1993) could be adopted, according to which each PA eGIS defines a schema portion, which is *exported*. PA eGISs may also *import* schema portions that have been exported by other "federation members", with each import augmenting the locally defined schema. The federated approach decentralizes schema maintenance tasks, with each PA updating the global schema portion for which it is responsible.

A methodology towards meeting both the requirements of multi-aspect modeling and context-specific behavior, while enhancing the overall system maintainability is the adoption of *two base constructs* for entity modeling: the first construct models fundamental behavioral system blocks, providing only the essential behavioral elements of the most abstract version of the modeled entity; this construct is termed *ATOMA* (Theotokis, 1997) and realizes the most basic collaboration and reuse contracts (Codenie, De Hondt, Steyaert, & Vercammen, 1997). Enhanced and context-specific behaviors are modeled using a second construct, namely *roles*, which are attached to atoma for modeling functional behavior related to a basic entity. Role attachment and removal can be performed dynamically, and multiple roles can be attached to a single entity, effectively modeling *facets* of this entity. Roles also implement their own collaboration and reuse contracts, through which operations are requested in the context of eGIS.

The Atoma framework is based on the concept of *separation of concerns* (Theotokis, 2003), which is a key concept in realizing deferred design decisions as it facilitates the notion of "injectable" behavioral adjustments in existing operational eGIS. The ATOMA model allows object-oriented design and code to be decomposed into units, describing basic behavior, as this is captured during the initial design phase from the contractual requirements, and units that specify either variations or changes to these requirements, or new requirements, as these emerge in time. Both at design and implementation level, the former are represented as standard object-oriented classes, while the later are roles that, when composed with classes, realize the ever-emerging requirements. Each role can therefore be refined separately to a code artifact, and the details of the code composition can be derived from those of the design composition.

THE ROLE-BASED MODEL FOR TAILORABLE E-GOVERNMENT SYSTEMS

eGIS Modeling Using the Atoma Framework

According to the atoma framework, for each real-world entity, a single atoma construct is defined, which encapsulates the fundamental data and functionality needed for managing this entity. The PA eGIS within which the construct is defined may be chosen on the basis of various criteria, such as administrative responsibility, technical know-how, expected access patterns and so forth. Once the construct for modeling a real-world entity has been defined, it may be *exported* for use by other eGIS, which will *import* this construct. Each eGIS also provides implementations for the roles that will be assigned to the atoma to be used within its context, either locally defined or imported. For example, the Ministry of Transport may define the roles *taxi* and *bus* that will be assigned to atoma of type *vehicle* (locally defined), while the Ministry of Finance may define the role *taxpayer,* which will be assigned to atoma of type *person*, a type imported from the Ministry of Social Security. Correspondence between roles and atoma types is not necessarily one-to-one: the Ministry of Finance may define the *taxable good* role, which can be assigned to atoma of types *building*, *car*, *value-added service* and so on. The communication between a role and the atoma construct to which it has been assigned is based on the collaboration and reuse contracts provided by the atoma construct; thus, the *taxable good* role can be assigned to any atoma construct that implements the collaboration contract *price*, which will be invoked to obtain the net price (before taxation) of the relevant real-world entity. During the period that an entity is assigned the *taxable good* role, its behavior is enhanced with the operations defined in the role (e.g., *tax amount*), while some of its operations may be overridden by respective ones implemented by the role (e.g., the *price* behavior will be redefined to return the net price plus the tax due). Note that both the role and the underlying entity may independently evolve without any disruption in their communication, as long as the collaboration contracts are respected. Moreover, the interaction between a role and the eGIS it is used within will function properly, as long as the existing elements of the collaboration contract implemented by the role are not altered (new elements may be added with no side-effects).

Similarly to atoma constructs, roles can also be *exported* by the PA eGIS that has defined them and imported by other PA eGIS for use, if the functionality they provide is useful in the context of the importing eGIS. For instance, the *taxable good* role, defined by the Ministry of Finance, may be imported by the Ministry of Commerce and assigned to atoma constructs, either locally defined (e.g., *value-added service*) or imported (e.g., *car*).

Maintaining Role-Based eGIS

When a new requirement is added or an existing one is changed, a new design aspect (a role) is created to address it. The new design aspect can then be composed with the existing design. Afterwards, the design aspect can be refined to a code aspect (role implementation), which is similarly composed with the existing code. The changes are localized without risking the rest of the system's stability, so there is no tangling, and both traceability and monitoring are preserved. In addition to this, dealing with the alignment problem, the decomposition into roles alleviates the monolithic nature of the design, and allows for concurrent development, while the composition underlying the ATOMA model provides a powerful mechanism for integration, evolution, customization, adaptation, tailorability and improved reuse.

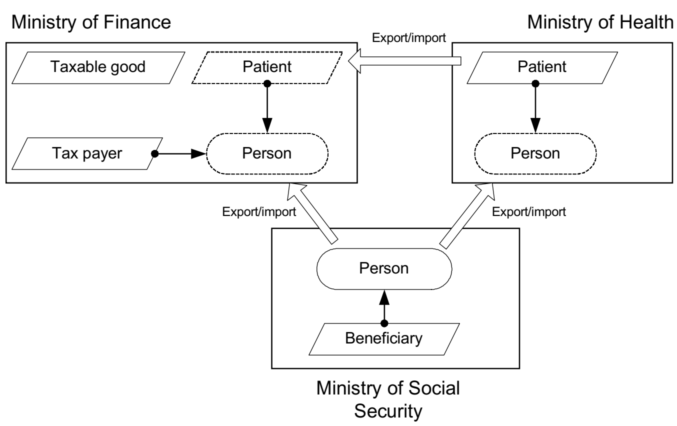
It is in fact this composition mechanism that provides a remedy to the problem of constructing rigid systems. The necessary inflexible mapping of requirements to design units is no longer required, and design decisions, which fix requirements into design, and subsequently code, are no longer necessary. By separating the various cross-cutting aspects of a system, modeling them independently and composing them back to deliver the required function of the eGIS, we advocate that deferred design decisions can be realized, and thus enable the construction of truly tailorable eGIS.

Using Atoma and Roles: A Case Study

Figure 1 presents an example of an eGIS with three constituent PA eGIS. The case study has been drawn from the Greek public administration, by studying the related legislation and practices. Atoma are represented as rounded rectangles, whereas parallelograms are used for roles. Solid lines indicate that the construct has been defined within the eGIS it is depicted in, while dashed lines indicate imported constructs. Role assignment to atoma is shown through arrows. Only one atoma construct is defined in this example, namely Person. This construct is defined within the Ministry of Social Security, which additionally defines the *beneficiary* role that it assigns to the person construct. In this manner, a *Person* exhibits the behavior of *beneficiary* only when it is treated within the context of the Ministry of Social Security, whereas outside the scope of this eGIS only the basic *Person* behavior is available. The two other ministries (Health and Finance) import the Person construct and assign to it locally defined roles (Patient and Taxpayer, respectively). The Ministry of Finance additionally imports the Patient role from the Ministry of health, and assigns it to the Person construct, since the hospitalization expenses (included in the Patient role's contract) are needed within the context of the Ministry of Finance's eGIS, to enable their deduction from the person's taxable income.

Since roles are independent of one another, it is possible that two or more roles implement different behaviors under the same collaboration contract. For instance in Figure 1, it is possible that both roles, *Patient* and *TaxPayer,* include a *Checkup* contract with different semantics (triggering clinical tests and initiates a detailed audit of tax records, respectively). Since within the Ministry of Finance's eGIS both roles have been assigned to the Person construct, an ambiguity issue is raised regarding which behavior should be selected. This ambiguity is resolved by defining priorities for role assignments, effectively dictating the order in which role contracts will be scanned for elements matching any individual contract use. It is generally expected that locally defined roles should be assigned higher priorities than imported roles, however no such restriction is imposed by the model. The atoma framework encompasses even more powerful methods for atoma and role combinations, such as molecules, which can be used in more complex cases (Theotokis, 2001).

Figure 1. Definitions, exports, and imports of atoma and roles



Comparing the Atoma Framework and Other Approaches

As noted in the background section, the dominant approaches for modeling multiple aspects of real-world entities within eGIS belonging to different PAs are; (a) the use of totally independent systems, (b) the introduction of a centralized repository where all schemata are consolidated, and (c) the use of a federated schema approach. These practices, however, have a number of disadvantages seriously impeding the design process, modeling of context-specific behavior, tailorability and maintainability.

The practice of using independent systems introduces multiple autonomous representations, which are a potential source of inconsistencies, both at the level of schema representation and at the level of stored data values (Lenz, 1996; Wiesman, et al., 2000). Indeed, if a change affecting the schema of the data used for a specific purpose is decided by the administratively responsible PA, this change should be communicated to all other PAs that handle such data, and their eGIS should be accordingly modified; the distributed nature and the scale of these maintenance activities increases the associated costs and the probability of errors. At data instance level, changes to data values stored in one eGIS do not affect the corresponding values in other eGIS, leading to discrepancies in the representation of the same real-world entity. Finally, multiple copies of the same information are maintained, increasing the overall storage requirements.

The centralized repository approach eliminates inconsistency problems (only one schema is defined and a single copy of each datum is stored), it hinders however the modeling of context-specific behavior for the entities. If entity behavior was modeled within the global repository, a single behavior would be provided for all eGIS using the entity, regardless of the context. If entity behaviors were provided separately by each PA eGIS, changes to the "global schema" would necessitate maintenance activities for all affected PA eGIS. Note also that global schema amendments and the PA eGIS maintenance should be performed "almost synchronously", since the PA eGIS data model should exactly match the repository data model upon any access.

Finally, the federated database approach cannot address the issue of context-specific behavior: if each PA eGIS fully models the behavior entities should have in its context, changes in some schema portion would again call for maintenance activities to all PA eGIS importing the modified schema; if the behavior were provided by schema publishers, context-specificity would be hindered and an additional concern would be raised, regarding where to code behavior that uses multiple schema portions, exported by different PA eGIS.

The role-based model presented above successfully tackles all these issues, by allowing organizations to model both the data items and the behavior pertinent to the entity within the role concept, which is attached to the basic atoma construct corresponding to the real-world entity. Roles can be shared between eGIS, at both schema and instance-data level, removing thus any inconsistencies due to multiple copies. Context-specific behavior is directly modeled through new context-specific roles and/or by fine-tuning the assignment of roles to atoma. Finally, maintenance is facilitated, since changes in existing requirements or emergence of new ones can be addressed through the modeling of new roles. Note that the creation and assignment of new roles (as well as the de-assignment of existing ones) can be performed at any instant, removing the need for fixing design decisions at early stages, and increasing the overall system flexibility.

FUTURE TRENDS

eGIS have emerged in the past few years, aiming to exploit information and communication technologies for providing public services with improved quality and reduced costs (Forman, 2002). Insofar, most of the work has been devoted to developing isolated informational and transactional services, but service interoperation and integration, which provides added value for service consumers [e.g., for handling *life-events* (Wimmer & Tambouris, 2002)], has not received comparable attention. It is expected that the research and implementation agenda for eGIS will include these aspects, for which the work presented herein provides the necessary technical infrastructure. Of equal importance is the provision of a methodological framework that would support the phases of eGIS requirements analysis and design, enabling involved stakeholders to unambiguously distinguish between basic and context-specific functionalities of real-world entities, providing appropriate input to the implementation phase. Methodologies extending beyond traditional service-provision systems, to include the dimensions of managerial effectiveness improvement and democracy promotion (Gil-Garcia, 2004; Cohen, 2002), providing a holistic framework for e-government will also be of essence.

CONCLUSION

In this article we have presented a framework for constructing tailorable eGIS. The proposed framework employs two basic constructs for modeling real-world entities, namely *atoma* for encapsulating basic representational needs and fundamental functionality, and *roles* for representing context-specific behavior that is attached to atoma on demand, according to the needs of the eGIS within which the entity is examined. By employing this design and implementation frameworks organizations enhance the overall system maintainability, since atoma and roles may evolve independently, provided that the reuse and collaboration contracts are respected along the evolution. New behaviors, necessitated by changes of existing requirements or emergence of new ones can also be seamlessly integrated into the system, by modeling new roles and attaching them to the pertinent atoma. Future work will address the formulation of a methodology for eGIS design according to the atoma framework, as well as issues related to migration and mobility of atoms and roles, as well as versioning and persistency.

KEY TERMS

Atoma: The most abstract level of representation of a real-world entity, encompassing only the most basic data and functionality for representing and manipulating the entity.

Centralized Representation Repository: A single database in which all real-world entity representation models are stored, and any information system willing to access a model retrieves if from there. This approach keeps the models consistent but shifts the maintenance issues to the client information systems.

Export/Import: Information systems may define atoma and roles and then *export* them to be used by other information systems. An information system may *import* any of the exported atoma and roles and use it in its own context.

Federated Representational Model: An approach for building representational models according to which each information system defines some aspects of an entity model, contributing thus to a "global" entity model.

Representational Diversity: the practice according to which real-world entities are represented through totally independent and unsynchronised models in different information systems, leading to inconsistencies and maintenance problems.

Role: A situation- or context-specific aspect of a real-world entity. A role may be dynamically associated and removed from an atoma construct when either the real-world entity evolves accordingly (e.g., a *person* becomes an employee or looses this property) or when the behavior modeled by the role becomes/ceases to be pertinent to the current context.

Tailorability: The dynamic accommodation of context-dependent behavioral variations in an existing software system.

Topology for Intelligent Mobile Computing

Robert Statica
New Jersey Institute of Technology, USA

Fadi P. Deek
New Jersey Institute of Technology, USA

INTRODUCTION

We discuss an *interconnectivity framework* for data and content delivery to *mobile devices* that allows data of higher priority to reach the mobile unit in the *shortest time* possible. Two possible scenarios are presented; one that connects the servers in an *N-cube* configuration network, and another that shows the same N servers connected in a grid type network. The goal is to minimize the rate of *data jumps* from server to server until it reaches the mobile device. As the mobile user travels, the mobile device registers itself with the next server and the session is migrated from the old server to the new one without interruptions, in an analogous way, cell phones move from one cell to another. Starting with the idea that all data is not equal (in importance/priority), this article suggest a framework topology for intelligent mobile computing that guarantees data will reach the mobile device in a minimum amount of time, assuring at the same time the privacy of transmission. The integration of this type of technology into the 3rd Generation (3G), and 4th Generation (4G) *mobile computing* is also discussed.

Pervasive computing is rapidly emerging as the next generation of computing with the underlying premise of simplicity (of use), minimal technical expertise, reliability, and intuitive interactions. As technology continues to advance and mobile devices become more and more omnipresent, the aim towards achieving easier computing, more availability and prevalence is becoming a given. Through the clever use of advanced technologies, the new generation of intelligent mobile computing has the opportunity to serve user needs via prevalent computing devices that are ever more transportable and connected to an increasingly ubiquitous network structure. *Mobile communication* is changing as the trends of media convergence including the Internet and its related electronic communication technologies and *satellite communications* collide into one.

A change is being ushered by the 3G (3rd Generation) mobile technology with the usability and usefulness of information delivered to mobile devices taking on added features. For example, *multimedia messaging*, as opposed to *voice transmissions*, being delivered to cell phones has rendered such mobile devices an integral part of people's lives and a core part of how they conduct their daily business rather than an add on tool (Buckingham, 2001).

The *3G mobile phone* system aims at unifying the disparate standards of current second generation *wireless systems*. The idea is to eliminate the different types of *global networks* being adopted with a single standard network. This will allow for the delivery of multimedia content and propagation through the network without the need for conversion from one standard to another. 3G systems need smaller cells thus the need for more base stations (mostly due to their operating frequency, power requirements, and modulation) and in many cases will not be feasible to install them in areas where population is not so dense (i.e., rural areas) (Garber, 2002). Because of these requirements and conditions, a better way to deliver the communication must be established. However, global access to such mobile devices will create *data delivery* challenges and servers can become clogged with unwanted communication, like that of wired Internet access. The need for moving relevant data to mobile devices in the shortest time possible becomes of utmost importance.

BACKGROUND

As the evolving functionalities of mobile computing take on primary roles at both the individual and the organizational levels, researchers and developers move to further enhance the technology. Bettstetter, Resta and Santi (2003) offer a random waypoint model for wireless ad hoc networks suggesting that the spatial distribution of network nodes movement, according to this model, is in general nonuniform and impairs the accuracy of the current simulation methodology of ad hoc networks. They present an algorithm that looks at the generalization of the model where the pause time of the mobile modes is chosen arbitrarily in each waypoint and a fraction of nodes remain static for the entire simulation time. They further show that the structure of the resulting distribution is the weighted sum of 3 independent components: the static, pause, and mobility (Bettstetter et al., 2003)

Xie and Akyildiz (2002) address the problem of excessive signaling traffic and long signaling delays in mobile IP. They argue that it is possible to have a distributed and dynamic regional location management scheme for Mobile IP where the "signaling burden is evenly distributed and the regional network boundary is dynamically adjusted according to the up-to-date mobility and traffic load for each terminal". This is suggested for minimizing the cost of content delivery over mobile IP networks (Xie & Akyildiz, 2002).

La Porta (2002) describes mobile computing as "a confluence of communication technologies (particularly the Internet), computing devices and their components, and access technologies such as wireless." He argues that a mobile computing environment will include not only real-time mobility of devices, but also mobility of people across devices, stressing the fact that the environment must include a wide range of devices, applications and networks (La Porta, 2002).

Zimmerman (1999) states that "The proliferation of mobile computing devices including laptops, personal digital assistants (PDAs), and wearable computers has created a demand for wireless personal area networks (PANs)" showing at the same time the fact that the mobility of such devices places considerable requirements on PANs not only for connectivity, cross-platform and networks but also for content delivery in minimum time (Zimmerman, 1999). This article further addresses the subject of data and content delivery to mobile devices with a keen interest in time and cost issues.

MOBILE COMMUNICATION SYSTEMS

There are four major categories in which data can be classified. These are real-time data, daily data, occasional data, and junk data:

1. **Real-Time Data (RTD):** Both hard and soft real-time is data that needs to be sent/received as soon as possible regardless of cost.
2. **Daily Data (DD):** Data that is sent only once or twice a day at a predetermined time (status reports, weather forecasts, etc.).
3. **Occasional Data (OC):** Data that is sent from time to time (software updates, customer service reports, etc.).
4. **Junk Data (JD):** Data that is considered useless (spam).

One way to speed up the data delivery is called data shorthand, where properly configured computers can send chunks of data based on data changes so only the changed data is sent to the mobile device (Ungs, 2002). But this type of data exchange requires mobile devices to store each of the exchange. Caching transmissions can be used successfully for non real-time data communication (like browsing the Internet, checking e-mail, etc.). For real-time message exchanges, caching cannot be used and other methods of speeding up delivery become necessary.

Convergence between broadband wireless mobile devices and access is currently a significant issue in wireless communications. With the recent technological advances in digital signal processing, software-definable radio, intelligent antennas, and others, the next generation of mobile wireless systems is expected to be more compact, with limited hardware and will feature flexible and intelligent software elements (Rao, Bojkovic, Milovanovic, 2002). Wireless mobile Internet (WMI) is a key application of the converged broadband wireless system where the actual device will be compatible with mobile and global access services, including wireless multicasting and wireless trunking. Some of the characteristics of these mobile devices will be: at least 90% of the transmission traffic will be data, voice recognition functions will be operational for every command, the mobile device will support multiple users and various service options, the mobile device will be adaptive and upgradeable, and the entire transmission will be encrypted for ensuring privacy of communication (encryption will be done in hardware for faster processing).

Mobile wireless communication implies support for user's mobility and the overall communication infrastructure needed to handle movements within the home network cell/servers map but also outside the home network in situations where communication is provided by other providers (Agrawal & Zeng, 2003; Rao et al., 2002). A mobile station (MS) should be able to communicate without session interruptions as it travels anywhere using local wireless infrastructure facilities. Because of this, session handoff between cells and mobile switching centers (MFCs) of various wireless service providers should be supported. As a MS travels from a location to another, it has to register itself with the next cell/server that serves that particular area. Each of the servers maintains a visitor location register (VLR) that is an index of the MS IDs that are in its active area. As the MS leaves a cell/server, an entry is made in the home location register (HLR) of the home network so the current location is known at all times. Based on these registers, data can be sent over the network to reach the mobile device. Our work is concerned less with the way the handoff of the communication session takes place, but more with how many times the data has to jump before it reaches the mobile device as is described below.

NETWORK INTERCONNECTION FRAMEWORK

First, we look at a possible N-cube configuration for mobile switching centers/servers. Each imaginary cube will have eight servers (one server in each corner of the cube). The worst-case scenario will be a maximum of three jumps inside a cube. Any server can be reached from any other one with 1, 2, or 3 jumps. The 2nd cube will also have eight servers and so on all the way to N cubes. The total number of servers will be N [cubes] $\times$ 8 [servers/cube]. Each of the MSCs will only have knowledge of their neighbors MSCs as well as the corresponding MSCs in the adjacent cubes. If we consider that for the real-time data (RTD) a maximum of 0.001 s propagation time between two MSCs inside the same virtual cube, and considering the propagation speed of the signal to be at $2/3 \times C$ (where C is the speed of light in vacuum=300,000 [Km/s]) then the maximum distance between two adjacent MSCs should not exceed: D = (2/3 $\times$C) x 100 ms = (2/3$\times$3$\times$10^8 m/s)$\times$0.001 s = 200 [Km]. This will make the worst-case scenario to be three jumps inside any given virtual cube that means a 3×0.001 [s] delay = 0.003 [s].

If the mobile station (MS) is not in the area covered by a cube, then a jump is needed from a cube to the next cube. If the MS is not registered with a cube, all eight servers/switching stations know that from the VRL list, so it will send the transmission to the next adjacent cube (1 jump only). If we consider the adjacent virtual cubes to be with in 200 [km] of each other, then the jump will not take longer than 1 micro second (0.001 s). In the case of N cubes, we have a maximum of Ln (8N) / Ln (2) jumps to reach the MSC that has the MS registered. In that case considering that every jump introduces a 0.001 [s] delay, in the worst-case scenario we will have 0.001 [s] $\times$ Ln (8N) / Ln (2). So if, for example, an MS travels, say, 5000 [km], that means that the area can be covered with the maximum 5000 [km] / 200 [km] = 25 virtual cubes.

If data needs to propagate from the HS (home station) to the position where the MS station is (5000 Km away), then the total number of jumps (in the worst-case) will be given by: Ln (8×25)/Ln (2) = 7.65 $\rightarrow$ 8 jumps. At 0.001 (s) delay for each jump, then the MS will be reached in minimum 8×0.001 s = 0.008 (s). Of course this would represent the best-case scenario ignoring the overhead and delays introduced by the switching equipment itself. If we use a safety factor of 2 (to cover the overhead delays) then in the worst-case scenario the MS at 5000 km away will receive the data 0.016 (s) after it was sent. This would apply to real-time data (RTD) that cannot be cached and needs to reach the MS the fastest way possible. For the data that is not real time and/or has smaller priorities, if channels in MSCs are available, it can be sent the same way as real-time data. But if the MSCs are busy routing real time transmissions, the lower priority data will be cached and put in a FIFO queue for later delivery.

Another possible interconnection of MSCs would be having the servers in a grid type network. Keeping the same constraints like for the virtual N-cube configuration, then the distance between each of the servers would be 200 [km]. Considering that each of the MSCs/servers can only communicate with a maximum of two other MSCs (no diagonal communication), and the grid has a square profile $(m \times m)$ with n number of MSCs, then the total number of jumps inside the grid would be 2(m-1). Considering the same example as above, with the MS traveling at 5000 [km] away. That distance can be covered by a 25×25 grid with each located at MSC at 200 [km] away from its neighbors. That would imply a number of jumps equal to 2(25-1) = 48. At 0.001 [s] delay per jump, the total delay in the case of a grid network would be 0.001 [s] $\times$ 48 jumps = 0.048 [s]. If we consider that the system has some residual delays, and if we use the same safety factor as in the N cube network, then we have a delay of 0.096 [s] which is six times worse than the virtual N cube configuration delay.

For the case when the MS travels outside an area covered by any of these two types of interconnections, a satellite service (MSAT-mobile satellite service) must be used to relay the data. MSAT are communication satellites in geostationary (Keplerian) orbits (35,786 km) and operate in the frequency range of 1626.5-1660.5 [MHz] for uplink and 1550-1559 [MHz] for downlink and currently serve only the US and Canada (Roddy, 2001). The periodicity of such satellite is 23 hr 56 min 4 sec which matches the Earth's periodicity. Some relevant points regarding this type of satellite: the satellite must move Eastward at the same rotational speed as the Earth, the orbit must be circular (and must maintain the same distance from the Earth), and the inclination of the orbit must be zero degrees (Roddy, 2001). Also, there is only one geosynchronous orbit thus communication via those satellites is still expensive for private use (for a two-way communication).

Satellite communication will introduce an additional delay due to the time it takes for the signal to reach the satellite and come back. At 35,768 [Km] away, a signal takes a time T= 35,768 [km]/300,000 [km/s] = 0.119 [sec] each way (Statica, 2002). So the round trip delay would be $2\times$ 0.119 [s] = 0.238 [s]. If we use the same safety factor of 2 (for delays due to sending acknowledgments, control signals, etc.), then the delay introduced by the satellite would be 0.238 [s] $\times$ 2 = 0.476 [s]. This time would be added to the time it takes to propagate through the terrestrial N cube or grid network when the signal arrives from the satellite.

Because the home location register (HLR) knows the exact location of the MS when is registered with any of the VLRs, when the value for a particular MS is not known by the HLR, two possibilities are considered: the MS is turned off (thus unable to communicate with any of the MSCs and register itself in a VLR) and the MS traveled outside an area covered by the terrestrial MSCs. At that point, if communication arrives at the HS for a MS that doesn't have the position known (registered) with any VLRs, then the HS must buffer the communication. When the MS comes on line and registers with a local MSC, even if that MSC is not directly connected to any N cube or grid network (for example is in another country where the HS is located), the MSC that has registered the MS will send a registration request via the satellite to the HS. At that time, the HS will know where to send the data for that MS and the transmission is relayed via the geosynchronous satellite. Of course satellite communication is not suitable for real-time data, due to the delays it introduces, but the MS can still get the data if needed (but not in real time).

FUTURE TRENDS

The push for advanced technology and the high demand for reliable, secure, low cost, high speed wireless connections as well as the high demand for access of data anywhere and anytime has revolutionized the wireless industry and moved the wireless systems from the secondary means of communications to a primary means crossing the line and merging at the same time the personal communication systems with business systems. Third generation (3G) wireless systems are in place, but there are already faster systems that will make the 3G network technically obsolete. Also, the fact that smaller cells are required for 3G systems would create a disadvantage when the technology is deployed over large and less populated rural areas. These systems considered to be the 4th generation (4G) aim at delivering high-definition video signals at rates 10 times faster than the 3G systems (and also cheaper). 4G systems will focus on integrating wireless networks and become the platform for mobile systems. Also, 4G systems will be IP-based multimedia services in a seamlessly integrated network that will allow users to us any system at anytime and anywhere.

The new generation of wireless communication will be multi-everything (multi-mode, multi-band, multi-functional) and is aiming to provide the best connection to users (Kim et al., 2003). 4G systems will also incorporate automatic switching functions for mobile networks, mobility control, fast hand-offs and rapid routing of packets. Because of these capabilities, it is estimated that the 4G systems will improve the coverage in highly populated areas and it will carry more traffic by utilizing various technologies and methodologies to deliver the best possible services in the most efficient way. Important advantages of 4G over 3G are higher transmission rate (almost double), higher capacity, higher frequency band (higher than 3GHz), single mobile device, increased area of coverage, and lower system cost.

As these new systems continue to be developed and improved, the need to be able to deliver data as fast as possible (with minimum delays) becomes a major factor that needs to be incorporated so the new systems live up to their promise of delivering real-time video and data to mobile units.

CONCLUSION

As the integration trend of voice and data transmissions and making them available on the same mobile device grows, it becomes important to route data from the home station (HS) to the mobile station (MS) in the shortest time possible. Moreover, real-time data (RTD) must have the highest priority, should not be queued, and ought to be delivered to the MS also in the shortest time possible. The framework discussed in this article presents a possible N cube configuration and a grid type interconnection of the Mobile Switching Centers (MSCs), which are actually data servers, so the data can jump a minimum amount of servers and reach the MS as quickly as possible. In the case when the HS does not have a direct connection with the network that the MS is registered with (while traveling), a possible satellite communication is suggested using a mobile satellite service (MSAT) network.

In an N cube configuration, it is shown that the worst-case delay would be given by the equation: $0.001\ [s] \times \mathrm{Ln}\ (8N) / \mathrm{Ln}\ (2)$, where N is the number of cubes the data has to jump. The number of cubes N is calculated based on the distance the MS is at, considering a distance of maximum 200 [km] between cubes (and between each of the MSCs inside a cube). In the square grid configuration it is shown that the worst-case delay is given by the equation: $0.001\ [s] \times 2(m-1)$, where m is the side of the square. Using the MSAT satellite will introduce a minimum of 0.476 [s] delay, only due to the propagation of the signal.

We found that having an N cube interconnection of MSCs will give the smallest time in data delivery to a MS. With relatively small number of cubes, we can cover a relatively large area of service. For example, for a 5000 [km] travel of MS we need around 25 cubes. The proposed topology fits well in the design of the 4G systems and will help in achieving the design parameters of the 4th generation wireless networks by allowing data to reach the end user the fastest (and cheapest) way possible.

KEY TERMS

Antenna: The part of a transmitting or receiving device that radiates or receives electromagnetic radiation (electromagnetic waves).

Bandwidth: The difference in Hertz between the limiting (upper and lower) frequencies of a spectrum.

Broadband: Refers to systems that provide the user with data rates in excess of 2MBps and up to 100 Mbps.

Cellular Network: A wireless communication network in which fixed antennas are arranged in a special pattern (hexagonal pattern) and mobile stations communicate through nearby fixed antennas.

Channel Capacity: The maximum possible information rate through a channel subject to the constraints of that channel.

Downlink: The communication link from a satellite to an Earth station.

Frequency: Rate of signal oscillation in Hertz.

Geostationary: Refers to geosynchronous satellite angle with zero inclination. So the satellite appears to hover over one spot on the Earth's equator.

Packet: A group of bits that includes data (payload) plus source, destination address and other routing information (in the header).

Transmission Medium: The physical path between a transmitter and receiver (can be wired (guided medium) or wireless (un-guided medium).

Uplink: The communication link from an Earth station to a satellite.

Wireless: Refers to transmission through air, vacuum or water by the means on an antenna.

Traditional and Internet EDI Adoption Barriers

Albert L. Harris

Charlie Chen
Appalachian State University, USA

INTRODUCTION

Electronic data interchange (EDI) is a conduit to innovative ways of conducting e-business processes, as well as facilitating e-business applications and services. EDI is the electronic exchange of business documents using standardized document formats (Blackstone & Cox, 2004). *Traditional EDI*, based on proprietary *value added networks (VANs)*, went through the early adoption stages in the 1990s (Clinkunbroomer, 1991; Premkumar, Ramamurthy, & Crum, 1997). Many factors caused the slow diffusion of the technology, including, but not limited to, high investment costs (Wilde, 1997), proprietary standards, poor integration capability with existing corporate systems, rigidity, poor scalability (Peters, 2000), poor performance in auditing trails, document certification needs, and the perceived need for hardcopies of the documents (Banerjee & Golhar, 1994). Despite these adoption obstacles, many large and small organizations have been leveraging the open architecture of the Internet to improve their agility and competitiveness. Unlike traditional EDI, *Internet EDI* adopts an open standard (extensive markup language or XML) and entails higher business agility by integrating the information systems of the business partners. Internet EDI is becoming an alternative to traditional EDI. Their natural differences pose an interesting, timely, relevant, and applicable research question: What would it take to accelerate the adoption of traditional and Internet EDI to support electronic business?

This article proposes a theoretical framework based on Rogers' (1983; 2004) *innovation diffusion model* and interorganizational theories. Major technological and managerial obstacles confronting widespread adoption of traditional EDI and Internet EDI are addressed. Future trends of these technologies are discussed as a conclusion.

BACKGROUND

Depending on the electronic means adopted, EDI can generally be classified as traditional EDI (connecting via proprietary VANs) and Internet EDI (connecting via the Internet using open XML standards). *Small- and medium-sized enterprises (SMEs)* have been reluctant to adopt traditional EDI due to a lack of financial (Ahlin, 1991) and technical support (Banerjee & Golhar, 1994), as well as the constraints EDI places on business practices. The Bank of America, NASA, and Avex Electronics Inc. allied with Premenos to initiate the first Internet EDI project in 1995. This pioneer project's success accelerated the popularity of Internet EDI. Internet EDI is an anticipated alternative for SMEs from the perspectives of economics, operation (e.g., faster establishment of customer-supplier relationships) (Lehmann, 2002), and scheduling. Internet EDI allows business partners to conduct business over the Internet and saves money in purchasing and learning expensive software. Traditional and Internet EDI have natural differences in closed versus open standards, high vs. low cost, and business rigidity vs. flexibility. Expectations are that Internet EDI will be superior to traditional EDI at some point in the future, although the transition is inhibited by (1) the reliability and security of the technology, (2) unrealized benefits of the existing investment in traditional EDI, and (3) immature legislative regulation (Threlkel & Kavan, 1999). It is vital to understand their differences in technological and managerial barriers of adoption.

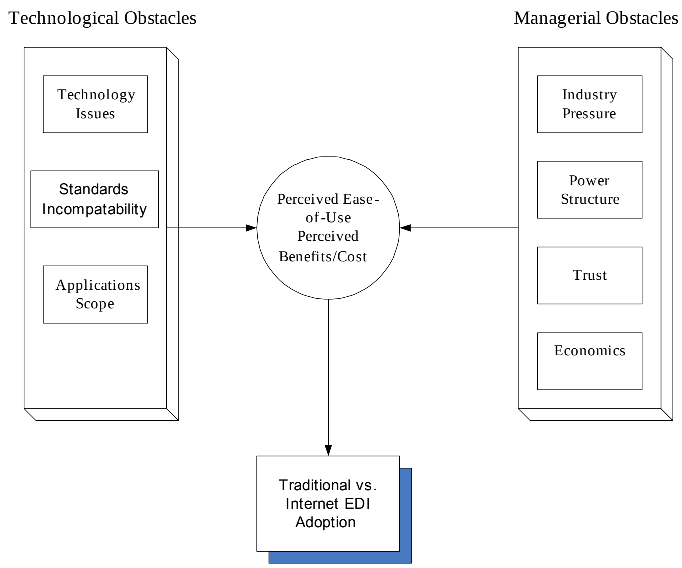
BARRIERS TO TRADITIONAL AND INTERNET EDI ADOPTION

Two major groups of obstacles present barriers for EDI reaching critical mass in its adoption curve: technological and managerial (Figure 1). Technological and managerial obstacles contribute to companies' perceived ease of use and perceived benefits/costs (Iacovou, Benbasat, & Dexter, 1995). These, in turn, impact traditional vs. Internet EDI adoption.

Technological Obstacles

Technological obstacles include technology issues, standards incompatibility, and application scope. Each is discussed in the following paragraphs.

Figure 1. A model to study EDI adoption issues



Technology Issues

The success of traditional EDI relies on the technological capability of dedicated, private or third-party proprietary VANs to interconnect heterogeneous systems and data communication *protocols*. Each company usually has unique ways to operate its business. Significant coordination and configuration efforts are imperative to reconcile the difference between trading partners. The installation of traditional EDI may also require changes in the existing business processes across different functions (Burrows, 1990). As a result, EDI adoption is usually susceptible to a sustainable and long learning curve. Technological barriers to the deployment of traditional EDI are even higher when supplier and customers use different VANs that do not have same coverage area or use incompatible technology. A Commonwealth of Australia report surveyed 227 respondents and found that "lack of EDI-capable business partners" (59%) and "integration of EDI with internal applications" (44%) are two major technological barriers to traditional EDI adoption.

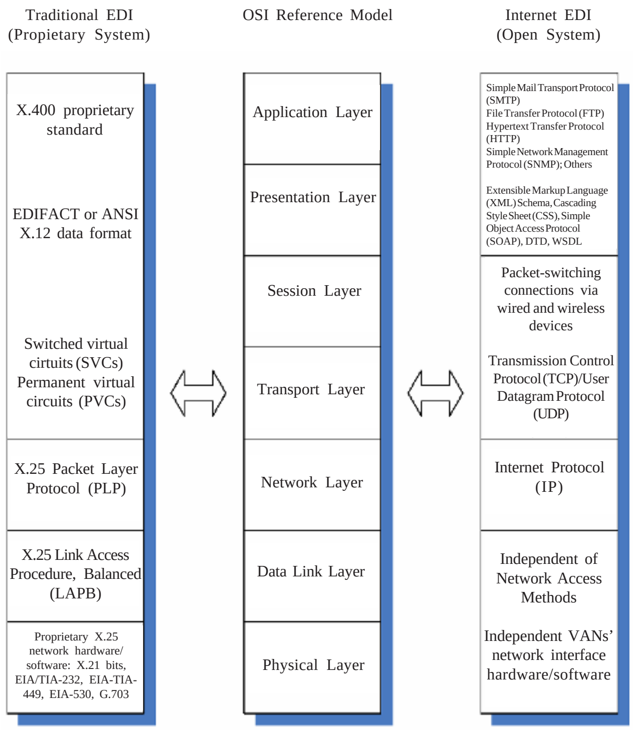
Internet EDI needs to overcome different technological obstacles. The "hub-spokes" model of traditional EDI based on the coverage area of a service provider (Angeles, 2000) is no longer a relevant issue. Instead, suppliers and customers need to decide which e-marketplace or trading community they want to be associated with. Once a decision on a particular community is made, the supplier or customer will be connected instantly to larger buyers' or suppliers' base. One major shortcoming with the Internet EDI is that data traffic on the Internet is less predictable. It is possible that Internet EDI slows or terminates during the transactional process due to the burst of data traffic. Therefore, Internet EDI is potentially weaker than traditional EDI in reliability and traceability. The mechanism for Internet Protocol security and networking management like Internet Engineering Task Force's AS2 (Applicability Statement 2) security protocol must be in place to monitor, detect, and correct network security and congestion problems.

Standards Incompatibility

How do we handle data that can vary in data format, document architecture, syntax, data type, and templates that are customized for the backend applications of suppliers and customers? How far along the value chain and supply chain can a company go with a proprietary traditional EDI? Will traditional EDI interfere with existing backend applications? How long will it take to coordinate and configure common global standards to reach a customer's suppliers? These are standards incompatibility issues. Figure 2 compares traditional and Internet EDI with respect to the Open Systems Interconnection (OSI) Reference Model.

Traditional EDI adopts the *EDIFACT* (Electronic Data Interchange For Administration, Commerce and Transport) or *ANSI X.12* (American National Standards Institute) protocols that map to the lowest three layers of the OSI reference model. These three layers are so strictly

Figure 2. Traditional vs. Internet EDI architecture



defined that business partners can only interconnect with each other via the proprietary standard. The upper service level covers four OSI layers. Traditional EDI needs to establish a virtual or dedicated circuit connection between business partners. VANs serve as a middleware or hubs to translate and integrate data generated by heterogeneous systems of trading partners.

In contrast, Internet EDI is refrained from the rigidity of EDIFACT or ANSI X.12 standards by modularizing tasks at four independent layers. Data move across networks in different data formats at different layers. Since each layer performs the same functions, data formats at the sender and the recipient sides are the same. This allows the interconnection and information exchange between customer and supplier without standardizing heterogeneous systems of trading partners. At the session layer, trading partners can adopt either public or private networks according to their business requirements for bandwidth. Wired and wireless devices adopting packet switching technology can converge with each other. Standardized port numbers and service protocols further increase the scope of applications.

Applications Scope

Top traditional EDI VANs were GE Information Services, IBM Global Services, Sterling Commerce, Harbinger, MCI, and AT&T. Major industries adopting traditional EDI were retail, transportation, manufacturing, health-care, high-tech and grocery. EDI can deliver: (1) operational benefits—cost reduction, automation of standardized procedures, improvement of information transparency, and enhancement of sensing and responding capabilities; and (2) strategic benefits—stronger customer-supplier relationships, increased barriers to entry, managing post-sales supply chain, and creation of new strategic possibilities.

The Internet's ubiquitous nature extends the use of EDI by SMEs. Internet EDI also improves the accessibility and cost-effectiveness of traditional EDI. For instance, the Global eXchange Services Trading Grid (http://www.gxs.com/) is a B2B e-marketplace where more than 100,000 business partners adopt Internet EDI to service more than 300,000 customers across industries worldwide. Such a large customer base is beyond the capability of traditional EDI. Organizations can electronically exchange volume-intensive data, such as product catalogue and product specification information which contains rich information such as images, audio- and video-on-demand without adding additional cost. However, to migrate from tradition EDI to Internet EDI, an organization needs to address many concerns: (1) standards and version control, (2) EDI tags modification for ease to read via a browser, (3) EDI files modification to be stored easily in relational databases (Hamdar, 2002), and (4) interorganizational and trading agreements between partners (Gottardi, Bolisani and Biagi, 2004).

Managerial Obstacles

Four key factors of an alliance—industry pressure, power structure, trust, and economics—can influence the decision of an organization to adopt EDI. These are discussed in the following paragraphs.

Industry Pressure

Industry pressure creates external pressure to influence the intention of suppliers and buyers to adopt EDI technology (Iacovou et al., 1995). Industry pressure includes strict standards, inter- and intra-industry competition, standards-regulatory, business partners, and government. The Internet Engineering Task Force drafted the AS2 specifications that detail how to securely transport an EDI file over the Internet. Industry EDI proponents often demand their buyers migrate from traditional to Internet EDI. RosettaNet (EDI for the computer industry), EDIFACT, and other XML-based EDI e-marketplace are products of the industry pressure. A company may have to comply with industry pressure to transact with business partners belonged to the industry association. When industry pressure creates the industry-level compliance, a firm can lower the degree of asset specificity and uncertainty (imperfect information), but increase the number of input resources (Williamson, 1971). Thus, it becomes easier for business partners to transact with each other using Internet EDI. From the comparative institutional perspective (Hennart, 1994), Internet EDI can potentially achieve three cooperative and exchange gains: (1) create awareness of gains through joint efforts, (2) discourage parties from bargaining their own gains, and (3) enforce agreed-upon agreements. Industry pressure creates pressure to adopt and increases perceived benefits of adopting Internet EDI.

Power Structure

Hart and Saunders (1997) asserted that a set of mechanisms should be deployed (ranging from convincing power to compulsory power) to influence an organization to adopt an *interorganizational system (IOS)*. EDI is an IOS to support business operations (Soliman & Janz, 2004). To realize the above mentioned benefits, power mechanisms are important considerations for EDI adoption. The convincing power mechanism focuses on reward and incentive approaches to encourage an organization to change; this is useful for maintaining a long-term alliance relationship. In contrast, the compulsory power mechanism, like punishment, is often used when an organization has many partners and needs to influence business partners with a relatively low bargaining power to implement EDI. When one party has a higher convincing power, it can influence the perceived benefit of implementing EDI for business partners. This pressure will help convince business partners to implement EDI. The convincing power of a business partner correlates with an organization's perceived benefits versus the actual cost of EDI implementation. An organization is more likely and willing to implement EDI when there are high benefits and low costs. (Premkumar & Ramamurthy, 1995).

Firms with dominating power over their business partners—such as the ability to penalize business partners by reducing or canceling orders—are more likely to force the use of interorganizational systems. Iacovou, Benbasat, and Dexter (1995) suggested a firm use compulsory power to pressure business partners to comply with its policy. The more bargaining power a firm has over its business partners, the higher the possibility that the organization can obtain resources from its business partners. This unbalanced relationship will force companies to maintain a relationship and make them more receptive to the adoption of Internet EDI.

Trust

Trust is another important factor that influences an IOS (Hart & Saunders, 1997; Smith, Carroll, & Ashford, 1995). Therefore, trust is also an important factor for the success of EDI. Trusting organizations are more willing to invest in EDI and share information with their business partners. Moreover, trust can stop opportunist behavior from appearing. When the opportunists' behavior declines, the opportunity to share information with business partners will improve. When business partners propose adopting EDI to facilitate their transactions, an organization trusting its partners is more likely to reach consensus in terms of the benefits they can realize with EDI. An organization may also think it is worthwhile to invest in EDI because of trusting its partners. An organization needs to face many security challenges of EDI to an interorganizational relationship. The first challenge is security in transmitting information between business partners. Internet EDI is potentially less secured than traditional EDI because transactional activities are highly distributed among users. It is easier to intercept confidential information when the information exchange process between the sender and recipient is widely distributed than one centrally managed. A supplier also needs to face the risk of leaking confidential information to its competitors by sharing confidential information with their same customers via

Internet EDI. This risk may potentially jeopardize customer-supplier relationships.

Economics

Mukhopadhyay's (1993) EDI framework is useful to assess the business values generated by traditional and Internet EDI. Internet EDI's network size is much larger than traditional EDI. Hence, its locus of impact on the operational and strategic benefits of adopters is higher. Because of sunken costs that have not been realized, traditional EDI adopters may not retire the technology immediately. The perceived significant cost savings in operational cost via Internet EDI have convinced traditional EDI adopters to seek middleware or upgrade their existing EDI software. The deployment of a traditional EDI is complex and needs continuous support to maintain the EDI system and train users. The deployment cost of traditional EDI includes purchasing EDI software, customizing EDI by developing conversion software, integrating EDI with the existing legacy information systems, and establishing the data communications and networking infrastructure with business partners. It is crucial to establish and maintain a reliable value-added network to support the successful deployment of traditional EDI. Many mega suppliers like Wal-Mart have perceived a significant savings of opportunity cost by replacing traditional EDI with Internet EDI. Manufacturers and retailers can save between $500,000 and $1 million for every $1 billion in revenue in the data synchronization effort alone according to the consulting firm A.T. Kearney (Bednarz, 2005). Another savings for Internet EDI is the operational cost measured by the cost per message. Traditional EDI message transmission costs are 13 times higher than Internet EDI for every 25,000 messages per month (Adhikari, 1996). The savings are being further increased with the decreased information communication and telecommunication cost. A typical SME can save approximately $2,000 a month by switching to Internet EDI from traditional EDI (Barlas, 2004).

FUTURE TRENDS

Most companies have been rationally weighing the benefits and cost of the EDI adoption in the traditional economic sense. Most companies seem to be reluctant to replace traditional EDI with Internet EDI immediately. Diffusion theory asserts that a newer innovation would replace the older technology when it becomes outdated and inefficient. Internet EDI has much higher relative advantages over its predecessor traditional EDI. To accelerate the adoption of Internet EDI, it is important to increase the urgency to replace traditional EDI with Internet EDI. This is not an easy task since many adopters of traditional EDI have not received enough returns from their investment. An organization needs to minimize the degree of resistance to the replacement decision. To accelerate the replacement process, an organization needs to create resistance to traditional EDI by promoting Internet EDI among innovators. It is also crucial to sidestep resistance by convincing early adopters that Internet EDI is much superior to traditional EDI in both technological and business arenas. Another emergent theme is the continuously increased industry pressure from large suppliers like Wal-Mart for a larger trading community via Internet EDI. Closer cooperation between standards regulatory institutions and suppliers is being forged to develop a more secured technology such as AS2 security protocol. Despite the mandatory use of Internet EDI by some larger suppliers, some trading partners are not convinced of the technology's reliability and security. Some firms are adopting phased development approaches to extend the applications of Internet EDI across functions and suppliers. Another trend is the increased demand for users to play the VAN role. For instance, salespeople who are using Internet EDI need to know how to generate expense reports, access customers' data, and get information about other parts of the company. Employees in the accounting department need to receive security awareness training to adequately verify the integrity of transactional data. A firm also needs to have a

Table 1. Assessing the business values of traditional and Internet EDI (Adapted from Mukhopadhyay, 1993)

Stages of Assessment	Traditional EDI	Internet EDI
Step 1. Examine the transaction sets and the application systems interfacing with EDI to determinate the locus of impact	Average of 2-10 transaction sets; Low impact	Average 10,000-200,000 transaction sets; High impact
Step 2. Find out the extent of the EDI network (e.g., number of trading partners) to assess the magnitude of the impact.	2-5 trading partners	1000-30,000 trading partners
Step 3. Study the production/operation process to identify control variables.	VANs	Membership
Step 4. Determine the exogenous industry or economy-wide trends that may mitigate the results	High entry barriers	Low entry barriers

help desk that is knowledgeable and responsible enough to respond to mission-critical problems. Training programs will become a necessity.

With the increased number and size of network communities, the awareness of relative advantages of Internet EDI over traditional EDI will be improved. Part of the delay of the innovation diffusion process for many innovations is the direct result of inadequate communication (Gatignon & Robertson, 1985). Internet EDI enables many-to-many relationships among business partners and increases the importance of their communications. In the future, the communication process will become more prevalent to narrow the gap of perceived benefits and costs between business partners.

CONCLUSION

Internet EDI innovation promises business benefits, including operational efficiency, operational innovation, and new business opportunities. Removing technological and managerial obstacles is the prerequisite to the realization of these benefits. This article proposes a theoretical framework to examine these obstacles based on innovation and interorganizational relationship theories. Technological obstacles include technical issues, standards incompatibility, and applications scope. Managerial obstacles include industry pressure, the power structure, trust among business partners, and economic issues. Future challenges are to remove the technological and managerial obstacles of Internet EDI adoption. Overcoming these challenges can effectively accelerate Internet EDI innovation diffusion, and retire traditional EDI applications.

KEY TERMS

T

ANSI X.12 (American National Standards Institute): The standard for the electronic exchange of business documents in North America.

EDIFACT (Electronic Data Interchange For Administration, Commerce, and Transport): An international standard for the electronic exchange of business documents widely used in Europe

Electronic Data Interchange (EDI): The electronic exchange of business documents using standardized document formats.

Internet EDI: The use of the Internet to exchange business documents using standardized document formats.

Interorganizational Systems (IOSs): Systems that provide information links between companies.

Protocols: Rules and conventions that define how data is transmitted over communications media.

VAN (Value-Added Network): Public data communication networks that provide basic transmission capabilities plus enhanced services (security, error detection, video conferencing, etc.).

Transformation of E-Fulfilment Industry Capabilities

Paul Alexander
Edith Cowan University, Australia

Janice M. Burn
Edith Cowan University, Australia

INTRODUCTION

Over the last decade, organisations have been forced to re-examine the role of ICT as a support tool and accept that it has become a major driver for business change (Ash & Burn, 2003, pp. 297-308.). Indeed, new business opportunities have arisen solely based on e-business: *e-fulfilment* is one such example (Alexander & Burn, 2004, p.1). These services were estimated to be worth US$1,006 Trillion in the United States alone, or 10.1% of their GDP in 2000 (Rogers, 2002). Furthermore, 21% of all logistics transactions are expected to be online by 2005, with the long-term possibility that traditional freight companies will ultimately cease to exist (Homs, Meringer, & Rehkopf, 2001). This article explores the concepts which are encompassed in the term e-fulfilment, and presents a model of e-fulfilment activities. This model is then validated through the analysis of *e-fulfilment capabilities* of 48 UK based e-fulfilment companies. The findings from this analysis lead to an extension of the model and suggest a long term transformation model for the industry as a whole.

BACKGROUND

A review of the literature on e-fulfilment and online retailing identifies the following issues, which need to be considered:

- **Location Design and Picking Systems**;
- **Packing:** Specific packaging for delivery of products, can include breaking original packages and repackaging, often must be customised for each order;
- **Customer Service:** Managing customer queries and complaints;
- **Financial Transactions:** calculating and including fulfilment costs, and electronically settling these with appropriate organisations;
- **Warehouse Costs:** associated with product storage;
- **Delivery:** Systems and delivery alliances;
- **Transport Mechanisms and Flows:** Using multiple delivery mechanisms to ensure deliveries arrive on time and undamaged;
- **Procurement Management:** Purchasing arrangements automatically (electronically) integrated with fulfilment suppliers, triggering delivery transactions;
- **Management Information Systems:** Concerned with integrating and managing all aspects of the process;
- **Front End (Ordering) Services:** Which electronically trigger the fulfilment process automatically from a Web-purchaser's mouse-click;
- **After-Sales Service:** To ensure fulfilment problems are resolved;
- **Returns:** Manage reverse logistics related to incorrect, damaged or fit-for-use product issues, this must not only ensure convenient and quick return of goods, but often must initiate re-delivery (of the correct goods);
- **Real-Time Tracking:** For management of all pools of product, and also commitment to promises made by front-end ordering systems.

These are recognised as integrated components which create virtual proximity between e-trader and customer and cover everything a company does to satisfy customer demand within an e-commerce framework, and a succession of activities which are necessary for the successful supply of customers and markets (Klaus, 1998).

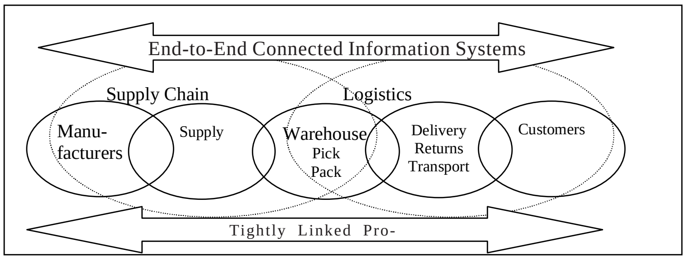
Figure 1 collapses these concepts into a single diagram, and illustrates the scope of what can explicitly be termed *e-fulfilment.*

CAPABILITIES MODEL DEFINES E-FULFILMENT

The annual report produced in the UK by *E.logistics Magazine* and known as the E-fulfilment Index (Rowlands, 2003), provided the basis to examine 48 third-party e-fulfilment service providers based in the UK.

T

Figure 1. E-fulfilment scope



The range of capabilities offered by the e-fulfilment providers examined is shown in Figure 2. These 13 capabilities are in the following categories, which align with aspects of the model outlined in Figure 1:

a. Capabilities for carrying out physical parts of the fulfilment process.
b. Capabilities that link processes. These are enabled by using call centres, and online track/trace capabilities.
c. Capabilities that extend fulfilment into the suppliers' and related providers' value chains.

Figure 3 shows the frequency distribution of the number of separate capabilities offered by each of the sample. It is clear from this that there are a minority of *specialists*, a large group of providers offering a half or more of the possible capabilities, and 30% of the sample offering *all* capabilities analysed.

Further analysis of these 48 organisations examined "*last mile*" capabilities, warehousing space, size and stability, turnover and relationships to parent organisations. Last mile is an area of intense interest with e-fulfilment providers (Alexander & Barnett, 2004; Alexander & Burn, 2004; Punakivi, 2001, 2002; Schulz, 2003). The capabilities include open customer delivery windows and alternative goods reception strategies.

Slightly more than 50% of the sample have already adopted most of these capabilities, or are willing to. But tellingly, almost 50% (almost all the remainder) are considering or are willing to offer these capabilities. Clearly, as these organisations feel the economic and operating pressures of last mile delivery, their activities in setting up new last-mile-specific solutions is frenetic. The data strongly indicates that the future direction for these businesses will include the provision of last mile capabilities.

Though almost all e-fulfilment providers are derived from, or are in their own right, established logistics/warehouse/transport operators, 68% are able and willing to provide new services such as Web development and hosting facilities. For established logistics providers, this

Figure 2. Percentage of sample showing specific e-fulfilment capabilities

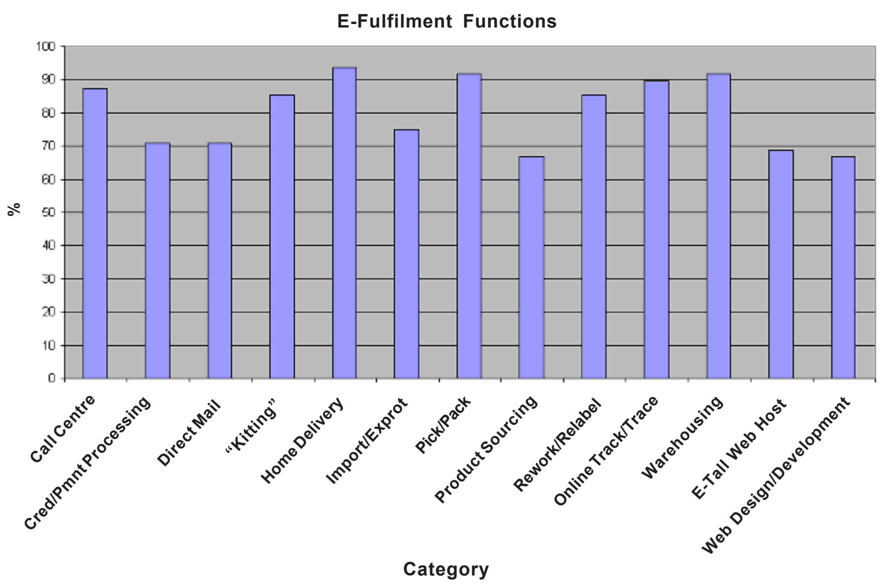


Figure 3. Specialists or generalists

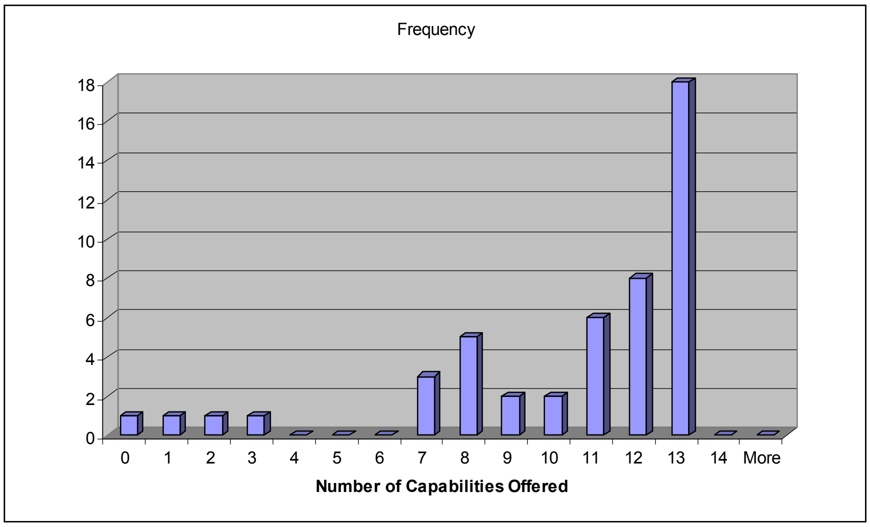


is an interesting development. Not only have these companies implemented the online and Web-based changes required to be a credible e-fulfilment provider, but they appear to be keen to offer these services to customers. This data clearly indicates new business opportunities in the industry as a whole; an idea that will be developed in the next section.

A TRANSFORMATION MODEL

These organisations all targeted online retailers, either primarily, or as a recognised sector of their market. (Duffy & Dale, 2002) recognised 10 critical support processes required for success by such retailers, and e-commerce operators in general (see Table 1). Of these 10, eight align

Table 1. Critical e-commerce success and e-fulfilment capabilities

E-commerce critical success capability (Duffy & Dale, 2002, p.432)	*E-fulfilment operator capabilities in the sample*
Order fulfilment	Yes
Revenue generation	No
Revenue collection	Last Mile capability
Financial control	No
IT/Web changes	Yes
Business processes	Significant integration
e-integration	Yes
Order generation	Integrated
Call centre integration	Yes
24/7 operation	Enabler
Consumer behaviour	Influences customer experience

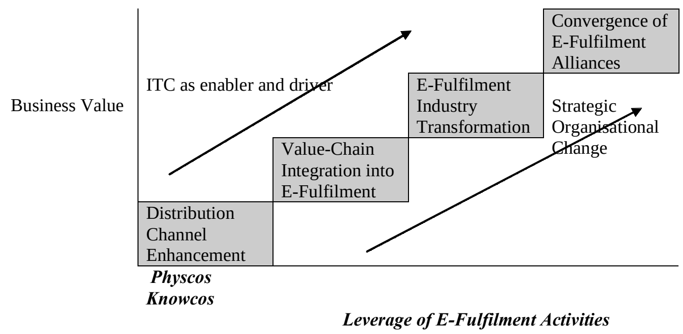
with capabilities exhibited in our sample (the remaining two cannot be evaluated at this stage). Evidently, they provide some or all of the range of services e-tailers consider essential, and therefore provide most or all of the services in the model we presented. They all have tight end-to-end electronic systems to control their processes, and provide facilities call centres, payment systems and online components to integrate their services with those of the online retailers.

In most cases, this integration appears to be to the point of providing a single outsourced solution for online retailers' e-fulfilment needs, which in turn appears to result in offerings of diverse sets of services, rather than specialists in particular services. However, there is significant evidence of the e-fulfilment organisations themselves outsourcing certain of their functions to specialists, particularly noticeable with Web site aspects of the businesses. When viewed as a whole, the online retailer, the e-fulfilment partner, and the specialist e-fulfilment service provider are all cooperating as a "virtual organisation." For instance, those with expertise and assets able to handle large-size products (e.g., furniture) are becoming aligned with online retailers with that product range.

A staged transformation can be seen taking place within the industry which can be related to a model of e-business change as identified by Deise, Nowikow, King, and Wright (2000). (See Figure 4.)

This begins with the use of ICT within the parent company (typically transportation or warehousing) to enhance distribution channels through some form of e-commerce. This is followed by the application of ICT

Figure 4. The e-fulfilment transformation model (Adapted from Deise et al., 2000)



within and across value chains, and extending into e-fulfilment. This inevitably leads to industry transformation as networks of organisations are formed through extended e-business operations; for example, the move we observed within e-fulfilment companies towards Web site design activities. And finally there will be a convergence where many e-fulfilment companies and their offshoots come together and work within the same e-space in virtual environments.

As e-fulfilment organisations move from left to right across the panorama painted by the *transformation model* (see Figure 4), they are likely to gain added value but also to encounter much greater risk. As they move through these stages, they will be looking to exploit means of revenue enhancement, cost reduction and relationship management. This transformation can be viewed as the transformation of a company reliant on physical assets to one which is solely dependent on knowledge assets.

As companies collaborate along their value chains the nature of the industry begins to change as organisations decide to outsource some of their traditional functions and focus only on their core competencies. The term "going to market" will no longer be defined as the way a company enters the marketplace but rather it will characterise the way an integrated group of companies creates a set of cascading values to transform the marketplace into a network of value providers.

At this stage companies will make a conscious effort to orient their strategies toward becoming knowledge-based "Knowco" or physical goods-based "Physco" companies (Deise et al., 2000). This is not normally a complete transformation but rather an orientation towards one or the other. Knowcos will focus on building brands, capturing ownership of the customer-end market relationship, and investing in knowledge-based core competencies such as e-marketing and Web services development. They may well expand into providing customer knowledge management services to other companies in their marketplace. Physcos will become hubs of processing expertise. Their success will be based on speed, quality and delivery.

FUTURE TRENDS

A survey with emphasis on companies' perceptions of near-future e-fulfilment challenges and opportunities, whether they were developing Physco or Knowco capabilities, and how they were preparing for these suggest two relatively discrete approaches to future environment, depending on whether the companies are "general outsourcers" (GOs) representing 30% of e-fulfillers, those providing a full range of capabilities, or "specialised outsourcers" (SOs) targeting a more niche-market strategy and with typically fewer capabilities. Whichever category they might fall in, they appear to be comfortable in that approach, with no intentions to alter their customer or geographic focus.

Strong pressures to move to non-traditional capabilities in the GOs, with some, but much less perceived imperative in the SOs, who are more focused on relationships with customers in their sector. This behaviour in turn appears to drive the nature of development of the capabilities. The GOs are developing new customer-facing capabilities while the SOs are more intent on improving internal processes and infrastructure of existing capabilities.

Regardless of their degree of specialisation, they are using and recognise the importance of Web facilities for their organisations, though it is the GOs who see online services as more significant. They are also more intent on increasing their expertise and developing these capabilities.

Though almost all e-fulfilment providers are derived from, or are in their own right, established logistics/

warehouse/transport operators, 68% are able and willing to provide new services such as Web development and hosting facilities. This data clearly indicates a strong desire to develop Knowco capabilities.

Interestingly, despite the importance of these services, most organisations are comfortable in outsourcing them. While this is understandable in SOs, who do not appear to regard them as so central, it is unexpected, given the GOs' intended direction. Nevertheless, it conforms to a pattern found within the general logistics market with outsourcing being heavily service driven (Wilding & Juriado, 2004).

In terms of future environments, e-fulfilment organisations are anticipating new opportunities generated by new software applications, and by delivery infrastructure enhancements, often relating to the postal service.

When it comes to threats, while all respondents are concerned with security (more particularly, online security issues), GOs are also concerned with substitutable products, which aligns with earlier noted intentions to enhance customer-facing capabilities.

CONCLUSION AND FUTURE RESEARCH

E-fulfilment businesses are both successful and stable in the UK, where they have in many cases evolved from traditional fulfilment-logistics-transport businesses into enhanced e-fulfilment businesses showing many of the features expected from the knowledge capabilities model outlined.

Many of these businesses have chosen to become *generalists*, offering the whole range of services classified under the heading of e-fulfilment. This is driven, at least for some businesses, by a perceived opportunity in outsourcing online retailers' fulfilment needs completely. Such a marketing strategy is logical when not only does the outsource provider have individual capabilities, but has developed systems and skills that link them closely together, enhancing efficiency and reducing problems (Hoek & Chong, 2001).

There is also a place for specialists, who although fully embracing online and general capabilities, are very focused on meeting their customers' needs with respect to efficiency and services offered.

E-fulfilment businesses are preparing for a market place they believe is incrementally expanding. They feel constrained by delivery infrastructure and threatened by a potential backlash from traditional retailers. But even though the market appears to be evolving steadily now, e-fulfilment organisations are transforming as a fast rate, acquiring knowledge-based capabilities that integrate them better with their customers. When those capabilities are integrated with online solutions such as customer Web-integration, we note that many companies have chosen to outsource these capabilities. This may well have been a suitable response to rapidly acquiring skills not part of the traditional e-fulfilment businesses from which many e-fulfillers are descended, but if this has suppressed development of core online skills then strategic decision-making in the area may be affected. Having such core skills may become a differentiator for gaining competitive advantage in the future.

Future research in this area is likely to focus on the evolution of e-fulfilment capabilities over time, with particular attention on the knowledge component of the capability. Representing this information as an "index" will also allow comparisons between businesses and over time, and relating such indices to competitiveness is a tantalising opportunity for which preliminary evidence already exists and if proven, can lead to practical and useful benchmarking measures for the e-fulfilment industry.

KEY TERMS

Capability Transformation Model: Traditional logistics, transport and warehousing capabilities are based on the ability to provide physical resources to assist the customer. These appear to be transforming, with the inclusion of knowledge-based skills and service additions. For example, an e-fulfilment provider may extend traditional supplier-pickup services (which is a physical outcome) to an offer to manage a complete supplier relationship (which is based on knowledge of contracts and supplier environment). Note that the mere inclusion of an information system (for example, a track-and-trace system in a transport operation) does not imply a knowledge capability, but rather is a means to improve a physical capability. Such a model can be used to assess each of a provider's capabilities for the balance between physical and knowledge-based outcomes and arrive at an index representing the overall degree of knowledge-based outcomes offered by the company.

E-Fulfilment: The activities required to ensure a product ordered through an online retailer is delivered to a consumer, and may also include reverse logistics (return of goods) activities. E-fulfilment providers provide services derived from those offered by traditional logistics, delivery and warehousing providers, as well as an emerging range of new capabilities. Such services may be provided by in-house departments or increasingly by third party outsourcers who offer a wide range of supply chain services to online retailers.

E-Fulfilment Capabilities: E-fulfilment providers may be identified from a well defined set of capabilities they utilise in offering their services. These incorporate traditional logistical, delivery and warehousing services as well as picking and packing, kit delivery and payment-taking systems. Increasingly, capabilities are incorporating knowledge-based skills and resources and include such services as online retail Web site development or hosting, supplier management and customer relationship management. These capabilities are not uniformly adopted by provider organisations.

Generalist E-Fulfilment (GO) Providers: Third party e-fulfilment providers may choose to offer a large range of e-fulfilment capabilities. These may be either Physco or Knowco in nature, though a greater proportion of GO providers are tending to concentrate on Knowco capabilities. GOs appear likely to compete in more open markets using innovation and cost-competition. Though these providers may have large customers, they are more likely to have a large range of customers.

Knowcos: E-fulfilment organisations concentrating on knowledge-based capabilities such as Web development, business consulting, supplier management and customer management are termed *Knowcos.* They concentrate on offering innovative services to become competitive through effectiveness of such services and the ability to outsource supply chains and customer-facing tasks for online retailers. The degree of Knowco-ness, and the range of capabilities it applies to varies for different providers.

Last Mile Capabilities: A new category of e-fulfilment capabilities which involves all aspects of delivering to customers' workplaces or homes. Quality, cost-effectiveness and flexibility of such deliveries is critical to the success of online retailers but includes a host of problems that must be overcome. Issues such as payments, security, extended delivery times, returns, customer presence, and handling of different-temperature and perishable deliveries have catalysed the development of new capabilities such as locked-boxes, wireless payment devices and innovative courier networks.

Physcos: E-fulfilment organisations concentrating on physical capabilities such as transport, warehousing and pick-pack services are termed *Physcos.* They concentrate on improving such services to become competitive through efficiency and scope of such services. The degree of Physco-ness, and the range of capabilities it applies to varies for different providers.

