

## INTRODUCTION TO THE SERIES

The aim of the *Handbooks in Economics* series is to produce Handbooks for various branches of economics, each of which is a definitive source, reference, and teaching supplement for use by professional researchers and advanced graduate students. Each Handbook provides self-contained surveys of the current state of a branch of economics in the form of chapters prepared by leading specialists on various aspects of this branch of economics. These surveys summarize not only received results but also newer developments, from recent journal articles and discussion papers. Some original material is also included, but the main goal is to provide comprehensive and accessible surveys. The Handbooks are intended to provide not only useful reference volumes for professional collections but also possible supplementary readings for advanced courses for graduate students in economics.

## 1. Introduction

### 1.1. Development and scope of the field

Over the last 30 or 40 years a substantial literature has grown up in which the tools of economic theory and analysis have been applied to problems in the arts and culture. Economists who have surveyed the field generally locate the origins of contemporary cultural economics (as the discipline is loosely known) as being in 1966, the year of publication of the first major work in modern times dedicated specifically to the economics of the arts [Baumol and Bowen (1966)]. Not only did the Baumol and Bowen book demonstrate that straightforward economic analysis could illuminate the supply of and demand for artistic services and the role of the arts sector in the economy, the work is also notable in retrospect for having put forward one of the most enduring theoretical propositions in cultural economics, namely the productivity lag or “cost disease” phenomenon which afflicts the live performing arts.

Nevertheless, although 1966 is generally agreed to be the birth year of the economics of the arts as a recognizable field of study, this is not to say that there was no pre-history. In fact, as Craufurd Goodwin (Chapter 2) shows, a number of economists of the past have been interested in the arts in one way or another, going back to well before Adam Smith. Goodwin notes that Hume, Turgot and later Smith speculated in some detail on the place of the arts in society, although their lead was not followed by the major political economists of the nineteenth century who (apart from Ruskin) saw little of particular interest in this area, apparently following Bentham with his famous remark about pushpin and poetry. Similarly, except for Veblen’s writings, not much was said about the arts by the American Institutionalists of the late nineteenth and early twentieth centuries, although across the Atlantic in England the Bloomsbury group, of which Keynes was a leading light, wrote extensively about the importance of the arts to individual and social well-being, and proposed ways in which governments could help through enlightened policy.

This brief summary of the pre-history brings us up to the point of departure of the modern discipline as noted above. Following the appearance of Baumol and Bowen (1966), interest in the economics of the arts initially expanded slowly. The first collection of papers in the field appeared in the mid-1970s [Blaug (1976)]; in his introductory essay to this volume, Blaug noted that there was as yet insufficient substance in this area of economic inquiry to justify a textbook, but that an assembly of articles would be useful. The works gathered together were focused mainly on public policy issues, in particular the rationale for public subsidy and the evaluation of public expenditure, issues that have remained prominent on the agenda of the economics of the arts ever since.

In 1977 the *Journal of Cultural Economics* was founded by William Hendon and his colleagues at the University of Akron and in 1979 the first of what was to become a regular series of biennial international conferences was held (in Edinburgh). By the early 1990s, a sufficiently large body of work had accumulated to warrant an overview and

assessment of the field in the *Journal of Economic Literature* [Throsby (1994)]. This survey reflected on the expanding variety of issues in the arts that had engaged the attention of economists up to that time. It began by pointing to the origins of demand for the arts as lying in the peculiar processes of taste formation and cumulative consumption that make the arts an “experience good”. Markets for art objects and for artistic labor were also covered, as well as issues in the performing arts and in public policy. Throsby’s overall evaluation of the state of cultural economics at that time foresaw a further expansion of the domain of interest in the field in the future.

In fact such an expansion was mirrored to some extent in the choice of articles reprinted in the major collection assembled in Towse (1997). In her Introduction to this two-volume collection, Towse pointed out that “culture” is a term with a wider embrace than “the arts” and hence that cultural economics, for the purpose of her project, could be taken to include the media and heritage as well as the arts. Again, however, the central themes of defining cultural goods, the cost-disease phenomenon, and questions relating to public subsidy of the arts were brought forward as the major defining issues that had characterized the development of the discipline over the period covered by her anthology.

The classification of topics in cultural economics that Towse used for her 1997 collection was taken up four years later by Blaug in his survey that asked “Where are we now in cultural economics?” [Blaug (2001)]. The list of topics that he discussed included demand, supply, industrial organization, the art market, history, labor markets, firm behavior (including the cost disease) and public subsidies. It seemed that by now, at the turn of the century and after three or four decades of research and writing by an ever-increasing number of economists, the list had become more or less settled, though Blaug noted in the conclusion to his survey that there was much further expansion of the field in store.

In another overview published in the same year, Ginsburgh (2001) observed that cultural economics is not well-defined because it is located at the crossroads of several disciplines: art history, art philosophy, sociology, law, management and economics. Nevertheless it was from economics that the literature he surveyed was drawn, covering again the principal topics noted above. Ginsburgh gave prominence to the policy questions surrounding public support for the arts, with a comprehensive listing of the various normative rationales that have been put forward, and a discussion of the means for intervention once a rationale has been accepted. He also saw markets for visual arts as providing particularly fertile ground for economists to work in, especially since this is an area where good data are available that open up possibilities for econometric investigation. Similar ground is traversed in the entry on the economics of art in the second edition of *The New Palgrave Dictionary of Economics* [Throsby (2007)]. This article points out that amongst the multitude of applications of economic analysis to the arts, the field of industrial organization remains under-represented, offering fruitful opportunities for future researchers.

The specific schools of economic thought and analysis that have been applied to problems in the arts and culture are usefully summarized by Towse (2003) in the final survey

of the field that we consider here. The basic analytical methods of neoclassical price theory and welfare economics comprise the main approaches that microeconomists have adopted in looking at issues of production, consumption and exchange in the arts and cultural industries; at the macroeconomic level relationships between the cultural and other sectors of the economy are implicated, and the familiar tools of macroeconomic policy analysis have been applied to policy-making affecting the cultural sector. Similarly public choice theory and the field of contemporary political economy have a bearing on policy formation relating to the arts, while institutional economics offers an alternative means for analyzing organizational structures and their influence on behavior. Towse also notes the relevance of the law-and-economics tradition deriving from Coase and others as the basis for analysis of transactions costs and property rights questions (especially copyright) relating to artistic goods and services.

What does the above survey of the surveys tell us about the scope and achievements of the economics of the arts and culture? At one level it suggests that a sufficiently cohesive body of work has accumulated for us now to be able to identify a field labeled “cultural economics” or “the economics of the arts and culture” with some confidence, even though the outer boundaries of the field remain somewhat fuzzy. It also suggests that the time is right for assembling a purposeful collection of essays commissioned from researchers working at the theoretical and empirical frontiers of the field, such as is contained in the present volume. At a deeper level our survey reveals that a basic issue that gives the field its particular appeal is that of defining whether and how cultural goods and services differ from other goods and services in the economy. Whilst it is the mysterious and possibly unfathomable nature of art in all its forms that ultimately must underlie much of the behavior of individuals, firms and markets in the arts, economics requires a more systematic basis on which its analyses can rest. We turn to these fundamental definitional questions in the next section.

### *1.2. Basic questions*

Several chapters in this volume begin with a discussion of what the words “art” and “culture” mean. Of course these are foundational questions in disciplines such as art history, art theory, philosophy, aesthetics, sociology and anthropology. By and large contributors to this volume accept in the first instance a broad-ranging view of culture as comprising or being defined by a set of attitudes, beliefs or values common to a group that somehow identifies and binds the group together. Thus it is possible to speak of a national culture, a religious culture, a corporate culture and so on. From the noun “culture” comes the adjective “cultural”, meaning reflective of the particular shared values. Culture is also defined in this book in a more functional sense to indicate the practices and products of cultural activity, including especially the arts. Within this meaning the terms “high culture” and “low culture” are frequently used to refer to the “serious” and “popular” arts, respectively. The arts as a whole are sometimes divided into the performing arts (acting, dancing, singing, playing a musical instrument, etc.) and the initial creative arts (visual art, sculpture, craft, creative writing, musical composition, etc.) though there

are obvious overlaps between these categories. According to these definitions the arts comprise a subset of culture more broadly defined.

This leads us in turn to considering the definition of artistic and cultural goods. The distinguishing characteristics of such goods (and services) that have been identified in the literature of cultural economics include the following, though by no means every characteristic will necessarily be present in every such good:

- cultural goods are experience goods, the taste for which grows as they are consumed in greater quantities; they are therefore subject to rational addiction;
- cultural goods have some public-good properties; in aggregate they yield positive externalities or diffused benefits that may be demanded in their own right;
- cultural goods result from production processes in which human creativity is an important input;
- cultural goods are the vehicles for symbolic messages to those who consume them, i.e. they are more than simply utilitarian but serve in addition some larger communicative purpose;
- cultural goods contain, at least potentially, some intellectual property that is attributable to the individual or group producing the good; and
- cultural goods embody or give rise to forms of value that are not fully expressible in monetary terms and that may not be revealed in either real or contingent markets.

This set of characteristics of cultural goods is illuminating in capturing most of the distinguishing features that such goods display in varying degrees, but it is problematical insofar as it does not indicate whether any one or any combination of the characteristics could be regarded as a *sufficient* condition for defining a cultural good, or, if this is not possible, which or how many of the characteristics would be regarded as *necessary* conditions. Nevertheless the list does at least represent a checklist if not a basis for a watertight definition.

A further problem lies in the question of whether, within such a set of characteristics, there is a difference between an artistic and a cultural good. Using an aesthetic definition of art and a broadly anthropological definition of culture, Roger McCain ([Chapter 5](#)) goes so far as to argue that artistic and cultural goods are non-overlapping sets; he sees the distinguishing characteristic of the former as lying in their aesthetic properties and in the creativity that has gone into their making, whereas objects reflecting a group's culture do not necessarily possess these qualities. McCain's approach stands in contrast to that indicated above. However if, as argued earlier, art is a subset of culture, the adjective "artistic" would presumably become a subset of the adjective "cultural", and hence artistic goods would be seen as a subset of the wider category of cultural goods, not in a separate category of their own.

Questions of aesthetics relate not just to definitional issues surrounding artistic goods, but go to deeper matters to do with the value of art. There has been little interaction between the disciplines of economics and philosophy in this area, yet philosophers have had much to say that is relevant to the ways in which economists might approach questions of value and valuation in the arts. Michael Hutter and Richard Shusterman ([Chapter 6](#)) trace the evolution of ideas about aesthetic value in philosophy from Plato

and Aristotle onwards, comparing and contrasting these ideas with those of economists from the seventeenth century to the present day. In doing so they raise the intriguing issue of the relationship between cultural and economic value, an area of emerging cross-disciplinary interest at the present time.<sup>1</sup>

In the remainder of this introductory chapter I provide a brief overview of the book. Instead of proceeding chapter by chapter, I adopt here a more wide-ranging classification system than that used in the volume itself, in order to give a broader integrated overview of the field. In Sections 2, 3 and 4 of the present chapter I consider the behavior of individuals, firms/industries, and markets, respectively. Section 5 draws together chapters that treat the role of the arts and culture in the economy, and Section 6 presents some conclusions.

## 2. Behavior of individuals

The origins of artistic consumption, production and exchange lie in the behavior of individuals, whether they are consumers who demand cultural goods and services in the marketplace, or producers who supply them. If we were to adopt a broad definition of cultural goods that embraced popular cultural forms such as sport, television programs, magazines, etc., we would open up an enormous field of interest in mass cultural consumption and production, a field that has been extensively explored within sociology, contemporary cultural studies, and media economics. Most of this work lies beyond our immediate scope; for present purposes we focus specifically on individual behavior in regard to the core creative arts.

Looking first at demand, we have noted already the processes of taste formation that are peculiar to cultural goods and that drive the evolution of individual preferences. In common with demand analysis elsewhere in economics, much of the empirical work on demand for the arts has taken tastes as given, and has concentrated on estimating the relative influences of the sorts of explanatory variables normally included in demand functions – own price, price of substitutes, income, sociodemographic characteristics of consumers and so on. Apart from studies of demand for art works (discussed further below), the majority of research on demand for the arts has focused on the performing arts – opera, music, theater and dance. As Bruce Seaman ([Chapter 14](#)) shows in his comprehensive appraisal of this field, results have varied surprisingly widely, and even apparently self-evident propositions such as that the arts are a luxury good are by no means universally confirmed. Nevertheless the empirical evidence suggests, amongst other things, that education is a stronger determinant of demand than income (a result consistent with the art-as-an-acquired-taste hypothesis) and that output quality plays a significant role in determining consumption behavior. Seaman goes on to observe that non-standard socioeconomic factors such as “life-style” characteristics may exert considerable influence on demand, and deserve to be better understood.

<sup>1</sup> For a collection of papers by economists and others on this topic, see [Hutter and Throsby \(2006\)](#).

Turning to the behavior of individuals in the production of art brings us of course to a consideration of the economic role of individual artists as producers of art works or as suppliers of artistic goods and services. An economic analysis of these roles can make the standard distinction between production and supply functions. But although this distinction can be drawn straightforwardly in conventional terms, application of traditional production models or labor supply functions to artists needs to account for the particular conditions under which artistic effort is deployed. Let us look first at production. Efforts to represent the relationship between the output of art and the inputs of factors of production such as labor and capital must immediately confront a fundamental question. As any artist will attest, the writing of a poem, the painting of a picture, or the composition of a flute sonata is not a mechanical process where criteria of technical efficiency and predictable input–output relationships can be applied. Rather, achievement in the arts is conditioned by ephemeral and possibly unquantifiable influences like luck, inspiration and imagination. In short, artistic output is critically dependent on the input of creativity, a characteristic of artists (as well as of some other occupations such as scientific researchers or inventors) that is as important as it is elusive. Nevertheless, as Tony Bryant and David Throsby (Chapter 16) show, some progress can be made in modeling creativity in economic terms. They propose a model in which the artist decides on an optimum level of creativity to apply in the production of “pure” and “commercial” art; the artist’s choice is determined in part by the levels of economic and cultural reward yielded by the output produced. Although the measurement of creativity is fraught with difficulty, Bryant and Throsby present some empirical results suggesting that modeling the creative input in artistic production processes is by no means impossible.

We turn now to the matter of labor supply. Markets for artistic labor, including the labor both of performing artists such as actors and musicians and of “initial creative artists” such as writers and painters, have been widely studied in theoretical and empirical terms in an effort to compare and contrast artists with other occupations in their labor market behavior. The picture is complicated by three features of artistic labor that combine to set artists somewhat apart from other workers. These features are

- financial rewards to professional artistic practice are generally lower than in other occupations with otherwise similar characteristics (education and training requirements, etc.); thus artists’ labor market profiles typically exhibit multiple job-holding;
- the level of variability of artistic earnings is generally higher than in comparable occupations, making an individual artist’s attitudes to risk an important determinant of his or her labor market participation;
- non-pecuniary motives are important in the allocation of an artist’s time between alternative labor markets, i.e. the “inner drive” to create art may dominate financial incentives or at least mediate their influence.

A considerable volume of empirical evidence has accumulated on all three of these aspects of artistic labor markets, as Neil Alper and Gregory Wassall (Chapter 23) show in their extensive overview of the field. They bring these three aspects together in the context of labor-market entry and exit decisions of artists, i.e. in the analysis of career

patterns in the arts. This is an area where, as Alper and Wassall demonstrate, availability of data is critical, whether obtained from official statistical sources such as censuses or from purpose-built surveys.

It is well known that in many countries at the present time labor markets across the board are changing, with greater casualization and increased occupational mobility in the workforce. Labor markets in the arts have been particularly susceptible to change, as Pierre-Michel Menger ([Chapter 22](#)) argues; long-term employment has been replaced by a project-based system of production relying on short-term hiring, large parts of business risk are transferred downwards onto the workforce, and artists learn to manage risk and to stay alive through multiple job-holding, occupational versatility, diversification of job portfolios and occasional income transfers from social security or other sources. Despite manifold deterrents to an artistic career, an excess supply of artists persists in many countries, attributable in part to the non-pecuniary attraction of work as an artist as mentioned above. The excess supply may also be influenced by the entry of large numbers of artists hoping to become a superstar, i.e. someone who breaks away from the pack, becomes a celebrity and enjoys earnings considerably in excess of those that marginal productivity theory would predict. A number of contributors to this volume make reference to this phenomenon, all of them noting the origins of superstar theory in [Sherwin Rosen's \(1981\)](#) classic paper. [Moshe Adler \(Chapter 25\)](#) provides an appraisal of this field, drawing attention to questions of efficiency in terms of the effects of superstardom on consumers' prices and on artists' psychic income. Empirical testing of various superstar hypotheses is relatively sparse and, as Adler suggests, offers prospects for some interesting further research, provided suitable data can be found.

A final question in our discussion of artists and their labor markets brings us back to first principles and provides a link between all of the chapters discussed above. The question is: to what extent does basic human capital theory help to explain all of the phenomena we have been discussing – the role of creativity and talent, the levels and variability of artists' earnings, multiple job-holding, career choice, and the superstar phenomenon? [Ruth Towse \(Chapter 24\)](#) examines this issue, arguing that human capital theory provides at best only a weak basis for explaining artists' decisions relating to investment in training and their choice of an artistic career. Notwithstanding the possible effects of education, training and on-the-job experience, it is ultimately the artist's innate talent that is likely to be the main determinant of artistic success. Moreover, some of the traditional features of the human capital model may be being undermined by technological developments; for instance, Towse argues that the reproducibility of artworks, together with the expansion of the reach of copyright law, overturns the view that human capital cannot be separated from labor. While this latter point may not be of great significance in itself, it does indicate a need for further research on the relationship between copyright and artists' labor supply decisions.

### 3. Behavior of firms and industries

Relatively few cultural goods and services pass from an individual supplier such as an artist directly to the final consumer; most are produced and/or marketed by firms. Across many fields in the arts and culture the predominant firm types in numerical terms are small or medium-sized enterprises constituted on either a for-profit or not-for-profit basis. Microeconomic theory offers straightforward means for representing the production and cost conditions of such firms. Much attention in the economics of the arts has been devoted to not-for-profit firms because of their prevalence in the “serious” arts where commercial for-profit production may not be economically viable. In examining the economic structure and operation of non-profit firms in the performing arts, Arthur Brooks ([Chapter 15](#)) looks particularly at product quality issues, cross-subsidization possibilities and Baumol’s “cost disease” as influences on the firms’ decision-making. The achievement of artistic excellence and the pursuit of innovation are often significant goals of these firms, objectives likely to be shared by potential donors both public and private; these considerations will influence the financial strategies pursued by non-profit firms in the arts, including their ticket-pricing behavior and their fundraising activities.

Profit-making firms in the arts and culture, on the other hand, present a different picture. While corporate enterprises producing movies, books, Broadway musicals, rock concerts, etc. share many of the economic features of commercial firms in other sectors, they are still distinctive on account of the artistic or cultural nature of the product they produce. Although profit-maximization may remain a dominant goal of such firms, it is likely to be mediated, sometimes quite profoundly, by the desire of the firm’s owners and managers to meet certain artistic or cultural standards or to strive for artistic success. While such behavior might be able to be rationalized simply in terms of the firm’s profit-seeking objectives if “better” standards are likely to be more profitable, there remains a sense in which some corporate satisfaction may derive, at least to some extent, from purely artistic or cultural achievement.

Be that as it may, an increasing amount of attention has been paid in recent years to the structure and operation of the so-called cultural or creative industries. The boundaries around these industries remain somewhat fuzzy – for example, do they include fashion, design, software, advertising? Nevertheless if the broad definition of cultural goods discussed earlier is accepted, the cultural industries can be defined simply as those industries producing such goods. In practice the cultural industries have been taken to include the arts, heritage, film, television and radio, the press, publishing, video and computer games, some aspects of tourism, etc. The organization of these industries depends on many types of contracts, the basis for Richard Caves’ ([Chapter 17](#)) analysis of their structure, conduct and performance. Caves distinguishes between simple cultural activities in which a single artist deals with one agent or firm (the writer of a book or movie script) and more complex situations in which several creative inputs are needed and combined by the firm (the production of a movie). The peculiar characteristics of the contracts involved derive from what he describes as the “bedrock properties” of creative work and creative products.

Four chapters in the present volume examine the features of a particular cultural industry in detail, dealing in turn with the media, the movies, popular music, and book publishing. All four industries are characterized by the fact that they produce under high fixed costs but negligible marginal costs, and under conditions of considerable uncertainty: the rate of success is small, but successes command large revenues. First, Simon Anderson and Jean Gabszewicz (Chapter 18) analyze the media industries as perfect examples of two-sided markets: in the case of television, for example, on the one side viewers watch (and pay for) programs, on the other side firms use the market to advertise their products. The two sides are coordinated by one or several platforms; in the television case broadcasters have to balance income from advertising by choosing the right mix of programs (which consumers want) and advertising (to which consumers are generally averse). The same idea applies to newspapers, magazines, the Internet and radio broadcasting. The authors' theoretical analysis is backed by data that show that the media industry is large not only in terms of its importance in GNP, but also because of its influence in shaping public opinion; in 2003, for example, the average American family spent almost eight hours per day watching television.

Second, another important cultural industry to have grown up in the twentieth century is movies. A particular economic characteristic of the movie industry is the fact that it is subject to "wild uncertainty", a phenomenon discussed in detail by Arthur De Vany (Chapter 19). He shows that the statistical laws that motion pictures obey are not normal, but stable Paretian. Each movie is unique in itself, very few are successful, although when they are they can be very profitable. Nothing is predictable, in other words "nobody knows", a property that Caves suggests applies to all cultural industries.

Music, of course, is a much older industry, but during the twentieth century its market has changed dramatically, going from the stage of small manufacturers acting in small venues to a large and powerful industry, in which "classical" music is declining and popular music is on the rise; in 1994, for example, rock and roll and pop music led with 45 percent of unit sales of CDs, while classical music reached less than 4 percent (down from 25 percent in 1950). Popular music is discussed by Marie Connolly and Alan Krueger (Chapter 20), who cover mainly the economics of live performances. Live appearances on stage provide the bread and butter for many performers, giving rise to the Bowie Theory; David Bowie is quoted as saying that performers should "be prepared to do a lot of touring because that's really the unique situation that's going to be left". Connolly and Krueger consider trends in the industry, including the difficult problem of measuring prices over time, and also make incursions into the world of broadcasting and the intellectual property issues that have appeared with the advent of file sharing via the Internet.

Finally, book publishing has also become an industry, in which authors, publishers, retailers and readers do not always agree, and have often called for government intervention, at least in Europe. Marcel Canoy, Jan van Ours and Frederick van der Ploeg (Chapter 21) describe these aspects, basing their analysis on insights from the theory of industrial organization. They conclude that there is in fact little need for public interven-

tion, except perhaps to promote reading. The chapter also provides a host of statistics on various aspects of the industry.

The four chapters devoted to the cultural industries outlined above make use of the theory of industrial organization, but they also draw attention to the special conditions under which art markets operate that lead to new insights and new models. Economic analysis of the cultural industries is obviously a field that draws upon, and can also contribute to, both theoretical and applied economics. In particular, as is made clear in Caves' contribution, there exists a host of contracts that look unusual, suggesting that this is a field that will repay further exploration using contract theory.

## 4. Behavior of markets

### 4.1. Historical aspects

Markets have always existed in the arts, and it is instructive for anyone interested in present-day markets in the arts and cultural sectors to look back to how markets for artistic goods and services have evolved over time. The first art markets in our meaning of the word flourished in the Renaissance in Italy (Florence) and in Flanders (Bruges and Ghent). The Dutch art market emerged somewhat later. Subsequently secondary or resale markets began to grow, leading to the development of auctions, mainly in Northern Europe and the United Kingdom. Several of the features of early auction processes survive today, as Neil De Marchi and Hans Van Miegroet (Chapter 3) demonstrate in their account of the evolution of art markets from the 14th to the 18th centuries. They point out that 17th century auctioneers produced printed sales catalogs containing a number of rules, including:

- successful bidders were required to pay a part of the price before leaving the sale (thus minimizing the risk of irresponsible bidding), a practice represented by the numbered paddle which identifies the buyer in contemporary salerooms;
- to accelerate the sale, some auctioneers suggested a minimum increment between bids – the contemporary equivalent of the “tick”;
- commissions, that is bids by the auctioneer himself or on behalf of absentees, were not allowed – this is not the case nowadays;
- in some cases, auctioneers committed to the disclosing of reserve prices – a rule that is partly followed in contemporary auctions, when a relation between the printed lower pre-sale estimate and the reserve price is announced.

De Marchi and Van Miegroet, as well as the late Michael Montias with his important work on Dutch inventories [Loughman and Montias (2000)], show how archives can be used to provide information on market structures which took about 250 years to develop; using such archives it is possible to demonstrate that by 1750 most of the ingredients of the art market that we know today were already present.

Similar remarks might be made about the evolution of markets for artistic labor. For example, employment of composers has always depended on the existence of a sufficiently lucrative market for the works they produce. F.M. Scherer (Chapter 4) points out

that employment possibilities for composers in the 17th century were mainly provided by courts and the church, though after 1750 the increase in private wealth led to more support from individual patrons, at the same time as publishing and concert tours began to provide more opportunities. The role of education in influencing musical tastes is illustrated in Scherer's analysis by the prevalence of music in Austria and Czechoslovakia from the mid-17th to the mid-19th centuries, a phenomenon he attributes to the schooling system in which schoolmasters, even in small villages, were expected to teach singing and violin to their pupils.

#### 4.2. *Present-day art markets and prices*

The two chapters discussed in the previous section illustrate that markets in the arts have existed for many centuries, but that their forms have evolved, quite dramatically in some cases. In the case of markets for art objects such as paintings, sculpture, jewelry, antiques, etc., most of the dealing today is still done by dealers and galleries as in the past. Auctions, however, whether occurring in salerooms or over the Internet, have become more important. The leading role played by auctions derives from the fact that this is where important works are sold. Auctions serve as a reference to the market in general, since they constitute the almost unique way to observe how the market and prices evolve over time.

Anderson (1974) and Stein (1977) were among the first to look into the financial performance of art, using some econometrics. They were followed by Baumol's (1986) very influential paper based on prices obtained at auction over a 300-year period (1650–1960). Baumol found that the average real rate of return was equal to 0.55 percent per year, some 2 percent lower than the return on bonds; the difference, according to Baumol, is attributable to the return provided by aesthetic pleasure. Baumol's paper was followed by a very large number of studies that almost invariably used prices observed at auctions. This led economists who were interested in art markets to take a closer look at how the art auction system works. In their wide-ranging review of this work, Orley Ashenfelter and Kathryn Graddy (Chapter 26) deal with two important issues. They first show how auction prices have been used to derive conclusions on: returns to art as an investment; portfolio diversification; the "masterpiece" effect (masterpieces are claimed to reap higher returns, which does not seem to be true); and the "burning" effect (the effect on the future value of a work if it is unsold). Second, they describe the various inefficiencies to which art markets and/or auctions are prone: prices of homogeneous lots sold in sequence decrease over time (the declining price anomaly); the law of one price does not hold, since systematic price differences across salerooms and/or countries are observed and may persist; and pre-sale estimates made by salerooms do not reflect all the information that is available to experts.

The difficulty in measuring returns and constructing price indices is due to the heterogeneous character of artworks. In order to homogenize, researchers have based their computations on resales of identical works only. This entails important limitations:

- the number of resales is often small and represents a small proportion of total sales;

- resales may embody a sample selection bias; and
- unobserved resales may also take place between observed sales at auctions and if one takes these into account, returns may turn out to be very different from those usually obtained.

The first two of these limitations are partly circumvented if all sales are accounted for and hedonic regression is used instead of repeat-sales regression.<sup>2</sup> Two of the estimation techniques developed to deal with the computation of returns (hedonic and repeat-sales regression) are surveyed by Victor Ginsburgh, Jianping Mei and Michael Moses (Chapter 27), who discuss some technical details that may help researchers to decide which technique to use given the data at hand, or how data should be collected. Some preliminary simulations reported in this chapter point to the fact that hedonic regression is as good as repeat-sales regression when the number of observations is large enough, but that hedonic regression gives better results when this number is small – this is usually the case when the time span is small, or when it is necessary to disaggregate and deal with finer markets or with individual artists.

The special case of copies of artworks presents a number of puzzling issues. While copies of artworks were sold at half the price of originals during the 17th century and before [De Marchi and Van Miegroet (1996)], the situation changed towards the end of the 19th century, at which time the relative price of copies dropped very sharply. Nevertheless copies continue to be produced and sold, raising a number of issues for economists, lawyers, philosophers, art historians and curators. In discussing these issues, Françoise Benhamou and Victor Ginsburgh (Chapter 8) point out that the development of a market for copies is part of a wider contemporary questioning of the boundaries between originality and copy. They analyze whether and how the various participants in the art market contribute to valuing (or de-valuing) copies, alongside markets for original works of art.

#### 4.3. Legal regulation affecting markets

There are several ways in which the interactions between law and economics find application in the arts. The most obvious revolves around property rights and transactions costs; following Ronald Coase it can be proposed, for example, that beneficial or costly alternatives, of which there are numerous examples in the arts, can be resolved through market processes if property rights can be defined and enforced and if transactions costs are negligible. Most of the theoretical and applied work of relevance to the arts in this expanding field has been concerned with the rights of artists, especially copyright. Copyright obviously puts restrictions on markets but, as William Landes (Chapter 7) points out, it can be rationalized as a mechanism for protecting the creative expressions of authors and artists and as a means of promoting economic efficiency in markets for

<sup>2</sup> Goetzmann (1996) points to an additional problem that is encountered when using repeat-sales regression, the risk of obsolescence: many artworks are never resold because they disappear for natural reasons (fire, physical decay, etc.) or they are dumped because they are valueless or at least thought to be such.

creative work. As well as discussing the economic rationale for copyright, Landes also considers other rights of artists, including moral rights, which protect authors against alterations and destruction of their works. The chapter also considers disputes of ownership, authenticity issues and resale rights, illustrating these various problems through cases.

New communications technologies present new challenges to the assertion of artists' rights. Patrick Legros ([Chapter 9](#)) argues that the so-called curse of the Internet, and of new technologies which allow for infinite copying, may in fact be a blessing rather than a threat to artists, since these developments foster the emergence of new artworks. Legros compares this situation to that which prevailed when photography was born. Artists can show their work on the Internet, bypassing any form of intermediation, and can still obtain revenues from their creative ideas, as long as interpretation is needed. He shows that strict copyright rules may have little to do with social efficiency, and that the preferences of artists for strict or weak copyright are related to their creativity. Good and bad artists may bless the curse, and opt for weak copyright, while others may feel protected by strong copyright.

Restrictions of another kind are imposed by censorship on the creation of art. The practice of censorship is inherited from ancient times. As Tun-Jen Chiang and Richard Posner ([Chapter 10](#)) point out, offensiveness, whether religious, political or scientific, is a concept that exists in all countries, is not objective, and changes over time. It affects markets directly, and may cause the emergence of informal or underground transactions as a means of circumventing the censorship restrictions. The most obvious cases of censorship are seen in literature and the visual arts, although theater and even music have been affected at various times.

## **5. Arts and culture in the economy**

We turn now to the role of arts and culture in the economy at large. At the outset we can observe the structural transformations that have affected economies in the industrialized world in recent times, loosely described as a transition from a manufacturing economy to a services economy and onwards to an information or knowledge-based economy. The so-called "new economy" which is emerging as this transformation process continues depends on increasingly rapid technological change in the communications sector. In the new business environment that has evolved as a result of these developments, creativity is seen as a key resource through which firms can maintain a competitive edge. This in turn throws the spotlight on the creative industries as discussed above, which are increasingly being promoted as primary sources of creative ideas to sustain the expansion of the new economy. The revolutionary growth of the new economy has profoundly affected the arts, as William Baumol ([Chapter 11](#)) argues. He points to the wide-ranging opportunities that new communications technologies open up for artistic creation, dissemination and preservation. In turn these developments raise pricing

problems surrounding the trade-off between the encouragement of creativity and the facilitation of dissemination.

Despite these changes, however, the interest of economists in the role of art and culture in the economy has focused on more traditional concerns – how does culture affect economic performance in developed and developing countries, and what are the many ramifications of the intersections between cultural and economic policy? We consider these issues in the remainder of this section.

### *5.1. Culture in economic performance*

If culture is defined as shared values and beliefs that identify and bind a group together, its influence on economic performance in developed economies can be interpreted at various levels corresponding to the extent of the group concerned, ranging from the individual firm or organization up to the level of the whole economy. The shared values might influence the articulation of the group's objectives and/or they might affect the group's economic efficiency in various ways – for example, does a shared Protestant work ethic increase labor productivity in the firm or in the economy? Mark Casson (Chapter 12) sees the culture of a group as being a particular type of public good created by leaders and shared by their followers. This may set up a basis for competition between groups. He defines four key dimensions of culture (individualism vs. collectivism, pragmatism vs. proceduralism, low-trust vs. high-trust, and high-tension vs. low-tension) and shows how they influence economic performance, leading to the rise and decline of organizations and of whole societies.

Somewhat similar remarks could be made about developing countries, where it might be expected that shared values, beliefs and cultural practices of various sorts would be closely related to economic performance. However, traditional development economics has largely neglected culture as an element in economic development, most writers either seeing culture as an obstacle to development or ignoring it altogether. Paul Streeten (Chapter 13) argues that this situation has changed recently through a shift in thinking from a goods-centered to a human-centered view of the development process. Such a shift is consistent with a more holistic view of the developing economy, in which economic, social, cultural and environmental systems are seen as interrelated; in these circumstances economic and cultural development can be seen to advance hand in hand. Streeten goes on to consider the role of conflict in bringing about social change, the impacts of globalization on the cultures of developing countries, and the economic significance of tourism in the Third World.

### *5.2. Cultural policy*

Cultural policy is emerging as an increasingly significant component of government policy formation at both national and international levels. There has been considerable scholarly interest in cultural policy studies in recent years in several countries, but much

of it derives from disciplines outside of economics.<sup>3</sup> Yet the intersections between cultural and economic policy are extensive, including in the following areas:

- the prospects for the cultural industries as dynamic sources of innovation, growth and structural change in the new economy, as discussed above;
- the appropriate levels for government support for the arts and culture, and the balance between direct (grant-related) and indirect (tax-related) means of support;
- trade policy in respect of cultural goods and services;
- the possibilities for public/private partnerships in the preservation of cultural heritage;
- the role of the arts and culture in employment creation and income generation in towns and cities, especially those affected by industrial decline; and
- legal and economic questions concerning the regulation of intellectual property in cultural goods and services, as discussed earlier.

At an international level, a newly-adopted UN convention on cultural diversity will, if eventually ratified, have important implications for cultural policy in both the developed and the developing world.

Having outlined the broad reach of cultural policy in general terms, we can go on to point out that its coverage and its level of importance in national policy agendas vary considerably between countries. In Europe, for example, there are substantial differences between countries in the volume of public resources they devote to the arts and culture and in the ways those resources are deployed. Administrative structures also vary, as Frederick van der Ploeg (Chapter 34) points out, ranging from arms-length arts councils to full-scale Ministries of Culture. There are also sub-regional and supra-regional interests in cultural policy in Europe; on the one hand sub-national regions with distinctive cultural identities promote their own artistic and cultural endeavors, on the other hand the European Union and the Council of Europe have interests in developing pan-European cultural policies in various fields.

In the United States, by contrast, there has never been a great deal of interest in the formulation of specific cultural policies at the central government level; rather the major players in the formation and execution of direct public expenditure programs in the arts and culture are located at sub-national levels of government. Nevertheless, as Dick Netzer (Chapter 35) points out, the largest share of government support for the arts and culture is provided indirectly, via tax concessions for gifts to not-for-profit arts organizations and also via tax concessions to private owners of cultural heritage buildings and sites. The role of tax incentives in stimulating cultural donations and the significance of philanthropy as a characteristic of American life are discussed by Mark Schuster (Chapter 36) and Stanley Katz (Chapter 37), respectively. Both authors refer to the peculiarly American tradition of individual and corporate giving that has sustained the growth of the arts in the United States for more than a century. Despite

<sup>3</sup> See, for example, the collection of readings in Lewis and Miller (2003), which assembles articles drawn from cultural studies journals and texts that focus on the political and social role of culture.

the emergence of what many see as a distinctive and successful “American model” for cultural support, Schuster warns that it may be difficult to replicate it in other countries where institutional structures, income levels and tax-price responsiveness may differ markedly from the US situation.

### 5.3. *Some specific policy areas*

In this section we take up four specific areas where cultural and economic policy intersect: support for the arts; trade in cultural goods; heritage; and urban and regional development issues.

First, as we noted in Section 1 above, the rationale for state support for the arts has been one of the longest-running issues to be discussed in the literature of cultural economics over the last 40 years. Despite the normative appeal of market-failure arguments, the empirical evidence is by no means extensive, and positive theories of assistance may be more useful in explaining levels and patterns of support actually observed in various democratic countries around the world. One of the earliest contributions to the debate was Alan Peacock’s (1969) classic paper on the welfare economics of public support for the arts, and he returns to this question in the present volume (Chapter 32). Peacock asks why, at a time when the trend is towards privatization in many sectors of the economy, the provision of government grants, tax relief and regulatory protection continues in the arts and heritage industries. The answer, he suggests, lies in governments’ skepticism that consumers know what is best for them; in these circumstances producer interests can exert a strong influence on government policy, with consequent effects on both allocative and productive efficiency.

The second specific policy area of interest is cultural trade. Acheson and Maule (Chapter 33) point out that there have always been international dimensions to cultural production, consumption and exchange, with longstanding traditions of movements of artists between countries, and of trade in cultural products. Nevertheless, the interests of contemporary economists in this field have focused on a particular issue of growing concern – whether cultural goods and services such as movies, television programs, magazines, etc. should be regarded differently from other merchandise in multilateral and bilateral trade negotiations. On the one side are those who argue that free-trade principles should apply universally, on the other are countries such as Canada and France who believe their own cultural identities are threatened by allowing open access to cultural products from other countries, especially from the US. Acheson and Maule suggest that arguments for protection versus openness for cultural activities are more complex and nuanced than for other economic sectors because of a wide range of views on how international cultural policy affects individuals and the national culture.

Thirdly, we turn to cultural heritage. Policy in this area has until quite recently been determined largely by cultural experts – archaeologists, anthropologists, museum curators, architectural historians, and so on. When economists first started asking questions about the opportunity costs of resources used in heritage preservation, or how the benefits of heritage were to be evaluated, their intrusion onto sacred ground was resented.

Now, however, there appears to be a stronger sense that economists have methods for analyzing heritage that can usefully inform policy-making processes, and that they are not insensitive to the cultural values that heritage yields. In particular the concepts of cultural capital and sustainability as discussed by Ilde Rizzo and David Throsby (Chapter 28), hold promise for representing and analyzing heritage conservation decisions in ways that link the economic and cultural dimensions of the problem. Valuation methods for non-market benefits that have been developed in the field of environmental economics have found ready application to cultural heritage assets, emphasizing the formal parallels between cultural and natural capital. The economics of cultural heritage is also particularly interested in policy-making processes in different jurisdictions, for example, in analyzing the optimal level of decentralization of decision-making in multi-jurisdictional systems.

An important means by which heritage is conveyed to the public is via museums, whether these are art museums displaying moveable heritage items such as paintings, sculptures and artifacts, or museums built around particular heritage buildings or sites. The number of museums has increased dramatically in recent years, and so have numbers of visitors. But the objectives of museums are also becoming more diversified and complex, as is stressed in the contribution by Bruno Frey and Stephan Meier (Chapter 29). The question of “what should be maximized” is becoming more crucial as organizations become more complex, and depends on whether a museum is private or public. Increasing the number of visitors is certainly a legitimate objective, but involves new challenges: rooms may be congested; services aimed at specific audiences have to be developed, etc. The resulting choices have direct implications for entrance fee policies, for the amount and diversity of funding (whether private or public), for acquisitions, for the presentation of permanent collections and for special exhibitions. Museums are generally wealthy, given the value of the assets they hold; at the same time, they are poor, since their assets are frozen and operating costs are growing. Frey and Meier discuss a number of issues related to museum economics including de-accessioning (selling works from the collection), the role of superstar museums, and the growing importance of blockbuster exhibitions.

The final cultural policy area to be considered here relates to the geographical location of arts and cultural facilities and of cultural industries. Given the relatively labor-intensive character of artistic production, and given also the role of the arts in fostering social cohesion, it is not surprising that the establishment of arts facilities, etc. has been seen as a means of urban revitalization and employment creation, especially in depressed areas. The attention of economists in this field has been directed towards quantifying the economic effects – both direct and indirect, tangible and intangible – of such processes. Studies have looked at the short-run employment and income-generating impacts of cultural facilities and events, and at the longer-term contribution of the arts and culture to sustained regional growth and development. In reviewing this field, Trine Bille and Günther Schulze (Chapter 30) look at the culture/development nexus from two points of view: they ask on the one hand how the arts and culture can generate urban development, and on the other how regional economic growth can in-

fluence the cultural sector. They point to agglomeration processes in cultural industry location, a matter taken up by Walter Santagata ([Chapter 31](#)) in his exposition of the phenomenon of “cultural districts”. In Santagata’s analysis, these are districts where firms producing particular cultural goods tend to cluster, opening up the opportunity for them to establish a collective intellectual property-right over their marketed output. Experience in developed countries in the establishment of such rights may be taken to indicate some potential for encouraging the formation of such cultural districts in the developing world.

## 6. Conclusions

The overview of the economics of art and culture that I have presented in this chapter has been intended to provide both an interpretation of the principal concerns of the field of cultural economics, as well as an introduction to the various chapters in this volume. Readers are now invited to turn to the chapters themselves, where they will find a much fuller discussion of the issues touched upon only fleetingly above.

There are a number of topics that my co-editor and I decided not to treat in this volume and that could, under a liberal interpretation of culture, have been included. An obvious one is the economics of religion, an area that has been gaining some prominence in recent years and that is pigeon-holed alongside the economics of art and culture under the “Z” classification in the *Journal of Economic Literature*. The economics of language is another area deserving of consideration, given the ubiquitous presence of language in many types of economic interactions. More broadly, an extension of the concept of culture further into popular culture than is attempted in this volume would open up the economics of sport and a wider range of media issues, taking us into areas that are so substantial they may well warrant separate volumes of their own.

Finally, it is worth noting that recent years have witnessed a steady expansion in the number of economists taking an interest in the economics of art and culture. Most chapters in this volume make suggestions for promising lines of future research; if these suggestions are taken up we are likely to see a continuation of this expansion in the future.

## Abstract

Attention to art and culture goes far back in the history of economic thought. In the seventeenth century those activities were viewed suspiciously as likely to be either wasteful extravagances of the aristocracy, or dangerous distractions for the working classes. Eighteenth century economic thinkers offered more positive and thoughtful speculations. Mandeville and Galiani observed that the prices of art works were determined almost entirely on the demand side of the market, often by fashion and the search for distinction. The Enlightenment economic thinkers were intrigued by various aspects of art markets. Hume and Turgot perceived positive social benefits emerging from the arts, and they attempted to understand of what these consisted. Smith picked up some of the hints that were dropped and looked at art markets in a depth that had not been undertaken before. Like some other Enlightenment thinkers, Smith pictured the arts as being mainly about the imitation of perfection.

Jeremy Bentham, with his emphasis on utility as a tool by which both to understand and judge market performance, insisted that the arts should not be distinguished from other forms of entertainment: pushpin, he asserted, equals poetry. Other political economists followed Bentham's lead and steered away from exploration of the economics of the arts. To some extent the void thus created was filled by humanistic writers, novelists, and essayists, notably Arnold, Ruskin, Dickens, and Morris, who were highly critical of the industrialization of the period and the emerging discipline of political economy that they perceived to go with it.

In the "marginal revolution" of the 1870s the Benthamite injunction against special treatment for the arts was largely observed. At the same time, several of the new economists, notably William Stanley Jevons, became "closet esthetes", enjoying their guilty pleasures but not often subjecting the arts to economic analysis.

Disappointingly little concerning the arts and culture can be found in the distinctive American economics of the late nineteenth and early twentieth century. There was almost a reversion to the seventeenth century view of the arts as the corrupt playthings of the idle rich. However, something like a return to the rich speculation of the eighteenth century Enlightenment occurred in the Bloomsbury Group that included the economist John Maynard Keynes. They rejected "Benthamism" and distinguished between the artistic experience and human consumption, and between the "imaginative life" of the mind and the biological activity of humans and other creatures. They discerned complex effects of the arts throughout society and placed arts policy high on the policy agenda.

## 1. Introduction

What may modern cultural economists learn from this chapter which reviews what earlier, mainly English-speaking, authors have written about the economics of art and culture? They may discover that their subject has roots that are far deeper than they ever imagined. And some of these roots have vigorous life still. “Cultural economics” came on the scene as a full-fledged sub-discipline of economics in the 1960s, marked soon by a journal, an association and canonical texts such as *Performing Arts: The Economic Dilemma* (1966) by W.J. Baumol and W.G. Bowen. In fact, however, many of the topics addressed by these new cultural economists had been under discussion already with greater or lesser sophistication for two centuries or more. The modern economist may find in this disparate literature insights and interpretations that have continuing relevance. Discovery and rehabilitation of some of these early texts may at a minimum reduce the need to reinvent the wheel. It is sobering to reflect on how long economists have struggled over some questions in cultural economics that now seem almost eternal: How to recognize and specify externalities arising from activities in the arts? Are there perhaps negative as well as positive externalities associated with the arts? Many in the eighteenth and nineteenth centuries thought so! Is there something about the arts that distinguishes their production and consumption from those of other goods that occur in society? Or could it be that the arts are simply a complex category of consumption dominated by conspicuous behavior and with its own collection of rent seekers? What forms of patronage work best to sustain and stimulate the arts, if they do indeed have special merit and deserve some sort of payment outside the market? What conditions strengthen the creativity of artists? Can the free market, even under the best of competitive conditions, be counted upon to sustain the arts and culture at levels approaching those that are socially optimal? If not, what is the proper role for the state as supporter, planner, and operator in this field? Is it possible that the best response of the state when faced with entreaties from the arts is to “just say No”? Definitive answers to these questions are not likely to emerge from an examination of the pre-history of cultural economics, but some light may be cast.

The terms art and culture came into common use with their modern meaning only in the late eighteenth century, and then as an evolution from earlier meanings. “Art” moved from signifying a particular skill to “a set body of activities of a certain kind”, “a particular group of skills, the ‘imaginative’ or ‘creative’ arts” [Williams (1958, p. xv)]. At the same time “art came to stand for a special kind of truth, imaginative truth”. “*The arts* – literature, music, painting, sculpture, theater – were grouped together, in this new phrase, as having something essentially in common which distinguished them from other human skills” (pp. xv, xvi). The word “culture” changed in rather the same way as “art” from meaning the “tending of natural growth” to several other definitions including “a general state or habit of the mind”, “the general state of intellectual development, in a society as a whole”, “the general body of the arts”, and “a whole way of life, material, intellectual and spiritual” (p. xvi). It must be remembered that at different times all these various meanings were intended by writers on economics as well as on

other topics over the several centuries spanned by this chapter. The chapter is broadly chronological, beginning in the late sixteenth century and culminating around the middle of the twentieth, i.e. just prior to the emergence of the “modern” sub-discipline of cultural economics referred to above.

## 2. The earliest years

### 2.1. *Art and culture as luxury, waste and dissipation*

Writers on economic topics before the middle of the eighteenth century were deeply conscious of the problem of scarcity and the need for careful allocation of limited resources. In a subsistence economy the price of waste could be starvation and death, and at a minimum waste meant sacrificing an important alternative goal. Sometimes the norm prescribed or implied for allocation of resources was achievement of the good life, sometimes it was national power, and sometimes it was the smooth running of a fast-developing market economy. For the most part economic writers appreciated that resources when wisely used could feed the working class, sustain the state in its various projects or adventures and permit the production of investment goods that would achieve growth in the future. Art and culture had little place in this picture, except in a few cases as means to some worthy end; they were at best an enigma and at worst an annoyance. Could they, critics asked, be any more than the extravagance of the monarchy, the aristocracy and the church, and therefore increasingly inconsistent with modernity? Were they not, as the modern economist might ask, in all respects noxious and demeritorious goods? Some early writers thought so – for various reasons. There was not organized controversy in this literature on this subject as much as uninhibited, undisciplined and somewhat random commentary.

Favorable attention was given from time to time to art and culture in the mercantilist literature when it could be shown that domestic production of artworks would contribute to a more favorable balance of trade, or when it was noted that domestic expenditures on culture sustained employment during a recession. But attention sometimes was also unfavorable. For example, in the 1730s there was a move to limit the number of playhouses in London as a way to reduce the urban vice that was said to be corrupting the nation. In the view of the pamphleteer Erasmus Jones, “the town” was fast becoming “a forge of vanity, a nursery of vice, a snare to the young, a curse to the old, and a perpetual spring of new temptations” [Jones (1736, p. 31)]. The arts were part of “our pretended diversion, viz. horse-races, cockpits, tennis-courts, balls, assemblies, and musick entertainments, &c . . . We are like so many bees in a garden, humming and roving from one flower to another, foolishly endeavouring to keep up our course of pleasure, by a continued succession, and circle of varieties” (p. 32). In this pamphlet commercial activity is presented as the only virtuous activity outside the home, while the notorious revels of the upper classes were the worst sort of vice. “Virtue only deserves the name of business, and none but they that practice it, can be truly said to be employed; for all

the world beside are idle” (p. 33). The arts necessarily suffered here by the division of all human activity into the vigorous and virtuous on one side and the idle and vicious on the other; they were placed unambiguously in the latter category.

Before the emergence of an economics discipline at the end of the eighteenth century, writers on economic topics often focused on the “passions” that supposedly motivated human action in markets as elsewhere. For the most part they perceived an inevitability about these passions that made it difficult to constrain, control, or balance them. However, to complicate the matter the passions – and the vices to which they sometimes gave rise – clearly helped to make the world go round or at least the economy to perform, and it might be dangerous to meddle with them. Bernard Mandeville’s recipe for economic growth depended heavily on arousing and harnessing the passions, among which envy, pride and covetousness loomed large. “Would you render a society of men strong and powerful, you must touch their passions. Divide the land, tho’ there be never so much to spare, and their possessions will make them covetous: rouse them, tho’ but in jest, from their idleness with praises, and pride will set them to work in earnest. Teach them trades and handicrafts, and you’ll bring envy and emulation among them . . .” [Mandeville ([1732] 1924, I, p. 184)].

Envy and emulation were seen by Mandeville as the forces that drove the art markets in particular: “the worldly-minded, voluptuous and ambitious man, notwithstanding he is void of merit, covets precedence every where, and desires to be dignify’d above his betters: He aims at spacious palaces, and delicious gardens; his chief delight is in excelling others in stately horses, magnificent coaches, a numerous attendance, and dear-bought furniture . . . His table he desires may be served with many courses, and each of them contain a choice variety of dainties not easily purchased, and ample evidences of elaborate and judicious cookery; while harmonious musick and well couched flattery entertain his hearing by turns” (p. 148). In Mandeville’s cynical eyes at least, the arts were not distinguishable in their role in the economy or greater in social importance than extravagant modes of transport, cuisine, and even flattery as means of responding to the demands for emulation.

Mandeville observed that exercise of the various passions through extravagant encouragement of the fine arts was happily less injurious to the health of the individual than the alternatives. Given the choice of “Wine, Women and Musick”, the well-advised wastrel following Mandeville’s suggestion chose the third. Identification of the fine arts with the luxurious vices rather than with virtues practiced in the market place, and hence seeing them as a waste of scarce resources, guaranteed them low status in the eyes of commentators on economic questions. John Bodin carried out a useful exercise in 1606 to spell out “in what order citizens are to be placed” in the “ceremonies of every city”, thereby establishing their social value. He recommended of course that in the front row should stand the monarch, followed by the clergy, senators, generals in the army, and so on. In the back there would be a motley crew, among whom would be the artists [Bodin ([1606] 1962, p. 402)].

## 2.2. *Early reflections on price, patronage and externalities*

Bodin, Mandeville, and Galiani were among the first to speculate about the determinants of the prices of art works. The general tenor of their comments was that all luxury goods, unlike subsistence goods which made up most of national product at the time and whose prices reflected their costs, were simply frivolous and their value was socially determined on the demand side. Bodin observed that luxuries rose in price when they were favored by the king because of his patronage and for no reason inherent in the things themselves: “The people conform always to the wish of the king, and consequently esteem and raise in price everything that the great lords like, though the things of themselves are not worth that valuation; for example, the Emperor Caracalla gave an inestimable worth to yellow amber, as history says, because it was like the color of the hair of his sweetheart” [Bodin ([1578] 1947, p. 34)]. Anticipating the comments of Thorstein Veblen on conspicuous consumption more than three hundred years later, Bodin went on to note that: “when the great lords see that their subjects have an abundance of things that they themselves like, they begin to despise them . . . This goes to show that the abundance of pearls has caused them to be disregarded, and from the indifference has come the low price” (p. 35). Improvidence among the rich was another reason for the relatively high price of luxuries, including works of art. In the case of precious textiles “The high price comes from the waste; for we are not content to dress the rascals and lackeys with it, but also we cut it up in such a manner that it cannot last nor serve but one master” (p. 36). Since the high prices of luxurious consumption goods were one of their attractive features for those who wished to demonstrate their wealth there were few pressures to constrain costs. “It is true that the excesses helped much to raise the price of food; for the rich, it is found, sometimes did not know how to spend their means; a thing that happened to Aesop, the tragedian, who to sharpen his appetite, had himself served a dish that cost fifteen thousand crowns, full of singing nightingales, starlings, blackbirds, and other birds, which had learned to talk, though such birds were unsavory and not tasty: however, the cost gave them a good taste” (p. 41).

Mandeville concluded that four factors were most powerful in determining the prices of art works: the fame of the artists, the reputation of their owners, their scarcity, and their faithfulness to nature. He wrote:

The value that is set on paintings depends not only on the name of the master and the time of his age he drew them in, but likewise in a great measure on the scarcity of his works, and what is still more unreasonable, the quality of the persons in whose possession they are as well as the length of time they have been in great families . . . Notwithstanding all this, I will readily own, that the judgment to be made of painting might become of universal certainty, or at least less alterable and precarious than almost anything else: the reason is plain; there is a standard to go by that always remains the same. Painting is an imitation of nature ([1732] 1924, I, p. 326).

And not only real nature, but nature with a positive spin! “It is not nature, but agreeable nature, *la belle nature*, that is to be represented; all things that are abject, low, pitiful and mean, are carefully to be avoided, and kept out of sight; because to men of the true taste they are as offensive as things that are shocking, and really nasty” (II, p. 33).

Galiani had two things to say about the determinants of price in the fine arts. The first concerned the force of fashion. “The power of fashion applies wholly to the beautiful, not at all: to the useful . . . The beautiful is of two classes: one is based upon certain ideas, which are engraved upon our mind from the beginning; the other, though it does not seem so, is merely an habituation of the senses, which makes a thing appear beautiful. It is only over this second class, which is considerably larger than the first, that the power of fashion extends” ([1751] 1930, p. 295). Galiani’s second observation about the prices of artworks concerned those that could be described as “unique, and monopolies, that is either things for which there is no substitute, such as the Venus de Medici, or those which become unique because there is only one seller” (p. 295). Galiani denied that the price of these goods was either “infinite” or “indefinite” “for I hold that every human thing possesses order and limits, and that the indefinite is no less foreign to them than the infinite. They have these limits, then: that their price always corresponds to the needs or desires of the buyer and the esteem of the seller combined, and forming a compound ratio. Hence it is that the value of a unique thing may sometimes be equal to nothing; and it is always governed by rule, though it may not be the same under all conditions” (pp. 295–296).

Mandeville argued that, at least among the fine arts, painting was concerned mainly with the magnificence and sensibilities of aristocratic patrons. “The painter has nothing to do with the truth of the history; his business is to express the dignity of the subject, and in compliment to his judges, never to forget the excellency of our species: All his art and good sense must be employ’d in raising that to the highest pitch: Great masters don’t paint for the common people, but for persons of refin’d understanding” ([1732] 1924, II, p. 35). The arts in general should represent moral principle more than an accurate reflection of nature or events. “There is a grandeur to be express’d in things that far surpasses the beauties of simple nature . . . What gentle touches, what slight and yet majestick motions are made use of to express the most boisterous passions. As the subject is always lofty, so no posture is to be chosen but what is serious and significant as well as comely and agreeable; should the actions there be represented as they are in common life, they would ruin the sublime, and at once rob you of all your pleasure” (II, pp. 36–37). Of special relevance to those concerned about the condition of social relations, the arts showed promise of modulating the human passions. In this interpretation by Mandeville the arts began to lose their reputation as always the companion of vice and dissipation and to emerge as, perhaps, a path to virtue. The opera, with the opportunity it presented for moral lessons set to music, was a prime case in point. “There is no place, where both sexes have such opportunities of imbibing exalted sentiments and raising themselves above the vulgar, as they have at the opera; and there is no other sort of diversion or assembly from the frequenting of which young persons of quality

can have equal hopes of forming their manners, and contracting a strong and lasting habit of virtue” (II, p. 40).

### **3. The eighteenth century: Imitation and imagination in the Enlightenment**

#### *3.1. David Hume*

A fresh approach to the fine arts appeared around the middle of the eighteenth century in the works of David Hume and Anne Robert Jacques Turgot. Hume rejected what he took to be the prior consensus that all “luxury”, including the fine arts, was necessarily wasteful and vicious. He argued that depending on what form it took luxury could be either virtuous or vicious, socially beneficial or pernicious. “Luxury is a word of an uncertain signification, and may be taken in a good as well as in a bad sense. In general it means great refinement in the gratification of the senses; and any degree of it may be innocent or blamable, according to the age, or country, or condition of the person. The bounds between the virtue and the vice cannot here be exactly fixed, more than in other moral subjects” [Hume ([1752] 1965, p. 48)]. In order to make the distinction between vicious and virtuous luxury Hume developed a line of argument that was to become influential in the humanities and the arts in the nineteenth and twentieth centuries, but in its attempt to establish the arts as exceptional would for the most part be rejected by the economics discipline. It was easy enough to demonstrate, Hume observed, that luxurious living carried to extremes was both wasteful and socially pernicious. But how about “innocent” luxury that included partaking of literature and the fine arts? From his historical studies Hume observed that “the ages of refinement are both the happiest and most virtuous” (p. 49). Moreover, achievements in the arts went along with accomplishments in other areas such as the economy and were not competitive with them. “The same age which produces great philosophers and politicians, renowned generals and poets, usually abounds with skilful weavers, and ship-carpenters . . . Thus industry, knowledge, and humanity, are linked together, by an indissoluble chain, and are found, from experience as well as reason, to be peculiar to the more polished, and what are commonly denominated, the more luxurious ages” (pp. 50–51). Indeed luxury seemed to provide some of the innocent incentives for economic development to proceed briskly: “where luxury nourishes commerce and industry, the peasants by a proper cultivation of the land, become rich and independent” (p. 56).

But it remained to be explained how luxury actually achieved these good results through time. Hume concluded that the answer lay in the psychological impact the innocent luxuries had on human behavior. “The mind acquires new vigor; enlarges its powers and faculties; and by an assiduity in honest industry, both satisfies its natural appetites, and prevents the growth of unnatural ones, which commonly spring up, when nourished by ease and idleness. Banish those arts from society, you deprive men both of action and of pleasure . . .” (p. 50). Hume found the taste for innocent luxuries, including the fine arts, to be closely linked to the level of contribution to private and public life.

But industry, knowledge, and humanity, are not advantageous in private life alone; they diffuse their beneficial influence on the *public* and render the government as great and flourishing as they make individuals happy and prosperous. The increase and consumption of all the commodities, which serve to the ornament and pleasure of life, are advantages to society; because at the same time that they multiply those innocent gratifications to individuals, they are a kind of *storehouse* of labor, which, in the exigencies of the state, may be turned to the public service. In a nation where there is no demand for such superfluities, men sink into indolence, lose all enjoyment of life, and are useless to the public, which cannot maintain or support its fleets and armies from the industry of such slothful members (pp. 51–52).

The arts, Hume concluded, meaning both the fine arts and all forms of human inquiry, had not only these positive economic externalities; they had political externalities as well and, indeed, were essential to a democracy. “The liberties of England, so far from decaying since the improvements in the arts, have never flourished so much as during that period . . . If we consider the matter in a proper light, we shall find, that a progress in the arts is rather favorable to liberty, and has a natural tendency to preserve, if not produce a free government” (p. 55). The arts and learning were critical to nurturing those psychological characteristics essential for civic virtue. “Here then is the chief triumph of art and philosophy: it sensibly refines the temper, and points out to us those dispositions which we should endeavour to attain, by a constant *bent* of mind, and by repeated *habit*” [Hume (1825, p. 168)]. Hume’s general conclusion seems to be that although the arts might be mildly vicious in their detraction from the production of more useful goods and services, they made important contributions by controlling other more damaging vices such as indolence and brutality.

### 3.2. Anne Robert Jacques Turgot

Like Hume, Turgot was intrigued by the differing rates of progress among nations and he speculated that the explanation might be in “the origin and growth of the arts and sciences and the revolutions which have taken place in them” [Turgot ([1750] 1973, p. 42)]. He concluded that success in the accumulation of what we would call today intellectual capital was the key to economic and political development. In the same way as Hume, Turgot drew his insight more from history than from models of economic and social behavior. In the case of economic growth he wrote: “nature, distributing her gifts unequally, has given to certain minds an abundance of talents which she has refused to others. Circumstances either develop these talents or allow them to become buried in obscurity; and it is from the infinite variety of these circumstances that there springs the inequality in the progress of nations” (p. 43). Turgot used the history of ancient Greece to demonstrate that artistic and intellectual progress lay at the heart of social development. Indeed, the arts usually came first before the humanities. “It was only after several centuries that philosophers appeared in Greece – or rather it was only then that the study of philosophy became the business of particular thinkers and appeared

sufficiently extensive in its scope to occupy them fully. Until then, the poets had been at the same time the only philosophers and the only historians. When men are ignorant it is easy to know everything” (p. 49). It was essential to the maintenance of Greek success that the fine arts retained their position of prominence. “Happy centuries, in which all the fine arts spread their light on every side, and in which the passion of a noble emulation was swiftly transmitted from one city to another! Painting, sculpture, architecture, poetry, and history grew up everywhere at the same time, as we see in the expanse of a forest a thousand different trees springing up, growing, and being crowned together” (p. 50).

No longer in Hume or Turgot is there any suggestion, as there had been in economic writers a hundred years before, that the fine arts are simply a particular kind of wasteful luxury; waste and corruption were a possibility in the fine arts, as they were in all human activities, but no more so. Turgot observed that through history “blind luxury, which, born of vanity, and judging works of art less as objects of taste than as symbols of opulence, is as opposed to their perfection as a civilised love of magnificence is favourable to it” (p. 52). Turgot drew an intriguing distinction between the sciences and the arts. Progress in the former, he suggested, was limited only by the cleverness of a few scientists acting as detectives to discover and proclaim the laws of nature. The arts on the other hand were constrained by the talent, imagination, and training of the entire artistic community: “Knowledge of nature and of truth is as infinite as they are: the arts, whose aim is to please us, are as limited as we are. Time constantly brings to light new discoveries in the sciences; but poetry, painting, and music have a fixed limit which the genius of languages, the imitation of nature, and the limited sensibility of our organs determine, which they attain by slow steps and which they cannot surpass. The great men of the Augustan age reached it, and are still our models” [Turgot ([1750] 1973, p. 52)]. It is not clear that Turgot’s distinction between the sciences and the arts can be sustained, but it does provide a case for education in and support for both these areas of human endeavor.

Turgot concluded from his historical studies that patronage of the arts was as critical to their development as was creativity within them. “Immortal names of the Medici, of Leo X, of Francis I, be consecrated for ever! May the patrons of the arts share the glory of those who cultivate them!” (p. 57). He saw troubled times ahead for the traditional patrons of the arts, but he was optimistic that out of turmoil new sources of demand would appear: “do the flowered stems of the fine arts grow when they are watered with blood? A day will come, and it is not far off, when they will beautify all the countries of Europe” (p. 57).

When he concluded that the cultural evolution of mankind helped to explain progress in all spheres including the economy, Turgot was led to explore an anthropological explanation of the emergence of the fine arts. He thought that they began with music, dance and poetry, which had “their source in the nature of man. Created to live in society, his joy manifests itself externally: he leaps and shouts. A common joy expressed itself in swaying movements, in leaps, and in simultaneous and confused shouts. Little by little people became accustomed to leap in a similar manner; the steps were marked

by sounds; and the latter were separated by regular intervals. The ear, with very little experience, and by following nature alone, learned to appreciate the primary relations between sounds. When it was desired to communicate the reason for one's joy in words, these were arranged according to the beat of the sounds. This was the origin of dance, of music, and of poetry, which was at first written in order to be sung" (p. 91). So also did philosophy emerge out of fiction. "The poverty of languages, and the necessity for metaphors which resulted from this poverty, led to the employment of allegories and fables to explain physical phenomena. They are the first steps of philosophy, as can still be seen in India" (p. 92). It was a similar story in the visual arts. "The arts of design, sculpture, and painting have many connections with poetry in the feelings which the artist experiences, and in those which he strives to communicate. They had a natural origin in the desire to preserve historical or mythological records; and genius in this sphere was heightened by that patriotic or religious zeal which sought to express with feeling, depth, and force the ideas and memories which these records were bound to recall" (p. 93).

Like Hume, Turgot suggested that progress in the arts, just as in other parts of the economy, required competition among as many aspirants as possible, a kind of evolutionary struggle that needed the presence of the unfit as well as the fit. For this there must be a sustained demand and "a market for pleasing objects and the employment of second-rate artists, among whom the great artists who shine out from them are formed" (p. 103). He contrasted the conditions for painters in several countries. "The Italians, the French, and the Flemish, and a very small number of Germans and Spaniards, have been the only ones to be successful in this art. The reason for this is that the English pay only for good pictures. By banning images from the churches, they deprived themselves of the means of supporting bad pictures, and even second-rate ones. And in all crafts where bad workers cannot gain a livelihood, and second-rate workers are not comfortably off, great men are not created" (p. 103n). The charge that the Reformation in England had paralyzed the art market and destroyed the industry by terminating the demand for run-of-the-mill pictures became a frequent subject for discussion in Britain thereafter.

Turgot found that conspicuous consumption was not a sound basis for patronage of the arts and was potentially destructive of artistic quality. When this element was dominant the arts were likely to be characterized by waves of fashion and technical virtuosity rather than by genuine creativity. Turgot's words on this point have a strikingly modern ring. "Extravagant luxury, where vanity causes ornaments to be accumulated because it regards them less as ornaments than as symbols of affluence, smothers taste. Men no longer seek for the pleasure which things afford to the senses and the mind; they no longer search their own hearts. They no longer listen to anything but fashion. The sure way to judge badly in any sphere is not to judge with one's eyes. When each individual judges, the multitude judges well, because its judgement is that of a large number of people; but when no one does anything but listen, the multitude judges badly. Another cause of bad taste was often the progress of technique in the arts. Men are always liable to mistake the difficult for the beautiful" (pp. 103-104).

Turgot was above all a social theorist rather than an empiricist and his writings are replete with speculations about the economics of the arts that might have been carried further by others and perhaps subjected to empirical test. Here is one more example. He suggested that the quality of the works of art that were produced at any time were determined by among other things the challenge presented by the materials available to the artist. For painters the challenge grew dramatically when their palette moved from black and white to polychrome materials. Great artists met this challenge successfully while lesser ones fell by the wayside. Similarly the quality of the literary arts depended upon the condition of the language in which writers worked. A complex language weeded out the weak but stimulated the strong. “The multiplicity of abstract ideas which our languages express, and which enter into our analogies, demand great dexterity in their employment. That is the disadvantage of perfected languages” (p. 112).

What economists nowadays think of as “demand” was often called “taste” in the eighteenth century, and Turgot reminded his readers that especially in the arts taste must be sustained consistently over an extended period. Great art was seldom a flash in the pan. “No art whatever can be cultivated during a long succession of centuries without passing through the hands of several inventive minds” (p. 116). A problem for the arts was that they were subject to great waves of fashion, and a variety of causes could lead to loss of demand. “Artistic taste can be lost as the result of a multitude of purely moral causes. The diffusion of a spirit of apathy and softness in a nation, pedantry, contempt for men of letters, eccentricity in the tastes of princes, tyranny, and anarchy can corrupt it” (p. 117).

### 3.3. Adam Smith

Adam Smith was exceptionally widely read and was thus able to draw from his predecessors and contemporaries when constructing his own analysis of the arts and culture. In the aesthetics that he set forth in *The Theory of Moral Sentiments* ([1759] 1976) he seemed to draw more from Mandeville than from his “never to be forgotten” teacher Hutcheson. But like Hutcheson (1729), Smith was particularly intrigued by the demand side of art markets. Why, he wondered, do people buy art? He thought that “notions of beauty and deformity” that presumably motivated buyers were affected especially by “custom and fashion, principles which extend their dominion over our judgments concerning beauty of every kind” [Smith ([1759] 1976, p. 194)]. These principles applied to all the arts. “Dress and furniture are allowed by all the world to be entirely under the dominion of custom and fashion. The influence of these principles, however, is by no means confined to so narrow a sphere, but extends itself to whatever is in any respect the object of taste, to music, to poetry, to architecture” (p. 195). Humans were naturally unwilling to concede that their responses to works of art were socially rather than individually determined, but it was true all the same. “Few men therefore are willing to allow, that custom or fashion have much influence upon their judgments concerning what is beautiful, or otherwise, in the productions of any of those arts; but imagine, that all the rules, which they think ought to be observed in each of them, are founded

upon reason and nature, not upon habit or prejudice. A very little attention, however, may convince them of the contrary . . ." (p. 195). The dominant place of fashion in the arts gave much importance to successful innovators. "An eminent artist will bring about a considerable change in the established modes of each of those arts, and introduce a new fashion of writing, music, or architecture" (p. 197). Smith cited the authority of "a learned Jesuit father Buffier" on the power of fashion in determining demand: "the beauty of every object consists in that form and colour, which is most usual among things of that particular sort to which it belongs" (p. 198).

Turning from the demand to the supply side of art markets, Smith observed that great artists seemed to develop a notion of "ideal perfection" in the arts and that they pursued and used this ideal as a goal and standard toward which they aspired even while knowing they would never achieve it.

In all the liberal and ingenious arts, in painting, in poetry, in music, in eloquence, in philosophy, the great artist feels always the real imperfection of his own best works, and is more sensible than any man how much they fall short of that ideal perfection of which he has formed some conception, which he imitates as well as he can, but which he despairs of ever equaling. It is the inferior artist only, who is ever perfectly satisfied with his own performances. He has little conception of this ideal perfection, about which he has little employed his thoughts; and it is chiefly to the works of other artists, of, perhaps, a still lower order, that he deigns to compare his own works (p. 248).

Notwithstanding the fact that great artists recognized imperfection in their work, Smith did observe a dangerous conceit among some of those who had achieved most success with the public. "Great success in the world, great authority over the sentiments and opinions of mankind, have very seldom been acquired without some degree of this excessive self-admiration" (p. 250). If not controlled, this self-admiration could lead to "a vanity that approached almost to insanity and folly" (p. 250).

In the *Wealth of Nations* Smith did not single out the arts and culture as a special topic for attention. However he did touch upon them quite often when dealing with other subjects. On the question of what determined the demand for luxury products of all kinds he was even more cynical than he had been in his discussion of the force of custom and fashion in *Theory of Moral Sentiments*. The desire for emulation was predominant. When he discussed prices for articles made from precious metals he observed that "The merit of their beauty is greatly enhanced by their scarcity" ([1776] 1976, p. 190). Then follows a passage that may have influenced Veblen in developing the notion of conspicuous consumption:

With the greater part of rich people, the chief enjoyment of riches consists in the parade of riches, which in their eyes is never so compleat as when they appear to possess those decisive marks of opulence which nobody can possess but themselves. In their eyes the merit of an object which is in any degree either useful or beautiful, is greatly enhanced by its scarcity, or by the great labour which it requires to collect any considerable quantity of it, a labour which nobody can afford

to pay but themselves. Such objects they are willing to purchase at a higher price than things much more beautiful and useful, but more common. These qualities of utility, beauty, and scarcity, are the original foundation of the high price of those metals, or of the great quantity of other goods for which they can every where be exchanged (pp. 190–191).

When he discussed the determination of the supply price for labor, Smith noted the need for compensating differentials in the wages of various occupations to cover such costs as education. He gave artists as examples as well as the learned professions. “Education in the ingenious arts and in the liberal professions, is still more tedious and expensive. The pecuniary recompence, therefore, of painters and sculptors, of lawyers and physicians, ought to be much more liberal: and it is so accordingly” (p. 119). Special compensation for trust was also due some artists. “The wages of goldsmiths and jewelers are every-where superior to those of many other workmen, not only of equal, but of much greater ingenuity; on account of the precious materials with which they are intrusted” (p. 122). On the other side of the ledger “public admiration” was for some artists a substantial part of the compensation they required to carry on their arts: “in poetry and philosophy it makes almost the whole” (p. 123). Yet the theater, opera, and dance also provided Smith examples that were the opposite of poetry and philosophy, where compensation for public obloquy was required to attract artists to these occupations. “The exorbitant rewards of players, opera-singers, opera-dancers, &c. are founded upon these two principles: the rarity and beauty of the talents, and the discredit of pursuing them in this manner” (p. 124).

On the question of productive versus unproductive labor, Smith observed that in general “The labour of some of the most respectable orders in the society is, like that of menial servants, unproductive of any value, and does not fix or realize itself in any permanent subject, or vendible commodity, which endures after that labour is past, and which for an equal quantity of labour could afterwards be procured” (p. 330). These orders included public servants and the military, and “In the same class must be ranked, some of the gravest and most important, and some of the most frivolous professions: churchmen, lawyers, physicians, men of letters of all kinds; players, buffoons, musicians, opera-singers, opera-dancers, &c. The labour of the meanest of these has a certain value, regulated by the very same principles which regulate that of every other sort of labour; and that of the noblest and most useful, produces nothing which could afterwards purchase or procure an equal quantity of labour. Like the declamation of the actor, the harangue of the orator, or the tune of the musician, the work of all of them perishes in the very instant of its production” (p. 331). In this distinction Smith emphasized that the results of unproductive labor did have legitimate value; they were simply intangible and could not lead directly to capital accumulation and growth. At the same time his use of words like “frivolous” and “meanest” to designate the arts harked back to the denigration of the Mercantilist pamphleteers.

In his later life Smith turned more seriously to the study of the fine or “imitative” arts as he called them. An essay by him on the subject was published posthumously

in his *Essays on Philosophical Subjects*. The relationship between the arts and imitation, a subject discussed by Aristotle in his *Poetics*, remained a puzzle for 18th century thinkers. Smith's essay reads like the musings of someone who has not himself had many aesthetic experiences but knows others who have had and wishes to understand them. He extends Hutcheson's (1729) notions that the arts are mainly about imitation, but like Burke ([1757] 1869) he stresses that they are not simply about copying; the arts involve the search for resemblance in a wider sense. "In Painting, the imitation frequently pleases, though the original object be indifferent, or even offensive" ([1795] 1980, p. 179). The interpretation that involves imitation often upgrades the original subject: "art cannot, without degrading itself, stoop to represent any thing that is offensive, or mean, or even indifferent" (p. 179). For imitation to be pleasing it is necessary for there to be sufficient disparity between "the imitation and the imitated object". This is why artistic success is harder to achieve in sculpture than in painting where all the colors of the palette are available to introduce variation (p. 180).

In this essay Smith returned to a point he had made in *Wealth of Nations*, that the arts could be addressed to various audiences, on the one hand to "the prudent and the wise", and on the other hand "to the rich and the great, to the proud and the vain" (pp. 182–183). With the latter "we ought not to wonder if the appearance of great expence, of being what few people can purchase, of being one of the surest characteristics of great fortune, should often stand in the place of exquisite beauty, and contribute equally to recommend their productions. As the idea of expense seems often to embellish, so that of cheapness seems as frequently to tarnish the lustre even of very agreeable objects" (p. 183). Smith used the case of topiary in different countries to demonstrate how relative costs and prices affected demands for works of art by the "proud and vain". In France low agricultural wages had made topiary widely available and therefore no longer able to signal great wealth. In England by contrast "Such ornaments, not having in that country been degraded by their vulgarity, have not yet been excluded from the gardens of princes and great lords" (p. 184).

In the second part of his *Essay on the Imitative Arts* Smith made what would become an heretical assertion for most later economists, that the products of the imitative arts are a distinctive feature of human civilization. Moreover the pattern of artistic production changes with the progress of mankind. Like Turgot he offered an anthropological hypothesis. First came music and dance: "In the progress of art and improvement they are, perhaps, the first and earliest pleasures of his own invention" ([1795] 1980, p. 187). But among the products of civilization these were inferior goods whose relative demand decreased with progress; they were too time-consuming for advanced societies: "In civilized nations, the inferior ranks of people have very little leisure, and the superior ranks have many other amusements; neither the one nor the other, therefore, can spend much of their time in Music and Dancing. Among savage nations, the great body of the people have frequently great intervals of leisure, and they have scarce any other amusement; they naturally, therefore, spend a great part of their time in almost the only one they have" (p. 187). The third of "those three sister Arts" that appeared in civilized societies after music and dance was poetry, an art form that demanded more of the artist and

the listener. “Poetry, however, is capable of expressing many things fully and distinctly, which Dancing either cannot represent at all, or can represent but obscurely and imperfectly; such as the reasonings and judgments of the understanding; the ideas, fancies, and suspicions of the imagination; the sentiments, emotions, and passions of the heart. In the power of expressing a meaning with clearness and distinctness, Dancing is superior to Music, and Poetry to Dancing” (p. 189). Smith proposed here a stage theory of cultural development and a qualitative hierarchy, somewhat parallel to his well-known stage theory of economic growth.

Smith explored in some depth the particular imitative powers of the various arts so as to discover why people patronize one art form over another. He found music limited in some respects but still more evocative than painting. “This power of exciting and varying the different moods and dispositions of the mind, which instrumental Music really possesses to a very considerable degree, has been the principal source of its reputation for those great imitative powers which have been ascribed to it” (p. 198). Music simply did not have the dimensions to imitate in any depth. “Instrumental Music, however, without violating too much its own melody and harmony, can imitate but imperfectly the sounds of natural objects, of which the greater part have neither melody nor harmony” (p. 200). Indeed, Smith seemed to wonder whether the metaphor of artistic creation as a process of imitation broke down in the case of music. “That music seldom means to tell any particular story, or to imitate any particular event, or in general to suggest any particular object, distinct from that combination of sounds of which itself is composed . . . The subject of a composition of instrumental Music is a part of that composition: the subject of a poem or picture is no part of either” (p. 205).

Smith’s observations about the fine arts were less systematic and confident than his pioneering work on the general principles of market behavior. But he was thoroughly intrigued by them, and like Hume and Turgot he was certain that they were a legitimate subject for social inquiry.

#### **4. Classical economics: The shadow of Bentham**

Considering the rich and suggestive menu of topics in the economics of art and culture left by Turgot and Hume and especially by Adam Smith, it is surprising how little was done with the subject by political economists in the nineteenth century. J.R. McCulloch’s comprehensive review of *The Literature of Political Economy* in 1845 mentioned the arts and culture not at all [McCulloch ([1845] 1938)]. The explanation for this silence may lie at two levels: first, the context of social relations and policy controversies of the time and second, the methodological issues that were arising in the emerging discipline of political economy.