Specialist E-Fulfilment (SO) Providers: Third-party e-fulfilment providers may choose to offer a subset of e-fulfilment capabilities. These may be either Physco or Knowco in nature, though a greater proportion of SO providers tend to concentrate on Physco capabilities. SOs appear to be driven by needs of dominant customers who dictate the services they need. Such providers are sensitive to such customers' needs, and will modify and add capabilities that address them.

Trust as an Enabler of E-Commerce

Narasimha Paravastu
Drexel University, USA

David Gefen
Drexel University, USA

INTRODUCTION

E-commerce is a viable mode of shopping. Forrester Research Inc. estimates that the U.S. online sales will reach $316 billion by 2010, which accounts for 12% of total U.S. retail sales. However, security, privacy, and delivery concerns remain issues of concern to both buyers and sellers. Since trust alleviates these concerns, while the lack of trust prevents buyers from buying online, managing buyer trust is crucial. This article discusses how institutional and interpersonal mechanisms can increase trust by reducing social uncertainty. An illustrative example based on eBay is included.

BACKGROUND

Trust is the willingness of a person or group to rely on another because of confidence in the trusted party (Mayer, Davis, & Schoorman, 1995; Zand, 1972). Trust is based on the expectation that the other party will not indulge in opportunistic behavior by taking advantage of the situation (Gefen, 2002). Generally, the need for trust arises because of social uncertainty (Deutsch, 1958; Johnson-George & Swap, 1982; Kee & Knox, 1970), which is the inability to predict human behavior with certainty because people do not always behave rationally (Lewis & Weigert, 1985). Since making calculated decisions requires reducing this social uncertainty, people tend to trust others and in doing so assume away the possibility of unacceptable social conduct (Gefen, 2000).

ROLE OF TRUST IN E-COMMERCE

Trust is essential in e-commerce because social uncertainty and risk are prevalent also in e-commerce, and more so than in other types of commerce because of the online nature of transactions (Lee, 1998). Online buyers and sellers may not have a prior acquaintance, may be separated in time and space, and may have no social cues which might enable a buyer to make judgments if to trust a seller (Gefen, 2000; Gefen, Karahanna, & Straub, 2003b; Gefen & Straub, 2004; Kim, Xu, & Koh, 2004; Reichheld & Schefter, 2000). Moreover, the Internet makes verification of real identity problematic (Ba & Pavlou, 2002; Gefen et al., 2003b). Trust reduces these perceptions of risk and makes e-commerce possible (Gefen, 2000; Gefen & Straub, 2004; Jarvenpaa, Tractinsky, & Vitale, 2000; McKnight, Choudhury, & Kacmar, 2002; Pavlou & Gefen, 2004).

DIMENSIONS OF TRUST

Mayer, Davis, and Schoorman (1995) conceptualized trust as being the product of three dimensions of trustworthiness beliefs: ability, integrity, and benevolence. Ability is the belief in the skills and competence of the trusted party. Integrity is the belief in the trusted party's adherence to the expected ethical or moral code. Benevolence is the belief that the trusted party cares about the buyer. This model of trust have been extensively verified (Gefen, 2002; McKnight et al., 2002; McKnight, Cummings, & Chervany, 1998). Integrity and ability are typically the most salient beliefs in initial contacts, with benevolence developing over time as the parties get to know each other (Mayer et al., 1995).

INITIAL AND ONGOING TRUST

Trust develops gradually over time (Blau, 1964; Lewis & Weigert, 1985; Zand, 1972). Typically, people enter new relationships with a degree of initial trust which develops into ongoing trust as the relationship develops over time. Initial trust and ongoing trust are different. Initial trust is not based on a detailed acquaintance with the trusted person or organization (Bigley & Pearce, 1998), but is a general credit extended to the other person based on unrelated considerations. After gaining experience in the relationship, people's initial trust evolves into ongoing trust. This ongoing trust is based primarily on prior experience with the trusted party (Gefen, Karahanna, & Straub, 2003a).

There are several modes of creating these types of trust, and these modes change in relative importance as the transition from initial trust to ongoing trust is made. Accordingly, initial trust may sometimes be greater than ongoing trust (McKnight et al., 1998). Both initial and ongoing trust are based on a person's disposition to trust (personality-based trust), on calculative-based trust, on institutional-based trust, and on transference-based (Stewart, 2003; Strub & Priest, 1976), but more so in initial trust (McKnight et al., 1998) because in ongoing trust familiarity with the trusted party takes the lead as the determinant of trust (Gefen, 2000).

Disposition to trust, also known as personality-based trust, is a general tendency to trust others based on a person's life experience and socialization (Gefen, 2002; McKnight et al., 1998; Rotter, 1980). As an example, a potential buyer at eBay, the leading online auction house, may refrain from taking part in any such activity because of fear of being cheated based on childhood experience of being taken advantage of by others whom he or she trusted.

Calculative-based trust is based on the assessments of whether it is worth the other party's while to cheat (Brewer & Silver, 1978; Lewis & Weigert, 1985; Meyerson, Weick, & Kramer, 1995). Calculative-based trust is a scrupulous estimate made by the trusting party about the probable behavior of the trusted party (Shapiro, Sheppard, & Cheraskin, 1992). It affects both initial trust (Doney & Cannon, 1997; Lewicki & Bunker, 1995; Shapiro, Sheppard, & Cheraskin, 1992) and ongoing trust (Gefen et al., 2003b). Calculative-based trust is formed based on a calculation that people will refrain from opportunistic behavior if it is not in their advantage to do so (Shapiro, Sheppard, & Cheraskin, 1992). To continue the eBay example, a shrewd buyer may decide to place a bid with one seller and not with another based on a calculated assessment of whether each seller could get away with cheating if it wished to, considering the type of product, seller location, and so on.

Transference-based trust is based on trusting an unknown person or organization because a person whom the trustor believes in trusts this person (Stewart, 2003; Strub & Priest, 1976). In our example of the eBay buyer, a person who has never bought from eBay before may decide to trust a seller because his or her friend recommends this seller. Trust transference happens from a trusted person (Uzzi, 1996), a trusted source (Henslin, 1968), a trusted institutions, or an industry association (Milliman & Fugate, 1988). Usually, transference creates trust when there is no prior interaction with the trusted party, but there is a high level of trust in the transference party (Ba, 2001; Lewicki & Bunker, 1995; Stewart, 2003; Uzzi, 1996). If a person trusts eBay, the transference party, he or she is more likely to trust an unknown seller in this online auction house (Pavlou & Gefen, 2004).

Institutional-based trust is based on the guarantee mechanisms provided by a trusted third party (Shapiro, 1987; Stewart, 2003; Zucker, 1986). These mechanisms may include situational safeguards and structural assurances that are built into environment (Ba & Pavlou, 2002; Gefen et al., 2003; McKnight et al., 2002; Pavlou & Gefen, 2004; Zucker, 1986), escrow services, credit card protection, and feedback mechanisms on a portal (Pavlou & Gefen, 2004). Institutional-based trust, when available, is a primary mode of trust creation (Gefen et al., 2003b; McKnight et al., 2002; Pavlou & Gefen, 2004). In the eBay example, institutional trust may convince a buyer to trust a seller based on the escrows, security, and privacy mechanisms eBay provides (Pavlou & Gefen, 2004).

Familiarity-based trust, in contrast to the above modes which are not based on a personal interaction between the parties (Kim & Prabhakar, 2004; McKnight et al., 2002), is based on prior experience with the seller. Generally, familiarity is the primary trust builder in ongoing trust, while institutional-based, when available, is the primary builder in initial trust. Knowing the trusted party based on previous interactions with it typically the primary creator of trust (Blau, 1964). These relationships are shown in Figure 1.

The modes of trust creation create a sense of trustworthiness and trust. This trust then results in behavioral intentions. In the eBay example, trust will be one of the contributors to the decision if he or she is going to place a bid with a specific seller. Also part of the model is the role of feedback. Positive and negative experiences (Holmes, 1991; Lewicki & Bunker, 1995) affect both trustworthiness beliefs and trust (Mayer et al., 1995), as well as the modes of trust creation (Marsh, 1994).

FUTURE TRENDS

Institutional-based trust (Gefen et al., 2003b; McKnight et al., 2002; Pavlou & Gefen, 2004; Zucker, 1986), disposition-based trust, calculative-based trust (McKnight et al., 2002; McKnight et al., 1998), and transference-based trust (Stewart, 2003) are salient modes in the formation of initial trust. In the lack of actual familiarity with the trusted party, these modes take precedence. These modes help to reduce buyers' perceptions of uncertainty in e-commerce transactions while providing a subjective measure of security and probability of success of e-commerce transactions. The importance of institutional-based trust as a major contributor to initial trust in online transactions is made possible by the availability of third party guarantees, accreditations, escrow, credit card guarantees and other security enhancing mechanisms (Pavlou & Gefen, 2004). After successive positive experiences, the salience of institutional-based trust decreases as familiarity takes

T

Figure 1. Conceptual model of trust relationships

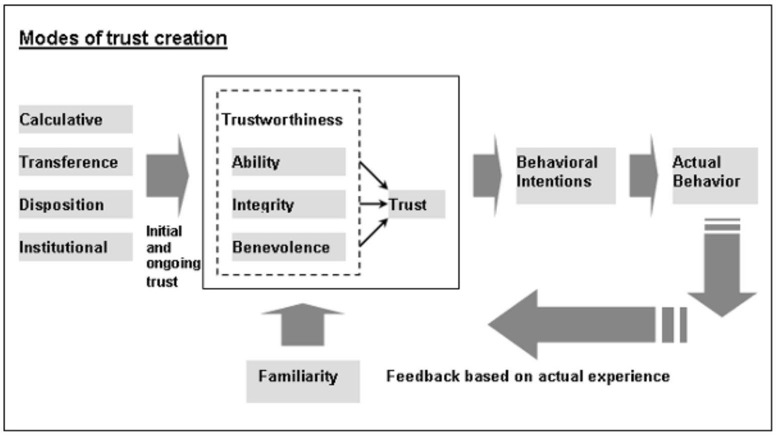

Figure 2. The relative change in trust modes with experience

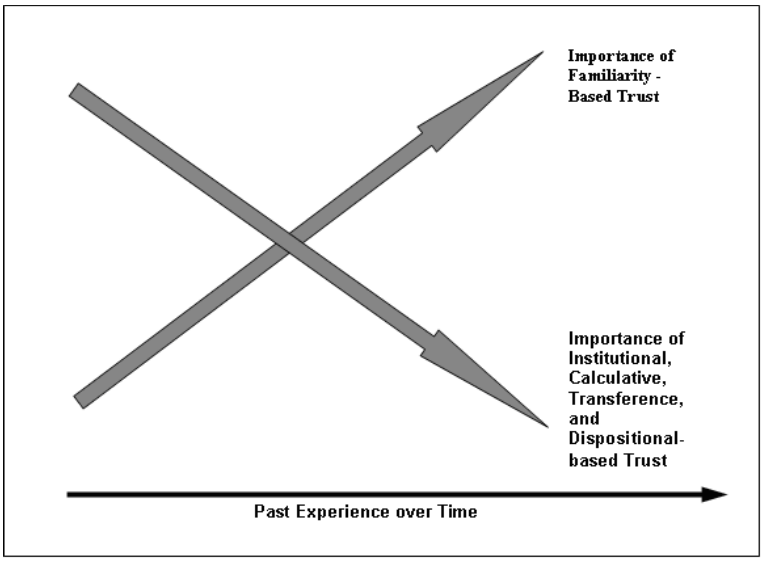

precedence. In the eBay example, a buyer, after many successful transactions, will trust a seller, even without relying as much on the institutional guarantees provided by eBay. This change in the salience of the trust building modes is shown in Figure 2. Institutional guarantee mechanisms, as well as disposition, calculative, and transference, are important primarily during the initial stages of trust formation. In the absence of personal interaction on which familiarity can be built, these modes reduce social uncertainty and in doing so create trust. As familiarity increases, the necessity of other modes decreases (Blau, 1964; Lewis & Weigert, 1985; Zand, 1972). Still, it should be emphasized, all these modes continue to continue to trust even as familiarity increases.

CONCLUSION

The changing salience of trust creation modes in e-commerce over time has not been extensively empirically tested. A growing interest in this transition is expected as trust and its creation modes become established artifacts of e-commerce research. Increased interest in the creation and maintenance of institutional-based trust structures, which to date have proven rather successful, is also expected.

KEY TERMS

Ability: The beliefs the trusted party is capable.

Benevolence: The belief the other party cares about the trustor.

Calculative-Based Trust: Trust based on the calculation that it is not in the best interest of the trusted party to cheat or take advantage of the situation, regardless of their trustworthiness.

Disposition-Based Trust: The socialized tendency to trust or not to trust others.

Familiarity-Based Trust: Knowing what to expect of the trusted party based on previous interactions with it.

Initial Trust: Trust in another person or organization before the trusting party gets to know them.

Institutional-Based Trust: Trust based on the guarantees of a third party.

Integrity: The belief the other party is honest and adheres to accepted modes of behavior.

Ongoing Trust: Trust after the trusting party knows the trusted party.

Transference-Based Trust: Trusting another person because someone else who is trusted somehow recommends them.

Trust: A willingness to depend on another person or organization based on confidence in the trusted party.

Trustworthiness: Beliefs based on which people are willing to trust. Typically, these are ability, integrity, and benevolence.

Trust in E-Government Services

István Mezgár
Hungarian Academy of Sciences, Hungary

INTRODUCTION

Based on the results of the information and communications technologies (ICTs), a new "digital" economy and society are arising. This new computer- and communication-networked environment needs new set of services and technologies besides new rules and values, which determine the behavior of its actors.

In the starting phase of information society the Internet, later on the Internet-based technologies (e.g., the Web) have changed the way business was done the world over, and is now changing the way government interacts with citizens and business sector. With the dramatic increase of the Internet as a business tool and the incredible growth of e-technologies have changed not only the economy but the society as well.

According to researchers, early e-government was a form of e-commerce as both used Internet-based technology for the benefit of the information society. Today, e-government can be defined as online government services, that is, any interaction one might have with any government body or agency, using the Internet or World Wide Web. As the mobility is an important characteristic of the information society, new e-government solutions apply wireless/mobile networks as well.

The insufficient security of many Internet services is an important limitation of using the Internet. Lack of trustworthy security services is a major obstacle to the use of information systems in private, in business as well as in public services. Trust is intimately linked to citizens' rights, like security, identification, authentication, privacy, and confidentiality. Secure identification, authentication of the users and communication security are main problems in today's networked systems. These demands for trust and security are valid in an increased extent in case of digital government applications.

BACKGROUND

Definitions and Types of E-Government

It is not easy to define e-government because of its multidimensional aspects. Many international organizations attempted to define it and there were many different approaches. Part of them focused on the functions of e-government by underlying the governance aspects (functional definition), others referred e-government through its different processes (descriptive definition), a few propositions tried to capture its essence (conceptual definition), others presented e-government by reference to e-commerce (definition by reference) and still others combined all of those elements together (complex definition). The main concept behind those definitions, however, was that e-government was more about *government* than about *e*.

A complex definition is given by the World Bank as follows: "eGovernment refers to the use by government agencies of information technologies (such as Wide Area Networks, the Internet, and mobile computing) that have the ability to transform relationships with citizens, businesses and other arms of government. These technologies can serve a variety of different ends, better delivery of government services to citizens, improved interactions with business and industry, citizen empowerment through access to information, or more efficient government management" (World Bank, 2005).

Implementing e-government can be risky, expensive and difficult, it is not sufficient simply to add "ICT" to "government" to have "e-government." Fundamental transformations and changes will affect all layers of e-government including, for example, the legal aspects that is a basic factor.

The basic types of connections in e-government are government-to-government (G2G), government-to-business (G2B), and government-to-citizens (G2C) solutions. There are different other classification of the connections among government and organizations or citizens, but this three category can be found in each approach.

The objectives of the three main e-government types are as follows:

- **G2G:** Government to government enable all levels of government to more easily work together to better serve the needs of citizens and businesses; federal government needs to streamline reporting requirements imposed on states and localities; changing the culture of the civil service from reactive to proactive; open and accountable government; cost-effective procurement.

- **G2B:** It is the concept that businesses and government agencies can use central Web sites to exchange information and do business with each other more efficiently than they usually can off the Web. For example, a Web site offering G2B services could provide businesses with a single place to locate applications and tax forms for one or more levels of governent. G2B may also include e-procurement services, can support the idea of a virtual workplace.
- **G2C:** Government to citizen provides non-stop, online access to information and services to individuals; citizens should be able to find what they need quickly and easily, and access information in minutes or seconds, instead of days or hours (24-hour/7-day/52-week access); receiving services that are citizen, not agency focused; disintermediation of civil service staff—delivering services directly to citizens; building and enhancing trust.

With the expansion of opportunity to perform transactions online, citizens are eager to take care of a variety of tasks on the Internet, including interactions with different levels of government. National, regional, and local governments are beginning to respond. Across the globe, governments are the latest participants in the promise of the Internet, and the way in which governments interact with businesses and citizens is in early stages of transformation. The different types of e-government can be realized on different levels as international (European Union, United States—federal), national (central), regional, and local.

The benefits of e-government applications are:

- improving efficiency of administrative processes,
- increaseing transparency,
- improving services,
- decreasing corruption,
- contributing to revenue growth, and/or cost reductions,
- helping achieve specific policy outcomes,
- contributing to economic policy objectives,
- major contributor to reforms, and
- helping trust building between governments and citizens.

Definitions and Forms of Trust

Trust can be defined as a psychological condition comprising the trustor's intention to accept vulnerability based upon positive expectations of the trustee's intentions or behavior (Rousseau , Sitkin, Burt, & Camerer, 1998). Those positive expectations are based upon the trustor's cognitive and affective evaluations of the trustee and the system/world as well as of the disposition of the trustor to trust. Trust is a psychological condition (interpreted in terms of expectation, attitude, willingness, perceived probability). Trust can cause or result from trusting behavior (e.g., cooperation, taking a risk) but is not behavior itself.

The structure of trust in digital communication according to Fukuyama claims: "Trust is the expectation that arises within a community of regular, honest, and cooperative behavior, based on commonly shared norms, on the part of the members of that community" (1995, p. 45). In shifting to electronic environments, Fogg and Tseng (1999) focus on trust among individuals mediated by technology, writing that trust indicates a positive belief about the perceived reliability of, dependability of, and confidence in a person, object (such as computers, networks, and software), or process (such as credit card transactions and airline e-ticket reservations). There are numerous additional definitions of trust; all fields where trust is important have developed its own definition. In spite of this diversity there are components that are included into most definitions of trust (Harrison, McKnight, & Chervany, 1996):

- willingness to be vulnerable / to rely,
- confident, positive expectation / positive attitude towards others, and
- risk and interdependence as necessary conditions.

Trust has various forms as well, according to different authors (e.g., Luhman, 1979) trust has forms such as

- **Intrapersonal Trust:** Trust in one's own abilities; self-confidence, basic trust (in others);
- **Interpersonal Trust:** Expectation based on cognitive and affective evaluation of the partners; in primary relationships (e.g., family) and nonprimary relationships (e.g., business partners);
- **System Trust:** Trust in depersonalised systems/world that function independently (e.g.,, economic system, regulations, legal system, technology); requires voluntary abandonment of control and knowledge; and
- **Object Trust:** Trust in nonsocial objects; trust in its correct functioning (e.g., in an electronic device).

Trust Building is More Than a Simple Approach

In building trust there are two approaches; information technology approach and human centered approach, based on culture and morality. Information technology approach means that security has to increase by different architectures, protocols, certifications, cryptography, authentication procedures and standards and this increased security generates the trust of users. This means access control (passwords, firewalls), protect integrity and privacy of messages and databases (cryptography), identification of users. Parallel stressing the effectiveness of these technologies for the humans (users) can cause that they will trust in the systems based on this convincing action. Based on the technological approach 100 % security never can be obtained (there will be always security holes somewhere in the systems), so full trust can not guaranteed based on these mechanisms.

The human side of trust is more complicated. There were different researches (e.g., Hoffmann, Novak, & Peralta, 1999) focusing on this side of trust. From this aspect user interface has the main role (i.e., the menu structure, the messages send for the user by the system). In case the user feels that is easy to use, it is transparent, he or she can control the system (even with low level computer knowledge); that is, the system is "user friendly," through this she or he can be convinced that she or he is using a trustworthy system.

It would be a mistake to think that applying only the human-centered approach would generate trust, the technological part has to be added as well (e.g., biometrical identification), so mainly the structured integration of the two approaches can result the expected level of trust.

ROLE OF TRUST IN E-GOVERNMENT

Communication Technologies for E-Government

The partners of the digital government are connected through different media according to the actual demands of the tasks. The conventional tools are the telephone, fax, writing letters. On the next level are the computer network-based solutions (e.g., e-mail, ftp, telnet). A higher quality of communication media is the Web-based communication solutions. Through Web pages a secure, easy, and fast communication can be realized. A new way of connection is the application of different wireless technologies for communication. Wireless technology means mobility, namely individuals is available independently from location and time. This mobility is an important attribute of today's organizations and people.

This mobility can be achieved by using different types of wireless networks as satellite communication, wireless wide area networks (WWAN—different types of mobile phone systems—GSM, GPRS, UMTS and iMode), wireless local area networks (WLAN, such as WiFi—also called mobile Internet (IEEE standard 802.11a/b/g) and Wireless Personal Area (or Pico) Network (e.g., Bluetooth). These networks can be connected, so the user can be reached really at any place through a type of wireless connection.

Mobile phones have Internet connections so they can handle e-mail and WEB pages. Multichannel access (e.g., Web site, mobile WAP; Call center; e-mail) to e-government services is an important factor of trust building especially when using the same interface structure (e.g., for Web and WAP).

Connection of Trust and E-Government

Transforming government functions through technology is harder than the infrastructures (conceptual, political and technical) created to support efforts into electronic government. Everything "e" this approach could not meet the expectations. The term digital government allowed for a more comprehensive view of governing through technology, but, if the act of governing were the central issue, then perhaps digital governance would focus the attention on the larger, more significant task. The ability to do the public's business and earn the public trust requires a new understanding of the interface between citizens and the act of governing.

The building and preservation of the public trust is the most critical issue facing the Internet technology today. With growing public awareness of online privacy and security issues, media attention to high-profile breaches of Internet security, and an increasing awareness of how citizen and customer data is being used by Internet and service providers, it is clear that government must address issues of public trust for e-government to be successful. Trust is the most critical factor facing the introduction of e-government, so governments must successfully handle the topic of public trust for e-government in order to have long-term success (NIC, 2000).

E-government services have a higher level of trust from the start than e-commerce sites because they are familiar for people and lack of competition. Although the starting level of trust is high, the confidence in government technology and safeguards is not. Most users expect good service and friendly handling from government agencies, so governments also have to earn user trust also by protecting their privacy and providing secure transactions.

This fact can be considered that e-government efforts might be more successful with high preexisting starting levels of trust, than developing more user-friendly Web sites, namely political efficiency can be important determinant of initial trust level for e-government (Parent, Vandebeek, & Gemino, 2004).

When citizens and business participants begin to interact with their governments in a great crowd directly, online and experience the increased benefits, trust in government may be raised to higher levels resulting more democratic processes, that also builds public trust (Holzer, Melitski, Rho, & Schwester, 2004). In this way developing public trust can become a self-inducing process.

The combination of experience-based trust with protection personal information will enhance adoption of e-government for citizens and businesses. Through protection of personal data, authentification, identity management, privacy and data protection, network and information security, the fight against cybercrime and general political efficiency could administration keep the needed level of public trust.

Technical Side of Trust Building: Application of Security Mechanisms

Approaching security from the side of trust, security is the set of different services, mechanism and software and hardware tools for generating trust with pure technology. More generally security is a condition that results from the establishment and maintenance of protective measures that ensure a state of inviolability from hostile acts or influences.

The building blocks, elements of security are the security services and the security mechanisms. The security services are, access control, authentication, confidentiality, integrity, and nonrepudiation. The means for achieving these properties depends on the collection of security mechanisms that supply security services, the correct implementation of these mechanisms, and how these mechanisms are used. Encryption, digital signatures and checksums/hash algorithms are the applicable security mechanisms.

The main factor of trust is confidentiality that can be achieved by technologies that convert/hide the data, text into a form that cannot be interpreted by unauthorized persons. The major technique to fulfil this goal is the encryption. Encryption is transforming the message to a ciphertext such that an enemy who monitors the ciphertext cannot determine the message sent (Schneier, 1996).

Human Side of Trust Building: Feeling of Trust

The feeling of security experienced by a user of an interactive system does not depend on technical security measures alone. Other (psychological) factors can play a determining role; the user's feeling of control can be one of these factors.

Trust is a dynamic process, and it alters, based on experience. Trusting process begins when an individual perceives indications that suggest a person/organization may be worthy of trust. These indications can include behaviors such as manners, professionalism and sensitivity and these forms are designed to represent trustworthiness. These formal claims to trustworthiness become strengthened over time and are eventually transformed into "character traits," such as dependability, reliability, and honesty.

It has to be analyzed why people feel safe and secure, what causes these feelings. The hypothesis of D'Hertefelt (2000) was that "the feeling of security experienced by a user of an interactive system is determined by the user's feeling of control of the interactive system." The more a user feels in control of an interactive program, the more the user will trust the site, the program, and the service represented by the site.

The process of building trust is slow; trust is formed gradually, it takes quite a lot of time and repeated positive experiences (Cheskin, 1999). Online trust can be described as a kind of human relationship. The initial stage is that of interest and distrust; there has to be a motivation, a need, to get interested in the service, or co-working. In subsequent phases the trust will evolve or in case of negative experiences the cooperation will terminate.

Trust is depending on the time span of cooperation and the type of connection as well. It can be stated that there are differences in trust building process in short-term and long-term relationships. In case of short-term relationships trust must be achieved quickly, and then maintain with no, or rare face-to-face interaction. In long-term relationships there are four factors that are influencing trust building (Rocco, Finholt, Hofer, & Herbsleb, 2001):

- greater investment in building trustworthy relationships,
- more time to establish trustworthiness through routines and culture,
- more communication channels,
- trust formation may assume a higher priority.

Tools for Trust Building

The tools for trust building can be hardware and software ones that protect user's privacy, provide secure transactions and generate the feeling of control. Interfaces, digital signature and encryption are the software parts for generating trust, while smart cards and personal trusted devices are hardware means that embody SW tools that can help in trust building.

Generating Trust By Human-Computer Interfaces

As a communication/information system term an interface is the point of communication between two or more processes, persons, or other physical entities. Interfaces are the key points for gaining the trust of the user/ customer. They are the first connection point between the user and the system, identification of the users take place at this point (e.g., password input, fingerprint reader, smart-card reader), the dialogues are realized by using the menu structure (feeling of control), so they have to be designed very carefully taking into consideration ergonomic and psychological aspects besides the technical ones.

Digital Signatures

A digital certificate is an electronic means of establishing the credentials of users when doing different transactions on the Web. It is issued by an independent certification authority. It contains the name, a serial number, expiration dates, a copy of the certificate holder's public key (used for encrypting and decrypting messages and digital signatures), and the digital signature of the certificate-issuing authority so, that a recipient can verify that the certificate is real.

Encryption

Encryption is the transformation of plaintext into an apparently less readable form (called *ciphertext*) through a mathematical process. The ciphertext may be read by anyone who has the key that decrypts (undoes the encryption of) the ciphertext.

Smart Cards

There is a strong need for a tool that can fulfil the functions connected to trustworthy services. Smart-card technology can offer a solution for current problems of secure communication by fulfilling simultaneously the main demands of identification, security and authenticity besides the functions of the actual application. Smart cards are bankcard size plastic plates that contain a chip. This chip can be programmed, can store different data and has all the basic functions of a computer. The major features mentioned for use of smart cards are that they

- contain identification information (e.g., biometric templates), application specific data (profile, rights, etc.), possibly updateable, public key certificates;
- support simple authentication of device and/or cardholder, electronic signature, exchange of encryption keys; and
- create valid electronic signatures, including cryptographic features.

Smart cards start their carrier now as they can be applied very well as (e.g., health care/ social security cards, electronic citizen and civil servant identification card with digital signature features).

Personal Trusted Device

As wireless devices (mobile phones, PDAs) are always with the users so they can become a personal trusted device (PTD) as well. Using PTD for trust building can make authentication and confidentiality easier, more reliable that support the services of e-government in a great extent.

FUTURE TRENDS

Citizens are choosing to meet their government online as the use of online government services in the United States stand at 43% at the end of 2002, with an increase of 9% in just the last 12 months. In selected program areas, up to 79% of users have chosen the Internet over all other channels in accessing government information and services. The advantages to the states are clear—the cost of providing a unit of service on the Internet is as much as 75% less than through conventional delivery channels. And these new channels are increasing government capacity by up to 93% (CDG, 2003).

Although the transition toward automated and electronic delivery of government services has begun, it will be a long and difficult process to achieve true e-government. Governments must invest significant financial and human resources into a technology infrastructure to support e-government transactions. These investments will be expected to yield both increased quality in government services and their delivery as well as create tax money savings. Citizens and politicians will have very high expectations for significant return on investment for e-government initiatives.

However, the challenges faced by e-government could be summed up as information infrastructure, efficiency, and quality of service, citizen participation, governance and public administration. Researches have to focus on these topics. In the citizen and business community participation the results of researches on trust building will define the rate of participation in e-government services in a great extend.

CONCLUSION

There is an international consensus that e-government has become an important challenge for the Information Society. According to numerous studies, surveys and researches, e-government offers potential solutions to leaders to better assume their responsibilities by providing efficiency, quality of services, citizen participation and enhanced public administration. E-government made it possible to establish a more open, inclusive, and productive public sector, in line with good governance. In the sense of e-government, good governance could be achieved by the proper combination of information and communication technologies, organizational innovation and improved skills.

In order to be able to realize all of these positive expectations the trust of the users of e-government services has to be gained as the first step. Without trust no one will use these brilliant systems, as it could be experienced at some spectacular, but "trust-free" e-business/e-commerce solutions.

Ultimately, e-government is about citizen's relationships with their civic institutions and the foundation of their next-generation communities. It is about extending the social contract to provide better services to all citizens and business participants.

KEY TERMS

Biometry (Biometrics): Generally, biometrics refers to the study of measurable biological characteristics. In computer security, biometric technologies are defined as automated methods of identifying or authenticating the identity of a living person based on his or her physiological (e.g., fingerprint, hand, ear, face, eye—iris/retina) or behavioral (e.g., signature, voice, keystroke) characteristic. This method of identification is preferred over current methods involving passwords and pin numbers, as the person to be identified is required to be physically present at the point of identification, so the person or user is identified, not the device, as in case of PIN and password.

E-Government: E-government focuses on the use of new information and communication technologies (ICT) by government as applied to the full range of government functions. In particular the networking potential offered by the Internet and related technologies has the potential to transform the structures and operation of government" (OECD, 2005).

Personal Trusted Device: The Personal Trusted Device has to be personal, always carried by user, small, cheap, battery works, and common user interface, secure as a smart card. Mobile phones can fulfill the role of a Personal Trusted Devices, as mobile phones are well placed as identity tokens, they have dynamic authentication already proven in GSM, mass market, and secure communications.

Trust: Trust can be viewed as a cognitive and social device able to reduce complexity, enabling people to cope with the different levels of uncertainty and sometimes the risks that, at different degrees, permeate our life. Without trust and individual would freeze in uncertainty and indecision when faced with the impossibility of calculate all possible outcomes of a situation. From a social perspective trust permits the necessary knowledge sharing of delegation and cooperative actions (Luhman, 1979).

Trust Chain: A solution for addressing trust is to build a chain of trust, where each link is strong but also connects to its neighbor by verifying its trustworthiness.

Trustworthiness: The ability to attain and maintain a "Trusted State," which is definable, measurable, validatable, and demonstrable over time. Digital Trustworthiness means a verifiable level of electronic process integrity, security, control, authenticity, and reliability, that captures, preserves, retrieves, verifies, renders and makes available in human readable form; the essential transaction content, context, notice, intent and consent, to meet the electronic forensic evidence requirements necessary for legal admissibility and regulatory compliance.

Trust in E-Technologies

Andrea Oermann
Otto-von-Guericke University of Magdeburg, Germany

Jana Dittmann
Otto-von-Guericke University of Magdeburg, Germany

INTRODUCTION

When reflecting the term *trust*, there are two main hypotheses which can be found in most of the literature: First, trust is presented as an amorphous phenomenon, which is difficult to measure empirically (Endress, 2002). Second, the characteristic of trust is rather fragile. Trust as a mediator of social interactions cannot be quantified precisely, it has to be generated and recreated at any time varying with its social context. Volken summarizes this particular connection between trust and the context in which it is created: "Trust is a complex construct with multiple dimensions, and their relative effects on innovative actions may be highly dependent on their respective social context" (Volken, 2002).

In the age of globalization trust is particularly important when one operates in the areas of e-commerce, e-government, and mobile commerce, or develops IT-systems which are touching the interface between technical innovation and its application by users. The latter live and work in a certain social context in which trust can be established in various ways. This necessarily has consequences for IT-solutions and IT-security which this article tries to explore. Giddens (1990) pointed out that "mechanised technologies of communication have dramatically influenced all aspects of globalization since the first introduction of mechanical printing into Europe [Johannes Gutenberg, 16th century]" (p.77).

Without Johannes Gutenberg, there would have been no Reformation, without information technology, there would have been no global information age. Both historical developments, as different as they may be, took place in a certain social context, of which technical innovation became a part. At the same time every society depends on the key ingredient, which is a requirement for social interaction: Trust.

As a reader of the Gutenberg *Bible* trusted that his book is complete and correct, any user of information technology trusts that the applied system functions properly and is reliable. The following questions arise: How does trust which basically is part of most social interactions fits within information technology using "0" and "1" to enable any sort of interaction? How is trust created, maintained and developed in the information age? Which forms of trust exist and are necessary to operate in an interconnected world?

The article will explore these questions by describing current definitions and concepts of trust outside and inside a context of information technology. After exploring the link to concepts of trust in social science and culture a new concept of trust in e-technologies such as e-commerce, e-government, and mobile commerce will be developed. Important trust-building factors such as transparency or participation will be analyzed in order to conceptionally deal with the increasing importance of trust in a virtual world.

BACKGROUND

As a background, an overview is presented about trust from the social science perspective. While trust is defined in various ways, this article concentrates on the most relevant definitions influencing e-technologies.

Trust in Social Science

Trust as a concept of social science was firstly written down by Georg Simmel, who differentiates three trust phenomena in the context of the "Philosophy of Money" (Simmel, 1989):

a. Microlevel ("natural trust" in direct, intuitive social relationships)
b. Mesolevel ("rational trust" in professionals and the role of a person)
c. Macrolevel ("systemic trust" in interactions which are mediated through symbolic tokens such as social subsystems, e.g., money)

Trust, its creation, presence and its maintenance extends through all three levels. By focussing on the meso- and macrolevel, this can be outlined as the first impact on the view of trust as a concept for e-technologies. Discussing trust regarding e-technologies means to clarify the relation of trust and virtual systems of information technology (IT systems). Thus, the circle of trusted dependencies is enhanced concerning e-technologies, and this creates sustaining trust of a wider scope considering more subsystems within the macrolevel, such as contracts, system hardware and several types of system software.

Further in this context, Simmel (1992) developed a second distinction of the term *trust* and positioned three hypotheses:

1. **Trust as a general confidence and as a "weak inductive knowledge":** Trust is the confidence in certain, constant elements in the human life or as a type of unspecific expectations, or alternatively, general hopes. But it has to be distinguish that "trust presupposes awareness of circumstances of risk, whereas confidence does not" (Giddens 1990, p. 31)
2. **Trust as a form of knowledge. Trust in somebody (or something):** Trust is the hypothesis of future behaviour, which is certain enough for establishing practical acting. Trust is the medium state between knowledge and ignorance. The one who has complete knowledge does not need to trust, and the one who does not have any knowledge cannot even develop trust. (Simmel, 1989)
3. **Trust as a feeling. Trust as a belief or faith in somebody. Trust as an inner *unreservedness* towards someone else:** Although trust is always partly determined through feeling and emotion, these aspects have no purpose in the debate about trust and IT-systems. When looking at IT-systems one proceeds from the assumption of an average participant and trust can be treated rationally compare to Giddens and Luhmann. Both are grounded in Simmel's statement of trust as a "week inductive knowledge" (Simmel, 1989).

Based on Simmel, Niklas Luhmann similarly differentiates between personal trust (trust in persons) and systemic trust (trust in social or technical systems). As professional knowledge is required to control systemic trust, it isn't for personal trust. (Luhmann, 1968) Luhmann, as a leading voice of modern sociology and father of the *system theory* (*Systemtheorie),* defines trust as a vital mediator between different systems. Therefore, trust is able to lower or bridge complexity to manage expectations and to increase space for action. (Luhmann, 1968)

The differentiation between personal and systemic trust is further supported and enhanced by Fukuyama's (1995) "radius of trust" with the goal to resume different types and contexts of trust to capture its whole concept. The greater the radius the more complex the concept of trust gets. The systemic trust in expert or abstract systems in relation to trust in products, absent others and organizations and institutions is the focus of this article.

Giddens as an extension of Simmel provides the major impact on trust regarding e-technologies. He characterizes trust as "a distinct from confidence based on weak inductive knowledge." (Giddens, 1990, p. 54). Besides other hypotheses of Giddens, the following are considered here: (1) Trust is related to absence in time and space. (2) Trust is not the same as faith in the reliability of a person or in a system; it is what derives from that face. (3) Trust may be defined as confidence in the reliability of a person or system, regarding a given set of outcomes or events, where that confidence expresses a faith in the probity or love of another, or in the correctness of abstract principles (technical knowledge). (4) Danger and risk: What risk presumes is precisely danger. The "acceptable" risk—the minimizing of danger—varies in different contexts, but is usually central in sustaining trust. (5) Risk is not just a matter of individual action. In his last point he indicates the relation of trust and security which will be referred to later.

James S. Coleman's logic of trust as a rational decision making model also fits the statement of this article and can be summarized as follows in four structured patterns (Coleman, 1990): (1) Placement of trust allows actions that otherwise are not possible. (2) If the trusted person (trustee) is trustworthy, the trusting person (trustor) improves his or her position; otherwise, he or she worsens it. (3) Trust is an action that involves the voluntary placement of resources (physical, financial, intellectual, or temporal) at the disposal of the trustee with no real commitment from the trustee. (4) A temporal delay exists between the extension of trust and the result of the trusting behaviour. These four patterns can be applied to trust in relation to e-technologies as it is later described in chapter three. According to Coleman's outlined relation between trust and rationality, the decision on trust is related to the trusting person's state of knowledge about possible surplus and loss. Following this, individuals as rational actors give trust in a rational way if the expected advantage (proof) is higher than the expected possible disadvantage (disappointment). Individuals rationally calculate and evaluate the win and loss based on the available information (Coleman, 1990). Coleman's second pattern is affirmed by Sztompka who says: "If the grounds for trust come down to a certain knowledge acquired by the trustor about the trustee, then it would make sense to accumulate such knowledge to arise the probability of wellplaced trust" (Sztompka, 1999, p. 70). In addition to the rational attribute of trust, the reflexiveness of trust needs to be outlined. "Reflexiveness" is defined as people acting on beliefs, knowledge, memory and interpretation of past experiences (Sztompka, 1999). Both, the rational and the reflexive attribute of trust are interdependent and must both be considered when exploring trust.

Similar to Simmel, Sztompka (1999) outlines three dimensions (cultural, rational, and psychological) of trust and completes the impact of trust for e-technologies. Culture is not only an essential focus in social science, but also acts as a key figure in terms of the acceptance of and participation in e-technologies.

He defines rational trust as reflected trustworthiness which is specified through "trust ratings." Trust ratings are divided. Primary trust bases on reputation, performance and appearance (personality, identity and status) and is analytically determined. "We tend to trust people who show such a control: who are more orderly, neatly, dressed, groomed, clean, and look healthy and fit" (Giddens, 1991, p. 57). Secondary trust bases on the external context and determined through derived trustworthiness. Psychological trust is defined by Sztompka (1999) as the inner trusting impulse. The cultural trust implies sediments of historically accumulated collective experiences of a given society, community or social group.

Considering trust as a social relationship the following statement can be referenced: "Trust … is a particular level of the subjective probability with which an agent assesses that another agent or group of agents will perform a particular action, both *before* he can monitor such action … *and* in a context in which it affects *his own* action" (Dasgupta, 1988, similar to Luhmann 1988 and also to Gambetta 1988, 2001). Trust is a condition for any social interactions. At the same time it is not of a natural character, it continually has to be created and reconstructed. Hence, its character is rather fragile. Trust is an inner persuasion of other individuals which either execute certain actions or don't. The trustor is aware of the risk the trustee's actions imply. Trust is a presumption. … The dynamic of the creation of trust can be displayed on a time axis. Trust is a balancing state when all necessary and sufficient conditions are fulfilled. This stage is further influenced by the perception of prediction, consistence and stability of the relevant trustees (Eisenstadt, 2001; Offe, 1996). The emphasized characteristic of trust as being fragile is additionally intensified by the nonavailability of resources of information. Interaction with other identities (individuals or systems) always includes risk, which has to be minimized. As it can be derived from the following statements, trust can act as a reducer of risk. "The clues employed to form trust do not eliminate the risk, they simply make it less. They do not supply complete information about the likely behaviour of the person to be trusted. They simply serve as a springboard for the leap into uncertainty" (Luhman, 1979). Sztompka described trust in relation to risk as follows: "Placing trust, that is, making bets about the future uncertain and uncontrollable actions of others, is always accompanied with risk. … Placing trust means suspending discounting, 'bracketing' the risk, acting as if the risk were not existent" (Sztompka, 1999).

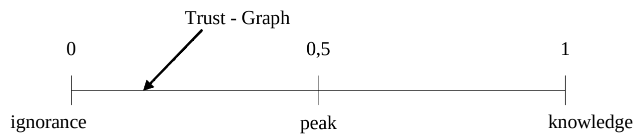
The difficulty of developing trust towards less tangible entities or expert systems like e-technologies is caused by the incalculable *risk* of the systems virtual characteristic. This problem is amplified through the sparse knowledge an average user of an IT-system has "enter other expert systems, of which my own technical knowledge is at best rudimentary" (Giddens, 1990, p. 28). Since "all interactive media require trust as a condition to operate efficiently," (Parsons, 1980, p. 215) trust needs to be generated. But to create trust in an IT-system, the risk has to be reduced to an acceptable level. This can be gained though "regulatory agencies over and above professional associations, which are designed to protect the consumers of expert systems" (Giddens, 1990, p. 29) and through transparency.

Trust, Culture, and Globalization

In times of *globalization* where e-technologies are the connecting mediator between communicating entities (persons or systems), the relevance of trust is even more apparent and additional factors in the creation and maintenance of trust have to be considered. Since networked entities can be located anywhere in the world, their interactions can span the globe. Therefore, "the ongoing process of global interdependency will only increase the demand for trust as an essential condition for cooperation" (Misztal, 1996, p. 269). Coping with strangers is part of globalization. But this turns out to be problematic since trust is rarely given to strange and unknown persons or things. "The stranger is the representative of the unknown … the unknown culturally defined space in which separates off the outside from the world of the 'familiar', structured by the traditions with which the collectivity identifies" (Beck, 1994, p. 81).

Local environments are globally connected through e-technologies. "Technology is eliminating the 'place'" (Tapscott, 1997). But a time-space distanciation negatively influences the creation of trust. "The conceptual framework of time-space distanciation directs our attention to the complex relations between local environments (circumstances of co-presence) and interaction across distance (the connections of presence and absence)" (Giddens, 1990, p. 64). He follows, that time-space distanciations are "stretched" in modern societies with networking expert systems and "the modes of connection between different social contexts or regions become networked across the earth's surface as a whole"

Figure 1. Trust-graph



(Giddens, 1990, p. 64). Thus, Giddens defines Globalization "as the intensification of worldwide social relations which link distant localities in such a way that local happenings are shaped by events occurring many miles away and vice versa."

"Access points" of abstract systems as a meeting ground of facework commitments (Giddens, 1990, p. 83) are necessary for the creation of trust, participation and acceptance of E-technologies. Trustworthiness is given through an establishment of these access points.

The creation of trust, the acceptance of, and the participation in e-technologies are controlled by *culture*. Culture constitutes features of social life such as cultural norms, values, attitudes and identity of persons which enable and facilitate the generalization of cooperative actions. Hence, e-technologies have to fit a culture's identity, their norms, standards and needs. "Trust depends on cultural resources" (Sztompka, 1999). When globally connecting local systems, trustworthiness has to be granted. Local norms and values which vary with the culture of a society and its governing structures have to be matched. Hence, the creation of trust in global connecting systems is a domestic matter.

MAIN THRUST: TRUST

Discussing trust as a concept for e-technologies, Bishop (2003) provides a precise definition: "In the field of computer technology containing hard- and software implementations trust is a belief or desire that a computer entity will do what it should to protect resources and be safe from attack" (p. 477). This definition acts as a fundament but has to be enhanced considering aspects of social science.

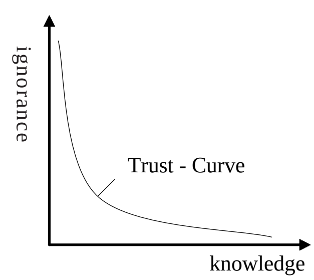
Trust and E-Technologies

Exploring trust in relation e-commerce, e-government and mobile commerce, Simmel's definition of trust in chapter two as a "weak inductive knowledge" and as a "medium state between knowledge and ignorance" is considered. The concept of trust in regard to e-technologies can be characterized as follows in Figures 1 and 2.

Two graphical presentations (Figure 1 and Figure 2) are introduced to capture the full dimension of trust. Figure 1 demonstrates the Trust- Curve, whereas Figure 2 demonstrates the Trust-Graph. Both are equivalent. Figure 1 illustrates the one-dimensional view of trust similar to a timeline on which trust dynamically varies over time influenced by certain factors. A threshold presents the probability of trust. The peak, as it is marked in Figure 1, indicates the point of balance at which a person ranges between trust and no trust. Full trust (trust = 1) is knowledge. No trust at all (trust = 0) is ignorance. Figure 2 is the two-dimensional view in which the Trust-Curve represents trust as a floating state between two limits. One limit is marked as knowledge, identical to Figure 1 (trust = 1), the other limit is signed as ignorance (trust = 0 in Figure 1). The Trust-Curve converges to either one limit or the other, but never reaches them. Both figures can be mapped on each other.

Trust is changing dynamically based on the accumulated experiences a participant of an e-technology system has and develops. Individuals as rational actors give trust in a rational way if the expected advantage (proof) is higher than the expected possible disadvantage (disappointment) (Coleman 1990). Based on his or her experience and the calculation of loss, the potential participant develops trust and decides at one point (above the threshold 0, 5 in Figure 1) that he or she participates in the system which he or she then counts as trustworthy. But at the same time, trust is not a stable state, its characteristic is rather fragile. The individual's participation can be disrupted at any time with an unexpected happening which disappoints the participant. These happenings can have

Figure 2. Trust-curve



variable causes. For example, a system (hard- or software) crashes, an IT solution is not comprehensive, or the interface is too complex. Trust also can be negatively influenced by disappointing entities such as a person in a virtual community like eBay, or established organizations such as partners in e-commerce and e-government. Also the not existing immediate result and nearby identity can be named as a factor negatively influencing trust towards an IT-system as Simmel (1978) described it. According to the fourth component of Coleman's logical definition of trust (Coleman 1990), a temporal delay exists between the extension of trust and the result of the trusting behaviour. In other words, to access the appropriateness of trust implies a temporal delay until the time when trust pays off.

Trust, Identification, and Participation

The achievement, as well as the condition for the acceptance of and participation in expert or better "abstract systems" like e-commerce and e-government is, as mentioned before, the *trustworthiness* of these systems. Generating and maintaining trust towards e-technologies depend on the trustworthiness of it, but also acts as a condition for the *participation* in the system. This reflects the dilemma of being informed and participating in something: "There is a merge between being informed and participating in the world.…You can't really be informed unless you participate, and you can't really meaningfully participate unless you're informed." (John Seely Brown, cited in Tapscott, 1997, p. 267). Trustworthiness is built on *reputation* and reputation, only can be gained to and through informed and participating identities. Hence, identification is a prerequisite for building trust.

In times of globalization, where IT-systems act as globalizing communication mediators, participating identities can be anywhere in the world. Due to this fact, the term *identity* implies certain characteristics which are of a gender, religious, national, ethnic, territorial, socio-biological nature. "Identity is people's source of meaning and experience….For a given individual, or for a collective actor there may be a plurality of identities" (Castells, 2004, p. 6).

For creating and maintaining trust towards e-technologies, identities have to be provided. In e-technology systems not only the identity of the partners (company, government) has to be known by a reliable reputation but also the identity of the particular used technology.

Systems which appear more transparent to the participant increase their trustworthiness and hence their reputation and acceptance. The more a customer understands and is able to crosscheck a certain process at any time an IT system or an IT solution is executing, the less trust needs to be created up front. If a banking customer sees how a system works, if he or she can check ratings of the bank and customer reviews of their internet banking division, for example, the less "blind trust" is needed. He or she develops trust in transparent systems from the start because he or she sees and can check if and how it works. When a customer (potential participant) believes that the system is reliable he or she feels confident using the system because his or her trust is on a higher level regarding the Trust-Graph in Figure 1 or the Trust-Curve in Figure 2. Considering these aspects, transparency has to be the goal of any IT system or any IT solution.

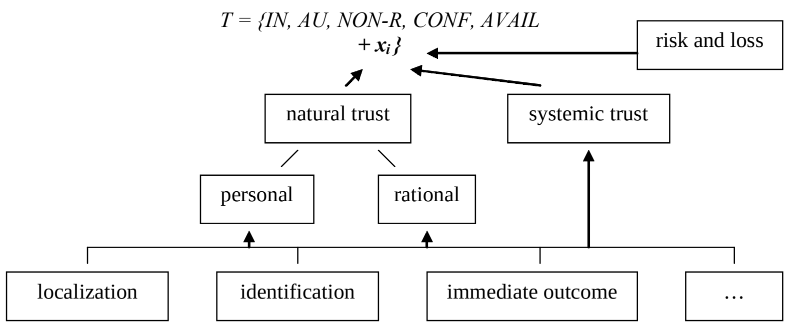
Trust and IT Security for E-Technologies

"An entity is trustworthy if there is sufficient credible evidence leading one to believe that the system will meet a set of given requirements" (Bishop, 2003, p. 478). These requirements determine the assurance to predict the level of trustworthiness of an entity.

As described below, the main security requirements for IT systems and their techniques can act as a basis for the further exploration of their effects on generating trust (see also Dittmann et al., 2001; Marotzki, 2003) These *security requirements* only concern the software as well as the information, which is displayed by and communicated through the medium. Furthermore, there are security measures which either pertain to the hardware, or have an external character such as physical locks, regulations concerning employees' behaviour, guidelines for actions, user training and security policy definition, or standardizations (Bishop, 2003; Stallings, 2003). These measures do not influence the generation of trust in terms of e-technologies and security. Influencing security measures are confidentiality, data integrity, data origin authenticity, entity authenticity, non-repudiation, and availability as defined in the key terms.

In this context, trust also acts as a security requirement, but in the way that it is determined through all other five requirements. Although the first five are mainly static challenges in terms of technical solutions, from passwords and digital signatures to watermarks or suitable soft- or hardware, the concept of trust is far more dynamic and complex in the sense that it is an underlying attitude which needs to be communicated to any user in order to convince them to even accept or buy a technical solution in the first place. For example: A credit card (*credit*, from the Latin *credere*, to trust) provider can possess the most modern IT security systems, but he has to build trust in order to attract clients. Therefore, trust can be seen as the result of the accumulation of the first five aspects of security assurance.

Figure 3. Determination of trust in IT systems regarding IT security and x_i factors



The effects of the five rather static IT security requirements for generating and maintaining trust in e-commerce and e-government systems can be demonstrated through a further enhancement of the Trust-Curve/Trust-Graph in form of factors which influence trust in IT systems like it is given in form of the following equation:

$$T = \{IN, AU, NON\text{-}R, CONF, AVAIL + x_i\}$$

Trust (T) is determined through the five static requirements of IT security, integrity (IN), authenticity (AU), non-repudiation (NON-R), confidentiality (CONF) and availability (AVAIL) plus x_i factors, which have been elaborated earlier in the first three paragraphs of this chapter. Depending on the context and the purpose of the IT system the factors and security requirements have to be weighted. This aspect of weighting belongs to the future work and has to be investigated in more detail. The outcome of this equation is a status between 0 (*ignorance*) and 1 (*knowledge*) as it is presented in the first paragraph of this chapter. Thus, the level of trust can be determined, and subsequently, the trustworthiness of an IT system can be estimated.

IT-security technologies and techniques have a remarkably positive influence on developing trust, trustworthy systems and participation in them.

FUTURE TRENDS

The focus of future work has to be on the development of techniques to ensure the requirements of IT security. Thus, an IT system can be designed and presented transparently which increases trust and the acceptance of and participation in the system.

Further future work is affecting the presented equation. Future developments have to consider a recursive iteration of the equation and an elaboration of the weighting of the influencing factors. This aspect of weighting has to be investigated in more detail.

The focus in future investigations is the achievement of accepted standardizations for IT systems and IT security techniques. In addition, security techniques have to be perpetually watched, evaluated and improved. The following listed problems have to be overcome:

- High costs of implementing secure and transparent systems, since establishing security is a never ending process, according to Schneier (2004), which underlies action and reaction. Therefore, one has to accept that designing transparency and developing absolutely secure digital systems can never be achieved. But, it can be approximated and that should be the aim.
- The lack of standards and policies, especially security policies to prevent attacks on IT systems and grant a sure and stable working solution or platform for e-commerce and e-government.
- The unrealiability of identities who participate in an IT system.
- The uncertainties. There are always events happening within an IT system, which can not be predicted.
- The difference in standards and needs depending on culture.

CONCLUSION

Summarizing this article and the relevance of trust for e-technologies such as e-commerce, e-government, and mobile commerce the following aspects can be specified:

Trust is a medium state between knowledge and ignorance and its characteristics are rather fragile. Trust is a dynamic status which varies over time influenced by certain factors. Trust acts as a condition for building trustworthy systems, while trustworthy systems act as a condition for creating and developing trust. Trustworthy systems are based on reputation and reputation can only be given through participating identities. Hence, trust is the key for generating acceptance of technological systems and the participation in them.

Delp (2004) emphasized the importance and relevance of trust in the 21st century considering multimedia and security in digital networking systems. IT security in digital multimedia systems is determined through security requirements such as confidentiality, integrity, authenticity, nonrepudiation and availability which can be directly fulfilled through certain techniques.

To access the appropriateness of trust implies a temporal delay until the time when trust pays off. The decision of a system being trustworthy is not given before that temporal delay.

Accepting the assumption that the creation of trust in global connecting systems like IT systems is a domestic matter, it is possible to develop trustworthy solutions for e-commerce and e-government. Thus, a virtual world can be established which is nearly as tangible as a piece of paper.

KEY TERMS

Assurance: Statement, indication, or presumption that inspires confidence while excluding doubt. Assurance is an aspect of trust. Given the fact that trust cannot be quantified precisely, assurance provides a basis for quantitatively or qualitatively specifying the level of trust towards a system.

Authenticity: is divided in two sections: Data origin authenticity and entity authenticity. Data origin authenticity is the proof of the data's origin, *genuineness*, *originality*, truth and realness. Entity authenticity is the proof that a person or other agent has been correctly identified, or that a message is stored and received as transmitted.

Availability: Availability indicates the assurance that resources, like information, services, or equipment, are working adequately and available at a specified time to authorized entities. An available system has to be safe and secure from attacks.

Confidentiality: Nonoccurrence of the unauthorized disclosure of information. The term confidentiality indicates aspects of secrecy and privacy. It implies the ensuring that information is accessible only to those authorized to have access.

Data Integrity: Preventing of forgeries, corruption, impairment or modification of resources like information, services or equipment. Data integrity is the quality or condition of being whole and unaltered, and it refers to the consistency, accuracy, and correctness of data.

Safety: Quality, state, or condition of being prevented of and/or protected against danger, risk, or injury, caused by accidental and unintentional effects or actions. Safety further includes the recovery from such accidental and unintentional effects or actions.

Security: Quality, state, or condition of being prevented of and/or protected against danger, risk, or injury, caused by intentional effects or actions such as access to information by unauthorized recipients and the intentional but unauthorized destruction or modification of that information. Security further includes the recovery from such unauthorized destructions or modifications.

Nonrepudiation: Service that provides proof of the integrity, origin of data, and the identity of a person, all in an unforgeable relationship, which can be verified by any third party at any time. Hence, it determines, wether or not a particular event occurred or a particular action happened.

Privacy: Right of the individual to be protected against intrusion into his personal life or affairs and the individual's right to decide what personal data of him or herself can be accessed and used publicly by others.

Trustworthiness: Ability to create and develop trust. Trustworthiness is the assurance that a system deserves to be trusted.

Unexpected Outcomes of Lean E-Collaboration

Ned Kock
Texas A&M International University, USA

INTRODUCTION

Over the years, many theories have been used to understand e-communication and e-collaboration behavior (Kock, 2004; Markus, 2005). Arguably, the most widely used among those theories has been media richness theory (Daft & Lengel, 1986) even though there has been mounting evidence that its predictions do not hold in a number of situations (Markus, 1994).

One key prediction of media richness theory is that communication media of low richness (e.g., e-mail as opposed to face-to-face) consistently leads to a decrease in the quality of the outcomes of group tasks. One of the complicating issues associated with media richness theory is that there is abundant evidence that low media richness leads to perceived obstacles to communication (Kahai & Cooper, 2003; Kock, 2004), which is consistent with the theory, yet it is obvious that media of low richness like e-mail are widely used, sometimes even when richer media are easily available (Kock, 2005; Lee, 1994; Markus, 1994).

Even though media richness theory was proposed a long time ago, well before the emergence of modern e-collaboration technologies and the Internet as we know it today, it addressed topics that are highly relevant now. It addressed the notion that characteristics of a communication medium may affect group work, which has been a recurrent issue in recent research (Alge, Wiethoff, & Klein, 2003). Media richness theory and its nonverbal-cues-suppression perspective set the stage for the study of behavioral e-collaboration phenomena at the individual level of analysis, such as "flaming" (Alonzo & Aiken, 2004), and at the group level of analysis, such as group decision making (Baker, 2002). The theory has also motivated research into technological solutions to the problems associated with lean media (Briggs, 2002; Briggs, De Vreede, & Nunamaker, 2003).

In spite of the large amount of research in connection with media characteristics and their impact on group tasks, there has been little empirical evidence that the adoption of a lean medium can lead to increased group outcome quality: a counterintuitive finding that goes squarely against predictions based on media richness theory (Daft, Lengel, & Trevino, 1987; Lengel & Daft, 1988; Markus, 1994). This article provides such evidence based on the study of five process-improvement groups in a New Zealand university.

BACKGROUND

E-collaboration technologies are broadly defined as electronic technologies that enable collaboration among individuals engaged in a common task (Kock, Davison, Ocker, & Wazlawick, 2001). The e-collaboration literature is filled with mixed findings (Orlikowski, 1992), where success in the introduction and use of e-collaboration technologies has been as commonplace as failure (DeSanctis, Poole, Dickson, & Jackson, 1993; Kock, 2004). A number of theories and theoretical frameworks has been proposed that provide a basis for the understanding of these mixed findings.

Among the many theories devised, media richness theory (Daft & Lengel, 1986) stands out for its influence as a deterministic theory of communication-media adoption and use since its development in the mid-1980s. The theory claims that different communication media can be classified as lean or rich according to their ability to convey knowledge and information. The classification scheme proposed by media richness theory places face-to-face as the richest communication medium, and e-mail as a relatively lean medium (Fulk, Schmitz, & Steinfield, 1990; Lee, 1994). Media richness theory claims that lean media are not appropriate for knowledge and information communication (i.e., equivocality and uncertainty reduction), and that the adoption of media and the outcomes of their use will usually reflect this fact (Daft et al., 1987; Lengel & Daft, 1988).

Other factors have been shown to influence group outcomes, and related evidence has been presented to show that those factors influence group outcomes in ways that are either compatible with media richness theory, or in ways that expand and refine the media richness perspective. For example, past research has shown that the nature of the collaborative task (e.g., whether it is simple or complex) can have a strong effect on its outcomes when certain e-collaboration technologies are used. Task-technology fit theory (Zigurs & Buckland, 1998; Zigurs, Buckland, Connolly, & Wilson, 1999) proposes a typology of tasks and e-collaboration technologies, as well as predictions regarding the pairing of certain tasks and technologies, and the impact of that on group outcomes.

Part research has also suggested that the mental schemas (also referred to as knowledge or background;

see, e.g., Kock, 2004; Kock & Davison, 2003) possessed by individuals may influence the impact of e-collaboration technologies on the individuals. This includes socially constructed schemas that may induce the individuals to interpret information in a particular way (Lee, 1994). Particularly, the degree of similarity among the task-related mental schemas possessed by different individuals engaged in a collaborative task (e.g., whether task experts are interacting with other experts, or novices) may significantly affect the amount of cognitive effort required to successfully accomplish the task using certain types of e-collaboration technologies. Kock (2004) argues that the higher the degree of schema similarity, the lower cognitive effort is likely to be required.

GROUPS STUDIED

Five process-improvement groups were studied. Those groups were conducted at a New Zealand university over 7 months. The groups had from 7 to 13 members, and took on average 41 days to be completed. Each group selected, analyzed, and conceptually redesigned one or more business processes; redesign proposals were later implemented and led in most cases to process-quality and productivity improvements. Forty-six structured interviews addressing perceived technology effects were conducted with group members within two weeks of the completion of their groups.

All groups voluntarily adopted an e-collaboration system, namely, an e-mail conferencing system developed by the author, as their main communication medium. The system allowed group members to post e-mail messages and attachments to their groups. The decision as to whether the system would be used or not, and how much, was completely left to the groups themselves.

CHOICE OF MEDIUM

All five groups voluntarily chose the e-collaboration medium for the vast majority of the group interactions, that is, those interactions in which the communication mode was many to many. Phone and face-to-face media were used predominantly for one-to-one communication. That is, the groups consistently favored the e-collaboration medium as their main medium for communication in spite of it being perceived as a leaner medium than the phone and face-to-face media.

When asked to explain their choice, the overwhelming majority of the interviewees assigned a reduction in disruptiveness, typically linked with the possibility of interacting with the group at the most convenient time for them, as the main reason for the choice of the e-collaboration medium.

ADAPTATION TO THE LEANER MEDIUM

Several members pointed out that they had perceived the e-collaboration medium as likely to add undesirable ambiguity to their discussions. The main reasons given by members were the lack of immediate feedback and the filtering of verbal cues inherent in the e-collaboration medium. These perceptions are highly consistent with predictions based on the media richness theory (Daft & Lengel, 1986).

Plausible predictions based on the media richness theory for future scenarios involving the five groups would have been (a) the perception by group members of an increase in ambiguity in individual member contributions, and (b) either a move to richer media (such as face-to-face) or the discontinuation of the groups, both as a consequence of the higher perceived ambiguity.

None of these scenarios became reality. On the contrary, not only did the groups continue using the e-collaboration medium for most of the group interactions, but also, somewhat to our surprise, most respondents spontaneously reported a perceived increase in member contribution quality.

The perceived increase in member contribution quality can be explained by an adaptation of the members to the leaner medium, an adaptation that was primarily aimed at overcoming obstacles posed by the e-collaboration medium due to what could be characterized as its inherent lack of naturalness when compared with the face-to-face medium (Kock, 2004). Two main pieces of hard evidence strongly suggest this adaptive behavior and some traits of its dynamics. First, members spent more time preparing their individual contributions, which is evidenced by a dramatic decrease in member contribution speed through the e-collaboration medium in comparison with face-to-face meetings.

The mean contribution speed in the e-collaboration medium was approximately 6 words per minute. In face-to-face meetings, this contribution speed has been estimated at 113 words per minute (McQueen, 1991; McQueen, Payner, & Kock, 1999). The contribution speed in the e-collaboration medium was calculated based on group members' estimates (as well as direct measurements) of time spent preparing and posting contributions to their groups and the actual word count of their postings. The low contribution speed through the e-collaboration medium could not be explained only based on the fact that typing is slower than speaking, as average typists are expected to be able to type between 60 to 70 words per minute, which points to a better preparation of the postings as an alternative explanation for the low speed observed.

Second, group members seemed to have provided much longer contributions (in terms of total number of words) through the e-collaboration medium than they would have usually done in face-to-face meetings, which suggests that e-collaboration-mediated contributions may have had more information and knowledge content than equivalent oral contributions in typical face-to-face meetings. An aggregate analysis of word counts per posting provides support for this perception. According to this analysis, the mean contribution length (per posting) was 297 words through the e-collaboration medium. In face-to-face meetings, this mean contribution length has been estimated at 18 words (McQueen, 1991; McQueen et al., 1999).

The two pieces of hard evidence presented above, based on estimates of member contribution speed and contribution length, suggest that the adoption of an arguably less natural e-collaboration medium by the groups led members to adapt their group communication behavior in a way that seems to have led them to overcome the limitations posed by the e-collaboration medium. This adaptation apparently led group members to prepare longer and better-thought-out contributions than in typical face-to-face meetings.

MEDIUM LIMITATIONS ARE PARTIALLY OVERCOME

Given that members perceived an increase in member contribution quality as a consequence of the adoption of the e-collaboration medium, it seems plausible to expect that group outcome quality—that is, the quality of process redesign proposals—would also be seen by members as being increased. This was indeed the trend of the perceptions gauged in interviews with group members after their groups completed their process redesign tasks. Forty-eight percent of the interview respondents perceived an increase in group outcome quality, and 22% perceived a decrease. The remaining respondents perceived no variation in quality.

One of the two main reasons given by members for the increase in group outcome quality was an increase in member contribution quality; the other reason was higher departmental heterogeneity enabled by the low disruptiveness inherent in the e-collaboration medium used (an asynchronous communication medium). The main reason given by the respondents who perceived a decrease in outcome quality was higher ambiguity in the discussion, also seen as directly caused by the unnaturalness of the e-collaboration medium used, when compared with the face-to-face medium. These explanations partially confirm our hypothesis that group members perceived the e-collaboration medium as a relatively unnatural medium, but they nevertheless decided to use it for the majority of their group interactions and adapted their behavior to overcome the limitations posed by a high medium equivocality.

FUTURE TRENDS

While the initial perceptions of group members of the e-collaboration medium were consistent with predictions based on the media richness theory (Daft & Lengel, 1986), the adaptive behavior displayed by the groups in this study was not so. This behavior is, nevertheless, remarkably consistent with that of groups in similar circumstances in different organizational settings (Kock & McQueen, 1996), and partially consistent with previous studies in which the adaptive power of groups has been illustrated (Majchrzak, Rice, Malhotra, King, & Ba, 2000; Markus, 1992; 1994; Orlikowski, Yates, Okamura, & Fujimoto, 1995). The final and somewhat surprising conclusion of this study is that the existence of media constraints to group communication led to an improvement in group outcome quality!

No single existing theoretical framework provides a solid basis for explaining the adaptive behavior observed in the groups in this study. Two emergent theories that go some way toward accomplishing that explanatory goal are the psychobiological model (Kock, 2004) and compensatory adaptation theory (Kock, 2005). These two theories allow us to predict that unnatural media will lead to perceived obstacles to communication, and that group members will compensate for those obstacles. However, the theories do not allow us to fully understand why that happens.

Future research should expand the basic tenets of the psychobiological model (Kock, 2004) and compensatory adaptation theory (Kock, 2005) so that a better understanding is achieved of what really goes on in groups performing knowledge-intensive tasks using e-collaboration technologies. One thing seems to be sure, however: Contrary to what media richness theory predicts, it seems that those types of groups can be quite successful in spite of what may seem as shortcomings associated with lean communication media.

CONCLUSION

The groups in our study had initially chosen the less natural e-collaboration medium for group communication because of some of its advantages, notably, low disruptiveness. Immediately after they had begun using the new medium, group members perceived the medium as likely to lead to more communication ambiguity. They then adapted their behavior in order to overcome the limitations posed by the new medium rather than moving to a richer medium such as face-to-face. This adaptation involved members preparing longer and more elaborate messages, which partially offset the higher equivocality perceived as inherent in the e-collaboration medium.

Another more established theory that may help us understand the behavior of groups in response to communication-media constraints is the adaptive structuration theory (DeSanctis et al., 1993; Wagner, Wynne, & Mennecke, 1993). This theory tries to explain media adoption and use by groups as an adaptation process, and it arguably could be combined with the psychobiological model and compensatory adaptation theory to provide a more complete view of e-collaboration behavior. However, the adaptive structuration theory assumes that adaptive behavior emerges based on social and cultural norms existing prior to the introduction of the new medium (Poole & DeSanctis, 1990; Poole & Jackson, 1993).

The adaptive behavior of the five groups in this study does not seem to have been caused by social and cultural norms of the group members prior to the introduction of the new medium. It rather seems to have been motivated by more general human cognitive patterns that are independent of such norms as, although groups had a heterogeneous departmental composition, they reacted in a very similar way. Although this study does not clarify the nature of such cognitive patterns, it clearly suggests the need for more research on the origin and structure of these patterns and perhaps the development of alternative theoretical frameworks to explain media adoption and use.

KEY TERMS

Business Process: A set of interrelated activities performed in an organization with the goal of generating value in connection with a product or service.

E-Collaboration Technologies: Electronic technologies that enable collaboration among individuals engaged in a common task.

Media Richness Theory: Theory that claims that lean media are not appropriate for knowledge and information communication (i.e., equivocality and uncertainty reduction), and that the adoption of media and the outcomes of their use will usually reflect this fact.

Medium Naturalness: The degree of similarity between a given communication medium and the face-to-face medium.

Medium Richness: The degree to which a communication medium can support knowledge and information communication among individuals.

Process Redesign: A task in which a group selects, analyzes, and conceptually redesigns one or more business processes.

Process Redesign Group: A temporary group of a certain size engaged in a process redesign task. In this study, groups had 7 to 13 members and took on average 41 days to be completed.

Universal Approach to Mobile Payments

Stamatis Karnouskos
Fraunhofer Institute FOKUS, Germany

András Vilmos
SafePay Systems, Ltd., Hungary

INTRODUCTION

An old saying coming from the telecom world states that nothing can be really considered as a service unless you are able to charge for it. The last several years have seen a boom in interest in mobile commerce, mainly due to the high penetration rates of mobile phones. Furthermore, there is evident the need for a real-time, open, and trusted payment service that can be used any time, anywhere, and that can handle any transaction in any currency. Such a service would promote not only content creating activities but would empower the electronic and mobile commerce area and kick-start new innovative services. The time is right for such a mobile payment service, because the infrastructure, the business models, and other conditions that favor its existence are realistic and in place (Vilmos & Karnouskos, 2004). Up to now, we have witnessed the rise and fall of several efforts in the area, ranging from realizing simple intangible good purchases, up to interaction with real points of sale (POS) and person-to-person (P2P) transactions. Day by day, new trials are initiated, targeting different sections in the MP area; however, there is still no solution that is open and widely accepted. In this article, we first introduce the reader to the mobile payment area, present the guiding forces behind it, and subsequently examine such an open, secure mobile payment approach that has been successfully designed, implemented, and tested. Furthermore we identify some midterm future trends that we consider will be of high importance to the further development of the area.

BACKGROUND

Payments are the locomotive behind the business domain and heavily depend on trust and security. A global study by Little (2004) estimated that m-payment transaction revenues would increase from $3.2 billion in 2003, to $11.7 billion in 2005, and to $37.1 billion in 2008 world wide. Mobile payments are seen as the natural evolution of existing e-payment schemes that will complement them (Heng, 2004). The increasingly popular ownership of mobile personal, programmable communication devices worldwide promises an extended use of them in the purchase of goods and services in the years to come (Mobey Forum, 2003). Security in payment transactions and user convenience are the two main motivation reasons for using mobile devices for payments.

The context of mobile payments can be defined as follows: Any payment where a mobile device is used in order to initiate, activate and/or confirm this payment can be considered as a mobile payment. A mobile payment solution can be used in multiple applications and scenarios. The simplest scenario involves only the user, the device and a single payment processor, such as a mobile operator, bank, broker, or an insurance company. The user identifies himself or herself to the mobile device through secure identification mechanisms, including physical possession and password or even via biometric methods; the device then authorizes the transaction to the payment processor for the money transfer. More complex transactions involve at least one additional party, the merchant. In this case, the merchant may be affiliated with a different payment processor; therefore the two payment processors must be able to interoperate.

Based on the amount to be paid we can have different categorization of mobile payments. Generally we have:

- **Micropayments:** These are the lowest values, typically under $2. Micropayments are expected to boost mobile commerce as well as pay-per-view/click charging schemas.
- **Minipayments:** These are payments between $2 and $20. This targets the purchase of everyday's small things.
- **Macropayments:** These payments are typically over $20.

Currently, there are several efforts at the international level to accelerate and solidly support emerging mobile payment solutions. Most of the heavyweight companies that deal with hardware or software products for the mobile market and companies such as the mobile network operators (MNO) and financial service providers try via international fora and consortia to define the guidelines to which such a system should comply. The aim is to produce an approach that is widely acceptable and that would reach a global audience and not address just a specific customer base or isolated scenario. Towards this end, several consortia have aroused such as Simpay (www.simpay.com—ceased operation in summer 2005), Starmap Mobile Alliance, Mobey Forum (www.mobeyforum.org), Mobile Payment Forum (www.mobilepaymentforum.org), Mobile Payment Association (mpa.ami.cz), Paycircle (www.paycircle.org), Mobile electronic Transactions (www.mobiletransaction.org), and so forth. Apart from these "pure" mobile payment consortia, whose work directly affects the mobile payments, there are also other actors that indirectly are evolved with the mobile payment area and come from the financial/banking sector. Karnouskos (2004) provides an overview of these consortia.

For mobile payments to succeed, several requirements need to be addressed. Simplicity and usability largely determines whether users will use a service. This includes not only a user-friendly interface but also the whole range of goods and services one can purchase, the geographical availability of the service, and the level of risk the user is taking while using it. A promising mobile payment service should be offered widely and in a transparent fashion covering the biggest range of mobile payment transactions such as person to person (P2P), business to consumer (B2C), and business to business (B2B), domestic, regional and global coverage, low- and high-value payments. It should be based on open standards that will allow it to interact with other systems and easily scale. It should also be secure by means of technology and processes, and preferably be built on existing trust relationships. The new systems should be, at the end, more cost effective than the legacy approaches (e.g., the technology used may cost more, but if the fraud is minimized, at the end of the day, it is a cost-saving solution). Furthermore, they should also create new revenue flows or better tackle existing ones in order to justify their existence. Finally, understanding the nature and key rules of each local market as well as providing integration with existing approaches (e.g., reuse existing infrastructure and legacy billing systems) may also lead to its rapid acceptance. It should also be kept in mind that, apart from the technology part, the right legislation framework must be in place and ease approaches, especially when we refer to a global payment service. Experience has shown that even when a common directive exists (for instance within the European Union), its full interoperable implementation at per country level still remains a challenging task (Merry, 2004).

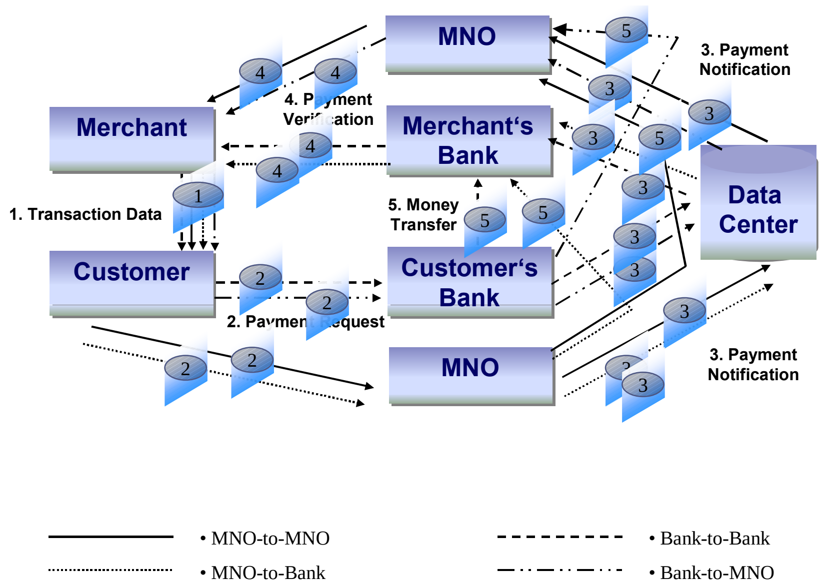
Within the past years, several mobile payment solutions have been developed. Some of them even managed to leave the prototype level and enter the commercial market. A detailed insight on these payment approaches is provided by Henkel (2001), Krueger (2001) and Karnouskos (2004). The mobile payment area is an active one and is rapidly changing. However still existing approaches have done little to fully address all of the requirements needed to establish a global, widely accepted open and secure mobile payment service. For instance regarding security in such services; most MP procedures today use SMS or IVR (interactive voice response) as a method to verify user's identity, methods that have been proven to be insecure. Furthermore, users are usually asked to provide their personal information to a third-party service provider in order for them to be able to register and get the service. Therefore they are asked to place immediate trust of their money and personal data on a previously unknown party. This third party is able to have the complete set of data for any transactions users make, therefore it is able to monitor users' private lives and of course do indirect profiling. It must be kept in mind that user-perceived security (the combination of technical security and trust in the procedures of the approach) is a critical factor (Heng, 2004) that decides on the success or failure of a payment service and therefore it has to be done correctly from day one. Generally existing solutions today are either not trusted, not available to a large enough audience, not speedy enough, not user friendly, not secure enough, tailored for special applications and transaction types, are only available to a limited closed circle of customers and merchants, or have a limited business model. SEMOPS, which we shortly present here, has designed and implemented an approach that realizes a secure, universal, real-time electronic payment service, which effectively covers most of the requirements such a global service poses. To our knowledge past and current mobile payment approaches (Karnouskos, 2004), address only fractions of the mobile payment domain needs, while SEMOPS takes a holistic approach, therefore complementing any existing system.

SEMOPS: A SECURE MOBILE PAYMENT SERVICE

SEMOPS is a mobile payment solution that is capable of supporting micro, mini as well as macro payment transactions. It is a universal solution, being able to function in any channel, including mobile, Internet and POS; it can support any transaction type, including person to person (P2P), business to consumer (B2C), business to business (B2B) and of course person to machine (P2M), with a domestic and/or international geographic coverage.

As in every payment system, SEMOPS is capable of transferring funds from the customer to the merchant or, in more general terms, from the payer to the payee. Typi-

Figure 1. SEMOPS transaction flow



cally, this transfer is realized via a payment processor, such as a bank or a mobile operator. The SEMOPS payment solution, however, is novel in that it enables cooperation between different payment processors (e.g., cooperation between banks and mobile operators), in achieving a global, secure, real-time, user-friendly, and profitable mobile payment service that can be used in both electronic and mobile commerce transactions. The payment service designed, developed, and currently in trial within the SEMOPS project establishes a customer-driven transaction flow and follows a simple credit push model. Basic principle of the business model is that it is based on the cooperation of banks and MNOs. This situation has two consequences (a) actors' resources can be combined and (b) revenue has to be shared. This is quite a challenge but SEMOPS proves that this is a win-win situation for all participants.

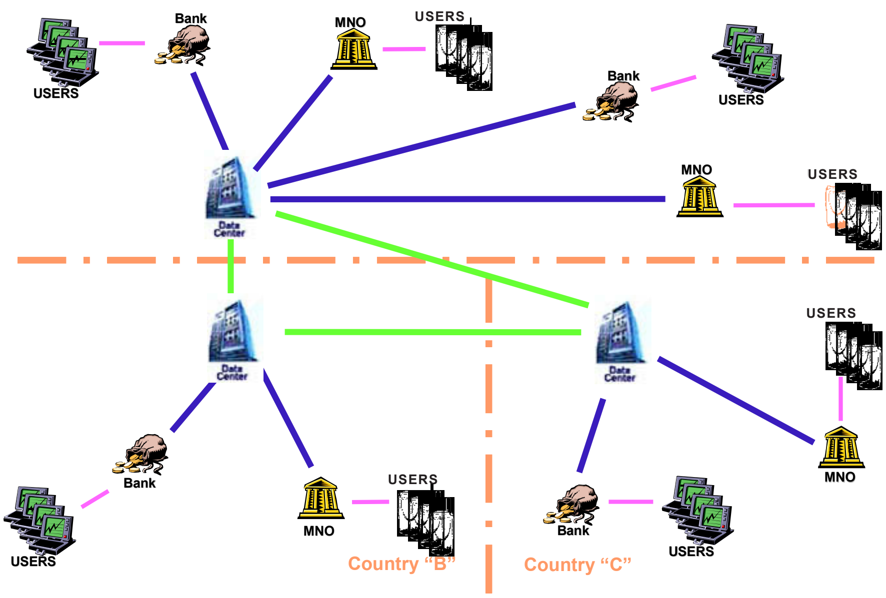
In Figure 1, one can distinguish the main players and components in a mobile payment scenario. Each user (customer or merchant) interacts with his or her payment processor (e.g., home bank or mobile network operator (MNO)) only. The banks and MNOs can exchange messages between them via the Data Center (DC). We should mention that the legacy systems of the bank and the merchant are integrated in the SEMOPS infrastructure and are used as usual. A typical scenario assumes that:

1. The merchant (generally any real/virtual POS) provides to the customer the necessary transaction details, invoices.
2. The customer receives the transaction data and subsequently initiates the payment request, authorizes it and forwards it to the payment processor (at the customer's bank or MNO).
3. The payment processor identifies the customer, verifies the legitimacy of the payment request, checks the availability of funds and forwards this request to the merchant's payment processor via the DataCenter (DC).
4. The merchant's bank receives the payment notice, identifies the merchant, notifies him or her about the payment being made, or requests from him to confirm or reject the transaction.
5. Once the merchant side confirmation comes, the fund transfer is done and all parties are notified about the successful payment.

There can be different combinations, depending on whether the user (customer or merchant) uses his or her bank or MNO account and whether the merchant accepts the payment in his bank or MNO account. The SEMOPS model (Karnouskos, Vilmos, Hoepner, Ramfos, & Venetakis, 2003) is extensible, therefore any third service provider that can offer the customer an account (e.g., credit card or financial service provider, even a utility company) can also easily slip in the role of the bank. It is however important to note, that although SEMOPS enables any account managers to play the role of a payment processor, the actual participation may be limited by legal constrains.

The new payment solution only has a chance to be accepted on the market if it makes good economic sense for the key players to promote the service. All the fea-

Figure 2. Distributed MP service architecture



tures, offered to the end users, the security, the comfort, the wide reach may be in vain if there is no economic incentives for the service providers. However it is obvious also that the service providers alone cannot make a success story of the service if the users are dissatisfied with either the service or the terms of the usage. The SEMOPS approach is based on decentralization. In each country where the service is introduced there is a local entity, the license holder, who organizes the service, contracts with the banks and mobile operators, contracts with the local service providers, ensures that local regulations are complied with, makes sure that the general service requirements are followed.

The flexibility of the model and its capability of integrating quickly new payment processors are critical for its survival. As it can be seen in Figure 2, the customers of any new financial provider that connects to the infrastructure can immediately transact with all other customers of the other providers in a transparent for them way. That will lead to a rapid expansion of the service that can establish it as a global payment service. SEMOPS follows a trust-delegation model. The new customers added do not have to place any trust into the SEMOPS approach itself; they need to trust the service that their banks and MNOs are providing to them (therefore extend the existing trust they already have placed to these institutions). The banks and MNOs are connected via a financial infrastructure with its own rating system and its own trust relationships that exist today. As a result, in a transaction scenario, user A does not have to know personally or trust directly user B to perform the transaction. The SEMOPS approach has several features, including means to secure transactions, notify in real-time its users and protect their privacy by even allowing anonymous payments to be made. Further info on the approach can be found in (Karnouskos, Vilmos, Ramfos, Csik, & Hoepner, 2004). Beyond using existing trust relationships among banks/MNOs and their customers, SEMOPS deploys also state of the art security (digital signatures and encryption) as well as processes that protect the user privacy (Karnouskos, Hondroudaki, Vilmos, & Csik, 2004).

FUTURE TRENDS

Currently, almost all existing approaches focus on 2G or 2.75G infrastructures in order to achieve the critical mass once they are commercial. However, the mobile network infrastructure itself is rapidly evolving. The début of UMTS, wireless LAN, WiMAX and other 3G and beyond technologies will provide new capabilities that will free MP from some its current limitations and allow more sophisticated approaches to be developed. Once this infrastructure becomes mainstream, we will witness also solutions that take into account the new security capabilities, which are nonexistent today, offered by such infrastructure for security, privacy and trust management.

The device manufacturers continue to bring on the market mobile phones that have advanced capabilities and host their own execution environment. It is a matter of time until advanced cryptographic services are integrated in these devices that will make possible diverse secure communication and authentication procedures. Mobile public key infrastructure (mPKI), mobile digital signatures, encryption, and biometric authentication are expected to be widely available in the near future. Furthermore Identity Management efforts are ongoing for the Internet community and several standardization consortia such as Liberty Alliance (www.projectliberty.org) work toward federated identity in the virtual world. If such efforts are successful, they will have a catalytic effect on MP domain, as they will provide a homogeneous identity framework capable of bridging universally the real and virtual world.

With the rise of technological approaches, other communication channels will flourish. Today the basic channels of payment services are the SMS, Voice, and lately IrDA and communication over GPRS/EDGE. However, other innovative approaches seem also promising such as instant messaging (IM) and near field communications (NFC). The IM will not only allow bridging together the Internet and mobile services and payments but will also make trivial P2P payments, where the two or more parties are not in the same physical space (Karnouskos, Arimura, Yokoyama, & Csik, 2005).

Digital Rights Management (DRM) is an integrated complex context covering not only technologies that limit or prohibit the unauthorized copying or distribution of these products but include also laws, contracts and licenses that regulate and restrict the use of such material (Becker, Buhse, Günnewig, & Rump, 2003). As content generated for mobile devices is increasing, mobile DRM systems are expected to play a significant role in the future (Beute, 2005). Standardization initiatives like the Open Mobile Alliance (OMA; www.openmobilealliance.org) work towards developing an advanced mobile DRM standard with the ability to support richer content business models. However rich payment capabilities also need to be in place and the existing MNO billing schemes will not be enough. In the future coupling content management with a global payment capability, preferably real-time (e.g., via instant messaging), will result in a powerful combination, where the mobile user any time anywhere can access legitimately content and instantly pay for it according to his preferences (Karnouskos, 2004).

CONCLUSION

Mobile payment has sparked a lot of interest in research and commerce communities and is viewed as an integral part of our future life. The area is an extremely active one, and rapid commercial evolvement is expected in the short and mid term. The need for a mobile payment service that can address in a global way existing needs is evident, and the first steps have already been done. However, although several mobile payment services have been designed, implemented and even commercialized, up to today there is no such service that can be widely accepted and cover adequately most of the transaction spectrum that we have referred to. For any service to evolve and reach the critical mass, several issues including business as well as technology aspects have to be approached in the right way.

SEMOPS (www.semops.com) presents a promising approach as it integrates state of the art technology, a flexible cooperative business model and builds over trust relationships that exist in the real world today. SEMOPS demonstrated a fully functional service with live users in the premier computer industry event CEBIT 2005 (www.cebit.de). Currently we are in the process of setting several pilots mainly in Europe, but later also in Asia and the United States, while the aim is to make SEMOPS a successful commercial service within the short-term future.

KEY TERMS

Authorization: Granting of rights, what includes granting of access based on access rights or privileges. It implies the rights to perform some operation, and that those rights or privileges have been granted to some process, entity, or human agent.

DRM: Digital Rights Management (DRM) is a concept for managing and controlling the access and utilization of digital assets.

Macropayment: These payments are typically over $20.

Micropayment: These are the lowest values, typically under $2. Micropayments are expected to boost mobile commerce as well as pay-per-view/click charging schemas.

Minipayment: These are payments between $2 and $20. This targets the purchase of everyday small things.

Mobile Payment: Any payment where a mobile device is used in order to initiate, activate, and/or confirm this payment can be considered as a mobile payment.

POS: Point of Sale is a location where a transaction occurs. This may be a realPOS (e.g., a checkout counter), or a virtualPOS (e.g., an e-shop in the Internet).

Using an E-Book for Learning

K. C. Chu
IVE (Tsing Yi), Hong Kong

Queendy Lam
Meinhardt (Hong Kong) Limited, Hong Kong

BACKGROUND

The vocational education system in Hong Kong is seen as changing in step with the development in industry (O & Chu, 2003). At the beginning of the '50s until the late '60s, Hong Kong was an entrepôt trade economy. However, skills and technology transferred from Shanghai, a steady immigration came from Guangdong, and increasing amounts of local investment had promoted Hong Kong's industrial foundation. By the early '50s, the Education Department of Hong Kong began to recognize "the increasing importance of Hong Kong as a manufacturing and industrial center," and time and effort were being devoted to the development of technical education. During this period of time, we witnessed the building of a vocational school (1953) and technical college (1957); they had aimed at providing vocational education and training for post-Form 3 and -Form 5 leavers. Successful textile manufacturing, followed by new international investments in other infant industries including electronics through the 1960s and 1970s contributed to the socialization of the workforce. By the early 1960s, there was a widely recognized link between industry and technical education. By the mid-1970s, education discourse and documents professed the need to increase the proportion of the curriculum devoted to "practical education" in general secondary schools (*White Paper: Secondary Education in Hong Kong over the Next Decade*, 1974).

Government land sales, efficient infrastructure planning, and the setting up of the economic zones in China all had contributed to a growth rate averaging 10% each year throughout the 1980s and the early 1990s; these achievements had further improved the investment climate. During this period of time, Hong Kong further expanded technical education at the tertiary level. The link between vocational education and training, and the newer infrastructure and high-technology-related forms of industrialization were clearly outlined in the *Report of the Advisory Committee on Diversification of the Economy* in 1979. All these changes in the economic environment had been well served by the corresponding changes in the vocational education system as evidenced by the rapid and high economic growth in the '70s, '80s, and the early '90s.

The VTC (Vocational Training Council) was established in 1982 under the Vocational Training Council Ordinance to provide and promote a cost-effective and comprehensive system of vocational education and training to meet the needs of the economy. Under VTC, preemployment and in-service education and training are provided by the Hong Kong Institute of Vocational Education (IVE), VTC School of Business and Information Systems (SBI) and its training and development centers. The mission of VTC is to provide cost-effective alternative routes and flexible pathways for school leavers and adult learners to acquire skills and knowledge for lifelong learning and enhanced employability (VTC, 2004).

Since the late '90s, the volatile employment market, declining industry, and desire to become a knowledge-based society have triggered yet another education reform. Two important documents have been published by the Hong Kong government to paint out the education reform and the blueprint for the education system in Hong Kong for the 21st century: *Reform Proposals for the Education System in Hong Kong* by the Education Commission (2000), and the *Report on Higher Education in Hong Kong* by Chairman Lord S. R. Sutherland (2002) of the University Grant Committee.

In response to the Sutherland report (2002), the Vocational Training Council formulated a strategic plan for the change. The plan is to increase e-learning within the VTC to

- promote an e-learning culture and to identify teaching staff who make effective use of the Web for teaching,
- encourage staffs to build a learning community on their Web sites,
- encourage staffs to provide students with an active Web site, and
- encourage staffs to conduct virtual (online) tutorials and virtual help desks.

USING E-LEARNING SYSTEMS

Textbooks may not fulfill all the requirements of fast-changing syllabi in this information era. This statement is especially true for those needing computer or IT knowledge for which information written in a textbook can be quickly outdated. Further drawbacks of textbooks are that they do not provide interactive learning but rather one-way knowledge transfer without any feedback that would train students to think in a deeper way. This learning approach does not fit the current student-centered learning model and does not meet the future career requirements ("Cathay Employees," 2004).

Decision makers also need to understand the fundamental differences in teaching approaches that are required in order to implement online training successfully. Otherwise, they risk implementing a high-content system that does not engage and retain students, and will make their organizations uncompetitive in the global educational market. The successful use of online learning is probably the biggest opportunity and challenge that universities are currently facing (Prendergast, 2004).

However, most distance learning development programs are focused on online lectures, tutorials, and assessment. Practical training systems that allow instruments to be monitored and controlled over the Internet leaves a lot to be studied. This type of training system can easily be turned into an online experiment that allows students at remote locations to control and obtain real-time measurements or experimental data (Tan & Soh, 2001).

Actually, some students like to read books to gain knowledge while others prefer to understand theories deeper through experiment (Chu, 1999; Whelan, 1997). Both of these knowledge-based and investigative types of learning styles have profound and different effects on the delivery and acceptance of engineering education. A virtual laboratory developed by using a simple matrix-assembly Java applet provides instrument simulators that form a powerful auxiliary, didactic tool to give students a basic idea of the instruments, control, and operation (Cabell, Rencis, & Grandin, 1997). Another laboratory running remotely via a Web interface allows users to conduct experiments in the Control Engineering Laboratory at Oregon State University (Shor & Bhandari, 1998). The Bytronic Process Control unit at Case Western Reserve University can also be accessed remotely via the Internet (Shaheen, Loparo, & Buchner, 1998).

The teaching of engineering subjects is bound to include a variety of rules, theorems, and devices, which involve primarily knowledge-based learning and must be understood by the students. But at the same time, students must also learn how to apply the learned knowledge through problem-solving and design exercises (Ericksen & Kim, 1998). This provides another good reason to support remote-access practical work for virtual learning.

A study at East Carolina University also finds that virtual laboratories help students to understand the concept and theory of those online courses (Yang, 1999). Compared with the traditional laboratory, a virtual laboratory is particular useful when an experiment involves equipment that may cause harmful effects to human beings. The laser virtual laboratory developed by the physics department of Dalhousie University (Paton, 1999) shows how to perform in real time with dangerous lasers, experienced by commanding equipment through the Internet.

E-BOOK SYSTEM

This e-book system provides a self-learning environment for students to learn an automation programming language called LabVIEW through the Internet. The main body of the e-book is produced by Flash. It looks like a book and contains dynamic actions on the final Web page (Figure 1). Animation, graphics, and videos for interactive learning are linked to the content of this e-book. If students cannot understand the explanation by means of text, they can learn clearly by watching those video demos, downloading data sheets, and trying the virtual laboratory.

The content of this e-book is shown in Figure 2. This content page contains links for pointing to the corresponding page of each topic. Visitors can choose any items that they find interesting and want to study deeper.

There are seven topics inside this e-book.

- **Syllabus:** Describes the details of the syllabus and assessment scheme
- **Introduction:** Introduces different automation applications in our daily life
- **Programming Technology Fundamental:** Introduces different types of programming techniques
- **Graphical Programming:** This section is the core knowledge of the e-book. Students can learn from this section how to build up a LabVIEW program
- **Industrial Communication and Control:** Describes the applications of the LabVIEW program in industrial communication and control
- **Web and Mobile Programming in Control:** Describes how LabVIEW can be applied in Web and mobile control
- **Reference:** Provides reference books to this subject

If this e-book was just constructed like a common Web page, it would not attract students to continue to read. Additional educational techniques are added to keep

Figure 1. Dynamic actions in the e-book

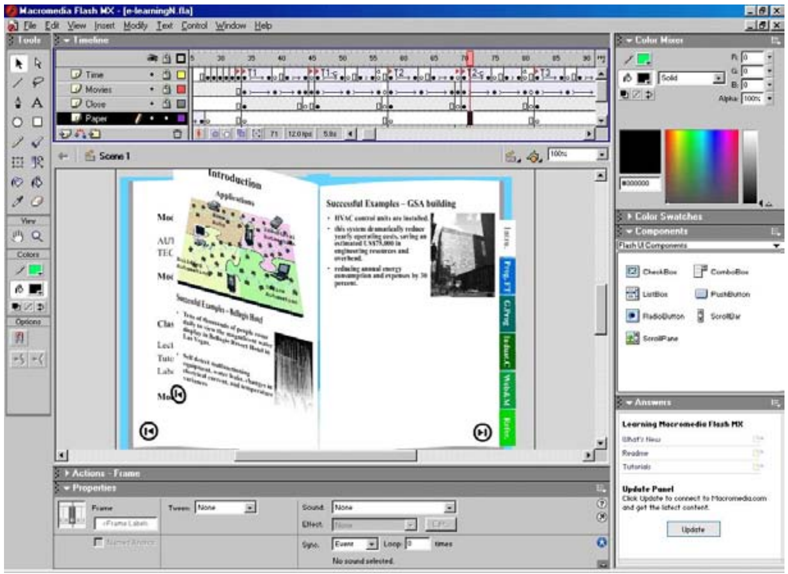

Figure 2. Content page of the e-book

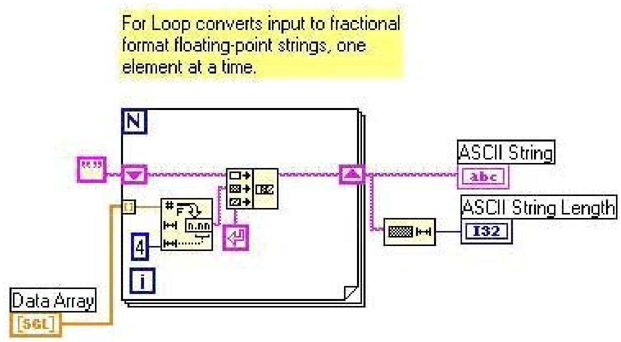
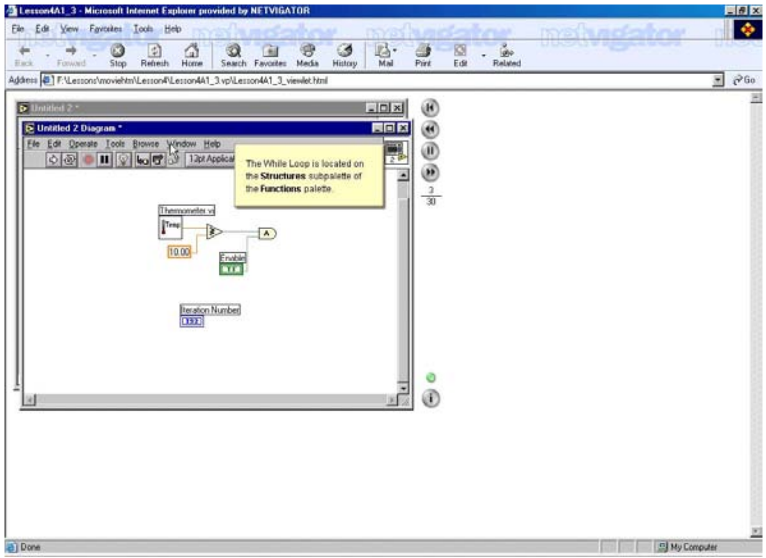
Figure 3. SBL for LabVIEW programming



students' interest to browse through different pages and to learn in a better way. These educational techniques include the following:

- **Scenario-Based Learning (SBL):** SBL was originally used to simulate a scenario that is close to the students' learning or future working environment (Chu & Leung, 2002). Using up-to-date information and multimedia technology, it can simulate issues and conditions similar to those encountered in the real world. Students can use this virtual environment to understand deeper the operation and the theory behind them. Further explanation will be displayed in a hierarchical way to suit the different backgrounds of the students.
  Different examples of LabVIEW programming (Figure 3) are placed in this e-book to help students understand how to use LabVIEW icons in different applications. Students simply click on those SBL links inside the e-book, and new windows will display the corresponding programming example. If students do not know what the icon means or want to know more about the icon, they just click on the icon and it will jump to the right place inside the e-book for further information.
- **Video Explanation:** Video is an important element for interactive e-learning. Students must find it

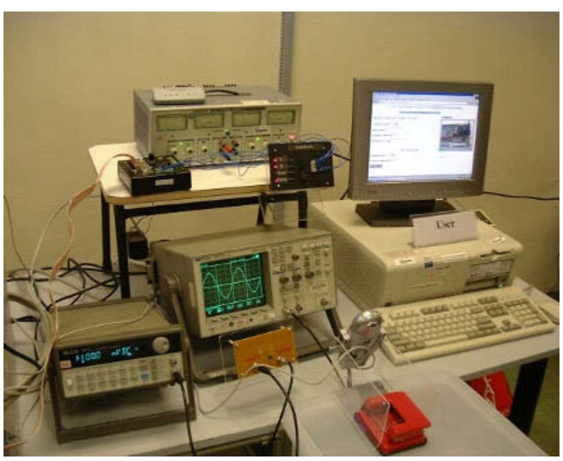
Figure 4. Video explanation for LabVIEW programming



boring if they are only given large amount of text without any figures, animation, sound, or video. This interactive video is even good for those students missing the normal class. Detailed step-by-step, verbal explanation will be found inside this video for every use of the LabVIEW software.

- **E-Lab:** Engineering students really like to experiment in order to enhance their understanding and practical skills. To fulfill this requirement, an e-lab is set up at our college (Figure 5) that allows students to control and monitor it from home. Students are also taught how to write this kind of remote control and monitoring of LabVIEW software in the e-book. For simulating the real signal generator and oscilloscope, animated ones (Figures 6 and 7) are created to allow students to have a feeling of control of the real signal generator and to monitor the result through the oscilloscope.

Figure 5. E-lab equipment setting



IMPACT OF THE E-BOOK SYSTEM

Sixty year-two subdegree engineering students at the Hong Kong Institute of Vocational Education (Tsing Yi) joined the pilot test of this e-book system. The e-book system was implemented to provide supplementary learning for a module called "Automation Programming Techniques."

Most of the students are male and all of them had their own computers or computers shared with their families. In this study, students were divided into groups with around 20 students each. A demonstration for each group about how to use this e-book system was arranged in a computer laboratory. After that, they could freely access this system at home.

In order to assess the students' views of this e-book system, a questionnaire was given to each student immediately after their first experience of using this system. In addition, students could freely write down their feedback to this study on the back of the questionnaire. Also, the more focused feedback was obtained through short discussions with some groups of students after using this system for 1 week.

The questionnaire aims mainly to obtain students' views toward existing functions of the system: about

Figure 6. Animated signal generator

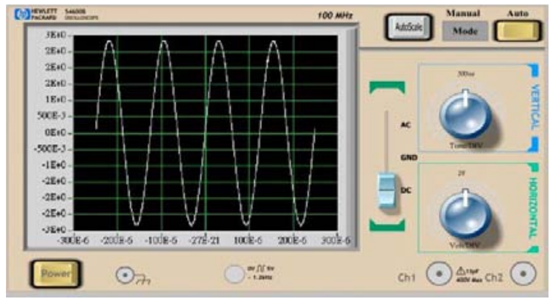


Figure 7. Animated oscilloscope

learning using the e-book, the user interface, and the needs of the students for this kind of e-book. All the students (N=60) responded to the questionnaire, and the results were analyzed. From the overall results of the questionnaire, most students show a positive attitude toward this e-book system.

When compared to the traditional book printed on paper, most students (98%) agree that this system is easier to read than the traditional one. The overall organization of the e-book lets students search for required materials easier, and the voices and animation also enables them to understand the content better. The tree-like links for each subtopic give students an overall picture of the content and make it easier for them to obtain the necessary information that they want to further investigate. These interactive facilities cannot be provided by the traditional paper book. Many students (85%) even reflected that they were encouraged to spend more time studying by using this e-book system.

Similarly, for the e-lab provided by this e-book system, students gave positive feedback, too. They found that it was faster and easier to work in the remote-control environment. The animated environment is so close to the real environment that they can operate the equipment without the necessity to read the user manual. Control parameters in the animated environment can be changed easily until the optimum solution is obtained. That is why students reported that this system is better than the normal laboratory environment in learning design work (78%) and learning concepts (76%).

CONCLUSION

Nowadays, e-learning is becoming a prevailing trend in education under the highly efficient and multifunctional computer-oriented environment. The virtual laboratory is an especially beneficial tool of e-learning for technical subjects, and it provides opportunities for students to conduct lab experiments at home and even be involved in dangerous experiments in a virtual situation.

In an e-learning approach, another widely used tool will be the e-book. The e-book system can be used for any topic in a self-learning environment. It is interactive and action oriented, which will make study more interesting. E-books particularly attract students who get bored when reading traditional text-dominated books. Educational techniques like scenario-based learning and video explanations are important features used in an e-book system.

Encouraging results from using an e-book were collected from 60 year-two subdegree engineering students. Positive feedback includes that the e-book is easier to read, that it is easier to search for information, and that voice and animation enables students to understand the content better. The e-lab provided by the e-book system also generated positive feedback, including that the learning of design work and concepts was better than in a normal laboratory environment. It is concluded that e-books will become popular learning tools in e-learning environments. Further development of the e-book assumes convenience, efficiency, and effectiveness in e-learning.

KEY TERMS

U

Distance Learning: Learners receive learning materials through CD-ROMs, the Internet, or satellite broadcasting. This saves learners' traveling time and promotes learning anywhere and anytime.

E-Lab: The same as a virtual lab, but is mainly delivered through the Web.

E-Learning: The same as virtual teaching.

LabVIEW: The graphical development environment for creating flexible and scalable test, measurement, and control applications. With LabVIEW, users can interface with real-world signals, analyze data for meaningful information, and share results and applications.

Scenario-Based Learning (SBL): SBL simulates a scenario that is close to the students' learning or future working environments. Using up-to-date information and multimedia technology, it can simulate issues and conditions similar to those encountered in the real world. For example, students can virtually experience an actual computer working environment. They can also take this opportunity to study how different accessories of a computer interconnect together, and how signals flow between different units. Students can use this virtual environment to gain a deeper understanding about operations and the theories behind them. Further explanation will be displayed in a hierarchical way to suit different student backgrounds.

Virtual Lab: An experiment is set up in the remote laboratory for users to access through the Internet at anytime and anyplace. Compared to the traditional laboratory, a virtual laboratory is particularly useful when an experiment involves equipment that may cause harmful effects to human beings. Another meaning of virtual lab is implementing a laboratory by means of software simulation.

Virtual Teaching: Students in the virtual teaching environment are given instructions by the lecturer on the requisite technology necessary to accomplish the virtual format of instruction. This technology includes instruction through accessing Web pages, e-mail, the World Wide Web, and newsgroups. To assure student competency, the virtual class may meet sometimes to review the previous instructions, thereby maximizing the ability to carry out the class in the virtual setting.

Using Collaborative Transportation Management in Global Supply Chain

Jonah C. Tyan
Taiwan Semiconductor Manufacturing Company, Taiwan

INTRODUCTION

Due to escalating global competition and a decline in profit margins, most multinational corporations pursue global sourcing through a *global supply chain (GSC)* in order to secure market share and improve profits. The practice of e-commerce and the business trend of mass customization force both manufacturers and retailers to shorten cycle time by managing GSCs more effectively. Successful applications of GSCs, such as that by Dell Computer, have been widely discussed and publicized in the supply chain literature. However, the physical distribution of GSC execution is recognized as its weakest link and can result in inefficient and unreliable product delivery. The collaborative integration with global *third party logistics (3PL)* to execute physical distribution dictates the success of any GSC application. This article introduces an application of logistic collaboration, namely *collaborative transportation management (CTM)*, which is a new business model that includes the carrier as a strategic partner for information sharing and collaboration in a supply chain.

BACKGROUND

The key reasons for the globalization trend are overcapacity in highly industrialized countries, significant disadvantages with respect to labor costs, and the emergence of worldwide information networks that connect corporate information systems (Arnold, 1999). An increasing number of firms are combining domestic and international sourcing through GSCs as a means of achieving a sustainable competitive advantage (Bonarth, Handfield, & Das, 1998). A GSC is currently viewed as a strategic weapon in the quest for improved performance and profitability through greater availability, quality, delivery and price advantage (Lee, 2000; Smith, 1999).

The principle and methodology of GSC management are similar to those of traditional *supply chain management (SCM)*, except that multiple countries are taken into consideration. Traditional SCM is the integration of functions from the procurement of raw materials to final customer delivery. The GSC model is more complex than SCM, as it includes different taxes and duties, differential exchange rates, trade barriers, customs clearance, and a sophisticated international transportation network (Vidal & Goetschalckx, 1997). Most companies establish a virtual integrated enterprise with their suppliers by implementing an e-business model in order to address the information and the finance flow of a GSC. However, the integration of physical distribution in a GSC appears to be the weakest link, due to the high level of investment required when construct in a global distribution network.

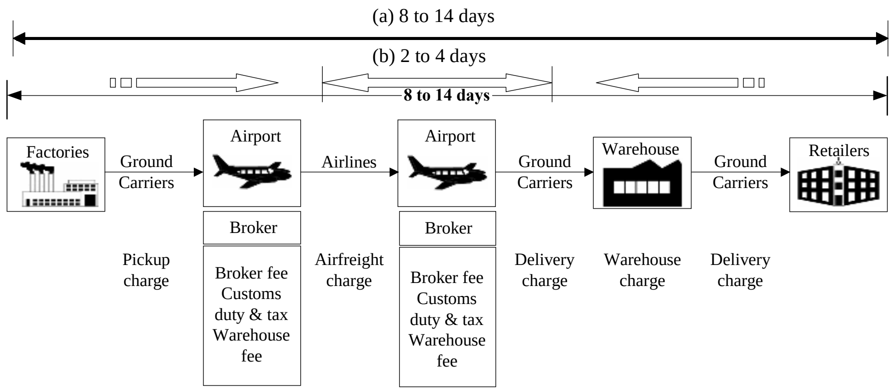
The traditional international shipping practice with extensive consolidation operations (Crainic, 2000) takes 8 to 14 business days, exclusive of manufacturing cycle time. The new economy calls for alliances to be made with 3PL providers in order to manage GSCs effectively by focusing on each player's core competencies (Lieb & Randall, 1999). Most high-tech companies select global door-to-door 3PL providers such as FedEx, UPS, and DHL in order to streamline logistic operations and to reduce delivery cycle times.

The typical benefits of a global *door-to-door delivery* service are shorter delivery cycle times, more reliable transit times, less complex customs clearance procedures, and real-time global tracking and tracing systems (Christopher, 1998). While the unit transportation cost is higher than that of traditional consolidated airfreight service, the total logistics cost is lower as a result of inventory and cycle time reduction throughout the GSC. The success of these integrated 3PL providers is determined by its global transportation network, warehousing network, and information network. Figure 1 depicts the international distribution cycle time by traditional consolidated airfreight model and a door-to-door service provided by a global 3PL provider can compress the distribution cycle from 8 to 14 days to 2 to 4 days.

DESCRIPTION OF COLLABORATIVE TRANSPORTATION MANAGEMENT

The level of collaboration amongst all players in the chain, determines the success of a GSC. Classic supply chain collaboration is found in retailer-supplier partnership programs (Tyan & Wee, 2003) such as quick response, U

Figure 1. International distribution cycle time of (a) a traditional international consolidated airfreight model and (b) a global door-to-door service model



continuous replenishment policy, and vendor managed inventory, which aim to reduce inventory and provide a quick response to consumer demand. The most recent developments in collaborative planning, forecasting, and replenishment (CPFR) is designed to further improve the retailer-supplier relationship. However, the carrier relationship with supply chain players was not considered until the introduction of CTM, which extends the supply chain collaboration to physical distribution partners (Strozniak, 2003).

CPFR, developed by the Voluntary Interindustry Commerce Standards Association (VICS), is a nine-step business process model permitting value chain partners to coordinate sales forecasting and replenishment processes in order to reduce the variance between supply and demand (Aichlymayr, 2000). Under CPFR, each party share information and compares calculations. Manufacturers and retailers exchange forecasts, including point of sale, on-hand and delivery data. They review the data and collaborate to resolve forecasting discrepancies. A VICS subcommittee recently initiated a new shipper-carrier partnership strategy, known as CTM, in order to reduce cycle times and inventory carrying costs for the retailer and its suppliers, while increasing asset utilization for motor carriers (Cooke, 2000; Tirschwell, 2004).

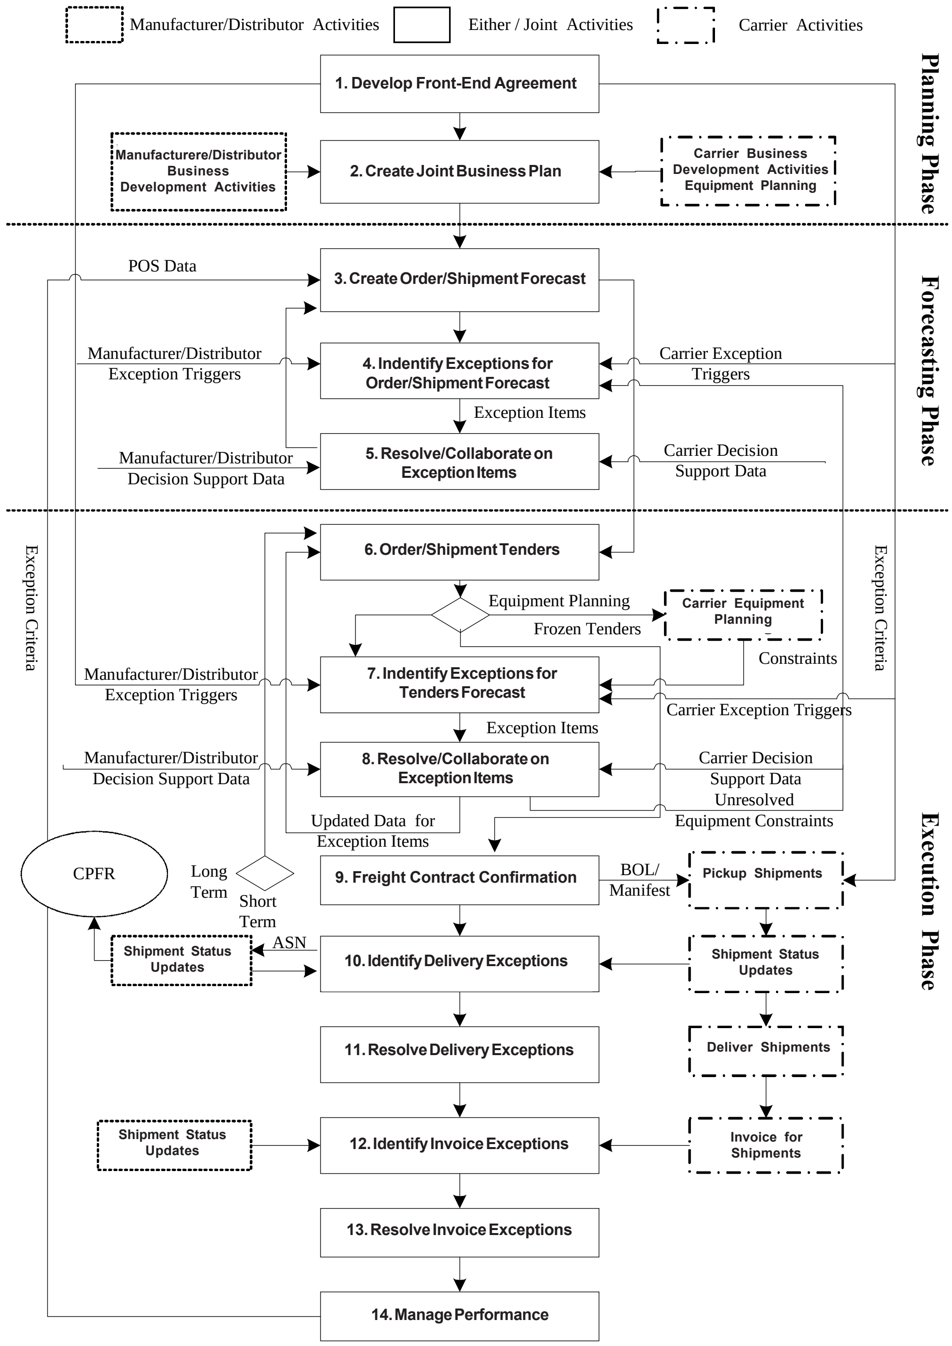
CTM Business Model

CTM is a new process for carriers, involving them in five key business activities: the creation of a joint business plan, order forecasting, order generation, freight order confirmation, and carrier payment processes (Browning & White, 2000). The CTM business model was proposed by VICS and consists of 14 steps. The CTM process can be further divided into three distinct phases: planning, forecasting, and execution, as shown in Figure 2.

The planning phase makes up steps 1 and 2. In step 1, the trading partners establish a collaborative agreement to define the relationship in terms of freight shipment, exception handling, and key performance indicators. Step 2 involves aggregative planning to determine resource and equipment requirements by matching the planned shipment. The forecasting phase includes steps 3 to 5. By sharing order and shipment forecasts in step 3, the carrier gains an insight into the planned volume changes and adjusts equipment requirements accordingly. Any exceptions caused by the manufacturer, distributor, or carrier are generated in step 4 and resolved collaboratively in step 5. Unlike the traditional 1- to 2-day advance notice of potential shipments, the carrier has ample time to handle the revised volume—1 to 4 weeks, depending on the forecasting horizon.

The execution phase consists of four stages: shipment tenders, distribution, payment, and a review in order to manage the entire distribution cycle. The shipment tenders stage covers steps 6 to 8 of the CTM. Step 6 is the creation of order/shipment tenders, based on the revised order forecast. Any exceptions based on the latest equipment availability or pickup and delivery requirements, are identified in step 7 and resolved collaboratively in step 8. The distribution stage—steps 9 through 11—involves the physical distribution and shipment status visibility. Step 9 is the creation of the final shipment contracts outlined in the collaborative tender acceptance and shipment terms. Shipment status is continually updated throughout the distribution cycle and any exception is identified during step 10. Step 11 is the resolution of delivery exceptions. The payment stage is covered by steps 12 and 13. Step 10 ensures that invoicing discrepancies between carriers and shippers are greatly reduced by the exchange of shipment attributes, such as weight, freight class, and destination. Any payment exceptions

Figure 2. Generic CTM business model (From Browning & White, 2000)



identified in step 12 are collaboratively resolved in step 13. Finally, the review phase in step 14 involves measuring the distribution performance against the key performance indicators and seeking opportunities for continuous improvement.

CTM Implementation Issues

The proposed CTM model is generic and can be modified to fit a specific supply chain application. We are interested in the application of CTM in GSC from the perspective of logistic operations. The benefit of CTM is the first issue to be addressed. The most obvious benefit to 3PL providers is the ability to develop business plans with their key customers in order to better fulfill distribution requirements. This is achieved through proactive participation in the planning, forecasting, and execution phases of CTM. The manufacturers and distributors, consequently benefit from better transportation transit times, shipment status visibility, and the payment process. The collaboration in execution between trading partners creates supply chain competitiveness and value. Other benefits include reduced costs, increased revenue, an improved service level, improved customer satisfaction, and increased asset utilization (Browning & White, 2000).

CTM technology requirements for are the next issue to be discussed. In order to foster collaboration, new information technology (IT) is needed to link between the carrier and the manufacturer/distributor. The CTM IT requirements proposed by VICS are vendor and platform independent, so that any trading partner entering into a collaborative relationship will not be hindered by technical limitations (Browning & White, 2000). The CTM information system integration across the entire supply chain can be achieved by the development of IT standards, IT infrastructure, e-commerce, and a supply chain system (Esper & Williams, 2003).

Organizational infrastructure is another CTM implementation factor, and is identified as the most important enabler of successful SCM implementation (Marien, 2000). It sets commitments and regulates all parties so they accept their responsibilities and share both the gains and risks, as outlined in step 1 of the CTM. GSC is a highly dynamic system and any changes may impact logistic activities. The core concept of CTM is to resolve these transportation exceptions collaboratively. In order to achieve the benefits of CTM, empowered designated personnel from each party are essential.

Case Study

This study discusses the case of a global 3PL provider that provides door-to-door distribution services for major notebook (NB) manufacturers in Taiwan. Manufacturing capability as well as cost and quality advantages enables Taiwan to be one of the most competitive strategic NB computer suppliers for many of the major personal computer manufacturers, such as Apple, Compaq, Dell, HP, IBM, and Toshiba. About 50% of the world's notebook computers are manufactured in Taiwan. In order to reduce cycle times and total costs simultaneously, Taiwan NB manufacturers transformed their international transportation from a consolidated airfreight mode to a door-to-door service. This practice is also called Taiwan-direct-shipment. In order to enter the Taiwan-direct-shipment distribution market, the global 3PL provider aligned with each NB manufacturer and formed a specific GSC with its retailer. The representative GSCs and transportation network are shown in Figure 3.

The NBs are delivered to customers throughout North America using a door-to-door guaranteed service, with a cycle time of 3 to 5 business days. The partnership was started in late 1999. In the beginning, the 3PL provider experienced a major challenge in attempting to manage service levels and aircraft capacities due to the volume

Figure 3. Transportation network of the notebook computer global supply chain

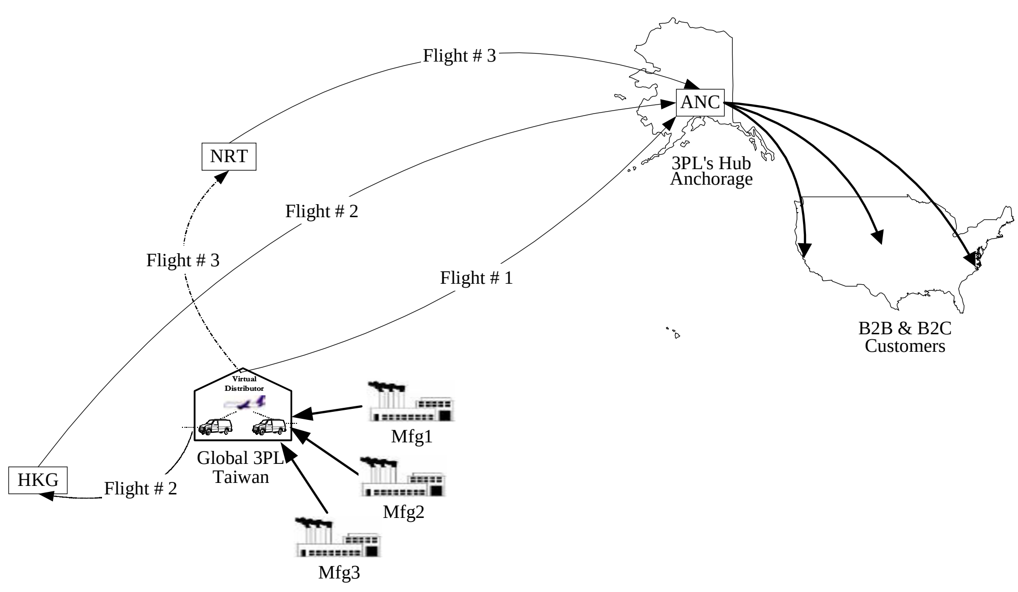


Figure 4. Architecture of integration IT and CTM in a NB GSC

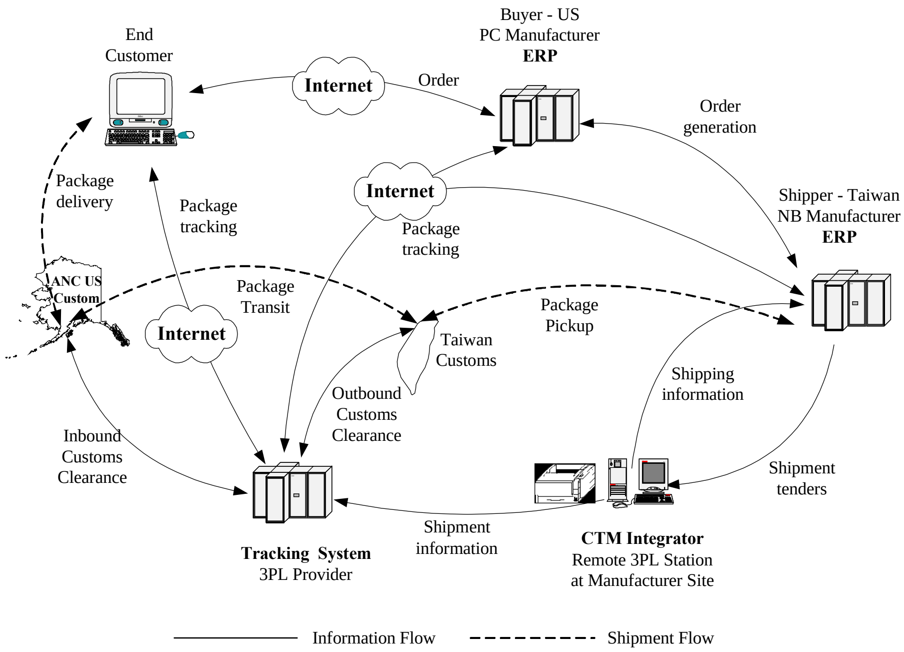


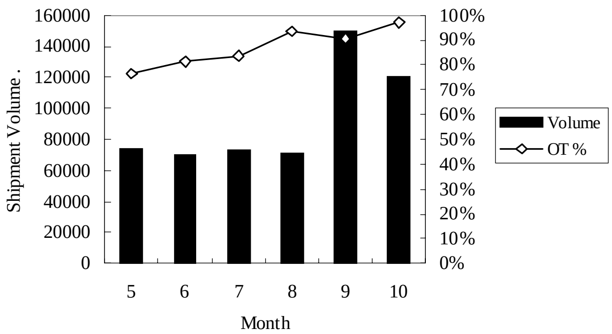
fluctuations of NB demands. For example, the aggregated daily shipment to the 3PL provider varied from 600 to 6,799 with a mean of 3,368 and a standard deviation of 1,535. The daily available aircraft capacity, on the other hand, could only accommodate about 4,000 shipments in that particular month.

In order to resolve the service level issue, the 3PL provider initiated a project to establish CTM partnership with key NB shippers in early 2000. The project objective was to achieve a 95% service level by the end of 2000 for all NB shipments. The project team—which consisted of personnel from sales, technology, engineering, customer service, and operation fields—was responsible for CTM implementation with respective NB shippers. In the CTM planning phase, shipping agreements were outlined to include rate, expected delivery cycle time, pickup cutoff time, and maximum daily guaranteed volume. If shipments were over the daily guaranteed volume, an additional transit day was added to the delivery cycle time. The 3PL provider performed capacity requirement planning based on the planned demands from shippers. In the forecasting phase, shippers updated monthly and weekly shipment forecasts to the 3PL provider for aircraft capacity planning. As a result, the 3PL provider gained sufficient time to acquire additional aircraft capacities for month-end and quarter-end peak shipment demands.

In the CTM execution phase, IT integration was first identified to facilitate the collaboration. A new CTM integrator was developed by the 3PL provider to link manufacturer ERP system in order to retrieve shipping information in the shipment tender stage. Outbound and inbound customs clearances are required processes for international shipping. The shipment manifest and commercial invoice were transmitted to the 3PL provider through the CTM integrator before the actual shipment pickup in order to process preclearance (i.e., to prepare and submit customs clearance before the actual shipment arrived at Customs) so as to eliminate customs delay. Once the shipments were picked up, a pickup confirmation notice was sent back to the manufacturer through the CTM integrator. A Web-API provided by the 3PL provider enabled the manufacturer to access the real-time tracking status via the Internet. The shipper would be notified of any delivery exceptions through e-mail and phone. The customer, as well, could then check the delivery status via the Internet or through customer service. The IT integration of the CTM model in the GSC is shown in Figure 4.

The CTM project was implemented progressively and three key shippers had entered into collaboration with the 3PL provider by June 2000. Through an aggregate planning process, the 3PL provider acquired additional aircraft capacity in October in order to accommodate volume growth. The key performance indicator identified by the 3PL provider was the delivery service level, measured by percentage of on-time deliveries. The delivery volume and

Figure 5. The 3PL provider shipment volume and delivery performance in the year 2000



delivery performance of the 3PL provider in 2000 was shown in Figure 5. Apart from September 2000, the service level achieved a progressive improvement.

This case also reported other findings such as the CTM implementation cost, total supply chain cost, and business growth. The CTM project incurred minimum cost for the 3PL provider by using existing IT systems and staff except for the CTM integrator that was developed by in-house development team. On the other side, the retailer and manufacturer brought in cost saving since their shipping activities were taken over by the 3PL provider partially. Moreover, the total supply chain cost was reduced with a significant improvement in delivery cycle time. The shipment volume growth indicated the CTM approach was a positive business strategy for all parties.

IMPACT OF COLLABORATIVE TRANSPORTATION MANAGEMENT

E-collaboration has emerged as the new focus for supply chains to seeking additional business and cost savings. Early adopters of e-collaboration such as retailer chains apply CPFR and CTM to synchronize manufacturing and shipping activities. *Drug Store News* (2001) reported a CPFR case that inventories for retailers have been reduced as much as 14%, whereas business has increased about 32%. Dutton (2003) reviewed a CTM application between Procter & Gamble and J. B. Hunt to include shipping into the supply chain. Carrier J. B. Hunt reported a 16% decrease in unloading time and a 3% drop in empty miles because of information sharing.

The success of e-collaboration in retailing chains motivates other industries to follow. This application examines the case of a global 3PL provider engaging in e-collaboration through CTM in global supply chain across continents. The improved service level implies the CTM is a successful logistic alliance to both distributor and manufacturer. At the same time, this alliance also implies that 3PL provider can attain multiple cost saving opportunities such as improved fleet utilization through various freight consolidation policies and reduced labor cost by automating shipping operations. A maximum of 18% cost reduction was reported by the 3PL for a particular month after the implementation of the CTM (Tyan, Wang, & Du, 2003).

The principles and process of the CTM application discussed can be generalized to cover other applications. A full scale CTM implementation as illustrated in the case requires a prerequisite of a well established IT infrastructure and streamlined business processes amongst supply chain participants. However, a reduced CTM model by eliminating unnecessary steps can be adapted to Small and Medium-sized Enterprises.

CONCLUSION

The trends of globalization and mass customization challenge the traditional single enterprise to respond and meet market demand. The new economy calls for alliances to be made with 3PL providers in order to form a GSC that focuses on the core competencies of each player. Companies that have implemented a GSC, such as Dell and Compaq, have gained a higher market share, improved profit margins and services, and increased response times. GSC management has become a strategic tool for reducing costs as well as enhancing a company value.

With the introduction of the CTM model, the carrier is able to establish collaboration with the manufacturer and retailer during the planning, forecasting, and execution phases of the GSC execution process. CTM brings to the carrier the benefits of better strategic capacity planning, increased asset utilization, and an improved delivery service level. In return, the manufacturer enjoys reduced costs, improved delivery reliability, increased visibility, and increased revenue. The illustrated NB GSC case shows that CTM is an effective approach for 3PL providers to deliver benefits to all parties in the supply chain.

Freight consolidation is identified as another opportunity for the global 3PL provider to realize the full benefits of CTM application. In an attempt to minimize the system-wide cost, the global 3PL provider can apply various consolidation policies in order to maximize aircraft utilization while simultaneously maintaining their service commitments. With real time logistic information exchange of CTM model, the global 3PL provider gains the benefits by selecting an optimal consolidation policy to minimize the total cost under capacity and service requirement constraints.

KEY TERMS

Distribution Cycle Time: The span of time between the beginning of the shipment pickup and the end of the shipment delivery.

Door-to-Door Delivery: Shipping service from shipper's door to receiver's door.

Freight Consolidation: The combining of small shipments into a composite truckload or other unit of volume that is sent to a destination point.

Inventory Carrying Costs: The costs associate with carrying the storage of supplies and final products.

Physical Distribution: A transportation service that accepts a shipment from a shipper and at destination separates and sorts the packages and distributes them to many receivers.

Taiwan-Direct-Shipment: A distribution practice that Taiwan manufacturers sends their notebooks to buyers through door-to-door service in order to reduce distribution cycle time.

Third Party Logistics: The activity of outsourcing activities to an independent company that perform client's management function of the logistic operations.

Using Failure to Develop a Successful Business

Ron Craig
Wilfrid Laurier University, Canada

INTRODUCTION

Can failure play an important role in developing a successful e-comm, dot-com, or Internet-based venture? This chapter shows that testing the firm's business model provides quick feedback concerning what works and what does not. Often the only way to test the assumptions of a business model is through implementation. Failure can (and should) be a learning experience, whereby a venture confirms or modifies components of its business model and moves forward. This article starts with a review of business model literature, considers a recent start-up, and concludes with lessons learned. References and a glossary of key terms follow.

DEVELOPING A SUSTAINABLE BUSINESS MODEL

There are three broad pillars upon which a new venture is built (Timmons & Spinelli, 2004). These are an attractive opportunity, a capable venture team, and sufficient resourcing. The opportunity must include a viable marketplace (customers, distribution channel, sales and service support, etc.). High-tech ventures usually start with a concept, which needs to be developed into an actual product/service. This requires significant time and effort, with risk that the market may reject the product/service, or a competitor may get there first. Secondly, a team is needed. This team must capably cover both technical and business sides of the venture, from conception to launch to successful market penetration. An ideal team has prior experience in successfully launching a venture. Without this experience, the likelihood of wrong decisions and the time required to determine appropriate action steps can increase. Finally, sufficient resources (including financing) are required to carry the venture through the development phase and into active marketing, to the point of positive cash flow. Venture capital sources will fund high growth potential ventures using successive rounds of financing.

These three pillars support the venture's specific business model. There has been considerable confusion about the terms business plan, business model, e-business model, Internet business model, and business strategy. Sometimes the terms are used interchangeably, and other times they are used in a broad or narrow sense. As Rayport (1999) states, "In the end an e-business is just another business." In this article, the business model answers the question, "What is our business and how do we make money?"

An excellent discussion of business models is provided by Chesbrough and Rosenbloom (2002). They identify six functions:

1. Articulates a customer value proposition
2. Identifies a market segment (*who* will use the technology for *what* purpose; specifies the revenue generation process)
3. Defines the venture's specific value chain structure
4. Estimates the cost structure and profit potential
5. Describes the venture's positioning within the value network linking suppliers and customers (includes identification of potential complementors and competitors)
6. Formulates the venture's competitive strategy

Magretta (2002) articulates a less detailed view of business models. She states, "A good business model begins with an insight into human motivations and ends in a rich stream of profits." To her, a business model contains a story (narrative) that explains how the enterprise will work. A financial model (pro forma P&L, etc.) supports this narrative and shows the numbers side. There are two tests to apply to any proposed business model:

- **Narrative Test:** Does the business model tell a logical story, explaining who the customers are, what they value, and how the venture will successfully provide them with that value?
- **Numbers Test:** Does the pro formal P&L make sense? Are the assumptions reasonable?

Others have suggested alternatives. Clarke (2004) succinctly states a business model answers the question, "Who pays what, to whom, and why?" Hoppe and Breitner (2004) apply business models to e-learning, distinguishing three interdependent submodels (market, activity, asset), which comprise the holistic model. Mahadevan

(2000) sees three streams: the value stream (value propositions for various stakeholders), revenue stream (plan for assuring revenue generation), and logistical stream (addressing various issues related to supply chain design). Weill and Vitale (2002) identify eight different 'atomic e-business models', each describing a different way of conducting business electronically and supported by various IT infrastructure capabilities. Singh (2002) defines a business model as a method of doing business, and provides a taxonomy of current and emerging e-commerce models (emphasizing technology and participants).

Porter (1996) provides several frameworks to guide firms in selecting their strategy and business model. His '5-forces' model, physical value chain network, and generic strategies are useful frameworks. Rayport and Sviokla's (1995) virtual value chain framework is particularly useful for firms using the Internet. Porter (2001), in response to the question of whether or not the Internet renders established rules of strategy obsolete (as some proposed), answers that it makes strategy more vital than ever. He concludes, "In our quest to see how the Internet is different, we have failed to see how the Internet is the same."

Several frameworks that segment evolution of a new firm provide a complementary approach to viewing venture creation and growth. Kaulio (2003) identifies four perspectives: (i) milestones and time-pacing, (ii) venture capital financing, (iii) growth stages, and (iv) market entry focus. Depending upon one's purpose, any (or all) of these frameworks can be useful. For purposes of this chapter, a growth stages model is considered: conception, start-up, growth, maturity; our emphasis here is on the first three stages, whereby the venture establishes itself and its business model.

Building upon this introduction, the following section tracks the recent history of an entrepreneurial team and their venture. Planned failure during execution of the business plan provided a means of refining their business model. Using a 'shotgun' approach to product development, the firm investigated four initial products, developing two and introducing them to a particular market. One product turned out to be much more financially attractive.

BACKGROUND OF THE BUSINESS

On August 31, 2000, Cisco Systems announced they had agreed to purchase PixStream Incorporated, a Canadian privately held provider of hardware and software solutions to distribute and manage digital video across all types of broadband networks. Founded in 1996, and situated in Waterloo, PixStream ranked 22nd on ProfitGuide's 2000 list of 'Hottest Start-Ups'. With 1999 revenues of $7.2 million Canadian, the firm experienced two-year growth of 812%, and was getting ready for an IPO. Cisco paid, in shares, the equivalent of $550 million Canadian.

Only eight months later, with Cisco in considerable financial difficulty, the new owner announced that PixStream would be shut down. This sudden reversal of fortune could have demotivated the PixStream team. Yet, having previously experienced the exhilaration of starting and successfully developing a high-growth business, the core group of managers and engineers considered their options and looked for new opportunities. From this, Sandvine was born. The team not only developed a plan for a new business and found venture funding, but also negotiated a phase-out contract with Cisco to assist current customer migration from the PixStream/Cisco product. This provided start-up money and time.

DESCRIPTION OF THE BUSINESS

Sandvine's history is chronicled in Table 1. Some four years after start-up, Sandvine's Web site describes their product as "award-winning network equipment (that) helps broadband service providers characterize what really happens on their networks, enabling policies that improve customer satisfaction, reduce operational costs and increase revenue per subscriber." Their target customers are broadband service providers, and their customer value proposition is to characterize, control, and secure broadband traffic, thereby increasing network profitability. Initially their product focused on managing the bandwidth consumed by peer-to-peer (P2P) file swapping, and then added the capability of managing worms, viruses, spam, and DOS attacks. Worldwide, these problems add up to hundreds of millions of dollars in extra costs for broadband providers and degradation of service for users. For the typical ISP customer, payback is 12 to 18 months.