In the nineteenth century many areas of inquiry evolved from being the undisciplined playground of amateurs, aristocrats, clerics and others to become rigorous sciences with accepted rules of procedure, authorities, professional journals and societies, and a

growing presence in university faculties and curricula. This was true of geology, anthropology, and the biological sciences, to mention only a few. Political economy also joined in the search for scientific status, a search that suggested amongst other requirements the need for simple and generalizable models of explanation and prediction. Exceptions had to be kept to a minimum to keep a paradigm viable, and when exceptions were proposed every effort had to be made to keep them inside the disciplinary tent. In the moral or social sciences, of which political economy was perhaps the strongest exemplar, the search for universal “laws” of behavior for the units under study led naturally to the postulation of optimizing and self-interested human beings. Any suggested exceptions to this postulate were in danger of threatening the scientific claims of the discipline. The speculations about the unique nature of aesthetic experience by the Enlightenment thinkers were exactly the sort that if accepted might throw into question the scientific legitimacy of political economy.

The threat perceived by the political economists to the scientific claims of their discipline from the Enlightenment approach to culture and the arts can be seen clearly in the writings of Jeremy Bentham, and especially in his *The Rationale of Reward*, published first in French, and in English in 1825. From his first reading of the *Wealth of Nations* Bentham argued for limiting the exceptions to Smith’s powerful market model. He claimed that except for a few very limited cases like patents and copyrights the state should avoid arranging for anyone to receive more than what the free market provided; the correct rationale for reward in almost all circumstances should be that free markets provided it automatically. The world was full of false claimants who argued for special treatment from government over and above what the market would provide. They should be resisted, argued Bentham, even in those special circumstances recommended by Smith such as the colonies and the capital markets. He observed that the arts contained an especially vocal collection of special pleaders who argued that they were distinctly different from other claimants and deserved favoritism. Bentham reported that for the most part he was not persuaded by these claims. He began by making a charge that was repeated often in the twentieth century, namely that public expenditures on the arts were usually regressive in their effects on the distribution of income and wealth. The rich despoiled the poor so that they could indulge their extravagant tastes. He condemned “Expenditure, of money, on articles, for the accommodation or amusement of the comparatively *opulent few*, at the expense of all, including, in prodigiously greater number, the *unopulent many*, who are incapable of participating in the benefit: productions of the *fine arts*, for instance . . .” [Bentham (1962, II, p. 251)].

Poetry was a frequent and symbolic target for Bentham because a case was regularly made for its public support and because it appeared to him to be a quintessential case of an art form that should be able to stimulate its own adequate reward from the joy it was supposed to give to the poet and the patron. “There are some countries in which the relish for literature is confined to such small numbers, that it may, upon the whole, be beneficial to encourage it by factitious rewards. But if we consider how intense are the enjoyments of the man born with poetic talents, the sudden reputation which they produce, and the ample profit they often yield, especially in the dramatic line, it will

be found that the natural rewards attached to them are far from being inconsiderable” (II, pp. 212–213). Bentham juxtaposed the fanciful structure of poetry to the hard facts and essential usefulness of science. “Happiness depends upon the correctness of the facts with which our mind is furnished, and the rectitude of our judgment; but poetry has no very direct tendency to produce either correctness of knowledge or rectitude of judgment. For one instance in which it [poetry] has been employed to combat mischievous prejudices, a thousand might be cited in which they have been fostered and propagated by it” (II, p. 213). He was incensed that the various forms of creative literature, but especially poetry, had appropriated the “imagination” as their point of origin, as if other intellectual endeavors did not have imaginative roots as well. “These, too, are all together placed under the head of *imagination*; as if, in the first place, to the exercise of all *these* branches of art, the exercise of the imaginative faculty were necessary; and as if, in the next place, it were not so to any of the *others*” [Bentham (1962, VIII, p. 76)].

Bentham took pains to point out often that the fine arts were simply “amusement”, by contrast with “the arts and sciences of curiosity” that were serious intellectual endeavor. “By arts and sciences of amusement, I mean those which are ordinarily called the *fine arts*; such as music, poetry, painting, sculpture, architecture, ornamental gardening, &c. &c . . .” (II, p. 253). Both amusement and the satisfaction of curiosity did give pleasure and therefore yielded utility to those who engaged in them, and their worth could be assessed from the additions to utility they contributed in relation to the utility that might be received from all other alternatives. In perhaps the most oft-cited and influential words in the history of cultural economics, Bentham expressed surprise that humans were, in fact, inclined so often to prefer the titillation of the fine arts to the truth that emerged from science and the innocent distractions provided by idle amusement. Certainly he could see no case for encouraging one over the other.

The utility of all these arts and sciences – I speak both of those of amusement and curiosity – the value which they possess, is exactly in proportion to the pleasure they yield. Every other species of pre-eminence which may be attempted to be established along them is altogether fanciful. Prejudice apart, the game of push-pin is of equal value with the arts and sciences of music and poetry. If the game of push-pin furnish more pleasure, it is more valuable than either. Everybody can play at push-pin: poetry and music are relished only by a few. The game of push-pin is always innocent: it were well could the same be always asserted of poetry. Indeed, between poetry and truth there is a natural opposition: false morals, fictitious nature. The poet always stands in need of something false. When he pretends to lay his foundations in truth, the ornaments of his superstructure are fictions; his business consists in stimulating our passions, and exciting our prejudices. Truth, exactitude of every kind, is fatal to poetry. The poet must see everything through coloured media, and strive to make everyone else to do the same. It is true, there have been noble spirits, to whom poetry and philosophy have been equally indebted; but these exceptions do not counteract the mischiefs which have resulted from this magic art. If poetry and music deserve to be preferred before a game of

push-pin, it must be because they are calculated to gratify those individuals who are most difficult to be pleased (II, pp. 253–254).

Bentham conceded that sometimes the arts had some indirect moral utility (what we might today call a positive externality) when they occupied what otherwise could be idle hands. But this was faint praise indeed. “All the arts and sciences, without exception, inasmuch as they constitute innocent employments, at least of time, possess a species of moral utility, neither the less real or important because it is frequently unobserved. They compete with, and occupy the place of those mischievous and dangerous passions and employments, to which want of occupation and ennui give birth. They are excellent substitutes for drunkenness, slander, and the love of gaming” (II, p. 254). He went on to suggest that it might even be claimed that credit should be given to the fine arts for an increase of pacifism. “It is to the cultivation of the arts and sciences, that we must in great measure ascribe the existence of that party which is now opposed to war: it has received its birth amid the occupations and pleasures furnished by the fine arts. These arts, so to speak, have enrolled under their peaceful banners that army of idlers which would have otherwise possessed no amusement but in the hazardous and bloody game of war” (II, p. 254). But surely this too was no justification for serious attention to the arts. Bentham had thrown down the gauntlet to those interested in the arts and culture to demonstrate that they were more than trivial and that they deserved the scarce time of those concerned with the analysis of public policy.

Bentham emphasized that as far as he could see “quality” in the arts was purely a matter of individual taste. Since the fine arts were all about amusement, how could anyone say – let alone dictate – what would amuse someone else and what would not. No one could state with any authority what is good art and what is bad. “It is only from custom and prejudice that, in matters of taste, we speak of false and true. There is no taste which deserves the epithet *good*, unless it be the taste for such employments which, to the pleasure actually produced by them, conjoin some contingent or future utility: there is no taste which deserves to be characterized as bad, unless it be a taste for some occupation which has a mischievous tendency” (II, p. 254). Those who called themselves art critics “under pretence of purifying the public taste” usually reduced the sum of happiness by depriving “mankind of a larger or smaller part of the sources of their amusement”. By declaring some works of art to be inherently inferior to the alternatives and removing them from consideration, critics effectively reduced the choice set of consumers. “These modest judges of elegance and taste consider themselves as benefactors to the human race, whilst they are really only the interrupters of their pleasure – a sort of importunate hosts, who place themselves at the table to diminish, by their pretended delicacy, the appetite of their guests” (II, p. 254). Bentham spelled out clearly the policy implications of his doctrine. No one should declaim to others on matters of taste, nor should the state favor any of “the arts and sciences of amusement and curiosity”, one over any other. Rewards might occasionally be offered for the discovery of new knowledge in the sciences that promised direct public benefit, but in the fine arts the market should be counted upon to issue most of the signals necessary to induce appropriate levels of production. “Among rich and prosperous nations, it is not necessary that the public should be at the

expense of cultivating the arts and sciences of amusement and curiosity. Individuals will always bestow upon these that portion of reward which is proportioned to the pleasure they bestow" (II, p. 255).

The contextual circumstances that in conjunction with the methodological concerns expressed in the works of Bentham help to explain the neglect of culture and the arts in the evolving body of classical political economy were of two kinds. The first revolved around the distinction made explicit by Adam Smith between productive and unproductive labor, and the second around a similar distinction made by the Physiocrats between goods that emerged from the "productive" agricultural sector and the goods and services that came from the unproductive urban sector. Under both of these distinctions the arts suffered by comparison. They had their roots in the prejudices of the seventeenth and eighteenth centuries against certain kinds of economic activity, especially those deemed luxurious or vicious, as discussed above. But later they were intended to focus attention on sectors that might or might not yield a surplus of physical products such as buildings or grain that could be added to the total fixed or circulating capital (wages fund) and thereby increase the output of the nation in later periods. Smith defined "productive labour" quite carefully as "the sort of labour which adds to the value of the subject upon which it is bestowed" [Smith ([1776] 1976, p. 330)]. The manufacturing laborer was the most obvious productive laborer for Smith, whereas for the Physiocrats it was the farmer. Recall that the stereotypical unproductive laborer for both Smith and the Physiocrats was the menial servant. Smith included the arts in this category, a depiction clearly intended mainly as an aid in classification, but one that was not complimentary to the arts. Smith had certainly conceded that unproductive labor and its output had value, but the denigration of them in the language used was undeniable. In the circumstances of the times the argument that the arts could not contribute to economic growth was damning indeed. The advice was not lost on his readers in the evolving classical political economy that they would be well-advised to direct their attention and study away from the arts to "productive" activities such as manufacturing, agriculture, and international trade.

Nevertheless, the distinction between productive and unproductive labor did attract some powerful criticism soon after it was formulated by Smith. For example, James Maitland (Lord Lauderdale) pointed out in 1804 what he took to be some of the absurdities that flowed from the distinctions proposed by the Physiocrats: "it is impossible to subscribe to the opinion, that the labour of the manufacturer and the artist are totally unproductive of wealth" [Lauderdale ([1819] 1962, p. 141)]. He also took issue with the application to art markets of the Smithian theory that under competition price would gravitate naturally toward the cost of production, which in the case of the arts would mean the subsistence wage of the artist: "it is impossible to believe that a painter, whose works have sold for thousands of pounds, and the value of which has been known to have increased for a century after his death, added nothing more to the value of the canvas than the value of his sustenance and an equivalent for the expence of his education" ([1819] 1962, p. 142). Lauderdale argued that in the arts unlike most other occupations talent imposed barriers to entry and that prices of works of art over time

and under competition would reflect increasing rents to artists of rare talent. He found Smith's distinction of unproductive from productive labor just as unsatisfactory as that of the Physiocrats. "It appears, therefore, impossible to contend, that the labour of the manufacturer and artist, or even the labour of that class whose services perish at the moment, are not, as well as that of the husbandman, to be considered as productive of wealth" (p. 153). One wonders if perhaps Lauderdale's place in the aristocracy, where in the early nineteenth century the arts were valued more than in other strata of society, caused him to react so critically to the treatment of the arts and culture in the growing literature of political economy.

Despite the cogency of the criticism of it, the distinction between productive and unproductive labor did not die easily. It was still alive and well in John Stuart Mill's *Principles* in 1848. Mill denied that "unproductive" should in any way be interpreted as a "term of disparagement" or as casting a "stigma" on certain goods and services [Mill ([1909] 1964, p. 44)]. Yet his disclaimer is contradicted by the tone of the examples he uses. In the case of the theater he seems to suggest that it would be better if people stayed home and saved their money; the only net gain to a nation from expenditures on performances that he could see arose if they were held abroad and there were foreign remittances:

... but what is gained by an actor is a mere transfer from the spectator's funds to his, leaving no article of wealth for the spectator's indemnification. Thus the community collectively gains nothing by the actor's labour; and it loses, of his receipts, all that portion which he consumes, retaining only that which he lays by. A community, however, may add to its wealth by unproductive labour, at the expense of other communities, as an individual may at the expense of other individuals. The gains of Italian opera singers, German governesses, French ballet dancers, &c are a source of wealth, as far as they go, to their respective countries, if they return thither (p. 50).

It is no coincidence that in a body of economic theory that emphasized cost of production as the most powerful determinant of value, in attempting to understand the economics of the arts as of other segments of the economy the focus should be on the labor that produced the artworks rather than the artworks themselves.

This is not to suggest that in all of nineteenth century classical political economy there was no commentary at all on intriguing questions in the economics of the arts; rather it is to indicate that comments were few and that the negative heuristics conveyed to scholars about study of these topics were substantially stronger than the positive ones. David Ricardo had established early on that the arts provided some of the best examples of those exceptional goods that although produced with labor could not reliably be reproduced. Their value as a result was demand-determined. His oft-repeated discussion in *Principles of Political Economy and Taxation* ([1817] 1948), in which artworks are grouped for analysis with various other extravagances, ran as follows:

There are some commodities, the value of which is determined by their scarcity alone. No labour can increase the quantity of such goods, and therefore their value

cannot be lowered by an increased supply. Some rare statues and pictures, scarce books and coins, wines of a peculiar quality, which can be made only from grapes grown on a particular soil, of which there is a very limited quantity, are all of this description. Their value is wholly independent of the quantity of labour originally necessary to produce them, and varies with the varying wealth and inclinations of those who are desirous to possess them.

These commodities, however, form a very small part of the mass of commodities daily exchanged in the market [Ricardo ([1817] 1948, p. 6)].

John Rae, ever the speculative thinker, struggled in his *Statement of Some New Principles of Political Economy* ([1834] 1965) with the question of why people in fact demanded products of the arts. He was unhappy with the implicit suggestion that interest in the arts was just like any other consumer demand, and a luxurious one at that. He suggested that

There is a pleasure in the sight of certain shapes and colors, and arrangements of them, which is quite independent of their cost; there is a fitness also; in the texture of certain fabrics, to preserve from the extremes of heat and cold, to add to the beauties of feature or form, and to correct their defects, that, of itself, gives pleasure; there are pleasures too which the mind creates to itself, out of the associations of these . . . The sight of statues, paintings, flowers, is also capable of affording a high degree of gratification to many minds. The degree of pleasure thus experienced is different in different individuals, and it is scarcely possible to ascertain what its exact amount is in any one; hence the difficulty in most cases, of determining what is, or is not, luxury [Rae ([1834] 1965, p. 272)].

Finally in this overview of classical political economy in the nineteenth century, we can refer to John Stuart Mill. Mill's positions on social and economic policies regarding the arts are reflected in his social theory. He was concerned about how practitioners of the arts could survive in a modern market economy, and especially one like that of Britain where there had been very limited respect for the arts. He looked with special concern at the condition of creative writers: "although the highest pecuniary prizes of successful authorship are incomparably greater than at any former period, yet on any rational calculation of the chances, in the existing competition, scarcely any writer can hope to gain a living by books, and to do so by magazines and reviews becomes daily more difficult. It is only the more troublesome and disagreeable kinds of literary labour, and those which confer no personal celebrity, such as most of those connected with newspapers, or with the smaller periodicals, on which an educated person can now rely for subsistence" [Mill ([1909] 1964, p. 397)]. He urged that more attention be given to this problem of sustaining the arts where a tradition was lacking and times were hard. He observed that in the sale of many artworks by fashionable artists there was substantial producer rent, and like many after him he wondered if this could somehow be extracted to support artists who were not so fortunate [Mill ([1909] 1964, p. 443; 1986, p. 1240)]. Using a variety of arguments, he advocated public education in the arts at all levels. Above all the quality of life of the people would be improved thereby. "The races and

nations whose senses are naturally finer and their sensuous perceptions more exercised than ours, receive the same kind of impressions from painting and sculpture: and many of the more delicately organized among ourselves do the same. All the arts of expression tend to keep alive and in activity the feelings they express" [Mill (1984, p. 254)]. In addition cultivation of the arts would lead to a more moral and tolerant citizenry: "There is, besides, a natural affinity between goodness and the cultivation of the Beautiful, when it is real cultivation, and not a mere unguided instinct" (p. 255). And finally he argued that the arts could instill quality control in a people, help to demonstrate the possibility of sublime accomplishment and reveal "the Good made perfect". This was because "No other human productions come so near to perfection as works of pure art" (p. 255).

## 5. Humanist critics

While political economists in the nineteenth century shied away from a sympathetic approach to the arts and culture, others moved in to fill the void, in particular poets, novelists and essayists who came to constitute a community of criticism. The result was a widening gulf between the evolving discipline of political economy on the one hand and the humanities and the arts on the other. Some of the subjects addressed by the critics could be described today as positive externalities of the arts and culture; others involved more profound speculations about the place of the arts in national life. Many novelists and poets worried in particular that the capitalist market economy was squeezing aside the arts and culture in favor of more prosaic goals [Grampp (1973)]. For example, Thomas Love Peacock complained that the nineteenth century had become the age of the "huckster" (*l'épicier*) in which all goods were produced in response to consumer demand without regard to their inherent merit, in the "literary market" as elsewhere [Peacock (1926, pp. 294, 297)]. The "march of mechanics" [progress of technology!] had been accompanied by "the days of political economy", and the result was "what we call *l'esprit épicier*. Applied to literature, to the arts, to the mode of living, and manifesting itself in manner, style, and taste, by something obsolete, vulgar, and awkward, tinged with the ridiculous, this spirit has created what we call *le genre épicier*" [Peacock (1926, pp. 295, 300)]. Despite all his talk of freedom, the huckster was essentially authoritarian. "His ruling passion is the love of 'order', because he has observed that in the days of political disturbances there has been a fall of a per-centage on his operations. The apprehension of anarchy, or, to speak more correctly, the fear of diminished sales and falling prices, has made him a fanatic of 'l'ordre public' . . . For him, order is a positive result which must be obtained at any price, without regard to the causes which may have produced a feverish over-excitement in any portion of society" [Peacock (1926, pp. 300–301)]. Because of his fear of disorder the huckster was the enemy of the artist and the intellectual, indeed it "had never happened to him to have an idea in the course of his life" (p. 301).

Three humanist critics of political economy went beyond such denunciations to make notable contributions to the relationship of the arts to the economy: the poet and essayist Matthew Arnold, the prominent artist, critic, and art historian John Ruskin, and the leader of the Arts and Craft movement, William Morris. We turn to them in the following sections.

### 5.1. Matthew Arnold

The main question raised by Matthew Arnold was a direct challenge to the political economists: Were the arts and culture more than merely a distinctive collection of goods amongst which consumers might make a selection for their amusement? Were they not in fact essential to healthy and successful social development? Arnold addressed squarely what was becoming one of the most frightening questions in nineteenth century political economy: Could economic development continue without causing destructive conflict between owners of capital on one side and labor on the other? Poets and novelists before him had often addressed environmental degradation and sufferings of the working class caused by the new factory system;<sup>1</sup> Arnold asked the follow-up question of how society could be held together where these sufferings persisted while the franchise was increasing steadily through the reform acts of 1832 and 1867. What was to stop those without property from taking it away from those who had it, either legally through Parliamentary action or illegally through violence in the streets? What was to stop democratization from degenerating into anarchy? After all, the French Revolution was only a few decades behind and the revolutionary year of 1848 even more recent. The answer to the threat of anarchy, Arnold suggested, lay in civilizing the population and more specifically in extending “culture” throughout the populace, defined in his influential book *Culture and Anarchy* ([1869] 1903) in Enlightenment terms as the “study of perfection”, “turning a stream of fresh and free thought upon our stock notions and habits” (pp. xi, 7). He argued that culture is “possessed by the scientific passion as well as by the passion of doing good” (p. 8). It would lead human nature toward “a harmonious perfection, a perfection in which the characters of beauty and intelligence are both present”, “a human nature complete on all its sides” (pp. 19–20, 25). Arnold’s definition of culture seems rather close to what is meant today by the results of a “liberal education”. Culture would not come painlessly or without hard work and cost. Contrary to Bentham there must be expert critics who would endeavor to learn and propagate “the best which has been thought and said in the world” (p. xi). They must guide others in their quest for culture.

The type of beneficent cultured citizen that Arnold claimed was essential for a healthy, advancing society was in his view in sharp contrast to the grasping self-interested creatures modeled by the economists, and to whom he gave a scornful name

<sup>1</sup> Creative writers in Great Britain in the nineteenth century who deplored the industrialization that was taking place and the evolving science of political economy that they associated with it included Robert Southey, Samuel Taylor Coleridge, William Wordsworth, Thomas Love Peacock, Anthony Trollope, William Cobbett, Thomas Carlyle and, most notably, Charles Dickens; see Grampp (1973).

that was to remain with them, Philistines. “The people who believe most that our greatness and welfare are proved by our being very rich, and who most give their lives and thoughts to becoming rich, are just the very people whom we call Philistines” (p. 17). He described two bundles of behavioral pressures operating within humans that, following Heine, he called Hebraism and Hellenism. Hebraism included conscience, obedience, duty, and subjugation of self, some of the qualities treated by Adam Smith more than a century before in *The Theory of Moral Sentiments*; Hellenism involved spontaneity, curiosity, intellectual flexibility, and appreciation of beauty, subjects dealt with in *The Wealth of Nations*. “The uppermost idea with Hellenism is to see things as they really are; the uppermost idea with Hebraism is conduct and obedience” (p. 123). Arnold saw human history as mainly a struggle between these two sets of forces: “by alternations of Hebraism and Hellenism, of a man’s intellectual and moral impulses, of the effort to see things as they really are, and the effort to win peace by self-conquest, the human spirit proceeds; and each of these two forces has its appointed hours of culmination and seasons of rule” (p. 134). A healthy individual or society, Arnold insisted, maintained a proper balance between these two bundles of behavioral characteristics. Bennett (2005) sees the ideas of Plato and of the Romantic poets Goethe and Schiller behind Arnold’s conception of culture. It is not hard for the economist to see as well the economic thinkers of the Enlightenment, all of whom had been concerned about what should be the context in which a society, economy and polity could operate smoothly. The political economists of Arnold’s day had begun to believe that the economy could reasonably be explored as separate from the society and polity, and that if the natural proclivities of humans were left untrammelled, optimal social and political as well as economic results may well emerge from free markets. Arnold seemed to be following up some of the hints we find in the early Smith that the recipe for economic efficiency may not be that simple. Moreover, there may be a case for concluding that markets for art and culture are truly exceptional, both in how they operate and in their effects on society overall. Contextual preconditions are necessary for the smooth performance of a market economy, and these could require institutions and actions remote from the conventional concern with technical efficiency such as the cultivation of the arts and culture through a liberal education. This was a message that not many nineteenth century political economists wished to hear, or with which they were prepared to engage.

## 5.2. John Ruskin

Another message about the relations of the economy with culture and the arts that was profoundly disagreeable to nineteenth century political economists came from John Ruskin. Whereas Arnold had questioned one emerging sacred principle of classical political economy, that it was reasonable to focus on market interactions without attention to the cultural context, Ruskin disputed another, that utility functions of consumers are stable for the most part and that wants should be treated as exogenous to economic analysis. Arnold’s concern was essentially macro, about the stability of the entire social and economic system, whereas Ruskin’s was micro, about the happiness of the individ-

ual in society. Like Arnold, Ruskin was insulting to the political economists of his day seemingly by design. Although he published works with titles like “The Political Economy of Art” [1857; published in Ruskin ([1880] 1905)] he took pleasure in reporting that he had read not a word of political economy, except for *The Wealth of Nations* in his youth. Like Arnold he also constructed his own vocabulary when needed and made no effort to connect with political economists who might have had an interest in his subject. Also like Arnold, Ruskin was happy to reject laissez faire as a policy principle. Indeed, he looked to an authoritarian and interventionist leader to make society a better place. Ruskin’s policy norm was formation of the happy individual who had “perfected the functions of his own life to the utmost” [Ruskin ([1862] 1905, pp. 84, 105); see also Moore (2005)], but he proposed to make this individual happier not by piling more and more goods and services upon him but by training him to make a better selection among alternatives and to appreciate more those goods that he could afford. Ruskin believed that by this approach political economy truly became a moral subject, and the science–ethics dichotomy in political economy that Mill had pointed out no longer existed. For Ruskin the notion that value depended upon cost of production was absurd, and he anticipated the marginal utility revolution of the 1870s by insisting that wealth was relevant only to the way in which goods were used. He insisted that “wise consumption is a far more difficult art than wise production” ([1862] 1905, pp. 98, 104). The natural conclusion Ruskin drew from his theorizing was that the community had a responsibility to make sure of the “life availing” qualities of the goods that were consumed and to educate consumers to make the best use of them. The artist and the art critic both had important roles in this process, and the market could not be counted upon to guarantee the maintenance of the artist and critic. He was an early and energetic advocate of public support of arts education, of distinguished public buildings, of museums (to protect old art), and of a national arts purchase fund (to provide demand for new art). He returned to and agreed with Adam Smith’s theme that vanity, if not constrained, could become the mistaken determinant of what was produced in the arts. The omnipresence of bad taste and ostentation were all the proof Ruskin needed of the necessity of public intervention in the arts on a grand scale.

Even though Ruskin’s writings on the economics of art were denounced, deplored, or ignored by most of the economics profession in his own time and thereafter, they lived on in the thinking and literature of the labor movement in Britain and America. To give only one example, the popular economics textbook for workingmen by Henry Clay, *Economics: An Introduction for the General Reader*<sup>2</sup> began with this observation: “No study of Economics, therefore, it seems to me, is worth making which does not include some consideration of the relation of the economic organization to political and ethical aims and standards; which does not, in other words, indicate what light Economics can throw on Ruskin’s question, ‘What is wealth?’” [Clay (1918, p. viii)]. In his final chapter on “Wealth and Welfare” Clay turned again to the question of what constituted

<sup>2</sup> First edition 1918 published and republished many times both in England and the United States.

human progress and he noted the paradox that times when great art was produced in abundance were not necessarily years when consumer goods were increasing:

If we compare different ages and countries, we are struck by the apparent unimportance of wealth. The materialist regards the vulgar plenty of the twentieth century as greatness; others will regard its art as a better index of an age or a country's temper. Whichever is right, the two great ages of art, the two periods when craftsmen were artists and the appreciation of art was general, were ages of extreme material poverty; and few will assert that the age of Arkwright was greater than the age of Pheidias, the civilization of Chicago than the civilization of Athens; few, who have studied both and compare achievement with opportunity, will place the art of the thirteenth century below the art of the Victorian age, the age that built the cathedrals below the age that restored them. As society has grown richer, art has become more and more the concern of little cliques and coteries, less and less a part of the everyday life of ordinary people, until to-day we have countries like the United States, so rich that its Whistlers and Sargents fly to the poorer countries of Europe (p. 420).

Clay left this puzzle for his working-class readers to ponder; clearly he thought it deserved more reflection.

### 5.3. *William Morris*

The third writer on the arts who was anathema to respectable nineteenth century political economists was William Morris [Upchurch (2005)]. His sin was partly that he was a seeming turncoat. After all, Arnold and Ruskin might be dismissed as just an ethereal poet and a half-crazed art critic; Morris was by contrast a successful businessman who made a fortune from the applied arts. He was also himself a talented artist and designer, and much of his celebrity came from his pioneering leadership of the early Arts and Crafts movement. Perhaps because of his deeper immersion in the realities of art markets Morris was more gloomy than Arnold and Ruskin about the prospects for change from piecemeal reforms. Both Arnold and Ruskin envisaged the possibility of much beneficial reform through education and a rather modest intervention by the state to support and shape the arts. Morris had grave doubts. He believed that the arts could prosper only under conditions of collective ownership of the means of production, either through conversion to a socialist state or through a communist revolution. He was not precise in his picture of why the arts would necessarily flourish outside the free market, but his assertion that they would was another fundamental challenge to the economic orthodoxy of his time. It is noteworthy that Morris had more to say about the potentially positive effects of socialism on the arts than did Marx himself or most of his disciples [Solomon (1979)].

## 6. The marginal revolution

### 6.1. *The marginalists' treatment of arts and culture*

The marginal revolution of the 1870s was about the construction of general laws in economics, and about the Benthamite urge to postulate simple and universal principles of human behavior, rooted in utility calculations, that could be used to model the economy. So where in this new vision of economics stood the arts and culture? Not very prominently! Special attention to the arts and culture, as to other particular segments of the economy, did not fit well with the philosophy behind the new marginal economics. The search for exceptionalism in the arts, as in other areas, came into direct conflict with the search for generality.

Several observations may be made about the treatment of the arts and culture during the early years of neo-classical marginal economics. First, the marginalists made far more references to the arts than did their classical predecessors, but less as interesting and exceptional special cases than as manifestations of the general case. Favorite illustrations from the arts used in presentations of economic theory stressed the unique and non-reproducible nature of many artworks. Examination of these cases demonstrated that the price of all consumption goods was demand rather than cost determined. For example, Carl Menger wrote: "A large number of goods cannot be reproduced (antiques, and paintings by old masters, for instance) and thus, in a number of cases, we can observe value but no possibility of reproduction. For this reason, any factor connected with reproduction cannot be the determining principle of value in general" [Menger ([1871] 1950, p. 147)].

Second, there was greater willingness among the marginalists than among the classical economists to posit the possibility of positive externalities emanating from the arts. A moderate position on the salutary effects of the arts on social relations – the Arnold assertion – came to be seen as quite reasonable. Characteristically Alfred Marshall wrote to a correspondent in 1900: "the growth of towns makes it doubly urgent to supply wholesome thoughts & suggestions, lest unwholesome should prevail; and to turn music & painting & other fine arts to account in filling the void in man's life caused by the want of the free light & freshness & beauties of nature" [Marshall (1996, II, pp. 270–271)]. Third, there appeared more prominent economists with deep personal commitment to the arts who were prepared to testify to positive externalities from their own experience. Finally, over time the marginalists lost many of their inhibitions about commenting on the arts; some of their observations were prescient, others were absurd. None of the main neo-classical texts had a separate chapter, or even part of a chapter, devoted to the economics of culture and the arts. The references to the subject were widely scattered throughout. A closer look at the writings of two of the most prominent revolutionaries, Alfred Marshall and William Stanley Jevons, may be illuminating.

## 6.2. *Alfred Marshall*

In a taxonomy of wealth taken from F.B.W. von Hermann, Marshall claimed that all goods related to the arts may be placed in various categories. Conventional artworks are “material”, “personal” and “internal”; “the faculty of deriving recreation from reading or music” is “internal” but “non-material”. “The laws which govern the birth of genius are inscrutable” except that more genius per capita comes from the higher orders than from the working class [Marshall ([1920] 1964, pp. 45–46, 176)]. Marshall argued that the demand for artworks has roots in some fundamental set of preferences that will ultimately prevail over the pressure of fashion. “For though the crudest and most ridiculous fashions in art and in literature will be accepted by the people for a time at the bidding of their social superiors, nothing but true artistic excellence has enabled a ballad or a melody, a style of dress or a pattern of furniture to retain its popularity among a whole nation for many generations together . . . traditional instincts played a great part in preserving the purity of the industrial arts in Oriental countries, and to a less extent in medieval Europe” ([1920] 1964, p. 177). Education in the visual arts as distinct from the rest of the arts, Marshall thought, was desirable for the progress of the economy, but less so than education in other more practical areas. He suggested that education in art stood on a somewhat different footing from education in hard thinking: for while the latter nearly always strengthens the character, the former often fails to do this. Nevertheless he believed that the development of the artistic faculties of people was in itself an aim of the very highest importance, and was becoming a chief factor of industrial efficiency: “We are here concerned almost exclusively with those branches of art which appeal to the eye. For though literature and music contribute as much and more to the fulness of life, yet their development does not directly affect, and does not depend upon, the methods of business, the processes of manufacture and the skill of the artisans” ([1920] 1964, p. 177).

## 6.3. *William Stanley Jevons*

With Jevons we see the appearance among economists of a new phenomenon: the closet artist or aesthete, the economist who either has a separate life as an artist or acknowledges having had a profound aesthetic experience while seeming unwilling to incorporate the artistic dimensions of life into economics. For Jevons music was the fine art that mattered most. But he saw all the fine arts as capable of enriching the lives of the working class beyond their own expectations and therefore yielding positive externalities. He envisaged the arts as being initially unlikely to interest the masses and needing to be administered rather like a dose of tonic. The arts imposed on unsophisticated people in this way would, Jevons believed, ultimately have the aesthetic impact that he himself had experienced. But this aesthetic experience could not be anticipated by those who had not already experienced it, and therefore the arts would not sell well in the market to begin with and would have to be delivered for a while below market rates.

An unpublished manuscript by Jevons entitled “On the Functions of Music” makes it clear that he himself had had aesthetic experiences that he tried to put into words. He wrote that his own response to music was similar to “the contemplation of subjects of Interest, Beauty or Sublimity, and consists of a gentle excitement, an engrossment of the thoughts by agreeable subjects and a general removal of the mind from its ordinary course of duties and frailties, and its continual mixture of slight pleasures and pains” [Jevons quoted in Mosselmans and Mathijs (1999, p. 151)]. Jevons evidently felt that his reaction to music was rather like intoxication or a drug-induced euphoria, suggesting that the experience might be more like an addiction than a conventional act of consumption:

When rising to an unusual pitch, the feeling of which I speak becomes an intense delight; it absorbs the attention completely, and causing it to forget ordinary affairs and thoughts, elevates it to a region of pleasurable sensations nowhere else discovered. It is indefinite however, leads to no conclusion, suggests it may almost be said no leading or strong thought or purpose and even of one’s future path in life, or unavoidable duties happen to occur to the mind in the midst of this sort of intoxication, they appear smoother than ever before, the difficulties have entirely vanished and oneself feels such a sort of confident moral strength, as will only too soon be found to disappear when this state of feeling has ended and the petty or great difficulties of life are once again visible in all their reality (pp. 151–152).

Indeed, it seems that Jevons experienced something like guilt after a musical “trip” was over. “Who that has attended a concert, play or other public performance, has not experienced this sudden and almost disgusting revulsion of feelings at its termination when the music has finally ceased & no longer rivets the attention, and a dreamy progress home, and a renewed circle of duties and the sorrow are all that seem to await one” (p. 152). He was unwilling to probe deeply into what had taken place during his aesthetic adventures and he agreed with Bentham and some other early economists that the aesthetic experience could not be improved by the application of reason or through the services of scholarly critics:

To investigate its cause would be to enter one of the most difficult and least certain of metaphysical subjects and be quite beyond our purposes. It will suffice to say that it does not depend in any particular degree on knowledge . . . the essential nature of Poetry it is universally acknowledged to be almost impossible to define, and lastly the sense of beauty or of melancholy arising from a simple succession of sounds, that is to say an air or melody, is equally inexplicable (p. 152).

Had Jevons lived longer and continued to pursue his interests in the arts he might be remembered today as the father of cultural economics. He certainly made some promising beginnings on topics that would concern his successors thereafter. In 1878 he followed up his interest in the external consequences of “the amusements of the people” and concluded that one of the most promising “methods of social reform” would be encouragement to “good moral public amusement, especially musical entertainments”.

He distinguished very firmly between serious music and what he described as “the mixture of inane songs, of senseless burlesques, and of sensational acrobatic tricks, which make the staple of a music-hall entertainment” [Jevons (1904, pp. 2, 4)]. No advocacy of consumer sovereignty here! He knew what the working classes needed among the arts even if they did not know themselves. Jevons speculated that neglect of the arts for the masses might be the result of a conspiracy by the ruling classes who feared the consequences of a liberating culture. He wrote: “Now I believe that this want of culture greatly arises from the fact that the amusement of the masses, instead of being cultivated, and multiplied, and refined, have been frowned upon and condemned, and eventually suppressed, by a dominant aristocracy. Amusement has been regarded as in itself almost sinful, and at the best as a necessary evil. Accordingly, villages and towns have grown up in the more populous parts of the kingdom absolutely devoid of any provision whatever for recreation” (p. 6).

Following up on this conspiracy theory Jevons abandoned *laissez faire* policy as well as consumer sovereignty theory. He urged governmental attention to the arts as a high priority for public policy: “Among the means towards a higher civilisation, I unhesitatingly assert that the deliberate cultivation of public amusement is a principal one” (p. 7). To buttress his case Jevons claimed that the fine arts and culture would keep the working classes away from various temptations that might be personally and socially destructive, and would yield positive therapeutic effects.

What some seek at the cost of health, and life, and reputation, from alcohol, and from opium, that they might obtain innocuously from music, if they could cultivate true musical taste. Of course there is some nervous waste even in the enjoyment of music, and it is greater as the attention is more excited. Tedium must usually follow an entertainment of two or three hours; but so soon as tedium approaches, the attentive attitude of mind is destroyed, and the corresponding nervous waste ceases. The music, in short, holds the mind enchained just so long as there is energy of thought to spare; in the meantime the body remains in a perfect state of repose (p. 10).

Jevons went so far as to charge that the authorities in Britain, in contrast to those on the Continent, had responded to the demands of the aristocracy and had sabotaged public arts by tolerating within them criminals of every kind – especially pickpockets and prostitutes. He asked indignantly: “Why do we tolerate a state of things under which a young man cannot seek an hour’s recreation without meeting an evil magnet at every turn?” (p. 25).

Another public policy topic in the arts that interested Jevons was what he called “museum economy”, an area in which he found himself a pioneer. He endeavored to arrive at some conception of the purposes in creating public collections and of the means by which those purposes may be most readily attained. “Although the subject has hardly received any attention as yet, I believe it is possible to show on psychological or other scientific grounds that much which has been done in the formation of Museums is fundamentally mistaken” (p. 53). He was deeply critical of British museums and the theory

on which they were based. “There seems to be a prevalent idea that if the populace can only be got to walk about a great building filled with tall glass-cases, full of beautiful objects, especially when illuminated by the electric light, they will become civilised . . . The well-known fact that the attendance at Museums is greatest on wet days is very instructive” (p. 54). He complained that most museums were over-crowded and chaotic: “a great multitude of diverse things is not only useless but actually pernicious, because it tends to destroy that habit of concentration of attention, which is the first condition of mental acquisition . . . It does not seem, however, to have occurred to the creators and managers of Museums, that so far as education is aimed at, a certain unity of effect is essential” (p. 55). Although Jevons’ extended commentary on museums does not in the end consist of much more than shrewd insights and unsupported opinions, he was surely a pioneer in suggesting that these institutions be opened to scientific study.

For the most part the marginal revolutionaries based their economic theory around the general proposition that a competitive market system in which certain conditions hold will yield the maximum human welfare from a given endowment of resources and technology. In principle the determining wants on the demand side of product markets were the demanders’ own business. As Jevons put it “In the science of Economics we treat men not as they ought to be, but as they are” (1905, p. 38). In practice, however, the implementation of this principle was not so straightforward. These Victorian moralizers might agree that in theory pushpin equals poetry but they did not really believe it. They had their own prejudices about what goods were morally superior to others and they did not try to conceal their views. They spoke of a “natural” sequence in which consumption would (should?) take place over the course of economic growth, and this came to be treated as self-evident. Food, clothing, housing was the presumed sequence, and if a consumer announced that a glass of gin and a lottery ticket were high priority consumer goods to precede food and clothing, this would undoubtedly be deemed unacceptable. The vocabulary used to describe consumption often revealed the approved hierarchy of values. Menger referred to “needs” and “requirements” rather than to “wants”; he also distinguished between “true” and “imaginary” goods, the latter being especially common among the demands of people at lower “levels of civilization”. These included the following items of which he clearly did not approve, even though they were demanded freely in the market: “most cosmetics, all charms, the majority of medicines administered to the sick by peoples of early civilizations and by primitives even today, divining rods, love potions, etc. For all these things are incapable of actually satisfying the needs they are supposed to serve” [Menger ([1871] 1950, p. 53)]. He also disapproved of goods that were produced “when non-existent human needs are mistakenly assumed to exist”. In this category he included “medicines for diseases that do not actually exist, the implements, statues, buildings, etc., used by pagan people for the worship of idols, instruments of torture, and the like”. Menger concluded optimistically that “As a people attains higher levels of civilization, and as men penetrate more deeply into the true constitution of things and of their own nature, the number of true goods becomes constantly larger, and as can easily be understood, the number of imaginary goods becomes progressively smaller” (p. 53).