MANAGING THE BUSINESS

Unlike most high-tech ventures, Sandvine did not start with a defined product concept. Hence, the company's start-up phase focused on identifying market opportunities and testing these. It took some two-and-a-half years to develop a viable product and become established as a leader in managing bandwidth activities. Based on the founding team's knowledge of video networking, and their previous experience at PixStream and Cisco, four potential product areas were investigated: (1) voiceover IP (VOIP) equipment, (2) enterprise storage area networks (SANs), (3) fibre to the home (FTTH) systems, and (4)

Table 1. Chronology of events for Sandvine

Date	**Event**
Q2, '01	Prospective firm makes initial contact with VCs
Q3, '01	Start-up; VCs fully subscribe ($19.5M); management owns significant minority
Q1, '02	Defined product area as "specialized equipment to provide ISPs with additional recurring revenue opportunities, and cost reduction through traffic shaping"; still operating in stealth mode; about 60 employees
Q2, '02	Products introduced at trade show; Revenue side—content filtering, virus checking; Expense side—traffic management; have initial customer/test site
Q4, '02	Several trials underway; one product ready for commercial sale, another in beta testing
Q1, '03	Customers (ISPs) not spending on capital equipment; decision made to stretch cash resources and seek government funding; waiting for market to recover
Q2, '03	1st U.S. telco sale; many field trials underway (North America, Europe)
Q3, '03	Receive $9.5M Technology Canada Partnerships investment
Q4, '03	Win "best of Next Generation Networks" award; half a dozen paying customers and more than two dozen trials underway; too much competition among subscriber services offerings—leave market and focus on traffic management and security solutions
Q2, '04	Increasing market penetration; over 50 customers (not all generating revenue); difference found between North American and European ISP markets
Q1, '05	Solid pipeline of customers and trials; surpass 20 million subscriber mark

network equipment for residential high-speed Internet service providers. Having negotiated an eight-month contract with Cisco for support of PixStream's former customers, along with taking over the office lease and acquiring all furnishings, the team was confident of its ability to find an excellent market niche. For most of the first year, the new venture operated in stealth mode, quietly searching for an attractive market and developing beta products while not publicly announcing its existence.

By late 2001, the extensive analysis of potential business opportunities was complete, and the decision was made to focus on service offerings for broadband ISPs. For the value proposition, both a revenue-enhancement and a cost-reduction approach were chosen. One product provided the ISP with incremental revenue via additional services (such as virus protection). The other product reduced network costs via traffic shaping. These became known internally as their service cluster and P2P products. With some 60 employees now, the firm worked hard on product development. The June 2002 Supercom trade show was targeted for product introduction, and a local ISP agreed to provide a test site.

By the end of 2002, the P2P product was ready for commercial sale, having proven itself in field trials. Sandvine moved into the growth stage, with management putting much greater emphasis on sales and marketing. The service cluster product (virus scanning, content filtering, etc.) was ready for beta testing. One obstacle with the P2P product arose due to P2P software migration to dynamic ports protocol to become more evasive; Sandvine was quickly able to incorporate this capability into its product and use it to competitive advantage. Its service cluster product was network based, unlike most competitors whose product was desktop based. The target customers were large telcos and cable providers, and this business segment had continuing restrictions on capital expenditures, so significant revenue was not expected for some time.

During 2003, major sales were made in both Canada and the United States. Product development continued on the P2P product, with many enhancements. Recognition for product superiority included a World Communications Award and Communications Technology Journal Readers Choice Award. By year end the market environment made it easy for Sandvine to decide to drop their subscriber services offering. There was growing competition in this market and little potential for significant profit. In contrast, Sandvine was recognized as a leader in the P2P field, and sales were gaining traction (evidence of a reasonable business model). Indications were that 2004 would be the first time in four years that telco and cableco capital expenditure budgets would not be reduced. This turned out to be true, and prospects for 2005 looked even brighter.

A European subsidiary was established in England early in 2003 to concentrate on the EMEA (Europe, Middle East, Africa) markets. A PixStream alumnus, with proven start-up experience, was hired as managing director. A little over a year later, offices were opened in France and Germany, and three sales managers hired.

With increasing market traction, management and financial backers can now start thinking more seriously of an exit strategy. It will be interesting to see whether a buyout or an IPO (initial public offering of stock) results.

SUCCESS/FAILURE FACTORS

A major contributor to Sandvine's success was the experience of its team. This is evident in the company obtaining financing and determining the product (two of the three venture foundations detailed earlier). Based on the team's past success, the VCs that funded PixStream were eager to support this team again. Sufficient funding was raised for the anticipated go-to-market process, without the usual steps of seed funding (initial funding which is often used to develop a business concept before the venture really starts), plus additional investment rounds. The founding team's equity contribution was limited to members' knowledge (both technical and market) plus the PixStream/Cisco wind-down contract.

Use of a funneling approach to settling on a particular product and market was another success factor. The team took the necessary time to identify several potentially attractive markets and products, narrowing this down to two product opportunities. When one product showed much greater potential than the other did, the team quickly made the sensible decision. Most new ventures start with a single product/service concept, which yields an all or nothing result.

With an experienced team, Sandvine experienced no turnover among senior management. The group knew each other's strengths and weaknesses before the venture started, and took on responsibilities that matched personal abilities. Together, the team members' expertise covered the technical management and business management needs of the venture. They knew what had to be done, when to start particular initiatives, and how to accomplish their goals. To an outsider the business was being managed smoothly, with no apparent problems; on the inside, management 'knew what they didn't know' and knew how to discover solutions and test assumptions. Their product selection process and ultimate market focus show discipline and depth. Failures along the road to success were expected and dealt with appropriately as learning opportunities.

LESSONS LEARNED

This case illustrates the opportunities and challenges of a start-up high-tech venture and shows creative approaches to both product development and financing. Starting with only one of the necessary three foundations (a team), Sandvine worked on the other two (resources, plus a viable opportunity within the company's field of expertise). With the team's successful record of accomplishment, it was easy to attract financing. The team's shotgun approach, investigating several products and potential markets, greatly increased its likelihood of success. Not many new ventures can choose this route, although it is an attractive one.

Sandvine illustrates an exception to the usual high-tech financing approach, one that is usually only available to venture teams with a proven success record (serial entrepreneurship). Financing is commonly obtained on an iterative basis of "rounds." Success in moving forward with the business model leads to additional financing, which in turn allows further refinement of the business model. When progress is slow, the next financing round may value the venture less (a "down round"). When progress supports the viability of the business model, an 'up round' is more likely. Moreover, if additional financing is unavailable, the venture must curtail its activities or even close down. Sandvine was able to obtain sufficient initial financing to carry the firm through the formative years without the usual additional rounds of financing every 6 to 18 months. A repayable government investment became available and was used to defer the potential need for further venture financing (also allowing the financial backers to maintain their proportional interests without injecting additional funds).

Kanter (2001) shows that dot-coms can be categorized in terms of style and substance. The former focuses on personality and style of the founder(s), and their ventures tend to follow an evolutionary path (the 'learn by doing' approach advocated by Gumpert (2003)). In contrast, the latter focuses on execution of a clear business model, with strong attention to the bottom line. Sandvine shows that these two dimensions are not necessarily mutually exclusive. At a macro level, Sandvine followed the latter approach (starting with a basic business plan and emphasizing the bottom line). At a more micro level (developing the company's product/market focus), Sandvine experimented and learned from the results. The feedback received during product development and beta testing allowed refinement of the business model—developing a fuller understanding of the market (whether or not it exists, and in what form; what it values; and how much it will pay for the product/service), clarifying the value proposition for customers, and ultimately clarifying the firm's competitive strategy.

The value-added services (or potential lack thereof) from VCs are usually significant. Developing a successful high-tech venture is difficult, and firms need all the support available. Investors who can add significant value to the firm's development, beyond their financial investment, are one of the keys to success. Methods of adding value include identifying key management members to round out the team (especially as the firm grows), linking the firm with support organizations (lawyers, accountants) and potential suppliers and/or customers, and assisting with future rounds of financing (including government grants). VCs will take a more active role if they perceive their investment to be at risk. In Sandvine's case, because of the experienced team and continued progress, there was much more of a hands-off approach. Members of the VC consortium did provide advice and assistance, but on an 'as-needed' basis.

A final lesson pertains to development and refinement of one's business model. In mature industries, there are one or more standard models to follow, and much is known about success/failure factors and best practices. In contrast, dot-com and e-comm pioneers developed new models, which followers could then emulate or build upon. The Sandvine team, using a generic high-tech venture creation model, and drawing upon previous experience, worked from the general to the specific. Over the course of four years, as the business moved through the concept, start-up, and into the growth stage, its business model was continually refined. Consequently, Sandvine now commands a strong position in a growing market.

KEY TERMS

Business Model: Means by which a new venture will attract and serve customers, in order to generate revenue and profit.

Financing Rounds: Successive stages of financing received by a new venture (seed, first, second, etc.); also called tranches; may be an 'up round' or a 'down round' (in an up round, the value of the venture has increased since the previous round).

IPO: Initial public offering; first sale of a venture's common shares to the public; usually results in large profits for early stage venture investors.

Serial Entrepreneurship: Starting a new venture, after having done so at least once previously; serial entrepreneurs have start-up experience.

Stealth Mode: Operating a start-up venture quietly, so competitors and the general business community are unaware of it.

Traction: Successfully putting a business model into operation, proving its viability.

Venture Capitalist: To provide funds and other assistance to start-up ventures.

Using Hospital Web Sites to Enhance Communication

Sherrie D. Cannoy
The University of North Carolina at Greensboro, USA

Lakshmi Iyer
The University of North Carolina at Greensboro, USA

INTRODUCTION

A large number of patients currently utilize the Internet to access healthcare-related information (Tobin, 2002). Many physician and health-related Web sites have been information portals lacking interactive services that could benefit healthcare partners through decreased costs, increased convenience, and communication. Patients typically visit Web portals to learn more about medical topics, often discussing this information with physicians.

Emerging Internet technologies can be a strategic asset for hospitals to impact physician bonding, patient self-service, and overall enterprise performance efforts. We conducted an investigation of Web sites of 10 hospitals listed in *U.S. News and World Report*'s Best Hospitals of 2004 Honor Roll, as well as a random selection of seven other hospital sites. An examination of each hospital's site was performed to determine what features were provided to enhance communication between the partners in healthcare. Partners are defined as patients and their families, referring physicians, insurance companies, vendors, pharmacies, job seekers, and the media. Communication-enhancing features are any features that have the potential to increase communication between the hospital and its partners. We focused on patient communication-enhancing features, since patients are the primary partners of healthcare entities.

BACKGROUND

Healthcare Basis

A medical Internet Usage Survey conducted by the Health on the Net Foundation (2002) found that 57.95% of the respondents had used the Internet for more than four years. Of the patients who responded, 21.62% correspond with their providers through e-mail and 75.52% have used online medical consultation services; 69.47% of physicians that responded stated that patients discuss information they found on the Internet with them, while 62.75% of those providers recommend specific information-based sites to their patients.

Healthcare can be improved through e-health services such as online patient pre-registration for admission, access to test results and medical records, insurance referrals and eligibility, access to reputable links for accurate healthcare information, patient forms and brochures, online support groups, access to clinical trial information, appointment scheduling and reminders, refill requests and authorizations, and e-mail capabilities. In implementing e-health "there is an urgent need for healthcare organizations to re-engineer their processes" (Wickramasinghe, Fadlalla, Geisler, & Schaffer, 2004), and physicians face obstacles such as "technologic barriers, resource priorities, and privacy issues" (Zingmond, Weilim, Ettner, & Carslile, 2001) that are secondary to providing excellent healthcare. Hospital and medical office sites can be enhanced to offer patient-centered services, while informing patients of their strongest services/specialties, convincing the patients that their organization is better than any general Web portal for accessing health-related information (Anonymous, 2001).

The drive for e-health initiatives can be patient driven, physician driven, or government mandated. "What is less clear is whether or not the services offered by healthcare organizations and the services that patients desire are the same" (Wilson & Gustafson, 2003). Government-driven initiatives include electronic health record implementation within the next 10 years which serves a dual-purpose: to allow hospitals and healthcare providers to access patient records in a standard format, and to decrease medical care errors. Veterans Affairs Secretary Anthony Principi stated that "one in every seven hospital admissions and 20% of lab tests occur because health records are not available to the clinician. More than one of every seven hospitalizations is complicated by medical prescription errors" (CNN, 2004). Thus, comprehensive electronic medical records which the patient, physician, or pharmacist can access are critical to reducing such errors. Access to these records may also be offered online so that patients can access them and check for accuracy or take them to a physician's office to which they have been referred for further tests.

In a related initiative, the National Quality Forum (NFQ) sponsored a National Summit on Information Technology and Healthcare Quality in March, 2002, to examine a national healthcare infrastructure. The design principles stated by NFQ to aid in the infrastructure development (NFQ, 2002) are:

1. Care based on continuous health relationships
2. Customization based on patient needs and values
3. The patient as the source of control—encourage shared decision making
4. Shared knowledge and free flow of information
5. Anticipation of patient needs

Theoretical Basis

The Internet can be considered a mass medium, and therefore, communications theories have been applied most frequently in this area (Merrill et al., 1996). Such theories applied include the learner-as-a-bucket theory in which the user searches for information and information is "poured" into the brain via a Web portal (Morris & Ogan, 1996). Another theory applied frequently is the critical mass theory, which states that the diffusion of innovation and adoption by about 20% of the population results in critical mass being achieved (Morris et al., 1996). Because use of the Internet, as well as other forms of electronic communication, is widespread now, it can be assumed that these are forms of media utilized by a critical mass.

In an article regarding physician communication skills, Kurtz (2002) outlines the domain of physician communication with patients. This could be expanded to any healthcare partners, and involves goals and approaches. Goals promote collaboration and partnership, and ensure increased accuracy of medical information, supportiveness, improving patient and physician satisfaction, and quality of healthcare. Approaches depend on the type of communication and can involve a well-conceived and delivered message versus communication for interaction, feedback, confirmation, and relationship. Kurtz (2002) also states that effective communication requires planning and should reduce unnecessary uncertainty—a critical factor in healthcare communication. Examples of Internet communication include e-mail, listserv, discussion forums/support groups, chat, and interactive site features (December, 1996). Features that enhance the communication between the doctor and the patient have not been explored. Prior studies analyzed sites of specialty practices (Smith-Barbaro, Licciardone, Clarke, & Coleridge, 2001), one specific type of communication such as e-mail (Moyer, Stern, Dobias, Cox, & Katz, 2002), Web portal information (Zhang, Zambrowicz, Zhou, & Roderer, 2004), or healthcare support groups or forums (Zrebiec & Jacobson, 2001). Our study specifically examines communication features offered on hospital Web sites.

WEB SITE ANALYSIS

Seventeen hospitals were chosen, with 10 of the Top Honor Roll hospitals (Group 1) selected from *U.S. News and World Report's* Best of Hospitals 2004 Report. Our premise was that the top 10 hospitals will be more likely to utilize technology to communicate better with patients, vendors, and insurance companies. Seven additional hospitals (Group 2) were randomly chosen from the *American Hospital Directory* (2004) for comparison of size and specialty, and site technology. Tables 1 and 2 display the selected hospitals.

Background information regarding bed sizes, hospital type, specialty areas, and accreditation were verified through the *American Hospital Directory,* the individual hospital sites, and the Directory of America's Hospitals (*U.S. News,* 2004b). Web site addresses listed in the *Directory of America's Hospitals* were selected as the URL locations to be examined.

Sites were examined in August 2004. Criteria chosen were adopted from related surveys by Zingmond et al. (2001) and Kind, Wheeler, Robinson, and Cabana (2004), and supplemented with features determined to be communication enhancing. The Zingmond et al. (2001) and Kind

Table 3. Feature coding

	Coding	
Feature not present	0	No link to form to complete
Basic feature was present	1	Downloadable or printable form to complete manually
Weighted Feature*--Increased functionality of feature	2	Ability to fill out information online

et al. (2004) studies examined only the type of content and quality of information in the sites, not specific features offered.

The criteria for Web site communications are listed in Table 3. Weighted features are noted by * in the descriptions of pertinent features discussed as follows.

1. **HIPAA* (Health Insurance Portability and Accountability Act):** Coding: 1 if there was a HIPAA statement only on the homepage, and 2 if the HIPAA statement was found on more than one page.
2. **International Patient Information/Languages*:** Some hospitals have an international presence and include such information as traveling, hotel information, specialty information, and so forth, as well as offering Web pages or forms in different languages. Coding: 1 if international patient information page was offered in different languages, 2 if additional pages or forms were offered in different languages.
3. **Support Groups*:** 56.34% of doctors that responded to the Medical Internet Usage HON survey recommend support groups to their patients (Health on the Net, 2004). Coding: 1 if support groups were listed and phone numbers given for a contact, and 2 if a support group was offered online, even if through a linked affiliated site.
4. **External Web Sites:** The availability of links to external sites, further information, or discussion groups was analyzed.
5. **Insurance Accepted:** Physicians' offices are frequently asked about the insurance companies with which they participate. Having this information available online could enhance communication by giving patients a list to refer to if their insurance companies change.
6. **Appointment Scheduling*/Fill Out Patient Information Online*:** These features would allow for great efficiencies in the check-in process for patients. If an appointment has been scheduled online or patient information has been filled out online, the check-in process for a patient is more efficient. Patients may be allowed to fill in their information online (Code 2) or they may be able to download a form to print (Code 1), fill out, and take to the physician's office at the appointment time. Appointments were coded as 1 if only requests for appointments were offered, and 2 if appointments could be made online.
7. **Patient Access to Records:** With mandates for Electronic Medical Records evolving, accessing patient records online will be important for partners. Often, patient records and lab test results are copied and/or faxed to a physician, and this may be more time consuming than allowing appropriate partners access.
8. **E-Mail Doctor:** Disadvantages of offering the physician's e-mail are privacy issues, timeliness of the response, liability issues, filing insurance on e-consults, and volume of e-mail that could be received, especially for large hospitals with international presence. Advantages are that the doctor can answer at his convenience and provide pa-

tients an avenue to ask embarrassing questions or clarify instructions. The limitations are most likely from the disadvantages of offering widespread access to physicians, including a patient's inappropriate use of e-mail (in lieu of office visits), security issues, and that physicians may be inundated with e-mails from not only their patients, but others seeking advice (Mandl, Kohane, & Brandt, 1998).

9. **Referring Physician Online Access*:** Allowing physicians to fill out a form online for patients who have been referred for tests, x-rays, or admission would save time and money, as well as decrease medical errors and medication interactions. Coding: 1 if contact information was given for the referring physician to call, and 2 if the referring physician could fill the patient information online.
10. **Intranets:** These serve the purpose of communicating between internal partners of the hospital. Policies, procedures, and other hospital information can be available through the intranet. Intranets may possibly include the capability for physicians to enter prescriptions directly to the hospital pharmacy.
11. **Interactive Content:** This includes features such as virtual tours, interactive maps, and videos.

One issue to be considered was that hospitals often operate underneath an umbrella of a parent organization, which also includes other medical centers and often educational organizations. Generally, there is a seamless navigation between hospital entities, therefore the extensiveness of sites was an advantage to the user, and no differentiation between the parent organization and its entities was made. All sites examined had search features which would search anywhere within the site for requested information.

Findings

Results of the site evaluation are in Table 4. All sites included general information and features such as a search feature, information about the organization, mission, services, privacy policy, parking and directions, news, employment, support groups, and general phone contacts. The following is a summary of the findings:

1. **HIPAA (Health Insurance Portability and Accountability Act):** It was expected that the sites would offer a main link, probably in the privacy policy, that explained HIPAA and its regulations regarding patient confidentiality. However, only five offered a direct link to HIPAA information through a HIPAA link or through the privacy policy. Searches of some sites found no results of "HIPAA."
2. **International Patient Information/Languages:** Group 1 offered more information in different languages. This is understandable, since hospitals on the Honor Roll list are larger and have an international presence. The top four of the Honor Roll list (Johns Hopkins, Mayo Clinic, Massachusetts General, and Cleveland Clinic) allowed a user to select a language in which to view the International Patient Information page.
3. **Support Groups:** Of the Honor Roll hospitals, 40% provided a main link for access to support group information, while 85.71% of the Group 2 hospitals provided a main link. However, all sites provided at least a link to support groups in each specialty area (cancer, etc.).
4. **External Web Sites:** 82% of the sites provided external links. Links to outside sites were generally to government or health organization sites. Sometimes the information given by hospital sites was generated by a purchased knowledge database, and it was difficult to determine if the information was generated by an outside site or a knowledge database. Knowledge database information was considered as internal information and not as a hyperlink to an external site. Only one hospital, New York Presbyterian, required the user to read a disclaimer and click to accept before accessing external health information.
5. **Insurance Accepted:** 70% in Group 1 provided insurance participation information as compared to 28.57% in Group 2. Many sites allowed searching for a doctor according to the insurance with which they participated.
6. **Appointment Scheduling:** Since the intricacies of appointment scheduling are vast, and result from specialty variations as well as individual physician preferences, some hospitals allowed requests for appointments in which someone would contact the patient to set up the appointment. Hospitals from Group 1 were more likely to offer appointment requests online, with 80% providing the service, as compared to 28.5% in Group 2.
7. **Patient Access to Records:** Only three hospitals (Cleveland Clinic, Duke University Medical Center, and Barnes-Jewish Hospital) allowed some type of access to the patient's records, including prescription refill requests, appointment requests, patient information updates, appointment reminders, online payments of balances, and self-assessments of healthcare.
8. **E-Mail Doctor:** None of the hospitals in Group 1 and only three in Group 2 had the capability to e-mail physicians directly.
9. **Referring Physician Online Access:** 71% of all sites allow referring physicians to fill out patient

information online. This would allow the hospital time to verify insurance information and send materials and brochures to patients before being admitted.

10. **Intranets:** The presence of an intranet was difficult to determine, since the intranet may be a different URL than the hospital URL. Of all hospitals, 41% had some type of intranet available. The intranet at Cleveland Clinic was confirmed to have physician access to medical records online.
11. **Interactive Content:** The two groups had equal participation in offering interactive content, which was in the form of audio, video, or Web tours of facilities.

Table 5 shows some of the interesting interactive and weighted features.

FUTURE TRENDS

Availability of comprehensive patient information and other hospital services will improve the efficiency and effectiveness of patient care through better communication among healthcare partners. Some hospitals which were contacted regarding intranet availability were in the process of electronic record conversion. EMRs (electronic medical records) would provide a concise map of a patient's medical history, and, if accessible by various healthcare partners, including the patient, could offer a means of communication by clarifying questions or documenting previous medical problems and medications.

Blogs such as those offered on the Cleveland Clinic and High Point Regional sites are being tested as a type of forum for patients to support one another. Blogs allow personal expression and diary-type entries for those who want to share health-related experiences. Ideally, communication could be customized by allowing the user to enter a username and password which will allow specific access to that person's information and personal preferences—a patient portal. Messages and reminders from physicians may appear, as well as charts showing, for example, one's diabetic sugar level readings for the past few months. Very few hospital Web sites offer the capability to pay bills online, and access to one's medical bill history online may decrease calls to the billing department regarding

Table 4. Analysis of results

Table 5. Sample of interactive features

Hospital	Features
Massachusetts General	Live surgery webcasts and e-consults for second opinions
Cleveland Clinic	e-clinic for second opinions
University of California, SF Medical	Sample bills available online
Loma Linda	e-cards and radio shows
Moses Cone Health System	Excellent library sources
High Point Regional Health System	Request callback; Extensive search feature--can search for a physician by name, specialty, gender, insurance accepted
University of Maryland Medical Center	Webcasts
St. Vincent Hospital	MyStVincent--access to personal information; can update insurance information online
Yale-New Haven	Call Me Later feature

balances owed. Patients may opt to receive automatic e-mails from physicians and healthcare partners for appointment reminders, test results, prescriptions, or to inform the patient if the pharmacy has the medication in stock. Telemedicine and videoconferencing are popular in other countries such as Australia and New Zealand, and could provide healthcare to those patients in remote areas, if the technology were provided.

CONCLUSION

Communication between physicians and healthcare partners, specifically patients, is critical to the quality of care provided. Forms of online communication need to be identified and researched further so that efficiencies and effectiveness can be gained for healthcare organizations' quality of care goals. Because patients are active in their medical care, healthcare organizations need to be aware of patient needs and preferences in their communications. What needs to be determined is how users decide to search for information on a specific hospital site. Which features are preferred by both physician and patient? As Bohn (1999) stated, "As sites grow ever more central to successful healthcare business, analysis of the way they are used becomes a fundamental issue." In this respect, the functionality of sites needs to be addressed—is it enough to offer such interactive features and anticipate that they will be found and utilized, or does this interactive functionality become part of emerging culture of healthcare? The opportunity to utilize Web technology to communicate with partners allows hospitals to become more strategically competitive while also increasing efficiency and effectiveness, and ultimately improving patient care.

U

KEY TERMS

Blog: A Web log which allows for a diary-style forum for posting one's personal thoughts and experiences.

E-Health: A concept in which Internet-based technologies are used to enhance access, delivery, quality, and effectiveness of health services, as well as information utilized by patients, physicians, healthcare organizations, and related partners such as pharmacies, vendors, and insurance providers.

Extranet: Allowing an organization's external partners (i.e., pharmacies, insurance companies, vendors) to access a computer system via a username and password.

HIPAA: The Health Insurance Portability and Accountability Act (1996) regulates the electronic exchange, privacy, and security of one's health information.

Intranet: Allowing access to a hospital's computer system to internal users via a username and password.

Privacy Policy: A disclaimer placed on Web sites informing users about how the organization handles one's personal information.

Telemedicine: The delivery of healthcare through the Internet or other computerized means such as videoconferencing.

INTRODUCTION

In the last 15 years, connectivity and communications have increased dramatically. As a matter of fact, from 1990 to 2Q of 2004, the number of mobile phone subscribers has growth from a few million to over 1.5 billion. In the same period, the number of Internet users worldwide raised from 2 million to 810 million (IWS, 2004; Juliussen, 2003). This means that today a large section of the population is dependent on communications and content, and wants to be connected any time and any place, even in their cars (Comunicar, 2002; Microsoft, 2005). To answer this requirement, telematics are being fitted into cars, giving rise to *vehicular telematics systems* (VTS). Indeed these systems represent the in-vehicle convergence of mobile communications and information processing, allowing drivers and passengers to stay in communication with the world outside their automobile. Vehicular telematics market is projected to be about $17 billion by 2006, equaling a growth by 280% since 2000 (Juliussen, 2003).

From a technological point of view, a VTS is composed of three basic components:

1. A two-way wireless communication (voice/data) system;
2. Some location technologies able to identify current geographic position;
3. Some computing technologies, to handle data and manage information flows from/to the user.

By fully exploiting the features offered by these systems, exciting new usage scenarios, opportunities, and markets are being available for both end-users and automotive manufacturers. As an example, drivers can receive contextual services, such as updated route calculations, basing on traffic alerts for the selected route, or can perform remote diagnosis of electronic car components, while passengers can access to e-mail and Web sites.

In the meantime, new business opportunities are being available for automotive manufacturers, since VTSs allow them to sell “services” and after-market upgrades, to have an open communication channel with buyers during the whole car life-cycle, and to understand their customers’ individual needs, thus providing an exceptional marketing link. This obviously is requiring deep changes in the business model for vehicular original equipment manufacturers (OEM). However, telematics is also affecting their design model, posing challenging technological issues, ranging from embedded real-time aspects, to context-aware ones, to the definition of innovative and safer human-machine interfaces.

In this article, we will provide an insight on the new mobile-commerce opportunities offered by telematics, together with the posed technological challenges. In particular, after a brief outline on the evolution of VTSs, we will analyze the services, the business challenges, and the opportunities that next-generation systems will offer. Subsequently, we will describe the technological difficulties posed by VTSs, with particular interest on human-machine interaction (HMI) and the safety issues. Finally, we will depict the future trends on this fascinating scenario.

BACKGROUND

A lot has happened since the first wireless technology (AM radios) was fitted into cars dashboards. Complex electronic systems began to be installed into cars in the 80s, with electronic injection, anti-lock braking system (ABS), etc. … Since then, the number of functionality provided to the driver/passengers by electronics constantly raised, and nowadays computing technologies are so massively present in vehicle’s interiors that top-class cars embed more than 1 Gigabyte of code (Pretschner, Salzmann, & Stauner, 2004).

In this scenario, telematics appeared only ten years ago, and still five years ago most advanced VTSs offered only limited navigation and entertainment (Tuner, CD) characteristics. Now almost all systems in production allow drivers to exploit a plethora of features, such as multiple audio sources (MP3, digital audio broadcasting, DVD), Web browsing, e-mails, phone calls, voice control, and so on. However, most advanced commercial VTSs (e.g., BMW *iDrive*, Fiat *Connect+* or GM *onStar*) are deeply changing the definition of product: they are starting to provide *services*, i.e. advanced functionalities involving interaction with a support centre. Typical examples are remote vehicle diagnosis, dynamic route calculation (taking into account contextual information about road, vehicle, traffic, and weather conditions), tele-aid, or hotel reservation.

Thus, VTS are opening new and exciting business opportunities. Automakers have to change their “mission” and business model, no more selling exclusively hardware but also services, shifting from the age-old one-time sale into an ongoing service-oriented revenue stream. In the meantime, there is the necessity to design and deliver context-aware services and information, creating great opportunities also for third-party content providers.

DEVELOPING EFFECTIVE TELEMATICS SYSTEMS

The definition of a vehicular telematics system is a very challenging task, involving substantial investments and a number of different skills, ranging from information and communication technologies (ICT) to marketing and psychology. In the following we will detail the posed business and technological challenges and opportunities.

Business Challenges and Opportunities

We can outline three main branches of business opportunities offered by VTSs: service selling, upgrade selling, and warranty claims reduction.

Service Selling

The main revenue opportunities can come from service-oriented businesses. With telematics, for first time car manufacturers have the opportunity to stay constantly in touch with their customers during the life of the car, and to understand clients’ individual needs. Thus OEMs and/or content providers can provide them with a plethora of pay-per-use or subscription services, such as traffic advices, hotel information/reservation, etc., limited only by the imagination of creative marketers. In the following we describe some push/pull services that are (or will be) part of VTSs, and that can generate attractive revenue streams:

- **(Dynamic) Navigation Systems:** Current VTSs offer localization and navigation features. In next generation systems, these will be improved with dynamic routing instructions, basing on real-time information about traffic or other infrastructure situations, provided by some data-centers, through wireless data connections.
- **Infotainment:** This can still be considered the crucial feature of a VTS, since people like to listen music during their commutes. Current systems provide a huge amount of entertainment sources, such as tuner (even digital or satellite), CD, MP3, TV, DVD players, etc… In perspective, future systems will be able to connect to Web-stores, such as *iTunes* (iTunes, 2005), to purchase and download further digital entertainment contents, such as audio tracks, video-games for kids on rear seats, movies, etc…
- **Communications:** VTSs include wireless voice communication features, based on 2,5-3G cellular infrastructure. So, they can exploit most of the services offered by mobile phone carriers, such as calls, SMS, MMS, voice-activated e-mail service, and high bandwidth downloads (even for data or software/service upgrades).
- **Remote Diagnostics:** A valuable new characteristic will be the ability to extract critical data from onboards electronics and transmitting them to the OEM, in order to perform remote vehicle diagnostics. Customers can pay an annual subscription to have their car’s health constantly monitored. This will significant reduce breakdowns, thanks to early problem detections. For example, a faulty sensor that could go undetected for months could be discovered almost immediately. In perspective, another exciting future scenario considers (controlled) interaction between vehicle and service centers. For instance, a tire sensors detecting flats could alert towing services, or in the event of an airbags opening, the system can automatically notify road assistance and physicians (Tele-aid).
- **Contextual Information Services:** By exploiting wireless communication and location awareness, VTSs will deliver a vast selection of customized information, ranging from weather news to stock price, traffic advices, movie show times, etc… Moreover, it is easy to extend these functionalities with traditional e-commerce services, for instance allowing driver to buy theatre tickets.
- **Location-Based Services:** such as assistance in case of breakdowns and stolen car recovery, can be easily provided in charge of a subscription.

In addition, the possibility of location and customer-based advertising could provide additional revenue for automakers.

The challenge however is about getting customers to pay for services. Currently, with new service-oriented systems, only a fraction of customers are willing to pay for premium services, even if marketing researches show that consumers are eager to pay $20/month for services like anti-theft security, road assistance, and Internet connectivity. It stays on marketing experts to design new content and services, able to attract buyers and to convince them to signing up annual agreements.

Upgrades Selling

With modular infotainment systems, designed keeping in mind easy replacement and upgrades, automakers can gain ongoing revenue opportunities, selling systems that can be upgraded or extended through the life of the car. For instance, features such as emergency roadside assistance, MP3Pro audio player, video games, or enhanced diagnostics could be purchased in aftermarket at gas stations. In the same way, systems can be extended with personal productivity applications (such as calendar, address book, etc.), as well as with new personal area network (PAN) wireless protocols, such as Bluetooth. To this aim, next-generation VTSs must be made extensible to allow and encourage consumers to frequently buy new upgrades.

Warranty Claims Reduction

The possibility to collect key operational data from on-board electronics, such as engine status and usage, braking, transmission system or catalytic converter status, allows automakers to perform trend analysis of vehicle performance, leading to early problem detection. For instance, if some values from sensors predict an incoming breakdown, OEM can inform the customer to get service prior the fault happens, with significant warranty costs reductions. Moreover this infrastructure will allow car manufacturers to diagnose faults not just in a single car, but also across entire model years of cars, eventually using data-mining approaches. Cost savings inducted by these reduction of warranty claims and improved operational efficiencies will be measured in tens of billions of dollars in 15 to 20 years (Juliussen, 2003).

Technological Challenges

The above depicted amount of offered applications is posing severe technological challenges to information and communication specialists. Designers have to embed many different (and often innovative) technologies into one device, possibly adopting a modular and plug-and-play architecture, to encourage future upgrades, and adopting specific user interfaces, to minimize driver's visual and cognitive workload. Moreover, to make things trickier, they must meet very strong industrial constraints (i.e., reduced available computing resources) both in terms of memory and CPU capacity.

About adopted technologies, current systems are exploiting most advanced solutions available on the market. About wireless connections, PAN typically exploits Bluetooth, while the wireless Internet access is based on the GPRS standard (new systems are about to exploit UMTS). Furthermore, location awareness is provided by the GPS satellite system (in perspective there will be a migration towards the European Galileo system, guaranteeing more precision and improved QoS).

Both Microsoft (Windows, 2005) and SUN (Java Automotive, 2005) are developing specific software platforms for automotive telematics, with a built-in support for the above depicted technologies. Nevertheless, there is still a lot of work to do, especially in the field of software engineering, to improve flexibility and modularity of those systems. Indeed, the problem is that current VTSs are usually built into devices specifically designed for one (or few) vehicle model(s). As a result, they are embedded, monolithic systems, characterized by high coupling between modules. This approach presents many drawbacks. It limits the possibility to easily add/remove features (i.e., middle-class cars can offer only some services, while top class the whole set). Moreover, future system upgrades are not permitted, as well as it does not allow car manufacturers to successfully demand the implementation of the various ITS subsystems to different suppliers (Costagliola, Di Martino, Ferrucci, Risi, Oliviero, & Freni, 2004a).

At the same time, deep improvements are also required for OEM's back-end technological and business infrastructures, which must be overhauled to provide new services, implementing flexible architectures that will allow for the integration of emerging applications and technologies.

Automotive Human-Machine Interaction Challenges

The diffusion of VTSs is posing profound safety concerns, because they can distract the user from the main task of driving the car, with potentially fatal effects. Since distraction is the most prevalent cause of crash (Wang, Knipling, & Goodman, 1996), many institutions have identified as a short term priority the research on HMI for the vehicular domain, to define new interaction devices and paradigms taking very carefully into account driver's visual and cognitive workload.

However, the definition of UI in the automotive field is an open and demanding research field. It is widely recognized that traditional techniques and approaches established for desktop applications turn out to be inadequate for the automotive domain (Cellario, 2001). This is due to many factors. First, the user/driver can dedicate only few bursts of his or her attention to interact with the VTS, because he or she is mainly focused on the primary driving task (Gellatly, 1997). Moreover, vehicular hardware has very firm limitations. Displays can show only a reduced amount of information, since they usually are between 5" and 7" and have a poor resolution, as well as Voice Recognition engines cannot rely on significant computational or memory resources. Finally, VTSs cannot use an input pointing device such as a mouse or a trackball, making the point-and-click paradigm no longer adequate.

As a result, the interaction with these systems is somehow far to be a well-established issue, being instead an open and active research field (Communicar, 2002), (Costagliola, 2004b). New interaction devices, paradigms, and metaphors are required, which carefully take into account the "safety" issue, not only considering the user interaction with the interface, but also understanding the effects of this interaction on driver-vehicle performances. Many studies indicates that a good solution can come from the use of multimodal interfaces, intended both as complements or alternatives to the visual channel, and able to exploit the other user's sensorial channels (Gellatly, 1997), since they do not require the user removes the glance from the road to interact with the system. In particular, considerable benefits can be gained from making greater use of the tactile channel as a complement to the visual one, especially for older people, because visual and auditory capabilities decrease noticeably with age (Burnett & Porter, 2001). However, great care must be posed with multimodal interfaces. Indeed, graphical user interfaces (GUIs) offer several benefits with respect to vocal or tactile ones which make them still one of the most important component of vehicular human interfaces. In particular, GUIs are definitely the best way to present graphical information, also allowing driver for a "self-pacing" of interaction, because data are shown in a parallel and persistent fashion, differently from auditory and tactile interfaces, which can further load human memory and attention due to their non static nature (Cohen, 2004). Moreover, tactile and auditory interfaces are characterized by a dynamic modality of interaction. Since this communication is serial and transient, user is not allowed to decide when interpret information and how long to spend for it.

FUTURE TRENDS

The VTS market is steadily growing. Analysts concord that a wide percentage of middle and top cars in 2010 will fit some kind of on-board telematics system. Today, electronics account for 18-40% of a vehicle's cost, and it is expected that in the future these numbers will significantly grow, through the integration of an ever increasing number of features. Compared to today's in-vehicle electronic systems, the list of capabilities that drivers and passengers will soon have at their fingertips may be limited only by the imagination.

But next VTSs have to change the definition of product, since three main problems must be addressed: road safety, life-cycle duration, and privacy. About the former issue, the availability of even more complex telematics can heavily affect driver's visual workload. As stated before, advanced user interface designs will be required, which carefully exploit multimodal interfaces, encompassing auditory and tactile sections, as well as heads-up displays, which project relevant information directly on the windscreen in front of the driver (as on military aircrafts). This eliminates the highly distracting task of taking out the glance from the road and looking at the vehicle dashboard.

The second fundamental issue is to reduce the difference of life-cycles between electronics and vehicles. Presently, a car is typically designed in 3-4 years, being in use for another 10 years. In comparison, electronics devices are designed in 6-12 months and are in use for 2-3 years (Fuchs & Spaur, 2004), with a high rate of obsolescence. To provide updated services through the whole car life-cycle, future VTSs will have to be delivered on plug-and-play platforms, whose functionality can be upgraded through software downloads or simple module replacement, or alternatively they will be akin terminals, where heavy computation is ran on remote servers (for example, offboard navigation), accessed through a wireless network, with significant reduction of production cost for automakers.

Finally, there are big challenges about privacy. A VTS-equipped vehicle collects a plethora of information about driver's behaviors, and it is technically capable of giving out these data, which could be potentially misused. For instance, service providers may sell customers' data to third parties without permission, or law enforcement agencies could use localization information to track individual movements.

To avoid that privacy concerns cause consumers to not want VTSs, end-users should be reassured about the safeguard of their own data. A possible strategy might be to pass laws imposing controls on the collection, usage, and storage of telematics-generated information. To this aim, European regulations yet provide strict rules on these data, as well as pending U.S. statutes may soon enforce this (Duri, Gruteser, Liu, Moskowitz, Perez, Singh et al. 2002).

CONCLUSION

The combination of computers and telecommunications has transformed our home and work environments, but in the automotive domain the application of these powerful technologies is still evolving. VTSs however can provide valuable new business opportunities for ICT and automotive industry, coming from the possibility to sell customized services, to deliver upgrades and to further reinforce customer loyalty.

However, as we depicted in this chapter, new and exciting challenges and issues are posed both to ICT and human-machine interface specialists by VTSs.

KEY TERMS

Context Aware Computing: A system that have information about the circumstances under which it is operating and can react/make assumptions accordingly. A VTS has a lot of information about its context, such as localization, user behaviors, vehicle operative state, etc.

GPS (Global Positioning System): A satellite-based system used for determining geographical positions, with a precision of 10 meters. It uses a constellation of 24 satellites and is controlled by U.S. Department of Defense.

GPRS (General Packet Radio System): A wireless data protocol suited for data transmission, available to users of GSM mobile phones. It's theoretical bandwidth is 170 kbit/s, while the realistic one is 30-70 kbit/s. Sometime it is referred as "2.5G", (i.e., a technology between the second (2G) generations of mobile systems), like GSM, and the third one (3G), like UMTS.

Infotainment: Word formed from information and entertainment. In the automotive domain, it identifies a set of features provided by a VTS, such as audio module, Web browser, etc…

Multimodal Interface: Human-computer interface able to exploit different user sensorial channels, to provide/gather information. For instance, user can vocally ask for a service and then read the results on the display.

PAN (Personal Area Network): A computer network used for communication among personal devices, such as cell phones, headset and PDA. The reach of a PAN is typically a few meters.

VTS (Vehicular Telematics System): An electronic on-board system with wireless communications and location technology, integrated by some computing technology, to handle data and manage information flows from/to the user.

Veteran Service Management and E-Government Service Delivery Performance

Assion Lawson-Body
University of North Dakota, USA

Glenn Miller
University of North Dakota, USA

Thomas M. Saddler Jr.
Veterans Service Office, USA

INTRODUCTION AND BACKGROUND OF ORGANIZATIONS

The importance of electronic service delivery was recognized at the beginning of the emergence of the Internet (Huang & Hu, 2004); thereafter much attention has been devoted to it as a solution to the issue of the traditional service delivery system (Cetiner & Ryan, 2004; Gassan, De Boer, Mourshed, & Rea, 2001). Too often there is little or no congruence between the image of the service communicated by the service firm and the service actually delivered. This leads to unmet customer expectations and probably to non-satisfied customers, who have lost their faith in the firm and its ability to keep its promises.

Governments also invest in veteran service management (VSM) and e-government to increase their service delivery performance. Veterans are the nation's population who have been discharged or retired after serving on active duty with the United States Armed Forces. E-government refers to efforts in the public sector to use information and communication technologies to deliver government services and information to the public (Gant & Gant, 2002; Gefen, 2002). Government agencies face challenges in making veterans aware of the benefits of online services they are receiving. Anecdotal evidence shows the Internet's Web portal can enable governments to increase their e-service delivery performance. However, there is little existing research that has tested how the use of Web portals to strengthen existing VSM can increase e-government service delivery performance.

The primary objective of this study is to examine how VSM, using Web portal aggregation, may impact electronic service delivery performance. Specifically, the study examines:

- the theoretical foundation of VSM,
- the theoretical impact of VSM on government service delivery performance,
- theoretically and empirically how VSM, supported by Web portal aggregation, may impact e-government service delivery performance.

This research focuses on government Web portals that deliver electronic services to veterans. The Web portal of the North Dakota Government Rural Outreach (GRO) Initiative has been selected as the sample U.S. government Web portal for this research. That Web portal has been chosen because it has a component dedicated to veterans and county veteran service officers (CVSOs).

Data were collected through open-ended interviews with CVSOs. A total sample consists of 10 CVSOs. The study used content analysis to analyze data obtained from a sample of CVSOs, using the GRO Web portal, to test the hypotheses. The CVSOs assist all veterans and their dependents in obtaining all benefits to which they are entitled, both federal and state. The CVSOs are chosen because they play the role of intermediary between veterans, veteran service and benefits providers, and government agencies. CVSOs interact on G2G (government to government) and G2C (government to citizen) basis in order to serve veterans.

CVSO and Veteran Population in North Dakota

A total of 22 CVSOs have an office in the north eastern part of North Dakota while 12 CVSOs serve veterans in the north western part of North Dakota. A total of 16 CVSOs serve veterans in the south western part of North Dakota while 18 CVSOs assist veterans in the south eastern part of North Dakota.

In terms of location, 18% of CVSOs cover the north western part of North Dakota; 32% work in the north eastern part; while 24% are located in the south western part and 26% in the south eastern part of North Dakota.

There are 14,840 civilian veterans in the north eastern part of North Dakota while 11,387 reside in the north western part of the state. Most of the civilian veterans (about 22,783) are located in the south eastern part of North Dakota. Approximately 7,116 civilian veterans live in the south western part of North Dakota.

In terms of location, 21% of civilian veterans are located in the north western part of North Dakota; 22% are located in the north eastern part; while 13% reside in the south western part and 44% in the south eastern part of North Dakota.

THEORETICAL FOUNDATION OF VSM AND DESCRIPTION OF E-GOVERNMENT

Several theoretical perspectives from information systems (IS) reference disciplines are relevant for this study. One of these IS reference disciplines is marketing. We draw upon role theory (RT) and service encounter theory to explore and understand the theoretical foundation of VSM. Those theories have been adopted by marketing researchers for examining service delivery (Bitner, 1995; Solomon, Carol, Surprenant, & Evelyn, 1985).

A service encounter theory is a form of social exchange in which participants normally seek to maximize the rewards and minimize the costs of the transaction (Solomon et al., 1985).

Usually, an encounter is especially relevant in situations where the service component of the total offering is a major element of that offering. In e-government delivery service, governments do not sell goods to the public or business, compared to the private sector.

In the public sector, the total offering is relatively stable, offering such as social security and unemployment benefits do not almost change and are pure service. A service encounter remains important in government e-commerce application because in many government services deliveries there is a high level of service encounter between CVSOs and veterans or government agencies.

Role theory (RT) is based on a dramaturgical metaphor (Solomon et al., 1985). It is the study of the behavior associated with a socially defined position and role expectations are the standards for role behavior. Each role that one plays is learned (Solomon et al., 1985). In many routine service encounters, the roles are well defined and both the customer and employee know what to expect from each other (Bitner, 1995).

According to RT, each participant in government service delivery has a role to play. Through the lens of RT, CVSOs and veterans' role in these relations are well defined and both know what to expect from each other. The RT also helps understand that each role that one (CVSOs, veterans or government agencies) plays is learned.

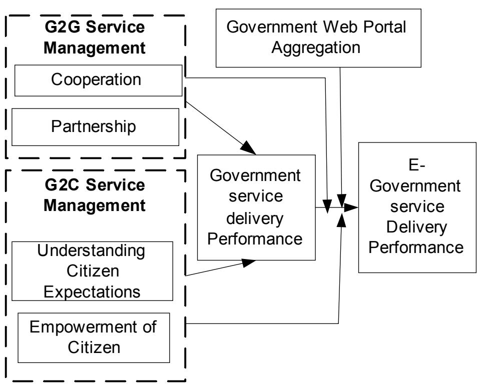
VSM, Service Encounter Theory, and RT

In fact, we build on foundational advances in RT and service encounter theory in examining VSM components.

In this study, a VSM is defined as the process whereby a CVSO understands veteran expectations, teaches veterans ways to secure services for themselves, develops partnerships of service, and cooperation with government agencies in order to serve veterans (Moon, 2002). The extent of VSM is split in two in this research: VSM from G2G perspective (G2GSM) and VSM from G2C perspective (G2CSM). The two major G2GSM components identified are: cooperation and partnerships of service. The two major G2CSM components identified are: empowerment of veteran and understanding veteran expectations. These components are analyzed through the lens of RT and service encounter theory. Further, we hope to test how the use of Web portals to strengthen existing VSM can increase e-government service delivery performance.

- **Cooperation:** It is defined in this study as coordinated actions taken by government agencies, veteran service providers, and CVSOs to achieve mutual outcomes. Cooperation promotes effective working relationship success. Wilson (1995) presented a cooperative model in which both parties achieve lower costs by working together to lower both buyer's and seller's operating costs. This enduring desire to maintain a valued cooperative relationship should, in turn, impact e-government service delivery performance.
- **Partnerships of Service:** Partnerships are created when CVSOs communicate and share information closely with veteran service providers or government agencies. In the management of service delivery, frequent quality communication needs to be in place to foster partnerships and cope with changing services needs (Moon, 2002). A partnership helps both parties stay on the course of mutual interests (Moon, 2002).
- **Empowerment of Veteran:** Empowerment of veteran generally refers to the process CVSOs adopt to educate, teach, encourage, and reward veterans who exercise initiative and make valuable creative contributions or do everything that is possible to help solve their problems. Most government agencies prefer to deal with empowered veterans because they are easy to serve, because they understand the

Figure 1. Research model



CVSO's preoccupations, and because they make only a few requests to government agencies.

- **Understanding Veteran Expectations:** This concept stresses the importance of CVSOs having the ability to identify their veterans' desires and to deliver to those veterans services which meet their expectation. Understanding veteran expectations is a strategy adopted by CVSOs and government agencies to generate more knowledge of veteran expectations and needs and to provide veterans with the best services.

E-Government Service Delivery Performance

Many authors have examined how governments can invest in e-commerce to improve their service delivery performance (Dufner, Holley, & Reed, 2002; Jain, 2004). After conducting six case studies and contacting over 50 government organizations, Cohen and Eimicke, (2001) found that e-government service delivery could change human resource deployment patterns and improve organizational performance. Another source of e-government service delivery performance is savings generated from reduced costs. When costs were assessed in the cases presented in their study, Cohen and Eimicke (2001) found that typically services delivered over the Internet were less expensive to deliver than those delivered in person.

Government Web Portals Aggregation

A portal is commonly defined as aggregated Web sites that offer a collection of services that help users, government agencies and their constituents navigate the Internet (Damsgaard, 2002). The dependency between government constituents and portal services is reciprocal or mutual (Damsgaard, 2002). Some portals cannot exist without a community of veterans or citizens, and the veterans will only visit the portal if there is a set of relevant services which they demand.

Research Model and Hypotheses

The key constructs of the research model, identified through the objective and the theoretical foundation of this article are as follows: the dependent variables will be drawn from government and e-government service delivery performance constructs, the independent variables will be drawn from the VSM construct and the moderating variables will be drawn from the Internet's Web portals aggregation construct.

This research model enables us to test the following hypotheses:

- **H1 (a, b, c, d, and e):** The VSM components (partnerships of service, cooperation, empowerment of veteran, and understanding veteran expectations) will have a positive effect on government service delivery performance.
- **H2 (a, b, c, d, and e):** The use of Web portal aggregation to strengthen existing VSM (partnerships of service, cooperation, empowerment of veteran, and understanding veteran expectations) will increase e-government service delivery performance.

PRELIMINARY STUDY AND IMPACT OF E-GOVERNMENT ON THE ORGANIZATION

Research Method

The study used content analysis to analyze the data obtained from a sample of CVSOs to test the hypotheses and analyze the research factors. The common response is obtained by using the generalized answer from all CVSOs. The procedure for data analysis was based upon totaling the overall counts of messages coded in each category and the analysis of the messages. Each research factor or variable has played the role of category. Occurrences of the messages in each category have been analyzed to determine relative importance. Higher relative counts reflected significance of the particular message within the specific category.

The objective of this preliminary study is to examine how VSM, using Web portal aggregation, may impact electronic service delivery performance. The Internet's Web portal aggregation can support the formation and maintenance of VSM because it facilitates the way CVSOs partner, cooperate, empower veterans, and understand veteran expectations. Content analysis techniques have been used to process and analyze data collected from a sample of 10 CVSOs using the GRO Web portal to serve veterans.

Highlights from the Findings of the Interviews

Impact of Cooperation Using Web Portals Aggregation on E-Government Service Delivery Performance

The following statement illustrates common responses from CVSOs:

We cooperate online with government agencies and we go back and forth. We try to keep a good relationship with the agencies. From the VA aspect, we discuss the cases because certain aspects of some cases need to be analyzed. Once you know these people they'll all go out of their way to help so it's the teamwork that really works. The CVSOs work pretty much together and we have an ability now with the Internet to assist each other. We work so close together and, we can use the Internet and get these things done for the veterans' benefit.

This part of the interview outlines that government Web portals must be extremely easy to use, since convenience and saving time (and consequently money) are the major thrusts for online cooperation. It is essential for CVSOs to offer online attractive services in order to convert potential veteran service providers to actual cooperators. Once potential veteran service providers are converted to cooperators, electronic service delivery performance will increase. CVSOs and veteran service providers cooperate when they use the same Web portal to maintain a working relationship (Moon, 2002). Both need to work together to identify all security risks and jointly develop measures for minimizing them (Moon, 2002).

Impact of Partnership of Service Using Web Portals Aggregation on E-Government Service Delivery Performance

The following statement indicates common responses from interviewees:

We keep government agencies updated about changes. Via the Internet, we can give them what they do not really know and make them aware of that. I guess, just to stay in online communication with government agencies, we share as much information as we can.

This part of the interview deals with monitoring service performance by collaborating on and sharing service problems, and negotiating for changing service needs. All require partnership and IT resources such as Web portals aggregation. Government Web portals bring together many services and agency Web sites onto one site (Stowers, 2001). Given the limited geographic scale of many public jurisdictions, using Web portals to develop projects in concert with other public and private entities is a sound strategy that creates both savings and productivity gains.

Impact of Empowerment of Veteran Using Web Portals Aggregation on E-Government Service Delivery Performance

The following statement exemplifies common views of CVSOs:

We help individual veterans fill out forms if they ask for the benefits. We tell them about what they are to do, and what social security may require, and get anything that way. A lot of individual veterans have been on the internet right now. Veterans may have to make the claims from their home. But they need to have the password. And may be if we make them more self sufficient as far as using technology that would empower them more. However they have to sign a lot more documents and digital signature is not available for them.

This part of the interview demonstrates that CVSOs are able, via the Web portal, to access information about their veterans. A Web portal then is a tool for veteran empowerment because once veterans are well informed about their government's Web portal, the veterans will most likely learn (Griffith, Sawyer, & Neale, 2003; Edgington & Chen, 2002) from CVSOs and be able to deliver government services and benefits to themselves. CVSOs often empower veterans to use Web portals for receiving service and benefits online. This veteran empowerment is carried out by e-mail or through online discussion (online conferences, forums, or chat rooms) and allows CVSOs and veterans to make the most of the online contact time provided by the Internet's portal to share their views. Government agencies and counties provide appropriate training for their CVSOs in order to be able to offer various services, solutions, or products during interactive online contact with veterans, and to modify on the screen the statements that governments use to deliver services to veterans on the basis of veterans' reactions and views.

Impact of Understanding Veteran Expectations Using Web Portals Aggregation on E-Government Service Delivery Performance

The following statement illustrates CVSO's common opinions:

We make sure we got the literature, and make sure many veterans come to the open house. We allow them to give feedback so we understand them better when they come back in for more services. We follow up with some veterans when we advise them some reference material that they can refer to and so on, such as Web sites. We take notes on everybody we talk to, what we talk about, then we open our notes up and say this is what we talked about.

This part of the interview shows that it is critical while improving government Web portals to clearly understand veterans' expectations (Cetiner & Ryan, 2004). Understanding veteran expectations is a continuous process, requiring CVSOs to solicit veterans' feedback to ensure that their needs are being addressed. A feedback system should let a government agency communicate with veterans and CVSOs. The feedback system shows its commitment to learning about and responding to veteran concerns.

Impact of VSM Using Web Portals Aggregation on E-Government Service Delivery Performance

The following statement indicates common responses from interviewees:

The use of the Internet will work out in the long-run. It will be cheaper when they get everything done. The Internet has obviously caught on, but it has not caught on to everybody because not everybody has access. The cost—I don't know how it would. If they don't come in here it's the only way it would decrease the cost. And many of them do not have the internet and I've had many of them come in—veterans and the dependents come in and say, "I tried internet. I can't get through it.

This part of the interview shows that usability of Web portal by veterans will reduce cost and increase veteran participation, therefore increased e-government service delivery performance will follow. When veterans help themselves at a Web portal instead of having to call a conventional help desk, reduced cost of veteran service delivery will follow. Good e-government service encourages veterans to use the Web portal more often, which means they become more likely to use it for transaction and support.

It is also important to be absolutely clear that e-government transactions within the government context do not replace face-to-face traditional government. If anything, it ensures that routine transactions can be handled more quickly and CVSOs have more time to devote to face-to-face interactions.

By automating the government service delivery process, electronic service relieves these CVSOs of having to perform many repetitive, yet critical time-sensitive tasks, thereby freeing them to support other strategic activities.

CONCLUSION

This article presents a theoretical discussion of how experts on IS and the Internet should inform government agencies, veteran service and benefit providers, and CVSOs about the theoretical impact of Internet network use on government service delivery performance.

The results reported are preliminary.

The result of this preliminary study shows that the challenge for a portal is to offer services that lock-in the government agencies, CVSOs, and veteran service providers. To increase e-government service delivery performance, veteran self-service needs to be promoted on Web portals. Then, e-government service delivery will free up CVSOs and allow them to focus less on routine tasks that could be easily handled by Web portals.

The way the application of RT to the public sector support the findings of this study may be explained as the following: if veterans or CVSOs play efficiently their role and adopt the appropriate behavior it ensures that routine transactions can be handled more quickly and CVSOs have more time to devote to face-to-face interactions. The application of RT to the public sector may let government reorganize its workforce or to enhance service delivery by redirecting employees to other activities.

The way the application of service encounter theory to the public sector supports the findings of this study may be explained as the following: because of the nature of government product (pure service), every time CVSOs interact with veterans or government agencies, a service encounter occurs. A service encounter in the context of e-government is a form of virtual exchange in which CVSOs seek to maximize service delivery to veterans or government agencies.

Even though the data we collected for this study focused on CVSOs, the research approach could be applied to any group of citizens. Further research is necessary as Internet technology evolves so rapidly. Finally, further research projects could be to apply the conceptual model used in this study to another category of government constituents. Quantitative analysis will be needed to perform more tests with the hypotheses developed in this study.

The Virtual Agency as a New Force in the Promotions Industry

R. Zachary Finney
University of South Alabama, USA

Angeline Grace Close
University of Georgia, USA, North Georgia College and State University, USA, and University of Nevada, Las Vegas, USA

INTRODUCTION

The virtual agency (VA) is a new form of advertising/promotions organization. By using technology to create ad hoc teams of promotions professionals, the virtual agency is changing the nature of the advertising business. In the following paragraphs, we (a) distinguish the virtual agency from traditional agencies and (b) explain why this is an important development for e-commerce and the advertising/promotion field.

Virtual agencies use the Internet as a means to redistribute the tasks traditionally performed at a single promotions firm. The completed work that the agencies perform for their clients is often similar to the work produced by traditional agencies. Virtual agencies, however, typically perform such work for a fraction of the traditional full-service agency's price

These new organizations are revolutionizing the promotions industry by the manner in which they distribute the tasks associated with creating a promotions campaign. To date, the agencies have not used the Internet to produce wholly new types of promotions. The virtual agencies instead use the Internet for simple communication; the Internet allows VAs to collaborate in a manner that was much more difficult prior to the widespread adoption of the Web.

BACKGROUND

Historically, full-service agencies have provided five key services to clients (a) account management and (b) creative, (c) financial, (d) media, and (e) support services. Limited-service (or "boutique") agencies offer only some of these services (Burnett, 1993). (To date, most scholars do not include electronic/new media services in the traditional definition of a full-service agency). Furthermore, the traditional advertising agency operates from a central geographic location with a "bricks and mortar" office that houses each of these respective departments.

Virtual agencies provide the same promotions services as traditional agencies, but in a very different manner. Specifically:

> *A virtual agency is a type of marketing communications firm formed by a collaboration of experts—typically from a pool of big agency expatriates experienced in creative development, account service, even the billing process. Just as ensembles of actors are carefully chosen for a film project, advertising freelancers band together for different advertising projects, thus creating the virtual agency.* (Bechard, 1999)

(Readers should not confuse the virtual agency with the cyber agency. A cyber agency specializes in providing promotions services through the Internet medium; a cyber agency may or may not also be a virtual agency; LORE, 2005).

SERVICE

The core personnel in a virtual agency typically form the virtual agency's account management team; in most cases, the VA's core personnel are owner-managers. Papsadore (1996) commented that "the account management team is your [i.e., the client's] single point of contact. They provide strategic direction, manage the project and provide all the financial services including estimating and billing." The owner-managers, then, address the strategic marketing issues related to creating a promotion while managing contact with the clients (Brandchannel.com, 2005). After the top personnel in the virtual agency have decided on an overall direction for a promotion, they may "then bring in, as required, excellence in advertising, design or PR" (Brandchannel.com, 2005).

By hiring the most appropriate members of the network for any given job, the virtual agency provides its clients with the full range of promotion services (Brown & Associates, 2005; Moscov, 2005). VAs' flexible organizational structure, advocates assert, allows these organizations to better meet customers' needs. The virtual agency "expands and molds to your [clients'] needs" (Blazic Design, 2005). Flexibility is important in today's customer-oriented "servicescape."

Virtual agencies claim that they have carte blanche when selecting the members of a client's creative team. "Creative teams can be matched to your project for several reasons—budget, style, industry expertise, or even history" [with the client] (Papsadore, 1996). To help craft effective promotions for clients, virtual agencies maintain an extensive network of contacts with various professionals, including "sculptors, musicians [and] directors" as well as "expert-level designers, artists, writers, photographers, video editors, and other independent creative professionals" (Feuer, 2000, Papsadore, 1996).

Some virtual agency clients maintain that the ability to "cherry pick" their promotions "team" actually provides them with better personnel than they would get at a traditional agency. One client glowingly described his virtual agency team: "If you went to an agency [i.e., a traditional agency], the chances of getting all this top talent in one room are slim. You're going to get a beginner in there somewhere. But you get the *crème de la crème* with the freelancers" (Bechard, 1999). Or, as Papsadore (1996) put it to would-be clients: "Maybe the best part of the whole [virtual agency] deal is that you will NEVER see a junior staffer ever again."

TECHNOLOGY

Although a virtual agency could use other means of communication (e.g., face-to-face, telephone), most VAs rely on the Internet as a key communication tool. Many virtual agencies have no formal headquarters. Prospective clients often learn about the agency and examine its work through the Internet and other forms of electronic communication. Many of the virtual agency employees provide client services without ever leaving their home offices. In lieu of meeting face-to-face, personnel at virtual agencies interact with each other and their clients through a variety of electronic communication channels. These include "phone, fax, and Internet… intranets, Web conferencing services, e-mail company newsletters, and conference calls" (Jarvis, 2002).

Virtual agency founder Scott Goodson explains how technology has shifted the balance of power among promotions providers: "The [Internet] technology for the first time is allowing us to have the same information and knowledge control as any of the big agencies. In the old economy, only the big corporations had the resources. Today, the Internet is democratizing information" (Koranteng, 2000). For consumers, however, the Internet may be associated with a digital divide between those with convenient, affordable online access and the rest of the world. In this sense, those who haves access to new technologies possess the means to advance socioeconomically. On the other hand, the "have-nots" (i.e., disconnected consumers) are continuing in a downward cycle due to a lack of timely information with which to make their everyday decisions.

As noted in the introduction, then, the virtual agency does not create new technologies (i.e., virtual agencies have yet to invent new forms of advertising). Instead, the virtual agency supplies its clients with traditional promotions. Virtual agencies create their promotions by parceling out the work involved among very loosely affiliated networks of promotions professionals.

The virtual agency, then, is consistent with the emerging phenomenon scholars label "computer-supported collaborative learning (CSCL)" (Borges and Baranauskas, 2003). CSCLs "…combine communications and computer technologies to support various activities involving groups in collaborative problem solving situations" (Borges & Baranauskas, 2003). Through these CSCLs, participants can accomplish a number of goals that would be much more difficult without the recent advances in information technology.

Virtual agencies not only form collaborative networks in a manner consistent with other CSCLs, these agencies also structure the work in a manner that is quite common among participants in these networks. "CSCL environments have a special participant, usually called a 'facilitator', who plays a fundamental role in coordinating and mediating the group discussions towards reaching the goals and learning objectives of the activities carried on" (Borges & Baranauskas, 2003). As noted earlier, virtual agencies generally have an account management team that makes the strategic decisions regarding the promotion and, subsequently, selects the other personnel who work on a given promotion. Virtual agencies, then, operate in a manner largely consistent with other CSCLs.

COSTS

By virtue of the fact that they offer a wide-range of services in a "bricks and mortar" office, traditional advertising/promotions agencies have to cover a high amount of overhead. The absence of costly office space and full-time personnel allows the virtual agency to offer a full range of services to clients at a low cost (Asheville Creative Services Group, 2005). Virtual agency clients note that "you're not paying for a whole agency; you're just paying for a person's expertise" (Bechard, 1999). Also, the diffusion of technology allows virtual agencies to create attractive advertising and promotional materials at a fraction of the cost required to create a campaign in the past.

As a result of these advantages, one virtual agency states that its prices are "30%-40% less than [prices charged by] traditional advertising agencies" (Blazic Design, 2005). Another virtual agency cites "30%-50% savings" over traditional agencies (PriMedia, 2005). As one VA CEO puts it: "The real key to a virtual agency is you can keep your overhead lower and pass that savings on to your clients" (Jarvis, 2002).

Advocates of the virtual agency maintain that these newer agencies' heavy use of technology and minimal bureaucracy can combine to offer clients another advantage: much faster service than they would obtain from traditional ad agencies. For instance, Amsterdam-based virtual agency StrawberryFrog won the account of printer manufacturer Tektronix from a much larger traditional agency. After obtaining the account, StrawberryFrog created a campaign for Tektronix in 18 days; Tektronix's old agency had required 8 months to accomplish the same task (Koranteng, 2000). This potential advantage is especially appealing to companies that are interested in being the first to market with a new product or service.

The advantages of the virtual agency have helped these upstart firms land a number of blue-chip businesses as clients. The well-known businesses hiring virtual agencies include: Nike, British Airways, Pharmacia, Volkswagen, the magazine *Elle*, and Heineken (Hammonds, 1999; Koranteng, 2000). While these well-known clients are impressive, some observers suggest that cost-conscious small businesses will be the biggest beneficiaries of the virtual agency phenomenon. Virtual agencies "are quickly becoming the preferred choice among smaller businesses that want to save money and get more bang for their advertising bucks" (Bechard, 1999).

NEGATIVES

Participants in virtual agencies do concede that drawbacks exist. Many of the perks associated with traditional agencies do not exist for clients of virtual agencies. In fact, one enthusiastic supporter of the virtual agency concedes that clients must be "ready to make the leap from Godiva truffles to a good old Hershey bar" (Papsadore, 1996).

One potential problem is the difficulty in obtaining personnel to "tweak" promotional materials at the last minute. Moreover, because of the virtual agency's relatively narrow margins, clients who request additional services must be willing to pay more. "When you ask for something extra… it goes right to the agency's bottom line, and they must charge you for it" (Papsadore, 1996). Therefore, prospective VA clients must weigh their desire to save money versus the types of services they desire.

Most virtual agencies have a cost advantage relative to traditional agencies; therefore, VA profit margins typically are lower than are profit margins at traditional ad agencies. Further, ad hoc combinations of promotions professionals may inadvertently combine personnel who do not work together well; indeed, some virtual agencies have even paired personnel who are professional rivals (Koranteng, 2000).

Scholars also note that the disconnected organizational structure of a virtual agency carries a number of potential drawbacks. Specifically, participants in virtual agencies must manage disparate coalitions of personnel while crafting effective promotions for clients:

> *At the same time, the virtual agency concept has major risks including inefficiencies due to organizational complexity, the danger of collective myopia, the problem of adopting standards too early, the difficulty of reaching objectives in a loose organizational structure, and the problem of properly balancing the tension between agency mission objectives and national policy agendas.* (Castro, Foster, Gunn, & Roberts, 2001)

Last, many traditional agencies enjoy long-standing relationships with their blue-chip clients. From the clients' perspective, it may be very risky to damage a good relationship and move to a new agency without a proven track record. Clients often base their selection of an agency on their relationship the agency's personnel (Crutchfield, Spake, D'Souza, & Morgan, 2003), it remains to be seen whether the virtual agency can foster these all-important relationships.

FUTURE TRENDS AND CONCLUSION

Observers predict that the virtual agency will not mean the death of the traditional agency. One J. Walter Thompson (JWT) executive said "that the Internet allows large firms to slash bureaucracy while still capitalizing on the immense global resources that virtual agencies will never have" (Koranteng, 2000). Nevertheless, the traditional agencies face a stiff challenge from their smaller, cheaper rivals.

Analysts predict that the virtual agency's business model will become a permanent part of the promotions industry's landscape. Indeed, the economic slowdown beginning around 2000 did nothing to decrease the virtual agency's appeal; instead, a number of traditional businesses (across a variety of industries) converted to the virtual business model. "One result of a slow economy has been to bring more companies to join… in the virtual niche as businesses, aiming to cut their overhead, have discovered that the virtual model is a viable way to do business" (Tanner, 2003).

In the future, virtual agencies must examine how they can make the virtual approach even more efficient. To date, the fact that relatively few businesses have adopted the model has given virtual agencies a cost advantage relative to traditional competitors. In the future, virtual agencies are likely to compete not only with traditional, bricks and mortar agencies, but with each other as well. Only the most efficient and effective virtual agencies will survive.

In order to retain their efficiency advantages, virtual agencies will have to consider—yet again—the manner in which they organize their personnel and technologies. After all, virtual agencies attempt to operate with personnel who are geographically dispersed; this situation can only add to the sharp differences often observed between the "creative" and "strategic" sides of a traditional ad agency (Koslow, Sasses, & Riordan, 2003). Personnel who are in different geographical locations may add to problems separated

A consultant from Bain and Co. argues:

Technology and telecommunications have driven the virtual phenomenon… But just having reliable and high-level performance in those systems isn't enough to make a business case for a company to operate as a virtual enterprise … A company has to be structured in a way that makes the virtual approach work, with incentives in place to support the system… employees must have the right capabilities, infrastructure and training and be empowered to take action. (Tanner, 2003)

The final hurdle to the virtual agency's acceptance lies in its ability to attract larger clients. To date, many blue-chip companies remain reluctant to hire virtual agencies. Whether a high percentage of the largest clients will become open to hiring virtual agencies is unknown at this writing. Many of these clients still aren't aware of the presence of virtual advertising agencies much less how their firms can benefit from hiring a virtual agency. Given that the client's buying center is often rather small when it comes to selecting an ad agency (Na, Marshall, & Son, 2003), virtual agencies seeking to obtain business from large clients may have to invest more in reaching the key decision makers among their potential clients.

It will be interesting indeed, to observe whether management at the top virtual agencies will be able to establish brand equity equivalent to that enjoyed by the top traditional agencies. Given that current research indicates that a firm or product's reputation is built over the long-term (Weilbacher, 2003), it is likely that virtual agencies will only establish such reputations after considerable amounts of time. Executives at some virtual agencies have become so frustrated by their inability to attract large clients that they have given in and established traditional offices; these former virtual agencies have had mixed results after adopting more traditional modes of operation (Slater, 2003).

For the foreseeable future, then, virtual agencies will quickly grow and continue to eliminate the distinction between full-service and boutique ad agencies. Because "no one tracks the total number of virtual agencies or how many make a go of it" it is difficult to predict precisely how much influence the virtual agency will have on the future shape of the promotions agency (Jarvis, 2002). One conclusion, however, is already apparent: "No longer can Advertising Agencies survive conducting business in the traditional manner" (PCF Virtual Advertising, 2005).

KEY TERMS

Boutique Agency: Promotions firms providing some, but not all five, of the services provided by full-service agencies. (A synonym for boutique agency is *limited-service agency*; Burnett, 1993).

Buying Center: All of those who have influence over a business' purchase of a particular product.

Cherry Picking: Process by which virtual agencies may choose the best available talent for each job. Full-service agencies, meanwhile, are stuck using the staff that they have on hand (Bechard, 1999).

Cyber Agency: Promotions firm specializing in providing promotions services through the Internet medium. A cyber agency may or may not also be a virtual agency; LORE, 2005).

Full-Service Agencies: Promotions firms providing the following five services: (a) account management, (b) creative, (c) financial, (d) media, and (e) support services (Burnett, 1993)

Limited-Service Agencies: Promotions firms providing some, but not all five, of the services provided by full-service agencies. (A synonym for limited-services agency is *boutique agency*; Burnett, 1993).

Strategic Marketing Issues: Broad, far-reaching questions concerning the manner in which a firm serves its customers. Top management generally addresses strategic issues (Brandchannel.com, 2005).

Virtual Agency: "A type of marketing communications firm formed by a collaboration of experts—typically from a pool of big agency expatriates experienced in creative development, account service, even the billing process. Just as ensembles of actors are carefully chosen for a film project, advertising freelancers band together for different advertising projects, thus creating the virtual agency" (Bechard, 1999).

Virtual Communities and E-Business Management

Carlos Flavián
University of Zaragoza, Spain

Miguel Guinalíu
University of Zaragoza, Spain

INTRODUCTION

As a result of the new possibilities offered by Internet managers are increasing options provided by the new technologies in strategic planning. The virtual community has become one of the more interesting options.

The general aim of this article is to explain the concept of virtual community, paying special attention to the most important strategies and management suggestions. Firstly, we will analyze the concept of community from a sociological viewpoint. We then define a virtual community and what causes an individual to belong to one. Secondly, we will show the main strategic implications of the development of virtual communities. Next we will detail a series of recommendations for the proper management of virtual communities. The two final sections present the future trends of research and the main conclusions of the article.

BACKGROUND

From a sociological perspective, Muñiz and O'Guinn (2001) consider that a community may be defined as having three principal elements:

- **Consciousness of Kind:** This refers to the feeling that binds every individual to the other community members and the community brand (e.g., admiration for Elvis Presley, or the passion for owning and driving a Volkswagen Beetle). It is determined by two factors: (1) legitimization, the process of establishing a difference between true and false members, that is, those who have opportunist behaviors and those who do not; and (2) opposition to other brands. In fact, identification with the rest of the group is mainly based on opposition; in other words, brand community is usually defined in comparison with another brand (e.g., the rivalry between fans of The Beatles and The Rolling Stones).
- **Rituals and Traditions:** These are processes carried out by community members which help to reproduce and transmit the community meaning in and out of the community. Members relate to each other with the memory of major events in the history of the brand and certain behaviors. All these processes help to reinforce brand consciousness and improve instruction on communal values.
- **Sense of Moral Responsibility:** This reflects the feelings which create moral commitment among community members. A sense of moral responsibility encourages conjoint behaviors and enables stronger group cohesion. As a result of moral responsibility, there are two types of fundamental actions: (1) integration and retention of members, which guarantees the community survival (e.g., by spreading bad experiences suffered by those individuals who chose a different brand); and (2) support in the correct use of the brand (e.g., by sharing resources and information about product properties).

Thanks to the Internet, social relationships can be developed in a new environment. Thus appears the idea of virtual community. The first virtual community was created in the seventies, specifically with the Talkomatic software, designed by Doug Brown of the University of Illinois in the autumn of 1973. However, it was not until the nineties that there was an exponential growth of this type of organization.

Several authors offer definitions of virtual community. Cothrel (1999) defines it as a group of individuals which uses computer networks as a form of primary interaction. Kardaras, Karakostas, and Papathanassiou (2003) consider it to be a group of individuals who communicate by electronic means such as the Internet, who share interests, without needing to be in the same place, or having physical contact, or belonging to a particular ethnic group. More specifically, the concept of virtual community is defined by Rheingold (1993) as a "social aggregation originated in the Internet when people discuss in this communication channel." Similarly, Yap (2002) explains that a virtual community is a social group originated in the Internet with certain beliefs, social forms (language, etc.), and traits that creates an emergent culture among its members. With a greater degree of complexity, Muñiz and Schau (2005) point out that a common aspect of virtual communities might be the potential for transcendent and magic-religious experiences. Finally, Preece (2000) states that a virtual community is formed by people:

- with a wish for interaction among them in order to satisfy their needs,
- that share a particular interest which is the reason for the community,
- with certain norms that guide the relationships, and
- with computer systems that favor interaction and cohesion among the members.

THE MANAGEMENT OF VIRTUAL COMMUNITIES

Strategic Issues Related to Virtual Communities

The exploitation of virtual communities may be implemented by means of two different marketing strategies: offering support or becoming a member of the group.

Strategy 1: Offering Support to the Community

This strategy supposes that a company manages the platform on which the community exchanges take place. This company is not a member of the community, but simply facilitates its existence by offering a Web site for communication purposes. For the development of this strategy, the main step should be an analysis of the real possibilities of creating a community via the Internet. These possibilities derive either from the particular characteristics of a product or brand, or else the pre-existence of the community offline. In the first case, the company should define the aspects which characterize the product or brand to ascertain to what extent these are likely to create an attendant community (e.g., the company Apple, http://www.apple.com/usergroups/, exploits the characteristics of Apple computers). In the second case, a new, better quality method of communication is offered to a group of individuals who are already linked outside the Internet (e.g., MarketingProfs.com, http://www.marketingprofs.com, facilitates communication between marketing consultants and educators).

Strategy 2: Become a Member of a Community

In this case, the company attempts to be perceived as a virtual community member. In this respect, obtaining the level of membership of a community will depend on the trustworthiness perceived in the company. According to established literature on trust (e.g., Roy, Dewit, & Aubert, 2001; Sako & Helper, 1997; Morgan & Hunt, 1994; Anderson & Narus, 1990; Dwyer, Schurr, & Oh, 1987; Anderson & Weitz, 1989; Bhattacherjee, 2002; Cheung & Lee, 2001; Gefen, 2000; Kolsaker & Payne, 2002; Luo, 2002; Walczuch, Seelen, & Lundgren, 2001; Geyskens, Steenkamp, & Kumar, 1998; Sabel, 1993), the organization needs to demonstrate its *honesty* (i.e., that it is sincere and delivers its promises); *benevolence* (being concerned for the welfare of the other members of the community, not acting in an opportunistic manner, and attempting to have compatible objectives); and *competence* (that is, it has sufficient capability for its contributions to the community to be significant and to generate value).

Hagel and Armstrong (1997) and Flavián and Guinalíu (2005a) show the virtual community as a tool that can increase the chances of success in the marketing and distribution of products over the Internet. The virtual community can boost a company's product differentiation by increasing commitment and emotional ties with the brand. Furthermore, brand awareness is increased, since the community acts as a catalyst in the transmission of word-of-mouth messages. Thirdly, the virtual community brings about a more effective market segmentation, increases consumer trust and security, acts as an information source, and can even become a major source of direct income. In a more detailed way, we can distinguish these managerial implications:

- **New Forms of Communication:** Hoffman and Novak (1996) notice the replacement of traditional communication models (one-to-many) with others in which the interactions between all the participants in the market are constant (many-to-many). The virtual community represents these changes. Thanks to social network and the use of the Internet, messages are transmitted to the community within a short period of time, obviating the need for costly investments in the mass media and thus reducing promotional costs (Barnatt, 2001; Guthrie, 2000; Kardaras et al., 2003; Wang, Yu, & Fesenmaier, 2002).
- **Information Source:** The virtual community becomes a relevant information source for the decision-making process (Hagel & Singer, 1999; Holmström, 2000; Barnatt, 2001; Kardaras et al., 2003).

- **The Creation of Barriers Preventing the Entry of New Competitors:** The virtual community creates barriers against new competitors (Barnatt, 2001; Hagel & Armstrong, 1997; Kardaras et al., 2003).
- **Increased Security and Trust:** The community creates a climate of security based on reputation and mutual trust. This phenomenon may be clearly seen in online auction communities (e.g., eBay), and in communities with risk-management systems based on reputation (Dellarocas, 2001; Kollock, 1999).
- **Facilitating the Development of Relationship Marketing Strategies:** According to certain authors (e.g., Guthrie, 2000; Wang et al., 2002), virtual communities are an ideal environment for implementing relationship marketing strategies.
- **Becoming a Source of Indirect Income (Wang et al., 2002):** In the case of virtual communities, it is customary to offer, through mailing lists, forums, or Web sites supported by the community, third-party products which might be of interest to the group. In this way, the business supporting the communication infrastructure of the community is financed (e.g., the company which supports the CRM professional community, http://crm.insightexec.com/). Likewise, some communities charge a fee in order to participate in debates (e.g., http://www.well.com).
- **A Source of New Clients (Kardaras et al., 2003):** Membership to a community creates a favorable predisposition towards the company supporting the platform for community interchange. For this reason, the community encourages members to recruit new members who ultimately will become new consumers.

E-Business Management Recommendations

Flavián and Guinalíu (2005a) identify the existence of some key aspects to guarantee the success of virtual communities. Specifically, these actions might be determined in light of the following issues:

- **Analyzing the Members' Needs:** The community should be created and managed according to the needs of its members, not the needs of the company which promotes it, the advertisers, or any other group not involved in the community.
- **Fostering Self-Management:** If self-management is technically impossible, they should try to create a situation in which the contents of the community are generated and published directly by its members.
- **Minimizing Control:** It is not advisable to establish control mechanisms on how the community members should mix with each other or the topics they should discuss in their conversations.[1]
- **Using the Most Suitable Technological Structure:** The type of technology used to manage a virtual community has a lot of implications. Flavián and Guinalíu (2005b) recommend using technological systems that are flexible, easy to manage, and visually attractive.
- **Specializing Roles:** Several sociological research studies have shown that inside a community it is common for individuals to adopt different roles which give the community a greater dynamism. Taking these findings as a reference, Flavián and Guinalíu (2005a) suggest the advisability of having this role assignment inside virtual communities.[2]

FUTURE TRENDS

For the immediate future, research into the concept of virtual communities is faced with some interesting challenges. Firstly, there is a need to analyze the influence of new methods of communication (e.g., Wi-Fi, Bluetooth, UMTS, or i-Mode), as well as the recent spread of other devices (e.g., Tablet PC, PDA, or Smartphones). Wireless technology will afford community members new means of interaction, while at the same time opening the way to alternative lines of business. Furthermore, there is a need to examine in more detail the application of virtual community marketing strategies aimed at specific sectors. Particularly interesting here is the use of virtual communities in political marketing strategies. Finally, it would be useful to analyze in more detail the role of virtual communities in corporate environments, such as CRM systems.

CONCLUSION

In this article we have proposed the virtual community as a useful ingredient of a successful e-business strategy. Virtual communities have a strong influence on strategic planning due to the fact that they offer a new form a communication, serve as a source of strategic information, generate barriers to prevent the entry of new competitors, increase consumer security and trust, facilitate the development of relationship marketing strategies, and may became a source of incomes and new clients. Nevertheless, the success of these strategies is dependent upon the monitoring of trends, such as helping self-management by minimizing control on the group dynamic, defining roles, or using suitable technologies.

ACKNOWLEDGMENT

The authors wish to express their gratitude for the financial support received from the Ministry of Education and Science and the Aragón Government (S-46; PM34) and Telefónica.

KEY TERMS

Bluetooth: Wireless telecommunications system which provides a way to connect and exchange information between devices like personal digital assistants (PDAs) or mobile phones.

Community: Social network whose members are characterized by a common interest, similar behaviors, and a sense of moral responsibility.

CRM (Customer Relationship Management): Systems with technological tools related to the implementation of relationship marketing strategies.

i-Mode: A wireless Internet service for i-mode mobile phones using http protocol.

Relationship Marketing: Marketing activities and strategies related to the creation, maintenance, and development of successful relationships.

UMTS (Universal Mobile Telecommunications System): One of the third-generation (3G) mobile phone technologies. This technology provides the mobile phone access to several services, such as videoconference.

Virtual Community: Community that uses the new communications technologies (e.g., the Internet) to maintain and develop social interactions.

Wi-Fi: Short for wireless fidelity"; a set of product compatibility standards for wireless local area networks (WLANs).

ENDNOTES

1 In this respect we may say that establishing control mechanisms on how members relate to each other is not very advisable. In fact, the use of a certain communication system cannot be imposed. Secondly, some freedom in the contents of conversations and messages should be granted. Obviously, any contents that may be offensive for the company or other members should be screened, but excessive control is not recommended. The community itself will create its own internal rules and will reject those participants who do not provide any value. In fact, it might be interesting to create a space where the members are free to talk about anything they want to, even though it has nothing to do with the community's primary aim. It is also advisable to publish on the Web site the community's conduct rules as soon as they are defined.

2 Some possible roles are: (a) social weavers: individuals who introduce new members to the community; (b) moderator: a respected member who channels the debates into a suitable direction and regulates conversations; (c) knowledge manager: a member who evaluates and searches for useful resources for the community; (d) opinion leader: a respected member who defines the community's ideological tendencies (establishing a system of scoring the members' comments is an interesting possibility for the group to define who is a leader and who is not); and (e) instigator: a member who, voluntarily and respectfully, proposes controversial discussion topics, thus encouraging participation.

Virtual Concept Use in the Construction Industry

O. K. B. Barima
University of Hong Kong, Hong Kong

INTRODUCTION/BACKGROUND OF ORGANIZATION

Introduction

History is laden with many technological breakthroughs which have had enduring impacts on business affairs (e.g., automobile, mass power generation, etc.). It also appears that modern information and communication technology (ICT) tools, especially the Internet, have had some impact on the way in which business and other task deliveries are conducted. Aligned to this is the emergence of virtual model in business where people are able to operate independent of time and space via dependence on modern ICT tools to attain specific goals. During the previous decade (1990s) various virtual organizations (or "dot-coms") emerged and they were touted to be the future of business, and hence with the potential to completely overthrow traditional companies (see, e.g., Mandel, Ho, Himelstein, Foust, & Muller, 2001; Ousthuizen, Koster, & Rey, 1998). Although the end of the 20th century saw the demise of most of these companies, however, a few surviving ones like the search engine company Google have made significant impact in recent times by overtaking traditional companies like General Motors and Ford Motor Co. in terms of market capitalization (via an estimated value of about $27 billion in year 2004) (see, e.g., Shinal & Kopytoff, 2004).

Further to the above generic review of the impact of the virtual organizations, seminal accounts also exist on the significant use of the virtual concept to support engineering task delivery by traditional companies. In the aviation sector, for example, Boeing Co. pioneered the use of the virtual concept to support task value delivery processes via its first virtual collaborative design using 230 design/build teams which started in 1990 and resulted in the unveiling of Boeing 777 in 1995 (see, e.g., Rayport & Sviokla,1999; Russell & Flack, 1998). Boeing Co. thus avoided the use of traditional physical airframe prototypes of the proposed aircraft, and leveraged information-based virtual product prototypes (with the relevant laws of physics and material science) assembled on computer, and this aided the avoidance for physical means to solve conflicts of space (Rayport & Sviokla, 1999; Russell & Flack, 1998). This initiative led to massive gains in terms of 75% reduction in rework, testing of many designs at lower costs, better speed, and hence gains in efficiency (Rayport & Sviokla, 1999; Russell & Flack, 1998). On the other hand, Ford Co.'s first initiative via the Advanced Vehicle Technology project to use virtual model across geographic locations over traditional physical collocation resulted in efficiency levels which were a third less than physical collocation delivery (Russell & Flack, 1998). To sum, the accounts given above concern the potential success and "failure" in leverage of the virtual concept in business activities, from both generic and specific applications. One may extend this thinking to explore what lessons may also be learned from other industries like the construction industry on the leverage of the virtual concept to deliver value? With the virtual model depending to a great degree on the use of modern ICT, a track of diverse research on ICT in construction may be useful to enhance comprehension of the trends of research in this area.

There has been useful research on the use of ICT and its related applications in the construction industry for both academic and non-academic purposes. Research on pedagogic applications for architectural "studio" studies (see, e.g., Dave & Danahy, 2000), or construction and technology purposes (see, e.g., Clayton, Warden, & Parker, 2002) have provided understanding in the use of the concept in training students to experience the virtual concept. Studies focused on virtual structural designing/analysis, etc. (see, e.g., Deng & Nguyen-Minh, 2003); or software development and description oriented studies (see, e.g., Connell & Tullberg, 2002; Craig & Zimring, 2002); or virtual realty tools for the management and operation of construction activities (see, e.g., Caneparo, 2001) have assisted in moving the field forward, and also enhance actual construction operations. Survey-based studies which track the generic use of IT in construction (see, e.g., Howard, Kiviniemi, & Samuelson, 1998; Rivard, 2000; Samuelson, 2002) provide awareness on the trends in the extent of use of ICT in construction generally. The case-based research like that of Rivard et al. (2004) which gave an account of specific applications of IT use in the Canadian construction industry offer knowledge on emerging pioneering trends in the industry. However due to the relatively “youthful” age of this area of research there appears not to be much empirical studies which focus on the use of the virtual concept in construction value delivery. This article explores the leverage of the virtual model in delivering value in the construction industry by a construction company in Hong Kong. First, general issues (which includes an overview of the research activities) and the background of the company is given, before descriptions and the impact of the applications are presented.

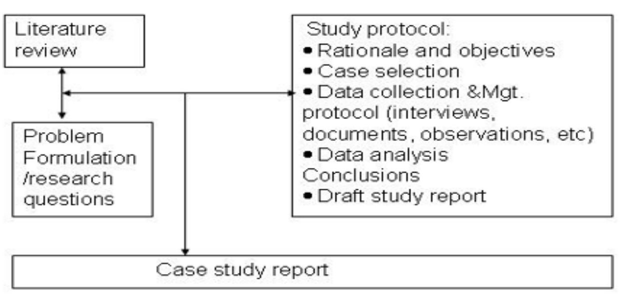
General Issues and Overview of Research Activities

The aim of the study was to explore the experience of the use of the virtual concept by a selected company in Hong Kong. Thus, to explore the question on how it uses the virtual concept in its task delivery processes to deliver value? This study (which is part of a broader study) is hence exploratory and descriptive in nature and has the unit of analysis at the organizational level. For the sake of confidentiality this company will be referred to as Case 1. This company is a construction contractor, and it was selected on purpose. A key reason for selecting this company was that it is perceived as one of the leaders in the local industry. The evidence provided herein is an analyzed data based on cross-verified in-depth interviews of senior company executives, archival data, observations, etc., and the use of a research study protocol (see, e.g., Rahim & Baksh, 2003) which set out (among others) the research rationale, objectives and methodology (which included procedures to guide the data collection process). A brief schematic diagram of the research activities is given in Figure 1.

A set of formulated questions was used to aid in the data collection process. This enabled gathering information on the following to achieve the aim of the research:

- The background information of the case company;
- The extent of leverage of the virtual concept in the firm; and

Figure 1. Brief overview of research activities



- Improvements attained (over previous traditional operational methods) through the use of the virtual concept in the case company; challenges and exploratory lessons learned.

The next sections give the details on the case company, descriptions of the application (with prior definition of key concepts), impact, before the conclusions are offered.

Background of Company

Case 1 is a construction company which is over 50 years old with headquarters in Hong Kong. Case 1 maintains other international branches (mainly in Asia) and it has an average annual turnover of about 1 billon dollars (U.S.). The activities of the firm cover a wide scope and include the construction of the following: residential houses (various types); railways, industrial buildings, varied commercial structures including shopping complexes, environmentally based projects and roads and bridges.

DESCRIPTIONS OF E-COMMERCE, E-GOVERNMENT, AND/OR MOBILE COMMERCE

General Issues

Before presenting descriptive applications of the concept, it may be useful to define the virtual concept and value delivery as applied in this article to aid comprehension.

Virtual Concept

Despite the varied inconsistent definitions which exist in literature for this term, this article will adopt this operational definition of the term virtual:

- When specifically applied to the organization or construction project to mean: the combination of skills by firms/groups/individuals (outsourced or otherwise) who depend on modern ICT to imitate the real world or operate independent of time and space, and collaborate to achieve common goals (see, e.g., Barima, 2003; Duarte & Snyder, 1999; Ousthuizen, Koster, & Rey, 1998).

To enhance understanding of the virtual model, a comparison with the traditional construction concepts may also be useful. In the traditional models there may be the reliance on traditional means like physical face-to-face, traditional postal delivery service, etc. for communication. Further in traditional construction processes the use of hardcopy versions of construction drawings, documents and designs, etc in addition to physical interactions between actors may be dominant. The extreme scenarios of the virtual and the traditional models may be perceived to be on the two ends of a continuum, with potential hybrids of them possible (Barima, 2003).

Value Delivery

While value delivery may have varied definitions to different people/stakeholders in a construction process, in this article this may be taken to mean the effectiveness and efficiency in delivering the tangible or intangible construction products from conception to asset disposal. The next section presents descriptions of the driving factors and leverage of the virtual concept in the company's operations before the impacts are offered and discussed.

Descriptions of Application of Virtual Concept

The Driving Factors, Management, and Creation of the Right Environment

Case 1 faced major problems and challenges with visibility and certainty in its task delivery and communication processes. Critical intra-company value delivery activities and processes, and also those with their key partners were deemed undesirable. For example, in a particular time span the company handled about 60 dispersed construction project sites, and not all activities including those at the headquarters were easily accessible and visible in real time to all the key staff. Aside the intra-company problems, the transactions and the activities of their key partners, like subcontractors, suppliers etc were also uncertain, invisible and involved a lot of paperwork and other bottlenecks. Such events obviously affected business efficacy, effective collaboration, and hence overall delivery efficiency and effectiveness. To overcome this problem, a vision was crafted to improve the construction value delivery processes via the use of ICT in a visible linked fashion across the company's value chain. This transformation process involved the primary adoption of enterprise resource planning (ERP) system to integrate functional activities both within the firm, and also with its key external partners (in the company's value chain). Apart from the ERP system other ICT tools like mobile phones, geographic positioning systems (GPS), video-conferencing tools, etc are also used to support virtual task delivery and collaboration to fit particular core needs. For instance GPS is particularly applied in tracking concrete delivery trucks, whilst the other tools are used to aid collaboration irrespective of time and location in value delivery efforts.

Top management created the right environment for the acceptance of the concept at the outset of the project, by emphasizing the important roles which every functional department had to play in this, as well as encouraging the active corporate involvement of both cross-functional staff and other key external partners. Top management also provided leadership via playing an active role in all key planning and implementation activities. For instance they demonstrated their proficiency in the use of the implemented ERP system to all relevant staff via accessing key information (in their domain) in real time which was previously not visible to others.

Observed Operational Changes

Observed changes from the previous traditional operational methods obtained through the use of the virtual model include the following:

- Real-time access to information and also improved collaboration between relevant staff and partners across its scattered construction project sites (which in particular periods may be about 60 in number).
- Innovative support for the production of concrete, a key product that is used in most construction activities. This is attained via the use of electronic communication across the various activities of concrete production (at the batching plant), transportation and delivery of the product to the final placing locations. The dispersed construction project sites daily communicate their demands electronically to the concrete production plant, then because of the integrated communication systems with the company's material suppliers (i.e. cement, aggregates and sand) these requests are then quickly fulfilled and paid for relative to consumption. Material storage is hence reduced, and this in turn provides associated cost savings. The company also uses GPS to coordinate and schedule the 'just-in-time' arrival of all trucks at the concrete batching plant, and also regularly track and evaluate the setting times of the concrete to optimally deliver the concrete at the destined locations for placing. It must be noted that the setting time of the concrete could affect the quality and hence the strength of the final constructed product.
- Electronic aggregation of clusters of material and other requisitions from all scattered construction projects sites, which provide the opportunity for lower costs via bulk purchases. Further, the electronic integration with all subcontractors and key

suppliers (e.g., fuel, etc.) across the value chain also enables easy generation of invoices and electronic payments which leads to savings in time, etc.
- Information capture to foster learning and hence the building of intangible capital for future potential construction projects.

Challenges

Problems faced within the case company in the leverage of the concept include occasional errors and computer bugs. Security issues are dealt with via use of firewalls and intrusion detection facilities. Further, there is the provision of 3 levels of security to aid detection and the tracking of any intrusions.

IMPACT OF E-COMMERCE, E-GOVERNMENT, AND/OR MOBILE COMMERCE ON THE ORGANIZATION

Observed Impacts in Value Delivery

The use of the ICT tools described above has enabled the company's staff and its partners to collaborate irrespective of time and location to improve on the efficiency and effectiveness in their task delivery. Thus improving on the company's value delivery processes relative to its previous traditional methods of operation. The impacts are particularly visible in the following:

- Improved visibility and certainty, as all relevant staff are able to see the company's activities in real time across the value chain.
- Reduction in the inventory of certain key materials (like cement, aggregates, etc.).
- Quicker fulfillment and payment for materials and other key inputs used on a daily basis (e.g., fuel, cement, etc.).
- Improved support for liquidity and other financial planning issues. Top management and all key staff are able to track in real time the status of invoices and any unpaid due amounts for certified work, and hence become aware in real time of any accountable units. This provides the opportunity to proactively avoid unnecessary delays in payments.
- Significant savings over previous traditional methods in terms of digital information storage, retrieval and dissemination via electronic value adding processes. This has for example saved the company the following in terms of storage space and associated costs:
    - Avoidance for the physical storage space for certain documents (drawings, pieces of paper, etc.). For small projects these documents are estimated to be about 8000; in large projects, this is between 35,000 to 50,000; whilst for particular very large projects this may be about 100,000.
- Relatively improved bidding rates and prices for competitive tendering for construction works, via leverage of key monetary savings and improved productivity in its operations. This in turn increases the chance of successful bids.

Discussion of Impacts

This case shows the potential benefits and positive impacts which could be obtained via the well orchestrated leverage of the virtual concept within the value delivery processes of a construction company. Whilst some of the benefits may be tangible like time savings, cost avoidance and savings, the intangible elements like visibility, certainty, convenience for all partners (could although be difficult to measure) have definite obvious benefits. One other important thing to note is the relative improvement in its competitive bidding capacity for works in the local construction industry where there is often fierce competition for works. On the other hand the problems faced like occasional errors and potential computer security issues prompt the important need to deal with potential risk management issues against complete systems breakdown via security breaches, etc. This could imply major negative impact for an activity like concrete production, transportation and placing with catastrophic related losses. Some of the identified benefits (improved efficiency, productivity, speed and better access to data) compare with certain research on IT use in construction in Canada (see, e.g., Rivard, 2000) and contrasts with Arif and Karam's (2001) survey study in South Africa which suggested the lack of conviction that the use of IT reduces costs.

CONCLUSION

This article presented an explorative descriptive case study on the leverage of virtual concept for value delivery in the operations of a construction company. The study demonstrates that the successful orchestrated leverage of this concept has definite potential benefits, since this has enabled the case company to attain tangible savings like time, cost, storage space and inventory reduction, and improved visibility across functional areas. One important issue is the potential ability of the company to leverage attained efficiency, savings, etc. to provide better competitive bid prices for the procurement of new works to increase the probability of successful bids in an industry where there is fierce competition for construction works.

KEY TERMS

Concrete: Is an important construction product which is formed via the combination of aggregates (fine and coarse), binding material (like cement) and water.

Construction Project Sites: Refer to the physical geographic locations where construction works are done to produce the physical construction products.

Construction Tendering/Bidding: Involves the process of selecting suitable firms to execute any proposed construction project. Various criteria which includes the firm's bid price and its capabilities may be used for selection.

Enterprise Resource Planning (ERP) System: Is an information technology tool with capacity to integrate a firm's business functions or facets (like: planning, manufacturing, marketing, human resources, finance, procurement, etc).

Geographic Position System (GPS): Is a satellite based system with applications for determining locations, navigations, and monitoring the movement of people and objects including provision of accurate times and velocities.

Virtual Collaborative Design: Refers to two or more designers working together irrespective of time and place to deliver a common design product with the use of networked information and communication technology tools.

Virtual Realty Tools: Computer tools which aid the imitations of the real world's scenarios, places, etc which a person could experience or part-take.

Virtual Enterprise Organization

INTRODUCTION

Competition among enterprises is changing. Initially competition was made between individual production systems. Now we are assisting to development of another kind of competition between production systems organized according to virtual enterprise (VE) concepts. This new focus is motivated by several aspects. The new global markets and the evolution of technologies and communications accomplished by the unpredictable consumer's attitude may be pointed out as the most relevant. Understanding social, economical, and technological changes, and taking advantage of them, is the path that will allow production systems to sustain their competitiveness. In this path, enterprises must make radical modifications, both inside their boundaries and also in their relations with partners and competitors. Coordination of participants in new forms of organization, such as virtual enterprises, global manufacturing, and logistics networks, and other company-to-company alliances, has become functionally and strategically important (Gunasekaran, Williams, McGaughey, 2005). The definition of each participant function in the organization and overall information exchange have become key components in their manufacturing strategies.

BACKGROUND

Opening countries' borders to external competitors, adding new international agreements between countries, and expanding industrialization processes to undeveloped countries are some of the aspects that have definitively contributed to the appearance of a worldwide economy concept (Alvi & Labib, 2001). New business opportunities are rising and become accessible as countries' internal economical protection borders are falling down. This economical globalization has increased competitiveness intensity and market uncertainty. It also has accelerated the decrease of product lifecycles (Kraemer, Gibbs, & Dedrick, 2002). In this new environment enterprises are allowed to access new technologies and new talents (Atkinson & Coduri, 2002).

Globalization will create new business opportunities, but also introduce worldwide competition. Information and communication technologies (ICTs) are considered one of the most relevant support factors to the latest world changes. In fact, they are an enabler of, and also enabled by, globalization (Kraemer et al., 2002). In a world that desperately claims for innovation, information and communication technologies are nowadays essential to catalyze and speed changes archived in managers' minds (Boyson, Corsi, Dresner, & Harrington, 1999). The ongoing evolutionary process of those technologies will affect enterprises in two different ways. First, considering a more proactive perspective, entrepreneur enterprises may take advantage of information and communication technologies to make an evolutionary jump in new collaborations, new partnership direction, and achieving new business and markets.

Another point of view reveals that enterprises must incorporate information and communication technologies as one of their strategic and operational components (Moodley, 2003).

This technological revolution also has a deep influence on the globalization process, supplying new tools that allow the capture of new global market opportunities. Using these new tools, enterprises became more agile and capable of dealing with changes in a more sensible way. The adoption of ICTs allows enterprises to stimulate a worldwide consumer appetite (Fraser & Oppenheim, 1997). In a global manufacturing environment, ICTs play a dominant role, as they allow the integration of production systems physically worldwide distributed (Gunasekaran, 1999).

One possible way to cope with these new organizational needs is the *virtual enterprise* paradigm (Wu & Su, 2004). A virtual enterprise is a temporary partnership of independent companies and/or individuals—suppliers of specific goods and services, customers—who are linked through modern telecommunications to exploit and profit from rapidly changing business opportunities. In a virtual enterprise, companies can share costs, skills, knowledge and access to specialized expertise, and access to regional and global markets, with each partner supplying what it can do best—whether a product or a service (VEA, 2002).

The virtual enterprise concept is in its youth and growing. In literature it is not possible to find yet a consensual and rigorous definition for all the concepts that surround it (Camarinha-Matos, Afsarmanesh, Garita, & Lima, 1998). More commonly found was the general term *virtual enterprise* and the concept of *extended enterprise*. At times it is possible to ease any confusion, to some degree, by looking at the utilization of each (Rolstadas, 1997). The virtual enterprise concept has a wider scope than extended enterprise and includes it in its meaning (Jagdev & Browne 1998; Camarinha-Matos & Afsarmanesh 1999). We may also be confronted with opinions that consider extended enterprise as the dominant expression. In a virtual enterprise the integration level is bigger and, comparatively to extended enterprise, the partnership agreements are shorter in time (Jagdev & Browne 1998).

In literature it is also possible to find a complete structure that allows developing virtual companies from virtual networks (Franke & Hickmann 1999). The virtual network concept is seen as the organizational part, with long-term duration and without time limit. This means that the set of enterprises that belong to that net are stable. Based on business opportunities, virtual companies are building up from that set of enterprises where the most adequate partners are selected. Virtual companies are dissolved when they have reached their purpose.

The idea behind the virtual organization concept looks to the virtual as being a dimensional organization and not as a distinguished factor (Steil, Barcia, & Pacheco, 1999). Virtual is used to describe an organizational logic especially relevant when geographical space, time limits, organizational units, and information access are relegated to a second level. This type of organization is based on the substitution of the traditional organizational structure by ICTs, seen as essential conditions of a non-institutionalized structure with time-limited cooperation (Sandhof, 1999). The cooperation time may be reduced to the fulfillment of a unique contract. In this sense, the subcontracting concept is being used to new limits (Golder & Brockie, 2001).

Virtual corporations (Davidow & Malone, 1993; Franke & Hickmann, 1999), variable production networks (Wiendahl & Helms, 1997), multi-site production facilities (Roux, Dauzere-Peres, & Lasserre, 1999; Zhou & Besant, 2001), virtual production networks (Tuma, 1998), logistic networks (Schonsleben, 2000), supply chain management, electronic commerce, cross-border enterprises, networks of enterprises (Camarinha-Matos et al., 1998), and virtual manufacturing systems (Davidrajuh & Deng, 2000) are other designations given to the same concept.

Concerning its lifecycle, a traditional enterprise may be seen as a stable organization that searches or creates business opportunities. A virtual enterprise formation is based on a business opportunity that may be seen as the virtual enterprise heart (Van-Schoubroeck, Cousy, Droshout, & Windey, 2001). By definition, a virtual enterprise will exist until the moment that the business opportunity will no longer be profitable. The time from the moment of virtual enterprise first steps formation until its dissolution is known as the virtual enterprise lifecycle (Goranson, 1999). Inside this lifecycle we find several concepts, including formation, reconfiguration or evolution, activity or operation, and dissolution or termination. Depending on the authors, the number of virtual enterprise lifecycle phases may change (Spinosa, Rabelo, & Klen, 1998; Strader, Lin, & Shaw, 1998; Goranson, 1999; Kanet, Faissat, & Mertens, 1999; Rocha & Oliveira, 1999; Biondi, Bonfatt, & Monari, 2000; Davidrajuh & Deng, 2000; Eschenbacher, Knuck, & Weiser, 2001; Katzy & Dissel, 2001; Van-Schoubroeck et al., 2001)

AUTONOMOUS PRODUCTION SYSTEM (APS) CONCEPT

Companies are traditionally organized in a hierarchical structure where the communication is established from top management to bottom levels and from bottom levels to top management through several levels of responsibility. In this type of organization, each department can only communicate with the outside world through the top management channel (Figure 1, top left).

In this work we assume that VEs based on the autonomous production system (APS) concept will increase their agility in coping with market needs (Carvalho, Moreira, & Pires, 2005). Thus, a company, instead of being organized as the traditional hierarchy of departments and sections, should become a network of APS, in a way that the relationships between its APS should be based on a partner-to-partner relationship (see Figure 1). In this way each APS could cooperate equally with an APS of another company for a particular business opportunity, as well as with an APS of the same company. An APS can be considered the smallest part of a company that, if divided, looses its autonomy. We will not concentrate on how APSs are generated. We will assume that they exist and virtual enterprises are APS based (Figure 1, top right). The big difference here is that VEs made from traditional enterprises use all the enterprise structure and APS-based VEs use only the needed APS (see Figure 2).

Figure 1. From enterprise traditional organization to APS-based virtual enterprise

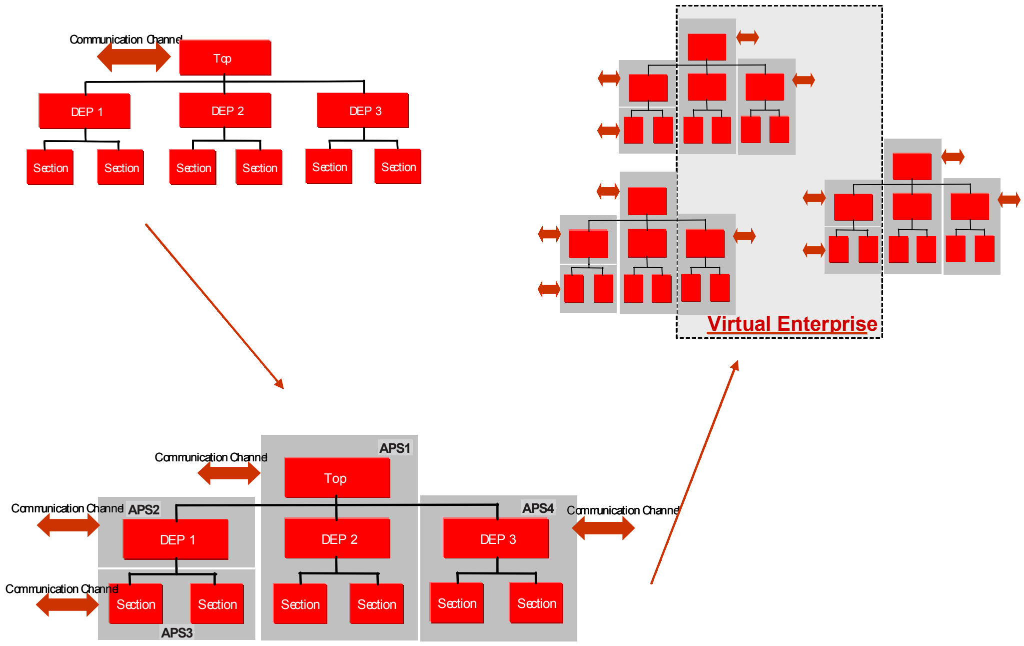

Figure 2. Virtual enterprise made from traditional enterprises and APS-based VEs

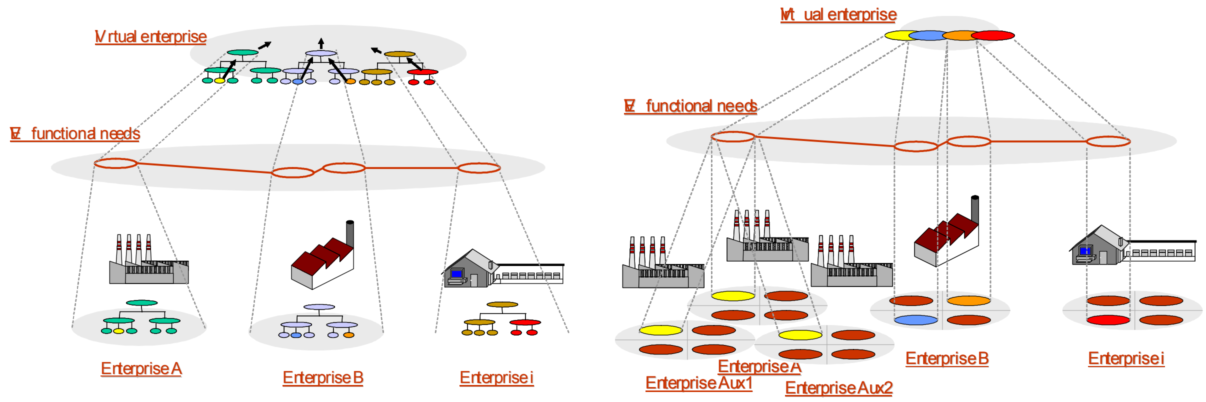


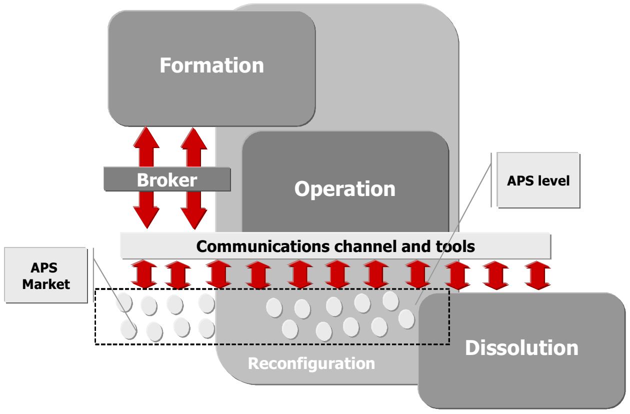
PROPOSED ARCHITECTURE AND FUNCTIONALITY

Some of the problems concerning virtual enterprises are directly connected with the knowledge of how to start up a virtual enterprise, how to find adequate partners to integrate it, how to proceed to manage them, if one can trust them, and who shares the risks, just to name a few.

Keeping in mind these new challenges that enterprises must pass through real integration, we propose a new reference architecture to allow an easier and faster integration, operation, and dissolution of virtual enterprise processes. This set of activities is shown in Figure 3, which represents the main activities of a virtual enterprise lifecycle.

Inside the scope of this work, the virtual enterprise formation is clearly initiated by the appearance of a specific set of conditions at a specific moment in time which we name business opportunity (BO). When a business opportunity is advised, it is necessary to start a rough strategic plan to transform the BO into a concrete business activity. This rough plan must answer ques-

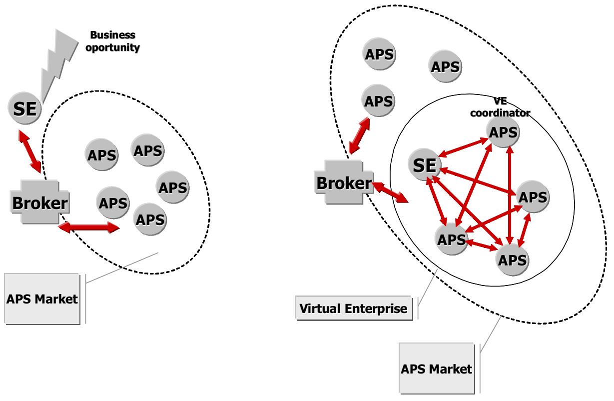
Figure 3. Virtual enterprise lifecycle activities



tions such as: Which tasks must be done to concretize the BO? Which resources and when will be necessary? Who may provide these resources, and how do we manage them? The proposed model intends to answer these questions, providing a set of entities and a functional structure that will aid in making the BO concrete.

The entity that detects the business opportunity, and that will be responsible for conducting the operations that will result in VE formation, is named *starter entity* (SE) (see Figure 4). In our opinion, this SE must have enough knowledge to make a rough process plan. Using this process plan, tasks to find partners to be assigned for necessary activities will be started. It is then necessary to know where to find resources that fulfill the activities specifications. These resources must obey a set of specific conditions, both technical and social. In this work, partners are APSs, and they exist in the APS market (APSM). This APSM is a functional structure where

Figure 4. Entities and structures that participate in VE formation



certified APSs are organized by their core competences. In APSM also exists accurate information concerning APS historic performance, VE experience, integrity, and so forth. Standard operational rules, standard procedures for APS integration in VEs, standard contracts to integrate VEs, and a set of tools to operate in the APSM are also available.

All the operations related to the APSM will be conducted by a certified entity that we call *broker* (see Figure 4). The broker is the APSM operator. Its main function is assisting the SE to find the APS to integrate the VE.

Partners' search activity is based on specifications collected from business opportunity analysis and specification. The search result may lead the broker to many different alternatives for the virtual enterprise configuration. This will be an iterative process until a set of APSs will be selected. All the information produced in these two activities will be worked in VE project activity (see Figure 5).

This activity is performed by: (1) partners' selection activity, (2) product and process specification re-analysis, (3) organizational definition and VE formalization, and (4) BOOM generation. Considering the global model, from the VE project will result a set of important entities and functional information (see Figure 6). The outputs of the VE project will be the base of all VE functionality. One important entity produced by the VE project is the *administration board* (AB). This entity is settled by delegates of each APS or APS set, and its function is administrating the VE. Some of its functions are formalizing standard contracts; defining VE strategy; dispensing, substituting, or incorporating the APS; maintaining legal responsibility; and providing other administrative needs. The VE manager or coordinator is another structural entity that results from the VE project. It is an APS partner whose function is to run the VE, based on the strategy defined in the AB.

Another important structure produced by the VE project activity is the Bill of Materials and Movements (BOMM). This is a nuclear structure of this VE lifecycle model functionality. It contains traditional bill of materials information, plus information about movement needs between each APSs; the assignment of each SPA to each production, purchase, movement, or manufacturing task; and information about the relative moment that a specific task must be executed. During the VE lifecycle, the BOMM may need changes according to product structure modifications, as well as changes occurring in the VE configuration. Reconfiguration tasks may originate from changes in demand. The ability of a VE being quickly redesigned as changes in demand occur is the main advantage of such organization. Consequently, the existence of a structure that immediately reproduces any VE structural modification is critical to deal with all dynamics that characterize the VE environment. It is necessary to have a structure or

Figure 5. VE formation activities in Idef0 format

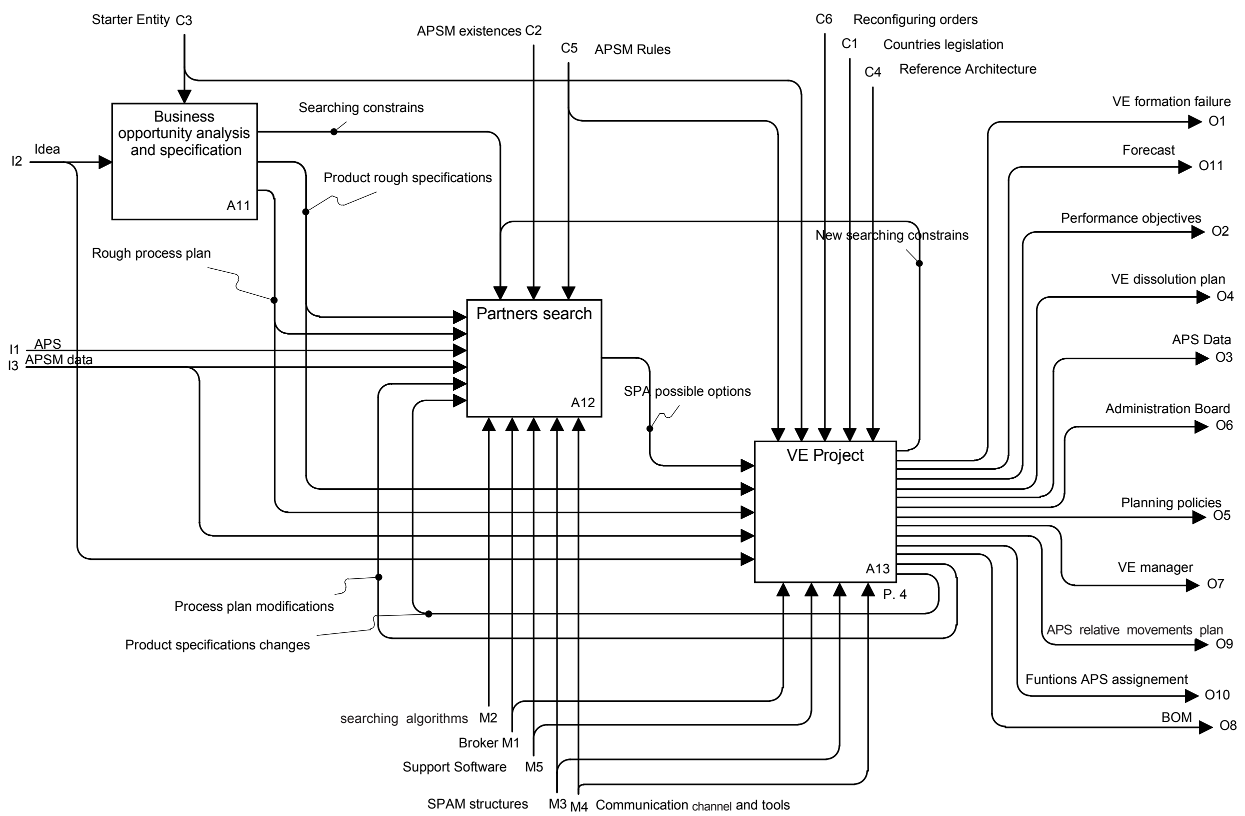


Figure 6. VE project in Idef0 format

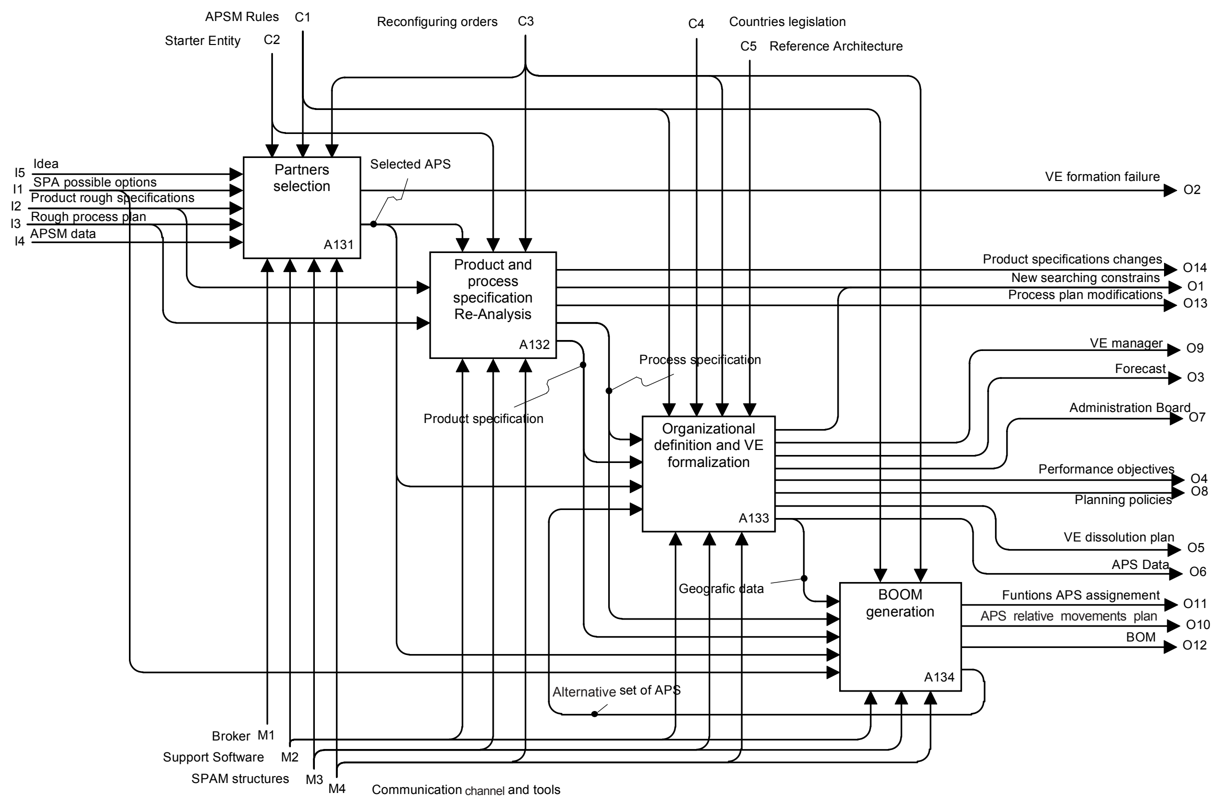

Figure 7. VE operation in Idef0 format

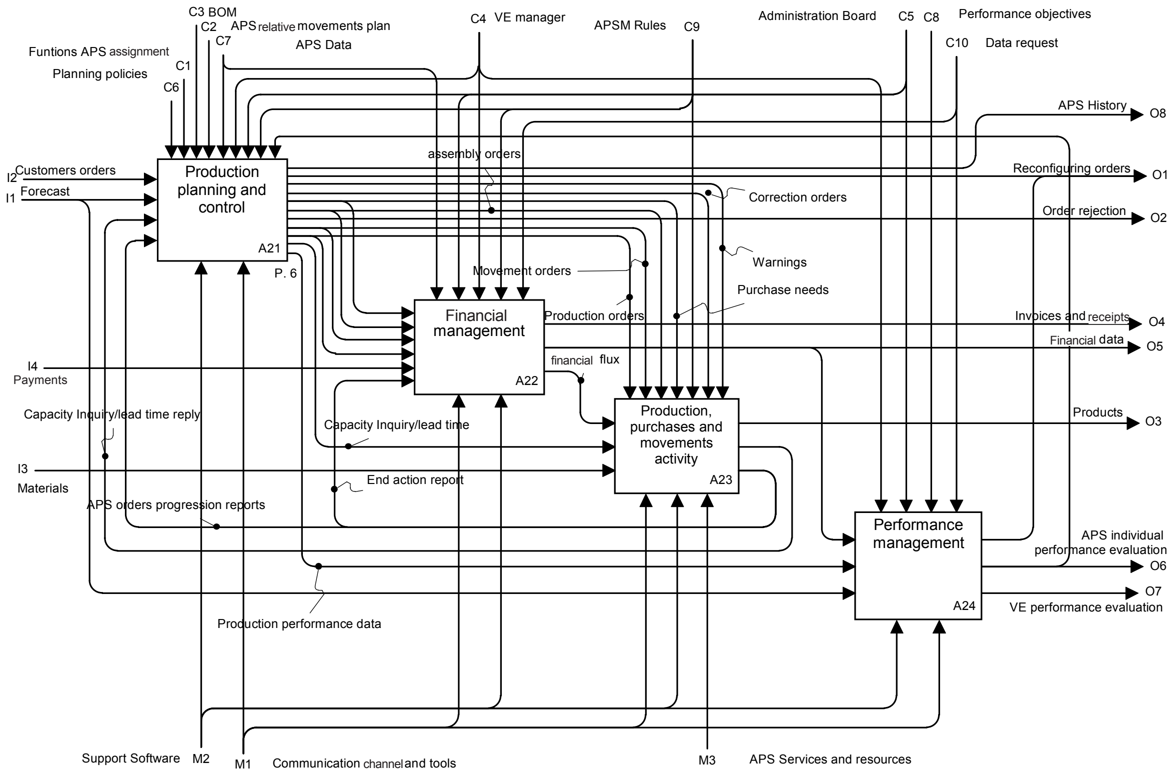

mechanism that relates the APS network production with the customer order or VE internal order at each moment. This aspect is often more important, considering the VE structure will change during VE operation. At the limit, it will change according to each customer order or VE internal order.

Virtual enterprise operation objectives are naturally similar to those of traditional enterprises. From the moment that the client order is placed, the VE has the responsibility to start internal procedures to satisfy the client order specifications. For us VE operation is performed in four main sub-activities (see Figure 7).

Production Planning and Control

This task will be responsible to perform high levels of coordination between all virtual enterprise partners. To do so it will use reengineered production and control tasks, adapted to this new environment.

Production planning and control activity in this model will be responsible to manage APS activity. Thus, production planning and control tasks will be implemented by the following activities: (1) master production scheduling will be performed similarly to those made in traditional enterprises, transforming customers' orders in a feasible master production schedule. These actions are supported in resources (APS) available capacity. If the orders are feasible for the available capacity, the system generates plans for production and movement orders through the (2) materials and movements detailed planning module. Between all those tasks are conditional plans that will check its feasibility until all tasks may be adequately done. PPC activity also includes the (3) production control and VE reconfiguration module and (4) production monitoring module (see Figure 8).

Other tasks that comprise VE operation are *financial management,* similar to those made in traditional enterprises; *production, purchasing, and movements;* and *performance management.*

Finally we have the dissolution phase of the VE lifecycle. Here we are not only concerned with VE dissolution. During the entire VE lifecycle, activities which will sustain the process of entrance and dispense of SPAs will be performed. VE dissolution will receive information from formation and operation phases. The dissolution phase will be sustained in four main sub-activities (see Figure 9):

1. **Continuous Viability Analysis:** Responsible for checking VE viability at all moments.
2. **Normal or Unfriendly Dissolution Process:** Used when VE is dissolved or when individual APS leave the VE. This process may be performed in two

Figure 8. VE operation activities in Idef0 format

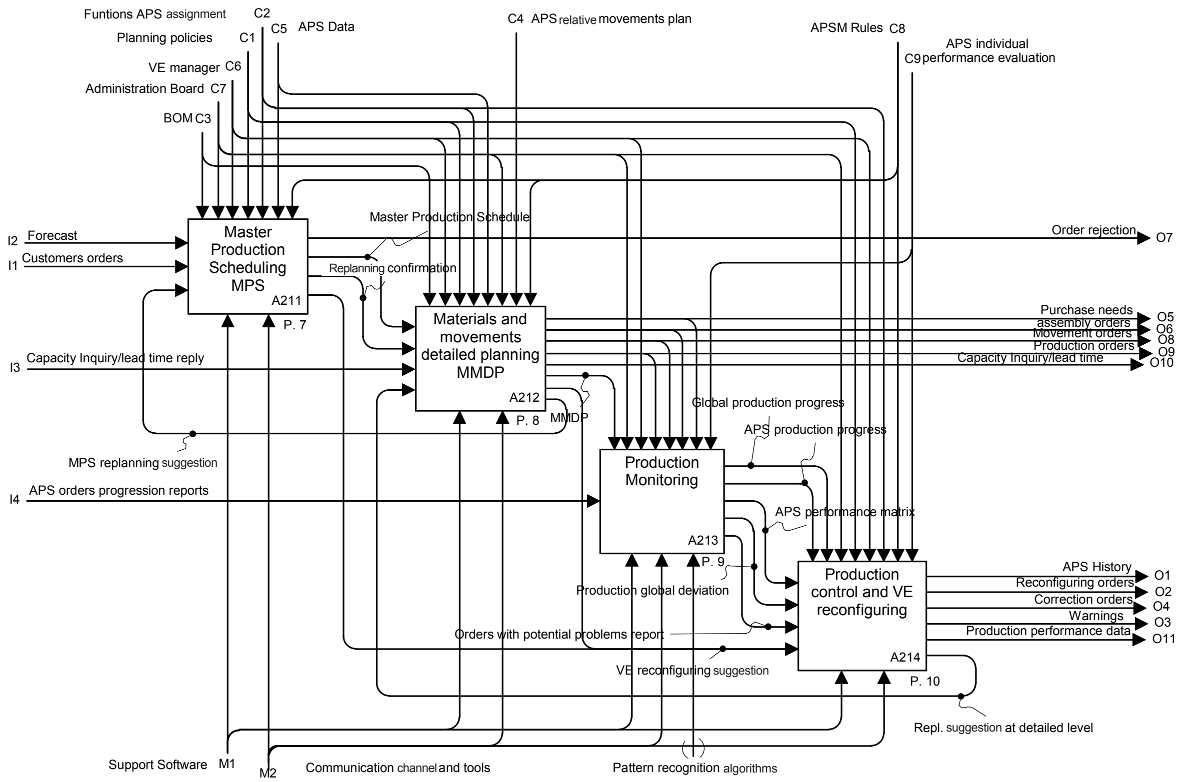

Figure 9. VE dissolution in Idef0 format

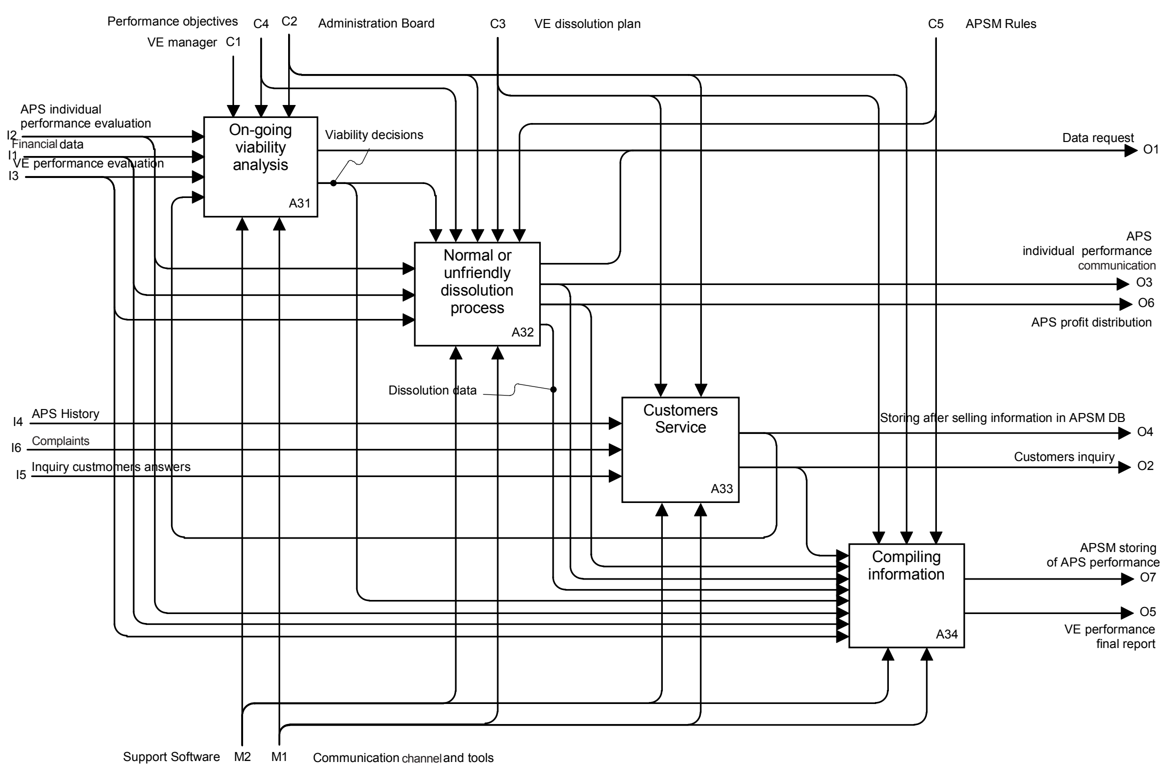

different ways: normal, according to the dissolution plan established in formation phase, or unfriendly.

3. **Customer Service:** Forms the bridge with costumers and is responsible for understanding the level of "product acceptance after sell" information. This will be important in questions concerning warranties and other after selling problems.
4. **Compiling Information Activity:** A functional activity that prepares all the information about this particular VE to store in databases of APSM.

FUTURE TRENDS

The rules are changing. A quick market evolution based on the introduction of new information technologies allows the appearance of new production systems characterized by a high level of automation and flexibility. It may also contribute to an increase in the competitive capacity of enterprises that decide to adopt it. Nevertheless, adopting this paradigm brings not only benefits or advantages; there are some limitations that enterprises must be aware of. The most relevant disadvantages relate to personal relationships, friendships, confidence, and legislation (Carvalho, Moreira, & Pires, 2003), as well the commercial level. Characteristics such as dynamics, great flexibility, agility, and responsiveness—near to the virtual enterprise concept—are potential problem sources (Martinez, Fouletier, Park, & Favrel, 2001). On the commercial level, the virtual enterprise must find the "commercial entry point" (Martinez et al., 2001). Virtual enterprises must work harder to convince the market of their product quality.

There are several subjects that virtual enterprises must cross to work properly, for instance questions concerning the guarantee and "after-selling assistance" problem. Virtual enterprises must have mechanisms that assure assistance even after their dissolution. In consulted literature we were not able to find a solution to this question. Virtual enterprises must also deal with the juridical problem. Countries (a large majority) have not yet adapted their laws to cope with the true meaning of virtual enterprise. Another important issue concerns the problem of confidence among virtual enterprise partners. This will be critical for the VE's success or failure (Chiles & McMackin, 1996; van der Meer-Kooistra, & Vosselman, 2000; Ishaya & Macaulay, 1999; Brutsch 1998).

CONCLUSION

We have presented the main guidelines to the formation of a VE under the APS concept, as well as a production planning and control model for the operation of a VE. Activities of VE dissolution are also depicted in the article. The proposed model does not intend to cover all VE types. It is designed only for VEs that produce low quantities of high-variety products during reasonable periods of time. We hope that the proposed model will also contribute to increase trust levels of potential VE partners.

KEY TERMS

APS-Based Virtual Enterprise: A net of distributed APSs with those same objectives of *traditional* virtual enterprises, but with higher flexibility managing partners' core competences domain.

Autonomous Production System: Part of a company directly exposed to the market which is able to become part of a virtual enterprise when an adequate business opportunity arises.

Bill of Materials and Movements: Includes in a traditional bill of materials the necessary movement of materials between virtual enterprise members.

Broker: Generically, a certified entity authorized to link two different layers.

Business Opportunity: Perfect time interval to efficiently match a specific market need to a core competence and available capacity.

E-Commerce: Means selling items over the World Wide Web. Consequently, enterprises must incorporate new technology information and communication means.

Virtual Enterprise: A temporary network of independent enterprises or enterprise units, connected by new communication and information technology, to share technical competences, costs, and risks accessing thus to new markets, answering to a specific business opportunity.

Virtual Enterprises' Accounting Difficulties

INTRODUCTION

The growth and expansion of enterprises into foreign markets presuppose the aggregation of financial information that includes non homogeneous elements. The purpose of this article is to present several accounting difficulties deriving from the establishment of virtual enterprises and consequently, to set some relevant management and cultural aspects. Emphasis is, also, given to the analysis of the accounting recognition and measurement difficulties deriving from recording accounting information in a virtual enterprise. In conclusion, although there are accounting, as well as, auditing problems of defined, measured and disclosed in a such a type of business, its importance will increase as the capital market grows.

BACKGROUND

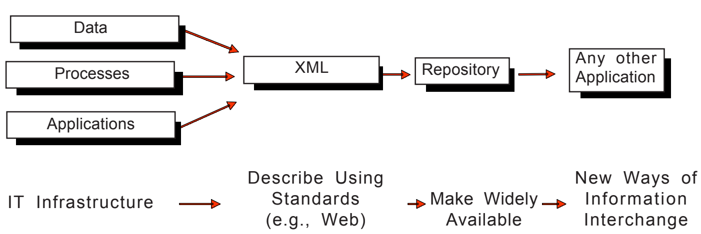
The development of technologies that can efficiently handle information, combined with the expansion of Internet for business process integration, will have a considerable impact on the worldwide market place. This information technology evolution will lead to the creation of a new economic paradigm, the virtual enterprise, where sets of economic actors are combined to provide a service by a single enterprise. Virtual enterprises have very limited resources of their own, but can achieve substantial outcomes using accessible resources of independent partners that become interdependent in achieving the virtual enterprise goals in their common interest. (Beckett, 2003).

One of the main research and development themes is the problem of the virtual enterprise integration, which means the task of improving the performance of the whole organization by managing the interactions among the participants. Its main objective is to improve teamwork and coordination across organizational boundaries (Zarli & Poyet, 1999) by increasing the effectiveness of the virtual enterprise as a whole (Figure 1).

Integration of an enterprise consists of putting components together to form a synergistic whole that transcends traditional external and internal corporate boundaries. Enterprise internetworking uses electronic network to form close ties with suppliers, distributors and customers (Ho, 1997). Problem solving and decision making are conducted by flexible teams cutting across the individual enterprises and distributed over time and space. It is a combination of horizontal integration for a better control of material and information flow and a vertical integration for efficient control of the decision flow.

An integrated virtual enterprise should, also, be able to overcome the changes in the internal or external envi-

Figure 1. Integration process



ronment and enable all the components to contribute to the overall objective in a coordinated way. The enterprise must react to the changes and accordingly adapt its operations.