In the same vein Jevons talked of the “higher pleasures” which were “almost incomparable in power and authority” but noted somewhat reluctantly that, because of the current stage of economic development, “It is the lowest rank of feelings which we here treat” [Jevons ([1871] 1965, pp. 26–27)]. Jevons cited the authority of T.E. Banfield on the natural sequence of goods to be consumed: “the satisfaction of every lower want in the scale creates desire of a higher character. If the higher desire existed previous to the satisfaction of the primary want, it becomes more intense when the latter is removed . . . The highest grade in the scale of wants, that of pleasure derived from the beauties of nature and art, is usually confined to men who are exempted from all the lower privations. Thus the demand for, and the consumption of, objects of refined enjoyment has its lever in the facility with which the primary wants are satisfied” [Jevons ([1871] 1965, pp. 42–43)].

The significance of these comments by Menger and Jevons is to show that they tended to see art and culture as human activity that occurred only after sustained economic growth. In their day, they believed, art works were demanded by consumers who from good fortune had already reached high levels of income. Since such goods were few they could safely be ignored.

#### 6.4. *Lionel Robbins*

The last great neo-classical economist who attended to the economics of the arts before the appearance of the cultural economics sub-discipline in the 1960s was Lionel Robbins. Like Jevons, Robbins had a deep personal interest in and commitment to the arts; in his youth he had hoped to become a poet and he rejoiced in the visual arts, the opera and the ballet. He was one of the most energetic and successful advocates for the arts in twentieth century Great Britain; his efforts on behalf of the National Gallery, the Tate Gallery, Covent Garden and other institutions in the arts are legendary. Susan Howson, Robbins’ biographer, reports that over his career Robbins expounded the full range of neo-classical economic arguments for public support of the arts [Robbins (1963); Howson (2005)]. He explained that some art works at least may be seen as public goods and because of their particular character and the external benefits to society that they yield will be underproduced if left entirely to the private sector. He also favored free public access to the arts on grounds of equity. But he struggled with the eternally challenging question of whether the arts are truly exceptional – different in kind from other consumption goods. Clearly he thought they were, but he recognized that the economics he practiced could not help him very much in making the case. He concluded it was a matter of “ultimate values”; clearly the arts imparted “quality and meaning to life on this planet by reason of their mere existence” but to understand why and how they did so was probably beyond the scope of economic science. Robbins was confident that through public education and exposure to the arts the taste of the public could be formed and they could be led to levels of appreciation that would not otherwise be attained. Robbins supported wider use in Britain of encouragement to private support of the arts through tax concessions to private donors, and he made a case for emergency

public purchase of great works of art at times when important private collections were being dispersed.

## 7. The arts in American economics

If treatment of the arts as truly exceptional – as a component of the economy that must be analyzed separately and with its own conceptual apparatus – could be found anywhere in the late nineteenth and early twentieth centuries, surely it would be in the work of those who would later be called the American Institutionalists. Typically these economists were in open revolt against the marginal revolutionaries of the 1870s and against Benthamite utilitarianism as an explanation for economic behavior and as a way of measuring changes in human welfare. They objected by and large to the universalizing strategy of picturing economic agents on both sides of the market as maximizing well-understood quantities like satisfaction and profit, and minimizing pain and cost. They postulated a much more complex system in which human behavior and its objectives are heterogeneous and not easily understood. Accordingly they examined many different types of economic agent, from the captain of industry to the trade union leader, the farmer, and the housewife confined to the home. They attended to behavioral drives that ranged from the instinct of workmanship through the propensity for emulation and the parental bent. They studied particular segments of the economy that especially interested them: agriculture, higher education, and the family, to mention only three. But how about the arts and the market institutions that sustained the arts in a competitive economy? Were the arts really distinct from other segments of the economy? Was pushpin, indeed, different from poetry? What made the arts tick? Rather surprisingly on these questions the Institutionalists had little to say.

In Thorstein Veblen's discussion of the arts in his *Theory of the Leisure Class* ([1899] 1934) there was a move backward to the cynical and dismissive tone often heard in the commercial pamphlets of the seventeenth century. Veblen described works of art from the past as having been intended mainly to demonstrate the wealth and power of the patron, something that had been accomplished most effectively by making art works novel, wasteful, idiosyncratic and expensive. Aesthetic considerations were usually subsidiary or absent. "The canon of beauty requires expression of the generic. The 'novelty' due to the demands of conspicuous waste traverses this canon of beauty, in that it results in making the physiognomy of our objects of taste a congeries of idiosyncrasies; and the idiosyncrasies are, moreover, under the selective surveillance of the canon of expensiveness" [Veblen ([1899] 1934, p. 153)]. He grouped the arts and culture loosely within the large body of wasteful and unproductive activities pursued by those concerned mainly with wealth and power. As in Bentham, the arts were arrayed with games and sport, but now for different reasons. For Veblen pushpin equaled poetry not for Bentham's reason that they were both just items in a consumer's choice set, but because they were both intended mainly to demonstrate someone's conspicuous leisure, past or current. Demonstration of the capacity to waste time on either pushpin or poetry was

what both these activities were all about; neither contributed to improvement of human welfare in any real sense. “Such immaterial evidences of past leisure are quasi-scholarly or quasi-artistic accomplishments and a knowledge of processes and incidents which do not conduce directly to the furtherance of human life” (p. 45). In effect Veblen revived the notion put forth by Bodin and Mandeville that the arts are something with which the idle rich rather than humans in general are mainly involved, and must be, therefore, wasteful and without redeeming social value.

Some of the later writers in the Institutionalist tradition showed more regard for the arts, and they developed the implications of a rejection of the Benthamite calculus for the valuation of art. John Kenneth Galbraith had a lifelong interest in the arts and even wrote a book on *Indian Painting* during his time as ambassador in New Delhi [Galbraith and Randhawa (1968)]. He was much devoted also to “the building of bridges between economics and the arts” but he encountered many obstacles. In the 1960s he inaugurated a seminar at Harvard on the Economics of the Arts [Galbraith (1986, pp. 137, 144)]. He reported that his “artist friends saw it – to the extent that they saw it at all – as a rather philistine performance; nothing could so surely degrade art as an association with economics . . . My fellow economists saw my enterprise as essentially frivolous, possibly even eccentric” (p. 144).

Galbraith’s views on various topics in cultural economics were presented in a chapter entitled “The Market System and the Arts” in his book *Economics and the Public Purpose* (1973). He explained the inattention to the arts among economists as a result of the necessarily anachronistic character of most artistic production. Firms producing art works were operated still by independent entrepreneurs and not by managers bent on the division of labor. Indeed in the large corporations the word “artist” was used as a term of contempt for someone unwilling to submit to discipline. At the same time the inability of most large corporations to make use of the artist constructively was reflected in their typically poor standards of design. “The automobile industry, the mass producers of furniture, the household appliance industry, the container industry and numerous others amply illustrate the point” [Galbraith (1973, p. 63)]. Galbraith focused mainly on how economic aspects of the arts had become different from the norm in the modern economy. For a start, since the arts were typically anathema to the “technostructure” of the large firm, when they were found to have some commercial value they were often hived off into small independent companies. Second, modern art works, even though necessarily the result of creative change, were typically resisted by demanders who had been trained to be very conservative; most modern demanders had been conditioned by their culture to reject artistic change. They came to accept and to celebrate change in due course, but only after a struggle. Galbraith’s contributions to thinking on the economics of the arts never went beyond shrewd observations and provocative speculations of this kind, and he never proposed an agenda for research as did the Bloomsbury Group, discussed next.

## 8. Keynes and the Bloomsbury Group

More than any economist before or since, John Maynard Keynes spent much of his life close to, and at times even embedded within, a community of artists and writers. He experienced the arts first hand. The core of this community was the Bloomsbury Group, but his contacts and interests extended well beyond this collection of close friends. Keynes did not himself make significant contributions to the vigorous and original thinking within Bloomsbury on the place of the arts in society and the economy. But by word, and most importantly by deed, he demonstrated that he was fully aware of and in sympathy with it [Moggridge (2005)]. Why did he himself not take this body of thought and inject it into the economics of his time, where he was such a prominent figure? We can only speculate. It may have been because of his concentration on the more critical issues of the decades in which he lived: international conflict, depression, and the need to construct a new and viable world order. Or it may have been that he inferred the likely lack of receptivity to the Bloomsbury way of thinking within the economics discipline and could not confidently see a road ahead in that direction.

There were at least five topics on which Bloomsbury thinking might be categorized as relevant to cultural economics today:

- (i) the place of the arts in human life, including economic life;
- (ii) the character of the artistic experience, both for artists and for their audience;
- (iii) the use made of the arts by artists and others to shape behavior in society and the economy;
- (iv) the nature of the demand for and supply of art works in art markets; and
- (v) opportunities for experiments with policy change and institutional reform.

### 8.1. *The arts in human life*

The Bloomsburys denied vociferously the view in much of the economics literature to date that artists were simply the producers of superior goods that were consumed only when incomes rose, or that they produced merely luxuries for times when other more important wants had been filled. The Bloomsburys believed the exact opposite, i.e. that everyone in society of any class or economic station could and should be engaged in or at least exposed to the arts. In fact they were persuaded that modern society, being the result of economic progress, was more likely to stultify than to stimulate the artistic impulse in humans. The arts, they insisted, were an essential element and building block in the achievement of true human civilization; the arts were a cause not a condition or consequence of that peculiar and precious set of civilizing circumstances that only liberated humans can produce. Indeed, “the economic possibilities for our grandchildren” toward which Keynes looked ahead wistfully in 1930 consisted necessarily of “the arts of life as well as the activities of purpose” [Keynes ([1930] 1972, p. 332)].

The Bloomsburys were among the first to praise the extraordinary artistic accomplishments of non-western peoples, denying thereby the assertion that the arts could flourish only at high levels of income. One of the first illustrations in the celebrated

book *Civilization* by Roger Fry's friend and disciple Kenneth Clark (1969) is not of a Michelangelo or of a Da Vinci but of an African mask owned by Roger Fry [Goodwin (2005)]. Fry also held two exhibitions of the drawings of children – one of drawings by children of artists and the other of drawings by uninhibited inner-city children – at his Omega Workshops (1913–1919) to demonstrate that before they had extensive exposure to the modern economy the children's capacity for artistic expression was at its peak [Collins (1984, pp. 144–145)].

## 8.2. *The character of the artistic experience*

One of the contributions for which the Bloomsbury Group became best known was a “formalist” theory of aesthetics, expressed originally in Fry's “An Essay in aesthetics” ([1909] 1998) and extended by Clive Bell in his extremely popular book *Art* ([1914] 1947). Fry and Bell claimed from the evidence of introspection that the aesthetic experience was fundamentally different from the satisfaction achieved from consumer goods and services. In effect they insisted upon exceptional status for the arts and set out to explain why. They conceded that the Benthamite utilitarian model might be appropriate for understanding the satisfaction of biological needs of humans and other animals. But, using the term “imagination” to refer to the activity of the human mind as Hume and others had done before, they argued that an understanding of the “imaginative life” required more powerful analytical devices than the felicific calculus. Indeed, many of the Bloomsburys concluded that the simple application of Benthamite principles to the arts had impeded the development of a richer and more truly enlightening body of theory. Keynes made this point in his posthumously-published memoir “My Early Beliefs”. He wrote: “we were amongst the first of our generation, perhaps alone amongst our generation, to escape from the Benthamite tradition”. And he continued: “It can be no part of this memoir for me to try to explain why it was such a big advantage for us to have escaped from the Benthamite tradition. But I do now regard that as the worm which has been gnawing at the insides of modern civilisation and is responsible for its present moral decay” [Keynes (1949, p. 96)].

A few highlights of the efforts of Bloomsbury to move beyond the Benthamite paradigm may be mentioned. The original impetus for inquiry came from an awareness among these artists and writers that their responses to works of art seemed fundamentally different from those experienced during their consumption of food or other conventional goods and services. Roger Fry in a brief autobiographical fragment talked about how on reflection he saw himself “always groping my way towards some kind of a reasoned and practical aesthetic” [Fry ([1920] 1998, p. 87)]. For Fry the groping led first to rejection of the notion of beauty inherent in an artwork. He was inspired by an essay of Leo Tolstoy that portrayed art as the communication of “aesthetic emotion” rather than some sort of production and consumption of a good or service. Fry and Bell went on to speculate that the “form” of an art work rather than the content helped to determine the effectiveness of artistic communication. Some of the Bloomsburys reached out to such pioneer psychologists as Sigmund Freud and Wilfred Trotter to help them

understand the aesthetic experience; others, including Keynes, looked to philosophy and especially to the ethicist G.E. Moore. Regardless of their success in developing a new understanding of the artistic experience, high on the priority list of the Bloomsburys was always a desire to demonstrate the exceptional nature of the arts, a task that had been largely ignored by thinkers in the English-speaking world since the eighteenth century.

### 8.3. *The arts in society*

Most economists by the twentieth century had come to view the arts and culture as merely a rather uninteresting dimension of human consumption, perhaps to be viewed as luxurious and with or without externalities depending on your judgment, but unlikely in any case to have much impact beyond themselves. By contrast the Bloomsburys were fascinated with the ways in which the arts and culture through the course of history had conditioned and helped to interpret society, polity, and economy [Goodwin (2000)]. On this topic the artists, the novelists, and the social scientists in the Group could find common ground. Great works of religious art and literature fascinated them in particular. They were intrigued especially by Old Testament stories such as the accounts in the Book of Genesis of Adam and Eve in the Garden, and of Noah enduring the flood. These art works, they believed, contained hidden but intentional messages that affected human behavior. From the account of the Fall in the Garden readers, or viewers of pictures, could infer that hard labor under difficult agricultural conditions was the inevitable lot of man and was partly at least the result of female miscalculation. From the Noah story, as from Marxian doctrine that the Bloomsburys so much abhorred, readers were intended to conclude that catastrophe – a flood or a revolution – must precede fundamental improvement in the human condition. They were fascinated also by classical mythology that played such a prominent role in English public school education. The myth of Cupid and Psyche strengthened the portrayal of the unreliability and fecklessness of women; by contrast the stories of Pan and of Daphne and Apollo warned of the need to protect the natural environment. The connection between works of art and literature and social and economic affairs was explored by nearly all the Bloomsburys but especially by the artists Duncan Grant, Vanessa Bell and Roger Fry, the novelists Virginia Woolf, E.M. Forster and David Garnett, the biographer Lytton Strachey, and the political theorist Leonard Woolf. In the writings of Keynes there were repeated references to biblical and mythological characters and events. For example, he noted that “the old Adam” in humans keeps them from spending money when expenditures are needed, and the delusion that struck King Midas still causes humans to hoard rather than to circulate gold [see also Skidelsky (1992, p. 425)].

### 8.4. *Art markets*

The Bloomsburys paid close attention to various aspects of the art markets, but they found the conventional models in economics unsatisfactory to explain them. On the supply side they found that price was seldom the most important determinant of supply

– artists were as anxious as anyone for a decent living but for the most part they seemed impelled more by internal psychological pressures than by financial reward to produce their best work. The Bloomsburys came to believe that the main challenge for those concerned about the health of art markets should be to generate sufficient demand of the right kind to sustain the artists. Here again they found that price was not the most powerful independent variable. Roger Fry led the movement within the Bloomsbury Group to examine the demand for the arts in its various components and to probe the psychological circumstances of all the actual or potential providers of support for the arts. Fry and the others identified a number of distinct categories of demander to whom they gave, with their typically irreverent style, names such as “snobbists” (following Thackeray), “Philistines” (following Arnold), “Classicists” and “the herd” (following Trotter) [Goodwin (1998)]. The Veblenian instinct of emulation played an important part in the demand for art, but there were also the church, the monarchy, the landed aristocracy, big business, and an aesthetically-sensitive component of the middle class. In the Bloomsbury decomposition of the demand for works of art and in their attention to the psychological motivations of the various components, it is not hard to see a methodological precursor to the later Keynesian identification of the components of aggregate demand in the *General Theory of Employment Interest and Money* ([1936] 1947). There is even a parallel in the compensating role for the state proposed in both cases; public support should be introduced in the arts or the macro-economy, the Bloomsburys insisted, when private alternatives had been exhausted.

### 8.5. Policy reform

The topic of policy reform was where Keynes’s leadership was so important. Most of the Bloomsburys felt a strong sense of social responsibility – perhaps inherited from their Victorian families – to respond to policy challenges as they saw them and not just to sit on the sidelines and theorize. Roger Fry’s unceasing travels across Britain lecturing to large audiences on art and Virginia Woolf’s commitment to the “Common Reader” were manifestations of their sense of social obligation. They were advocates above all of private sector solutions to problems when these seemed possible.

The Bloomsburys concluded from their extensive personal experience that most artists were ill-equipped by training and emotional make-up to set up or operate firms that could effectively market their products to the complex mix of potential demanders. Accordingly they set out to experiment, often collaboratively, with a range of innovative market devices. The Hogarth Press and the *Nation* magazine, the latter directed by Keynes, were two publishing outlets designed to insulate the writer as much as possible from intrusive business and editorial pressures. The Omega Workshops started by Roger Fry and the London Artists’ Association managed by Keynes attempted to secure a regular minimum income for those artists who were willing to limit their outlets and trade off some sales opportunity for economic security. One of the most interesting private sector experiments (with which Keynes was involved as well) was designed to take account of the role of the critic, a matter about which the Bloomsburys felt strongly. The Con-

temporary Art Society was established in 1909 with Fry and Bell among the founders, to provide seals of approval to living or recently deceased British artists through certification by critical authorities. They hoped thereby to “educate the artistic opinion of the country” and engender confidence in inexperienced buyers of art. CAS members paid annual subscriptions and certain designated experts made purchases with CAS funds or made gifts of the works of artists whom they favored; these works were then exhibited, publicized and passed along on loan to local museums. Like the Book of the Month Club founded a few years later in the United States, the CAS was a pioneering attempt to correct what was perceived to be a unique market failure in art markets. The founders appreciated that it typically took years to establish an artistic reputation and by this time an artist could be impoverished. The CAS would correct an information gap and thereby help to assure support for those artists who deserved to survive.

Education and research in the humanities and the arts were desiderata for the Bloomsburys that they hoped could be accomplished by activities in the public and private sectors. Education in the liberal arts was justified on the ground that it was training for life, just as much so as vocational education. Technical education was justified typically on the ground that it increased the output of goods and services from a given set of resources. In exactly the same way education in the arts and literature was justified for its capacity to enable humans to experience a better life through gaining access to the best in the arts and literature. Research in the arts and literature was predicated on the proposition that there *was* a legitimate distinction between good and bad art and writing, and that good quality could be discerned and explained by trained people after sustained study. Just as education made possible extension of the *breadth* of use of the arts and literature, so research could increase the *depth* of this use. To the extent that enough people with resources perceived the social significance of education and research in the arts and culture, their nurture could be left to the market and private philanthropy. To the extent that the private sector proved inadequate, however, it would be necessary for the government to intervene.

The best-known public sector policy initiative with roots in Bloomsbury was the British Arts Council, established after World War II as a public funding mechanism with Keynes and Kenneth Clark as chairmen [Moggridge (2005); Goodwin (2005)]. By channeling public support for the arts mainly through private sector intermediaries the Council hoped to strengthen public support for the arts but lighten the heavy hand of governmental bureaucracy.

It may not be too much to speculate that if Keynes had successfully introduced the ideas of his Bloomsbury friends on the economics of art and culture to the economics profession, as he did his ideas on macro-economics, the result might have been just as revolutionary. Indeed the two approaches are strikingly similar. Both call for more contact with the discipline of psychology, and with other disciplines too, for explanations of how human actors behave in different market situations. At a time when applied micro-economics was beginning to assert its pervasive explanatory power because of the generality of its models, this call for a return to particularities and the evidence of experience would have been heresy. But the explorations started by this new line of in-

quiry might have been stimulating beyond a narrow focus on the economics of the arts and culture; they might have extended at least to the sub-field of industrial organization where the theory of the firm seemed of limited usefulness in the arts, and to the sub-field of public economics where it might have been conceded that the arts as an area of economic activity had established its exceptional nature and deserved scrutiny beyond conventional considerations of externalities and public goods. The parallels between Keynesian macro-economics and the Bloomsbury intimation of a cultural economics also go beyond economic theory. The richness of the Bloomsbury array of policy experiments in the arts is reminiscent of the recommendations of the young Keynesians as they explored ways to increase and manage aggregate demand.

## 9. Conclusion

By Keynes's death in 1946 attention to the economics of art and culture had not gone far. As this chapter has shown, there had been promising starts on important questions made by eighteenth century Enlightenment thinkers and in the twentieth century by the Bloomsbury Group, but they were not followed up. The development of a distinctive sub-discipline to address this subject was held back initially by suspicions of luxury, vice, and conspicuous consumption and subsequently by claims that all significant questions could be answered satisfactorily by the simple application of the emerging tools of marginalist micro-economics. All the same, numerous issues had been raised that remain before the economics profession still, notably whether positive externalities generated by the consumption of art justify public support. Those who today address either theoretical puzzles in cultural economics, or policy challenges, would do well to begin by reviewing the efforts of those who went before.

## Abstract

Treating markets as arenas where relative advantage is contested, this entry explores the emergence and evolution of Western markets for paintings, 1450–1750, in terms of the players, their creative moves to secure gain, and the rules they devised to maintain order. Primary markets for paintings arose as a derivative of the commission market for one-off, mainly religious paintings in places such as Florence and Bruges, in the second half of the 15th century. Demand from foreign merchants eager to obtain works in the new medium, oil, gave Bruges an edge. So did a demand for easel paintings on thin linen, and even in oil on panel, as cheap substitutes for tapestries. Variety and cost also played a role. Emulation among differently-trained artists generated novel products plus extraordinary cost reductions, and painters discovered a latent demand among the less wealthy. Some novel products were exported, as were new techniques. The retail market in Florence was limited in size and largely confined to serving a need for cheaper versions of unique, public commissions. A mass demand for paintings across the social spectrum occurred principally in Northern cities: e.g., Antwerp, and later Amsterdam, though also in Spain. Resale markets followed retail with a lag, recycled paintings being handled by second-hand clothes dealers. This sequence – commission nexus, cost-reduction and novel sorts of paintings, mass retail, then resale markets – occurred in cities across Europe. As mass markets emerged, so too did specialist dealers. A large part of the entry is devoted to detailing their creative marketing moves. There were tensions as to whether only artists might sell, but demand mostly overrode guild reluctance to relinquish control of distribution. Widespread distribution came to require efficient sales mechanisms, hence public sales and auctions. The entry explores auction rules and techniques within the broader sequence identified above.

## 1. Approach, focus and scope

Competition is a notion linked to a particular sort of market structure and its associated set of equilibrium properties; in the practical realm, however, competition is very clearly a creative struggle for advantage. Focusing on the latter, as we will, it makes sense to think of markets as arenas within which various players engage flexibly in experimental strategizing for relative gain.<sup>1</sup> Historically, at an early stage, regulations or rules tend to be put in place to govern such competitive struggles. Those rules, along with certain structures – avenues for seeking the redress of grievances, for example – constitute institutions which, together with the creative strategies adopted by the players, come to define the structure of a market and the way markets function.<sup>2</sup> The gaming analogy implied in talk of players and rules derives its force from the fact that games too have a structure, and typically it is one that allows for probing, rule-challenging and rule-modifying plays.<sup>3</sup> Our history of art markets will be guided analytically by the categories roles, rules and creative plays, though we will also try to maintain a sense of chronology.

Some disclaimers about our scope are in order. Though certain mechanisms of art markets have quite ancient and non-Western origins – auctions, for example – we will confine ourselves to the emergence of such markets in Europe during the Renaissance and Early Modern period, roughly 1450 to 1750. As to regional concentration, the Low Countries have been the focus of much of the available research; as to terminal date, all the main innovatory elements we now know as standard were in place by about 1750. Finally, most research deals with paintings, and we will follow the available research.

Research on the history of art markets depends heavily on surviving guild records, inventory studies and legal documents. Survival being a matter of historical accident, the record is patchy. Our overview, unavoidably, will reflect this, and will thus be both episodic and somewhat disjointed. A nine-point synthesis is provided in a coda (Section 6) that may usefully be read in advance.

Prices have not been adjusted for inflation but have been expressed in terms of Florentine gold Florins, a money of account. Conversions are indicated in-text and in notes.

<sup>1</sup> De Marchi and Van Miegroet (1994, p. 452).

<sup>2</sup> Rules and structures may be informal and depend for their effectiveness on mechanisms such as loss of reputation or the ostracizing of offenders. As Grief and others have shown [Grief (1993); Grief, Milgrom and Weingast (1994)], such forms of self-regulation can work even in the absence of an official legal basis.

<sup>3</sup> Our conception of markets derives in part from North (1990), and is in part inspired by Grief's work. For illustrations of our conception at work see De Marchi and Van Miegroet (2000b).

## 2. Early local art markets, primary and resale

### 2.1. *Forms of exchange*

Makers and buyers meet in exchange relationships, which take various forms: commission exchange and gift exchange are at one end of a spectrum, market forms at the other. Both commission and gift exchange involve a more or less unique product, and contact is between one buyer and one seller, often direct, or mediated at just one remove by an agent. Valuation is involved in both these forms, but in neither is the primary motivation of a purchase asset value – the painting as potentially re-saleable, for gain. Power, decorum, honor and display were important within gift exchange and these criteria were culturally rather than market-determined.<sup>4</sup> Artistic and functional (mainly religious) value entered significantly into commission exchange, along with reputation (on both sides: purchasers and artists). Prevailing norms also affected the value of artists' services. Yet there was room in these parameters for negotiation and for individuating the terms of an exchange. Thus, historically, in the Central Italian commission nexus of the 15th century, prices fixed in advance were rare; more usually a range, or a maximum, or a minimum, was specified. Price – and implicitly the artist's reward – would then be determined as part of an assessment of the end product, the estimation usually being done by a committee assembled for the purpose. Both commission and gift exchange were practiced within certain strata and segments of society in our period; here, however, we can do little more than acknowledge that fact and use these forms as a foil.<sup>5</sup>

In contrast to both commission and gift exchange, market exchange – our principal concern – involves buyers and sellers who are relatively numerous; moreover, valuation takes place via bids and offers for products that, while they may be somewhat unique, are also regarded as reproducible.<sup>6</sup> Markets may be primary (first sale) or secondary (resale), and transactions in both may be primarily retail or mixed retail/wholesale, but the basic distinction is between primary and resale. Historically, primary markets involved artists doubling as dealers – in their own and other artists' products – long before specialist, professional dealers emerged. We find the first substantive European evidence for primary markets and the retailing of paintings in 15th-century Florence and Bruges. Resale markets, temporally, followed primary markets with a lag of fifty years or more. The clearest evidence concerning the auctions that served resale markets pertains to early 17th-century Amsterdam, late 17th-century London, and to Paris in the first half

<sup>4</sup> For the values implicit in gift exchange see Welch (2003) and references there cited.

<sup>5</sup> Commission exchange is best approached through the study of contracts, for which the basic source is Glasser (1977); see O'Malley (2005) for a valuable study of altarpiece contracts and their prices in 15th- and 16th-century Central and Northern Italy. Details on commission contracts for the Netherlands in the same centuries, especially the 15th, are scarce.

<sup>6</sup> This implies recognizing, as was the case, (a) that techniques for copying were part of best workshop practice, (b) that copies were accepted – even asked for – by the best collectors, and (c) that prints were a widespread form in which imagery was enjoyed, and not only at the low end of the market.

of the 18th century. But their earliest manifestations were in the form of estate sales and forced – court-ordered, and bankruptcy – sales. Those who traded in these early resale markets were dealers in second-hand goods, initially used clothes. Specialist dealers in paintings in the resale or secondary market followed, but for a long time appear to have shared the trade

- (1) with artists, who frequently dealt in paintings on the side and indeed were often the only people allowed by the guild to market paintings;
- (2) with agents who served as intermediaries and advisers to those who did not want to get personally involved in finding paintings or haggling over price; and
- (3) with street dealers in new and old paintings, stallholders at fairs, and with shopkeepers.

For the latter, more often than not, paintings were just one line within a broader range of merchandise.

The sequence just sketched applies across Western Europe, north and south of the Alps, though much of the creativity that interests us was expressed, as we would expect, with significant local differences. Indeed, as secondary markets join primary sales, it is the ingenuity of specialist dealers and auctioneers, or dealer-auctioneers, bent on expanding or maintaining markets, who supply much of the fascination. In some cities the primary art market always had a sizeable import component; other cities tended to be, or to become over time, net exporters of paintings. This difference is apparent from the information assembled in [Appendix A](#). Dealers in net-importer cities – pragmatically, those with ratios equal to or less than one – tended to function primarily as intermediaries and arbitragers across space. Dealers in net-exporter cities, on the other hand, often had to devise strategies to secure market share in other places, near and far, in order to sustain a production capability in paintings at home following a slowdown in the growth of local demand. Antwerp and Mechelen/Malines are prime examples.

We shall begin with the primary market first observable in Florence, probably a net-importer city, in the second half of the 15th century. The early phase of a secondary market – when second-hand dealers dominated – can also be observed there, from around the turn of the 16th century. This experience will then be contrasted with that of contemporary Bruges, the pre-eminent *entrepôt* of the western world, and a net exporter of paintings. Thereafter we will introduce local developments, in roughly chronological sequence, as noted, though emphasizing creative dealing, and related behaviors which inject intriguing variants into the general sequence sketched above.

## 2.2. The primary market in 15th-century Florence

Florence was perhaps the single most prolific center of the new painting, and of ideas concerning painting, that we associate with the Renaissance. Much of the work that has survived and is widely admired was commissioned: for churches and their chapels, or for religious orders, or for charity hospitals, guilds, and civic buildings. Some was intended for distinguished private houses (*palazzi*). In many instances involving a public commission, a competition was conducted, and a selection made from among mod-

els, fashioned according to published guidelines and submitted for consideration. The guidelines, however, did not preclude artistic ingenuity; indeed, it was favored. This made each commission unique, even if there was a certain formalization of modes of representation and an expanding number of well-rehearsed subjects. Uniqueness, or discreteness of design, meant that demand was discontinuous. Moreover, though in the course of the 15th century the Medici family acquired more and more power, Florence remained a republic; there was no Ducal Court.<sup>7</sup> For this reason and because commissioning bodies were many, with a variety of goals, there was no “single dominating authority” around which taste might coalesce.<sup>8</sup>

The resulting fragmentation of, and discontinuity in, demand was accentuated by artists themselves: their very competitiveness conditioned buyers to expect ever more ingenuity.<sup>9</sup> Within the commission circuit, therefore, competition was confined to the artistic; it could not express itself in cost-saving innovations in the way production was organized. Yet, as the surviving business records of the Florentine painter Neri di Bicci illustrate, a retail market existed in ready-made and made-to-order altarpieces, painted wooden tabernacles (containing one or more devotional scenes or images) and painted devotional forms in gesso and terra cotta relief. Often these were based on works produced within the commission nexus, though Neri di Bicci’s altarpieces were also recognizably his own.

As we would expect, the average price of the “derivatives” made in this market was below that of commissioned works or those chosen for a private collection. Table 1 shows this to have been the case. Neri di Bicci’s clientele ranged from barbers to patricians; the largest segment (40 percent), however, were middling sorts of persons: artisans and politically successful members of the lesser guilds, or members of lower-status patrician families.<sup>10</sup> Such clients could limit their outlay by opting for smaller variants of standard items and restricting the number of figures, though without forgoing ornamentation such as richly carved surrounds, the use of gold and silver leaf, gold filament for the detailing of fabric, etc.<sup>11</sup> In these ways Neri di Bicci managed to supply devotional imagery inspired by the publicly-displayed creations of artists in the commission circuit, and sharing some of their artistic values, yet suited to lower budgets. And he was successful at this: a wealth tax assessment of 1480 placed him ahead of all other painters in Florence.<sup>12</sup> Moreover, he was included in a listing of 1470 by Benedetto Dei of artists who maintained a workshop in Florence, along with some famous names.<sup>13</sup> It

<sup>7</sup> This changed in the 1530s, when the ruling member of the Medici declared himself a Duke.

<sup>5</sup>All prices in Florentine florins.

is worth noting that original paintings in Amsterdam inventories, 1620–1660, averaged about 2.2 florin-equivalents, below Neri di Bicci's minimum prices.<sup>14</sup>

Neri di Bicci shared two difficulties with artists in the commission circuit: the difficulty of maintaining a workshop between sales, and the need to advertise.<sup>15</sup> Unlike those artists, however, he was able to organize his business so as to reap the cost savings associated with repetition: he sub-contracted for bulk orders of standardized gesso and terra cotta reliefs, and for similarly standardized wooden tabernacles.<sup>16</sup> He differed from those in the commission circuit also in that his margins, generally, were quite low – Kubersky-Piredda estimates 10–15 percent of the price, to cover his fee as well as minor materials and food costs. This was significantly less than the margins paid painters of superior ingenuity and skill, such as Sandro Botticelli who, late in the century, could earn 35–45 percent of the total cost of commissioned altarpieces.<sup>17</sup>

<sup>14</sup> Montias (2002a, p. 118). The estimated average price in Holland was about 13 guilders (of 20 stuivers). The guilder of 20 stuivers had been equivalent to the gold Carolusguilder when the latter was first issued in 1521, and the Carolusguilder was equivalent to 0.7 of a Rhineguilder, which in turn was equivalent to 0.75 of the Florentine gold florin. The Carolusguilder disappeared from circulation in the course of the 16th century; but, based on gold content, the original guilder of 20 stuivers had slipped to the equivalent of just 0.17 of a gold florin by the 1620s. In terms of equivalences in 1521, the following relationships had held: 1 guilder (20 stuivers) = 1 Carolusguilder = 0.7 of a Rhineguilder = 0.75 of a gold florin; so that 2 guilders (of 20 stuivers)  $\approx$  1 florin. Because of debasement, however, in the 1620s it would have taken roughly 5.9 guilders of 20 stuivers to purchase 1 gold florin. Silver guilders were of much lower value. See De Vries and Van der Woude (1997, pp. 80–81, and graph on p. 85).

<sup>15</sup> See Wright (2003, pp. 225–236) on the goldsmith-artist Antonio Pollaiuolo and his marketing devices. Thomas (1995, pp. 88–93), discusses variations in di Bicci's workshop size, and Matthew (2006), in De Marchi and Van Miegroet (Eds.) (2006), notes Neri di Bicci's promotional pricing of portraits.

<sup>16</sup> Kubersky-Piredda (2003, p. 116).

<sup>17</sup> Blume (2003, pp. 152–153). Two observations only. Data are scarce, so these figures may or may not be representative.

We possess only anecdotal evidence of dealers in the primary market in Florence. Kubersky-Piredda supplies information on three such dealers in the period 1450–1500. Two of the three purchased from Neri di Bicci, but for each, paintings were merely a side line. Their primary business lay elsewhere: in banking, haberdashery, and jewelry, precious stones and other high value-added objects.<sup>18</sup> Specialized dealing, as noted, is first observed in the trade in second-hand goods.

### 2.3. Florentine estate sales: Early specialization among second-hand dealers

Regular estate sales were common in most cities in Europe and they were dominated by second-hand dealers, corporations of which date from the late 13th century. In most places these dealers were given a name that reflected their main line, old clothes and cloth goods in general, in various states of disrepair, often just rags: hence *stracciaroli* or *strazzaroli* in Venice, *rigattieri* more generally across Italy; *oudecleerkopers* (second-hand clothes dealers) in the Netherlands; *fripriers* in France; rag and bone men in England. Sometimes more generic designations were used, for instance, to indicate that one of their principal roles was to clear out the house of a deceased person (hence *uitdraagsters* in the Dutch Republic), or to repair household goods preparatory to recycling them (hence “upholders” in England).

In Florence, in the last decades of the 15th century, signs of specialization begin to appear in the meticulous records kept there of the public auctions of estates. Records of the sales include the names and bids of all bidders for each lot, including of course but not limited to the winning bid. In principle, therefore, we are able to identify concentrations of types of bidder for particular sorts of goods. By late in the century lots at estate sales were being organized so as to separate cloth goods from other household movables (e.g., furnishings, including paintings), suggesting that a specialization of sorts had already begun among the *rigattieri*. The 1479 inventory of a *rigattiero* contained only artworks and furniture, while an auction of 1498 listed a lot comprising 26 works of art, including paintings, and the winning bidder was from a family of known second-hand dealers.<sup>19</sup> With a lot of 26 objects, we should add, a sale almost qualifies as part of a wholesale market.

The distinction in Florence within the ranks of the second-hand dealers became sharper with time, and presumably was mirrored elsewhere, though a terminological distinction to match the situation on the ground seems to have been rare.<sup>20</sup> In any case,

<sup>18</sup> Kubersky-Piredda (2003, p. 117).

<sup>19</sup> See Lydecker (1987, pp. 214–216).

<sup>20</sup> In Spain, France, England and the Netherlands (north and south) no distinct terminological acknowledgement was made of the specialization among second-hand dealers. Nor was there any in Rome; while even in Naples, far from the specialization being named, it was not even accepted: *li mastri della Giudeca* were confined, late in the 17th century, to dealing in clothes and *not* allowed to deal in other household goods [Allerston (2003, p. 311, n. 57), citing information supplied by Christopher Marshall].

as far as we know, nothing comparable occurred in Bruges.<sup>21</sup> It was not until 1588, and then in Antwerp, that we find two men registered in the painters' guild – officially required of those wishing to deal – but as “second-hand clothes dealer, also trading in paintings” (*oudecleercoper ende handelt met schilderijen*).<sup>22</sup> By the middle of the 16th century the recycling market in Florence had developed to the point where the city designated a sales venue in the city center, opened a warehouse to store goods pending their sale, hired estimators to value each lot (which estimates became the starting point for bids), and ordained that any citizen might hold sales – not only estate sales – using the facilities.<sup>23</sup>

#### 2.4. *The primary market in 15th-century Bruges: Scale; foreign demand; artistic emulation*

In the fourteenth century Bruges was the most important trading center in Western Europe, and the second-largest city (after Ghent) north of Paris, with a population of some 46,000. It was surrounded by textile-producing towns, but never itself became an industrial city. Its strength was trade – *entrepôt* trade – and the city developed sophisticated institutions to maintain its pre-eminence in that sphere: space for displaying the textiles immediately preceding its May fair; inspection arrangements and quality guarantees; and a system of licensed brokers, through whom deals outside fairs were to be closed. Innkeepers, many of whom also hired brokers to close deals, supplied storage and provided financial services.<sup>24</sup> These institutional arrangements were strictly supervised for the most part, brokerage fees, and tolls, being important sources of income to the city.<sup>25</sup> The same predilection for oversight, order and control was also reflected in guild regulations, and in the strict boundaries between crafts. The city's painters fell under the same restrictions as other crafts though, as will be seen, the magistrates could also wink at breaches of guild regulations when the city's trade was at stake. By the mid-15th-century Bruges' population had fallen to about 40,000, and in the next five decades the city's economic prospects were damaged by serious, continued silting of its access river and, after 1582, by political differences with the claimant to the privileges exercised by successive Burgundian dukes, the future Holy Roman Emperor Maximilian I. The dispute resulted in the decamping to Antwerp – at first temporary, but later permanent

<sup>21</sup> We know of no documentary indications of specialization or re-naming among the *uitdraagsters* in the Dutch Republic even in the 17th century, though we know a good deal about individuals and their participation in sales involving paintings from Montias' study of Amsterdam Orphan Chamber Auctions, 1597–1638 [Montias (2002b)]. By the mid-17th century the Friday (estate) Market in Antwerp had become a place to acquire old paintings, many of them not cheap. But at that time it was frequented for the purpose by knowing, specialist dealers, and their agents, not just old clothes dealers.

<sup>22</sup> See Vermeylen (2003, note 37, p. 132).

<sup>23</sup> Lydecker (1987, p. 217).

<sup>24</sup> See Murray (2000), Stabel (2000) and Greve (2000), all in Stabel, Blondé and Greve (Eds.) (2000).

<sup>25</sup> Nicholas (1992, pp. 204, 296).

Figure 1. Numbers of newly apprenticed cloth and panel painters, Bruges, 1456–1500. Note: Our source excludes masters’ sons. Our numbers therefore differ from some other counts, but omitting masters’ sons captures more accurately the incentives in play. Source: [Vanden Houte \(1913\)](#).

– of the foreign “nations” (resident foreign merchant communities). Painters fared better than many crafts during the decades of decline, partly because they were able to generate new demand at the low end of the retail market.

That demand can be inferred from the numbers of new master painters registering during the second half of the 15th century; and even more clearly from the numbers of new apprentice painters. As [Figure 1](#) shows, in some years the number of new apprentice painters exceeded twenty. No comparable record exists for Florence. By way of crude comparison, however, the total number of painters with a workshop in Florence in 1470, according to Dei’s list, was under 30. That estimate roughly accords with a separate list of “figure painters” in the Company of St. Luke, a confraternity of painters, in 1472.<sup>26</sup>

One factor clouding the numbers for Florence is that artisans there could move freely between crafts without acquiring official membership in any guild but that of their original training. Andrea del Verrocchio, for example, having failed as a goldsmith, moved successfully into painting (as well as carving and casting). Antonio Pollaiuolo, on the other hand, who also trained as a goldsmith, maintained a successful goldsmithing workshop whilst freely collaborating with his brother on painting projects.<sup>27</sup> Lower recorded numbers of painters registered as such in Florence may thus understate the true supply of artists’ services.<sup>28</sup> Both Verocchio and Pollaiuolo, however, made it onto

<sup>26</sup> [Wackernagel \(1981, p. 300\)](#). Wackernagel notes that 42 were listed as members adding, however, that some were not painters at all, while others were engaged in related crafts such as gold leaf production. Dei’s own list included several painters already deceased.

<sup>27</sup> [Wright \(2003, pp. 227–228\)](#).

<sup>28</sup> It also disadvantages Florence to count only figurative painters there; the Bruges lists are more inclusive.

Dei's list, suggesting that he was a knowing observer. In any case, there are strong indications that painters in Florence faced less favorable conditions than artists in Bruges. They found themselves having to advertise, as noted earlier. Moreover, many of them moved to other cities in pursuit of work.<sup>29</sup> By contrast, in Bruges, between 1466 and 1496, almost one-third of new masters in the image makers' guild, to which painters belonged, were immigrants.<sup>30</sup> Since new painters accounted for more than two-thirds of all new master image makers in this period, it seems safe to assume that there was also substantial net immigration of painters.

There is also evidence of a quite different sort that distinguished Bruges from Florence. Demand in Bruges included a component contributed by foreign merchants. And in that respect Bruges reaped collateral benefits that Florence lacked. An annual international fair, plus resident foreign "nations", meant a whole infrastructure of institutional arrangements to facilitate exchanges.<sup>31</sup> These, as noted earlier, were the city authorities' conscious contribution towards maintaining Bruges' pre-eminence as a trading center. Textiles predominated but the two-way exchanges of goods in Bruges differed according to the offerings and needs of participants, and the merchants present included Catalans, Castilians, Portuguese, Lucchese, Milanese, Genovese, Florentines, representatives of the Hanseatic towns, French, English and Scottish. It is thought that foreign merchants and their assistants might have numbered 1000 outside the period of the May fair in Bruges, and perhaps double that during the fair – or roughly one in ten heads of households there.<sup>32</sup> Florence, by contrast, sent bankers and merchants abroad, but there was no established mechanism or tradition of foreign merchants visiting or congregating in Florence, much less staying there for extended periods. Florence, paradoxically, was a city of home-grown merchants, yet not the host of an international market. Or, as Goldthwaite puts it, "the Florentine marketplace ... for all the city's position in international banking and commerce, had only a regional scope".<sup>33</sup>

Nor was the contribution of visiting and resident foreign merchants to Bruges limited to their numerical strength; on average, they had greater buying power than the local population.<sup>34</sup> Moreover, the wealth-elasticity of demand for art among them may

<sup>29</sup> Goldthwaite (1982, p. 420). Goldthwaite notes that in provincial Verona they even outnumbered locals.

<sup>30</sup> Blockmans (1996, p. 20).

<sup>31</sup> Goldthwaite (2003, p. 432). Stabel (2006) notes that the paintings market in Bruges could draw on a whole history of such infrastructural elements as part of the city's longstanding contribution to exchange.

<sup>32</sup> Blockmans (1995, p. 15), and Stabel (2001, p. 191). A moneychanger's records for 1366–1368 contain the names of 990 foreign merchants: Murray (2000, p. 7).

<sup>33</sup> Goldthwaite (2003, p. 432).

<sup>34</sup> Direct evidence of this for Bruges is lacking – though see Nicholas (1992, p. 296) – but it is a fair inference from what is known of the Amsterdam merchant population, which in the early 17th century included a significant proportion of immigrants from the Southern (Spanish) Netherlands. Montias has shown, from inventories, that "virtually all" the paintings valued at 10 gulden (1.7 florins) or more were owned by individuals who paid a minimum of 5 guilders in tax (0.8 florins) in a 1631 wealth assessment in Amsterdam. "The bulk of this demand [moreover] originated with merchants, along with a few brewers, sugar refiners, and other small-scale 'makers of goods'. They are the people who paid 50 gulden [c. 8.5 florins] or more in

well have exceeded 1.0. The available estimates of the wealth elasticity of art are for 17th-century Holland; there, most paintings were purchased by merchants, and several separate data sets put the elasticity above unity.<sup>35</sup> Though we lack such estimates for Bruges, an illustration of the significance of merchant demand is to be found in the case of Hans Memling, a German-born artist who settled in Bruges. The socio-economic status of the buyers of almost half of the works attributed to Memling is known; over 60 percent of them were foreign merchants.<sup>36</sup> But if local demand in Bruges was supplemented importantly by the demand of foreign merchants, things were the other way around in Florence. There, the merchant/bankers *imported* paintings made in Flanders on commission or obtained at the annual fairs. Inventories of the Medici family in the 15th century show that close to one-third of the 142 paintings registered in the 1492 inventory of Lorenzo the Magnificent were imports from Flanders, or Antwerp in the neighboring Duchy of Brabant.<sup>37</sup>

There is yet another factor that distinguished conditions in Bruges: competition among different sorts of specialist painters. We have mentioned artistic emulation among artists vying for success in competitive commissions in Florence. The competition in Bruges was different, and had a quite different impact on the primary market for paintings there. Three distinct crafts of painting were recognized in Bruges. The image makers' guild included two of them; there were painters in oil on wood panels and painters using pigment mixed with rabbit skin glue – a mixture called “watercolor” – on thin linen. These were the *clederschrijvers*, or *cleerschrijvers* (literally, “writers” on cloth/clothing). The third group was the illuminators or miniaturists, who had been shunted off into the *librariers'* guild. The number of the illuminators is not known, but as an artistic force they were significant; no less a painter than Jan van Eyck was trained as an illuminator, though that is not the kind of influence we have in mind here. The three crafts competed for market share, and the competition was by product type as well as by price. Moreover, for all that the groups maintained a separate identity, their engagements with each other as competitors issued in mutual borrowings and adaptations of each other's subject matter, techniques, formats and supports. The result was increased variety, including many items not seen before, and products available at every level of price. Again, to judge from the numbers of apprentices taken on by *cleerschrijvers* and panel painters in the image makers' guild – a whopping 242 between 1456

taxes, the top quarter of the distribution of taxpayers” [Montias (2002a, p. 117)]. Gelderblom (2000, p. 227), has shown further that of the 477 taxpayers assessed 100 guilders (c. 17 florins) or more in the 1631 assessment, 56 percent were merchants, more than two-fifths of them of southern origin. Montias' conclusions give substance to the shape of the tax “pyramid” in Amsterdam: see Figure 2.

<sup>35</sup> Montias estimated 1.23 in a study based on Delft inventories: (1982, p. 265); 1.37 for “works of art” sold at auction in Amsterdam, 1598–1638: (1996, pp. 75–76); and 1.46 from a random sample of Amsterdam inventories (1620–1660): (2002b, p. 34, table). No comparable studies exist for Bruges, or Antwerp, both because surviving inventories do not contain valuations and because no wealth tax assessments were conducted in either city for “normal” years.

<sup>36</sup> Blockmans (1996, pp. 23–24), citing the work of Maximiliaan Martens.

<sup>37</sup> Nuttall (2004, p. 106).

and 1490 – the changes must have elicited fresh demand.<sup>38</sup> Thus we may think of the foreign merchants as adding to final demand for a given range of products, while competition between the three groups of painters issued in novel products, which in turn also spawned new demand.

The differences in technique and end-product between the three sorts of painter in Bruges were so clear – each craft of painting occupying its own market segment – that the three ought to have been able to co-exist peacefully. Thus, by tradition the miniaturists' business was manuscript illumination; they decorated texts, but did not intrude on the making of easel paintings or hangings. The cloth painters' medium enabled large surfaces to be covered easily and quickly. They painted on thin linen, readily available in Flanders, and sometimes even known as *draps de Bruges*. And, since their material support was cheap, and relatively little labor time was involved in this sort of painting, cloth painters, for the most part, occupied a distinct segment of the market for easel paintings and hangings: banners, flags, temporary decorations, for example. But not all their products were fleeting or inexpensive. They also made the cartoons for tapestries and some of their larger, narrative scenes were bought as tapestry substitutes. Those could be costly: one such cloth painting owned by the Medici was valued at 10 florins, and another at 25. Nonetheless, oil painting on panel was the preferred technique for altarpieces, portraits, and devotional paintings of superior artistic pretensions. That technique called for layers of pigment interspersed with multiple lightly-tinted glazes. The work was tedious and time to dry long, and the labor-cost therefore relatively high. At the same time the contrasts, depth, shading and intensity achieved with oil were greater, giving a satisfying impression of richness to warrant, and match, a higher price.

Despite these traditional, technical distinctions, two changes in Bruges in the second half of the 15th century created strains. Of the 242 new apprentice painters between 1456 and 1490, 134, or 55 percent, were aspiring cloth painters, reversing a slight balance in favor of the panel painters at the start of that period. The second was that the illuminators began to make and sell single-leaf miniature paintings. Detached miniatures were new, and might have seemed an intrusion on the product space of the cloth and panel painters. The growth of apprentices among the cloth painters, meanwhile, must have made the panel painters uneasy.

Both developments at first produced blocking moves by the oil painters. They charged the illuminators in 1457 with importing detached miniatures. Probably this was mistaken – the miniaturists replied that they actually *exported*, and on a daily basis – though that would hardly have calmed fears of displacement among the panel painters.<sup>39</sup> Then, in 1459, the panel painters alleged of two cloth painters that they were displaying panels in oil, which was not permitted them, though nor might they display *any* paintings for

<sup>38</sup> Compare this with just 14 new inscriptions in the Company of St. Luke in Florence, 1492–1502, at the height of artistic activity in that city: Wackernagel (1981, p. 300, n.1).

<sup>39</sup> Campbell (1976, p. 190) records this incident.

sale, even of their own craft.<sup>40</sup> Initially the oil painters won support from the magistrates against the cloth painters, but in 1463 the magistrates reversed their own ruling, affirming that the cloth painters might display and sell in the open, “as they are used to doing”, on and near the St. John’s bridge, where ships tied up and unloaded, a step from the toll-house and close to the foreign “embassies” and the Exchange (*beurs*).<sup>41</sup>

These episodes involving the cloth painters, and the magistrates’ 1463 decision, tell us two things. Firstly, that the cloth painters were attempting actively to interest foreign captains and merchants in their wares; they were not content simply to hope that the foreigners would visit their workshops, as the regulations assumed. Secondly, the resulting deals must have grown to the point where to suppress open display might have harmed the city’s revenues from brokerage.<sup>42</sup> This is inference on our part, but something like that must have moved the magistrates. It is not known how large the traffic in cloth paintings was, but 17th-century records of Antwerp dealers show them purchasing cloth paintings made in nearby Mechelen by the hundreds and shipping them abroad on the same scale.<sup>43</sup> In this context it is probably significant, too, that, whereas the Medici in the 15th century had only four Flemish panels among their household movables, they had 38 cloth paintings of Flemish origin.<sup>44</sup> In the years 1461–1470, in Bruges, no fewer than 40 new apprentices attached themselves to cloth painters, while only 25 joined workshops of panel painters, a startling shift. Perhaps the magistrates detected early signs of this and went along with it, in the greater interest of the city.

Was price a factor in the improving fortunes of the illuminators and cloth painters? Undoubtedly. The average valuation of the Medici cloth paintings was a mere 3.38 florins, whereas that of their four Flemish panels was 23.5 florins. Again, Antwerp dealers in the 17th century paid around 1.6 guilders on average for cloth paintings, the equivalent of about 0.3 florins.<sup>45</sup> Interestingly, the price was about the same for 1 as for 100. For further comparison, a small sample of Flemish altarpieces commissioned by Italian buyers in the second half of the 15th century, averaged 23 to 42 florins per square meter.<sup>46</sup> Michelle O’Malley’s database of prices for Central Italian altarpieces generates a comparable range, though it also reveals that there were fewer altarpieces commissioned at higher prices. That relationship is not a demand curve, since each altarpiece was unique, but it is a price-sensitivity curve of form similar to a demand curve. Cloth paintings, in any case, clearly were very much cheaper, on average, than high quality panel paintings. The same must have been true with respect to the illuminators’ single-leaf miniatures. Matthijs Musson, one of the 17th-century Antwerp dealers

<sup>40</sup> *Ibid.*; and transcript of 1459 proceedings, kindly supplied by Peter Stabel.

<sup>41</sup> Martens (1998, p. 21).

<sup>42</sup> Unlicensed brokers were not unknown, but there is no hint that the cloth painters were actually closing deals themselves, to evade brokerage.

<sup>43</sup> See, for example, Duverger (1969, pp. 83 and 96) for purchases and a shipment by the dealer Musson.

<sup>44</sup> Nuttall (2004, Appendix 1).

<sup>45</sup> See Denucé (1931, pp. 28, 34, 63, 64, 73, 284, 289) for the dealer Forchondt; and Duverger (1969, pp. 83, 95, 96, 98, 102, 103) for the dealer Musson.

<sup>46</sup> De Marchi and Van Miegroet (2003).

just alluded to, obtained paintings on parchment for 0.04 guilders each, the equivalent of just 0.007 of a florin apiece.<sup>47</sup> If we were to translate the information just given for cloth paintings in Antwerp and for panels/altarpieces in 15th-century Florence and Bruges into price-quantity space they would reveal a horizontal demand curve for cloth paintings with a very low price intercept (in fact a narrow range, centered on 0.3 florin-equivalents), and a distinct price-sensitivity line covering a much higher price range. And were we to use the cheapest Medici panel (4 florins) as the low point of that price-sensitivity line, it would *start* at a point 13.3 times higher than the price intercept of demand for cloth paintings.

Such price differences had always been present. What really was new was competition in terms of products, supports, sizes, subjects and technique at the low end of the market. Here are a few instances. The illuminators, as noted, began selling single-leaf miniatures, painted on sheets of parchment or paper – a shift towards easel painting but still using their traditional skills in manuscript illumination. And they began making pocket-size portraits – as small as 6 × 9 cm. The panel painters responded to the latter by miniaturizing their own oil portraits on panel. Meanwhile, the panel painters freely imported the naturalistic landscape elements of illuminated Books of Hours, into their own narrative religious scenes. Cloth painters, for their part, began to create substitute panel paintings, attaching cloth to cheap panels. Some panel painters – Van Eyck, for example – also experimented with seccatives in their oil medium to shorten drying time; others, Memling among them, further reduced time to completion through a more economic use of paint: fewer paint layers, less glazing and an increased deployment of lead white for highlights to create surface effects.<sup>48</sup> Cloth painters, as noted, had long been responsible for making the cartoons for tapestries. In the case of the horizontal (*basse lisse*) looms commonly used in Flanders, the cartoons could be laid under the warp threads and the pattern directly transferred into the woven textile; but drawings for such cartoons could also be used to make series of painted substitute tapestries on linen. The substitute tapestry was a new product for the cloth painters, but techniques for transferring designs or motifs were employed by all three sorts of painter, saving costs for everyone, and benefiting the buyer, whichever kind of work was fancied. Many of these innovations could also be realized, at still lower cost, in the form of printed sheets, the technology for which was available in Bruges (and Venice) from mid-century, and was intensively applied in Antwerp in the sixteenth century.

These product innovations and cross-craft adaptations generated in Bruges an array of imagery not previously available and – importantly – affordable by those in the lowest income groups. The three sorts of painters found themselves, whether by intention or merely to retain or increase market share, tapping into a previously latent demand. This new market was distinct from the commission nexus: prices were much lower, but for the most part the products were not artistically derivative in the same way as were those

<sup>47</sup> Duverger (1969, p. 99, folio 14).

<sup>48</sup> Galassi (1997, p. 346).

of di Bicci in Florence. The former division between expensive, commissioned, panel paintings and cheaper cloth paintings of course remained, and cost-conscious buyers such as the Medici continued to purchase both sorts. At the same time, developments in Bruges marked the beginning of what would soon become a widespread habit: owning and displaying pictures of relatively low value, in considerable numbers, even in modest dwellings. This spread throughout the Low Countries, and in lesser degree elsewhere.

With the beginning of selling to the masses, new mechanisms for display and sale were called for. Before turning to some of them, however, it is worth dwelling for a moment on differences between Florence and one of the 17th-century northern seats of mass production and widespread ownership of paintings, Amsterdam.

### 2.5. *Wealth, and the ownership of paintings: Florence versus Amsterdam*

There was a comprehensive wealth assessment for tax purposes in Florence in 1427, and one in Amsterdam, in 1631; both imposed a tax rate of 0.5 percent. Unfortunately, no similarly comprehensive assessment exists for a contemporary Flemish city. For our purposes, however, a Florence–Amsterdam comparison serves. After converting the wealth and tax classes in Amsterdam from guilders into florin-equivalents, we obtain Figure 2. We adopt four tax ranges: class IV: <5 florins (<29 guilders); class III: 5–7.5 florins (29–44 guilders); class II: 7.5–50 florins (44–295 guilders); and class I: 50–580 florins (295–3422 guilders). In all 4110 persons were taxed in Amsterdam, and 6745 in Florence. Since the population ratio was c. 115,000 to 37,144, or 3 : 1, in favor of Amsterdam, it is clear that the tax base was much narrower there. The proportion of Amsterdam taxpayers in the highest three wealth categories, however, was greater than in Florence – 52 versus 24 percent – as were the absolute numbers: 2128 persons in Am-

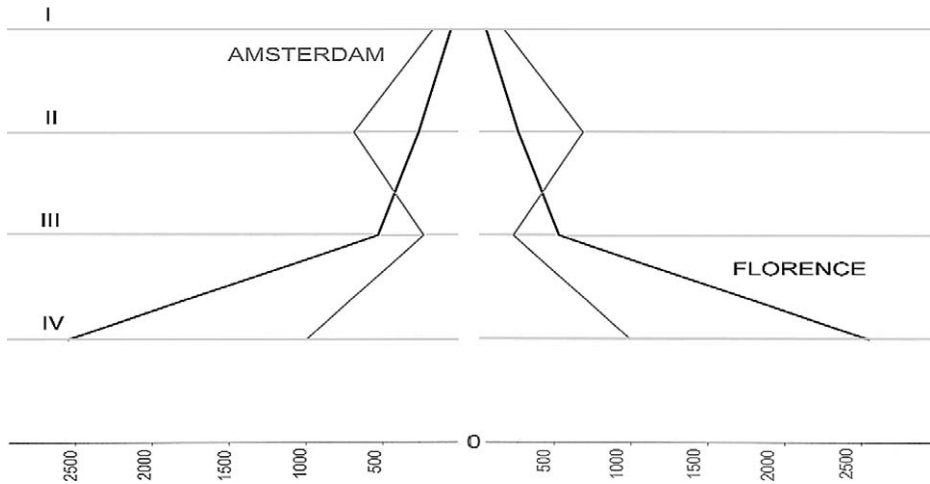

Figure 2. Numbers in wealth and tax classes (I–IV), Florence and Amsterdam.

sterdam, versus 1649. If we could also show that paintings in Amsterdam were cheaper, the combination of more persons of wealth and cheaper paintings would suggest that, other things being equal, there should have been more paintings owned by the top three *taxpaying* groups of households in Amsterdam than in Florence.

The data to check that expectation are lacking at the Florence end; but in any case the culture of filling the walls of a house with easel paintings was not one that developed at all strongly there. It is telling, however, to take as reference point the value of the *cheapest* panel in the Medici collection, an unattributed *Head of Christ*, at 4 florins, and compare it with the minimum average value of *attributed* paintings in Amsterdam inventories, 1620–1660, which was 9 guilders, or roughly 1.5 florins. This suggests a significant unit cost advantage in Amsterdam.

Did that translate into more actual purchases? Again, unfortunately, the question can be addressed comparatively only for cities north of the Alps. Table 2 gives the picture for Antwerp and Amsterdam, and for Paris and Metz. We do not possess ownership data for Bruges, or for Florence. However, taken together with the estimates given earlier for wealth-elasticities of demand for paintings in the Dutch Republic – all greater than 1 – Table 2 can be used to infer a pattern of increasing ownership over time in the Netherlands, north and south, both absolutely and relative to France. The pattern for the Netherlands thus establishes a standard of sorts against which to measure ownership in Florence and other Italian cities in future inquiries. It is perhaps worth noting that

Table 2  
Ownership of paintings in the Low Countries, and in France

	1530s/1540s	1565–1585	1620–1645	1630/1631	1645–1672
<i>Antwerp</i> (per house)	≈5.75 <sup>1</sup>	1–11 rooms: 6.8 <sup>2</sup> ≥12 rooms: 22.2		13.3 <sup>3</sup> 45.3	
<i>Amsterdam</i> (per inventory, by wealth-tax class): <sup>4</sup>

Upper end of lowest bracket:				9 originals +20 cheaper	
Top 2 brackets:				23 originals +23 cheaper	
<i>Metz</i> (per inventory) <sup>5</sup>					5.5
<i>Paris</i> (per inventory) <sup>6</sup>			8.7		

<sup>1</sup>Per house, judicial inventories, houses of all sizes: Martens and Peeters (2002, p. 881).

<sup>2</sup>Per house, various sorts of inventory: Vermeylen (2003, p. 148).

<sup>3</sup>Various inventories, excluding only houses of 16 or more rooms: Blondé (2002, pp. 382–383).

<sup>4</sup>Montias (2002a, pp. 122–123, Table 1). “Originals” were priced at the florin-equivalent of 2.3 and up.

<sup>5</sup>Benedict (1985, pp. 103, 105).

<sup>6</sup>Schnapper (2001, pp. 425–426), citing unpublished work by Mickaël Szanto.

the average of 23 original paintings per inventory in the very top two tax brackets in Amsterdam were valued at just under 6 florin-equivalents. The Medici – certainly in the top tax bracket in Florence – owned only 6 comparably cheap paintings, out of the 142 recorded in the 1492 family inventory.

Against this background of a rising ownership of paintings in the Netherlands – over time, and with increasing wealth – we will now trace some of the means by which sales were effected in numbers greater than would have been possible via direct sale from an artist’s workshop. For this purpose we shall turn, first, to the two cities Antwerp and Mechelen/Malines, which, in our terms (see [Appendix A](#)), comprised a net-exporter complex. Then we shall turn to Haarlem and Amsterdam in the province of Holland. Amsterdam, the dominant urban center – population c. 1660 of 200,000 – was a net importer of paintings and was linked with other cities via a canal network, which allowed that situation to continue. De Vries estimates that the population of other cities accessible within a day’s travel from Amsterdam was c. 350,000.<sup>49</sup>

### 3. Distributing paintings across markets

As production in volume became normal – in 16th-century Antwerp and Mechelen, 17th-century Holland and 17th-century Rome – institutions and mechanisms for the bulk marketing of images also developed, or were adapted for the purpose. These display an interesting variety of form as well as in the rules used to structure sales. In the case of Antwerp the city authorities played a central role, adapting to paintings and prints an older marketing institution – the display hall, used for textiles at fair times in Bruges.

#### 3.1. *The panden in 15th- and 16th-century Antwerp*

Antwerp in the 16th century took specialization and division of labor to new heights. The city benefited from natural and political forces that caused a decline in the Bruges economy during the 15th century. Antwerp’s river access, long restricted by sand bars, was improved thanks to freak floods in 1375–1376 and 1404, eliminating Bruges’ monopoly up to that point on traffic using larger sea vessels.<sup>50</sup> As to the political, as noted already, following a decision to oppose the centralizing moves and claims to dominion (and power to tax) over Flanders by the future Emperor Maximilian I, in the 1480s, Bruges was punished. Maximilian offered incentives and safe passage to foreign merchants to relocate to Antwerp, which had sustained his cause. After some hesitancy and a temporary return by some merchants in the early 1490s, by the 1620s all the foreign “nations” had moved permanently to Antwerp. In subsequent decades Antwerp

<sup>49</sup> De Vries (1981, p. 75, Table 3.7).

<sup>50</sup> Nicholas (1992, p. 390).

quite superseded Bruges as the world's *entrepôt*. This reorientation was greatly assisted by a monopoly in the distribution of spices granted to the city by the Portuguese at the start of the 16th century, plus a realignment of commercial traffic along land routes in accordance with the new mining wealth and burgeoning money markets of West-Central Europe. The adjustment occurred in several waves, between 1460 and 1540. Italian bankers suffered an eclipse in that region, and Venice became linked to Antwerp chiefly via land routes that ran through Cologne, Nürnberg and Vienna, as well through Cologne, Augsburg and the Tirol.<sup>51</sup> The distribution of Antwerp and Mechelen paintings in the 17th century can be traced partly along these routes, which complemented an older traffic – still maintained – to Paris, the Iberian Peninsular and the Americas.

The resettlement of the foreign “nations” to Antwerp contributed positively to the development of an art market there, in the same way as it had in Bruges; but there were additional elements that were unique to the Brabantine city. One was an extraordinary openness within the Antwerp St. Luke's guild, which was all-inclusive, coming to comprise, by early in the 16th century, some twenty crafts including painting, and as many as forty-eight by mid-century.<sup>52</sup> During that century dealers also begin to show up as registered members, though not all dealers bothered with guild membership.<sup>53</sup> More importantly, the guild did not forbid different sorts of masters cooperating with each other.<sup>54</sup> This all but eliminated the boundaries set according to technique and product that were officially espoused in Bruges, even if, as we have seen, practice could be less rigid.

A second distinctive feature in Antwerp was the deployment of cloister-like structures known as *panden*, some of them operating for the selling of paintings on a year-round basis. Strikingly, the city authorities took an active role in promoting these dedicated sales venues.<sup>55</sup> The first recorded *pand* involving paintings was in the cloister of the Dominican friary. It dates from 1445, and – unusually – was a combined initiative of the Antwerp jewelers' guild and the painters' guilds of Antwerp and Brussels. This *pand* lasted for more than a century, though in 1481, following a dispute, the painters switched to a new building near the cathedral church of Our Lady. There, from 1484, they enjoyed a monopoly, guaranteed by the city, on the sale of paintings during fairs. Our Lady's *pand* was also the first to function as a continuous or year-round sales site,<sup>56</sup> an interesting outgrowth of Antwerp's two annual fairs, in mid-May and late August,

<sup>51</sup> On these developments see Blanchard (1996).

<sup>52</sup> Martens and Peeters (2002).

<sup>53</sup> Vermeylen (2003, p. 134).

<sup>54</sup> *Ibid.*, p. 138. Martens and Peeters (2002) note that, contrary to belief, there were very few large workshops in Antwerp, and that many practitioners of other crafts who registered with the painters' guild also held membership in another guild. It would appear that within-workshop division of labor was relatively less important than openness and cooperation across crafts.

<sup>55</sup> Vermeylen (2003, p. 28).

<sup>56</sup> *Ibid.*, p. 26. The pioneering study of this *pand* is that by Ewing (1990).

each of which lasted for about six weeks. At those fairs luxury items of every sort could be had, including paintings.<sup>57</sup>

This last marks two other important differences from Bruges. It is unlikely that paintings were displayed in the open for sale at the Bruges fair. Guild regulations envisaged display and selling principally from shops; moreover, it is improbable that paintings were shown in the damp outdoors at the spring fair, unless perhaps during the three official viewing days.<sup>58</sup> In addition, though the city opened a *pand* in 1482, at the request of the jewelers' guild, it was not until 1511 that the restriction on painters just mentioned was lifted and they were allowed to participate in the annual *pand*.<sup>59</sup>

Various other *panden* were set up in Antwerp, for the display and sale of specialty products such as tapestries, but the last and greatest such enterprise for paintings was the one in the new Exchange that opened in 1540. Undertaken at the city's behest, this *pand* comprised 100 stalls on the upper floor of the Exchange building for the exclusive display and sale of paintings, prints, frames, etc.<sup>60</sup> One artist-dealer who rented a slightly larger-than-standard space in this artists' *pand* was Jan Van Kessel; at his death in 1581 he had a stock of 610 paintings there, exclusive of prints and various other things such as copper plates, paper, and chests for storing paintings.

Van Kessel's inventory gives us an opportunity to guess at the possible volume of production in Antwerp. If he was representative, and if we assume that his stock turned over completely every three years, there could have been something like 17,661 paintings added every year to the stocks displayed above the Exchange – at least in the good years up to the 1580s.<sup>61</sup> Most of these paintings would have been relatively standard, on canvas or cloth, and quite cheap. They would also have been new and anonymous;

<sup>57</sup> Campbell (1976, p. 196).

<sup>58</sup> Blockmans (1996, p. 22). This suggestion concerning display prior to the spring fair is not at odds with the fact discussed earlier that cloth painters found ways to display their paintings in the open, in the port area.

<sup>59</sup> Wilson (1983, p. 477 and Note 10).

<sup>60</sup> Vermeylen (2003, p. 50ff).

<sup>61</sup> For the information from which we have calculated Van Kessel's share of rented space in the *pand* see *ibid.*, pp. 60–61 and Appendix 2, p. 194. Van Kessel had space 1.152 times larger than the standard stall, so of the 100 stalls available, there could have been only 87 of Van Kessel's size.  $87 \times 203$  new paintings per stall-holder per year = 17,661 paintings. This is the crudest possible way to arrive at an estimate of total output. Montias has articulated a more sophisticated method: first calculate the number of artists in a city; then, using archival information on average yearly earnings for artists, plus average prices of paintings (from inventories), infer the weekly productivity needed to generate such an income. Applying this to Amsterdam, he arrives at a figure of one painting every three days (or 90 paintings in a year of 270 working days) for more expensive paintings (those averaging 13 guilders or florin-equivalents of 2.2 each and measuring c.  $63.5 \times 89$  cm), and 2.5 to 3.3 per week (or 135 to 180 a year) for cheaper paintings (5–9 guilders or 0.85–1.5 florin-equivalents apiece). Using Montias' estimated proportions for paintings in each category, the weighted average total for a year comes to 124 paintings. For an estimated artist population of 100, this would have meant a total output of 12,400 paintings per year, though with a maximum of 18,000 – assuming all paintings made were of the cheaper sort [Montias (2002a, pp. 117–120)]. We can check our crude calculation based on Van Kessel's inventory by applying elements of Montias' method. Thus, if we assume that the paintings sold at the exchange in Antwerp were mostly cheap, and employ the total number of registered painters in 1585–1586 – 108 – then total production at that point in time could have been  $108 \text{ artists} \times 180 \text{ paintings per year} = 19,440$ . In fact we are

indeed, the inventory of Van Kessel's stock for sale at the *pand* contained just one older work, "an old painting on canvas by . . . Bosch".

Guild openness, civic encouragement, widespread dealing,<sup>62</sup> plus specialization and division of labor practiced in the many crafts making up the painters' guild, and especially between masters' workshops, as well as a marketing and exporting orientation – all these features marked Antwerp as an environment for the production and sale of paintings the like of which had not been seen before. Moreover, Antwerp was complemented in the production of paintings by its near-neighbor Mechelen/Malines. Mechelen was a much smaller city, but it had been advantaged by the placement there during the rule of the Burgundian Charles the Bold (1467–1477) of a court of appeal (*parlement*), as well as of the Chamber of Accounts for all of Burgundian Flanders. The court was diminished under his successor and the Chamber returned to Lille. Charles' granddaughter Margaret of Austria, retained Mechelen as a seat till, in 1530, the court removed to Brussels. After a half-century of such losses Mechelen might have retreated into itself; instead a decision appears to have been taken to specialize in watercolor paintings on cloth, including cartoons for the tapestry industries in Brussels and, possibly, Oudenaarde, as an export business. The guild of painters reorganized in 1533 and was soon recruiting apprentices in extraordinary numbers for a city of maybe 30,000. Close to 80 apprentices were added between 1538 and 1568, and another 192 between 1598 and 1619 – a recovery after the re-capture of Antwerp by Spanish forces in 1585 and resulting emigration. The data on new master painters move similarly to, though they led those in Antwerp over the period 1568–1630.

The former of those two numbers for new apprentice painters in Mechelen – 80 – may be taken as evidence of the success of the Antwerp *pand*; it is known that paintings from Mechelen were sold by stallholders at the *pand* in the 16th century. The surge in

inclined to think this number, higher though it is than our own first guesstimate or Montias' calculated total for Amsterdam, is too low. The reason is that some paintings on cloth, made in Mechelen, were sold through the Antwerp *pand* – Van Kessel's records refer to such paintings (private communication from Filip Vermeylen), and Antwerp dealers are known to have constituted a major conduit for exports of paintings from Mechelen (cf. Footnote 43 above). Cloth paintings were certainly quickly made and very cheap, as we have seen – no more than 1.45 to 1.78 guilders apiece (weighted averages) to two 17th-century Antwerp dealers. A sales contract between a Mechelen painter and an Antwerp dealer in 1654 gives 1.8 guilders for a "large" and 1.25 for a "small" painting. We adopt these as proxies for more and less costly paintings. We also have a contract specifying the day wage of a painter, in 1634: 0.8 guilders. The relation of wages to prices remained roughly constant even though the levels of both changed between the mid-16th century and the early 17th. Assuming these contracts were representative, and applying both day wage and prices to the 1560s – Mechelen's zenith as a center for paintings production – an artist there could produce 103 more costly or 148 cheaper paintings in a year of 38.5 six-day weeks. We estimate that there were 159 painters in the city in the 1560s, yielding total annual output in the range 16,377 (more costly) to 23,532 (cheaper) paintings. There remained something like 69 painters in 1632. For documents see Van Autenboer (1949) and Monballieu (1971). A conservative annual average total production for Mechelen and Antwerp combined therefore might be 30,000, and more in years when the combined artist population exceeded 200, as it probably did at times.

<sup>62</sup> Vermeylen (2003, pp. 66–67 and Appendix 3), counts 17 persons registered in the guild as specialist dealers in the sixteenth century plus 24 more so named in other (non-guild) documents.

numbers early in the 17th century, on the other hand, marks a change in the style of marketing. The *pand* was then no more, but by the 1620s its place was being taken by international dealers such as Chrisostomo Van Immerseel and the brothers Goetkint, and presently by firms such as the partnership of Matthijs Musson and Maria Fourmenois, and the family business of Willem Forchondt and his sons. Records of the latter two firms, and letters of Van Immerseel, attest to the hundreds of Mechelen paintings they bought, for re-export.

The economic situation in Antwerp had begun to decline by the 1580s. First, in 1576 there was a destructive riot by unpaid Spanish troops garrisoned in the city. Then, in 1583, a fire destroyed the *beurs* and with it the artists' *pand*. Though rebuilt, the new exchange was finished only in May, 1584, by which time Antwerp (at the time Calvinist) was under siege and merchants had begun to withdraw from the city. The steady decline of the *pand* from this date,<sup>63</sup> combined with the huge emigration – 50 percent – in the four years after the city capitulated to Spanish forces in 1585, including some hundreds of merchants who moved to Amsterdam,<sup>64</sup> obliged artists and artist-dealers to look to external markets. And while new, rebuilt, or refurbished churches and religious orders in the period from about 1590 through 1625 created a fresh local demand for sculpture and painting, the subsequent slowdown renewed the pressure to seek sales abroad. We shall consider here incursions made by Antwerp dealers into Paris and Holland.

### 3.2. Dealer-led incursions into Paris, and to Dutch cities

Given the circumstances in Antwerp after its re-capture by the Spanish in 1585 we would expect the number of new apprentices to have fallen off, or artists to have switched professions, or to have emigrated. All those things occurred, yet artists there and in Mechelen quickly regrouped, first restoring and thereafter sustaining a production capability in paintings well in excess of the needs of local buyers. A tradition of family artist dynasties possibly slowed the adjustment process in both places, while the cooperative guild tradition in Antwerp also contributed towards a flow of novel products even in the face of, or possibly as a response to, the slowing of demand.<sup>65</sup> However, the dominant response was to turn more aggressively to dealing abroad, maintaining Antwerp and Mechelen as production bases.

Paris was one target of this aggression. There is evidence that Antwerp dealers visited the internationally-important pre-lenten fair of Saint-Germain-des-Prés, held just outside Paris, in the late 16th century. By early in the 17th century Antwerp dealers had become major stallholders at the fair. This also gave them influence in the Paris market itself, in part because they began leaving stock not sold during the fair with associates

<sup>63</sup> Annual rents tell the story: see Vermeulen (2003, p. 54, graph 3).

<sup>64</sup> Gelderblom (2000, Appendix 4), records some 285 in the decade from 1585 and many more in the subsequent decades up to 1630.

<sup>65</sup> For discussion of some of these see De Marchi, Van Miegroet and Raiff (1998).

in Paris for subsequent sale, in contravention of regulations.<sup>66</sup> The annoyed response of the corporation of painters in Paris, the *maîtrise*, was to request, in 1619, that foreigners be excluded from trading, except at the fair, and that, even there, the paintings they offered be subject to assessment by *jurés* of the *maîtrise*. There is evidence of fines being imposed on foreign dealers if their paintings were deemed inappropriate. Independently of this deterrent, dealers from Antwerp, by the late 1620s, feared sequestration of their goods should war break out between France and Spain, and they began to switch from owning extended leases at the fair to renting stalls on an annual basis. Several also pursued naturalization or other means that would allow them to settle legitimately in Paris.<sup>67</sup> Foreigners never were excluded from the fair, but it remained difficult for them to obtain permissions to establish in Paris. The corporation of painters, sustained in the crucial early decades of the century by the magistracy, was strong enough to continue to threaten and to restrict entry by outsiders. Antwerp dealers, with few exceptions, were confined to visiting during the fair, though some who did settle continued to be supplied from Antwerp. We shall see below that, in the case of Lille, where, in the third quarter of the 17th century, there were also almost annual incursions, the numbers, relative to the local population of artists, were only slightly more alarming than in Paris: 10 dealers relative to maybe 40 guild artists in Lille; perhaps 15 Antwerp dealers compared an estimated painter population in Paris (in 1611) of 75.<sup>68</sup> Tellingly, however, in Lille the local magistrates withheld their support from the painters (see Section 5.3 below).

There came an interesting reversal in the way the one-way flow of paintings from Antwerp to Paris throughout the 17th century was managed. That traffic, dominated by Antwerp dealers in the early decades of the century, is reflected in significant Netherlandish holdings in many late 17th- and early 18th-century Parisian collections.<sup>69</sup> Throughout the 17th century, the marketing of paintings in Paris was more or less controlled by painters, French-born or foreign, including some from Antwerp. Early in the 18th century, however, some trader-merciers (*marchands-merciers*) in Paris began to ease control of the market away from artists. They took the initiative in bringing Netherlandish paintings to Paris themselves. One such merchant-mercier was Edme-François Gersaint, but he was followed by others, among them Alexandre-Joseph Paillet and Jean-Baptiste Pierre Le Brun; all three went regularly to Flanders and Holland to view collections and buy at auction there, for resale in Paris.