In selecting the partners for a business opportunity in a virtual enterprise, there are many factors to be taken into consideration. These factors include cost, quality, trust, credit, delivery time, and reliability. (Wu & Su, 2005). The design and management of an efficient and flexible virtual enterprise is a very complex task. It involves different approaches regarding technology, management and cultural elements. High quality business process in an integrated business chain requires properly designed operations. Moreover, it is necessary to use methodologies, reference models, information infrastructures and computer enterprise engineering tools that help in the coordination of different objectives during the virtual enterprise design and management.

An important issue to consider is accounting services of the virtual enterprise specifically when the enterprise spans the boundaries of a country including partners from different continents with very dissimilar accounting standards.

ACCOUNTING ISSUES IN VARIOUS VIRTUAL ENTERPRISES ORGANIZATIONAL MODELS

Virtual enterprises refer to enterprises that consist of groups of people working together on an undertaking, regardless of their physical location, across enterprises and countries (Bobek, Potocan, Sternad, & Spicka, 2002), in real time (synchronously) or deferred time (un-synchronously). A virtual enterprise is a temporary organization of companies that come together to share common costs and skills to address business opportunities that they could not undertake individually. (Gou, Huang, Liu, & Li, 2003). Their existence will challenge large traditional corporations by being able to set up and offer a wider scale of innovative services with less capital in less time and with considerably less financial risk. Aside from competitive advantages, this new organizational model could, also, have other social side effects like, less office space, increased staff productivity and differently balanced work and employees' family life.

Although the idea of virtual enterprises is still in its infancy and every virtual enterprise works under its own agreements between the partners, the virtual enterprise organizational models can be categorized in three types: The supply chain, the hub and spoke (or more commonly referred to as the star), and the peer-to-peer models.

Concerning accounting, the valuation of expenses and revenues for reporting purposes depends upon the reporting objectives and concepts applied. In this case, if the objective is to measure and report the individual assets of the firm for each period, the only alternative is to measure the value of the firm as a whole and subtract from this value the valuation of other specific net assets (Tahinakis, Protogeros, & Ginoglou, 2004). However, if the objective is to measure and report specific assets, in order to provide the users of the financial statements with an indication of the resources available to the firm, an independent measurement of the intangibles might be desirable.

Peer-to-peer topologies and star topologies seem to be the most prevalent for virtual organizations, while supply chain topologies might not require special relationships between companies. The main virtual enterprises categories are:

Static Virtual Enterprises

In static virtual enterprises (SVE), a set of business partners are linked together in a static and fixed way, for example, the shared business processes are tightly integrated (Caraminha-Matos & Afsarmanesh, 1999). The business relationships and the process interfaces are predefined, tightly coupled, fixed, well integrated and customized among partners. The network is fixed and predetermined and thus the structure of the virtual enterprise is static and predetermined as well. Based on the distribution and management style of the network, two types of static virtual enterprises can be identified, namely centralized and decentralized.

The accounting difficulty is connected with the expenses that become a particularly important part for the enterprise. In this case, accounting for the costs requires careful analysis of the department activities. Usually, enterprises undertake costs in the hope of future gains, rather than only present benefits. The knowledge gained is either an asset of the firm or an increase in the value of the existing assets. The return on capital employed will only give a true measure of the company's profitability, if the deferred development expenditure is included in the capital employed (Garrison & Noreen, 2002).

Centralized Static Virtual Enterprises

In centralized static virtual enterprises (CSVE), a dominant business domain (also called business integrator) coordinates the business relationships among network members (Caraminha-Matos & Afsarmanesh, 1999). It enforces the technical interfaces for application integration among partners, integrates the process of the partners by creating shared processes and manages the underlying technical infrastructure and it creates shared business processes for partners in a static and centralized way. Partners and central organization form long-term relationships and focus on investment returns over the lifetime of that relationship. Also, the establishment of the virtual enterprises is performed manually in a customized way and under the full control of the dominant organization. The required integration, development and re-engineering costs are high for all members.

The accounting difficulty connected with the disclosure which should provide adequate information to users of financial statements. In this case the disclosure requirements are intended to improve the financial reporting of business combinations (Wechsler & Wandycz, 1990). This can be achieved by enabling users of financial statements to gain a better appreciation of the business acquired of the extent to which the results of the combined entity are attributable to trading performance.

Decentralized Static Virtual Enterprises

In decentralized static virtual enterprises (DSVE) different business partners are linked together in a rather autonomous and decentralized way (Vesterager, Larsen, & Gobbi, 1999). This type of network is similar to the previous one, except that there is no central, dominant, management organization and each member of the network may cooperate with many other domains. None of the partners has full control over the network and the underlying infrastructure, the integration of which among the business processes of the members is performed in a joint, coordinated and incremental way. Partners with long-term business relationships gain investment returns during the life cycle of those relationships. Moreover, the establishment of the virtual enterprise is performed manually and in a customized way addressing the specific technical requirements of the partners (Karcher, Knarr, & Jungkunz, 2002). The development and integration costs are rather high, while the evolution of the network is difficult.

Every partner plays a role in the virtual enterprise and contributes primarily with their own core competencies, like business processes and resources. In a high tech manufacturing company a member of a virtual enterprise can work on the production of new products, as well as on the distribution of products to different re-sellers.

The accounting difficulty connected with an obligation arises from a contract where the amount and time of payment of the obligation are specified or determinable from the conditions of the contract. Thus, an obligation should be classified as a liability if it can be reasonably measured or if a meaningful range of values or probabilities can be assigned to it. Liabilities can not be included in the balance sheet as separate items unless they can be quantified (Anthony, Reece, & Hertenstein, 1995). However, an inability to quantify an obligation does not imply that it is not a liability in this can it must be disclosed by footnote rather than by listing among the liabilities in the balance sheet.

Dynamic Virtual Enterprises

In dynamic virtual enterprises (CSVE) a set of business partners are linked dynamically on demand and according to customer requirements through the development of a virtual marketplace. The business domains do not have fixed business relationships and thus the virtual enterprise is not static and might continuously change based on market-driven criteria. The virtual marketplace provides services for the registration of partner processes based on certain generic and globally specified process templates. Business domains wishing to form virtual enterprise relationships can register in the marketplace related to certain process templates. Whenever a business domain wants to use a particular process, it searches the marketplace and locates all the potential partners that can provide the service (Katzy & Schuh, 1998). As soon as the list of virtual enterprise candidate partners for one particular process has been found, the selection process begins. The selection process between the domains is usually performed through negotiation. This process might be either manual or automated, while the result is usually a short-term contract that regulates the business relationship among the involved domains. In the development of virtual marketplaces there are no explicit static business relationships among partners and thus no integration is required among the processes of the partners.

The accounting difficulty derives from the treatment of interdivisional transfer pricing. In this case, the final service (product) of one department can be the raw material of another within the same enterprise, so that if transfers are made in excess of cost income will appear at the time of the transfer rather when the final service (product) is sold to the customers. The internal prices affect the reported revenues of the selling segments and reported costs of the purchasing segments. Two broad categories of transfer prices exist, the market and cost based. In general, it is considered that the market based transfer price system is more appropriate because the divisions do business with each other, as well as, in the open market and divisional managers are supposed to react to internal prices as they would react to external market prices (Hendriksen & Van Breda, 1992).

Marketplaces

Marketplaces are usually globally organized specifying services or product templates that can be offered by different vendors (Tarabanis, Protogeros, Walsh, & Koumpis, 2001). The marketplace is a matchmaking mechanism that brings potential process providers together with potential users of these processes. Although marketplaces and matchmaking mechanisms, they have been used for some time for business-to-consumer (B2C) electronic commerce purposes and have not been actually deployed for dynamic virtual enterprise purposes. (Perrin & Godart, 2004). The main reason was the lack of technologies that enable the easy and flexible definitions of process templates, mechanisms for automated negotiation and autonomous interaction among different domains. Due to the advent of eXtensible Markup Language (XML) (W3C) and its ultimate acceptance as Internet, meta-language concepts like virtual marketplaces have started to appear. Furthermore, Web services based on XML is a promising technology that permits the description of business processes in a standard way.

The accounting difficulty connected with the reporting on segments of a business and the decision regarding how logical breakdown should be made for reporting purposes. The main function of segmental reporting is to provide financial information, among others, to investors or potential investors about segments of a business connected with its profitability, risk and growth mainly in order to give them a better understanding of an enterprise's past performance and thus a better idea of its future prospects (Boyle, 1990).

ACCOUNTING RECOGNITION AND MEASUREMENT DIFFICULTIES

Most of the technologies developed today are in their infancy and still under development, requiring considerable effort for the implementation and configuration of comprehensive virtual enterprises support infrastructures. In fact, even the most advanced infrastructures deriving from leading research and development projects still require complex configuration and customisation processes, which are hardly manageable by small and medium enterprises (SMEs).

From the existing literature on the accounting treatment of expenses, it is clear that there are three opposing views as to how expenses should be treated in the balance sheet, as well as, in the profit and loss accounts. However, once a company has selected the appropriate method, it should apply it consistently.

The inherent difficulty in the capitalising and amortising method lies in the high degree of uncertainty associated with the expenses. At the beginning, the management would be required to identify the expected revenue-benefit to be generated and the expected duration. Thus, only when the product is successful should its associated costs be capitalized and amortized through the income statement, by matching the expense with the revenue (Welsch, Zlatkovich, & White, 1972).

An alternative to full capitalization and amortisation is the case of capitalising only costs that relate to specific projects with expected net revenue contribution streams. Under this method all direct and indirect costs are charged and allocated among the specific projects according to the absorption basis. The costs of projects not producing useful results should be charged, according to *accrual concept*, against revenues of the accounting period, in which the uselessness is determined (Lewis & Pendrill, 1995). Costs of successful projects should be capitalised and amortised over the future periods benefited. Thus, these special projects are treated like investments in plant and equipment and the amortisation is similar to the depreciation concepts.

Another treatment is that, all costs should be charged to expense when incurred due to the uncertainty of future benefits, lack of causal relationship between expenditures and benefits. It is, also, based on the lack of interpretation of the assets, on grounds that it does not reflect the value of specific future benefits. If those benefits do exist, their value is not measurable. An immediate write-off may result in lower net earnings, return on capital employed and share price and thus, it renders a company weaker to the threat of a hostile takeover bid. In addition, managers are very concerned with earnings per share and they assume that these numbers are used in the investment decision process (Warren, Reeve, & Fess, 2003).

The choice of an appropriate accounting treatment for expenditure focuses on the application of fundamental accounting concepts. More specifically, the *accrual concept* means all revenues and costs that are accrued and matched within the same economic year. The *prudence concept* by which revenue and profits are not anticipated but recognized only when realized in the form either of cash or of other assets, the ultimate cash realization of which can be established with reasonable certainty. It is an inference of the *prudence concept* that expenditure should be written off in the period in which it arises, unless its relationship to the revenue of the future period can be assessed with reasonable certainty (Schiff, 1974).

Finally, one indirect difficulty is connected with the auditors' responsibility which is to obtain sufficient materials in order to assess the credibility of the financial statements presented by the management. In this regard, there are audit problems including the problem of materiality and the application of materiality criterion in the audit of the financial information disclosed for each asset, especially, the use of market base and the allocation of common cost. The auditors' task is, therefore, difficult because there is no clear guideline by which they are able to evaluate the management decisions.

FUTURE TRENDS

The present article is subjected to a large number of limitations deriving from the fact that realism in experimental research is difficult to be achieved, since the idea of virtual enterprise is still in its infancy. The inclusion, exclusion or replacement of factors could easily lead to significantly different conclusions and results. However, further research studies should be useful to this area. It would be interesting, and also useful, to examine the quality controls and interpersonal factors. More research is, also, needed into the area of impartial and adequate distribution of tasks and protection of proprietary know-how of each industrial partner, as well as, company independence.

CONCLUSION

Virtual enterprises can be considered as a new alternative of organizational form supported by information technologies using and adding to the variety of organizational instruments. The general trade-off flexibility and production efficiency becomes stronger through the use of information technologies and the emergence of new organizational forms. The main goal lies in the description of the modern technologies that enable the integration of virtual enterprises.

An outcome of this study is that there are accounting problems of defined, measured and disclosed accounting information, deriving from a virtual enterprise to users of financial statements. However, the expansion of virtual enterprises together with the extensive use of new information technology will not only enhance the quality of the services offered to customers but will, also, lead to higher benefits and greater economic resources for the government. Despite any difficulties, the importance of such types of business will increase, as the capital market grows and there is a constant need to supply reliable accounting information.

KEY TERMS

Accrual: Concept means all revenues and costs that are accrued and matched within the same economic year.

Assets: Can be characterized as these having physical or non physical existence and their value being dependent on the rights that possession confers upon the owner.

Centralized Static Virtual Enterprises: Refers to a dominant business domain (also called business integrator) coordinates the business relationships among network members.

Dynamic Virtual Enterprises: A set of business partners are linked dynamically on demand and according to customer requirements through the development of a virtual marketplace.

Liabilities: Can be defined as probable future sacrifices of economic benefits arising from present obligations of a particular business to transfer assets or provide services to other entities in the future as a result of past transactions or events.

Marketplaces: Are usually globally organized specifying services or product templates that can be offered by different vendors. The marketplace is a matchmaking mechanism that brings potential process providers together with potential users of these processes.

Prudence: Concept that expenditure should be written off in the period in which it arises, unless its relationship to the revenue of the future period can be assessed with reasonable certainty.

Static Virtual Enterprises: A set of business partners are linked together in a static and fixed way, for example, the shared business processes are tightly integrated. The business relationships and the process interfaces are predefined, tightly coupled, fixed, well integrated and customized among partners.

Virtual Enterprises: Refer to enterprises that consist of groups of people working together on an undertaking, regardless of their physical location, across enterprises and countries, in real time (synchronously) or deferred time (un-synchronously).

Virtual Government in Singapore

Leo Tan Wee Hin
Singapore National Academy of Science, Singapore

R. Subramaniam
Singapore National Academy of Science, Singapore

INTRODUCTION

Governments are a strategic necessity, as they provide the overarching administrative machinery to ensure that national (and citizens') needs are taken care of. The need for the civil service to be more cognizant of citizens' concerns has been reiterated in several recent studies (e.g., Tarabanis, Peristeras, & Koumpic, 2000; Janssen, Wagener, & Beerens, 2003). People interact with the government for a variety of needs, for example, payment of bills for utilities, seeking approvals for licenses, and so on. While this has served citizens well, there is a general perception that governments are generally lackadaisical in terms of response times. Citizens and businesses in today's society have high expectations and demand that their governments be more responsive to their needs. Though upping of civil service head count and decentralizing of official machinery have met with a good degree of success, it has been at the expense of a cost factor which may not be that easy to justify or sustain in the future, especially when there are so many pressing sectors of the economy needing fiscal injections. Any productivity increments achieved in maximizing use of government manpower and resources through various enabling tools means that the savings realized can be deployed back into the economy. The emergence of the Internet has given governments an opportunity to act in this regard. This has given rise to what is known as e-government.

BACKGROUND

The term e-government refers to the use of the Internet to improve work processes in the public sector. It started in the United States in 1995 (Heeks, 2000; Prins, 2001; Ronagan, 2002; Jakob, 2003; Holden, Norris, & Fletcher, 2003).

An e-government allows people to be connected to the bureaucracy at all times. Owing to various factors—basic telecommunications infrastructure is not yet pervasive, presence of vested interests, best practices in e-government are still evolving, and so on—the "off-line" public sector is still firmly entrenched, especially in many developing countries.

In Singapore, a developing country, the e-government has matured tremendously over the past few years (Tan & Subramaniam, 2005). This article describes the infrastructure and standards supporting the e-government in Singapore, provides information on some of the key services that have been "virtualized", and offers a commentary on the efforts of putting in place an e-government. As Singapore was among the pioneers of the e-government movement, its experience would be of relevance to other countries. The Singapore e-government Web site is located at http://www.egov.gov.sg.

INFRASTRUCTURE FOR E-GOVERNMENT

Modern Telecommunications Network

A modern telecommunications network is a must for the smooth transition to e-government. An e-government by itself has little effectiveness if efforts are not translated into promoting connectivity for the citizenry. A technology-neutral approach was taken to deploy a modern telecommunications network in the 1990s. Major telcos were encouraged to roll out different platforms for access. To ensure a level playing field for all operators and to promote the spirit of competition, an independent regulator was appointed.

Five principal telecommunication platforms are now in place:

- Public Switched Telecommunications Network (PSTN)
- Asymmetric Digital Subscriber Line (ADSL): For broadband access
- Hybrid Fiber Coaxial (HFC) Cable Modem service: For broadband access
- Asynchronous Transfer Mode (ATM): For broadband access as well as for linking ADSL and HFC

cable modem service to the ordinary telecommunications network
- Wireless access

These have been addressed in detail by Tan and Subramaniam (2000, 2001, 2003).

With the telecommunications network operating on a plurality of platforms which are interoperable, a competitive landscape has emerged for the cost-effective delivery of services. Table 1 shows the maturation of the telecommunications market in Singapore over the years.

Public Services Infrastructure

The Public Services Infrastructure (PSI) constitutes a core feature of the e-government architecture in Singapore, and comprises a three-tier framework (http://www.sun.com/br/government/feature_psi.html):

- an infrastructural ICT framework;
- a middle layer, which inter-links all government agencies and allows them to host their data in a central data storage facility, as well as integrates all the database software of these agencies; and
- an applications layer, which has security features for safe financial transactions.

Before the installation of the PSI, there was recognition that if the existing ICT systems of the various agencies are to be integrated, the complexity of the various systems and the plurality of the user interfaces would present technical difficulties in migrating these services onto a central portal. The legacies of these systems would also come in the way of restructuring work processes with those of other agencies in an effective manner. All this would come in the way of promoting effective delivery of a citizen-centric range of services.

The PSI enables the various agencies to realize operational synergies and cost savings by riding on the same platform (http://www.sun.com/br/government/feature_psi.html).

For example, e-payment channels, electronic data exchange, and security features of the framework can be used by all government agencies. The cost of introducing new services to the public is also dramatically decreased. This means that economies of scale in the operations allow for significant overall cost savings to be realized by the government.

A tool called the eService Generator allows government agencies or their appointed vendors to introduce new services and applications rapidly and securely on the PSI without the need to worry about source codes. When the New Singapore Shares scheme was introduced in 2001 by the government to reward citizens for their contributions to the economy, the amount of shares allotted to each citizen was determined by factors such as age, income level, and type of housing. An e-portal which allowed Singaporeans to check on their share allotment was conceptualized and rolled out in three weeks on the PSI—compared to six months if it were to be launched on any other platform.

ISSUES IN RELATION TO IMPLEMENTATION

The transition to e-government must proceed in a phased manner. There was little guidance on best practices that Singapore could follow when it started to e-enable its civil service—after all, it was among the forerunners of the e-government movement when it started in 1995 with a Web site offering the public a range of information for their needs. A phased evolution allowed adequate time to sort out bottlenecks and bugs in the system, set the standards, fine-tune the workflow processes of the various government agencies for riding on the Internet, learn from other e-governments, and allow for policy issues to be better understood for proper implementation.

As the civil service started its computerization in the 1980s, it was well positioned to ride on the Internet platform. Workflow processes in the various agencies were streamlined internally before up-linking these to the Internet platform.

As part of the ongoing support for the e-government, an investment of S$1.5 billion was made in June 2000 with the specific aim of reaching out to three segments of the

Table 1. Timeline showing growth of fixed-line telephony, mobile phone, and Internet market in Singapore (Source: http://www.ida.gov.sg)

Sector	1997	1998	1999	2000	2001	2002
Fixed Line	-	1,751,500	1,850,700	1,935,900	1,948,900	1,993,700
Mobile Phone	743,000	1,020,000	1,471,300	2,442,100	2,858,800	3,244,800
Internet Dial-Up	267,400	393,600	582,600	1,940,300	1,917,900	2,000,700

Table 2. Comparison of selected services on civil service and e-government platforms (Source: http://www.egov.gov.sg)

Item	Civil Service	E-Government
Opening new entertainment outlet	2 months for approval	2 weeks for approval
Incorporating new company	S$1,200 to S$35,000, depending on size of company Approval time of 2 days	Online incorporation at a cost of S$300 Approval time of 2 hours
Submitting business plans	Entails separate submission of documents to 12 departments	One-stop submission at G2B portal Savings of S$450

citizenry through the migration of those government services which can be put online. These are now addressed.

Government-to-Citizen (G2C) Portal

This facilitates online access for people with the government any time of the day, unlike the traditional public sector routine of 8:30 a.m. to 5:30 p.m. on weekdays, and 8:30 a.m. to 1:00 p.m. on Saturdays.

The G2C portal hosts a range of information and services which citizens need. That it is well used can be seen from the fact that the number of hit counts registered increased from 240,000 in October 2001 to 8.7 million in May 2003 (http://www.egov.gov.sg/g2c.htm).

In March 2003, SingPass was introduced for citizens aged 15 and above. This offers them a single password to transact safely with any government agency where authentication is required. Previously, government agencies had their own authentication systems for such access.

Government-to-Business (G2B) Portal

This portal sought to show the pro-business face of the government to local and multinational businesses (http://www.egov.gov.sg/g2b.htm). It is common for businesses to interact with governments for various matters, either through mail or visits to the respective agencies. The availability of the necessary information and services on this portal means that businesses can realize cost and time savings by transacting online.

An indication of the effectiveness of the G2B portal for businesses can be seen from data displayed in Table 2.

As many businesses depend on government contracts, competitive bidding for these contracts not only allows the government to get the best value for its money, but also ensures that all businesses stand a chance to get these contracts. Such procedures promote transparency and help to check on any lapses on the part of the government. The Government Electronic Business (GeBIZ) portal was thus set up as an online procurement system for the public sector. This allowed businesses to access a one-stop portal for government contracts. In the year 2002, over S$262 million worth of transactions were done on this portal.

Government-to-Employees Portal (G2E)

This is a portal for civil servants (http://www.egov.gov.sg/gt2.htm). As service levels of the e-government hinge on the quality of the human resources in the public sector, the need for officers to be ICT savvy and be abreast of new developments in technologies and work processes is important. The G2E publicizes the numerous ICT training programs available for staff development.

E-Citizen Center

This portal marks a drastic shift in the manner in which the public interacts with the bureaucracy. Launched in April 1999, all kinds of services that citizens need are listed here (http://www.ecitizen.gov.sg). Annual savings of over S$40 million are realized through this portal (Poon, 2000).

Currently, over 1,600 online services in 16 categories, based on the common needs of citizens, are featured in this portal. Some of the more important ones are indicated below:

- **Education:** Searching for information on schools; registering for GCE N-, O-, and A- level examinations; applying for government scholarships; etc.
- **Housing:** Checking availability of public flats for sale, balloting for allocation of flats, etc.
- **Business:** Registering a business, getting a license or permit, etc.
- **Employment:** Searching for jobs in the public sector, filing income tax returns, checking balances in the employee's Central Provident Fund account, etc.

- **Defense:** Registering for national service, seeking permission for traveling overseas, allowing reservists to book a date for their annual Individual Physical Proficiency Test, etc.
- **Family:** Registering birth and marriage, applying for work permit for foreign maid, etc.
- **Travel:** Applying/renewing of international passport, etc.
- **Parking:** Paying of fines for traffic offenses, etc.

Three world firsts are also in place:

1. **E-Judiciary System:** Set up in 2001, it is the world's first paperless civil court system (Wee, 2000). Established at a cost of S$29 million, it has almost eliminated paper transactions in civil litigation cases since lawyers are now required to file their legal papers online. This allows workflow processes in the judiciary to be streamlined, thus contributing to more effective dispensation of justice. The waiting time for litigation cases has been reduced from two years to a few months. This system alone contributes to a savings of about S$4 million a year.
   A survey of law firms in 2003, however, indicated that e-filing has not only resulted in higher costs for them, since their clients have to bear the expenses related to scanning of the large numbers of documents before uploading these online, but has also added to their workload because of the labor-intensive nature of such tasks. Also, court officials did not particularly warm towards the system, preferring instead hard copies of documents. This led to a review of the e-filing system in early 2003 and has resulted in online fees being decreased by 20% and the requirement for e-filing of the voluminous amounts of trial documents to be waived (Lum & Ho, 2003).
2. **TradeNet:** This is an electronic trade clearance system (http://www.tradenet.gov.sg). In effect, the process of obtaining clearances from multiple agencies such as port authorities and customs departments has been migrated to one site. What formerly required the completion of 35 forms has been reduced to just a single form. Processing time has been dramatically reduced from 2-7 days to less than a minute. As a result of these initiatives, it has been estimated that businesses save about 50% on processing fees and 30% on their own administrative costs—this is equivalent to about US$1 billion in savings a year. Currently, over 25,000 companies use TradeNet.
3. **E-Stamping System:** This service allows lawyers and realty agents to get all the documentation for leasing, renting, mortgaging, and other processes to be annotated with an online electronic stamp (Wee, 2000). The repository of documents uploaded onto the agency's Web site also helps to build up an electronic archive, which facilitates easy retrieval of documents. Over S$7 million in transaction costs are saved annually through this service. About 100,000 documents are e-stamped annually.

COMMENTARY

The e-government in Singapore has matured significantly over the years and has cornered several accolades (see Table 3).

It has to be recognized that investments in e-governments cannot be made on a one-off basis. Governments have to be committed to periodic investments to sustain operations at efficient levels. Accumulated experiences and cognizance of evolving practices elsewhere necessitate the need for changing or fine-tuning the format of

Table 3. Ranking of Singapore e-government by international agencies (Source: http://www.egov.gov.sg)

Year	**Agency and/or Award**	**Rank**
2000	Commonwealth Association for Public Administration and Management International Award	Bronze medal for eCitizen Portal
2001	Accenture's 2nd Annual Survey on E-Government	2
2002	Stockholm Challenge Award for Portal Information	1 for eCitizen Portal
2002	Accenture's 3rd Annual Survey on E-Government	2
2002	Economist Intelligence Unit's E-Readiness Rankings	11 out of 60
2003	World Economic Forum's Global Information Technology Report for E-Government Category	1
2003	Accenture's E-Government Leadership in Engaging the Customer Report	2

services delivered online and improving service delivery. Ultimately, these investments will be more than recovered from the savings in manpower and the greater generation of economic activity by businesses. For example, in Singapore following the S$1.5 billion invested by the government over the years 2000-2003, another S$1.3 billion has been made available for the years 2003-2006 in order to further improve services to the public through the integration of the functions of the various agencies (Soh, 2003).

Citizens will not warm towards e-government initiatives if the services are not accompanied by decreased fees and increased conveniences. The payment protocols for services must thus be simplified for the public to make use of these. In putting counter services online in Singapore, the fees payable have been decreased to ensure that more people can transact online.

On the productivity enhancements afforded by the e-platform, a good example is the e-filing of income tax returns. Established at a cost of S$2.2 million in 1998, this system contributes to savings of S$2.70 per e-filing—chiefly through less paperwork, absence of mailing expenses, and e- storage of documents (Poon, 2000). Taxpayers' penchant for warming towards this initiative can be seen from the fact that the number of people e-filing their tax returns has been increasing over the years: 113,000 in 1998, 484,000 in 2000, 690,000 in 2001, and 700,000 in 2003.

In moving onto the e-platform, dismantling and simplifying of various work processes and protocols are necessary. Though these are necessary for the civil service to function, too many bureaucratic procedures can affect the effectiveness of public administration—in Singapore, an e-government has been a welcome development to do away with unnecessary procedures and legacy protocols of yesteryears!

The hierarchical matrix of the bureaucracy in Singapore has been flattened significantly with the establishment of an e-government. E-mail addresses of public officers, including ministers and other elected representatives, are available in the public domain, and people can contact or follow up with them for their requisite needs. The fact that the top administration officers are within e-mail reach by citizens poses additional responsibility on the civil service to remain effective and answerable—a challenge which has to be met by improved service levels and commitment.

Though the effectiveness of e-governments is not an issue, there are some perceived drawbacks. It is heavily skewed in favor of people who are ICT savvy and who have network access. Those on the wrong side of the digital divide can be marginalized from participation. The human face of the government, which is reassuring in normal public sector participation, can be increasingly missing. With more services going online, rationalization of civil service headcounts in some agencies is an issue which needs to be grappled with. The foregoing concerns apply to all e-governments, and Singapore is not an exception.

Singapore's compact city state structure and well-developed ICT infrastructure are factors which have helped in the maturation of its e-government. Such conditions may not exist elsewhere and, accordingly, some of the practices may not be easily replicable in other countries. However, as one of the top three e-governments in the world, Singapore—through experience—does offer useful ideas on best practices and what works.

FUTURE TRENDS

In Singapore, the e-government initiative is well entrenched and attracts good support from the public and businesses. As it is, the world is now running on Internet time, with the expectations of citizens and businesses at a level that are not that easy to be realized by traditional public sector work processes. The e-government movement in Singapore will thus become more pervasive in the years to come—support for this viewpoint emerges from the observation that there is a growing trend among people to transact online rather than offline for many kinds of government services. This is likely to put additional pressures on those who are interacting face to face with the bureaucracy to learn to move online in order to realize conveniences and cost savings.

More government services will move online in the near future. Further integration among the various government agencies is currently underway, and this will help to streamline work processes for people and businesses through the emergence of one-stop solutions for their needs which are previously catered for by multiple agencies.

There will also be greater participation by the citizenry in the process of decision making by the government as it grapples with various policy issues that affect the country. All this will help to usher the country into "new age" governance with even more transparency. Of course, the traditional public sector will still be there, but it will be leaner due to productivity increments achieved through the migration of many government services online.

CONCLUSION

An e-government is accompanied by increased levels of responsibility for the civil service. This recognition is crucial for positioning the bureaucracy for "new age" governance. More importantly, political vision is the key prerequisite to morph public administration onto an e-government platform, and this has been a key factor in the success of the e-government in Singapore. This has been indispensable in providing the necessary momentum for government agencies to reinvent themselves. It is suggested that aspects of the Singapore experience would be useful for other countries.

KEY TERMS

Broadband Network: Telecommunications network that allows for rapid transmission of voluminous amounts of information.

E-Commerce: Transaction of goods on the Internet using electronic payment protocols.

E-Government: The Web-based equivalent of the public sector.

G2B: An abbreviation for government-to-business, it refers to government contracts and other services available online for businesses to bid for.

G2C: An abbreviation for government-to-citizen, it refers to the various government services that citizens need access to.

Portal: A one-stop site on the Web that provides a range of information and services for people.

Public Services Infrastructure (PSI): An integrated Web services framework that allows for rapid development, deployment, and ease of management of online services.

Category: Applications of E-Technologies

Virtual Marketplace for Agent-Based Electronic Commerce

Sheng-Uei Guan
National University of Singapore, Singapore

INTRODUCTION

Information overload has become a real problem with the ever-increasing amount of available online resources. One possible solution is the application of software agents in e-commerce. Intelligent agents are already on the Web, freeing people from some of the drudgework of searching and automatically keeping them up to date. There are now many examples of software agents currently available on the Web. Shopping agents like BargainBot, Excite's Jango and Andersen Consulting's BargainFinder are but a few. They have their shortcomings, however, such as a lack of purchasing capability and a limited range of product selection. Furthermore, the current Web front-end to an online storefront is not conducive to autonomous browsing by search agents.

A more comprehensive solution would therefore be to build a virtual marketplace whereby producers and consumers can come together, and with the help of software agents, actively participate in and conduct e-commerce. There are currently several agent-based marketplace systems that have been developed for the purpose of e-commerce, and these include Kasbah (Chavez & Maes, 1996), MAGMA (Tsvetovatyy & Gini, 1996) and MAGNET (Collins, Youngdahl, Jamison, Mobasher, & Gini, 1998). These systems have certain limitations, however, and shortcomings that make them questionable for e-commerce applications. An example is the Kasbah system architecture that did not include any form of payment mechanisms. Another is MAGMA, which is felt to be rather expensive on network bandwidth and the system performance is heavily reliant on network latencies as it communicates through socket connections. The objective of my research is to build a new virtual marketplace prototype whereby producers and consumers can meet and conduct e-commerce in the cyberspace with the help of software agents.

DESCRIPTION OF MARKETPLACE ARCHITECTURE

A marketplace is where buying and selling agents meet to negotiate transactions. It is important, therefore, that the architecture of the virtual marketplace is designed to facilitate interactions between agents by providing a secure and reliable environment for the conduct of electronic commerce. A business-to-consumer model has been adopted for implementation in the virtual marketplace.

The architecture of the virtual marketplace can be divided into three separate elements: the Control Center, Business Center, and Financial Center (see Figure 1). Specialist agents reside in each module and work independently as well as collaboratively with the other agents in the virtual marketplace to achieve their goals and objectives.

Financial Center

If a marketplace is to become anything more than a toy, it needs to provide the necessary banking and financial services that are required by the transacting agents (Tsvetovatyy & Gini, 1996). The financial center (see Figure 2) is aimed at achieving these objectives by housing within it various authorized banks, which are able to provide these services. It is a virtual financial hub that

Figure 1. Virtual market architecture overview

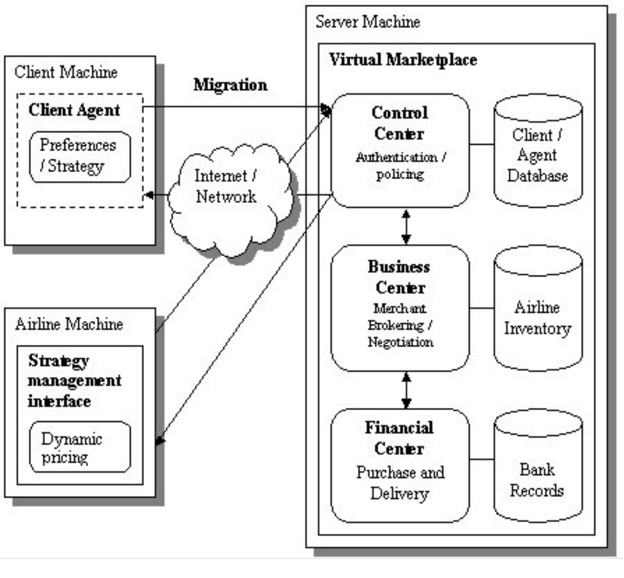

Figure 2. Architecture of financial center

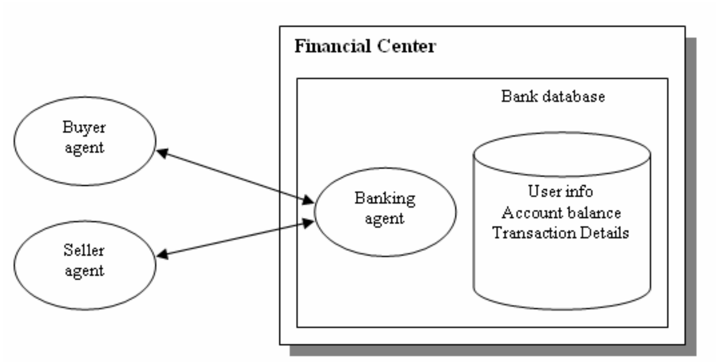

Figure 3. Control center architecture

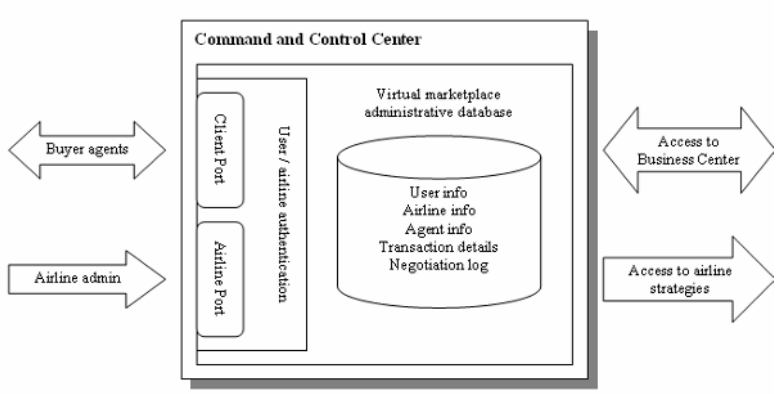


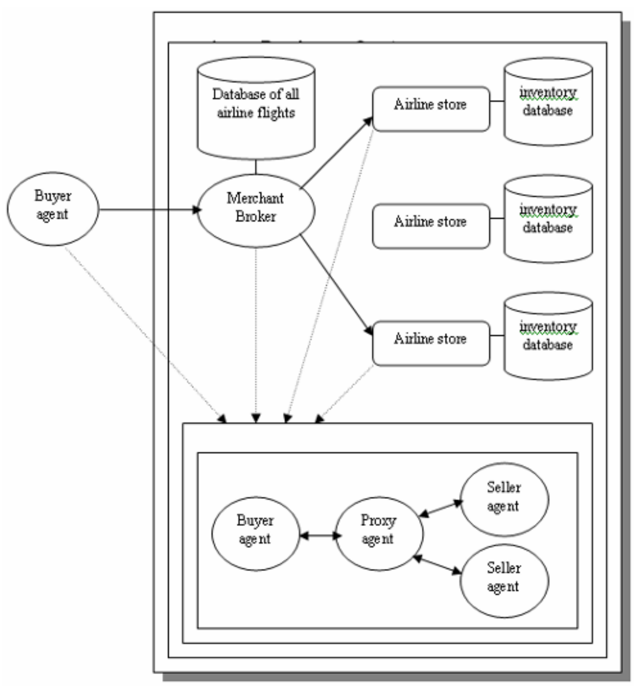
handles all necessary payment activities within the virtual marketplace. The individual banks themselves are represented by their own agents. These agent representatives handle such tasks as verification of legal transactions and assisting in fund transfers from the parties involved in the transaction. They also manage their clients' bank accounts and help carry out the necessary paperwork involved in marketplace transactions. Communication within the financial center, especially those between agent-to-bank or bank-to-bank, needs to be encrypted and secure.

Control Center

The control center (see Figure 3) acts as the administrative center of the virtual marketplace and is the main gateway used by all agents roaming to and from the marketplace. For reasons of security, all potential users of the virtual marketplace will first have to register an account with the control center before its agents are allowed to participate in marketplace activities. Once registered, important user information will then be stored in the market database, to be retrieved for various purposes such as user authentication and user alert notifications. Besides clients, the airlines themselves can also log into the marketplace for purposes of viewing and updating their own customized negotiation strategies. The control center accepts airline connections on a different port to distinguish between client and airline access. To gain access to the server, the airlines will still have to be authenticated.

The control center keeps a list of all active buyer agents currently residing within the virtual marketplace, and it also acts as the policing authority within the virtual marketplace. The agent and transaction monitoring capability is the most important function of the control center. From the time a buyer agent enters the marketplace until it returns home to the client machine, the control center keeps a record of all its activities. Details such as the time the agent entered and left the marketplace, the duration of

Figure 4. Business center architecture



stay, and the owner of the agent are all noted and recorded in the database. If a successful transaction was completed by the buyer agent, the control center will also keep a record of the exact details of the item in question, in this case, details such as flight times, number and cost of each ticket bought, the time the transaction was completed, and so forth. The control center goes a step further by keeping a log of the entire negotiation process that took place between the negotiating parties, regardless of whether a sale was concluded.

With such a monitoring mechanism in place, it is hoped that fraud and misrepresentation by buyers and sellers can be more effectively controlled within the virtual marketplace. This in turn will help increase the level of trust and confidence that users will have in the system.

Business Center

The business center is the heart of the virtual marketplace and is where buyer and seller agents meet to negotiate deals. This research has been modeled after the business-to-consumer model of electronic commerce, and clients are therefore capable of only sending buyer agents into the marketplace to negotiate for items that they would like to purchase. The business center (see Figure 4) consists of several virtual storefronts belonging to various airlines. These storefronts are controlled by seller agents representing the various airlines. Virtual stores are tied into their own individual inventory databases, and they maintain a permanent presence in the marketplace. The agents controlling the stores are akin to sales personnel, and may adopt different marketing strategies based on preferences set by individual airlines.

After a buyer agent has been authenticated by the control center, it arrives at the business center, where it is matched to relevant seller agents by marketplace merchant brokers. The service that merchant brokers provide frees the agents from having to do this additional work. This is important, as incorporating too many functions will inevitably increase the size of the buyer agent, and this will make them more costly to transport through the network. More importantly, it reduces the security risks by not allowing the buyer agent to gain access to the virtual marketplace's database and other system resources. This step can be classified under the merchant brokering stage of the consumer buying behaviour (CBB) model that has been proposed by the Software Agents Group at MIT Media Lab (Maes, Guttman, & Moukas, 1999).

Once potential merchants have been identified, buyer and seller agents can then commence the negotiation stage of the CBB. All negotiations take place in their own particular negotiation session container. This session serves as an encapsulation for a transaction in the marketplace. Furthermore, in the virtual marketplace, negotiations between buyer and seller agents take place through an intermediary, appointed by the marketplace, for reasons of trust, security, and transaction monitoring. This intermediary, which resides within the session, is the marketplace's proxy agent.

After negotiations have been concluded, the finalized deal, together with the respective seller and buyer, are then passed to the banking agent for payment in the financial center. This forms the final, purchase and delivery stage of the CBB. Once the final stage in the buying process has been completed, the buyer agent will then be returned to the client.

Client Application and Airline Management

The design of the client application for the virtual marketplace architecture is crucial. A well-designed client application will facilitate the acceptance and adoption of the application. To facilitate ease of use, it is designed with a user-friendly GUI (see Figure 5) that allows easy configuration of the agent parameters and monitoring of agent activities in the virtual marketplace. It consists of various functions, such as agent retrieval and termina-

Figure 5. Client application interface

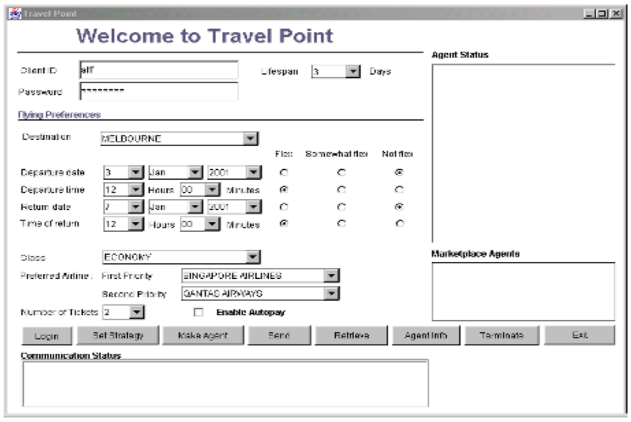


Figure 6. Screenshot of airline pricing strategy management

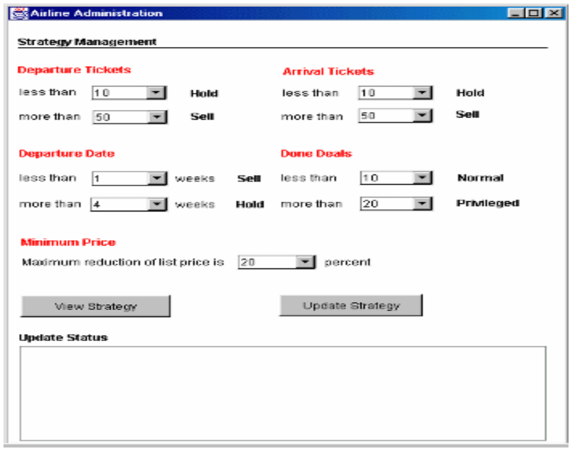


tion. As a business-to-consumer model has been adopted for this research work, the user's role is solely as a buyer looking to purchase airlines tickets in the virtual marketplace that match his or her preferences. Besides flight preferences, the user is also able to configure a custom negotiation strategy.

Airlines are also able to manage their stores within the virtual marketplace via a strategy management interface (see Figure 6). To be granted access to the airline's strategy settings, the airline administrator must first log in and be authenticated by the control center. This strategy management tool allows the individual airlines to customize and personalize its pricing strategy using real-time, individualized analysis. This dynamic pricing capability is an important feature of the virtual marketplace architecture.

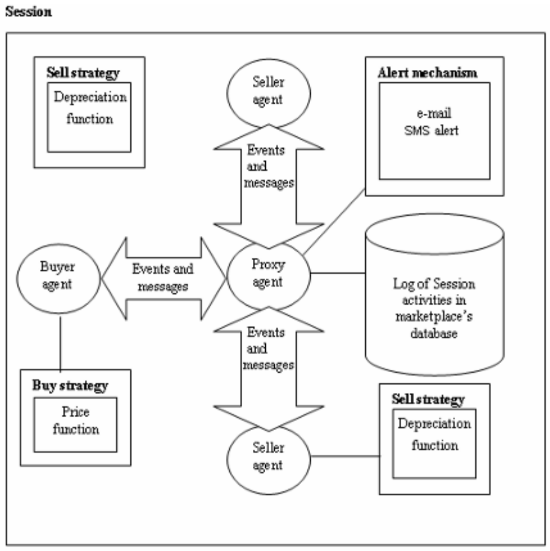
IMPACT OF MARKETPLACE ARCHITECTURE

There are three features of the marketplace architecture that deserve special attention: the negotiation session, the dynamic pricing mechanism, and issues on security, trust, and privacy.

Negotiation Session

A session is created with the creation and implementation of the proxy agent (see Figure 7). To join the session, the buyer or seller agent must first register with the proxy agent. This is done by providing the proxy with an individual, unique agent identification and a reference to itself. The proxy agent thus maintains a list of all agents participating in the session. Initially, the buyer agent is the only party in the session, and it waits patiently for the respective airlines to send forth their representative sellers into the session. Negotiations commence as soon as the first seller agent enters the session and initiates with an offer to sell. It is always the seller agent that initiates the negotiation process. Thereafter, all arriving seller agents will also initiate their own negotiation process. The buyer agent thus has to simultaneously keep track of each individual negotiation with each individual seller agent. Each negotiation process between the buyer and a particular seller is independent of other concurrent negotiations within the session.

Figure 7. Session negotiation mechanism



The session thus serves as an encapsulation for a transaction in the marketplace. This is where all the negotiations between buyer and sellers take place. The session always contains only one buyer agent but may house several different sellers. Due to security issues, these negotiations take place through an intermediary, a proxy agent, designated by the virtual marketplace. There are two benefits to using a proxy agent. First, the agents never have a direct reference to one another, and as such, the security risks posed by malicious agents are reduced considerably. Second, the marketplace is able to closely monitor and log all agent negotiations, which instills an element of trust and confidence in the system by guarding against cases of misrepresentation and repudiation.

Another unique feature of the session is that negotiation is a nonbinding agreement, thus allowing the buyer agent to negotiate concurrently on several items and thereby increasing the chances of obtaining a successful match and a better deal (Morris & Maes, 2000a). The motivation for adopting this design approach stems from a limitation in the Kasbah system, wherein agents always accepted the first offer that met their asking price. In the Kasbah architecture, once an agent makes a deal, it ceases to negotiate with other agents and is removed from the active list (Chavez, Dreilinger, Guttman, & Maes, 1997). In this research, the buyer agent has the capability to wait until all negotiations have concluded before making a comparison. The agent is therefore able to make an informed decision on which is really the best deal on offer, as it is able to compare the various finalized offers instead of just picking the first acceptable offer.

The session is concluded when the buyer agent finally pays for a ticket or rejects all the offers and decides not to purchase anything. Subsequently, all agents associated with the session are stopped and terminated, and the buyer agent is returned to the client machine.

Dynamic Pricing Mechanism

Although the negotiation process currently tends to favour the buyer, the virtual marketplace architecture adds benefits to airlines by providing them with a strategy management tool that allows them to formulate a negotiation strategy based on complex criteria and real-time data, not just price alone (see Figure 6). There are currently four nonprice criteria by which the airline uses to configure its pricing strategy. These are the number of departure flight tickets remaining, the number of arrival flight tickets remaining, the time left to the departure date of the flight, and the number of previous deals that the user has completed with the airline.

Each time a seller agent is dispatched into the session to negotiate with the buyer, the airline store will have to first set the selling strategy of that seller agent. With the dynamic pricing mechanism in place, the airline can customize the pricing strategy of each flight ticket it sells, based on a set of criteria and real-time data from its inventory database. Such criteria will include real-time factors such as the number of tickets left for the flight in question or the length of time left until the departure date. For example, if a flight that is less than 1 week away has more than 50 tickets remaining for that flight, the airline could indicate to its sales representative (seller agent) to adopt a more eager approach to selling those tickets and, as a consequence, would be able to offer the ticket for a cheaper price and eventually made the sale. Therefore, by allowing airlines to formulate their strategies based on a just-in-time, individualized analysis of the immediate situation, it gives the airlines a greater ability to maximize revenue over each flight with better precision (Morris & Maes, 2000b).

Security, Trust, and Privacy

Security, trust, and privacy are important considerations given any electronic commerce application (Corradi, 1999; Greenberg, 1998; Marques, 1999). Furthermore, with the introduction of agent autonomy, these issues become even more crucial. If the trading mechanism cannot be trusted, or is perceived to be insecure to protect privacy, then acceptance of the application will be severely limited. To address these, the following design issues have been adopted.

Secure Transport and Agent Integrity

Because this application is based on a mobile agent concept, the agent and its data will be susceptible to "attack" whilst it transverses the network, especially if this application is deployed over the Internet. Therefore, a secure transport mechanism is required (Guan & Yang, 1999); for example, encryption of the agent before transportation. Agent integrity can also be achieved using a similar mechanism, as in Wang (2001).

Trusted Client Applications

Fellow agents and the virtual marketplace have to be protected from malignant agents. To ensure that only trusted agents are allowed into the marketplace, only agents manufactured from trusted agent factories (Guan, 2001; Guan et al., 2000; Zhu, Guan, & Yang, 2000) are allowed into the server. In this particular implementation, only agents constructed and verified by the provided client applications are granted access to the marketplace. The disadvantage of doing so is that this does not allow clients to custom build their own agents that might have greater intelligence and negotiation capabilities, but this downside is seen as minimal since most users would not bother to go through the complexities to do so anyway.

CONCLUSION

In this research, an agent-based virtual marketplace architecture based on a business-to-consumer e-commerce model has been designed and implemented. Its purpose is to provide a conducive environment for self-interested agents from businesses and clients to interact safely and autonomously with one another for the purposes of negotiating agreements on the behalf of their owners.

The three fundamental elements of the marketplace architecture are the control center, the business center and the financial center. This implementation has been concentrated on development of the control and business centers. Of particular interest are two of the design elements that warrant greater attention: the negotiation session mechanism and the dynamic pricing strategy management scheme that was implemented.

At present, the pricing strategy of the buyer agents are still limited and based on some simple time-based functions. Future work should therefore try to address this issue and work on enhancing the buyer agent's pricing strategy with greater room for customizability by the owner.

Other than the priority airline settings, users are able to evaluate an item based only on its price. This price-based paradigm is a disservice to both buyers and sellers because it does not allow other value-added services to be brought into the equation. Further work needs to be done in this area to address this limitation. A possible solution would be to set up a rating system similar to the Better Business Bureau, which is currently in use in the Kasbah system (Chavez & Maes, 1996). This new system should allow buyers to rate the airlines on factors such as punctuality, flight service, food, and so forth. Users will then be able to evaluate air tickets based on more than just the price and can include the aforementioned criteria listed within the rating system.

Finally, in the current implementation, all sellers (and buyers) are assumed to reside within a single marketplace. This does not fully illustrate the migration capability of buyer and seller agents. Future work should accommodate this aspect.

WEB ACCESSIBILITY

The power of the Web is in its universality. Access by everyone regardless of disability is an essential aspect. (Tim Berners-Lee, W3C Director and inventor of the World Wide Web)

INTRODUCTION

Accessibility means making resources usable by the largest number of people possible, or alternatively, allowing people with some kind of disability to effectively participate in day-to-day activities, including the use of services, goods, and information. The evolution of civil rights enhanced the physical world with several accessibility aids, such as ramps to remove architectural barriers for wheelchair users or bells near elevators for blind users. To address the size of the "disable world", let us consider that only in the European Union there are about 37 million people with disabilities. Disabled people find in the Internet a major reference for their daily necessities to overcome their difficulties in moving and communicating. As institutional, economical, and social services provided through the Web become increasingly central to our lives, to avoid the risk for severe social exclusion, there is the need for "accessibility aids" for the Web. Informally, it means that Web-based content should be presented in a way that allows disabled users to maximally and equally benefit from the information, as well as have the faculty to fully interact with the site. People with physical, cognitive or even technological disabilities should be enabled to effectively read information, browse sites, compile forms, navigate links, download documents, and so on. This goal can be achieved by using a mix of hardware/software solutions, suited to provide specialized input and output capabilities. For example, text-to-speech systems read text on the screen, allowing blind users to navigate Web sites. However, to work effectively, such solutions require Web designers to use Internet technologies accordingly to some recommendations. Incidentally, the recommendations and principles that form the accessibility foundation are very similar to the factors affecting Web quality (Fitzpatrick, 2000; Top of the Web, 2003), and thus can provide benefits to every user of the Internet, whether disabled or not. As a result, accessibility should represent one of the most important references for Web developers.

In this article, we provide an insight into the development of accessible Web sites. In particular, we will start by outlining the historical background about the accessibility issues. Then, we will focus on the design of Accessible Web sites inspired to the *universal design* principles (Follette, Mueller, & Mace, 1998) and *World Wide Web Consortium*'s (W3C) directives, and on the solutions to verify and validate accessibility. Finally, we will give an insight on future trends and challenges due to novel Internet technologies.

BACKGROUND

In order to avoid a growing digital divide in access for people with disabilities, many efforts have been devoted on developing accessibility solutions for the Web. As a result, most of the digital barriers for disabled people can now be easily avoided if site designers follow a set of simple rules, which were mainly defined by the *World Wide Web Consortium's* (W3C) *Web Accessibility Initiative* (WAI) (W3C WAI, 2005). Funded by government, industries and W3C members, the WAI is responsible to create technical guidelines regarding accessible content, browsers and authoring tools. The *Web Content Accessibility Guidelines* version 1.0 (WCAG 1.0, 1999), recognised as a *de facto* standard for the design of accessible Web sites, has three conformance levels (*A*, *Double-A*, and *Triple-A*), depending on the accessibility rank. To ensure an effective level of accessibility, Double-A is recommended.

In many countries, the evolution of disability rights laws have resulted in the understanding that access to information and communication is a civil right for people with disabilities (Waddell, 1999). Then, many governments around the globe, such as European Union, United States, Canada, and Australia, issued laws and regulations demanding accessibility for public organization sites, usually starting from W3C WAI technical recommendations.

European Union resulted very sensitive on this issue, since Web accessibility results to be a strategic objective of the European Commission's Information Society. In particular EU is promoting the concept of *e-inclusion*, aimed to prevent "risks of digital exclusion", that is to ensure that disadvantaged people are not left behind and to avoid new forms of exclusion due to lack of digital literacy or of Internet access (EU 6th FP, 2004).

United States legislation widely covers Web accessibility aspects. The Section 508 of the Rehabilitation Act of 1973, revised in 1998 (Section 508, 1998), imposes strict accessibility requirements for electronic and information systems developed, maintained, procured, or used by federal agencies. Title II of the Americans with Disabilities Act requires institutions to take appropriate steps to ensure that communications with persons with disabilities "are as effective as communications with others" (Section 504). Office for Civil Rights has repeatedly held that the term "communication" in this context means the transfer of information, including the resources of the Internet. This means that U.S. institutions must provide documents in an alternate format in order to remove communication barriers regardless of its original format.

About solutions for making computers more accessible, there are on the market many hardware and/or software products suited to this aim, and collectively named *assistive technologies*, or accessibility aids. Among these there are:

- **Screen Readers:** Making the information presented on the screen available as synthesized speech or through a refreshable Braille display.
- **Screen Magnifiers:** Supporting people with low vision by enlarging a section of information on the screen.
- **Speech Recognition Engines:** Useful to mobility impaired, by allowing people to control the computer via vocal commands.
- **Alternative Input Devices:** Such as larger keyboards or mice, eye-gaze pointing devices, and sip-and-puff systems controlled by breathing.

DEVELOPMENT OF ACCESSIBLE WEB SITES

Integration of the basic accessibility pre-requisite requires careful design and testing phases. In particular, during the design phase, the designers planned the tasks to be performed in order to build accessible Web pages, so that both graphic and textual Web contents could be navigated by disables and could be understood by all categories of users. During the testing phase, testers should carry out a complete and exhaustive verification which combines semi-automatic, manual, and user testing of accessibility features.

Designing Accessible Web Sites

The greater level of accessibility can be achieved by applying the principle of the *universal design*, which states that every design activity has to consider the different requirements from all potential users (Follette, Mueller, & Mace, 1998). When dealing with Web sites, this principle can be applied by designing applications that are easy to use, (i.e., directly accessible from every category of users), possibly in combination with assistive technologies.

The application of the *universal design* principle does not necessarily introduce restrictions in the development of software systems and does not limit the expressiveness of Web developers. Indeed, it should be seen as a creative challenge for everyone involved in Web development and not as a limitation. Currently, many Web sites effectively combine accessibility issue with visual appealing. An example is the Web site of the international project VISUAL (*Voice for Information Society Universal Access Learning*) (VISUAL, 2004), a portal aimed to create an e-community for visually impaired people, and supported by the Information Society Technologies Programme of the EU. Another interesting example is the Web site created for the Exhibition "Edvard Munch. The graphics at Kupferstichkabinett Berlin" (EMKB, 2003).

For Web sites characterized by a significant amount of interactions with users and data sources/sinks, the accessibility requirement is more suitably gained if the design is based on the separation of the contents from the presentation modality. Nowadays, this separation is facilitated by the diffusion of the *markup* languages and the use of *style sheets*.

In the following we provide some recommendations that should be taken into account to design and develop accessible Web sites. They are based on WCAG 1.0 guidelines (WCAG 1.0, 1999) and focus on the design and development activities concerning the accessibility design goal.

Web Site Structure

- A basic task during the design phase is the definition of an overall editorial plan meant to describe the Web site structure and the navigability criteria to adopt. The document usually includes a navigation structure whose thoroughness and formal correctness is ensured by the designer. Moreover, usability criteria should also be followed to avoid the overcrowding of links, and the generation of too length textual sections and complex navigation structure.
- The Web site should include an interactive navigation map to improve the structure comprehension and a search engine characterized by an integrated orthographic checker.
- Moreover, a uniform structure should be preserved.

Web Content Accessibility

- In general the development of an alternative accessible Web site to meet both a high level engagibility and the accessibility is not recommended. Indeed, multiple/parallel versions of the same Web site induce greater difficulties during the modification and/or the updating of the system. However, if the construction of an alternative Web site is the only solutions assuring an acceptable accessibility level, Web engineers should guarantee the consistency between the content of the main Web site and the content of the accessible version. When repairing an existing Web site in order to obtain an accessible version suitable transformations following the (WAI) accessibility guidelines should be performed.
- The design and the development of the documents should be carried out trying to satisfy the necessities of all categories of users. As an example, the options *noframes* and *noscripts* can be used in the case of browser not supporting these type of documents.
- Web developers should avoid to insert too many multimedia objects into the graphical user interface and should identify the right compromise between an attractive graphics and ease of use. Indeed, the use of such components should be limited to the case of true usefulness. However, for each graphic or auditory presentations the corresponding textual descriptions or an equivalent visual alternative should be produced in order to provide the same information to users that cannot access these multimedia components. The equivalent textual description can be simple labels associated to the components or detailed descriptions inserted into other pages connected to the graphical elements through links.
- The use of images as background is advised against. Indeed, figures as background can disturb the perception of the overlapped text by users with cognitive or visual disabilities.
- The use of interactive components is limited to the case of true usefulness, and alternative visualizations are provided when they cannot be managed with assistive technologies for disable people.

Information Formats

- A compressed version should be provided for each high dimension document, together with the necessary files required to navigate it off-line by using a relative link. The formats should be accessible and not property owner (e.g., HTML and text).
- The Web content, its structure, and the presentation should be separately modeled by using style sheets (CSS) in order to ensure consistent transformations of the Web pages when different visualizations can be chosen by the users.
- Tables should be built so that they make sense when they are read cell by cell or row by row, and an equivalent alternative is provided when the mean is not clear. In particular, for tables that have two or more logical levels of row or column headers markup should be used to associate data cells and header cells. Moreover, in some cases a description of the data organization can be useful for a better comprehension of the provided information (e.g., by a legend).

Accessibility Verification

Several tools are currently available for validating Web site accessibility, HTML syntax and style sheets in semi-automatic fashion such as *Bobby* (Bobby, 2005), *HTML Validation Service* (W3C Validator, 2004) and *CSS Validation Service* (W3C CSS Validator, 2004). However, since accessibility involves not only the syntax of the HTML code but also the semantic of the Web content, the above listed tools are not sufficient to guarantee accessibility, but also the human control is needed. Thus, a procedure able to simulate the use of the Web site by disables should be used to assess accessibility. To this aim, some checks can be carried out in order to identify accessibility problems. Several graphical user interface browsers, such as Internet Explorer, Netscape and FireFox, by considering also different versions and different screen resolutions, can be used to verify page selection. Images and sound can be turned off to verify the presence of alternative and appropriate text, and the usability of Web pages can be verified by varying the font-size. Furthermore, the adequacy of color contrast can be evaluated by changing the display color to grey scale, and the accessibility through keyboard commands for all HTML links can be verified. By executing these checks Web developers can perform an initial accessibility verification which is not strictly related to the assistive technologies employed by users with disabilities. In particular, these verifications cover all the necessities of people not affected by sensorial limitation but that cannot take advantages of multimedia components due to the environment conditions or the use of not advanced technologies. Indeed, these checks are based on the deactivation of one or more functionality and simulate disability conditions (e.g., deactivation of graphics to simulate blindness, deactivation of sound to simulate deafness, etc.).

Moreover, when assistive technologies are adopted, like screen readers, alternative keyboard and mouse, we have to verify that the information is equivalent to that provided by a graphical user interface browser, and is understandable when serially read. In particular, such type of verification allows to suitably simulate the operating conditions of users with disabilities.

Now, let us observe that in order to ensure accessibility a testing phase involving also people with different disability is necessary. Indeed, a Web site can still be hard to use by disables even if the system follows the technical accessibility standards. On the other hand, it is widely recognized that the only technical accessibility does not ensure usability. Indeed, when dealing with Web sites several usability features should be taken into account in order to meet the usability requirements (Nielsen, 2000). In particular, ease of learn, orientation, navigability, and content comprehension are all factors that contribute to gain user satisfaction.

FUTURE TRENDS

We are at a technology crossroad. Internet technologies are continually evolving, moving toward multi-modal, ubiquitous, and context-aware computing. We are also experiencing a shift from Web content publishing to Web applications. Such profound changes can be an interesting challenge from the accessibility point-of-view. Some of these novel technologies have requisites very similar to the accessibility, such as Internet-enabled smart phones, automotive information systems, Web TV, etc. This can be a very strong motivation for the development of accessible contents, since Web accessibility is one of the best foundations for device-independent access to the Web (NCDDR, 2001).

Another branch with potential huge benefits for Web accessibility is the Semantic Web Activity, which focuses on the development of machine-understandable data on the Web. It deals also with the possibility to link resources on the Web that can support accessible description and/or rendering of Web content.

On the other side, new emerging technologies allowed by large bandwidth (audio/video streaming, Webcast, etc.), as well as solutions available for digital rights management (DRM), can pose heavy accessibility challenges, while some other areas of evolving Web technology can be a two-edged sword. For example, vocal interfaces can be a concrete benefit for people with visual impairments, but also a barrier for people with auditory disabilities.

However, to address these new issues, many efforts are devoted by international Web community. Now, technologies developed by W3C are reviewed for potential accessibility barriers prior to be released. For example, WAI worked internally in W3C to address potential accessibility concerns in the development of scalable vector graphics (SVG). In the mean time, W3C WAI is currently working on a new version of accessibility recommendations, currently available as a draft and named WCAG version 2.0 (WCAG 2.0, 2004).

CONCLUSION

Since few years ago, many organizations deemed the creation of a text-only alternative to be enough for disabled users. However it is now clear that accessibility does not necessarily limit the expressiveness and creativity of Web developers, but instead it is a kind of usability, and then accessible Web sites are usable Web sites.

Moreover, providing accessibility brings both ethical and business benefits. Putting accessibility at the forefront of the development process will reduce in the long-term costs of the site (Arch & Letourneau, 2002), as maintenance and server overheads are reduced. Moreover, Web sites that are simple to navigate will bring repeat visitors to the site, creating an environment that will bring more users in contact with services and products. Thus, developing accessible Web sites is an important social requirement, but it is also a way for increasing market share and audience reach, and improving Web sites efficiency (Arch & Letourneau, 2002).

A fundamental goal of the international community should be the removal of technological barriers, for giving the users the possibility to navigate through Web sites in order to efficiently accomplish their needs. Several technologies are now available to effectively eliminate those barriers and make the Web accessible to all people to ensure e-democracy.

KEY TERMS

Accessibility Legal Issues: Many governments around the globe issued laws and regulations demanding accessibility for public organizations sites, usually starting from W3C WAI technical recommendations.

Assistive Technologies: A set of solutions, both hardware and software, aimed at supporting disables in interacting with digital contents.

Digital Divide: Gap existing between communities regarding their ability or possibility to effectively access information and communications technologies.

Universal Design: A principle stating that every design activity has to consider the different requirements from all potential users (Follette, Mueller, & Mace, 1998).

Validation Tools: Tools available for semi-automatic validation of Web site accessibility. Such tools test only the code syntax and style sheets, without considering semantic aspects, where the human control is needed.

W3C WAI Guidelines: A set of guidelines defined by W3C for designing accessible Web sites. It has three conformance levels (A, Double-A, and Triple-A), leading to different accessibility rank.

Web Accessibility: Presentation of Web-based contents in a way that allows disabled users to maximally and equally benefit from the site content. It can be achieved by using some assistive technologies (cfr.).

Web Design Dimensions and Adaptation

Carlos Miguel Tobar

Ivan Luiz Marques Ricarte
DCA/FEEC—UNICAMP, Brazil

INTRODUCTION

Recent developments in the World Wide Web infrastructure enabled the development of highly interactive hypermedia systems for e-commerce, e-government, and mobile commerce. Such applications have much to gain exploring adaptation, through the use of adaptable and adaptive mechanisms to customize services and interfaces.

Adaptable systems are those that can be configured by the user before or during their use. Adaptive systems automatically acquire input data in order to infer adaptation opportunities and react accordingly. Adaptable and adaptive systems consider three different adaptation targets: human matters, interaction matters, and computer matters. The first target regards preferences, interests, and other personal information to allow system personalization. The second target regards goals and activities that are intended by the user in order to adjust the system according to the dialogue with the human being. The third target regards resource-availability discovery and optimization, such as needed by mobile applications due to limitations in computation and communication infrastructure.

The design of modern hypermedia systems requires an integrated approach contemplating modeling principles, evaluation frameworks, and reference models. Several approaches and methods exist, but it is difficult to understand how they complement or interfere among themselves during a design. Fischer (1989) considers that systems with strong interactive requirements, such as those related to usability, lack structure and present design instability. Adaptation aggravates this difficulty.

Tobar and Ricarte (2005) believe that one of the main reasons behind the difficulty in developing and evaluating adaptable and adaptive systems is the absence of a *reference* (normative) *model* for describing them from different perspectives. They provided some clues toward this missing type of model through the E-ACM (extended abstract categorization map), used to present modeling dimensions. It is a graphical representation to capture different aspects of hypermedia systems and models, considering all types of adaptation. It can be used before system authoring and design to a broad spectrum of hypermedia applications including e-commerce, e-government, and mobile commerce.

BACKGROUND

Complementing design dimensions is a strategy to model complex systems. For adaptable and adaptive systems, these dimensions help to:

1. identify coverage overlapping between modeling methods or systems, aiming potential integration;
2. compare modeling methods;
3. specify a new authoring methodology; or
4. assess the adherence of modeling methods to specific available tools.

Four dimensions concerned with adaptable and adaptive hypermedia design are considered: services, traditional concerns, abstraction levels, and goal conditions.

Services

Services, such as navigation and presentation, offer representation mechanisms to establish how users perform different data manipulation activities. They also support problem-modeling issues that are the kernel of some hypermedia modeling methods.

The Dexter reference model (Halasz & Schwartz, 1994) pioneered a dimension for modeling separating navigation from presentation and interaction issues. Brusilovsky (2001) also considers a similar dual vision for adaptive hypermedia services. This dimension is the most commonly used as orientation to develop and assess adaptable and adaptive systems.

Traditional Concerns

The traditional concerns dimension includes representations for structure (data), behavior (process), and constraints. It is the usual modeling dimension to develop software.

Oppermann (1994) introduced a *process-oriented* approach for adaptive systems, with three main components: to gather observation data (afferential), to deal with user characteristics (inferential), and to adapt the system (efferential). Several other authors, inspired by Oppermann's proposal, use layers for dealing with processes behind adaptivity, such as Weibelzahl (2003).

Other proposals presented *data-oriented* approaches. De Bra, Houben, and Wu (1999), based on the Dexter model, proposed the AHAM (adaptive hypermedia application model) reference model. It focuses on the storage functional layer, with models for domain, user, and teaching.

There are also hybrid approaches, such as the one proposed by Paramythis, Totter, and Stephanidis (2001) with two data-oriented components and several others process oriented.

Abstraction Levels

Different models can represent the same aspect, each with a different abstraction level. A pioneer work regarding abstraction levels is the reference database architecture defined by the American National Standards Institute (Tsichritzis & Klug, 1978).

Stephanidis and Savidis (2001) considered abstraction by proposing three levels of interaction at which adaptation is applied: semantic (different metaphors), syntactic (dialog patterns), and lexical (grouping and spatial arrangement). Benyon and Imaz (1999) exploited modeling methods developed toward one of three abstraction levels: intentional, conceptual, and physical. They consider *goals* as guidelines for the specification of entities at the intentional level.

Transitions between levels have been used in approaches for bottom-up or top-down development. Some proposals define mappings between adjacent levels to smooth detail generation (Tobar & Ricarte, 1999).

Goal Conditions

Goals are what the user has to accomplish using the application and represent the *why* of the system existence. Although important, the goal dimension is not well exploited in the literature.

Goal conditions are underneath application descriptions, and are related to external concepts to be considered by an application realization, such as a collaboration requirement to take into account. For instance, this goal condition affects the way services are provided to users, imposes new data and behavioral requirements, and requires ad hoc computational mechanisms.

Combination of Dimensions

Separation of concerns—that is, the use of dimensions—facilitates the reuse of successful design practices (Karagiannidis & Sampson, 2000). Mutually influenced design dimensions have long proved to be a powerful and helpful strategy.

Efforts to combine dimensions were initially directed toward open hypermedia systems (Rossi, Schwabe, & Guimarães, 2001) and required a combination of modeling methods. This same idea of combining methods has been exploited in development methodologies and respective supporting languages, such as the Unified Modeling Language—UML (Fowler, 2003).

A HYPERMEDIA AUTHORING SYSTEM: AHA!

AHA! (De Bra et al., 2003) is a representative tool to build adaptive Web applications. It is a generic and open adaptive hypermedia platform, originally developed to support educational applications, composed of an authoring system and an adaptive support system. Its goal is to offer guidance through explanations and conditional navigational options during user interaction. AHA! uses three techniques to achieve this goal:

1. a user model based on concepts,
2. the use of adaptive link hiding, and
3. the conditional inclusion of fragments.

To construct applications with AHA!, an author creates concept and page templates. Page templates contain the fragments to be conditionally included, coded with the standard language for Web pages, XHTML (W3C, 2002). Concept hierarchies and relationships are created using the *graph author,* a tool to create a domain-adaptation model in a high level of abstraction. AHA! also provides a *concept editor,* which offers low-level access to define condition-action rules and conceptual attributes.

The AHA! platform, in which adaptive applications are processed, has as its main functional component an inference engine, and as its main data components a user model and a combined domain and application (adaptation) model. The AHA! engine, responsible by adaptive effects, uses a Web server to provide user interaction and navigation. User requests are intercepted by engine servlets, small applications integrated to the Web server which access the combined models to trigger adaptation rules. Thus, page fragments may be included in a page according to conditions in these rules. Presentation of link anchors considers Boolean conditions over user model values.

USING E-ACM TO ASSESS ADAPTIVE HYPERMEDIA SYSTEMS

In the design of an adaptive Web application, the different degrees of support provided by tools and platforms yields a natural question: Which one is appropriate for the designer needs? The extended abstract categorization map aids to answer this question.

The E-ACM provides a chart with three layers and seven services to indicate the existence of modeling mechanisms in a system, tool, or platform. If present, the mechanism is classified according to its abstraction level, related computational service, goal condition, and traditional modeling concerns.

A categorization requires a set of orientations such as:

- Any mechanism that is oriented to one of the services, mainly to those strongly related to hypermedia (navigation, perception, and interaction), cannot be considered at the external level.
- The existence of a mechanism, no matter how simple, is always represented.
- The basis for defining the degree of sophistication could be a reference model, such as AHAM (De Bra et al., 1999), which should be highlighted as playing this role. Some of the services could stay without reference, when they are not considered among the possible chosen reference models. In this case, the analyst is responsible by defining the reference level explicitly.

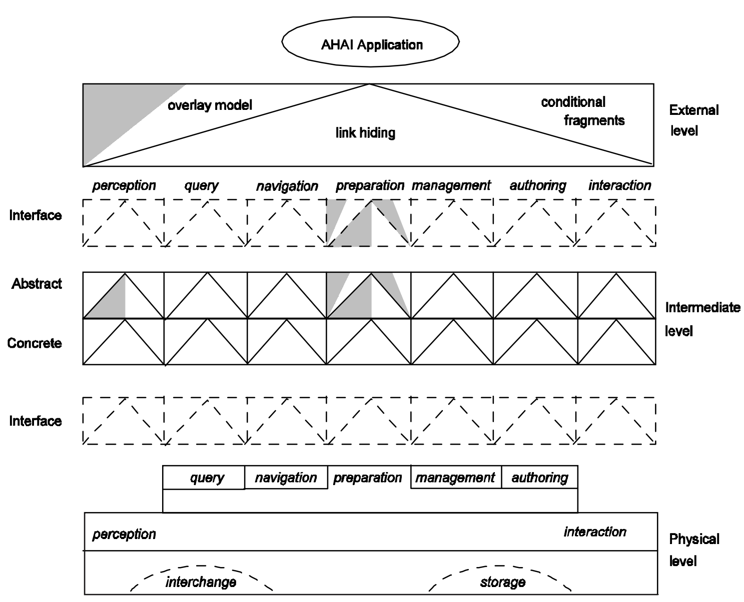
In order to indicate the sophistication of a mechanism to be represented in the map, a simple scale is proposed. Different patterns used to fill a region represent sophistication degrees. Total fulfillment of the region represents high sophistication. Half coverage of the region represents intermediate sophistication. A small solid circle inside the region represents basic sophistication.

AHA! categorization using E-ACM (see Figure 1) is used in the sequence to discuss the map structure. As can be observed in Figure 1, all represented mechanisms present the half coverage pattern, since the architecture of AHA! is heavily inspired by AHAM, which is used as reference model.

The External Level

The top dimension is related to goal conditions. Represented mechanisms in the external level depend on the application. External modeling methods on the top of the map help individuals to perceive and represent goal-oriented information in the problem domain. They are used to identify elements, their characteristics, and rela-

Figure 1. AHA! categorization



tionships, without any concern with low-level descriptions in a computational platform.

Considering AHA! techniques for goal achievement, there is in Figure 1 an indication regarding the user model. The graph author supports high-level definition of concepts and offers automatic translation to lower-level specifications.

The Intermediate Level

In the E-ACM, conditions and services are projected toward each other through the intermediate abstraction level and interfaces, creating columns and cross-regions. In Figure 1 there are seven columns and 12 cross-regions in each column. These regions are triangles, since three goal conditions were identified.

The E-ACM offers a separation of concerns strategy based on these cross-regions. Each one of them can be marked to point out the presence of computational elements oriented to the respective dimensions that curb the region. If several different mechanisms exist and relate to the same region, the indication of the most sophisticated prevails.

Mappings between levels and sublevels are required to progress from one level of description to another (Benyon & Imaz, 1999). The easiness of a mapping between modeling methods that belong to different abstraction levels depends on available mechanisms supported by the higher-level modeling method, and which are named *mapping facilitators*. A mapping facilitator presents some type of direct translation for elements specified through it into elements obtainable through a lower-level modeling method. The existence of mapping facilitators is captured in E-ACM by filling cross-regions in the interfaces between abstraction levels.

Through the AHA! graph author, it is possible to generate attributes and adaptation rules automatically whenever a concept is created. The translation from high-level constructs to the low-level adaptation rules is performed automatically, based on templates. These are considered mapping facilitators and are represented in the interface between the external and intermediate levels.

With the concept editor, a designer can associate a requirement expression with fragments in a page. Depending on the expression, the fragment is rendered or a second fragment is used. The indication of such facility appears in Figure 1 at the abstract intermediate sublevel.

The Physical Level and Data Manipulation Services

The bottom of the map considers physical data modeling methods. Computational elements are usually specified from already defined information elements and respective goal conditions, resulting in code and data structures at the physical level after a series of modeling through the intermediate sublevels. Physical data schemas, code, and software and hardware information sensors should be specified as a result of semantic mappings from higher abstraction levels for each service.

The two traditional services, presentation (here named perception) and navigation, are present in the map. The five additional services, which result from a deeper separation of concerns, are: interaction, query and search, management, preparation, and authoring.

Because AHA! specification mechanisms produce relatively high-level descriptions that are interpreted by AHA! itself, there is no indication in the physical level nor in the abstract intermediate sublevel.

Traditional Concerns

The traditional concerns dimension, although not visible in E-ACM, exists behind the map as an orthogonal and implicit dimension, which is considered from the intermediate abstract level to the physical level.

When using the E-ACM to categorize a modeling method, a complete framework is considered, with all possible data structures, functional modules, and constraints. Once one of the cross-regions is selected for a mechanism, it becomes implicit which framework components are going to be affected by the use of this mechanism under the dimensions that define the cross-region.

The AHA! adaptation model defines how to update the user model. The user model contains some user characteristics and an overlay model, which consists of a set of attribute pairs for each concept. The adaptation and user models are behind the authoring tools, whose constituents result from definitions such as new attributes for concepts created through the preparation and perception services. These mechanisms are represented in Figure 1.

FUTURE TRENDS

As can be observed in the previous section, a system such as AHA! does not need to provide modeling mechanisms for every service, or to cover all abstraction levels. Gaps in the categorization map show where other systems can be used to complement existing functionalities, as well as opportunities to extend the system.

Combining modeling dimensions, from the open hypermedia field to those already accepted by the adaptive hypermedia community, is a promising approach toward a more comprehensive normative way to describe adaptable and adaptive systems.

Separation of concerns applied to the services dimension restrains what information can be used to infer adaptation, offering a rich ground for adaptation opportunities. For instance:

- The query and search service needs stable personal data, such as personal intentions and task goals, to exploit adaptation through interest representation and updating, according to filtering parameters, and localization of information.
- The preparation service acts upon historical information that is highly mutable and is related to the user evolution on her/his interaction with the system to exploit adaptation during rendering and modality processing, through selection of media and content (optional explanations, optional detailed information, hints, etc.).
- The perception service is related to output devices and drivers concerned with presentation issues to exploit adaptation through spatial structure, background, color, fonts, sound level, and media synchronization.
- The navigation service is based on browser history and hyperspace visibility to exploit link structure, overview map and location, resources already visited, bookmarks, and so forth.
- The interaction service is concerned with input interfaces and devices to exploit adaptation through configuration of devices, hot keys, tool control, control and query languages, and so forth.
- The authoring service is concerned with authoring utilities and facilities that exist in an adaptive application, such as with a graphical editor for CSCW. Adaptation can be exploited with possession control, admission policy, election instrument, and also with authoring tool preferences.
- The management service is concerned with resource operation to exploit policies for configuration, and options for troubleshooting, security and privacy, and QoS (performance).

In the management service, there are interesting adaptation options to explore in mobile applications.

One other interesting effort to invest in is to investigate what existing modeling methods present the potential to be integrated in order to produce broader horizontal and vertical coverage of the E-ACM map.

CONCLUSION

Hypermedia applications, such as e-commerce, e-government, and mobile commerce, are beginning to explore adaptation techniques in order to offer attractive services and interfaces. Moreover, adaptation can be also exploited in situations where severe constraints apply, for example with bandwidth communication fluctuations or users with physical disabilities.

There are several proposed frameworks and models to help designing hypermedia applications. With almost no exception, they combine incomplete software functional components with abstraction layers or with information categories. These approaches must be extended to provide a consistent and integrated vision in the form of a normative model, which allows easing system development. Toward this end a tool, the extended abstract categorization map, is presented through an example.

The E-ACM provides graphical representations for the existence and sophistication of specification mechanisms according to their abstraction level, the computational service to which they are oriented, and the goal condition that must be considered to model elements that represent domain entities in computational terms. The proposed map is a step towards the integration of modeling dimensions that are not usually combined.

As an example, AHA! is categorized using E-ACM according to the two constituents of AHA!: authoring tools and the runtime system. It is possible to observe that modeling actually occurs through the authoring tools, and comprises the preparation and perception services. Only two of three abstraction levels are covered by AHA! modeling mechanisms.

The E-ACM tool can be used to perceive what modeling mechanisms can be included in a system such as AHA!, and thus it allows consideration of its integration to another system.

KEY TERMS

Abstraction Levels: A model is an abstraction, and as such it may represent an aspect of reality with some level of detail. Different models can represent the same aspect, each with a different abstraction level. The abstraction level is directly related to the amount of detail represented in the model.

Adaptability: One says this of a system that can perform adaptation based on configurations set by the user before or during the execution of the system.

Adaptation: A system characteristic concerned with the capacity of adjusting its behavior according to one or a combination of targets: the user, the human computer interaction process, or the computational platform.

Adaptivity: One says this of a system that can perform adaptation automatically. Generally, the system acquires and analyzes external data in order to make inferences and execute adaptation actions.

Data Manipulation Services: A set of computational services responsible by some functional facility that could exist in a hypermedia system.

Design Perspectives: A designer can abstract characteristic types of the modeling object and exploit only one characteristic type, such as behavior, and using that dimension she/he develops a model that represents that object.

Goal Conditions: These are underneath application descriptions and are related to external concepts to be considered by an application realization, such as a requirement to contemplate collaboration.

Traditional Modeling Concerns: Traditionally, modeling concerns are related to representations for structure (data), behavior (process), and constraints.

W

Web Portal Gateways

Arthur Tatnall
Victoria University, Australia

INTRODUCTION

The term *Web portal* is overused and takes on a different meaning depending on the view of the author. This article will investigate the concept of a portal, the various types of portal, and how portals are currently being used. A Yahoo search of the Web in February 2004 revealed 85 million entries for the word *portal,* and even allowing for a considerable degree of overuse and overlap, portals are seen everywhere and span a bewildering range of topics and interest areas. It would be difficult to make any use of the Web without encountering one.

In general terms, unrelated to the World Wide Web, the *Macquarie Dictionary* defines a portal as "a door, gate or entrance" (Macquarie Library, 1981, p. 1346). More specifically, a Web portal is seen as a special Internet (or intranet) site designed to act as a *gateway* to give access to other sites (Tatnall 2005a). A portal aggregates information from multiple sources and makes that information available to various users. In other words a portal is an all-in-one Web site whose prime purpose is to find, and to gain access to other sites, but also one that provides the services of a guide that can help to protect the user from the chaos of the Internet and direct them towards an eventual goal. More generally, however, a portal should be seen as providing a gateway, not just to sites on the Web, but to *all network-accessible resources,* whether involving intranets, extranets, or the Internet. In other words a portal offers centralised access to all relevant content and applications (Tatnall 2005b).

Historically, the Web-portal concept probably developed out of search engine sites such as Yahoo!, Excite, and Lycos, which can now be classified as first-generation portals. These sites, however, quickly evolved into sites providing additional services such as e-mail, stock quotes, news, and community building rather than just search capabilities (Rao 2001). Eckerson (1999) outlines four generations of portals whose focus, in each case, is: generic, personalised, application, and role. The success of a portal depends on its ability to provide a base-site that users will keep returning to after accessing other related sites. As an entranceway onto the Web (or an intranet) it should be a preferred starting point for many of the things that a particular user wants to do there. A useful goal for those setting up a portal is to have it designated by many users as their browser start-up page.

BACKGROUND

There is no definitive and generally agreed categorisation of types of portal, but Portals Community (http://www.portalscommunity.com/) offers the following list: Corporate or Enterprise (intranet) portals, e-business (extranet) portals, personal (WAP) portals and public or mega (Internet) portals. Another categorisation (Davison, Burgess, & Tatnall, 2004) offers: general portals, community portals, vertical industry portals, horizontal industry portals, enterprise information portals, e-marketplace portals, personal/mobile portals, information portals and niche portals. Unfortunately, as the categories are not mutually exclusive some portals fit into more than one while others do not fit well into any. To further complicate any attempt at categorisation some implementations can span several different portal-types blended into a form of hybrid solution. A discussion of various different types of portals follows.

- **General (or Mega) Portals:** Portals aim to provide links to sites that can be either closely related or quite diverse. In the case of general portals the intent is to provide links to all sorts of different sites of the user's choosing. Many of these general portals have developed from being simple search tools (such as Yahoo), Internet service providers (such as AOL), and e-mail services (such as Hotmail). They now try to be the one-stop port-of-call for all (or at least many) user needs. An important goal of a general portal is to become the page a user returns to each time they want to access something on the Web. It will be successful if it can provide most of the services, information and links that users want. General portals often include services such as: free e-mail, links to search engines and categories of information, membership services, news and sports, business headlines and articles, personalised space with a user's selections, links to chat rooms, links to virtual shopping malls and Web directories. General portals make their money by selling advertising material. The success of a general portal depends on it generating a large volume of visitor traffic and this involves attracting new visitors, keeping them at the site for as long as possible, and on convincing them to return. The profitability of general portals, however, has not been high (Sieber & Valor 2002, 2005).

- **Vertical Industry Portals:** Usually based around specific industries. They aim to aggregate information relevant to particular groups, or online trade communities of closely related industries to facilitate the exchange of goods and services in a particular market as part of a value chain. Vertical industry portals often specialise in business commodities and materials such as chemicals, steel, petroleum products or timber. Some specialise in services like cleaning, food, transport, staffing or publishing. Others specialise in interest areas such as camping, hiking or fishing equipment.
- **Horizontal Industry Portals:** Portals can be described as *horizontal* when they are utilised by a broad base of users across a horizontal market. Horizontal industry portals are typically based around a group of industries, or a local area.
- **Community Portals:** Often set up by community groups such as eLaunceston (http://www.elaunceston.com/) and Cape Breton, Canada (http://www.centralcapebreton.com/) or based around special group interests such as GreyPath (www.greypath.com) (Lepa & Tatnall, 2002), iVillage (http://www.ivillage.co.uk/) and Women.com (www.women.com). These portals attempt to foster the concept of a virtual community where all users share a common location or interest, and provide many different services depending on their orientation. The extent to which some community portals represent the interests and views of their *entire* community is, of course, open to interpretation.
- **Enterprise Information Portals:** The term *enterprise* (or *corporate*) *information* portals is now often applied to the gateways to corporate intranets that are used to manage knowledge within an organisation. These are designed primarily for business-to-employee (B2E) processes and offer employees the means to access and share data and information within the enterprise (Stein & Hawking, 2005). They may include facilities such as: a categorisation of information available on the intranet, a search engine covering the entire intranet, organisational news, access to e-mail, access to common software applications, document management, links to internal sites and popular external Web sites, and the ability to personalise the page. Variations include business intelligence portals that are designed to act as gateways to decision-making processes and to provide competitive intelligence, business area portals that support specific business processes such as personnel or supply chain management, and facilities designed to support the field sales force.
- **E-Marketplace Portals:** These extended enterprise portals often offer access to a company's extranet services and are useful for business-to-business processes such as ordering, tendering and supply of goods. An example is provided by the Swiss company ETA SA Fabriques d'Ebauches (http://www.eta.ch/), a member of *The Swatch Group* that produces watches for brands including Omega, Rado, Longines, Tissot, Certina and Swatch. The group consists of a number of individual companies that focus on producing components and movements for watches. The portal was set up principally to improve cost efficiency and facilitate quicker order processing between members of the group (Alt, Reichmayr, Cäsar, & Zurmühlen, 2002). E-marketplace portals can also be used for business-to-customer transactions, and a classic example is provided by the bookseller Amazon.com (www.amazon.com). Another example comes from the Association for Computing Machinery (http://portal.acm.org/portal.cfm) digital library.
- **Personal/Mobile Portals:** Following the trends towards mobile (or pervasive) computing, personal/mobile portals are increasingly being embedded into mobile phones, wireless PDAs and the like. Some appliances are also being equipped with personal portals aimed at allowing them to communicate with other appliances, or to be used more easily from a distance.
- **Information Portals:** Although these, in most cases, can also be classified into one of the other categories, information portals can also be viewed as a category in their own right as portals whose prime aim is to provide a specific type of information. The Sports Information portal ESPN (http://msn.espn.go.com/) is one example of such an information portal. Another is Portals Community (http://www.portalscommunity.com/), a portal dedicated to providing information about portals.
- **Specialised/Niche Portals:** Designed to satisfy specific niche markets. In many cases these can also be classified as Information Portals. For example, ESPN (http://msn.espn.go.com/) is targeted towards 18- to 34-year-old males, while iVillage (http://www.ivillage.co.uk/) is targeted towards women. Other specialised portals provide detailed industry information, often available only for a fee.

WHAT IS NEW ABOUT PORTALS?

A colleague recently remarked that there is nothing new about portals. In this comment he is both partially right and completely wrong. A simple definition sees a Web portal as a special Web site designed to act as a gateway to give convenient access to other sites. In a sense there is nothing new about this as Web sites have contained hyperlinks to other sites since the Web's inception. What is new is the way that these special Web sites are now being used to facilitate access to other sites that may be closely related, in the case of special purpose portals, or quite diverse in the case of general portals. What is also new is that the marketers have discovered the portal concept and its advertising potential.

Research by Tatnall, Burgess and Singh (2004) indicated that small businesses can also benefit from the use of portals, especially in the provision of a secure environment for online trading, opportunities for new partnerships, and improved customer management.

SOME CURRENT USES OF WEB PORTALS

The uses of portals are legion. There are government portals such as: www.gouv.qc.ca (Québec) and www.vic.gov.au (Victoria). Science portals include: http://sdcd.gsfc.nasa.gov/ESD/portal (Goddard Space Flight Centre), www.eco-portal.com, and www.environment.gov.au. Community portals cover many regions and interest areas including: http://melbourne.citysearch.com.au/ (Melbourne), www.greypath.com (Greypath), and www.portalscommunity.com (Portals Community). Many portals relate to the IT industry, including: www.ifip.org (IFIP) and www.microsoft.com/sharepoint (Microsoft SharePoint portal). There are a number of education portals such as: www.educatorsportal.com and www.edmin.com (for educational administration), and www.sofweb.vic.edu.au/ (for schools). Portals relating to other interest areas include: libraries—http://portal.unesco.org, music—www.bach-portal.com, sport—www.thebaseballportal.com, health—http://www.betterhealth.vic.gov.au/, and genealogy—www.genealogyportal.com. There is even an antiportal portal for those who dislike portals—http://internetbrothers.com/aortal.

The marketing value of portals has not gone unrecognised, and Schneider and Perry (2001) note that Web managers have discovered that increased sales and advertising income can result from the portal's ability to attract more people and retain them longer. They point out that Web portal companies have added *sticky* features like chat rooms, e-mail and calendar functions, in order to retain visitors longer at their sites. Kleindl (2001) notes that portal sites will soon attract 40% of all commerce revenue and gain 67% of advertising dollars. The success of the portal industry is closely linked to marketing but Michael (2005) points out that advertisers and marketers are yet to understand the full potential of the Internet. Michael argues that a key function of marketing is to match buyers and sellers and to facilitate transactions, but that to do this a proper institutional infrastructure is required. He points out that marketers need to be aware of new demographic segments that are being attracted to the Internet for searching and shopping purposes and that portals should be regarded as strategic tools in the marketing process.

Government portals are rather like business enterprise portals, except being outward rather than inward looking, and Aitkenhead (2005) notes that government portals are becoming gateways or central access points for many e-government initiatives around the globe. They perform this task well as they provide a consistent and easy-to-use interface that allows citizens access to a range of government services. There are many business factors driving the implementation of government portals including the massive proliferation of Web sites, the large amount of duplicated information, the advantages portals offer in positioning businesses for future integration of information from a single point, and the strengthened security they provide.

Portals are also of interest to the scientific research community. An article in *Portals* magazine (Roberts-Witt, 2003) describes the National Biological Information Infrastructure (NBII) in the United States (www.nbii.gov and a number of private sites) as a government-to-government/partner/citizen portal, based on Plumtree Corporate Portal software. The NBII portal allows biologists (researchers and students) to share geographic and geospatial data, without the need to know exactly where the data is housed and to whom it belongs.

Moon and Burstein (2005) review the way portal technology can assist in the search for medical information and assist users in broader community contexts. In particular, they look at how portals are employed for meeting community medical information needs and how medical portals could be improved so that they could assist users with these needs. They explore the extent to which these portals behave intelligently in addressing users' needs, discussing what constitutes an intelligent portal, outlining the desirable components and attributes of such a portal and how these can be implemented to meet the needs of diverse users.

The Web has the potential to be a major source of information for older people, and Lepa (2005) describes Greypath—a portal aimed at serving the needs of older Australians. He notes that statistics show that the proportion of older people will increase dramatically over the next 25 years and that the Web has the potential to improve the lives of these people. Older people could use specially designed older person portals as their first port of call on the Internet and use the links provided to access the informational and recreational activities they are interested in.

Portals are being used to a significant extent in all levels and aspects of education. In one example, Bajec (2005) describes the use of portals in institutions of higher-education, and examines the motivating factors that drive these institutions to use portal-based solutions. He notes that almost all universities are either developing or purchasing portal solutions for systems integration, utilisation of e-business technology, and provision of wider access to data and services on existing systems.

FUTURE TRENDS

The demise of the portal has been predicted for a long time, and particularly since the dot-com crash of several years ago. Several years ago, *Online Publishing News* (1999) ran a story entitled: “The Portal is dead. Long Live the Vortal?” suggesting that general portals had seen the end of their usefulness and that vertical industry portals would grow in importance. A recent report by Gartner (Phifer, 2003) titled: “The Portal is Dead. Long Live the Portal” takes this theme further and argues that portals are evolving into integrated software suites containing portal functionality. White (2003) notes that portals are undergoing a metamorphosis in which they are merging with technologies such as content management, collaboration and business intelligence. Predictions that the portal would disappear into application servers have also proved untrue (Plumtree Software, 2003). Like Mark Twain’s (Partington, 1996, p. 706) exclamation in 1897, however, reports of the portal’s death appear to have been greatly exaggerated.

CONCLUSION

The concept of a gateway is one that is very relevant to the World Wide Web, and the importance of the Web portal has thus grown considerably in recent years. Because of the huge size of the Web, users need some assistance in finding anything useful, and the portal has moved to fill this role. Far from a concept that is dying as was suggested by several authors a few years ago, the use of portals continues to grow. The portal is an evolving entity that has an important part to play in the future of both corporate intranets and the World Wide Web.

KEY TERMS

Community Portals: Often set up by community groups or based around special group interests, they attempt to foster the concept of a virtual community where all users share a common location or interest, and provide many different services.

E-Marketplace Portals: Extended enterprise portals that offer access to a company's extranet services.

Enterprise Information Portals: The gateways to corporate intranets that are used to manage knowledge within an organisation. These are designed primarily for business-to-employee (B2E) processes and offer employees the means to access and share data and information within the enterprise.

General (or Mega) Portals: Portals that provide links to all sorts of different sites of the user's choosing, often from a menu of options.

Horizontal Industry Portals: Portals utilised by a broad base of users across a horizontal market.

Information Portals: Can also be viewed as a category in their own right as portals whose prime aim is to provide a specific type of information.

Personal/Mobile Portals: Portals embedded into mobile phones, wireless PDAs, appliances and the like.

Specialised/Niche Portals: Portals designed to satisfy specific niche markets. Sometimes they provide detailed industry information, often available only for a fee.

Vertical Industry Portals: Usually based around specific industries, they aim to aggregate information relevant to these groups of closely related industries to facilitate the exchange of goods and services in a particular market as part of a value chain.

Web Portal: A special Internet (or intranet) site designed to act as a gateway to give access to other sites.

University of California, Santa Barbara, USA

INTRODUCTION

Web services are changing the way in which the World Wide Web is currently being used. The Web was created originally to support human-to-computer interactions with textual and graphical data. Today, people use the Web to read the latest news, buy consumer goods, search for information, and obtain stock quotes. However, the Web does not yet support effective computer-to-computer interactions between software applications of different enterprises.

Web services can enable Internet-based software applications of different enterprises to interact with each other directly by providing application programs with the ability to invoke operations that otherwise would be invoked manually by a human through a browser. Web services can run not only on mainframe computers and server computers, but also on desktop computers and client handsets. Web services allow individuals and organizations to publish links to their software applications, just as they publish links to their Web pages.

Web services solve the enterprise application integration (EAI) problem by enabling interaction among different applications within the same organization. They can also enable computer-to-computer applications of different organizations to interact without human intervention. For example, Web services can be used for reservation systems, order-tracking systems, and business supply chains. In the example shown in Figure 1, Company A (a customer) orders goods from Company B (a distributor). Company B checks the availability of the goods from Company C (a supplier), and then arranges for payment and shipping of the goods to Company A without human intervention.

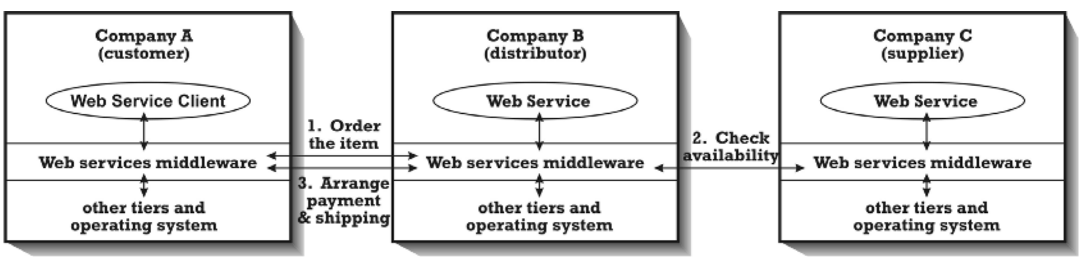
Performance, security, and reliability are factors that will limit the use of Web services unless those issues can be properly addressed. Nonetheless, the potential widespread use and benefits of Web services are very compelling. Web services allow disparate computing systems and applications to be coupled together, and they enable enterprises to streamline and automate their business processes.

BACKGROUND

The term Web services is used today with alternative meanings. Sometimes a Web service is considered to be any application that is accessible over the Web. This usage is very general and is not what we mean here by a Web service, nor is it a Web service as defined by the standards organizations.

The Universal Description, Discovery and Integration (UDDI) Consortium (2001) has described Web services as "self-contained, modular business applications that have open, Internet-oriented, standards-based interfaces." This definition emphasizes the need to be compliant with Internet standards. It also requires a Web service to be open, which means that it has a published interface that can be invoked by another computer program over the Internet.

Figure 1. Use of Web services in business-to-business interactions



The World Wide Web Consortium (W3C, 2002) has gone further to define a Web service as "a software application identified by a URI [Uniform Resource Identifier], whose interfaces and bindings are capable of being defined, described, and discovered as XML [eXtensible Markup Language] artifacts. A Web service supports direct interactions with other software agents using XML-based messages exchanged via Internet-based protocols." This definition emphasizes that a Web service must be capable of being defined, described, and discovered so that it is possible to create client software that binds to and interacts with it using the defined interfaces. It also states explicitly that Web services are based on XML.

Webopedia (Jupitermedia Corporation, 2004), an online technical dictionary, has given an even more specific definition of a Web service as "a standardized way of integrating Web-based applications using the XML, SOAP [Simple Object Access Protocol], WSDL [Web Services Description Language] and UDDI [Universal Description, Discovery, and Integration] open standards over an Internet protocol backbone. XML is used to tag the data, SOAP is used to transfer the data, WSDL is used for describing the services available, and UDDI is used for listing what services are available." In addition to XML, this definition requires the use of SOAP, WSDL, and UDDI.

Other useful Web-services references include Alonso, Casati, Kuno, and Machiraju (2004), Fisher (2002), Newcomer (2002), and Zimmermann, Tomlinson, and Peuser (2003).

WEB SERVICES TECHNOLOGY

Web Services Architecture

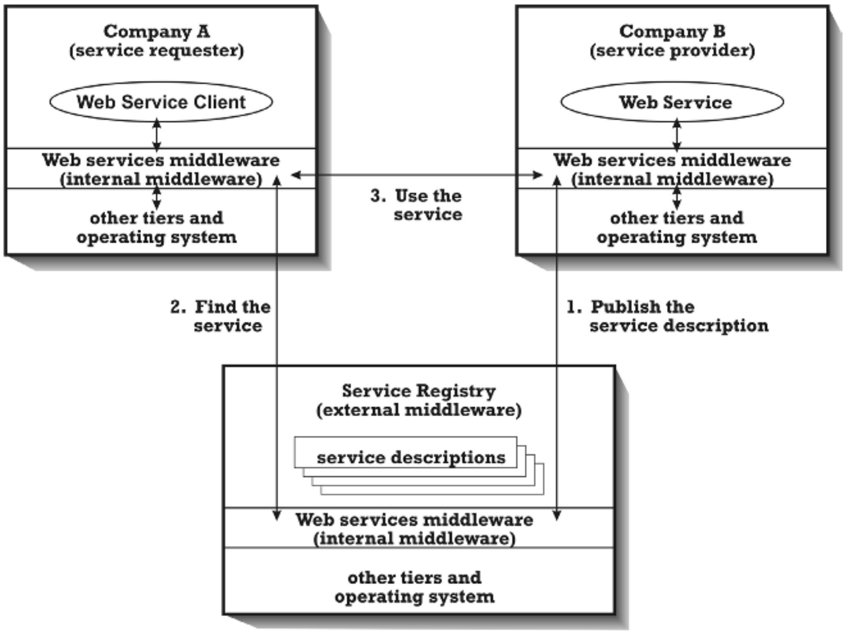
The Web services architecture, developed by the World Wide Web Consortium (W3C: ARCH, 2004), is described briefly below and is illustrated in Figure 2.

Viewed externally, a service provider creates a Web service and defines an interface for invoking that service. The service provider also provides a service description for the Web service and makes the service known to the world by publishing the service description in a service registry. The service registry uses the information in the service description to catalog the service and to search for the service when it receives a request for information about the service from a service requester.

When a service requester tries to find a service, it queries the service registry. The service registry replies with a service description that indicates where to find the service and how to invoke it. The service requester can then bind to the service provider by invoking the service. The service registry is itself a Web service, the address and interface of which are known a priori to the service requester.

Internally, Web services can be viewed as a tier on top of the other tiers of an enterprise architecture. The internal middleware for Web services packs and unpacks messages exchanged between Web services and converts

Figure 2. Web services architecture



them into the format supported by the underlying middleware.

The Web services architecture is based on the following technology and standards.

- Extensible markup language (W3C: XML, 2004), which defines the syntax of Web services documents so that the information in those documents is self-describing
- Simple object access protocol (W3C: SOAP, 2004), which provides a standardized way to encode different protocols and interaction mechanisms into XML documents that can be easily exchanged across the Internet
- Web services description language (W3C: WSDL, 2004), which is an advanced form of Interface Definition Language (IDL) that has been augmented to define aspects of a service description
- Universal description, discovery, and integration (Organization for the Advancement of Structured Information Standards [OASIS]: UDDI, 2004), which is used by the service registry and is where service providers publish and advertise available services, and clients query and search for services

The UDDI registry can be viewed as external middleware for Web services.

Extensible Markup Language

XML (W3C: XML, 2004) provides a common syntax for Web services documents and defines the rules to which a document must conform in order to be well formed. The goals of XML are interoperability, portability, and automatic processing with data independence for different programming languages, middleware systems, and database-management systems.

Like the HyperText Markup Language (HTML), XML has elements, attributes, values, and tags. XML elements and attributes provide type and structure information for the data. XML element tags describe the data items that they enclose. The following is an example.

```
<Supplier>
    <Name>Disco</Name>
    <PhysicalAddress>1 Hard Drive, San Jose, CA
     95131<\PhysicalAddress>
    <PhoneNumber>408-123-4567<\PhoneNumber>
    <URL>www.disco.com<\URL>
<\Supplier>
```

XML provides a standard way to define the structure of documents so that they are self-describing and, thus, are suitable for automatic processing. An XML parser can determine that a document contains a certain element and can extract the content associated with that element.

XML schemas and document-type definitions are used to define document types and to state that a document is of a certain type. An XML document verifier can be used to check whether the structure and content of a document is consistent with the prescribed type. Currently, XML schemas and document-type definitions do not provide semantic information about the document or the elements within it.

More precise tagging instructions have been defined for various vertical industrial sectors. In particular, the Organization for the Advancement of Structured Information Standards and the United Nations Center for Trade Facilitation and Electronic Business (OASIS & UN/CEFACT, 2004) have developed the electronic business XML (ebXML) standard as a successor to the electronic data interchange (EDI) standard. The ebXML standard defines an architecture and specifications designed to automate business-process interactions among trading partners.

Simple Object Access Protocol

SOAP (W3C: SOAP, 2004) underlies all of the interactions between Web services. SOAP defines how to organize information using XML in a structured and typed manner so that the information can be exchanged via messages.

SOAP supports loosely coupled applications that interact via one-way asynchronous messages using a protocol such as the Simple Mail Transfer Protocol (SMTP). It can also be used to implement conventional Remote Procedure Calls (RPCs). The procedure call is encoded in a SOAP request message, and the results produced by the procedure are encoded in a SOAP response message. For RPC, a synchronous protocol such as the HyperText Transfer Protocol (HTTP) is used to transport the messages.

SOAP messages are used as envelopes in which an application encloses whatever data it wishes to send. An envelope consists of two parts, a header and a body, as shown in Figure 3. The header is optional and the body is mandatory. Both the header and the body can have multiple subparts in the form of header blocks and body blocks.

A SOAP message has a sender, a receiver, and an arbitrary number of intermediaries (nodes) that process the message and route it to the receiver. The information that the sender wishes to transmit to the receiver is in the message body. Additional information needed for intermediate processing or for value-added services (such as transactions or security) is included in the message header.

The two interaction styles of SOAP, document style and RPC style, are also shown in Figure 3.

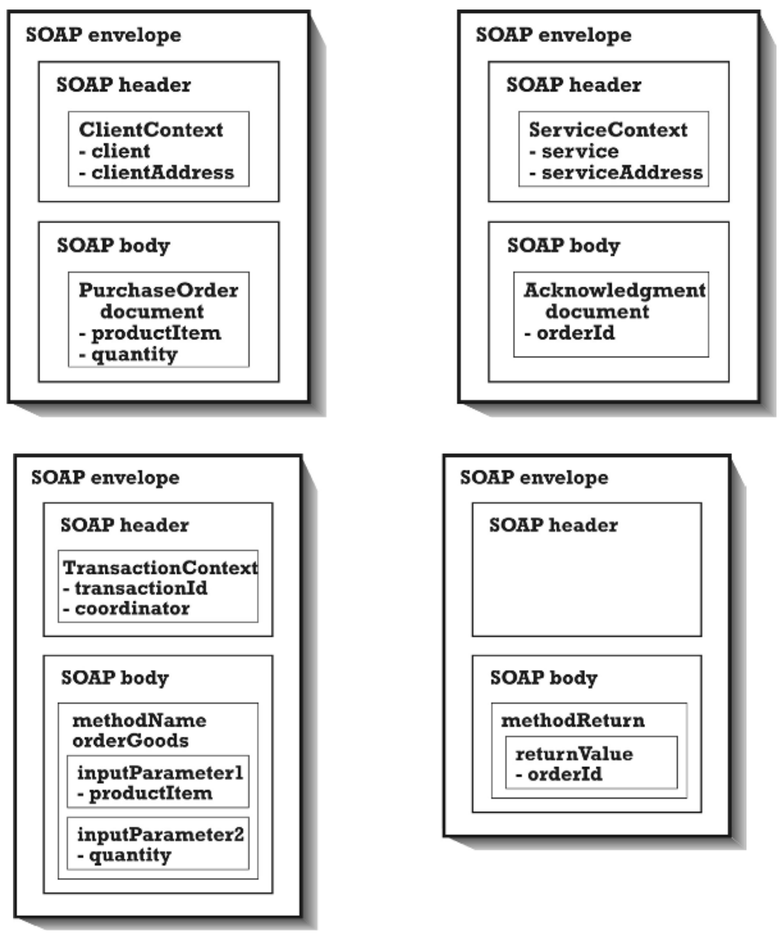
In document style, the two interacting applications agree on the structure of documents to be exchanged, and the documents are transported in SOAP messages from one application to another. For example, a client that orders goods from a supplier creates a PurchaseOrder document. The body of the SOAP message consists of the items and quantities requested. The header includes information that identifies the client to the supplier. The supplier creates an Acknowledgment document that contains the order ID of the confirmed order, and then sends it to the client in a SOAP message.

In RPC style, the body of the request message contains the procedure call, including the name of the procedure being invoked and the input parameters. The body of the response message contains the result and the output parameters. The two interacting applications must agree on the RPC method signature rather than the structures of the documents. For example, a client that orders goods from a supplier creates a SOAP message containing the procedure name orderGoods, as well as the parameters productItem and quantity, in the body of the SOAP message. The supplier creates a SOAP message containing a confirmation of the client's order as the response. Any additional properties associated with the RPC are included in the header. In particular, for a transactional RPC, the request header includes the transactional context, which enables the receiver to process the request.

Web Services Description Language

WSDL (W3C: WSDL, 2004) is similar in purpose to the IDL of other middleware platforms, such as the Common Object Request Broker Architecture (CORBA). A WSDL description specifies how to interact with the Web service, what data must be sent, what operations are involved, what protocol is to be used to invoke the service, and what data can be expected in return. A WSDL description can be used as input to a compiler that generates

Figure 3. Structure and content of a SOAP message showing an envelope with a header and a body, and two different interaction styles: document style at the top and RPC style at the bottom



stubs and skeletons, and can be used to capture information that allows reasoning about semantics.

A WSDL description consists of an abstract part and a concrete part, as shown in Figure 4. The abstract part is analogous to conventional IDL, and uses type, message, operation, and port type constructs. These four constructs are called abstract because there is no concrete binding, no encoding specified for them, and no definition of a service that implements them.

Types allow the exchanged data to be interpreted correctly at both endpoints of the communication. By default, WSDL uses the same basic and structured types as XML schemas.

A message is a typed document that is divided into parts, each of which has a name and a type. For example, a message for a procedure call with integer and floating-point-number parameters contains a part containing the integer and a part containing the floating-point number.

Operations are classified as one way, notification, request-response, and solicit-response. One-way and notification operations involve a single message, whereas request-response and solicit-response operations involve two messages. One-way and request-response operations are initiated by the client, whereas notification and solicit-response operations are initiated by the service.

A port type in WSDL is analogous to an interface in IDL. A port type consists of a set of related operations.

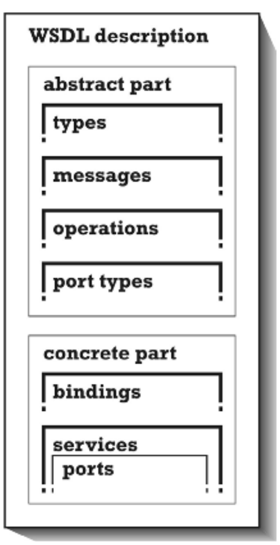
The concrete part of a WSDL specification defines an instance of a service and uses interface bindings, ports, and service constructs.

An interface binding specifies the message encoding and protocol bindings for all operations and messages defined in a port type. In particular, it specifies the encoding rules to be used in serializing the parts of a message into XML. It can also be used to specify that an operation is document style or RPC style, or that the messages of the operation must be communicated using SOAP with HTTP or SMTP bindings.

A port combines the interface binding information with the network address, specified as a URI, where the implementation of the port type can be accessed.

A service is a logical grouping of ports, typically related ports at the same address.

Figure 4. A WSDL description



Universal Description, Discovery, and Integration

The UDDI specification (OASIS: UDDI, 2004) provides a framework for describing and discovering Web services. UDDI is based on the notion of a business registry (essentially, a naming and directory service). UDDI defines data structures and APIs for publishing service descriptions in the business registry and for querying the registry to look for published descriptions.

UDDI supports application developers in finding information about Web services so that they know how to write clients that can interact with those services. It also enables dynamic binding by allowing clients to query the registry and obtain references to services in which they are interested. In addition, it supports the idea of a Universal Business Registry (UBR) where anyone can publish service descriptions and query the registry for services of interest.

The information within a UDDI registry can be categorized as follows:

- Listings of organizations, contact information, and services that those organizations provide;
- Classifications of companies and Web services according to taxonomies that are either standardized or user defined;
- Descriptions of how to invoke Web services, by means of pointers to service description documents, stored outside the registry, for example, at a service provider's site.

A UDDI registry contains Web services descriptions with four different kinds of information elements described as follows:

- **businessEntity:** An organization that provides Web services, including the company's name, address, and other contact information.
- **businessService:** A group of related Web services offered by a businessEntity. Typically, it corresponds to one kind of service (such as a procurement or reservation service). It might be provided at

different addresses, in multiple versions, or through different technologies (e.g., different protocol bindings).

- **bindingTemplate:** Technical information needed to use a Web service, such as the address at which the Web service can be found and references to documents (called tModels) that describe the Web service interface and other service properties. It also defines how operation parameters should be set and what the default values are.
- **tModel:** Technical model, which is a container for any kind of specification. For example, it might represent a WSDL service interface, a classification, or an interaction protocol, or it might provide the semantics of an operation.

UDDI registries have three types of users to which they expose their Application Program Interfaces (APIs): service providers that publish services, service requesters that look for services, and other registries that need to exchange information. Interaction with a UDDI registry takes place as a sequence of exchanges of XML documents, typically using SOAP.

As yet, there is little experience of software applications that use a UDDI registry to discover a Web service, and then invoke that Web service using its WSDL interface. Rather, in current practice, client applications are designed explicitly to invoke Web services with known WSDL interfaces and URIs.

FUTURE TRENDS

Today, Web services are used mainly for conventional enterprise application integration within a single enterprise rather than between different enterprises. Most systems that support Web services employ XML, SOAP, and WSDL, and to a more limited extent UDDI. It is generally accepted that UDDI registries will be used by humans to find interface information rather than by computer programs to create dynamic bindings.

In the future, Web services will move from the client-server model of distributed computing to the peer-to-peer model, with protocols that the interacting parties execute cooperatively. Peer-to-peer interactions will require more coordination among the Web services, which requires correspondingly more coordination among business partners rather than simply interfaces between service requesters and providers.

Major factors that will limit the use of Web services are performance, security, and reliability unless those issues can be properly resolved.

Performance is an issue because Web services consume large amounts of network bandwidth, memory space, and processing cycles because XML documents are text-based (rather than binary-based), self-describing, and interpreted. Even precompiled distributed computing middleware, such as CORBA, has quite high overheads; Web services incur much higher overheads. Special hardware, such as new types of routers and accelerators, might offset the adverse performance impact of Web services. The use of binary attachments to XML documents in SOAP messages might address the performance issue, but it loses the self-describing and interoperability advantages of XML.

Security is a major concern for Web services when software applications in one enterprise invoke software applications in another enterprise over the Internet. Even if the messages pass through the firewalls of the enterprises, they must pass all the way up the protocol stack to the applications, where security breaches can occur. Web services are vulnerable to several kinds of attacks: identity-based attacks in which a hacker poses as an authorized user to access a Web service, malicious-content attacks in which an intruder forces a server to perform an unauthorized activity, and operational attacks in which a hacker manipulates an XML message to tie up server resources. Security appliances that parse XML messages, ensuring that known business partners originated them and that they contain no hidden instructions, can help to address the security issue, as can the Secure HyperText Transfer Protocol (HTTPS), Internet Protocol (IP) filtering, and the new Web services security standard (OASIS: WS-Security, 2004).

Reliability is also a concern for Web services. There is no guarantee that SOAP messages sent over HTTP or SMTP will be reliably delivered to the applications. End-to-end reliable delivery requires that the intended destination applications receive the messages exactly once and in the correct order. The Web services community is currently working on several different reliable messaging specifications, including WS-Reliability (OASIS: WS-Reliability, 2004) and WS-ReliableMessaging (IBM, BEA, Microsoft, & TIBCO, 2004). In addition, Web services must support long-running business transactions across multiple enterprises that provide data consistency and protection against faults. Work on such business-transaction standards includes the WS-Coordination, WS-AtomicTransactions, and WS-BusinessActivity specifications (IBM, 2004). Without agreement on specific standards, reliable messaging and business transactions will be implemented in ad hoc manners, unnecessarily complicating interoperability, portability, and extensibility.

The ultimate goal of Web services is dynamic interaction among businesses in an open community, with automated clients that browse UDDI registries, find services and service providers, discover how to interact with those services, and invoke those services without human intervention. Automated dynamic interactions among business partners will not be possible until the partners agree on the semantics of the documents to be exchanged. Currently, the Web and Web services specifications focus primarily on the syntactic aspects of representing and communicating information. Semantic Web services (McIlraith, Son, & Zeng, 2002; W3C, 2001), in contrast, aim for the complete automation of Web services by standardizing the representation and handling of semantic metadata to describe Web services and how to use them. Semantics are very difficult even for humans, and initial use of semantic Web services will be restricted to very narrow, well-defined domains.

The ability of an application to locate an appropriate Web service, and to select among competing alternative Web services, will require major advances in the automated analysis of semantic information, an activity that is currently research rather than practice.

CONCLUSION

Web services are intended to provide computer-to-computer interaction of software applications over the Internet. Web services depend on the use of XML to structure and tag information so that it is self-describing, SOAP to convey XML documents in messages between service requesters and providers, WSDL to describe Web services so that they can be easily accessed, and UDDI to publish and discover Web services. Web services aim to establish and maintain interoperability between applications within a single organization and between organizations over the Internet.

Extensions to Web services standards are needed before Web services can be used for dynamic business interactions among business partners rather than only for conventional enterprise application integration. The use of Web services is likely to grow as these extensions are added and as Web services standards become more widely accepted. The development of semantic Web services will facilitate the movement from the existing Web of unstructured information without semantics to a semantic Web of services through which the computer systems of customers and service providers can conduct business automatically without human intervention.

KEY TERMS

Electronic Business XML (ebXML): An architecture and set of specifications designed to automate business-process interactions among trading partners.

eXtensible Markup Language (XML): A standard language for defining the syntax and structure of documents with the goals of interoperability, portability, and automatic processing of applications among different enterprises; the data in an XML document are tagged and thus are self-describing.

Semantic Web Services: Web services that incorporate semantic metadata that describe Web services and how to use them in a standard way in order to achieve the automation of Web services.

Simple Object Access Protocol (SOAP): A standard protocol that defines the way in which information is formatted and packaged before it is exchanged.

Universal Description, Discovery, and Integration (UDDI): A specification that provides a framework for describing and discovering Web services based on the idea of a business registry.

Web Service: A software application identified by a URI whose interfaces and bindings are capable of being defined, described, and discovered using XML, and that supports direct interactions with other software applications using XML-based messages via an Internet protocol. Web services provide a standard way of integrating Web-based applications using XML, SOAP, WSDL, and UDDI over the Internet.

Web Services Description Language (WSDL): A standard language that is used to describe Web services and service interfaces as XML documents, including the operations offered by a service, the mechanisms that can be used to access the service, and the location of the service.

Web Services and B2B Collaboration

Susy S. Chan
DePaul University, USA

Vince Kellen
DePaul University, USA

INTRODUCTION

Web service technology is moving into the mainstream. HTTP-based integration is proving more useful than prior approaches for integrating heterogeneous and distributed systems. Web service architectures are quickly advancing beyond and becoming more complex than their initial XML (extensible markup language)/SOAP (simple object access protocol)/UDDI (universal description, discovery, and integration) architectures. With added specifications, Web services are creating a service-oriented computing paradigm with their attendant terms and concepts, such as Web service networks, Web service management platforms, and service-oriented architectures (SOA), among others. Aided by Web services, business-to-business (B2B) integration topologies are growing in diversity to support various options for B2B collaboration. Web services are now the primary technical direction enabling this diversification of B2B collaborations (e-collaboration) among value chain partners and customers. They form the foundation for the development of a new generation of B2B applications and the architecture for integrating enterprise applications (Kreger, 2003). Web services promise to increase these partnering companies' flexibility, agility, competitiveness, as well as opportunities to reduce development cost and time.

BACKGROUND

B2B Collaboration

The Internet has reshaped industry value chains and redefined e-business as collaborative commerce. In this environment, companies collaborate with suppliers, distributors, service providers, and customers to produce value for customers. Such collaboration turns participating companies into virtual enterprises that emphasize rapid exchange of information among participating companies and inter-organizational systems to facilitate communication, coordination, and collaboration. A new IT-enabled intermediation and an integrated virtual value chain are emerging. The Internet facilitates supply chain integration through greater coordination and collaboration among all members of a company's supply chain (Lee & Whang, 2001). Such integration emphasizes information sharing, transparency, data integrity, and flexibility. Its benefits are clear: cost and time reduction, real-time communication, lead-time reduction, and improved collaborative planning and forecasting.

Web Services Growth

Businesses have indicated strong interests in deploying Web services in the near future. A recent Yankee Group survey of 437 companies reports that 48% of respondents have already deployed Web services and another 39% expect to deploy the technology within a year (Scurmacz, 2004). The top reasons for early adoption include: (1) the ability for an enterprise to enhance its capability to collaborate with external partners (77%); (2) the ability to reduce complexity in distributed applications (66%); (3) the ability to drive increased revenue in the next two years (66%); and (4) the ability to lower development costs (58%).

In a February 2002 Gartner survey, 27% of the IT respondents indicated that they would be using Web services in a systems integration project within 12 months. By February 2003, that number had risen to 42% (Cantera, 2003). The technology research firm, IDC, predicts that Web services will spur software, hardware, and service sales of $21 billion in the U.S. by 2007 (Muse, 2003).

WEB SERVICES TODAY

B2B e-commerce is entering a phase of technological maturity in which major open standards are adopted to enable inter-firm integration and collaboration. Web services are a significant enabler of this move toward inter-firm cooperation by promoting technology trust between enterprises through their deployment and use. The role of Web services in B2B e-commerce builds technology trust and indirectly influences performance outcomes.

Types of B2B Collaborations

Companies have various options in pursuing B2B collaborations (Ranganathan, 2003). Web service technology can be implemented to support these collaborations through various means. Table 1 identifies these options and the opportunities to adopt Web service technology for each option.

Web Services Standards

Web services can be thought of as a means by which an application service may be provided to other applications on the Internet. XML is the foundation technology in Web services, as all access to the services are delivered in XML documents via HTTP. Web services are described in the Web services description language (WSDL). Web services can optionally be registered in the UDDI repository where other applications can both register and discover services. Web services can be revealed and accessed within a company and between companies, as well as on the public Web.

Web service technologies address heterogeneity problems that previous technologies could not overcome. For years, IT organizations have sought increased system reuse and interoperability between systems (Lim & Wen, 2003). Since Web services operate via the HTTP protocol, they are more firewall-friendly than older object-oriented technologies. With UDDI, Web services have a consistent approach to introspection that older object-oriented technologies do not. And with SOAP, access to objects can be standardized as well, unlike object-oriented technologies such EJP, CORBA, and COM+.

Web services are now increasing in sophistication. Service-oriented computing and architectures are taking Web services beyond supporting simple XML interactions to more robust business interactions within and across enterprises (Curbera, Khalaf, Mukhi, Tai, & Weerawarana, 2003). Specifications for quality of service and service composition such as business process execution language (BPEL) for Web services (BPELWS) currently authored by IBM, Microsoft and BEA, WS-Coordination, WS-Transaction, WS-Security, WS-Reliable Messaging, and WS-Policy will allow for far richer, higher-level delivery of computing services via a Web services management platform (WSMP). Papazoglou and Georgakopoulos (2003) describe three layers of services: basic services, composite services, and managed services. Basic services manage publication, discovery, selection, and binding. Composite services facilitate coordination, conformance, monitoring, and quality of service. Managed services provide market certification, rating, service-level agreements, and operations support.

Business Drivers for Web Services

Because Web services can be layered on top of existing software applications and accessed across a value chain, Web services are a modest, incremental technology investment with a fast return. Development time for solutions spans weeks, not months. Different industries will have different drivers for Web services. For example, financial services will need business process improvements over the next four or five years. Web service solutions that support supply chain integration and collaboration first require streamlining business processes. Some companies will find a way to offer their core competencies as Web services to customers, enhancing their revenue streams (Boynton, 2003).

Organizations can benefit from Web services at three levels—infrastructure, operations, and strategic (Huang & Hu, 2004). Infrastructure values stem from using industry-accepted standards and protocols to ensure interoperability among diverse systems. Standardization facilitates information sharing and knowledge transfer within and across firms. Operational values stem from efficient applications development and reuse, based on standards, resulting in efficient and effective business operations. Strategic values relate to SOA, which facilitates the adaptation of IT functions to exchange data internally and with collaboration partners. A flexible IT infrastructure can enhance organizational agility. The

Table 1. Web services for B2B collaboration: Options, requirements, and value propositions

Collaboration Options	**Requirements**	**Values of Web Services**
Buyer-based, one-to-many private exchange	Forge a strong collaboration with supply chain partners	Lower cost of transactions, increased integration
Seller-based, one-to-many private exchange	Foster collaboration with the end customers	Customer retention
One-to-one proprietary linkages	Extend a firm's traditional EDI- or EAI-integration	Enhanced application integration
Independent, public many-to-many exchange	Strengthen the role of intermediary in the exchange	Economies of scale, security, access
Consortia-based many-to-many exchange	Attain common goals of participating companies	Process integration, flexibility

adoption of SOA promises to have significant benefits for e-business collaboration.

Enterprise Adoption of Web Services

Enterprises face various barriers to the adoption of Web services for B2B integration. These challenges include: limited returns on return of investment, inadequate employee skills to support implementation, insufficient senior management support, a lack of technical standards, concerns over security, and poor application interfaces (Charlesworth & Jones, 2003). A multi-case study by Ciganek, Haines, and Hasemanet (2005) of Web services adoption in the financial industry reveals that environmental factors—un-readiness of business partners, industry inertia, security, and standards—seem to play a dominant role in delaying the adoption decision. In comparison, innovation factors of Web services—visibility, complexity, and tools—pose marginal challenges to adoption decisions. Organizational factors, such as IT skills, software development, IT architecture, and financial justification, only have modest effects. Therefore, a strong business need fueled by the demand of key customers or suppliers could drive the growing adoption of Web services.

Gap in Public Web Services

Public Web services also promise to facilitate e-business collaboration. These services are available on the public Web as opposed to applications in intra-corporate scenarios. However, a review by Fan and Kambhampati (2005) of current public Web services reveals that most of the available services (84%) are for data sourcing, number conversion, sensing, or data processing. Only seven public *e-business* Web services were identified. Currently, the industry does not offer sophisticated public Web services that have the potential to interact with other services to support e-business collaboration. Furthermore, very few ways of composing services are available online, mainly due to the lack of services and the correlations among them.

Integration Models

Web services for e-collaboration require the integration of data, application, and business processes. Data-level integration requires an understanding of both database structure and its usage. An enterprise-wide metadata repository will help to define the mappings and necessary transformations required to move data between applications. Application-level integration enables integration of messages from any source, often using an asynchronous message flow to reduce dependency between applications. Process-level integration, which defines the business processes underlying corporate strategies, addresses business processes crossing application boundaries (Charlesworth & Jones, 2003). Business process integration is essential to e-business collaboration.

Security and Standardization

Security is usually viewed more as a business or standards issue rather than a pure technological issue. However, the perceived immaturity of standards poses a substantial challenge for Web services adoption. Organizations are hesitant to provide Web services publicly outside their firewalls. Attention must be paid to rigorous authentication, integrity, non-repudiation, encryption, and security matters. Key threats include: (a) the security of information that is shared between the broker, the requester, and the provider; (b) the security of the network; and (c) the security of the programming model at design time. Trust in e-business also incorporates the notion of trust in the underlying technology infrastructure for facilitating transaction. The dynamic nature of the Web services architecture presents new opportunities for technology trust building (Ratnasingam & Pavlou, 2002).

Standards for Web services security are continuing to mature. Most Web transactions today use secure sockets layer/transport layer security (SSL/TLS) protocols for basic security. However, to address more complex business requirements, designers of Web services have found the SSL/TLS protocols inadequate to address enterprise security concerns. For those complex transactional models involving many trading partners or needing more granular security control over the data, implementers are now beginning to use WS-Security, a maturing standard in Web service transaction security. WS-Security mechanisms are embedded within data objects and persist with the transaction whenever it is moved, including whenever transactions are archived. In contrast, SSL/TLS security can only protect a point-to-point transmission. WS-Security can be used in conjunction with SSL/TLS, and both sets of standards are likely to continue to evolve (Wagner & Heiser, 2005).

FUTURE TRENDS

Web Service Network Providers

Web service network (WSN) providers are emerging to support different business needs. A WSN provides security, services tracking, integration and application services, and trading partner services such as provisioning, non-repudiation, and support. WSNs support different topologies: (a) hub and spoke topology in which a management platform is resident within the WSN; (b) hub and spoke topology in which each partner maintains unilateral control over Web services provisioning and security; (c) unilateral peer-to-peer (P2P) topology; (d) facilitated P2P topology; and (e) facilitated switched-based WSN topology (Lheureux, 2002). Companies will begin to consider a WSN product to manage the exchange of Web services between applications in its internal environment and a WSN service to manage the exchange of Web services with trading partners (Lheureux, 2002).

Web Services Management Platforms

While initial implementation of Web services may be simple, over time B2B integrations will become complex. To alleviate the challenges in managing meshed and chained Web services, Web service management platforms are likely to become mainstream technologies by 2006 (Smith, Andrews, & Abrams, 2003). This increase is also being fueled by Microsoft's aggressive distribution programs, and the entry into the Web service management market of major vendors such as Hewlett-Packard. Business process integration may be aided by the increased adoption of BPEL or other standards such as business process management for Web service flow composition (Smith et al., 2003).

Impact on ERP Vendors

Web services may contribute to the decline of ERP vendors for numerous reasons. Web services can integrate dissimilar systems and enable rapid acquisition of innovative applications. These services can reduce large development budgets by allowing companies to implement change at a pace the organization can absorb, not the pace the ERP vendor demands. Web services accept diversity in architecture, but its adoption rates are slow and will only increase after an IT organization is restructured to shift attention away from computing and onto communications (Strassman, 2003).

Web Services Technology for Private Exchange

Web services will be increasingly used within private exchanges, on either the buyer-side or seller-side one-to-many exchanges. Factors include: the need for companies to maintain agile relationships with partners and the need to protect the identity of services the business offers from anonymous access, and to cement relationships through business agreements, not simply through business process integration. Web services are a more dynamic architecture for enabling a business to rapidly adjust its services, and the private exchange allows companies to maintain some level of secrecy in services (Plummer & Andrews, 2001).

Alignment with E-Business Strategies

An organization needs to align Web services with its strategy in order to realize the strategic benefits of these services. Using these services to improve innovation and learning could result in information sharing and collaboration, and organizational agility. Web services could lead to process automation and acceleration, interoperability, integration, and process redesign. Improved value propositions strengthen relationships with customers and e-business partners. Thus, the alignment would result in better financial performance and shareholder value through reduced operational cost and increased revenue (Huang & Hu, 2004). Enterprise adoption of Web services is expected to evolve over four levels—from technical solution (level 1), IT solution (level 2), internal business solution (level 3), to external business solution (level 4). At level 4 adoption, an organization will engage in process integration with customers or suppliers. This is the case when Web service technology is used for substantial B2B interaction, such as in supply chain applications (Haines, 2004).

Businesses frequently cooperate with one another at all phases of a product's lifecycle in a transient or temporary manner. Instead of forming enduring structures binding the businesses together, businesses form virtual enterprises to reduce costs, increase flexibility, and focus on core competencies (Tolle & Bernus, 2003). For example, Web service technologies are being used to streamline process integration in financial services through a concept known as "straight through processing," reducing cycle times on transactions from several days to one (Khoshafian, 2002). Workflow, business process management standards, and dynamic lookup and binding provide the infrastructure to support the agility and flexibility that virtual enterprises require.

To facilitate rapid creation of virtual enterprises, designers of Web services will increasingly rely on reference models and ontologies. Reference models are system design patterns which can be readily copied and implemented. Many ERP modules are reference models that businesses frequently have to customize for a specific advantage. Ontologies, a formal specification of a shared set of concepts, reduce or eliminate confusion in concepts and terms, and may play a key role in Web collaborations (Gu, Chen, Yang, & Zhang, 2004). For example, e-commerce marketplaces, which bring together many suppliers and buyers, require participants to integrate complex product catalogs. Companies are beginning to apply emerging ontology-based knowledge management tools to assist with the mapping of concepts and syntactical rules between trading partners (Omelayenko, 2001). This fusion of virtual enterprises, Web services, ontologies, and reference models is helping businesses execute flexible, agile, and rapid business strategies.

CONCLUSION

Information technology is again shaping and accelerating the convergence of many forces. Various standards bodies are creating new, higher-level specifications. Nearly every major vendor has committed to a Web service architecture strategy. P2P technologies and Web services are beginning to blend naturally. Service-oriented computing and Web service architectures are allowing companies to deliver more business services across the Internet. Web service technology is supporting a wide variety of collaboration relationships across simple and complex value chains. Despite the challenges that Web services are facing in reaching ubiquity, they are already allowing a rich arrangement of B2B collaborations and new dimensions of competition.

KEY TERMS

Peer-to-Peer Architecture (P2P): An approach to building distributed systems characterized by an increasing decentralization and autonomy of components.

Service-Oriented Architecture (SOA): A component model that integrates the different functional units of an application (services) through well-defined interfaces and contracts between those services. The interface is independent of the hardware, operating system, and programming language.

Simple Object Access Protocol (SOAP): The current industry standard for XML-based messaging in Web services. SOAP consists of three parts: an envelope that defines a framework for describing the contents of a message, a set of encoding rules for expressing instances of application-defined data types, and a convention for representing remote procedure calls.

Universal Description, Discovery, and Integration (UDDI): A mechanism for holding descriptions of Web services. UDDI defines a data structure standard for representing Web service description information in XML. It is also a mechanism, or a directory, for finding Web services.

Web Services Description Language (WSDL): An XML-based language for describing Web services and their interfaces.

Web Services Management Platform (WSMP): Software for managing and monitoring the quality of service in a Web services environment. It manages faults, capacity, availability, performance, service-level agreements, and service levels of Web services.

Web Services Network (WSN): An intermediary brokering service that supports electronic collaborations between applications based on Web services standards (WSDL, SOAP, and UDDI).

INTRODUCTION

Web services provide a standard architecture for heterogeneous systems to share and exchange information over the Internet (Iyer, Freedman, Gaynor, & Wyner, 2003). In this context, Web services are based on the building-block approach of using prior Internet protocols and standards as components of Web services. The building blocks include HTTP, adopted as the transport protocol, and XML, used as the format of the messages that are transferred between cooperating applications (Lim & Wen, 2003).

For e-businesses to fully realize the benefits of Web services, security issues need to be addressed. Security has become a major concern for all enterprises exposing sensitive data and business processes as Web services (Bhatti, Bertino, Ghafoor, & Joshi, 2004). In this regard, this research proposes an integrated security approach for Web services architecture.

The proposed approach, which is an addendum to the Web services security specifications, is built on XML-role-based access control (RBAC) for Web services business processes. Basically, it supports protocol-independent declarative security policies that can be enforced by Web service providers, and descriptive security policies that clients can use to access the services in a secure manner.

BACKGROUND

The sharing of information and knowledge resources is the main motivation for constructing distributed systems. According to Coulouris et al. (2001), a distributed system is one in which components located at network computers communicate their actions only by passing messages. Today, e-commerce is evolving into a dynamic business network where participants have distinct IT platforms and applications. The problems associated with heterogeneity in platforms and applications require technological solution that provides integration without sacrificing past IT investments. In this context, Web services can be considered as the best choice from the different options among distributed environments (Iyer et al., 2003).

Before entering into the security aspects of Web services, it is of vital importance to understand what Web services are. Sleeper (2001, p. 1) defined Web services as "loosely coupled, reusable software components that semantically encapsulate discrete functionality and are distributed and programmatically accessible over standard Internet protocols." In other words, Web services provide a standard way for heterogeneous applications to share and exchange information. Web services are based on the following open standards (Iyer et al., 2003):

- Simple object access protocol (SOAP),
- Extensible markup language (XML),
- Web services description language (WSDL),
- Application programming interface (API), and
- Universal description, discovery, and integration (UDDI) (See Key Terms for more information).

Web service is conceived as a new paradigm for distributed computing environments. However, Web services architecture is still vulnerable to potential security threats (Chatterjee & Webber, 2004). For instance, some of the message level security threats include: message alteration, confidentiality, man-in-the-middle, snooping, denial of service (DoS), and reply attacks.

The most common security techniques used for overcoming these issues are the following: authentication mechanisms, authorization, data integrity and data confidentiality, integrity of transactions and communications, non-repudiation, end-to-end integrity and confidentiality of message, audit trial, and distributed enforcement of security policies. However, such techniques by themselves are not sufficient because they do not consider the holistic view of the e-business processes' security.

The foundation of Web services security is the Web services security plan and roadmap developed by IBM and Microsoft (IBM & Microsoft, 2002). The specifications of this security roadmap are WS-Security, WS-Policy, WS-Trust, WS-Privacy, WS-SecureConversation, WS-Federation, and WS-Authorization.

Several models to address Web-Services security issues have been proposed. In this regard, Joshi et al. (2001) provided an evaluation and comparison of the discretionary access control (DAC) model, the mandatory access control (MAC) model, and the role-based access control (RBAC) model.

The RBAC models have received wide acceptance. They classify the elements of the system into users, roles, permissions, operations, and objects. Because the administration of RBAC is separated from its access control functions, the security administration is made easier and more efficient (Bhatti et al., 2004; Sandhu, Coyne, &Youman, 1996). In addition, a very important characteristic of RBAC models is that they are able to represent organization policies. Chen and Sandhu (1996), who established the foundations for constraints RBAC, explained how organizations policies can be represented and enforced using constraints. In the context of Web services, RBAC does not incorporate the content and context of the information workflow; therefore, RBAC is not appropriate to secure Web services transactions.