Returning to the 17th century, Antwerp dealers also tried smaller-scale incursions into the cities of Holland – Dordrecht, Delft, Gouda, Leiden, Amsterdam. This continued

<sup>66</sup> Szanto (2002; 2006).

<sup>67</sup> Szanto (2001).

<sup>68</sup> The number of visitors in Paris is based on the size of a group of 14 in 1628 [for which see Szanto (2006)]; the figure 10 for Lille is an average drawn from signatories to requests to hold sales in the years 1677–1688. The Paris artist population is from Schnapper (2001), taking the ratio of painters to sculptors as two to one, in a combined population – painters and sculptors – of 100–115 in 1611; that for Lille is based on the guild's 1679 complaint that 35–40 families had been ruined by the incursions: see De Marchi and Van Miegroet (2005c).

<sup>69</sup> Schnapper (1994); see also Van Miegroet (2005).

for a period of maybe three decades or so, starting very soon after 1585. In this case, as in Paris, the local painters protested. After initial attempts to address the problem by obtaining ordinances against the interlopers, however, local artists' guilds and informal groups of painters gradually began to act more like Gersaint and his ilk, conducting sales under their own auspices. In Amsterdam the local guild received only tepid support from their magistrates, probably because the dominant buyers of paintings were merchants, many of them immigrants from Antwerp, and the city's commercial prosperity was more importantly served by them than by its painters.<sup>70</sup> In this broad respect, and in related details, the guild misconstrued the changes underway in Amsterdam: from a static environment in which guilds could expect to safeguard the income of members by protecting their market against foreign intrusions, to an open, dynamic world of changing ideas, products, processes and tastes.<sup>71</sup>

The Amsterdam guild alleged that the southern dealers brought with them, and sold in illegal auctions, only inferior paintings – mere copies and student work – yet represented them as originals.<sup>72</sup> Local buyers, they added, being unable to tell the difference, were being duped. By implication, local artists would suffer, because, as buyers became skeptical, they would hold back and the market would collapse, as per Akerlof's "lemons" model.<sup>73</sup>

This did not happen; but nor does the evidence support the key charge, that buyers were duped. Montias has shown for contemporary, legal auctions – those held by the Amsterdam Orphan Chamber – that, in the years 1597 to 1619, 54 percent of known buyers were themselves immigrant southerners.<sup>74</sup> Of known buyers, too, one in three was a merchant, 60 percent of them of southern origin.<sup>75</sup> It is highly likely, therefore, that the majority of buyers at the illegal sales organized by the interlopers were also immigrants from the south, happy to purchase paintings of a sort with which they were very familiar. Far from these buyers being undiscerning, then, their origin and their enthusiastic participation in the official Orphan Chamber auctions suggests that they must have known exactly what they were getting. The demand in Amsterdam, we may infer, was segmented: knowing southerners, versus allegedly undiscerning locals. This seriously restricts the possible scope of application of the guild's claim that the market would collapse. In addition, since the allegedly undiscerning could observe what

<sup>70</sup> Gelderblom (2000, p. 227) shows that merchants of southern origin in Amsterdam were wealthy, if less so than local merchants.

<sup>71</sup> It is worth noting that, despite the Amsterdam guild's public face, cost-saving techniques pioneered in the Southern Netherlands made their way in the next few decades into Dutch cities, via Amsterdam: see Montias (1986) and Sluijter (2000).

<sup>72</sup> See De Marchi (1995) for references to original sources.

<sup>73</sup> Akerlof (1970). De Marchi (1995) applies Akerlof's model to the Amsterdam situation on the assumption that the guild's arguments were well-founded. Montias' research (see below) has since provided an empirical basis for concluding that they were not.

<sup>74</sup> Montias (2002b, p. 63).

<sup>75</sup> Ibid. and p. 47.

knowledgeable buyers were willing to pay at auction, it is simply implausible that the asymmetrical information driving Akerlof's model was present.

As noted, gradually guilds in other Dutch cities began to explore the possibility of benefiting by public sales. In fact from the 1640s guilds and informal organizations of painters in Leiden, The Hague and Haarlem became active in setting up display-facilities for their members and/or in holding regular public sales. The external threat of the first decades of the century was tamed in Holland by the artists' organizations accepting public sales and bringing them under their own auspices.<sup>76</sup> In the 1680s, however, there was a new threat from Antwerp dealers, directed to the south. Lille (and neighboring cities) was the prime target, but a group of dealers, including many of those who traveled to Lille in the same period, also appeared in Ghent, with the same request: that they be allowed to hold auctions outside the times of the fair. In Ghent, however, the painters held more power than in Amsterdam, and their magistrates denied the request.<sup>77</sup> Again, the Lille experience will be addressed below in Section 5.3.

It is worth inserting here that for all its openness the Antwerp painters' guild reacted just as negatively as guilds elsewhere when foreign dealers came to Antwerp and sold outside the twice-yearly fairs and the weekly "free" Friday market-day. The language used by the Amsterdam guild in its first protest, of 1608, could have come from a 1575 request by the Antwerp guild that an older statute proscribing dealing in any form by non-guild members be re-affirmed. Similar language was retained in later revisions of the statute. Officially, then, openness in Antwerp was limited. The practice, however, was very flexible. Close to one third of known Antwerp dealers in the 16th century were not registered with the guild, yet prosecutions were rare; non-registered dealers held office in the guild, and they were among the stall-holders at the city-backed *beurs pand*.<sup>78</sup>

### 3.3. *The market in Holland as a network*

In recent years ingenious estimates have appeared of the output of paintings in the Dutch Republic during its decades of growth, roughly 1590 through the 1660s, and for Amsterdam separately. If we extend the period to a full century, the total for the whole Republic, in the period 1580–1680, is put at 4.7 to 5.3 million paintings.<sup>79</sup>

Those numbers are impressively large, though in relative terms not out of line with our estimates for 16th-century Antwerp–Mechelen, which rest on comparable productivity per artist.<sup>80</sup> Yet, throughout the period, Amsterdam was also an importer of

<sup>76</sup> See Romein and Korevaar (2006) for details.

<sup>77</sup> Raux (2004).

<sup>78</sup> See Vermeulen (2003, pp. 66–67 and 131–136), and Appendix 5 for the 1575 document.

<sup>79</sup> Two very different methods have been used. One is due to Van der Woude (1991), whereby the number of paintings is inferred backwards from surviving paintings and estimated rates of depreciation; then the number of active painters is calculated for particular years. Finally the productivity necessary to connect those two sets of estimates is derived. The other is that of Montias, for which see Footnote 61 above, and Montias (1990, p. 70).

<sup>80</sup> See the discussion in Footnote 61 above.

paintings (attributed and unattributed, that is, originals and copies), to the tune of perhaps 20 percent of its demand.<sup>81</sup> How was the lack supplied?

In a sample of Amsterdam inventories covering the period 1620–1679, and attending only to original paintings, Montias discovered that just 35 percent of these were attributed to artists who worked solely in Amsterdam. The percentage rises to 53 if artists are included who worked in Amsterdam *and* other places.<sup>82</sup> The percentage of Haarlem artists in Haarlem inventories, however, was much higher, 74.<sup>83</sup> But whereas tiny fractions of holdings in Haarlem came from other cities in the Republic, 14 percent of holdings in Amsterdam came from artists residing solely in Haarlem (24 percent if artists who worked in Haarlem and elsewhere are included), and another 12 percent from Antwerp. An additional 8 percent came from artists who worked only in Utrecht.<sup>84</sup>

How did Haarlem come to supply such a solid portion of Amsterdam's net imports of paintings? Boers has shown that the supply of paintings in Haarlem began to outgrow demand there around 1625,<sup>85</sup> and that two complementary changes occurred to right the imbalance. First, dealers stepped in: 12 were recorded in Haarlem in 1634, two of them women, in an artist population of only 90. Several of those dealers either originated from elsewhere (two from the southern Netherlands) or were actually based in another city (two in Rotterdam). These dealers took off surplus paintings, reselling them in markets such as Rotterdam and Amsterdam. Second, several Haarlem artists migrated to nearby Amsterdam.

Montias' basic finding implies that some 65 percent of attributed originals in Amsterdam inventories were made by out-of-town artists. There is a pattern to where the paintings came from. It correlates loosely with the system of canals built from the late 1620s onwards, in two periods of investment. The canals were used for slow but reliable passenger-carrying, horse-drawn barges (the *trekvaart* system).<sup>86</sup> There was an earlier, strictly local market-boat system, and an inter-city system as well, but the latter involved circuitous routes imposed by local water-toll authorities, who restricted travel possibilities so as to maximize their receipts.<sup>87</sup> The *trekvaart* system was the first water-based passenger service between cities using canals that followed the most direct routes. The Utrecht–Amsterdam link was in place by the late 1620s, and in Amsterdam inventories from the next two decades, 1630–1649, Utrecht painters account for 11 percent of the attributed originals (more than a third above the 8 percent average for Utrecht over the

<sup>81</sup> Montias (1985; 2002a, pp. 127–128).

<sup>82</sup> Montias (1991, Table 8).

<sup>83</sup> Montias (1985, Table 8).

<sup>84</sup> Montias (1991, Table 8).

<sup>85</sup> Boers (2000). Painters in Haarlem as a percentage of the city's population grew from 0.05 in 1605 to 0.13 in 1625, and 0.21 in 1635: figures from Sluijter (2000, p. 137), note 19 citing Boers estimates of the number of painters, including artists whose name appears in archival records but for whom there is no known surviving work.

<sup>86</sup> De Vries (1981, pp. 27ff).

<sup>87</sup> *Ibid.*, p. 19.

whole period 1620–1679). The Haarlem–Amsterdam link – just twelve miles long – came into service in 1632 and in the succeeding three decades 16 percent of holdings in Amsterdam were accounted for by Haarlem artists who worked only in that city (above its 14 percent average for the whole period) – a one-seventh difference, less dramatic than for Utrecht, possibly because the distance by road was so small to begin with. Cities such as Leiden, Rotterdam, Delft and The Hague, for many years without direct canal links to Amsterdam, continued to account for tiny percentages of the attributed originals in Amsterdam inventories.<sup>88</sup>

This is weak evidence of a network of paintings flows facilitated by a transportation infrastructure. It has been put to us that unframed paintings are low bulk, high value-added goods, so that freight costs cannot have been responsible for the geographical pattern of production. But our argument is not that; it is that local specializations among artists emerged for a variety of non-economic reasons, and were reinforced by local guild membership fees, which everywhere favored the sons of local masters. With an efficient transport infrastructure, local surpluses in specialist paintings could be redistributed, to align supply more closely with demand without change being needed in where production occurred. In other words, and although some artists did migrate, the *trekvaart* system made it quicker and easier for arbitraging dealers to function – as they did in Haarlem immediately after the Haarlem–Amsterdam barge link was forged – instead of forcing artists themselves to move. Even a short trek like that between Haarlem and Amsterdam was eased – made quicker, more reliable, and less dangerous – by the barge service, since it supplanted a route that required passage over a stretch of sometimes dangerous open water and via an equally squally river.

The canal network complemented and assisted the dealers, while the dealers facilitated collecting by individuals. Dealers and the canal network together enabled Amsterdam to sustain a paintings trade imbalance throughout its “golden” age. The network also permitted local specialization in paintings to occur in many small cities – too small for efficient specialization, considering only local demand. Thus it fostered collective diversity with excellence by supplementing local demand to the point where specializing was feasible even among small populations of artists and buyers.

### 3.4. *Trading in paintings: The traffic from Antwerp to New Spain, via Seville, c. 1540–1670*

Finally, in our set of illustrations of dealing to supplement inadequate local demand, we look at traffic in paintings from Antwerp, through Seville, to the Americas. Such a trade existed from at least the second half of the 16th century. This trade has not been systematically studied, but according to Falomir it passed through three stages.<sup>89</sup> These chart a transition from a commission nexus through artist–dealers to specialist,

<sup>88</sup> Montias (1991, Table 8).

<sup>89</sup> Falomir (2006).

professional dealers, much like the progression encountered in Antwerp – perhaps not surprising, since the traffic for many years was dominated by merchant–dealers based there. The stages are as follows:

- (1) Prior to the 1540s paintings for New Spain and other parts of Spanish America were commissioned directly from Spanish artists by the *Casa de Contratación* and the finished works shipped to the viceroalties.
- (2) From about the mid-sixteenth century painters began to take the initiative. They also assumed the risks, producing paintings that had not been commissioned which they then shipped through intermediaries, in many cases ships' captains, with instructions to sell as well as possible in the ports of America and return the proceeds, for a percentage.
- (3) Though intermediaries continued to be used, the potential profits on the traffic with America – prices there might be 3 times higher than those in Spain – increasingly drew in professional merchants, who shipped paintings and prints along with *escritorios* (writing desks), cabinets with doors and tiny drawers to which small paintings on copper were affixed, painted keyboard instruments, books, textiles (including tapestries) and clothing.<sup>90</sup>

Prominent among these professionals were Flemish merchants. Some stayed in Antwerp and filled orders for paintings received via agents abroad, receiving payment prior to or not long after shipment. Others, such as Chrisostomo Van Immerseel, were more vertically integrated; he initiated commissions in Antwerp himself – though in response to advice from his wife, Maria Fourmestraux, in Seville – and the couple carried the risk themselves.<sup>91</sup> If final sale was to occur in America, paintings (and other goods) would be shipped to Seville, and later Cadiz, for forwarding to “the Indies”. Shipments across the Atlantic were sometimes prepared to order, sometimes on spec (without a known client or clients in view). Limited evidence relating to the latter suggests that shipments were deliberately mixed as to supports, sizes, subjects and prices, as if the merchants involved were consciously spreading their risks so as to achieve on average, as with an investment portfolio, a target rate of return.<sup>92</sup>

How large was the traffic in paintings from Antwerp to America via Seville? Falomir suggests that it may have peaked just before or around 1600, which would roughly coincide with the peak in the tonnage of shipping between Spain and New Spain.<sup>93</sup> Nonetheless, though with ups and downs, the average shipments per year even during the second half of the 17th century remained substantial. Between 1583 and 1599, on average, 144 paintings each year were exported, with occasional exceptional numbers:

<sup>90</sup> *Idem.*, citing Páramo (1999) and Echeverría (2000).

<sup>91</sup> Van Immerseel started in his father's trading business, which included trading in tapestries. Typically, in that industry, merchants supplied capital to sustain the workers during the long preparation process, as well as handling orders and distribution/sale. It would have been natural for him to treat his trade in paintings in a similar way.

<sup>92</sup> De Marchi and Van Miegroet (2000a).

<sup>93</sup> Lynch (1969, p. 283, Table B).

e.g., some 637 shipped in a single three-month period in 1586. Between 1651 and 1700 the numbers ranged from 150 to 910 per year.<sup>94</sup> Yet the highest number, 637 in three months, or 2185 on an annual basis, is still only 7.3 percent of the very conservative estimate we offered above (note 61) for annual production in Antwerp/Mechelen combined, of 30,000 paintings per year. We should note that orders were also placed in Italian cities – Naples and Rome – and in France and Madrid, not just in Antwerp, though on those flows there is only scattered evidence.<sup>95</sup>

Taking just exports from Antwerp and Mechelen, the Americas trade shows this production complex in a new light. The professional merchants involved were not dealers making forays into markets a day or two distant, but integrated international traders in paintings, involved in production, yet obliged also to be sensitive to buyers' wishes. In having to translate preferences expressed in Spanish into the Flemish of the artists who would fill the orders, dealers found themselves mediating not just between different language communities but between distinct production and visual traditions. That is what the international agents of patrons and collectors had always done, only now it was being accomplished in bulk, not item by item.

#### **4. Selling paintings I: Artist–dealer relations**

We move now to some less neatly-packageable aspects of markets in paintings, involving relationships between artists and dealers or dealers and collectors. They are included because our emphasis on markets as experimental plays leads us to think that a certain degree of messiness was normal and should not be shunned; we also value the variety of routes taken as markets moved towards maturity. We shall look first at artists' pay and how it was shaped by traders who viewed original paintings they commissioned as capital, capable of generating an income, via copies. Then we turn to the less studied situations of dealers and how they related to artists in Venice and Rome.

##### *4.1. Securing payment for invention*

One aspect of the Van Immerseel–Fourmestraux vertically-integrated trading business enabled a change in the way artists were paid, in Antwerp certainly, and perhaps elsewhere. Painters in 15th-century Florence were regarded as skilled artisans and paid accordingly. To illustrate, we noted that Neri di Bicci showed up in the tax assessment of 1480 as the wealthiest painter in Florence. Goldthwaite points out, however, that this would have left him “entirely within the ranks of artisans and shopkeepers as delineated

<sup>94</sup> García Fuentes (1988, p. 58); Kinkad (1984, p. 305); Echeverría (2000). These numbers all depend on how many paintings it is assumed went to make up a “roll”, which was the unit of record. We have followed Falomir in assuming 100 paintings per roll.

<sup>95</sup> Falomir (2006).

by the more authoritative *Catasto* [tax assessment] of 1427".<sup>96</sup> Day-wage equivalents for painters in Florence are extremely hard to come by, but even the highest salary in the construction industry, paid to foreman of the cathedral Brunelleschi, amounted only to something like 1.5 to 1.75 times the de facto average rate for skilled artisans.<sup>97</sup> Little changed in Florence over the course of the 15th century where, as noted earlier, artists' services seem to have verged always on being in over-supply.

In terms of rewards for artists relative to those of other artisans, the situation in late-14th-century Bruges was similar. A partial survey of Bruges tax lists for 1394–1396 records no painters in the two highest tax categories; instead, painters and saddlers – members of the same guild – appear in the lowest or second lowest tax bracket, a biased distribution paralleling the income structure for the population as a whole.<sup>98</sup> Over the course of the 15th century the picture probably altered little in Flanders.<sup>99</sup>

Shift forward to early 17th-century Antwerp, however, and there we find reproducibility being exploited to sustain payments for artists' services in excess of the rates paid other skilled artisans. Jan II Brueghel, grandson of the famous Pieter I Brueghel, and a second-tier painter, claimed payment for his invention. In itself this was not novel. Invention – *ingegno* – was expected by patrons in 15th-century Florence but often not paid for.<sup>100</sup> Jan II Brueghel, however, priced original paintings by themselves at roughly twice the cost of a copy of the same by his own hand. Assuming that size, support, and medium were the same, only invention in the original could account for the price difference. But how could a second-level painter make such a claim to payment for invention stick? The circumstances are somewhat special, though perhaps telling. Brueghel supplied paintings to Van Immerseel, who recorded at one point that he regarded the originals as capital assets. As such, they were not to be sold – Van Immerseel likened them to a shoemaker's last – but rather to be used to generate a (limited) number of copies.<sup>101</sup> The creator of such income-generating capital assets could easily be paid something extra when it was averaged over the entire stream. This was impossible within the commission nexus in Florence, with its one-off projects. Neither was

<sup>96</sup> Goldthwaite (2003, p. 437).

<sup>97</sup> *Ibid.*, pp. 318, 321.

<sup>98</sup> Blockmans (1995, p. 12).

<sup>99</sup> A large decorative project at Lille, in 1454, for the Burgundian Court, employed 38 painters at day rates. The rates for ordinary free masters on this project were one third above those for skilled artisans generally: see Martens (1999, Table 1). However, this is not conclusive evidence of an improvement in the situation of Flemish artists precisely because of the Court origin of the commission.

<sup>100</sup> Securing payment was always an uncertain business [Thomas (1995, p. 183)], but *ingegno* introduced special difficulties. This was because patrons – rightly, in many cases – perceived the originating idea as theirs. Moreover, patrons might even claim, as the poet Carbone put it, that “the merits of princes are reflected in the talents of their subjects”, hence that the talent of an artist is just a channel for transmitting their own worth and merits no special reward. See Syson and Thornton (2001, pp. 135, 142–143) for the example of the patron Isabella d'Este, and p. 156 for the case of the artist Cossa, who complained that he was paid as a journeyman.

<sup>101</sup> For details see De Marchi and Van Miegroet (1996).

it present in 15th-century Bruges, where artists sold directly out of their workshops, keeping only motifs, and drawings of heads and hands, to be copied.

As if in acknowledgement of the potential involved in arrangements such as those set up by Van Immerseel, however, the Flemish and Dutch word for an original painting of some quality from at least the late 16th century onwards was *principael*, in English principal, a capital sum, though the term applied to paintings primarily meant first-class. Dealers in 17th-century Rome also retained originals for copying, but it is unclear whether they treated the income stream from copies as a fund for paying artists for their invention.<sup>102</sup>

In Antwerp the implied mechanism took. Brueghel was not alone among his contemporaries in securing payment for invention, while there is fragmentary evidence there from later in the 17th century that puts the day-rate-equivalent of common master painters at between two and four times that of skilled artisans.<sup>103</sup> It is possible that the special conditions which allowed Jan II Brueghel and others successfully to claim such a differential became conventional during the ensuing period because numerous artists found themselves working for vertically integrated trader-dealers. Montias suggests that a comparable differential was enjoyed by artists in 17th-century Holland, where the putting-out system was also practiced.<sup>104</sup> But putting out could also result in slave wages, as seems to have been common in 18th-century Venice (see Section 4.2 below). A lot depended on local circumstances, and in Flanders and Brabant there was a tradition of viewing as capital cartoons for tapestries and engraved copper plates in the print industry. An 18th-century English example combines both painting and printing: the portraitist Joshua Reynolds calculated the value of a painting made for the publisher Boydell in terms of the revenue expected from the print run.<sup>105</sup>

#### 4.2. Selling paintings in Venice and Rome

Late in the 16th century, in Venice, a second-hand dealer (*strazzarolo* or *rigattiero*) was charged with stocking some new paintings. A few years later one of the city's official auctioneers was charged with having new paintings displayed above his stand, presumably to sell on own account. Of the second-hand dealer it was said that he actually had an arrangement with painters, something additional documents show to have been not uncommon.<sup>106</sup> Such arrangements were illegal in that only artists were supposed to sell in the domestic market – non-artists could buy for resale abroad.

<sup>102</sup> Lorizzo, private communication.

<sup>103</sup> De Marchi and Van Miegroet (1996, pp. 60–61).

<sup>104</sup> Montias (1990, p. 64ff; 2002a, p. 119; 2001, n. 3). Montias' generalization is not consistent with all available data; see, e.g., Van Zanden (1993, Table 3.1).

<sup>105</sup> The example of the painter Sir Joshua Reynolds is particularly striking. For his negotiations with the enterprising print publisher Boydell see Zablotney (1999). William Hogarth presumably made similar calculations in arriving at the subscription price to charge for prints after his paintings.

<sup>106</sup> Favaro (1975, pp. 71–72); Cecchini (2000, p. 194). Matthew (2006) details the use of such arrangements by the 16th-century artist Lorenzo Lotto.

The rationale used in Venice for insisting that new paintings be sold in the domestic market only by their maker or by another guild-registered artist had two parts to it. On the one hand, it was feared that, without such a restriction, unscrupulous individuals, including unregistered masters, or even non-masters, might garner a share of the market properly belonging to legitimate guild masters. On the other hand, if this occurred it would undoubtedly involve means that could not be countenanced – the employing of non-registered artists, and apprentices, probably in hidden locations, to turn out works of dubious quality.<sup>107</sup> Unfortunately the restriction took no account of a market that was expanding – as it was in 16th- and 17th-century Venice – and in which the specialized services of intermediaries might be needed to allow painters to concentrate on what most of them did best, making pictures.

Venetian artists had long enjoyed the freedom to make paintings other than those commissioned, and, during the 15th century, additional concessions were granted affecting both display and sale.<sup>108</sup> Local and mainland artists could sell at weekly markets in the quarters of San Polo and San Marco; moreover, as elsewhere in Europe, even foreigners were free to sell during the *Sensa* fair. Yet, as late as 1513, the prohibition against selling by others than artists was repeated, and even a century later, in 1607, the same proscription was renewed.<sup>109</sup> While the earlier concessions might be read as attempts to adjust to a growing demand for Venetian paintings, the guild, supported by the civic authorities, by continuing to insist that only registered artists should sell, actually heightened the potential for conflict in the way artists' allocated their time.

That conflict, however, was just one effect of the ban. Proscribing selling by non-artists – exports excepted – invited evasion, confirmed by the examples cited at the outset of this section. At the same time, to the extent that the ban was respected and enforced, it obviously favored exporting. In the seventeenth century both local and foreign demand was strong. A repayment of public loans from 1577 injected a large amount of spending power, which fed an emerging preference to put pictures on the walls of houses. Through the mid-seventeenth century paintings large and small came to adorn Venetian houses of every sort.<sup>110</sup> At the same time, however, the population of Venice grew, but only fitfully; by the late seventeenth century, and in the eighteenth, the market was increasingly driven by foreign demand. The problem of artists having to divide their time and intellectual capital between making and selling was masked while demand grew strongly. Nevertheless, it did put artists at a disadvantage in the export market, compared to merchants and specialized dealers in paintings, both of whom had the advantage in experience, networks of contacts with foreigners, and access to capital. This meant that, when the growth in local demand slowed relative to export demand,

<sup>107</sup> Cecchini (2000, p. 193). We find this rationale spelled out only in a document from 1638, but it seems reasonable to assume that it also informed earlier constraints on selling.

<sup>108</sup> Ibid., p. 192; Favaro (1975, p. 73).

<sup>109</sup> Cecchini (2000, p. 192).

<sup>110</sup> Cecchini (1998) and Borean (1998).

Venetian artists could not just turn to the export trade and expect to compete there as dealers on equal terms.

The result was that, by the early decades of the eighteenth century, the business of trading paintings had fallen significantly under the control of merchants and specialized dealers, and artists, in many instances, began to find themselves working, not directly for the market, but to fill orders placed by these traders, as if “in the galley”. This last is backward inference. A tax list of the College of Artists from 1719 shows that the dealers who belonged to the College were much wealthier on average than the artists. Those among dealers who paid the minimum tax still paid more than did two-thirds of the artists.<sup>111</sup> The situation appears not to have improved in subsequent decades: a document of 1757 reported that many painters worked for dealers, producing “quadri dozenali”, an expression meaning shoddy work but also encompassing the idea of serial painting. The latter sort of production is exemplified by a shipment by an eighteenth-century merchant, to Spain, of paintings that included a series depicting saints, and by a sale in 1751 by a dealer to a visiting German nobleman of 49 readymade portrait and cityscape paintings all within a week, many of the same dimensions, and all at prices between 5 and 6 ducats.<sup>112</sup> Dealers, the 1757 report alleged, often paid despicable amounts (“prezzi vilissimi”) for “quadri dozenali”, but sold them on at prices that were much higher (“assai migliori”).<sup>113</sup>

This view of things is further sustained by the fact that specialist dealers are first mentioned in the late seventeenth century, in records of the new College of Artists, which admitted dealers who were trained as artists, though not on an equal basis.<sup>114</sup> That is very late, compared to, say, Antwerp, where the rule that marketing be in the hands of artists (except for exports), as we have seen, was conveniently ignored, at least during the good years of the mid-sixteenth century. But this does not define the extent of the difference. We find the artist–dealers who were members of the College in Venice, as late as 1769, caught in a sudden lurch toward greater strictness: the College insisted that from that moment the dealers should no longer register with them but with the guild of furniture painters, since they had shown that they did not know how to use the brush.<sup>115</sup>

Why were the painters of Venice, supported by the city authorities, bent on maintaining a policy towards the marketing of paintings that was at odds with their own long-term interest? Any answer must be speculative; Cecchini suggests, however, that there might have been less deliberation than inadvertence involved. The other luxury trades – Turkish cotton, Persian silk, spices, and domestic manufactured and finished goods such as textiles, glass and lace – on which Venice’s wealth rested much more

<sup>111</sup> Montecuccoli degli Erri (2003, pp. 145–146).

<sup>112</sup> Cecchini (2006); Montecuccoli degli Erri (2003, pp. 152ff). The Venetian ducat was equivalent to the Florentine florin.

<sup>113</sup> Montecuccoli degli Erri (2003, p. 146).

<sup>114</sup> Cecchini (2006); Shaw (2006).

<sup>115</sup> Cecchini (2006).

than on paintings, probably absorbed the lion's share of attention.<sup>116</sup> And, after all, the export of paintings did not suffer, nor the wellbeing of the more successful artists. A comparison with the glassmaking industry, however, shows that masters on the lagoon island of Murano, where the industry was concentrated, insisted that dealers in Venice itself only be allowed to sell the most common sorts of glassware. Fear of losing their independence led the masters to retain the exclusive right to sell all high-value sorts of glass, and something similar may have motivated the painters.

Whatever the reason, the marketing of paintings in 17th-century Rome was much less ordered than in Venice, and in part because it was beyond the ability of any authority to control it, the retail market flourished there. The Academy of Saint Luke in Rome prohibited full members from dealing, and, from 1633, levied a tax on all in the city who did engage in marketing paintings. But dealing could not be effectively policed, and there is evidence both that Academy members did trade in pictures, while many others who dealt in them did not pay the tax.

Haskell, in his classic study of the seventeenth-century art market in Rome, noted that artists and buyers were plentiful, and that there was "a growing appreciation of pictures as pictures rather than as exclusively the records of some higher truth".<sup>117</sup> Nonetheless, he passed quickly over dealers, because they "played little part in the lives of the more important painters". That is to say, there are few instances of "distinguished artists" who worked "systematically" for dealers, and few dealers who "ever ventured much beyond the relatively unknown painter".<sup>118</sup>

Recent research, however, unconstrained by Haskell's focus on "important" artists, has begun to reveal numerous instances of artisans selling paintings on the side at low prices, and of quasi-specialized dealers in the mid- to upper reaches of the market.<sup>119</sup> At those levels, archival finds relating to one specialized dealer, Pellegrino Peri (1624–1699), in particular, reveal five new facets of dealing activity in Rome.<sup>120</sup> First, Peri was not just a professional dealer but specialized in "genre" paintings. (He was also the only dealer known to date who made his money solely from paintings.) Then too, of at least six artists known to have worked for him under contract, at least four graduated fairly quickly to independent status, a dynamic for which we have no comparable evidence in the case of Venice. Third, Peri, though his paintings were mostly modest in price, also supplied prominent collectors, including the Pamphilj and Pietro Gabrielli in Rome and Giuseppe Maria Durazzo in Genoa, his home city. Fourth, he sold a *bloc* of paintings to the Pamphilj, a mode of transacting that became more frequent in the course of the seventeenth century, at times in the form of purchasing paintings, though at times also renting, by the room. *En bloc* purchases, and rentals, we might note, were made both by

<sup>116</sup> Ibid.

<sup>117</sup> Haskell (1980, p. 130).

<sup>118</sup> Ibid., p. 122, and p. 123, n.1.

<sup>119</sup> For the former see Cavazzini (2004) and – for the early years of the 18th C. – Coen (2004).

<sup>120</sup> For the details that follow see Lorizzo (2003b, 2006).

those knowledgeable about paintings and by those who sought pictures only as decoration. Fifth, Peri, at his death in 1699, left a stock of 2491 paintings, four times as many as the dealer Van Kessel in Antwerp in 1581, hinting at a market in Rome the scale of which might have matched, or even exceeded, that of Antwerp.

Still other recent archival finds suggest that even renowned collections in Rome might have been formed largely by acquiring paintings on the street, or at dealers' shops, but in either case by direct purchase and *not* via commissions.<sup>121</sup>

These revelations point towards a large, vibrant, and mainly unfettered retail market in 17th-century Rome, of the sort that Venice might have seen but did not, for the reasons we have identified. It is impossible to quantify elements in this market, but we do know that the market in Rome was driven with help from a large transient population, as well as by patronage stemming from the Papal Court. As to residents, Rome grew only modestly, from c. 110,000 in 1625 to c. 120,000 in 1675. But grow it did, while Venice declined, from c. 180,000 in 1550 to perhaps 150,000 in 1600, and c. 140,000 in 1625. Moreover, the resident population in Rome was enlarged by around one-quarter each year because of pilgrims and other visitors, and in a jubilee year it could more than double.<sup>122</sup> The annual demand for newly-made, cheap religious images, therefore, was substantial, quite apart from the patronage of wealthy families and of the Papacy and individuals close to the Popes. As to the population of artists, available contemporary records are not very helpful.<sup>123</sup> Nonetheless, to construct a possible point of reference, we might start with the Academy's list of dealers (*rivenditori di dipinti*) who submitted to the tax on dealing in 1675, a list likely to be more accurate than earlier ones because the tax had recently been reduced. This number was 40. Only some of this number would count as specialist dealers, but if we take an arbitrary fraction, 0.625, or 25 artist-dealers, and multiply it by seven, the average ratio of artists to specialized dealers in Venice from the tax lists of 1712 and 1719, this yields an estimate of 175 artists in Rome in 1675, a number we have used in our [Appendix A](#). It produces a ratio of about 1.5 artists per thousand (resident) population, which agrees with recent estimates by Bonfait based on studies of the residents of two parishes.

Whatever the true number of artists, there were important advantages stemming from the fact that dealers and buyers in Rome (as in Venice) were concentrated by location. The Piazza Navona was a major node.<sup>124</sup> This enabled a wealthy and knowledgeable collector, local or foreign, to shop around within a narrow physical compass and compare offers. The papal palazzo occupied (from 1651) by Prince Camillo Pamphilj, for example, was on Piazza Navona, a step from Peri's shop and those of several other dealers. It was also to this Piazza that John Evelyn went regularly during a visit to Rome in February 1645, drawn by those there who sold "medals, pictures, and such curiosities".

<sup>121</sup> This is argued persuasively, for the famous Colonna collection, by Natalia Gozzano (2003, 2004).

<sup>122</sup> Spear (2003, p. 310); Hibbert (1985, p. 202).

<sup>124</sup> Ibid.

## 5. Selling paintings II: Auctions

We move, finally, to resale markets using the auction method. Here our focus will be on the evolution of rules.

### 5.1. “Dutch” auctions in Amsterdam

The interlopers from Antwerp who held illegal auctions in early 17th-century Amsterdam were said to have used the descending price method. In the same document it was noted that descending price was a method used only in estate sales.<sup>125</sup> In fact it seems likely that only in estate sales where second-hand clothes dealers were expected to predominate was the method used.<sup>126</sup> But perhaps the complainants knew that and mentioned it only to cast a slur on the interlopers’ auctions by association. In any event, the method is no longer employed for sales of paintings. It works best where speed is important (as in sales of perishables); where the goods are more or less interchangeable – so that someone who misses out on a lot can expect to bid for another just like it – and where buyers are very knowledgeable: they do not need the extra information provided in the ascending price, open outcry system. That last sustains our earlier conclusion that the buyers at the interlopers’ sales in Amsterdam were not likely to have been duped.

### 5.2. Magistrate-imposed rules for transparent auctions in 17th-century Lille

Perhaps the most concerted and sustained grab for market share by Antwerp dealers and artists occurred in 17th-century Lille.<sup>127</sup> It began, as far as surviving records allow us to state with certainty, in 1667 – though it probably started much earlier – and continued, more or less regularly, for at least the next forty-five years. There was a long-standing ban against foreigners selling outside the times of the fair, but the Lille magistrates, at a certain point, decided that dealers and some accompanying artists from Antwerp could better serve local buyers than could the city’s own artists. They therefore granted permission to these interlopers to hold auctions after the fair, and extended the period of those sales till all the items brought by the visitors were sold. Surreptitious selling after a fair was not uncommon,<sup>128</sup> but conducting auctions outside the fair openly and with full authorization might have been unique.

The decision to grant permission for post-fair sales was a concession by the Lille magistrates to powerful local buyers, who must have persuaded them that the painters of the city could not supply them with paintings comparable to the “rare and excellent things” brought in by the dealers from Antwerp. Implicitly therefore, the magistrates

<sup>125</sup> See De Marchi (1995) for details.

<sup>126</sup> Montias (2002b, pp. 21–22, pp. 259–260, notes 45 and 46).

<sup>127</sup> See De Marchi and Van Miegroet (2005c). This is our reading of documents rediscovered by Raux, and first analyzed by her in relation to public sales and collecting in Lille, for which see Raux (2002, 2005).

<sup>128</sup> Antwerp dealers did the very same in Paris, as we have seen.

were acknowledging a mutuality of interest between Lille buyers and Antwerp dealers; their permissions in effect promoted a coalition between those two groups, to the disadvantage of Lille artists.

The dealers' overriding interest was to get rid of all their stock – of course at prices that would give them the usual rate of return in their line of business. What did they stand to gain from selling everything? The dealers themselves said that it would save them money on exit tolls and carriage; but they might have added that they would also avoid being stuck, back in Antwerp, with old and tainted stock, and that they would save on interest costs by turning over their capital in a single season. There was also a certainty attached to those gains compared to selling during the fair, and it meant that the dealers could be satisfied with a return from the auctions even a bit below normal for dealers.

It was the buyers' interest as collectors to be supplied, on a sustained basis, with quality items – the Antwerp dealers did not only bring paintings with them. And if clearing everything was so important to the sellers, then buyers too could not but support after-fair sales.

At the fair, sellers, wanting to retain an attractive set of objects for the after-fair sales, set prices artificially high. A few buyers – those with a weak budget constraint, or those who, being risk averse, did not want to lose a piece they admired – would purchase during the fair. But the fair was basically an occasion for display and viewing. Once after-fair auctions became normal procedure, buyers could expect to get a better price for a desired lot at the sales than the deterrent prices posted during the fair.

This was a reasonable expectation, because the magistrates proscribed the devices that sellers commonly use to skew sales in their favor. The Antwerp dealers had to conduct their sales without reserves. That meant everything had to be sold – something dealers wanted anyway – but the magistrates also insisted that everything sold must be by open outcry: no private sales on the side. Finally, the magistrates prohibited false bidding.

These three rules ensured transparency and fairness on the part of the sellers, which in turn gave buyers confidence that the sales would not be rigged against them. As a result, buyers too would have been inclined to play fair. They would have no reason not to bid up to their true valuations, lot by lot, and – equally important – would have felt no need to resort to bidding rings to keep winning bids down. But under those incentives, sellers would also be less inclined to seek out new ways of gouging buyers. In short, the magistrates, knowingly or not, created conditions for the sales that probably improved the chances of mutual fair play, and prices that both buyers and sellers would find acceptable.<sup>129</sup>

<sup>129</sup> This is in line with economic auction theory, which suggests that where auctioneers fully share information with potential bidders their revenue is higher, since no rents accrue to winning bidders who secure a lot with a bid lower than the true value simply because they know – or are assumed to know – something that others do not. See *Milgrom and Weber (1982)*. The transparency insisted upon by the Lille magistrates seems to approximate the full information assumption.

No mechanism could guarantee such an outcome, certainly not lot by lot, or even sale by sale. But, given the desire of both parties to meet each other again and again, dissatisfactions could be signaled – bidding not serious; auctioneer seeming to favor certain bidders – and slight adjustments be made in the course of a selling season. Group interest here dominated individual interest, and any recalcitrant individual ignoring a complaint would be punished. Buyers who did join a ring might face aggressive bidding from other buyers as a way of imposing a “winner’s curse”, while a wayward and non-compliant seller would not be invited to form part of the group from Antwerp the next time around. We are not privy to such behind-the-scenes behavior, but one way or another the system worked: the sellers did come back, and buyers were pleased.

There are hints that Antwerp dealers also sought permission to hold auctions after the fair in Tournai, Douai, Cambrai, Valenciennes, Arras and Ypres. And, as noted earlier, they tried the same aggressive tactic in Ghent in the 1680s, though without success.

### 5.3. Auctioneer-contrived rules, London, late 17th century

The rules insisted upon by the Lille magistrates are unusual in the history of paintings auctions. A set more familiar, at least to Anglo-Saxon audiences, is the rules contained in printed catalogues for auctions held late in the 17th century, in London. Printing rules was done at the initiative of the auctioneer-organizers, who did not pretend expertise – they came to paintings via book and print sales – and who, it seems, were mainly concerned with turnover, on which their fee was based, and with protecting themselves against irresponsible bidders: those who bid for fun and left without paying for lots they had won.