Koshutanshi and Massacci (2003) proposed a security architecture for orchestrating authorization and security of the Web services processes (see Figure 1).

The XML-based RBAC approach proposed by Bhatti et al. (2004) provides access control for Web services at the element-level granularity. This approach includes the core RBAC primary elements (users, roles, permissions, operations, and object) as well as the role hierarchies and separation of duty constraints (Bhatti, Joshi, Bertino, & Ghafoor, 2003; Ferraiolo, Sandhu, Gavrila, Kuhn, & Chandramouli, 2001). Moreover, in order to capture the context information, this approach utilizes a location-based technique. Bhatti et al. (2004) uses XML-based specification language to represent each RBAC element and their relationships.

As it was mentioned earlier, Web services still present security issues that need to be addressed. According to Joshi et al. (2001), in order to take care of the Web-based security issues, comprehensive security frameworks are required. Hondo et al. (2002) stated that a Web service security model must support protocol-independent declarative security policies that Web service providers can enforce, and descriptive security policies attached to the service definitions that clients can use in order to securely access the service.

Even though Koshutanshi and Massacci (2003) approach addresses many security issues related to Web Services processes and information flows, it is still not sufficient. The framework by itself secures only the Web services processes and information flows from the client, which can be seen as an enterprise to the application server and vice-versa. As a result, the security of the Web services processes and information flows within the client (enterprise) is neglected. However, using the access control model created by Bhatti et al. (2004), the Web services process and information flows within the enterprise can be secured.

Using Bhatti et al. (2004) and Koshutanki and Masacci (2003) models as a foundation, an integrated architecture for Web services security is developed. Such architecture allows Web services business processes and information flows to be secured across enterprises, and at the same time inside of each enterprise.

A NEW APPROACH FOR EXTENDING THE WEB SERVICES' SECURITY

Essentially, the proposed approach provides for controlled access, secure sharing and distribution of information based on content and context, secure workflows, and secure interoperation in a Web services environment. It is important to keep in mind, that the proposed approach is an addendum to the Web services security specifications. Moreover, it is assumed that for securing the message the W3C and the IETF specification for the XML-signature (Bartel, Boyer, Fox, MaMacchia, & Simon, 2002) and W3C XML-encryption (Imamura, Dillway, & Simon, 2002) are being used. Figure 2 shows the proposed architecture.

The proposed architecture for Web services security consists of different components that interact in two different stages: client registration and client authorization. Figure 3 presents the building blocks of the pro-

Figure 1. Cross-section view of the architecture (Koshutanshi & Massacci, 2003)

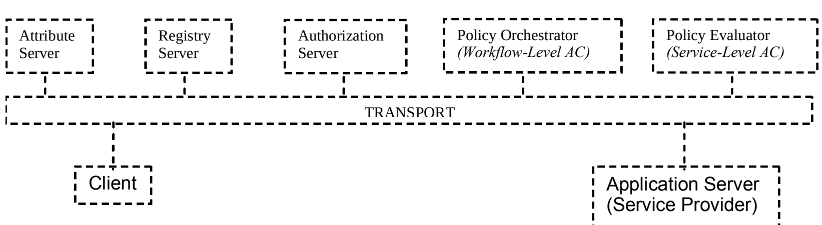

Figure 2. Web services security: Proposed architecture

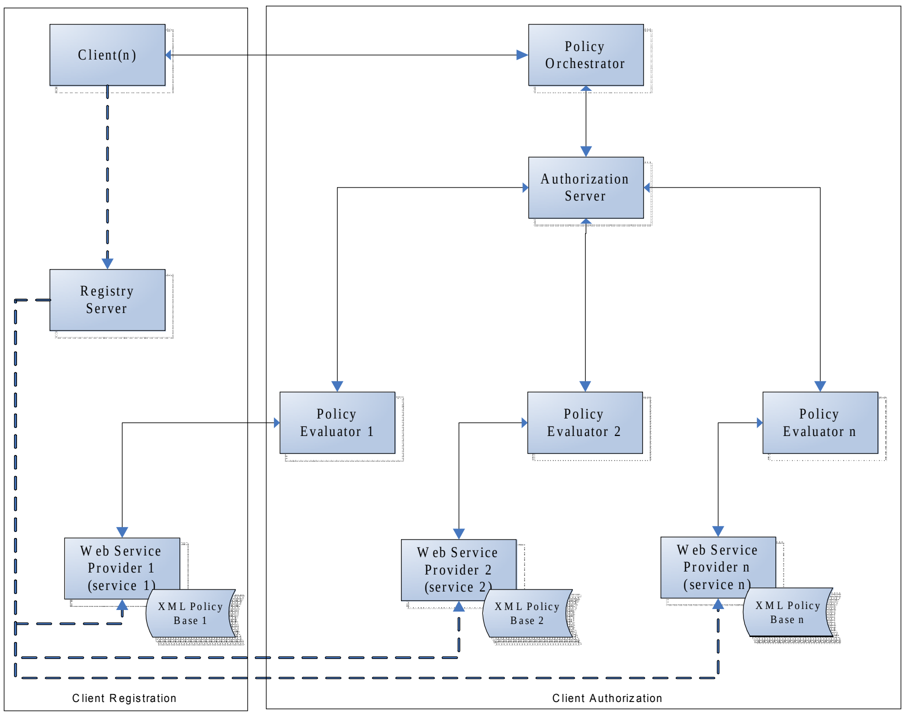

Figure 3. Building blocks of proposed architecture

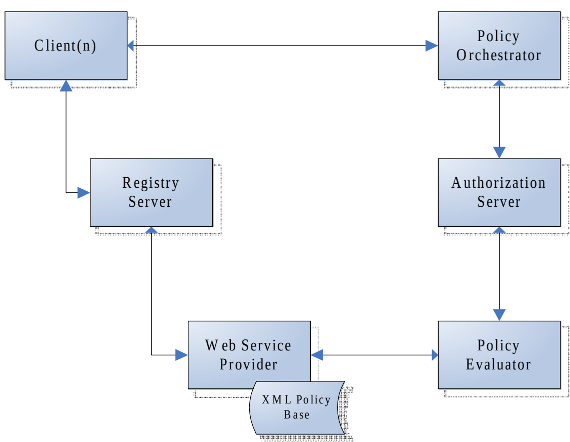

posed architecture and Figures 4 and 5 show the client registration and client authorization process respectively.

This architecture consists of the following building blocks:

- **RegistryServer:** This component maintains the information related to the relations between services and service provider instantiating a particular service (Koshutanshi & Massacci, 2003).
- **AuthorizationServer:** It is in charge of locating, executing, and managing all needed *PolicyEvaluators* and giving an appropriate result to the *ApplicationServer*. In addition, the *AuthorizationServe* runs the actual authorization process by querying each *PolicyEvaluator* (Koshutanshi & Massacci, 2003).
- **PolicyEvaluator:** This element is responsible for attaining endpoint decision on access control. It is

important to keep in mind that each partner involved in the business process is represented by a *PolicyEvaluator* (Koshutanshi & Massacci, 2003).

- **PolicyOrchestrator:** It is one of the most important components of the architecture. It is in charge of the workflow level access and release control. In addition, the *PolicyOrchestrator* is responsible of the Policy Composition Service (Koshutanshi & Massacci, 2003).
- **XMLPolicyBase:** It is a repository which contains the security policy base. The policies relate to activities, roles, and resources are expressed in XML documents, so that, the *PolicyEvaluator* is able to understand and execute them (Bhatti et al., 2004)

Moreover, it is important to keep in mind that the information flows inside the client and Web service provider is made secure by using Bhatti et al. (2004) XML-based RBAC approach, which consists of the following components:

- **Document Composition Module:** It allows for composing XML schemas for RBAC elements and policy administrator documents.
- **Access Control Module:** It is the heart of the architecture. It interacts with others components and makes authorization decisions based on the policy base.
- **Session Management Module:** It monitors session activities and captures dynamic context information that updates user credentials.
- **Document Classification Module:** It manages the classification and clustering of all documents. In addition, this component handles the classification of new documents entering the source.
- **Credential Evaluator, Context Extractor, and Role Mapper:** The credential evaluator component assesses the credentials presented by the access control module and assigns the user to an existing credential type or creates a new credential type if there is not a match of the user credential type and the existing ones. In addition, the credential evaluator component, with the help of the role mapper, maps the credential to a role based on the assigned credential type. The context extractor evaluates the context information.
- **Repositories:** Three main repositories are used in this approach. The first repository is the referenced object base, which contains the physical objects from which the system administrator builds the XML document. The second one is the XML schemas and instances, which contains actual XML sources. The third one is the XML policy base, which contains all policy-related XML documents.

As it was mentioned earlier, the information flow logic in this architecture is a two stage process. In step 1, each

Figure 4. Web service security: Client registration

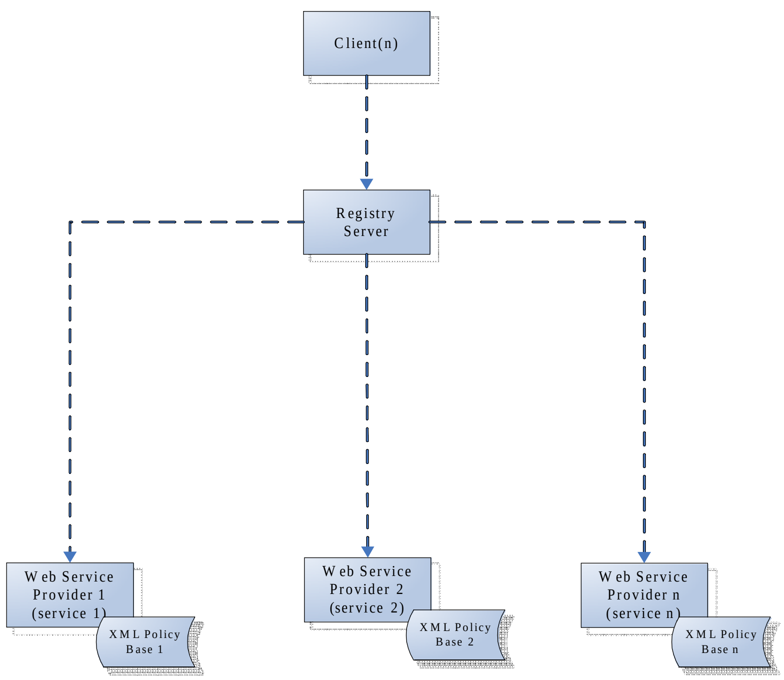

Figure 5. Web service security: E-business process authorization

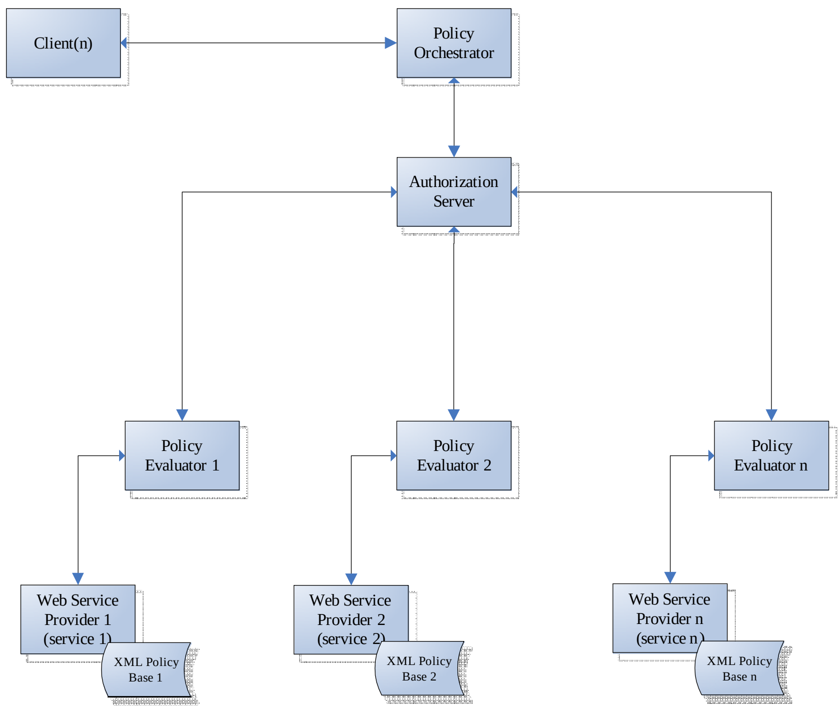

enterprise (client) must be registered at each Web service provider involved in a business process, prior to access the service. This activity is performed through the *RegistryServer*. By using a XML-based RBAC the Web service provider examines its *XMLPolicyBase* and creates a XML document with access control specification (user-to-role mapping) for that particular client. This document is stored along with the user credentials at the *XMLPolicyBase* for later use. Figure 4 depicts the data flow logic for step 1, which is also depicted in Figure 2 as *Client Registration.*

After the client has been properly registered at the different Web Service providers involve in the e-business process, the step 2 which is the process of client authorization takes place. In this step, an enterprise (client) requests to execute a specific e-business process, which encompasses multiple activities (services) taken place at different partners (Web service provider). Figure 5 shows the data flows for step 2, which is also depicted in Figure 2 as *Client Authorization.* In this context, the client asks the *PolicyOrchestrator* for executing a workflow. The *PolicyOrchestrator* determines all the services involved in the workflow and then passes the information to the *AuthorizationServer,* which determines whether or not the client has the right privileges to access and execute the Web Service.

The *AuthorizationServer* queries the *PolicyEvaluator* of each Web service provider involved in the workflow and forwards the client credentials to each *PolicyEvaluator*. Subsequently, each *PolicyEvaluator* examines its *XMLPolicyBase* and determines the right privileges for that particular client and service.

After the *AuthorizationServer* had assessed the response from each *PolicyEvaluator* involved in the workflow, the client is either granted or denied to execute the services. The authorization to execute the e-business process is granted if and only if the client has the right privileges to access/execute all the services required by the workflow. By doing this, the business process as a whole is made secure.

FUTURE TRENDS

Future developments in the area of Web Service security should include technology such as intelligent agents and autonomic computing. A limitation of the proposed approach to secure Web services is that it still needs the human intervention to work properly. In fact, a security administrator for the Web Services architecture is required. Future e-businesses will require discovery, selection, and execution of business process in a dynamic way.

By using intelligent agents and the principle of autonomic computing, a secure Web Service architecture that dynamically changes depending upon new security polices, new business partners, and security threats could be designed.

Information transparency is needed in order for initiatives such as e-marketplaces works efficiently and effectively. However, a secure environment is mandatory as well. Web services are clearly a new paradigm and they will play an important role in the integration of disparate information systems in a secure way.

Finally, Web Services is paving the road for service-oriented architecture (SOA). Under SOA applications are designed and developed as reusable building blocks (services) that react to changing business condition. The research opportunities in the SOA area seem to be unlimited. For instance, the proposed Web services security approach could be extended in a way that SOA is made secure using the e-business process view.

CONCLUSION

Web service is conceived as a new paradigm for distributed computing environments. Web services allow the integration of heterogeneous networks and systems. However, in order for e-businesses to fully realize the benefits of Web services, security issues need to be solved. Even though many models have been proposed to address Web services security issues, they have failed in providing a complete and integrated solution. In order to properly secure Web Service architecture, a holistic view of the e-business processes needs to be considered.

This research proposed a security integrated approach that combines the orchestration authorization of web services processes and information flows with the XML role-base access control. Such approach guarantees an end-to-end secure Web services environment by providing controlled access, secure sharing and distribution of information based on content and context, secure workflows, and secure interoperation. The key of the proposed approach is that the authorization to execute the e-business process is granted if and only if the client has the right privileges to access/execute all the services required by the workflow. By doing this, the interorganizational business process as a whole is made secure.

Some of the advantages of the proposed approach include:

- The proposed approach is protocol-independent because it is based on XML RBAC.
- It leverages in the existing Web service security specifications; therefore, it can be easily integrate with existing standards and implementations.

Although the proposed approach is based on solid grounded theories, future research should be aimed at testing and improving it.

KEY TERMS

Access Control: According to Hondo, Nagaratnam, and Nadalin (2002), it is a process by which the use of resources is regulated based on security policies and is permitted by only authorized system entities according to that policy.

Extensible Markup Language (XML): It was created as an extensible data format to address the limitations of HTML; however, it has become a standard for communication (Hondo et al., 2002). XML has been named "the universal format for structures documents and data on the Web" (http:www.w3c.org/XML). Some of the most important characteristics of XML are that XML resembles HTML, XML is human readable, XML is verbose, XML is a suite of technologies, XML is modular, and XML is license-free, platform-independent, and well supported (Chatterjee &Webber, 2004).

Security Policy: It is a set of rules and practices that establish how a systems or organization provides security services to protect resources (Hondo et al., 2002). Furthermore, security policies can be considered as the criteria used to grant or deny access to critical information resources.

Semantic E-Business: According to Singh, Iyer, and Salam (2005), semantic e-business is defined as "*an approach to managing knowledge for coordination of e-business processes through the systematic application of Semantic Web technologies*" (p. 20). The foundations of Semantic e-business are semantic Web technologies, knowledge management, and e-business processes.

Simple Object Access Protocol (SOAP): It is a simple, lightweight, and extendable XML-based mechanism for exchanging structured data between network applications on top of widely used Internet standards such as XML and HTTP (Hondo et al., 2002). A SOAP message is an XML document whose root element is called envelope. The envelope includes two elements: the first one is the SOAP header, which contains data from various Web services protocols that augment the basic of SOAP infrastructure. The second element is the SOAP body, which carries the application payloads (Chatterjee & Webber, 2004).

Universal Description, Discovery, and Integration (UDDI): UDDI is an industry standard that allows users to find Web services in a dynamic way. A UDDI registry is used by businesses that want to publish services, and by businesses that need to get certain services (Lim & Wen, 2003).

Web Services Description Language (WSDL): In short, WSDL is a language for describing Web services. WSDL is an XML IDL (interface definition language) that provides a way to describe the function and interface of a service. WSDL can be used to specify the interfaces of the Web services bound to a number of protocols including HTTP GET and POST. In addition, a WSDL interface logically consists of two parts: The abstract parts that describe the operations the Web service supports and the types of messages that parameterize those operations; and the concrete parts that describe how those operations are tied to a physical network endpoint and how messages are mapped onto specific carrier protocols which that network endpoint supports (Chatterjee & Webber, 2004).

Web Traffic Aggregation

Robert S. Owen
Texas A&M University—Texarkana, USA

INTRODUCTION

One reason for registering domain names is for use in funneling Web traffic to a particular destination. Procter & Gamble (P&G) owns many domain names based on generic words that can be used to funnel visitors toward P&G brands. Cough.com, germs.com, and sinus.com all currently bring visitors to a page that takes United States visitors to the single Web site, vicks.com. Vicks.com in turn promotes P&G's Vicks-branded line of products that are associated with cough, germ, and sinus remedies. Gooogle.com, gogle.com, goolge.com, googel.com, and foofle.com are all owned by Google, used to *redirect*, or automatically take, visitors to a single Web site, google.com. In this way, Google is *aggregating* Web traffic, generated from all people who type these misspellings, to a single Web site.

Unfortunately, such *traffic aggregation* is sometimes used in ways that can create victims. A child who uses the URL (uniform resource locator) whitehouse.com with the intention to research a school assignment on the American White House (at http://whitehouse.gov) will be taken to a Web site with adult content. Someone who believes that he or she is using the URL of a Web site devoted to gun control could end up at a Web site with a threatening message by an opposing group (cf. "Hacker Intercepts," 2000; Montgomery, 2000). Someone who types what is thought to be the name of a popular children's Web site might be taken to a site that tricks people into downloading malicious software (cf. Happy Trails Computer Club, 2004; "IIS Exploit," 2004; MIT IS&T, n.d.; Spector, 2002). People might click on an index link or a personal bookmark to visit a school or church Web site, not knowing that the organization is using a new Web address, and be taken to a Web site with adult content (Markovich, 2001; cf.Bryant, 2001; Hardy, 2001).

BACKGROUND

Through the careful selection of domain names, P&G is possibly attracting visitors to Web sites that promote brands related to the generic words that it has registered. Through the selection of domain names related to common misspellings of its brand name, Google is attracting visitors who might otherwise get lost and not find its Web site. In either case, if these organizations were not using these domain names, someone else might. While attracting visitors to its Vicks brand with the use of domain names based on generic words, P&G is able to keep a competitor from using these words to push visitors toward a competing brand. If Google had not registered misspellings of its brand name, someone else could use those domain names to gain visitors to increase traffic to Web sites that are completely unrelated, such as those presenting pornography or gambling.

A *traffic aggregator* can, then, acquire domain names that generate traffic, but which will take visitors to Web sites with a purpose or theme that is unrelated to the apparent content of the domain name. The aggregator can then push ideological or commercial messages that Web visitors might otherwise not seek, can sell products that the visitor might not otherwise have purchased, can trick the visitor into divulging personal information (e.g., a credit-card number), or can download malicious software to an unsuspecting visitor's computer (cf. Marsan, 2002). Such a scheme can cause visitors to be victims.

In many cases, a traffic aggregator will acquire old, existing, abandoned domain names to redirect traffic to and thereby increase traffic to Web sites with gambling and adult content. In this scheme, the acquired domain names are often ones that have been deliberately abandoned by organizations that no longer need them. The abandoning organization probably does not realize, however, that the abandoned name has value to an aggregator because it still generates some traffic by being listed in link indexes, in peoples' browser favorite lists, and such. The victims in these cases are not only visitors, but also those who maintain link lists that include the abandoned domain names. The abandoned domain name is not simply a dead link when it is reacquired by such a traffic aggregator; it is now a link to objectionable material. In this way, organizations such as the United Nations and the U.S. Department of Education have found themselves accused of maintaining Web sites with links to pornography (Marsan, 2002).

THE EMERGENCE OF TRAFFIC-AGGREGATION ACTIVITIES

Domain-name speculators registered domain names in the early days of the World Wide Web on the expectation that they had future value either for personal use or for resale. Procter & Gamble was once the owner of dozens of domain names such as armpit.com, beautiful.com, diarrhea.com, and flu.com, reportedly asking for more than $1 million each for at least some of the nearly 100 names that it auctioned in 2000 (Associated Press, 2000; McCarthy, 2000; Oppenheimer, 2000; VeriSign, 2000). The purchaser of the $7.5 million domain name Business.com, eCompanies, believed that its high purchase price for this name was a wise investment because the name would drive traffic and thereby lower advertising expenditures (Mack, 1999). But such names were long ago registered, and the resale values are now high enough that few can afford to make such an investment.

Domain-name squatters register the names of famous trademarks, organizations, or people on the hope that those identified with these might someday want to purchase them or on the expectation that these could be used to drive traffic to a Web site with unrelated content. Ron Gonzalas, candidate for mayor of San Jose, CA, found that the domain name Gonzalas2002.com had already been registered to someone who had similarly registered future dates with the names of mayoral candidates in other large U.S. cities as well as the names of U.S. senators. San Francisco mayor Willie Brown's name was registered on multiple domains as a way to drive traffic to content that was unfavorable to the mayor (Learmonth, 1999). Arbitration decisions that have favored a challenge by someone who would appear to have more legitimate rights to the name, existing trademark laws, and new laws, however, will probably decrease such interests in domain-name squatting in future years (cf. Mariano, 2001; *Anticybersquatting Consumer Protection Act*, 1999).

Typosquatters and *Web spoofers*, however, rely on using traffic that is already generated by a particular name or Web site. Spoofers and typosquatters register an alternate spelling or a misspelling of a name or Web site that generates traffic (visitors). This could be through transposing words or inverting a phrase. Whitehouse.com, for example, is an adult site that is deceptively similar to whitehouse.gov. Cartoonjoe.com is a transposition of joecartoon.com, and dinsey.com is a misspelling of disney.com; these domains were used by the convicted porn peddler John Zuccarini. The U.S. government alleged that Mr. Zuccarini earned as much as $1 million annually through typosquatting variations of Web sites associated with entertainers, celebrities, and cartoon characters popular with children. Mr. Zuccarini was eventually jailed, but only after the passage of a law that now makes it a crime to use a misleading domain name with the intent to attract a child to a pornographic Web site (Edelman, 2003a; "Report on Reaction," 2003; *Truth in Domain Names Act*, 2003; Whois Source, 2004). Typosquatting and Web spoofing are not in themselves illegal and are not necessarily always unethical, but as can be seen in this case, these can be lucrative ways to aggregate traffic to a revenue-generating Web site if no laws are broken.

Domain-name grabbers watch for names that are about to expire and immediately grab or register them when released by the registrar. Domain-name grabbing is different from *domain-name hijacking*, the latter being an increasingly difficult scheme in which the registrar is fraudulently tricked into transferring ownership of the name. In many cases, grabbed names had been deliberately abandoned by the original owners who did not realize how much value the name might have. The most desirable grabs to traffic aggregators are domain names that are highly linked from other Web sites, that are highly placed in search engines, or that were once popular and are likely to be saved in bookmark or favorite lists on personal Web browsers. Two years after the American River College deliberately abandoned an old domain name, it found that some people were still linked to the old name, but that the links now pointed to an adult-content Web site (Hardy, 2001). The Catholic Diocese of Brooklyn, New York, and the Ballet Theater of Maryland similarly found that their abandoned domain names were grabbed to point to adult content (Markovich, 2001; cf. Bryant, 2001; Hardy).

Tina's Webcam perhaps best illustrates the value of abandoned Web sites to traffic aggregators. Edelman (2003b) conducted an archival analysis on the Tina's Webcam site, finding 4,525 distinct domain names that redirected to it. Prior titles were available for 2,991 of these names, and none were found to have previously hosted content related to what was on Tina's Webcam. These domain names were found to have been very popular previously with regard to being linked and accessed. Links from search-engine listings and from others' Web sites could provide pointers for such traffic aggregators for years.

FUTURE TRENDS

Emerging schemes for taking control of domain names for use in traffic aggregation are based on issues that are not easily regulated by industry practice or law. Possibly the most serious issue is that it is not uncommon for organizations—churches, schools, children's groups, or families—to deliberately abandon a domain name, perhaps in favor of a new name. The abandoned name might still have value to a traffic aggregator, however, if it is linked from many other Web sites or if it is still bookmarked by many people. A traffic aggregator could use a *domain back-order service* to automatically reregister the name immediately after it expires as a way to drive traffic to an unrelated and perhaps image-tarnishing Web site. Although it is possible to argue in arbitration proceedings that a domain name should be returned to the first owner after it is allowed to expire either accidentally or deliberately, such an argument has been more difficult to make in recent years.

Domain names are more likely in the future to be taken "fairly" by parties who are interested in traffic aggregation and to be taken through ways in which harm to a third party is not immediately apparent. Domain-name misspellings that are registered by typosquatters are likely to go unnoticed for a long time or even to go completely unnoticed because they will not be something that individuals would bookmark or post on Web-site link lists. A domain name that is grabbed upon expiry and release might be more quickly noticed by those who keep Web-page link lists and such, but this, too, can go unnoticed until a visitor takes the time to complain.

Except in the case of large corporations with the resources to wage costly trademark lawsuits, most domain-name owners are likely to only have the resources to use arbitration in asking for the domain name to be taken away from a typosquatter or grabber (ICANN, 2001). Winning such a case is not guaranteed, whether through arbitration or through the courts. Arbitration cannot award damages, but can merely decide who should be permitted to own a domain name. To a small organization that chooses to use arbitration rather than the courts, the cost will still be a minimum of $1,500 and will require a lot of time and annoyance.

A traffic aggregator who has registered a domain name, on the other hand, is not required to invest any time or financial resources in responding. Although a nonresponse to arbitration will cause a forfeit in the complaint, a traffic aggregator has nothing to lose in such cases. The cost of registering a domain is now less than $10. The traffic that is generated through redirection to, say, an adult site needs only to generate a single $10 order to pay for itself before it is lost to arbitration. A loss through forfeiture in arbitration could take months if an issue ever even moves to this level. While the cost in time and money is relatively great to a small organization that is attempting to gain control over a disputed domain, it is almost nothing to a traffic aggregator who views the domain name as a disposable, cheap, and easily replaced commodity that need not be defended. The traffic aggregator actually has a greater incentive to hold out for the payment of a modest ransom than to agree to an arbitration settlement.

CONCLUSION

Domain names often have greater value to traffic aggregators than many realize. Schools, churches, children's groups, or individuals with personal Web sites often do not realize that an abandoned domain name, a spoofed domain name, or a typosquatted domain name can have value to someone with unwholesome interests. More publicity is needed regarding the interests of traffic aggregators and the trouble that they could cause to innocent and unwary parties.

For those who have a concern about an organization's reputation:

- Alternative domain names and spellings (spoofs and typos) should be registered to redirect at the primary Web site as Google has done.
- Abandoned domain names and spellings (spoofs and typos) should be registered to redirect at the primary Web site as Google has done.
- Links from search engines, indexes, and link lists should be checked to ensure that the organization's name is not being used by a traffic aggregator in ways that will tarnish the organization's name.

KEY TERMS

Domain-Name Back Order: A service provided by domain-name registrars that will watch for a domain name to be released upon expiration and will automatically register that name for the client when this happens.

Domain-Name Grabbing: Registering an abandoned or lapsed domain name immediately after it is released by a registrar.

Domain-Name Hijacking: Obtaining a domain-name transfer of ownership through fraud.

Domain-Name Speculation: Registering or purchasing a domain on the speculation that it could be used in the future to drive traffic or can be resold in the future at a higher amount.

Domain-Name Squatting: Registering a trademark, an organization's name, or a person's name as a domain name with the intention to profit from traffic to an unrelated Web site or by reselling the domain name back to the person or organization.

Malicious Software: Harmful software, such as applications that set the user's browser home page to a Web site (e.g., points to an adult content) without the user's intentions, applications that install viruses without the user's knowledge, or applications that report information about the user without permission to do so (spyware). Some applications can also be known as malware.

Redirection: Sending a visitor to a Web-site address that is different from what was typed into the browser URL window or a link.

Traffic Aggregation: Using a domain name, often multiple domain names, to drive traffic (visitors) to one Web site.

Typosquatting: Registering and using a domain name that is a misspelled variation of a trademark or organization name.

Web Spoofing: Registering and using a domain name that is deceptively similar to a trademark or organization name. This could be through transposing words or inverting a phrase.

Web-Enabled Portals for E-Business Workplace

Wita Wojtkowski
Boise State University, USA

INTRODUCTION

Portals are information systems that support the user in his or her individual process with information production and communication. The term portal, in information technology terms, appeared in late 1990s at a time of the widespread use of the Internet by individuals and organizations (Finkelstein & Aiken, 1999; Dias, 2001; Bristow, Dickinson, Duke, Henry, & Makey, 2001; Collins, 2001, 2003).

There are many types of portals on the Internet: portals for general consumer use and entertainment (my.yahoo.com), for specialized information (www.brint.com), for specific communities (Austrian Academic Portal at www.portal.ac.at/), for business enterprises (NEC global portal at www.nec.com, NEC US portal at www.necus.com/, NEC European portal at www.neceurope.com). In general, portals can be divided into two categories: public and enterprise (Goodman & Kleinschmidt, 2003; Forrester, 2003).

Public portals started as Internet directories (Yahoo!) or search engines (Excite, Lycos, AltaVista, and InfoSeek). Services that require user registration such as free e-mail, customization features, and chat rooms were added to allow repeated use, and to make users stay longer at the site.

Enterprise portals started as intranets and extranets, the "enterprise webs" that were intended to provide easy-to-use, secure, and personalized sites that may extend to an organization's employees as well as to its customers and business partners. Enterprise portals evolved to include collaboration tools so that customers, business partners, and employees are empowered to maximize their value to the organization. Portals that combine Web communications and thinking inside large enterprises are considered as both a labor-saving and a cost-saving technology. Enterprise portals are also referred to as corporate portals. Some corporate analysts predict that portals spending will be one of the top five areas for growth in the Internet technologies sector.

BACKGROUND

While there are multitudes of enterprise portal deployments, each can be assigned to one of three distinct groups. These groups, in increasing order of complexity, are classified as fundamental, integrated, or collaborative (Strauss, 1999; Terra & Gordon, 2002; Moore, 2002; Plumtree Software, 2005; *Portals Magazine,* 2005).

Fundamental Portals

Fundamental portals are those that offer a framework where users can find Web applications from a single entry point. They provide very little functionality and are essentially a means to connect legacy applications. Portals of this type do not attempt any type of enterprise process integration and typically function as a list of links.

Integrated Portals

Integrated portals integrate the applications and the delivery of customized, role-based content, while providing access to information across the organization.

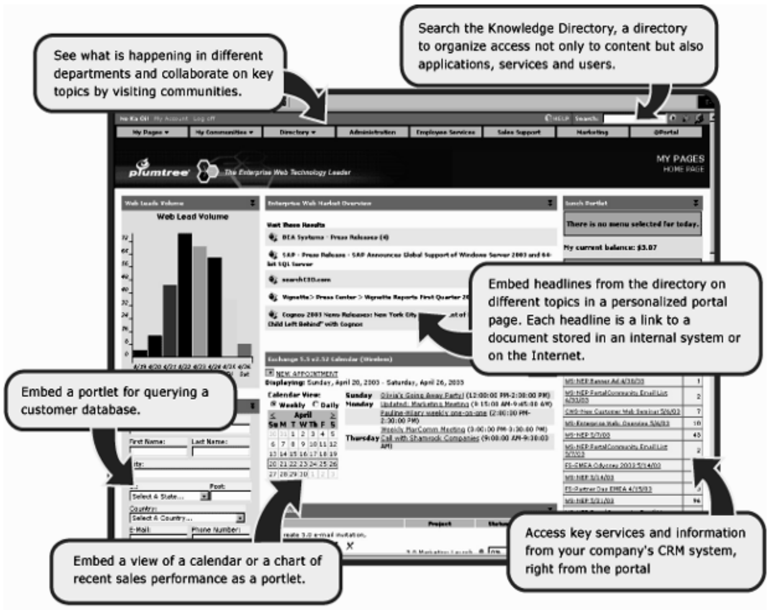
Integrated portal initiatives in organizations focus on providing access to information and to streamlining information technology and business operations. However, these types of solutions are not able to integrate fully people, processes, content, and applications.

Collaborative Portals

Collaborative portals integrate users, content, and collaborative tools. Collaboration services such as presence awareness, instant messaging, Web conferencing, and third-party applications in the context of business processes are integrated into the portal. The user of the collaborative portal can tap into different resources throughout the enterprise, leveraging various collaborative tools through a consistent interface.

A collaborative portal requires that an enterprise looks at itself as a collection of business processes (financial management, product development, etc.) rather than functional departments (marketing, manufacturing, or human resources) or simplified segments (business-to-employee or business-to-customer). Collaborative portals offer more than just access to applications and content. The most evolved collaborative portals enable key business processes, appear integrated and personalized for each individual's roles in the organization, and allow access to

Figure 1. Plumtree portal page example



people and expertise through collaboration (Plumtree, 2005).

FEATURES OF ENTERPRISE PORTALS

The features of enterprise portals include (Sribar & Lynn, 2003; Pushmann & Alt, 2004):

- **Single Touch Point:** The portal is the delivery mechanism for all business information services.
- **Collaboration:** Portal users can communicate synchronously, through chat or messaging, or asynchronously, through e-mail and blogs.
- **Content and Document Management:** Services that support the full lifecycle of document creation and provide mechanisms for authoring, approval, version control, scheduled publishing, indexing, and searching.
- **Personalization:** The ability for portal members to subscribe to specific types of content and services. Users can customize the look and feel of their environments.
- **Integration:** The connection of functions and data from multiple systems into new components.

Figure 1 shows an example of the customized and personalized component of an enterprise portal from Plumtree Software (2005). Through a personalized portal page such as this one, the user is able to access services and content (both static and dynamic), as well as aggregate disparate applications (these are identified in Figure 1 with heavy arrows and boxes containing explanatory text).

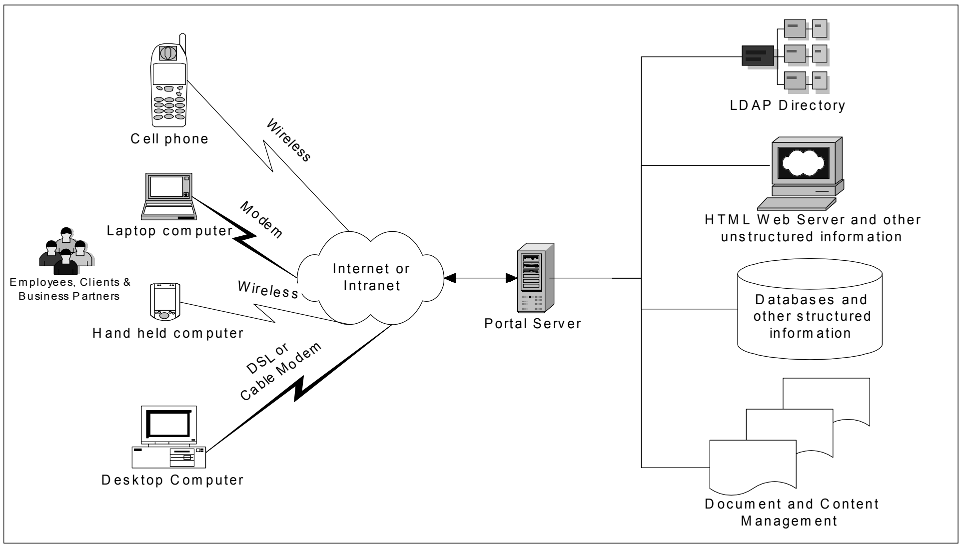
Since the enterprise portals are now designed to allow collaboration, a portal's content (or part of it) should be accessible on multiple platforms such as personal computers, personal digital assistants, and cell phones (Portals Community, 2005). Generic portal ecosystem components are shown in Figure 2.

The Working of a Portal

When a user requests actions, such as searches or information retrieval, the portal server locates and initiates the appropriate gadget. These gadgets perform the requested task and send the results back to the portal server, which formats and sends the reply back to the client. Gadgets can be a simple pass-through to an HTML page or they can be complex applications. Both the portal itself and the gadgets run on a servlet engine inside an HTTP Web server. An HTTP Web server is software that renders and presents HTML pages to browser applications.

A servlet engine is a computer program that runs within an HTTP Web server and takes specific requests from the Web server, processes them, and then hands them back to the Web server in HTML format for it to render.

Figure 2. Generic portal ecosystem components



The open source Apache HTTP Web server (http://httpd.apache.org/) is an example of a Web server. The servlet engine could be the Tomcat (http://jakarta.apache.org/tomcat/index.html), which is written in Java (http://java.sun.com).

Portal Environment

The elements of the portal environment are these:

- **Application Server:** An application server provides the underlying development and runtime infrastructure for the portal. Examples of J2EE application servers include Sun ONE, BEA WebLogic, IBM Websphere, Oracle 9iAS, and JBoss. Many of the application server vendors incorporate portals as add-ons to their base product. For example, IBM Websphere Portal Server, Oracle Portal, and BEA Portal are all built on top of the corresponding application server and in some cases are sold as one package. Several of the stand-alone portal products, such as Plumtree, Epicentric, and Corechange, have Java components or are Java based and take advantage of an application server.
- **Web Server:** A Web server works in conjunction with an application server to provide the runtime environment for client requests. The HTTP Web servers used with portals include Microsoft Internet Information Server (IIS), Apache, and so on. When a customer brings up the portal page, the Web browser makes a request of the Web server. The Web server then passes the request to the application server. The portal (and its associated gadgets) runs on top of the application server.
- **Database:** Most portals have an underlying database (such as Oracle, DB2, Sybase, or SQL Server) that they use to keep track of information specific to the portal—such as users, personalization settings, available Web services/gadgets, and security. This use of the database is in addition to the use of the database by a transactional system (for example, ERP, CRM, or SCM system) that a portal might query in order to present application-specific data to customers.
- **Taxonomy:** A taxonomy is a classification scheme to organize a collection of information. Ideally, a taxonomy would take a set of documents and make it easy to browse, search, or otherwise navigate information in which the user is interested. A taxonomy is analogous to a folder structure, with the additional functional components of metadata for document classification as well as the rules for categorization. Most enterprise portals have a taxonomy for this purpose; some may have automatically generated taxonomies based on the metadata provided.
- **Crawler:** A crawler is an automated process that reads, indexes, and classifies documents at a predetermined interval. A Web crawler, for instance, would crawl target Web pages periodically to determine if the content has changed. The content is then indexed into the taxonomy so that customers

can easily find it. The crawler does not necessarily make another copy of the crawled document; rather, it indexes it by creating a virtual card that describes the document. The card then lives in the portal index.

- **Metadata Repository:** A metadata repository contains metadata about the content within the portal and the structure of that content. This includes metadata about the taxonomy, as well as metadata for the individual documents. For example, each document placed in a folder called Clients might have a metadata field called "Client" which would have one or more values. The value of the Client field for a particular document is metadata about that document.
- **Gadget:** This is a user interface for presenting data and functionality from multiple applications on a single Web page. Gadgets encompass the presentation layer and business logic. They also tie into back-end data sources and are given different names by vendors (portlets, blocks, Web modules, Web parts). Many portal vendors have gadgets for connecting to enterprise systems (such as SAP) as well as for collaboration, news, and other functions.
- **Categorization Engine:** A categorization engine is used for sorting documents into the folders of taxonomy. The categorization engine may do this based on metadata in the documents, business rules, the content of the document, search criteria or filters, or some other scheme.
- **Filters:** A filter is generally available in a taxonomy to restrict the documents that are admitted into a particular folder or that are returned as part of a search. A filter can be word based (for example, if a document has the word "IBM"), concept based (for example, if the document is like another document), or rule based (for example, if the field called Client has a value of IBM).
- **Index:** An index is a collection of information that allows for fast query and retrieval of information. Within the context of a portal, an index is usually a combination of a full-text index and a metadata repository for the documents/content that are included within the portal.
- **Virtual Card:** Within an index or metadata repository, a virtual card is a description of a single document or piece of content within the portal. The card usually contains information about where the content physically resides and contains the values of one or more metadata fields about that document. The card is the "placeholder" for the document within the portal.
- **Web Service:** A Web service is a program that accepts and responds to requests over the Internet. Typically, a Web service accepts requests in an XML-based format. The actual format of the request and the response depends on the XML standards that are being used. One such standard is SOAP. There are public registries and languages—such as UDDI, WSDL—which are used to catalog the different available Web services. A calling program can query the UDDI registry to find an appropriate Web service, then use WSDL to determine which parameters the service needs, and finally use a calling protocol and XML standard like SOAP to make the call to the Web service.
- **User Profiles:** Each portal contains a profile for each of its users. This profile is used for customization and personalization. Each of the gadgets in a portal has access to this user profile and can use it to store preference information about a user or a class of users. This profile determines how the user configures the home page of a portal, and chooses which gadgets show up and what information they show.
- **Content Management System:** Most enterprise portals contain a content management system, which allows approved users to submit information into the portal. There is typically an approval process that eventually results in the content becoming available in the correct part of the portal's taxonomy. A content management system can deal with documents in their original formats (for example, Microsoft Word or PDF) or might contain Web editing features to allow users to author Web pages.
- **Enterprise Application Integration (EAI):** EAI is an umbrella term for all software and services meant to integrate enterprise applications with one another. An EAI layer is needed so that queries can be coordinated, and results consolidated. Given the complexities of each type of application (for example, sales, manufacturing, service, purchasing), this can be a difficult and expensive process. A number of vendors have released software that makes this process much simpler, including Crossworlds, WebMethods, Tibco, NEON, and IBM. EAI impacts the portal because the portal ideally will show consolidated information from multiple backend systems.

On Portal Vendors

Portal technology is both infrastructure and a software application. Those who want to implement portals in organizations are faced with various levels of vendor, technology, and budget risk. Moreover, portals, like any information technology purchase in an organization, are required to prove their value. Valuation of portals is especially difficult because the portal market is always in a state of flux. An excellent site, www.portalscommunity.com/ (Portals Community, 2005), is highly recommended for those interested in an unbiased view concerning portal technology and the portal market.

FUTURE TRENDS

Portal software is maturing from a simple interface for accessing multiple systems to a powerful platform for delivering new, composite applications. The survivors in the portal market have grown by incorporating new technologies for content management, collaboration, search, and single sign-on. The result is the emergence of an enterprise-wide working environment on the Web (Plumtree, 2005). This environment may remain open, or may yet become part of application servers, which have begun to offer functionality beyond the Java 2 Platform Enterprise Edition standard (Pushmann & Alt, 2004). At stake is whether the portal, and the entire enterprise Web, is merely an extension of client-server infrastructure, based on a single type of application server, or an environment that is open in a fundamentally new way. This openness is in the interests of any organization that anticipates having to support multiple application servers. For this reason openness will triumph in the portal market, as it has in virtually every other information technology market.

CONCLUSION

Interest in portal solutions remains strong, and 'enterprise portal software' is one of the 'highest priorities', ranked only behind security technology and wireless networks (Sribar & Lynn, 2003). Two types of players are currently competing to gain control of the enterprise portal market: pure-play and infrastructure. The pure-play vendors offer an independent layer to accommodate various competing systems. Vendors in this segment promote flexibility and claim to solve business problems of enterprises that are running operations on various platforms and building services in a range of programming languages. Examples of the key pure-play vendors include Plumtree and Epicentric. On the other side, the infrastructure vendors claim to deliver portal technology as an essential link in the emerging Web services market. This segment includes IBM, BEA Systems, Sun Microsystems, Oracle, and Microsoft. These vendors advocate scalability and access to serious application server resources, including load balancing and clustering. They consider the portal as a vital part of the infrastructure, tightly linked with the application server and Web services. According to infrastructure vendors, pure-play portal technology cannot utilize all the reliability, scalability, and development tools of an application server. In our opinion, however, a business selecting a portal vendor should look to meet the core purpose of the portal first. Then the business should look for portal products that can be used to meet some of the organization's other needs.

KEY TERMS

Communities: A destination within the portal used to deliver applications and group workspaces. For example, portal users can create communities to bring a team of people together to collaborate on a project or to deliver an employee services application to the entire company. Communities are assembled using portlets, and can be created from templates that control the community's functionality and appearance.

Corporate Portal: Corporate portal and enterprise information portal descriptors are used interchangeably.

Collaboration Server: Helps users work together via the Web, supporting tasks, projects, communities, calendars, discussions, and document sharing with version control.

Content Server: Allows publication and management of Web content for portals and Web applications, with forms-based publishing, templates, and workflow.

Knowledge Directory: An enterprise-wide taxonomy for organizing content from Web sites, document databases, and file systems, as well as portlets, communities, and user profiles.

Personalized Pages: Personalized view of content and applications assembled by the portal. A personalized page can, for example, highlight a user's deadlines across many Collaboration Server projects or the latest resources added to a Knowledge Directory topic. The page typically also shows the user key services from a wide range of applications, such as call center queues from a customer support application or expense report requests from an employee services application. Such a page may also include personal productivity services such as the user's e-mail or stock quotes. Personalized pages are assembled from portlets.

Portlet: A reusable Web component that displays relevant information to portal users.

Search Server: Indexes and searches all the documents, information, applications, communities, Web sites, and other content accessible through the portal.

User Profile: A profile on a portal for each user that defines customization for that user.

Web Services Integration Technologies: Technologies that connect the portal to enterprise systems, repositories, and resources, with equal support for both .NET and Java integration.

INTRODUCTION

During the last decade mobile communication networks follow the evolution of fixed networks in order to provide moving subscribers with all the services and applications of fixed subscribers. This however is unfeasible due to restrictions and limitations imposed by the hostile radio channel. The global system mobile (GSM) network, known as 2G technology (Mouly & Pautet, 1992), is adequate in meeting voice communication speeds of a typical subscriber since it offers limited communication capabilities (< 9.6 kb/s). The ideal mobile network would be able to provide moving subscribers with continuous access to every possible voice or data network, leading to the realization of a "mobile office." The result of this effort (although somewhat restrictive in terms of realizable bit rates) was another evolution in mobile networks, the general packet radio service (GPRS) network (usually referred to as 2.5G), with available data rates of approximately 40 kb/s up to 100 kb/s.

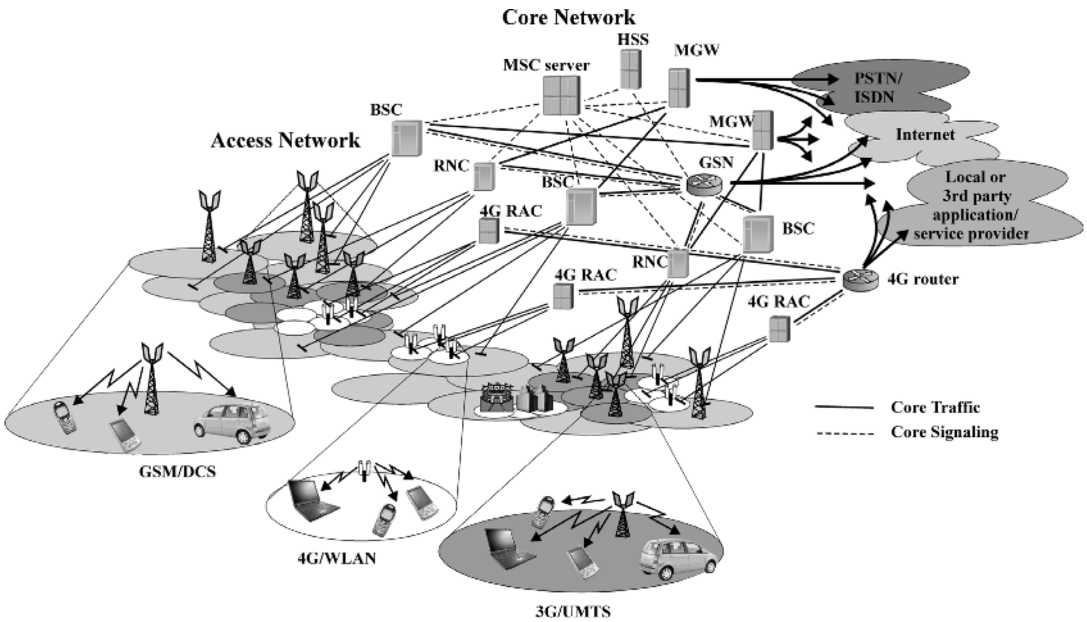
The universal mobile telecommunication system (UMTS) (usually referred to as the third-generation cellular network or 3G), with competitive rates of 300 kb/s and a future possible upgrade up to 2 Mb/s, is the realization of a new generation of telecommunications technology for a world in which personal services will be based on a combination of fixed and mobile services to form a seamless end-to-end service for the subscriber. Its realization at least requires provision of a unified presentation of services to the end user, mobile technology that supports a very broad mix of communication services and applications, and finally on-demand flexible bandwidth allocation reaching 2Mb/s per subscriber. Moreover the exploitation of pure (not tunneled) Internet protocol (IP) interconnection of network elements between each other for data exchange and operation and maintenance purposes should be available, along with the provision of flexible end-to-end all-IP connectivity in terms of user information.

3.5G and 4G (Esmailzadeh, Nakagawa, & Jones, 2003) systems are already under investigation. Aiming to "context-aware personalized ubiquitous multimedia services" (Houssos et al., 2003), 3.5G systems promise rates of up to 10Mb/s (3GPP Release 5), while with the use of greater bandwidth, these rates may raise even more in 4G (Esmailzadeh et al., 2003). On the other hand, the last five years a standardization effort has started for the integration of Wireless local area network (WLAN) in order to support higher bit rates in hotspots or business and factory environments, with a cell radius on the order of 100m. In any case, 4G and WLAN technology are going to be based on an IP backbone between access points (APs) and access controllers or routers and the Internet. Mobile IPv4 and IPv6 are already under investigation (Lach, Janneteau, & Petrescu, 2003) to provide user mobility support for context-type services.

BACKGROUND

In Europe, the delay of 3G cellular networks deployment and the large investment demand for a new spectrum led mobile operators to search for innovative ways to improve the current offerings to customers with services similar to those of 3G. Today cellular networks seem to offer data services to customers using GPRS as the global and successful solution. However GPRS has the main disadvantage of the limited potential of supporting high data rates, required in business and multimedia applications. Therefore, since 2.5G technologies are insufficient to meet market needs and 3G cellular data technology is not yet (with moderate future employment) available, mobile operators are becoming interested in the WLAN technology. This recent interest of mobile operators is justified because of the recent global evolution and successful deployment of WLAN networks. This worldwide approval of WLAN networks is a result of very high data rates providing superior bandwidth compared to any

Figure 1. Integrated cellular/WLAN network architecture



cellular technology. As a result, IEEE 802.11 variants face data rates of up to 11Mb/s (802.11b) and 54Mb/s (802.11a/g), while rates in excess of 100Mb/s have already been acknowledged (Simoens, Pellati, Gosteau, Gosse, & Ware, 2003). On the other hand a GPRS handset offers a theoretical data rate up to 172 kb/s (typically 42 kb/s) and the third-generation terminal up to 2 Mb/s (typically 144 kb/s). The future mobile operator networks shall be a combination of several radio communication technologies, such as GPRS/UMTS/WLAN.

WLAN penetration is expected to be widely deployed in public locations such as hotels, commercial centers, airports, ports, and enterprise buildings. The architecture of deployment is based on the hotspot solution. In order to increase the revenue, operators must provide a seamless experience among current cellular and WLAN access networks. The target is to utilize infrastructure investments of existing cellular networks and interconnect the WLAN network architecture into the core cellular network. The operator WLAN system should maintain compatibility with the existing GSM/GPRS mobility management procedures (location update, authentication, roaming, and billing functions), minimizing the investment in the merging network deployment. A universal subscriber identity module (USIM) (Spiros, Louvros, & Iossifides, 2004) is a natural choice for WLAN subscriber management, since it is widely deployed and enables roaming to existing GSM/GPRS handsets and networks. Moreover, subscriber identity should be used in all access networks to enable seamless service availability.

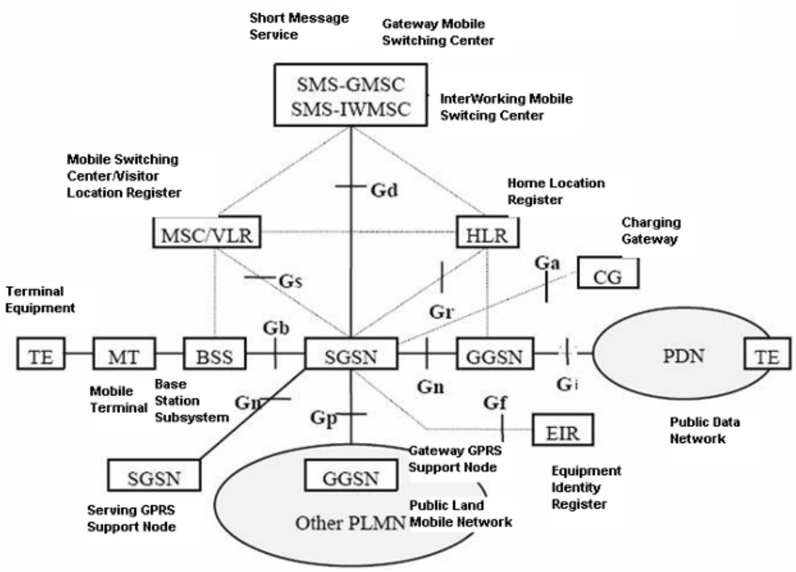
An example of future mobile network architecture, engaging almost all forms of aforementioned technologies, is presented in Figure 1. All the technologies will coexist in the next decade, and smooth transfer of end user services and information rate among them has to be considered carefully (3GPP is already under a standardization process of interoperability between GPRS/UMTS and WLAN) (ETSI TR 101 957), (3GPP TR 22.934 v1.2.0).

INTERWORKING SYSTEM ARCHITECTURE

Presentation of the Idea

The general idea is that a cellular data customer can use the resources of WLAN whenever possible in order to increase its data rates and to make use of all the available multimedia services without delays. Of course the deployment of the WLAN network is based on Hotspots architecture. Hence the coverage of a WLAN network will be limited in special places, where most of the customers can use a laptop or a PDA to use the offered services. Such places are commercial centers, city center areas like cafeterias or hotels, enterprise buildings or airports, and finally crowded domestic areas. There is no need for full coverage of the whole geographical area of a city or a country, since in the areas of no WLAN coverage, GPRS solution is enough to provide the mobility freedom to

Figure 2. GPRS interfaces



cellular customers with satisfactory moderate data rates. In such a case the cellular customer might start a session with the best network coverage, say WLAN in a hotspot area. While the customer is waiting, he can take advantage of the high bandwidth of WLAN in order to gain access to the offered services. As the customer moves away from the coverage area of the hotspot, the end device detects the failure of service provision and seamlessly should switch the data flow to the next available data network—that is, GPRS. What is important is that this flow switching is seamless to the end user, and also that when the end user gets back to a place with WLAN coverage, the flow should be handed back to the WLAN network. Generally speaking, the integration of the WLAN network within cellular networks always depends on the ownership or management of the WLAN network. There are two general scenarios. The first case is that the cellular operator owns and is responsible for the management of the WLAN network. In such a case the operator has the advantage of providing preferred billing and customer management policies. Additionally operators can use the existing cellular authentication and billing mechanisms with the customers that are using the WLAN access network. The other case is that the WLAN is not owned by the cellular operator, but by a Wireless Internet service provider (WISP). In such a case there must be certain roaming contracts in order to allow the usage of the WLAN access network in certain hotspots. In this solution, it is more difficult to implement the seamless session and flow switching, as discussed earlier, since in most cases of roaming, the IP-based session should be broken down and restarted.

Interworking Architectures

The integration of WLAN with cellular networks has been specified by the European Telecommunication Standards Institute, ETSI (ETSI TR 101 957), (3GPP TR 22.934 v1.2.0) in two general approaches, so-called *loose coupling* and *tight coupling*. In the loose-coupling approach, the deployment of WLAN is designed as a complementary access network to GPRS, using the subscriber GPRS databases without using the core network (3GPP TS 23.060 v3.12.0). In Figure 2 the GPRS architecture is presented with all the interfaces between building elements. The interface connecting GPRS to other IP networks, bypassing the core elements of serving GPRS support node (SGSN) and gateway GPRS support node (GGSN), is the Gi interface from GGSN to PDN, which is also connected to database home location register (HLR). Hence it is obvious that the loose coupling would be to the Gi interface. Tight coupling integrates the WLAN network towards the GPRS core network in the same way as any other access network. Access networks are connected to the core elements, bypassing all other wireless radio environments.

In Figure 2 the interface to GPRS core network element (SGSN) is the Gb interface. As a result (3GPP TS 23.060 v3.12.0), it is obvious that the tight coupling uses Gb interface to interconnect the WLAN access controller to SGSN. The current preferred solution by the operators seems to be loose coupling, using a USIM-based authentication and billing. With this solution the customer may use his USIM card to access a set of wireless data services over the WLAN network. There are also two main advantages for using loose coupling vs. tight coupling. First, the WLAN network may be owned by a WISP operator; in that case roaming/billing agreements have to be enabled through a dedicated connection between the cellular operator and the WLAN operator. Also, the interoperability is guaranteed and there is no need for a cellular operator to deploy a WLAN network and invest more for the services. On the other hand, tight coupling exists only when the WLAN network is owned and managed by the cellular operator, since the integration is inside the cellular architecture. Second it is not necessary to introduce cellular technology firmware in the WLAN network as it is with the tight coupling.

Loose-Coupling Solution Overview

In Figure 3 the integrated WLAN/GPRS (IWLAN) system architecture is presented, consisting of the WLAN access network that is interconnected to the existing GPRS cellular core network, through Gi interface, towards the IP backbone. A single USIM should be used in all access networks to enable smooth roaming and seamless services availability. In order to use the potential of the already deployed GPRS core network, authentication, billing, roaming, and security issues of WLAN should be compatible. In that way the effort is to minimize the modifications in the already deployed GPRS network and to allow less infrastructure additions in the WLAN interworking boundary.

The authentication server (AS) is the major control point of IWLAN subscriber management. A single AS entity in the network may support several access controllers (Rigney et al., 2000) providing authentication and billing services for thousands of roaming users. When the user disconnects, the authentication server works as an inter-working entity. It receives accounting data from the access controller, converts them into GPRS billing format (ETSI TS 101 393), and issues the charging data records (CDRs) to the cellular billing system. The authentication server interconnects in a seamless way the core cellular infrastructure with the WLAN access network. It provides a gateway to the cellular core network elements (HLR and GPRS charging gateway). The authentication server sends standard GSM authentication signaling to the HLR using Common Channel Signaling # 7 (CCS#7) protocol that connects various operator networks together. The cellular network uses the standard identification procedure with GSM International Mobile Subscriber Identity (IMSI) code stored in the USIM card. The authentication server always checks if the roaming user has subscribed to the WLAN service.

The access controller (AC) provides an Internet gateway between the radio access network and the fixed (WISP provider- or operator-owned) IP core. It functions in the same way as the SGSN node in GPRS network, allocating IP addresses to the mobile terminals and maintaining a list of the authenticated terminals' IP addresses. The AC tracks the addresses of each incoming or outgoing IP packet and discards the packets that come from a

Figure 3. The Integrated WLAN/GPRS network architecture using loose coupling

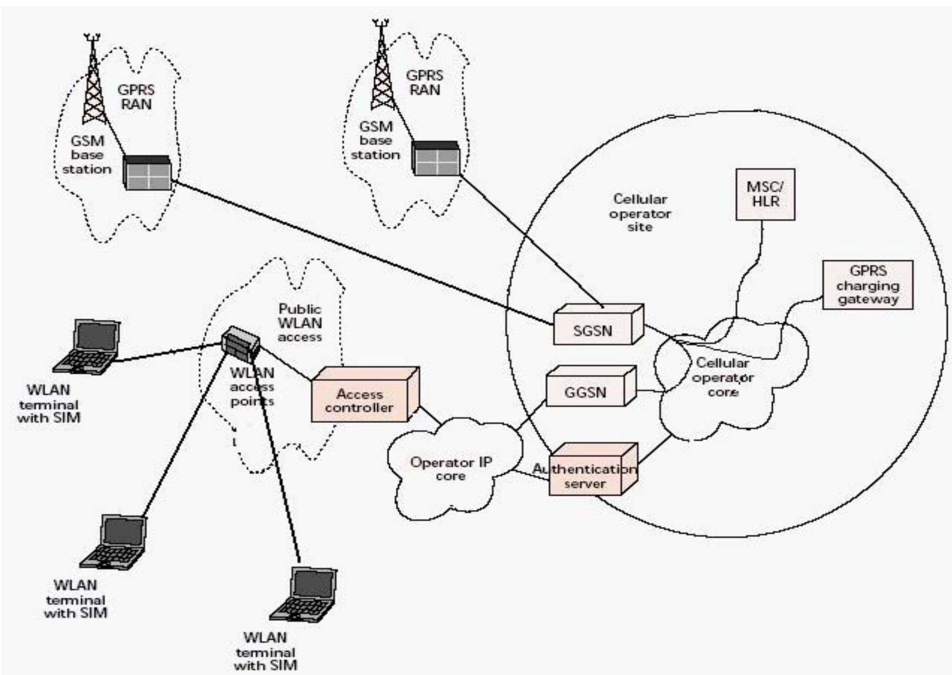


Figure 4.

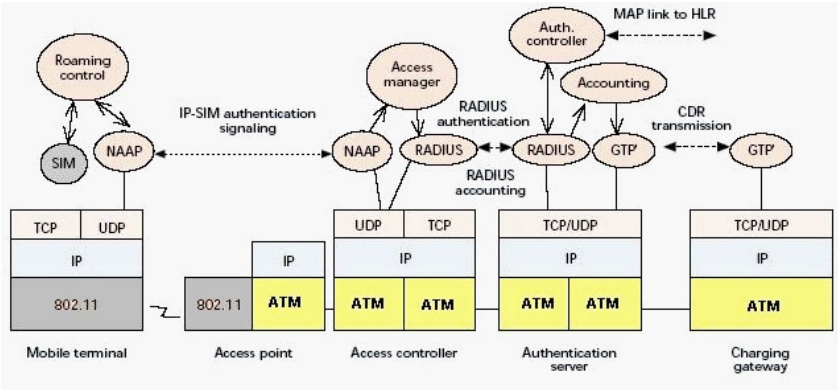

non-authenticated terminal. The access controller separates the mobile terminals using a terminal IP address and a unique WLAN link-layer-specific medium access control (MAC) address. The MAC address verification works as a filter for a duplicate IP address that might be used by a hostile user. The AC gathers accounting information for billing purposes and forwards them to the AS.

The access point (AP) offers a wireless link between the mobile terminal and the fixed local area network (LAN). The access points are the hardware infrastructure to provide the electromagnetic coverage to a hotspot area. During the network deployment, several APs are connected to the same core LAN with the AC. The typical coverage range of a single AP is 50-100 meters indoors or up to 500 meters hotspot outdoor coverage. The coverage can be extended using directional antennas and radio network planning tools.

IWLAN customer terminal might be available for any terminal with WLAN radio access capability and a USIM reader. The customer terminal technology may develop either an integrated WLAN card with a USIM reader or a WLAN card and an external smart card reader. Laptop vendors might in the future develop laptop models with integrated smart card readers. The IWLAN terminal may detect the correct roaming WLAN network by using predefined network profiles that contain the list of the roaming partners' radio network identifiers. When entering a new location, the terminal compares the names of available WLAN networks with the roaming profile and associates to the correct WLAN. The operator may distribute the profiles by using a Web server.

FUTURE TRENDS

The mobile operators have extremely high error tolerance and resilience requirements for the networking infrastructure. To meet these requirements the operation of the AP, AC, and AS must be reliable and the system has to offer sufficient redundancy characteristics. The critical part of the operator WLAN system is the fault tolerance of the authentication server since a single AS may serve several radio access networks and thousands of mobile users simultaneously. The loose coupling has been presented in this manuscript and the major design issues have been discussed, resulting in a specific architecture. The loose coupling is, from the operator's point of view, the cheapest and most reliable way to meet the integration requirements since the cost is limited, the infrastructure requirements are limited, and the revenue is augmented. The already functioning GPRS/UMTS network, used in this proposed integration as a core network, is the warrantee of the functionality, integradability, and scalability of the network.

Future research has to be done towards the tight-coupling solution. The advantage of this solution is the connection of WLAN as a typical access network to the GSM/GPRS/UMTS platform of a cellular operator. However, from the operator's point of view, this is not the best since much firmware has to be included in the APs of WLAN and the access part of the cellular network, increasing the deployment cost. Recently, several WLAN standardization bodies (ETSI BRAN, IEEE 802.11, IEEE 802.15, MMAC) have joined a Wireless Inter-Working Group toward specification proposals for the integration of WLAN and cellular networks. From the cellular networks representatives, the Third Generation Partnership Project (3GPP) standardization body evolves the UMTS specifications towards WLAN/GPRS integration (3GPP TR 23.934, volume 3.0, June 2002). During this research six inter-working scenarios have been specified according to the operator's requirements and infrastructure.

Moreover the intersystem handovers (Krishnamurthy et al., 1993, 1998; Pahlavan et al., 2000) have to be studied deeper since, according to Figure 1, the intersystem handover in heterogeneous networks is still under consideration (Karaboulas, Louvros, & Kotsopoulos, 2005) to minimize complexity and to integrate already used protocols in a general proposed solution.

CONCLUSION

In the last decade the customer's demands are not in voice applications, but mainly in data applications and multimedia services. The cellular operators have failed to provide satisfactory data rates to the customers, even with the latest technological evolution of third-generation networks. The operator's community is looking for the ultimate solution to increase the offered data rates to the customers, hence increasing the revenues. WLAN seems to be the most promising technology so far regarding the data rates (11 Mb/s). The main disadvantage of the WLAN network is the high demanding deployment cost. Due to tremendous investment requirements, WLAN is initiated mostly as an "hotspot" architecture in crowded areas and not as a wide area coverage network. Moreover, so far there is not a general strategy among the different WISPs to design a universal network with specific roaming procedures and interoperability capabilities. The most familiar idea to deploy the WLAN coverage in a large geographical area is the merging of WLAN with different cellular network technologies, as the cellular operator's GSM/GPRS network. The key idea is the use of USIM for both GPRS and WLAN networks. From the operator's point of view, this solution is feasible with loose coupling since the infrastructure demands in both GPRS and WLAN are minimized and the revenues are increased. From the cellular subscriber's point of view, this is a very attractive solution, allowing the entrance to the broadband access market using the same subscriber management agreements of the cellular network.

KEY TERMS

Authentication: A signaling procedure in cellular networks to identify the subscribers when access to certain services are demanded.

Billing: A signaling procedure in cellular networks to transfer call-related data to the billing center for charging the subscribers.

CDR (Charging Data Record): A specific file format that contains call-related data readable from the billing center server.

IMSI (International Mobile Subscriber Identity): A specific number of subscriber, used exclusively in GSM network, according to international numbering standards referred as E.212.

Location Update: A signaling procedure in cellular networks to locate the subscriber in the geographical area of coverage and update the location information to specific databases.

Roaming: A signaling procedure in cellular networks to allow the provision of services in different networks.

Session: Flow of IP data packets between the end user and the network.