Thus a basic rule required buyers to leave part of the purchase price before vacating the premises, a precaution against irresponsible bidding, or bidding to drive the price up for fun, but where the winner had no intention of paying. Further rules were soon added. One, widely copied, was a minimum increment-of-bid rule. The auctioneer who first introduced this rule stated that it was for his own convenience. The average time per lot in these sales was 1.4 to 2.4 minutes (in Sotheby’s auctions today it is less: 0.5 to 1.2 minutes). Thus the auctioneer had little time to raise the bid, and specifying a minimum increment would have both helped him move bids to a satisfactory level and saved him from the temptation to pull bids from the ceiling. Still other sales advertised that no false bidding would be used and that no commissions – bids by the auctioneer on another’s behalf – would be accepted.<sup>130</sup> The latter rules were appended to a very few sales, implying that the norm was precisely their opposite; that bidders could expect false bids and bids by the auctioneer acting for a seller or for an absent buyer, in both cases for a cut. Finally, in larger sales or more ordinary paintings it was often announced that there would be no undisclosed reserves, possibly a move to encourage and sustain

<sup>130</sup> In modern auctions the seller may not bid; the auctioneer may do so on the seller’s behalf, by prior arrangement, but only up to an agreed minimum. But the auctioneer may bid on another’s behalf.

attendance.<sup>131</sup> Again, by implication, in other sales bidders could expect undisclosed reserves. Today, the major international auction houses announce the relation between reserves and the lower pre-sale estimate, Christie's promising that the reserve will not exceed that figure, Sotheby's that as a rule it will be 75 percent thereof.

The London rules no doubt were an improvement on having no advertised rules at all; nonetheless the auctioneer's hand, and interest, is apparent in them. Intriguingly, modern international rules bear a closer family resemblance to the early London rules than they do to those imposed in Lille which, in turn, are distant kin to modern French rules which, among other practices, preclude buy-ins which end up in the hands of the auctioneer himself.

#### 5.4. *Creating value through auctions: The dealer Gersaint in Paris, 1733–1750*

As we have seen, one control exercised with unusual effectiveness by the Paris painters' corporation in the 17th century was the requirement – akin to the rule in Venice – that would-be dealers first be accepted as artists. A way around the requirement was to train as a *marchand-mercier*, specializing in paintings and related wares.<sup>132</sup> This route was taken by Edme-François Gersaint (1694–1750), and by some before and after him. But Gersaint used his status to effect major changes.

He started out modestly enough but through astute joint ventures and by acquiring expertise in several fields (print-making, porcelain, shells, antiquities, semi-precious stones, and so on, as well as paintings), he was able to realize economies of scope. The great range and exotic character of the goods he stocked (*chinoiserie*, Indian screens, *naturalia*, etc., as well as things in the fields already listed) made of his shop a sort of non-stop fair. He attracted clients at all levels, including those sensitive to price. On the whole, however, his paintings were expensive. He could justify this by claiming special knowledge which enabled him to be selective and could back the claim with an unmatched experience: he made frequent buying trips north to acquire Flemish and Dutch paintings, knew collections and collectors in Flanders and Holland, and had intimate knowledge of auctions there. Gersaint introduced Parisians to the ascending price auction without private side-sales; his sales had printed catalogues; and there were pre-sale viewing days. His catalogues were discursive and instructive, and his sales leisurely, allowing potential buyers to become familiar with paintings, and to form their valuations partly by discussing with, and observing the direction and strength of bidding by, others. In these several ways Gersaint eased control of the Paris market away from artist-dealers.

Among Gersaint's more radical notions was the idea that anyone, in principle, could become amateur lovers of paintings and form a respectable collection, even those without the money, leisure or learning to become true connoisseurs. In pursuit of this ideal

<sup>131</sup> On all this see De Marchi (2004).

<sup>132</sup> The *marchands-merciers* or generalist trader/mercers in Paris were not to produce, but could sell anything made outside Paris.

he sought to wean viewers and buyers from an excessive absorption with the painting *per se*, and especially with authorship and subject. Instead he invited them to consider paintings as bundles of pleasure-yielding properties, an idea similar to Lancaster's fresh approach to demand, adumbrated in the 1960s.<sup>133</sup> Gersaint's marketing ploy was so novel and sophisticated that it merits being spelled out in full. If the viewer's pleasure in a painting is made the primary ground for preference, it becomes possible to argue that paintings by any one of several artists supplying similar desired characteristics – even if differently-bundled – might be considered substitutable for one another. Such paintings constitute a “family” cluster. (In applying his ideas, of course, Gersaint made it clear that any paintings he offered for sale should be understood to be of collectable quality.) The paintings in such clusters, needless to say, would likely fetch different prices. A buyer could choose from among the paintings in a cluster that subset for which each painting yielded equal pleasure for the price. (Price here is to be read as expected price at auction; in other words, Gersaint's informed pre-sale estimates.) A final choice could be made by a bidder from this subset according to what his or her budget would permit.<sup>134</sup>

It was integral to Gersaint's convictions that individual viewers have the right to impart their own value to a painting. This was radical at the time but became a formative idea among artists of the Romantic and later Modern Art movements. The importance of the ideal is that it held the potential to extend the demand for paintings. This was taking dealing beyond the acceptance of marketing as a natural complement to making; it expanded the concept of the dealer to include one who nurtures the love of painting, a role now taken for granted among those who deal in the secondary market.

## 6. Coda

Our overview has been thematic but unavoidably also episodic. We have been reporting on research that is based on scattered documents which have survived or been uncovered largely by good luck, or which exist in large numbers but have not yet been fully explored. There are therefore serious gaps, and the record, such as it is, is always for individual cities. Do the truncated segments of a history we have been able to offer add up to an integrated whole? We began with a temporal sequence in the maturation of an art market, but we can now also attach dates and place names to the several stages, and link them across locations. As a result, too, some new details and emphases can be introduced here.

- (1) In the second half of the 15th century we observe, in Florence, made to order and on spec production in a nascent retail market, parallel to, though artistically derived from, the paintings generated within the commission nexus. A retail market

<sup>133</sup> The parallel is very close. See, e.g., Lancaster (1966).

<sup>134</sup> This decision process is illustrated for a cluster of artists painting Italianate landscapes, and for a cluster of artists who produced Flemish peasant scenes, in De Marchi and Van Miegroet (2005a, 2005b), respectively.

emerged at the same time in Bruges. It was larger, more vibrant, and offered a wider range of novel and differentiated sorts of imagery. Much of the production was cheap, eliciting demand from lower income groups and creating a deeper market than in Florence. The innovativeness of the visual imagery in Bruges stemmed from emulation among artists and competition for market share between three well-defined crafts of painting. The market was also supported by a large, resident and temporary population of relatively wealthy foreign merchants; by the existence of an annual international fair; and by an institutional infrastructure created by the city to facilitate exchanges – elements lacking in Florence.

- (2) Where Florence excelled was in the structuring of estate sales, out of which, around the turn of the 16th century, there grew something resembling a wholesale recycling market. This was dominated at first by old clothes dealers, certain of whom, over time, began to specialize in household movables, paintings among them. The city organizers facilitated this development by separating out lots with art objects. Late in the 16th century, in Antwerp, dealers appeared for the first time as members of the painters' guild, described, however, as second-hand clothes dealers who also traded in paintings.
- (3) The development of new products at the low end in Bruges fostered the habit of buying and displaying easel paintings in large numbers in the home. That particular transition was easier in the Low Countries than in 15th-century Florence, where easel paintings had to compete with paneling and with intarsia (wood inlay) "paintings".
- (4) In the 16th century various designated sales venues for paintings are to be found in Antwerp, the chief of them on the upper floor of a new trading Exchange. Antwerp and nearby Mechelen comprised a formidable production complex, painters in Antwerp specializing in oils and those in Mechelen in watercolors. Paintings from both centers were sold through the Exchange *pand*. Artists in the two cities, combined, numbered at least 200 in the mid-16th century, and were capable of producing upwards of 30,000 paintings per year. This was the first instance of a production capability consciously established to export paintings, though export had occurred earlier in a less planned manner, as in Bruges. Production on a large scale, for export, in Mechelen/Malines and in Antwerp – in the latter city via designated, year-round sales venues – were nonetheless natural outgrowths of the popular market created earlier in Bruges and its textiles display halls.
- (5) Venice, too, emerged in the 16th century as a major center of artistic production. However, in contrast to Antwerp, for example, where the rule that only artists should sell paintings was flexibly applied in the sixteenth century, in Venice it was insisted upon. Artists were allowed to make paintings that had not been commissioned, but only artists were allowed to sell – except for paintings to be exported. This posed time-allocation problems for artists, and predictably led to various selling arrangements being made with others – crafts persons in the same guild, friends and associates, and shopkeepers with no links to painting but

eager to move into their marketing. The ban also favored exports, but it was not easy for ordinary artist-dealers to move into the export trade in paintings, which required specialized experience, networks of contacts, and capital. When local demand slowed relative to the export trade, therefore, artists found themselves dependent on traders and specialist dealers, and having to work for them under contract, on unfavorable terms. That was the situation for much of the first half of the eighteenth century. Yet, in 1769, even dealers who had been allowed to join the College of Artists were told to register in future with the guild of furniture painters. The motive behind this is uncertain, but the proscription on selling by non-artists, it seems likely, was born of a desire to maintain control, albeit one that did not benefit painters in the long run. Venice joins Paris among cities whose painters' guilds resisted the marketing of paintings by others, to their ultimate disadvantage.

- (6) The phenomenon of artists working as "in the galley" was not unknown elsewhere, including 17th-century Amsterdam, Paris and Rome. However, in Antwerp, painting for a dealer was also an arrangement within which artists for the first time were able successfully to claim payment for invention. Vertically integrated dealers operating there treated original paintings made for them as means to generate copies and thereby an income stream, out of which payment for invention could readily be made. Viewing the original as capital was the conceptual and practical perspective within which this made sense. Earlier conceptual models may have existed in tapestry cartoons and the engraved printing plate, both of which were considered (and priced as) capital assets. With original paintings viewed as capital, however, even lesser painters had a framework within which they could successfully claim payment for invention. This was a first; artistic ingenuity had been valued within the commission nexus in Florence but was not necessarily paid for, patrons often claiming the originating idea as their own.
- (7) The period 1600 to 1750, the opposition of selected artists' guilds notwithstanding, was the era of the dealer. Quasi-specialist dealers arose in Rome in great numbers, as they had in Antwerp. Whereas in Antwerp the demand of foreign traders was important, however, in Rome demand was swelled by pilgrims and other visitors. The differences between Venice and Rome widened over the course of the seventeenth century. Specialist dealers in Rome employed beginning and newly-arrived artists, established themselves in concentrated areas close to wealthy buyers, and gave their artists such exposure that in many instances these artists could become independent upon serving their contracts – a dynamic not noticeable in Venice. Evidence is also emerging which suggests that even prominent collectors in Rome bought major portions of their collections on the piazza, or from dealers, probably using the great numbers and the physical concentration of artists and dealers to create a bargaining advantage for themselves. Recent research has also begun to reveal details of a low-end market in Rome, where non-specialist dealers also flourished. And it is showing that renting whole

rooms was not uncommon, certainly among those merely seeking decoration but also, for reasons that need to be explored further, among collectors.

- (8) Specialist dealers in a net-exporter market – the Antwerp–Mechelen complex, for example – displayed a wide variety of creative plays to secure market share. Traders based in Antwerp became involved in shipping large quantities of paintings abroad. But Antwerp dealers who chose to stay when local demand showed signs of slowing, found themselves engaging in forays to other cities accessible by land, to increase their share of those markets. Various stratagems were tried, ranging from experimenting with the descending price auction in Amsterdam, to holding post-fair auctions in Lille, though on conditions for transparency laid down by the local magistrates. There were also individual Antwerp-based dealers who drove a sophisticated and far-flung traffic in paintings, using agents, to Augsburg, Vienna, Paris, Lisbon, Bilbao, Seville, Cadiz and the Americas. Such specialist dealers were not merchants with a sideline in paintings. They employed business practices developed by international trading firms and indistinguishable from them, except that as suppliers to foreign markets they were, inevitably, also involved in mediating visual culture across traditions. In a net-importer city such as Amsterdam, by contrast, dealers served more as arbitragers, helping to supply local demand by redistributing surplus supplies originating in other cities. By the 17th century, too, dealers were trading in both new and older – recycled – paintings; in the latter trade they competed with second-hand dealers, who also at times tried to enter the first-sales market.
- (9) If the 17th century was the era of the trader–dealer in many variants, the 18th was the century of the auction. Regular auctions involving paintings were held by the Amsterdam Orphan Chamber in the early decades of the 17th century. However, the first auctions for which we possess printed catalogues with rules, are sales held later in the century, in London. Those sales, nonetheless, were mostly got-up affairs, organized and run by bookseller-auctioneers with no special knowledge of paintings. Paris became the more innovative center in the first half the 18th century. There, extensive, informative catalogues were printed; viewing days were provided; and the sales themselves were leisurely, serving as occasions for arriving at private valuations partly through social exchange. A higher tone was set than in London, where the rules were written by and for the auctioneers. The first prominent dealer and organizer of auctions in Paris, Gersaint, voluntarily adopted the no-friendly-sales rule that magistrates had insisted upon in Lille, and took a responsible attitude towards attribution, at the same time seeking to wean potential buyers away from an undue preoccupation with authorship and subject. He stressed instead that value stems from the pleasure a painting gives to its viewers. Others took up Gersaint’s model – professional dealing by a non-artist – and, by the 1770s, 20–40 sales a year were being held in Paris, surpassing London’s early lead.

## 7. Some developments since 1750

Our coverage ends around 1750, but we can indicate briefly and selectively some more recent developments.

A partially integrated auction circuit developed during the 18th century, incorporating Amsterdam, Brussels, London and Paris. It did not result in common prices for the same artists because tastes differed; moreover, transport costs and the associated risks limited the physical movement of all but high-end paintings. These impediments did not outweigh the arbitrage possibilities for dealers operating between sales centers. The Amsterdam sales in particular served to recycle 17th-century Dutch collections to Germany, while many French collections were dispersed internationally through auctions in the 1790s. Private and public purchases on behalf of Catherine the Great, in the second half of the 18th century, supplied the core of the exceptional collection of the Hermitage in Saint Petersburg. Late 19th- and early 20th-century buying in Western Europe also built the collections of wealthy Americans, most of which, under positive incentives in the US tax code, have since become, or made their way into, public museums. The first great museums in Europe, eventually all open to the public, were established in the 18th century,<sup>135</sup> and have grown subsequently in lockstep with legislation in many countries restricting the export of “national treasures”.

The structure of the international market in paintings quickly acquired the features by which it was characterized in the 20th century. The two great auction houses, Christie’s and Sotheby’s, both date from the mid-18th century, and their rules reflect those preserved for us in the printed catalogues of the late 17th-century sales in London. Transparency, however, has increased, though it is still less than total.

The rules followed by the leading international auction houses are still not universally adopted; moreover, the degree of transparency shown by Sotheby’s and Christie’s is still rare. Until quite recently, too, the international auction market was less than fully integrated, being circumscribed by national restrictions. Thus many countries insist on an export license, which tends to keep international-quality paintings off the market altogether; and in France and Spain, for example, a right of preemption is assumed by the state, while in France until very recently auctions could be conducted only by French auction houses.

Another peculiarity of the international resale market is that the two dominant houses, Sotheby’s and Christie’s, do not constitute a conventional duopoly. Both represent sellers in the first instance, and sell services: they are not producers. They battle, therefore, chiefly to secure collections in markets where stocks are small and declining. This entails making concessions to potential sellers which cause costs to rise. Costs increase, for example, because lesser works (which cannot be refused) often are more difficult to

<sup>135</sup> A short list, supplied by Sophie Raux, includes: the British Museum (1759), the Pinakothek in Munich (1779–1793), the Capodimonte in Naples (1739–1793), the Louvre (1793), the Vatican Museum (1784) and the Imperial Museum in Vienna (1781).

authenticate, and because the seller's premium must be discounted or price guarantees given to a seller on single items and even whole collections. Such concessions and the higher costs they entail led, in 1995, to an agreement between Sotheby's and Christie's to apply a common, non-negotiable sliding scale of seller charges. This was exposed later in the decade as illegal collusion, at which point Phillips auction house was positioned by its new owners, the French consortium LVMH, to topple the leaders. The tactic used was to offer concessions to sellers of the very sort the leaders had concluded they could no longer afford to make. When the art market slowed in 2001, this strategy turned out to be a loser, and the two leaders again find themselves unchallenged at the top, though they are also rumored to have re-started competitive inducements to sellers. Recent reports also suggest that they may be expanding into the territory of dealers, and increasingly engaging in private sales.

The unsustainability of the competitive pressures in select, older markets, such as those in Old Master paintings, drawings and prints, and Impressionist paintings, probably helped induce the proliferation in recent decades of sales in new fields, including, in the case of Christie's Amsterdam, sales of copies. Sotheby's also flirted briefly with online auctions. This has ended, except for relatively low-priced items, but both auction houses retain their lower-end physical auctions in separate locations in London. The market in Contemporary paintings and more generally for low-priced works has continued to expand, aided by new online information services (e.g., Artprice) and by online auctions such as eBay and Lauritz.com.

Gallerists proliferated in the 20th century, especially in the primary market for Modern and Contemporary art. This is a segment of the art trade characterized by the same radical uncertainty as movies – discussed by De Vany in his entry in this Handbook. The idea that the modern gallerist – one who invests in beginning artists' careers – originated in late 19th-century Paris, has been disputed. The true model of this type it seems is a post-World War II New York phenomenon. The modern contract between a beginning artist and a gallerist, however, currently often involving a fifty-fifty split of sales revenues after costs, is to be found in early 20th-century Paris.

As to the status of artists, their right to have the artistic integrity of their work protected came to be widely recognized in the 20th century, as was an artist's right – or that of heirs – to a share of the proceeds of secondary sales. It is not clear that this last supports those who need it most – unknown artists will continue to need willing, risk-loving gallerists – while those who benefit are likely to be relatively few, and the benefits necessarily accrue after the greatest need for income is past. Nonetheless, there is momentum to enlarge the number of countries with an artists' resale right. Copyright law, meanwhile, as shown in the entry on copies in this Handbook by Ginsburgh and Benhamou, continues to evolve, courts tending to recognize that even replicas, provided they embody considerable skill and labor, are not in breach of copyright. The status of digital images, however, remains uncertain.

## Appendix A

### A.1. Number of painters per '000 of population, by city, 1470–1764

The following chart (Table A.1) summarizes estimates of artists per thousand inhabitants of various cities in the early modern period. Where possible more than one observation is provided. Many of the estimates are to be taken as having a large potential range of error, not only because population numbers are uncertain, but also because numbers of artists often have to be inferred. Moreover, it is not always clear from the sources whether “artist” is to be taken in the narrow sense of one trained in design and figurative painting, or has a broader connotation. The value of the exercise lies not in the accuracy of any single estimate but in broad consistency of the ratios presented here with other things that are known about a city. For example, it is known from fairly reliable counts that Amsterdam, even at its peak as a center of production of paintings (c. 1650), continued on balance to be net importer of paintings. This is reflected in the ratios of artists per thousand inhabitants not rising above 1.0. Ratios significantly above

Table A.1

	Florence	Bruges	Valencia	Venice	Antwerp	Mechelen	Haarlem	Paris	Amsterdam	Rome
1470/72	0.8	1.4								
1488		2.8								
1496					0.6					
1513			0.3							
1520		1.7			2.0					
1526					2.4					
1530				0.8						
1542/43					1.5					
1550					1.4					
1566/68					1.5	5.3				
1585/86					1.3					
1588/89					1.8					
1605							0.4			
1611								0.4		
1612					2.2					
1615							0.8			
1619						3.5				
1625							1.1			0.4–1.5
1630/31					1.7				0.9	
1632						3.5				
1635							1.9			
1640				1.1						
1650							1.8		1.0	
1675										1.2
1677								0.5		
1764								1.0		

one, on the other hand, are consistently found for cities such as Bruges, Mechelen and Antwerp which, on other grounds, can safely be dubbed net exporters of paintings. As a rough rule of thumb, therefore, a ratio consistently somewhat above 1.0 inclines us to think that a city was a net exporter of paintings, an inclination always to be checked, however, against collateral historical evidence. In some cases the ratio rises or falls over time indicating, in principle, an alteration of status (e.g., Haarlem, Rome and possibly Paris).

## A.2. *Sources and methods*

*FLORENCE*. Benedetto Dei [1470, for which see Gilbert (1980, p. 183)] listed some 30 painters with their own workshop. However, several on that list were already dead. Wackernagel reports “about thirty” figure painters listed in 1472 as members of the Accademia di San Luca, which artists were supposed to join [Wackernagel (1981, p. 300)]. We have used the number 30. Population in 1469: Herlihy and Klapisch-Zuber (1985, pp. 40, 332) [also in Goldthwaite (1982, p. 33)].

*BRUGES*. In the years 1456–1470, 44 new masters were added to panel and cloth painters, joining 12 members in 1456, for a total of 56 in 1470, assuming zero deaths, retirements, or net immigration of artists. Population in 1449, c. 5000 [Nicholas (1992, p. 371)]. We have adopted this number, amplified by 500 to allow for some net immigration. By 1488 the population might have been 36,000 [Blockmans (1995, Table 2)], while the number of painters – same assumptions as above – had risen to c. 90. By 1520 the number of artists was about 60 while population was still c. 40,000.

*VALENCIA*. A tax record from 1513 lists 19 workshops of figurative painters (one workshop with two masters) [Falomir (1996, p. 211)]. The population early in the 16th century is estimated from the number of houses in 1510 – 9,879 (ibid., 109) – to which we have applied the generous assumption of 6 persons per household, yielding a population of c. 60,000.

*VENICE*. “Figurers”, gilders and miniaturists in 1530 numbered 110, if the same ratio applied to all 230 guild members as to the 77 with a craft listed [Favaro (1975, pp. 137ff., doc. I.1)]. Population in 1530 c. 130,000 [Beltrami (1954, p. 59)]. For artists in 1640, we have used the number 138, based on a guild list for tax purposes of that year [Favaro (1975, pp. 163ff., doc. II.2)], and for population, the figure of 120,300 for 1642 [Pezzolo (2003, p. 151)].

*ANTWERP*. Three absolute counts of painters are known from guild lists: 14 in 1453, 108 in 1585–1586, and 76 in 1588–1589 [the latter two reported by Vermeylen (2003, p. 112, n. 19)]; the number for 1453 and all other estimates arrived at from a list of annual guild inscriptions for master painters [Martens and Peeters (2002)] plus conservative assumptions about length of career (15 years 1453–1467; thereafter 20), zero net emigration 1453 through 1500, thereafter 5 masters per year through 1604, 7 through 1609, 10 through 1617, and 15 through 1625. This results in estimates of the number of painters of 23 in 1496, 102 in 1520, 131 in 1526, 124 in 1542–1543, 140 in 1550, 152 in 1568, 121 in 1612, and 95 in 1630. Population figures: Vermeylen (2003, Table 2, p. 37) and references there cited, plus, for 1520, 1550 and 1630: Van Houtte and Van Buyten, in Wilson and Parker (1977, p. 82).

*MECHELEN/MALINES*. We used the contemporary count of 150 workshops, adjusted downwards by the ratio of known *painters* to total masters, and adding in assistants in the ratio of 27 per 100 master painters, from a 1632 document, to yield 159 painters for 1566, when population might have been 30,000 [Previer and Blockmans (1986, p. 79)]. In 1619, 95 masters protested

against out-of-town dealers. The transcript of a 1632 *Rekenboek van het schildersambacht van Mechelen* recorded 100 workshops [Monballieu (1971, p. 75)]. Known master *painters* plus assistants in those years averaged 69, in a population of perhaps 20,000–21,000 (latter figure from Van Houtte and Van Buyten, in Wilson and Parker (1977, Table 4.3).

**HAARLEM.** Artist and population figures, except for 1650, due to Boers, reported in Sluijter (2000, p. 137, n. 19): 11 artists in a population of 30,000 in 1605, 29 in 35,000 in 1615, 44 in 40,000 in 1625, and 80 in c. 42,000 in 1635. For 1650, Montias estimates 68 artists in a population of c. 38,000 (1990, p. 61). All numbers for painters very conservatively counted.

**PARIS.** Schnapper (2001, pp. 424–425) estimates painters and sculptors in 1611 at 110–115 in a population of c. 300,000. We have applied the 17th-century ratio of 2 : 1, painters to sculptors, to arrive at an estimate of 75 painters in 1611. For 1677, Schnapper estimates painters alone at 185, in a population of c. 450,000. For 1764, he determines that there might have been some 600–700 painters, assuming a ratio of painters to sculptors of roughly 2 : 1, and allowing something for widows and “demoiselles”, who were not counted in the 17th century, in a population of perhaps 600,000–650,000.

**AMSTERDAM.** Montias puts artists in 1630/31 in the range 90–120 [Montias (2002a, p. 117)], in a population of c. 115,000: Frederiks and Frederiks (1890, v.). For 1650, Montias estimates 175 artists in a population of 175,000 [Montias (1990, p. 61)].

**ROME.** The number of artists in 1625 is from a house-by-house census: Lorizzo (2006). Population in 1625 (c. 110,000), from Sonnino (1998). We have estimated the number of artists in 1675 by assuming, first, the same number of specialist dealers as in Venice (average of two observations: tax documents from 1712 and 1719), and using the same ratio of artists to dealers there, namely 7 : 1 [Montecuccoli degli Erri (2003, pp. 145–146)]. We applied this ratio to a fraction, arbitrarily set 0.625, of the number of self-declared dealers in paintings in a 1675 tax list in Rome, namely 33, yielding an estimate of the number of artists of 144 in that year. [For the tax record generating 33 dealers see Lorizzo (2003a, pp. 331–332).] The population in 1675 is estimated to have been about 120,000 [from Sonnino (1998)]. The number 175 is close to that estimated by Bonfait (2003), who found for two parishes in the early decades of the 17th century roughly 1 to 3 artists per thousand population, and takes 1.5 as a reasonable per annum average for the century as a whole. A detailed count of artists who authored public works, using older published sources, has been undertaken by Spear (personal communication). His yearly average total of artists active in Rome falls short of Bonfait’s estimate but provides a solid base from which to make upward adjustments for obvious under-counting (e.g., of works in private collections, and of foreign artists). There is conflict between Bonfait’s 1.5 yearly average number of artists per thousand population and our number for 1625, but we have included both to give a range.

**Abstract**

This chapter traces the development of markets for music over the past several centuries. Formally organized music was at first supported primarily by churches and the nobility. Indeed, during the 18th century there was a kind of “arms race” in which noble houses competed for prestige through the quality of their orchestras and operas. Gradually, however, the role of churches and the nobility declined and more market-oriented venues, including vibrant markets for free-lance performance and composition, became dominant. A survey of 646 musicians born between 1650 and 1849 quantifies these trends, along with the increasing tendency for composers to earn their livelihood in part by teaching in conservatories and other music schools. The same data set is tapped to show the various ways in which composers learned their musical skills. When the data are analyzed in still another way, Austria is found to be the most intensive employer of composer–musicians per million population and also to have given birth to the largest number of composers relative to its population. The territory that in 1990 was Czechoslovakia was second in births; Germany was second in employment. One means by which composers derived income, especially with the ascendance of free-lance composition, was publication of their creations. The evolution of publishing technology and music copyright is traced. Gradually, as income per capita grew in the industrialized nations, audiences for musical performances broadened until by the end of the 19th century mass markets came into being. Radio and the phonograph radically transformed the ways music was enjoyed and widened the market for music even more. The electronic media in turn intensified a tendency that was already evident in the early 18th century – the ability of a few “superstars” to achieve spectacular financial success.

## 1. Introduction

Music has been a vital part of human society for as long as there is recorded history. The oldest known musical instrument, a seven-hole Chinese flute, was carbon-dated in 1999 to the year 7000 BC. Not long after the Israelite exodus from Egypt, Joshua is said in the Old Testament to have breached the walls of Jericho by having seven priests blow ram's horn trumpets while circling the city. In the mythology of ancient Greece, the god Apollo playing a stringed lyre is said to have won a competition, judged by the muses, against the flute-playing satyr Marsyas.

One characteristic making music interesting from the perspective of economics is that it is an activity that eventually came to be market-oriented, giving rise to a complex set of vertically-linked enterprises. Consumers derive satisfaction from hearing music and performing it themselves. When individuals or families perform music, they must be trained to do so, often by specialized teachers offering their services privately or through schools. Most of the music they play is composed by other specialists, whose works reach the players through the intermediation of music publication firms. Music is performed on instruments produced by still another specialized industry. And when consumers enjoy music performed by others, the performances are typically organized by patrons, churches, or concert management organizations, which employ professional musicians either regularly or in a series of ad hoc market transactions. Or in more recent times, the music is supplied by electronic recording and/or broadcasting enterprises.

These various industries together entail a substantial amount of economic activity, only parts of which are systematically measured. In the United States during 1998, 183,000 persons were employed as musicians and/or composers [US Bureau of the Census (1999, p. 242)]. Sales of musical recordings in 1996 amounted to \$12.5 billion; instrument sales were \$1.17 billion; and in 1997, music publishers had sales of \$1.36 billion (*Ibid.*, p. 587). For 45 of the estimated 350 professional classical music-performing orchestras in the United States on which systematic data for the 2001–2002 season are available (usually for the more prominent ensembles), annual budgets totaled \$1.14 billion. The largest single budget, at \$197 million, was that of New York's Metropolitan Opera [American Federation of Musicians (2003)].

This chapter focuses on facets of the music “enterprise” that are either explicitly market-oriented or occur within organizational frameworks, with emphasis on the composition and performance of classical music. This by no means denies the fact that in many nations there are long traditions of folk music passed on informally from generation to generation, or that “popular” music now enjoys much wider market appeal than the classical music emphasized here.

## 2. The evolution of music performance venues

Since the earliest times, markets have gradually come to play an increasingly prominent role in the organization and supply of music. Two of Richard Wagner's operas

deal with alternative modes in which musical activity was organized in Europe during the Middle Ages. Under one mode, skilled minstrels wandered from town to town performing their music and enjoying the hospitality (including financial support) of local barons. *Tannhäuser* embellishes on an actual gathering of German minstrels around the year 1210 (documented in the *Codex Manesse*) at the Wartburg castle near Eisenach (much later, the refuge of Martin Luther and the birthplace of Johann Sebastian Bach). Organized by Duke Hermann von Thüringen, it was a competition among the best-known minstrels, including Wolfram von Eschenbach, Walther von der Vogelweide, and Klingsor from far-off Hungary. In the opera version, the prize is the hand of the duke's daughter Elisabeth in marriage. What the actual prize was remains unclear; it must at least have been Olympian prestige and probably also a monetary reward. Wagner's *Meistersinger von Nürnberg* parodies the amateur singing societies or guilds that sprang up in German towns during the middle ages – in the case depicted by Wagner, in the commercial town of Nürnberg during the early 16th century. Strict rules were enacted for the forms in which songs could be sung, and members of the guild performed in periodic competitions with the goal of winning temporary possession of a silver necklace prize awarded to the entrant who committed the fewest singing errors.

### 2.1. Church support

A venue for music performance with even longer historical roots was the church, or more accurately, the assortment of Christian orthodoxies. Plainchant was a significant but growing component of Roman Catholic services from at least the conversion of the Roman emperor Constantine (312–337). By the eighth century, it became known as Gregorian chant. During the middle ages, song during church services began to be accompanied by an organ, first in monasteries and then in lay churches. The music performed in Roman Catholic churches became increasingly elaborate, culminating in the exquisite antiphony and polyphony of Giovanni da Palestrina during the 16th century. In 1562 and 1563 the Council of Trent considered a mandate requiring music during the Catholic mass to retreat toward monophonic forms that “may be clearly understood by all”. Although guidelines were adopted, rigid rules were opposed by Holy Roman Emperor Ferdinand I, and as a result, subsequent popes chose to decentralize musical decisions to local prelates. One hundred flowers were allowed to bloom, leading *inter alia* to the richly orchestrated masses of Johann Sebastian Bach, Joseph and Michael Haydn, Mozart, and Beethoven.

Meanwhile, Martin Luther, who spearheaded the Protestant Reformation with the posting of his 95 *Theses* in 1517, argued that music, as an “excellent gift from God”, should have a central role in religious services – among other things, in the form of chorales sung by the entire congregation. Within the Protestant denominations there were strong differences of opinion. Music flourished in German Lutheran parishes, as it did within the Church of England. In Switzerland, on the other hand, followers of Huldreich Zwingli eliminated singing and organs from their services, and in England under Puritan Oliver Cromwell (between 1649 and 1658) music was banned from church ser-

vices and organs were removed or even destroyed. The Restoration under Charles II among other things returned music to the churches. Thus, both in England and on the European continent, diverse opportunities opened up for the employment of musicians as choir directors, organists, choir members, and (in the better-endowed parishes) orchestra members. Some of the more important parishes also maintained choir schools that trained many generations of fledgling musicians.

As the Middle Ages gave way to the Renaissance, musicians became less itinerant and began to move from amateur status to regular employment. Churches provided one important locus of long-term employment. European towns also hired musicians to be “pipers”, performing regularly on flutes, trumpets, and drums with local militias and at town celebrations. And wealthy, typically noble, households began retaining musicians as regular members of their staffs, rather than relying upon occasional visits by wandering minstrels.

## *2.2. Support from noble courts*

In many parts of Europe, church and state were closely linked. Kings and local feudal lords were responsible for sustaining church services at their residences, and as such, established chapel musical establishments. The chapel musicians were commonly asked to do double duty performing at festive occasions and in some cases regularly during meals. Gradually a division of labor emerged, with some musicians assigned primarily to chapel duties and others assigned to provide entertainment in the royal household. This duality existed, for example, at Versailles during the reign of Louis XIV (1659–1715).

What happened in central and southern Europe was of the utmost significance for the development of music as a professional activity. Between 1618 and 1648 most of Europe was enmeshed in a devastating Thirty Years War. When the war ended with the Treaty of Westphalia in 1648, what is now Germany was divided into several hundred individual kingdoms, principalities, and dukedoms, some Protestant and some Catholic, each required to yield only minimal deference to the Holy Roman Emperor. In Austria, which also controlled Hungary, what later became Czechoslovakia, and parts of northern Italy, political power was more centralized in the Kaiser-Emperor, but feudal lords governed at the local level. The parts of Italy not under Austrian subjugation were also divided into many smaller political units, some under Spanish or French rule, some under papal domination, some surviving as feudal states under local kings or dukes, and some (such as Venice) as independent city states.

Especially in the German-speaking parts of Europe, populations were decimated by casualties, famine, and disease resulting from the Thirty Years War. Most of the arable land was controlled by feudal lords with noble titles, e.g., king, prince, or duke. With fewer mouths to be fed, land rents at first fell. But as populations were restored following the Treaty of Westphalia, rents gradually rose, and noble landlords profited. Somehow – the exact historical dynamics are uncertain – it became fashionable for local sovereigns and lords to establish their own court orchestras and, in the larger dominions, their own

opera houses. Individual local nobles began competing for prestige through this form of conspicuous courtly consumption. See especially *Elias (1969)* and *Raynor (1972)*. The competition escalated in a kind of cultural arms race, so that by the first half of the 18th century, no self-respecting court in what had been the Holy Roman Empire could be without its court orchestra or other group offering regular musical entertainments.

This proliferation of noble courts with musical ensembles is said to have given rise to a golden age of musical creativity. Augmenting a similar hypothesis advanced by sociologist *Norbert Elias (1991)*, *William and Hilda Baumol (1994)* asserted:

Obviously, economic and political conditions cannot create talent, but they certainly can either inhibit it or provide opportunities for its exercise. Our main hypothesis is intended to narrow the pertinent geography – to help account for the striking level of composing activity emanating from Germany and Italy. This hypothesis suggests that the political division of the Holy Roman Empire and the Habsburg possessions into many petty states worked to produce the circumstances (notably substantial demand and a profusion of jobs) that help to explain the profusion of musical productivity (p. 172).

Although the noble courts provided abundant employment opportunities for musicians and, for those with the creative talent to rise from the instrumentalist ranks, for composers, court employment was not without its disadvantages. Once a musician had secured a court position in what was a fairly competitive job market, he could not leave that position without the lord's express permission (or under some contracts, until the lord's death). Johann Sebastian Bach was imprisoned for nearly four weeks in 1717 when he attempted to break his contract with the Duke of Weimar. Mozart was fearful that if he returned in 1783 to visit his father in Salzburg, he would be imprisoned by Prince-Archbishop Colloredo, whose employ he left without permission two years earlier. On the other side of the ledger, a musician could be discharged summarily at the lord's whim – an experience that led Georg Philipp Telemann to remark that “whoever seeks life-long security must settle in a republic” – that is, in a job not dependent upon feudal lords. In addition to addressing their masters in the most abjectly deferential language, musicians were required to wear the livery (uniform) prescribed by the master. Niccolò Paganini was discharged for his failure to do so in Parma. Among other things, masters stringently limited outside dissemination of works composed by their court musicians. When Nicolò Jommelli left the service of Duke Carl Eugen of Württemberg in 1769 during a budgetary crisis, he was not allowed to take with him copies of the operas and other works he had composed. And discrimination in the wages paid musicians could be extreme. The highest salary Carl Philipp Emanuel Bach (son of Johann Sebastian Bach) received as harpsichordist and composer in the court of King Frederick the Great of Prussia was 500 thaler per year (about £80 at the exchange rates prevailing at the time), while Johann Quantz and Karl Heinrich Graun were paid 2000 thaler and leading opera singers employed by the court were paid as much as 6000 thaler.

During the second half of the 18th century and early decades of the 19th century, noble court support of musical ensembles was substantially reduced. There appear to have

been three main reasons for this change. First, major wars, notably, the Seven Years War between 1756 and 1763 and the Napoleonic wars between 1792 and 1815, drained the treasuries of many local and territorial governments. Second, the “arms race” in conspicuous musical consumption raised the costs of maintaining a suitable musical program to the point at which many courts found themselves unable to keep pace. Third, feudal oppression of the peasants employed on feudal lords’ vast landholdings (encompassing a majority of the continental European population in 1750) lost its intellectual support as a consequence of Enlightenment philosophical arguments and because it proved to be much less efficient than agriculture carried out by well-motivated land-owning smallholders.<sup>1</sup> Emancipation of European peasants was accelerated by revolution – notably, the French revolution of 1789 and the brief revolutions of 1848 – and the abolition of many feudal rights by French occupying forces during the Napoleonic wars.

Feudal reform also reduced the resources available to religious establishments, and especially the Catholic Church, for the support of musical activities. In particular, lands owned by clerical establishments were confiscated in Austria under enlightened Emperor Joseph II during the early 1780s and in France following the 1789 revolution.

### *2.3. The rise of private sector support*

Replacing court and church support of musical activity to some extent was the growth of middle-class citizens’ demand for musical performances and training. The industrial revolution originating in England during the 18th century and spreading gradually to the European continent increased both the number and wealth of middle-class merchants, manufacturers, financiers, and barristers with means sufficient to enjoy the consumption of music in its various forms, notably, through both home performance and participation in public concerts. London, vanguard of the industrial revolution, developed a thriving private-sector concert life during the 18th century.<sup>2</sup> Amsterdam and some of the leading mercantile cities of Germany and Italy (notably, Venice) expanded private-sector music venues in parallel. Other European cities gradually followed suit. For musicians, there were increased opportunities to obtain employment with orchestras organized outside feudal courts, to undertake free-lance virtuoso performances, to give music lessons to the children of an expanding middle class, to compose works that would yield revenue through publication or commissions from private orchestras, and to join the faculties of a growing number of music schools and conservatories. Part of this change entailed a shift from one mode of employment to another under less servile conditions. Part represented a shift from earning a living as an employed musician to market-oriented free-lance activity.

In opening up opportunities for free-lance music composition and performance, opera was the leading-edge sector. The prototype for modern opera, Claudio Monteverdi’s

<sup>1</sup> See Blum (1978) and Delon (2001).

<sup>2</sup> See McVeigh (1993).

*Orfeo*, was performed under the sponsorship of the Duke of Mantua, Italy, in 1607. As enthusiasm for opera spread, some noble courts in Italy, Austria, France, Germany, and Russia emulated the pattern established at Mantua. The sovereign or feudal lord built an opera house, created a managerial structure and participated in its decision-making, and provided regular subsidies to sustain continuing performance schedules. This had two disadvantages: given the competition for prestige among various courts, a tendency toward excessive or even ruinous expenditures; and the inflexibility or stifling of creativity that can come from bureaucratic decision-making.

An alternative originated in the free mercantile city of Venice with the opening of the first public opera house, San Cassiano, in 1637. Under the pattern established in Venice, a group of wealthy citizens joined to contribute funds needed to build an opera house, obtaining in exchange for their contributions preferred boxes and the right to nominate a management committee. The management committee retained an impresario, who, with the advice and consent of the committee, laid out a program of performances, chose libretti for new operas, negotiated with composers ad hoc contracts to provide the necessary musical score in collaboration with the librettist, hired singers, musicians, scenery designers, and the like; and attended to the thousand-and-one details required for successful performances. The impresario also accepted some of the financial risks attending the performances he organized, not infrequently sustaining substantial losses and fleeing creditors in the dark of night. Noteworthy also in this organizational schema is the fact that composers, librettists, and leading singers competed on a free-lance basis to make their contributions. The Venetian system was widely emulated in other parts of Italy and eventually in some German cities (notably, those not controlled by feudal lords), London, Vienna (beginning around the onset of the 19th century), and New York, among other locations.<sup>3</sup>

### 3. A quantitative perspective

How these complex changes evolved over time can be seen through a quantitative analysis, drawn from Scherer (2004), of a sample of 646 music composers born between the years 1650 and 1849. The composers were chosen on the basis of two criteria: for creating works with sufficient survival value to be listed in the *Schwann Opus* catalogue of recorded music for Fall 1996; and by leaving a sufficient historical record that their biographies were published in the *New Grove Dictionary of Music & Musicians* [Sadie (1980)]. The number of composers in each of the four half-century birth date cohorts was 141 for 1650–1699, 148 for 1700–1749, 168 for 1749–1799, and 189 for 1800–1849.

Each composer's biography was coded for various attributes, including places of birth, family background, educational background, how the composers earned a living, and the geographic locations in which they worked during their lifetimes. Figure 1

<sup>3</sup> See Bianconi and Pestelli (1998) and Rosselli (1984).

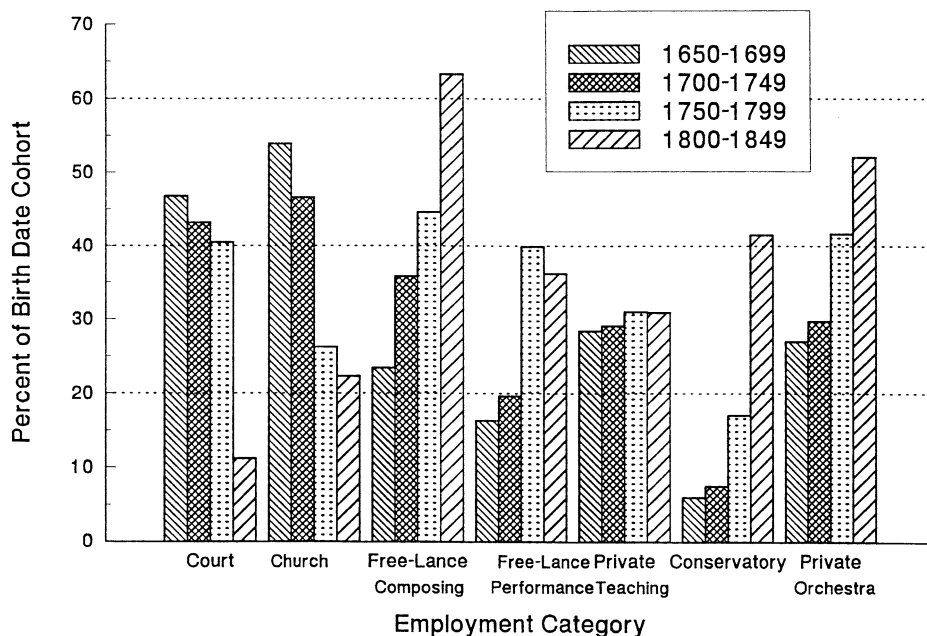

Figure 1. Trends in composer employment over two centuries.

provides broad insight into the ways composers earned their living. Only activities classified as “primary” or “secondary” to a sample member’s occupation are counted. Six categories are traced by 50-year birth date interval:

- (1) employment with noble courts, excluding the receipt of subsidies not conditional upon regular employment duties;
- (2) employment as a church musician or music director, excluding religious duties unconnected with music;
- (3) seeking compensation as a free-lance artist composing music for impresarios, publishers, or performance in self-initiated concerts;
- (4) free-lance performance on self-initiated concert tours or as an ad hoc featured soloist in orchestral concerts;
- (5) teaching in a conservatory or other public music school;
- (6) free-lance teaching (outside the scope of organized music schools and conservatories); and
- (7) participation as either a performer in or director of orchestras unaffiliated with church or nobility.

Needless to say, sample members often pursued more than one of these activities, either at successive career stages (e.g., when Johann Sebastian Bach left his job as Kapellmeister for the Prince of Köthen to become director of music in four Leipzig churches and the Thomasschule), or simultaneously (e.g., when Bach moonlighted

as director of a private concert-giving ensemble, the Collegium Musicum, during his church and school employment tenure in Leipzig). On average, composers born in the 1650–1699 period, as Bach was, were coded as engaging in 2.01 primary or secondary activities, as categorized in Figure 1. For composers born in 1700–1749, the average was 2.11; for 1750–1799, 2.41; and for 1800–1849, 2.57. Thus, composers tended to embrace a wider array of occupational categories with the passing years.

We observe sharp decreases over time in the fraction of sample composers employed in courts and churches, with the most dramatic changes materializing for composers born during the first half of the 19th century for court employment and the second half of the 18th century for church employment. There was a concomitant rise in the fraction engaging in free-lance composing and performance activities. The increase in free-lance composing was fairly steady over time, whereas for free-lance performance, activity peaked for sample members born between 1750 and 1799. Further analysis reveals that most but not all of the 33 composers from the 1650–1699 birth cohort with primary or secondary free-lance composing wrote at least two operas – an activity in which free-lance efforts predominated. There is no clear trend in private tutoring, which ranges from 28.4 to 31.0 percent over the four birth date cohorts. Conservatory teaching rose briskly for composers born between 1750 and 1849. So also did participation in private-sector orchestras.

To extend the sample into later periods, a much smaller and less representative sample of ten classical music composers born after 1850 was drawn. With birth and death dates in parentheses, it includes Edward Elgar (1857–1934), Gustav Mahler (1860–1911), Arnold Schoenberg (1874–1951), Ottorino Respighi (1879–1936), Béla Bartók (1881–1945), Paul Hindemith (1895–1963), Aaron Copland (1900–1990), Kurt Weill (1900–1950), Dimitry Shostakovich (1906–1975), and John Cage (1912–1992). The composers in this “modern” sample are uniformly more prominent than the median composer in the earlier, larger sample of 646. When the biographies were coded using criteria matching as closely as possible those applied to the larger sample, only one composer is found to have been employed by “nobility” – Shostakovich, supported by agencies of the Soviet Union such as the Union of Soviet Composers. None had significant church employment. All engaged in significant free-lance composition. Four were free-lance performers; six performed in and/or directed private-sector (including municipal) orchestras; at least five gave private lessons; and eight taught for substantial periods of time in conservatories or their modern equivalents, the music departments of universities. Confirmed with particular strength are the tendencies toward declining noble and church employment and the increase in free-lance and conservatory teaching activity.

To sum up, over a period of two-plus centuries, there was a transition from support of music composers – the elite of professional musicians – by churches and the nobility to support through more market-oriented institutions, and especially free-lance activities. The changes were gradual and evolutionary, and not linked closely to particular composers such as Mozart and Beethoven, as some students of musical history have suggested.

### 3.1. Building human capital

From the sample of 646 composers born between 1650 and 1849, insights can also be gleaned on how the sample members learned their trade. For 532 composers, there was sufficient historical information to identify principal learning modes. In many cases several forms of learning were pursued by a single individual; thus, young people might initially be tutored by a family member, then move to instruction from an unrelated professional musician, and then, at least in later periods, receive formal conservatory training. Altogether, 1.83 codes were assigned on average per sample member.

Figure 2 summarizes the results. Within-the-family tutoring was evident in nearly half of all cases, and, because of gaps in the historical materials, its incidence is undoubtedly underestimated. By far the most ubiquitous form of human capital building was private instruction with a professional musician. Although no attempt was made to assess the quality of named teachers, the high incidence of well-known names was striking. Talent is attracted to talent, which in turn leads to professional success. As conservatories were established throughout Europe, there was a sharp rise in formal conservatory training for musicians born between 1800 and 1849. Church choirs and affiliated choir schools provided training for more than a quarter of the sample members born during the second half of the 17th century, but their role faded as the years advanced. Especially in Czechoslovakia and Germany, as defined according to 1992 borders, the primary and secondary school curricula included substantial musical education. The self-teaching

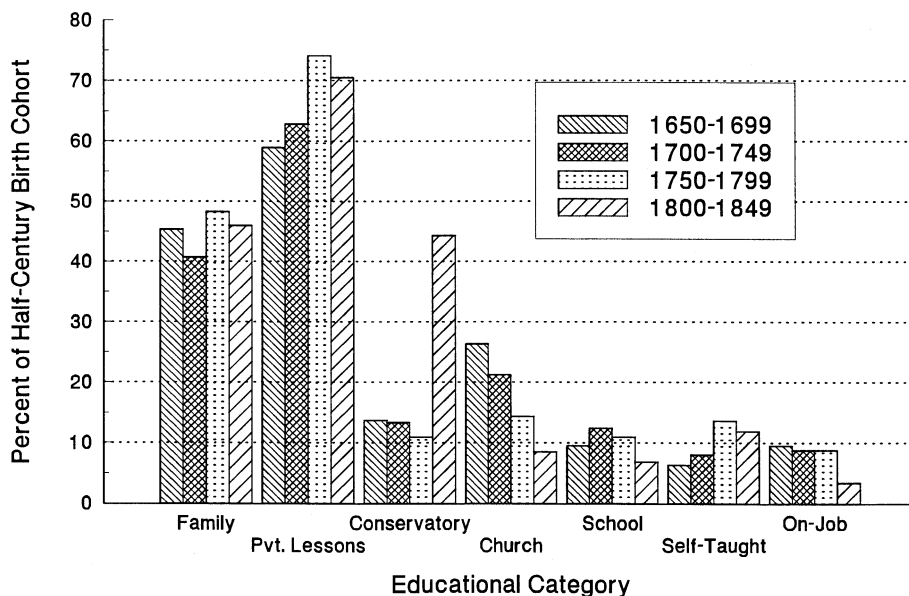

Figure 2. Percent of half-century cohorts with diverse career preparation modes.

and on-the-job-training categories were coded conservatively, counting only cases in which no other training was evident at a formative period or in which a youth joined a court orchestra long before reaching maturity.

### 3.2. *National differences*

Classical music composition during the 18th and 19th centuries was preponderantly a European enterprise. Among the sample of 646 composers born between 1650 and 1849, only 17 were born outside Europe, notably, in North and South America. Figure 3 shows for the principal European nations and national groups, as defined by borders existing in 1992, the number of composers born and employed per million population. The raw counts are divided by national population estimates at the time of birth for birth data and at age 35 for the employment counts. The employment counts are for “working life equivalents”. That is, for any given sample member, the number assigned to a nation in which the composer worked for two years or more was the fraction of the composer’s life from age 20 on spent in that nation.

Austria – home to Mozart, Haydn, Schubert, and (in his mature years) Beethoven, among others – led other nations in both composer births and working-life-equivalent years of residence relative to its (modest) population. The other remnants of the Holy Roman Empire – Germany, Italy, and Czechoslovakia – were the next most prolific producers of composers relative to their population. Russia, with a huge serf population and a particularly small class of noble and middle-class music consumers, trails far behind on both dimensions. Germany, with the richest proliferation of independent noble courts, was second in employment of composers per million residents.

Dividing the employment counts into the birth counts, one can see which nations were the most vigorous importers of composer–musicians and which were exporters. Austria leads the list of importers, with 1.66 equivalent composer working lives per birth; England, with wealthy London as a magnet to immigrant musicians, was second; France with Paris as a magnet was third. Czechoslovakia was in relative terms the leading exporter, followed by Italy. Czechoslovakia’s inability to retain its numerous home-grown composers was the result of both demand and supply-side forces. On the demand side, its leading city, Prague, was small relative to most other European nations’ capitals, and many Bohemian nobles spent the most fashionable seasons, when music performance was at its peak, at their town houses in Vienna, the imperial capital. On the supply side, there is probably truth in Hector Berlioz’ observation that “I must say – since it is a matter of public notoriety – that the Bohemians are the best musicians in Europe, and that the love and feeling for music are universal in all classes of society” [Berlioz (1966, p. 414)].

Apart from this cultural factor, which cannot readily be measured, three main hypotheses contend to explain the intensity with which diverse nations or national groups attracted composers into employment. More employment per million population is expected:

Figure 3. Births and employment of composers per million population.

- (1) in the four remnant nations of the Holy Roman Empire, especially before the decline of feudal courts as the 19th century dawned;
- (2) in nations such as England, France, and Austria with rich magnet cities; and
- (3) in richer nations, as measured by gross domestic product per capita.

Where WORKLIVES is the measure of equivalent working lives per million population plotted in Figure 3; GDP is (crudely estimated) gross domestic product per capita, measured in 1990 dollars; COURT is a zero-one dummy variable with unit values for Germany, Austria, Czechoslovakia, and Italy for each of the first three half-century periods; and MAGNET is a zero-one dummy variable for nations with magnet cities (with Russia added only for the fourth half-century interval); the resulting regression equation was as follows:

$$\begin{aligned}
 \text{WORKLIVES} = & -0.29 + 0.00080 \text{ GDP} + 1.127 \text{ MAGNET} + 2.497 \text{ COURT}; \\
 & (0.41) \quad (1.41) \qquad (2.70) \qquad (5.58) \\
 R^2 = & 0.505; \quad N = 40.
 \end{aligned}$$

T-ratios are given in subscripted parentheses. All three variables have the expected signs and help explain variations in composer employment per million population across four half-century intervals in ten nations or national groupings.

Russia began to absorb western European musical culture on a significant scale during the reign of Catherine the Great (1762–1796). St. Petersburg and Moscow attracted numerous traveling musicians in the first part of the 19th century, during which time a Russian school of composition also grew under the leadership of Mikhail Glinka.

The United States was an even later arrival, but arrive it did. By 1850, New York City had a larger population, excluding suburbs isolated by water barriers, than any European city excepting London and Paris. The New York Philharmonic Society began a regular concert series in 1842. An opera series was established at the New York Academy of Music in 1854. The Academy was displaced following the success of the Metropolitan Opera, whose creation was precipitated in 1883 by a dispute between old and new wealthy factions over the allocation of boxes.<sup>4</sup> Many prominent European music performers, composers, and directors were attracted through the high salaries offered by New York organizations and the orchestras of other leading American cities. At the beginning of the 20th century, as the United States moved ahead of England in having the world's highest average gross domestic product per capita, most of the musicians in the Metropolitan Opera orchestra were from Europe, and rehearsals were conducted in a combination of German and English.<sup>5</sup> But as formal musical training expanded with the founding of the Boston Conservatory in 1867, the Michigan University School of Music in 1892, and the forerunner of the Juilliard School in 1905, among others, the United States began to generate its own indigenous supply of musicians and moved into the forefront of world musical culture.

#### 4. Music publishing and intellectual property

One way music composers could earn free-lance income was by selling their works to publishers or, when the music publishing industry was still in its infancy, engaging in self-publication. In the late middle ages, church music was printed using fixed wooden blocks into which staves, notes, and other symbols were carved. Adapting Johannes Gutenberg's 15th century movable type invention to music printing was difficult because music notation is much more complex dimensionally than simple letter text. Improvements in printing music with movable type accumulated over a period of three centuries. During the 18th century, printing music engraved onto copper or pewter plates was the dominant technology, and there was a proliferation of music publishing houses, a few of which (e.g., Breitkopf & Härtel, Schott, and Ricordi) survived into the 21st century. In the 19th century, lithography appeared as a viable lower-cost alternative to typeset and engraved printing. High-speed rotary presses and computerized note-setting have reduced relative costs even more.

Through much of this formative period, hand copyists provided important competition to music publishers. Opera houses retained copyists to produce parts for the various

<sup>4</sup> See Fiedler (2001).

<sup>5</sup> See again Fiedler (2001, p. 16).

ensemble members, and composers employed copyists to make copies for distribution to patrons and potential publishers as well as for the musicians performing new compositions. Under the traditions prevailing in Italy during the 18th century, the impresario for a new opera had the right to the composer's original score and the copyist to the first copy. The copyists then made additional copies which they sold to provincial and foreign opera houses. When composers hired copyists, it was not uncommon for the copyist surreptitiously to make an additional copy, from which they then derived additional copies for sale to a network of music lovers. Noble courts made copies of their composers' works for exchange with other courts in order to expand their performance repertoire, and once a copy reached some other domain, it was difficult to prevent further copying and circulation. The copies that proliferated in this way were often riddled with errors, but the business thrived.

Music publishers often obtained musical manuscripts through these indirect channels and published a printed version without the composer's permission. Absent effective copyright protection, publishers also pirated for distribution in their home market the works published by their peers in other territories. Rampant piracy limited the revenues composers could derive through authorized publication of their creations.

Music composers were not without some rights to the works they created. Plagiarism, i.e., claiming another person's creation as one's own, was widely condemned. In the 16th through 18th centuries, the principal opportunity for obtaining more secure intellectual property rights in one's musical creation came through the granting of "privileges" by national or local governments. A composer could appeal to the sovereign for an exclusive privilege to publish works within the relevant domain, or publishers could obtain exclusive privileges to publish certain classes of musical compositions. To be sure, political connections and/or bribes might be necessary to obtain a privilege. However, Hansjörg Pohlmann (1962, p. 186 ff.), the leading student of the history of musical property rights, argues that in some parts of Europe, the privilege system was sufficiently open and transparent that it resembled a modern copyright system. Yet even when privileges could be obtained, they were difficult to enforce. And when a geographic area was fragmented into many independent political entities, as Germany was following the disintegration of the Holy Roman Empire, a privilege issued, say, in Mainz had little or no jurisdictional reach to prevent the piracy of a musical work in Leipzig, Munich, or Hamburg, let alone in non-German-speaking lands.

England was the first nation to enact a modern copyright law, the Law of Anne, in 1709. Its application to musical works was first clarified in 1777 through a law suit brought by Johann Christian Bach, the son of Johann Sebastian Bach. France replaced its privilege system – probably the most effectively functioning one in Europe – with a copyright law following the revolution of 1789. The United States passed a copyright law for the protection of domestic residents in 1790; under it, the works of foreign authors and composers could still be pirated legally. In Germany, Austria, Czechoslovakia, and Italy – as we have seen, the most intensive centers of musical composition – copyright law was slower to come. In 1825 a petition drafted by composer Johann Nepomuk Hummel, urged on among others by Ludwig van Beethoven, asked the assembly

of German-speaking nations to overcome their differences and enact uniform copyright laws to prevent publishers from “getting fat by robbing without penalty their neighbors’ property”. The petition is reproduced in Benyovszky (1934, pp. 131–133). It spurred the formation of a committee to study the problem, and eventually, in the late 1830s, most of the German states passed copyright laws protecting *inter alia* musical works. The Austrian version covered Austrian possessions in northern Italy as well as Czechoslovakia, and in 1840 Austria entered into a mutual copyright accord with the Kingdom of Sardinia (including Savoy), so that the opportunity to secure musical copyright extended to much of Italy, excluding the Kingdom of Naples and the Papal states. The Berne Convention of 1887 allowed composers (and authors) to obtain copyright in any signatory nation, so in effect, the copyright system became world-wide. In the United States, a relatively late signatory, the number of musical copyright applications rose from 9132 in 1890 to 29,151 in 1920 and 52,309 in 1950. In 1950, there were nearly as many copyright applications for musical works as there were for periodical prose works.<sup>6</sup>

Giuseppe Verdi was the first composer of note to derive substantial advantage from the Austrian–Sardinian copyright regime. With his publisher Giovanni Ricordi, he began collecting opera performance fees from the numerous provincial opera houses, at first on a flat fee basis and then, when Ricordi recognized that price discrimination would yield higher revenues, on a graduated “ability to pay” basis. They also aggressively published “reductions” of individual opera arias for voice and piano, solo piano, violin, flute, string quartet, and many other combinations, selling them to the countless opera-loving families of Italy. Through these activities Verdi became quite rich, and as his wealth grew, he reduced the pace of his opera-writing efforts, from 14 operas in the decade of the 1840s to seven in the 1850s, two in the 1860s, and one each in the succeeding three decades. From Verdi’s letters emerges introspective evidence that his was in effect a backward-bending labor supply curve.<sup>7</sup> It cannot be ruled out, however, that the fortune Verdi accumulated by selling his works had a demonstration effect, inspiring others to try their hand at composing.

## 5. The popularization of musical culture

Up to the onset of the 18th century, paying to hear music performed was a pastime enjoyed mainly by the nobility and the wealthiest members of a relatively small middle class. Gradually, however, increasing prosperity plus technological and organizational innovations broadened audiences and ultimately engendered nearly universal public access to professionally performed music.

One event that signaled a change in audiences for music was the London premiere in 1728 of John Gay’s *Beggar’s Opera*, an irreverent pastiche of already-popular and

<sup>6</sup> See US Bureau of the Census (1960, p. 606).

<sup>7</sup> See Scherer (2004, Chapters 4 and 7).

new English-language songs that enjoyed 62 performances during its first season and was repeated in every London season for the next seven decades. (The plot was later adapted successfully in the Brecht–Weill *Threepenny Opera*.) Several public gardens were opened beginning in the 1730s, presenting open-air concerts during the summer and charging admission sufficiently modest that, according to a contemporary 1786 account:

There were last night above 6000 persons present, among them some of the first people in the kingdom, but as is always the case at Vauxhall, it was a *melange*; the cit and the courtier jostled each other with the usual familiarity; the half guinea was no repellant to the middling order; John Bull loves to shoulder his superiors in rank . . . and where he pays as much for admission, he never considers them to be more than his equals [quoted in McVeigh (1993, p. 41)].

In Vienna during the early decades of the 19th century a counter-part to Vauxhall Gardens emerged through ball rooms in which members of the middle classes waltzed to the music of Joseph Lanner and Johann Strauss Sr. At the peak of Strauss' popularity, these venues were expanded so that they could accommodate 50,000 participants simultaneously. By 1830, Strauss had 300 musicians under contract, whom he deployed in groups of 25 to play in the various ball rooms.<sup>8</sup>

In Paris another means of providing music to large numbers of listeners, “the monster concert”, was pioneered by Hector Berlioz. Berlioz' first such concert, in 1844, was held in an industrial exhibition shed, attracting an audience of 8000 to hear music performed by a thousand instrumentalists and singers.<sup>9</sup> A later monster concert organized by Berlioz in 1855 attracted an audience estimated at 40,000. The pinnacle of 19th century monster concerts was probably reached in the Boston (Massachusetts) Peace Jubilee of 1872. For it, Johann Strauss Jr. was paid \$100,000 plus traveling expenses to direct an orchestra of 2000 and a chorus of 20,000 performing Strauss compositions before audiences estimated at 100,000 persons [Fantel (1971, pp. 194–195)].

The performance of music at home provided a market for instruments and sheet music. Julia Moore (1987, pp. 50–64) punctures the myth that in music-loving Vienna during the time of Beethoven, there was a piano in every house, showing that the original source claimed a piano in the home of every educated family – a major difference in a time when higher education was rare. However, as education spread and prosperity increased, so also did the presence of pianos in homes. Using estimates by Ehrlich (1990, p. 222) and then US Census of Manufactures data, Figure 4 traces trends in new piano production in the United States from 1850 through 1930. Solid circles mark the years for which production estimates are available; the connecting lines are interpolated. Piano production did grow rapidly during the first seven decades, at an average rate of 4.3 percent per year. Scherer (2004, Chapter 2) estimates an income elasticity of piano

<sup>8</sup> See Fantel (1971, pp. 36 and 194–195).

<sup>9</sup> See Holoman (1989, pp. 308–311 and 476–477).

Figure 4. New piano production in the United States, 1850–1939.

demand over this period in the range of 3.16 to 4.32, depending upon the econometric specification used. Transforming the production data into cumulative (but depreciating) stocks, it is estimated that in 1850, the maximum home ownership rate (assuming no ownership by schools, churches, and taverns) was 5 percent. By 1923, it peaked at approximately 23 percent.

The steep decline in piano production during the mid-1920s, a time of extraordinary prosperity, cries out for explanation. (The earlier decline in 1921 was attributable to a sharp but brief recession.) The answer is simple: home radios entered the market in the early 1920s, followed by the introduction in 1924 of electrical phonographs with fidelity far superior to that of the acoustical phonographs previously in use. By 1927, 10 million American homes had radios, and a roughly equal number owned phonographs. A new different way of consuming music (and much else) in the home had appeared, changing radically the character of American family life and making music available every day to families that otherwise would have attended public concerts only rarely.

Electronics also changed the criteria for success as a musical performer. For vocalists in particular, power in an amplifier substituted for the previously essential vocal cord power.

During the 1920s it was believed that radio would allow wider dissemination of classical music, educating and upgrading public tastes. There was in fact an abundance of classical music programming. But especially in the United States, where radio transmitters were more dependent upon advertising than were the publicly-owned stations of Europe, sponsors soon found that broadcasting popular music was more effective in attracting the mass audiences they sought. The weekly Guy Lombardo show was

an early success beginning in 1928. By the late 1930s, the Lucky Strike Hit Parade, which offered renditions of the week's ten best-selling tunes, drew one of the largest radio audiences. As additional channels became available with the introduction of FM broadcasting following World War II, radio stations began to specialize in the content provided. Among the nearly five thousand US stations specializing in music broadcasts during 1994, the largest number (2642) emphasized country music – many, to be sure, in remote rural areas with small populations. There were 44 classical and fine arts specialists [*World Almanac* (1999, p. 186)].

Phonograph records and later compact disks also tapped mass markets for all kinds of music. The first year in which more than one billion musical recordings (including a relatively new genre, music video tapes) were sold in the United States was 1994. In that year, rock and roll music, which achieved popularity in the 1950s, led the market with 35.1 percent of unit sales, country music was second at 16.3 percent, and “pop” music placed third at 10.3 percent. Classical music records had a 3.7 percent share [*World Almanac* (1999, pp. 187–188)]. The share of classical record sales declined over the years, e.g., from 25 percent in 1950 and 5 percent in 1980, in part because each new record must compete with the established repertoire accumulated over three centuries, much of which had already found its way into record buyers' libraries.<sup>10</sup> In the more popular forms of music, the life span of the typical new composition is short, but there is a constant proliferation of new varieties seeking to differentiate themselves from previously recorded tunes.

The decline in classical music market shares parallels another more ominous alleged trend – the “graying” (i.e., aging) of audiences for live classical music performances, combined with a tendency for music directors to force upon audiences *avant garde* music appreciated by few.<sup>11</sup> However, a 1997 survey yielded optimistic signs [*US Bureau of the Census* (1999, p. 275)]. On average, 16 percent of the surveyed Americans had attended at least one classical music performance during the preceding year. The highest attendance rate by age category – 20 percent – was for persons 45 to 54 years old. Respondents in the 18–24 year old category, however, had the same 16 percent rate as the entire population, suggesting a potential for future audience-building. The lowest (11 percent) rate was for persons 25 to 34 years old. Not surprisingly, attendance at live classical music performances rises with income per capita and education, reaching maxima of 35 percent for those with annual incomes above \$100,000 and 45 percent for persons who have attended graduate school.

The ability of musical composers and performers conveniently to reach a market encompassing the entire world intensified a phenomenon already evident three centuries earlier: superstardom.<sup>12</sup> At the outset of the 18th century, the leading musical superstars were castrati singers, who were in demand throughout western Europe and who

<sup>10</sup> See Arnold (1997).

<sup>11</sup> See, e.g., Holland (2003).

<sup>12</sup> See especially Rosen (1981) and Hamlen (1991).

traveled to wherever the rewards were highest. Before he retired to Spain and became chamber musician and confidential advisor on matters of state to Kings Philip V and Ferdinand VI, castrato Farinelli (whose given name was Carlo Broschi) earned £5000 during the 1735–1736 opera season in London, the most lucrative market, at a time when English building craftsmen averaged £30 per year.<sup>13</sup> A century later Niccolò Paganini, considered the most brilliant violinist of all time, netted £10,200 from six concerts in London after a spectacularly successful tour through Continental Europe. The most successful classical music superstars of the late 20th century were the Three Tenors – José Carreras, Plácido Domingo, and Luciano Pavarotti. Their concert during the 1994 World Cup football championship games in Los Angeles attracted a “live” audience of 56,000 persons, was broadcast throughout the world on television, and yielded record sales of some 9 million units. For a follow-on concert at the 1998 World Cup playoffs in Paris, the Three Tenors received an advance payment against anticipated broadcast and record sales royalties of \$18 million. Their receipts paled, however, in comparison to those of the most successful popular music stars. The best-selling musical record of all time is said to be Michael Jackson’s album, “Thriller”, which from its launch date in 1992 achieved sales of 46 million copies. In 2002, Jackson’s accumulated financial net worth was estimated to be in the range of \$250 to 350 million. But by that time Jackson’s reception from the public was fading visibly. Similar popularity declines befell most superstars during the heyday of classical music composition – that is, in the 18th and 19th centuries. But Jackson, unlike his golden-throated predecessor Farinelli, is unlikely to find a second career as advisor to national sovereigns. In that sense too, conditions change.

**Abstract**

This essay addresses the definition of artistic and cultural goods by the commonsense and pragmatic assertion that they are respectively goods that carry artistic and cultural (non-economic) values. However, these categories of non-economic value are themselves highly contested and require clarification for the definitions to be viable. The essay suggests an interpretation of the distinction of economic and non-economic values, and of non-economic cultural value, by drawing on the ideas of Nozick. For artistic value, the essay argues that creativity is a central concept, and explores the learning on creativity to be found in cognitive science. Cognitive science sees creativity as requiring both novelty and appropriateness to a particular cultural community. These insights underline some of the characteristics of markets for creative goods, including artistic goods, that cultural economists have stressed in their work independently of cognitive science. For artistic goods in particular, consumers join in the creativity of the artists, and this joint creativity enables us once again to invoke Nozick's concepts of intrinsic value and identify artistic value as a particular instance of non-economic value. The definitions are defended as coherent in the light of their consistency with economic thinking on stimulus goods and learning-by-consuming. Intellectual property is seen as overlapping but not necessary to artistic and cultural goods. Nothing in this essay should be taken as final, but, rather, as a possible starting point for a substantive discussion of non-economic values in these fields.

... we should define [terms], so as to agree with the sense in which they are understood in [the] ordinary use of them. When the sanction of this authority is not attainable, on account of further distinctions being required, the next best authority is that of some of the most celebrated writers in the science, ... It is acknowledged, however, that a change may sometimes be necessary; and when it is, the natural rules to be attended to seem to be, ... That the alteration proposed ... on the whole be obviously more useful in facilitating the explanation and improvement of the science. [Malthus, *Definitions in Political Economy* (1827)]

## 1. Introduction

Cultural or artistic goods bring to mind the famous comment about pornography. The appropriate definition of “cultural goods” or “artistic goods” is far from obvious. On the one hand, there may be common underlying, or interconnecting phenomena that lend themselves to definition of a range of commodities reasonably called “cultural” or “artistic”. On the other hand, not everything can be stuffed into the definition. Some associations have to be left for empirical demonstration<sup>1</sup> and some may simply be fallacious. It may be that common usage is inconsistent, so that no definition can account for all of it, or a definition intended to correspond to common usage might be so broad (though consistent) and consequently so vague as to be useless. A definition must be definite. It seems fair to say that we have no definitions for cultural or artistic goods that are authoritative in either of Malthus’ first two senses, so a definition of these categories of goods will have to be justified by “facilitating the explanation and improvement of the science”.

For the “improvement of the science”, empirical reliability is one important criterion of success, but coherence is also important. Like value, coherence is “not just some vague laudatory term”.<sup>2</sup> As I use the term, a discourse is coherent if it is consistent with (though not necessarily deducible from) a compact set of fundamental propositions. One way to show that a discourse is coherent is to display the set of fundamental propositions and show that other propositions in the discourse are deducible from the fundamental set, with a few auxiliary assumptions that may vary from case to case. Neoclassical economics is highly coherent in that sense, and it seems that economists place a high value on coherence. In any case, one objective in defining terms is to assure that the terms admit of a coherent discourse, and a major objective of this essay will be to argue that the definitions offered here do that.

<sup>1</sup> This reflects the methodological stance known as operationalism. Bridgeman (1952) observes that, in order for empirical tests to be performed, there must be at least two distinct sets of operations that may or may not be correlated. To attempt to include all possible associations in the definition would prejudice the empirical issues.

<sup>2</sup> The quotation is from Nozick (1989); see further below.

## 2. Definitional issues

### 2.1. Culture

We might begin by adopting a consensus definition of “culture”. However, the word “culture” presents yet another complex of difficulties of definition. In the broadest anthropological sense, culture is more than “high culture” and “popular culture” taken together. Rather, culture in this sense encompasses everything that people derive from their tradition and heritage, including folklore and kinship patterns, “material culture”, religion, and so on. In what follows, the word “culture”, otherwise unqualified, will be used in this anthropological sense, although it is an open question whether there is a definition of culture that is applicable across cultures. Kroeber and Kluckhohn (1963) devote a large book – and the power of their knowledge of anthropology, the human science that focuses on the study of culture – to the search for a viable definition of culture in the anthropological sense. Economists might well hesitate to retrace their steps.

How then may we distinguish artistic and cultural goods and services from other goods and services? It would be convenient if we could say that cultural goods are goods that carry cultural values, and that artistic goods are goods that carry artistic or aesthetic values. These conceptions of values are, if anything, even more contested. Nevertheless, that will be the strategy of this essay. Because of the contested nature of all the relevant issues, the essay is unavoidably rather speculative, but is offered with the hope that it will provide some “fit”. While that “fit” cannot be finally demonstrated, an attempt will be made to show that some of the ideas and concerns with long histories in cultural economics are unified by the proposed definitions.

### 2.2. Economic and non-economic values

“Economic values” as discussed in neoclassical economics are derived from the preferences of individuals. The claim that there are non-economic values distinct from economic values implies that the non-economic values are intrinsic or objective in the sense that they are independent of individual preferences. Critics sometimes assert that neoclassical economists neglect non-economic values, focusing only on economic values. This is a misunderstanding. In a passage many neoclassical economists regard as definitional, Lord Robbins (1952, p. 30) writes “Aesthetics is concerned with certain kinds of ends. The beautiful is an end which offers itself for choice in competition, so to speak, with others. Economics is not concerned at all with any ends as such”. From this point of view, there is no difficulty with non-economic values; economics has to do not with any particular realm of values, but with the balancing of different values and different realms of value.

But this view is an obstacle to communication between economists and others interested in cultural and other forms of public policy. It does seem that the issue here is

pragmatic:<sup>3</sup> advocates of active cultural policy pose their proposals in terms of a distinction between economic and cultural values. If economists cannot speak to such a distinction, then economists cannot contribute to the solution of the problems posed. The difficulty, then, is to construct a scheme in which one can meaningfully distinguish economic from non-economic values.

As a tentative basis for a distinction, consider the ideas of Robert Nozick, a social philosopher known for his free-market views and his affinity to neoclassical economics. Nozick (1981, pp. 162–164) writes:

The notion of value is not just some vague laudatory term. Some things have value only as a means to something else that has value. And some things have a value of their own, an intrinsic value.<sup>4</sup> This notion of intrinsic value is the basic one; other kinds of value exist by their relation to intrinsic value. . . . Let us consider things frequently said to be valuable in themselves. We begin with works of art. Recall what happens in art appreciation classes. You are shown how the different parts and components of a painting are interrelated . . . You are shown how the painting is a unity . . . A painting has aesthetic value, theorists have held, when it manages to integrate a diversity of material into a tight unity often in new and striking ways. Such a “unity in diversity” was termed an *organic unity* . . . The greater the diversity that gets unified, the greater the organic unity, and also the tighter the unity into which the diversity is brought, the greater the organic unity . . . Its organic unity *is* its value.<sup>5</sup>

Nozick’s concept of value is not special to art, even though it begins with an aesthetic example. Indeed, Nozick’s argument is that the same unity-in-diversity is the basis of all intrinsic value, and Nozick promptly extends it to scientific value (and specifically, by implication, coherence: p. 163), to the value of an ecological system (p. 164), and to the value of the mind-body unity of a thinking being (p. 165). However, it might

<sup>3</sup> Like everything else of concern to this chapter, pragmatism has its own problems of definition. For a useful survey of pragmatism, see Haack (2004). Haack stresses the differences among pragmatists, especially between the founders and more recent philosophers who have taken that name. She concludes “ask, rather, what we can borrow from the riches of the classical pragmatist tradition, and what we can salvage from the intellectual shipwreck of radical contemporary neo- and neo-neo-pragmatisms” (p. 34). However, the centrality of *the problem* is expressed in the editorial note to the first issue of the journal *Contemporary Pragmatism*, which precedes Haack’s survey: “A scholarly journal, like any intellectual enterprise, has meaning only insofar as it contributes to efforts to resolve some practical problem” [Shook and Ghirdelli (2004, p. 2)]. This understanding of the meaning of an intellectual enterprise is characteristic of pragmatism.

<sup>4</sup> Utilitarians would criticize the notion of intrinsic value as confused thinking, along the following lines: to say that something is good is to say that it does someone some good, so that intrinsic value – something that is good regardless of whether it does anyone any good or not – is simply confusion. Nozick does not attempt to refute this critique, nor shall we. For a related argument see Baron (1994) and my comments on it [McCain (1994)].

<sup>5</sup> Emphases in the original. Of course, the discussion of intrinsic value has a history of thousands of years, but contains various concepts, many of them theological. In the interest of coherence, this essay relies *specifically* on Nozick’s conceptualization.

not even be a complete account of aesthetic value. It strongly suggests an Apollonian, not a Dionysian beauty. Nietzsche (1871) writes “that in the Greek world there exists a huge contrast, in origins and purposes, between visual (plastic) arts, the Apollonian, and the non-visual art of music, the Dionysian”. For him the highest art arises from the unification of these radical opposites, the Apollonian and Dionysian, unity in diversity even in aesthetic principles. On the other side, value in Nozick’s sense needs not be additive nor partible, even if it is measurable – and Nozick disavows any attempt to measure it. Is something that is possibly unmeasurable, not additive and not partible, really value? Partisans of the labor theory of value will have their doubts!

It should be observed that Nozick does not represent this as the last word on intrinsic value (nor does this essay). On the contrary, Nozick’s objective, as explained in *Philosophical Explanation* (1981) and *Invariances* (2001), “is to open possibilities for consideration, not to close them . . . the reasons . . . to support them are meant to launch them for exploration, not to demonstrate that they are correct” [Nozick (2001, p. 3)]. The discussion of value in this essay is presented in the same exploratory spirit. On this basis, what can we say about *economic value*? A human being is a remarkable unity of a diversity of parts, tiny material parts and spiritual and mental parts, a thing of great intrinsic value. And since the capacity to choose between alternatives is one important function of such a creature, her choices derive a certain instrumental value as realizations of herself. This, then, is the basis of economic value, measurable by willingness to pay (perhaps with adjustment for ability to pay), and as such, additive and partible. The apparatus of economic theory, including preference systems and Pareto-optimality, is well adapted to considering the choices of individual human beings without giving distinction more to one than another; that is, to the analysis of economic value as it is constructed here. But this would be only one sort of value, indicating the truth in the idea that neoclassical economics is focused on economic values.

### 2.3. *Cultural value*

Human groups may also have their distinct value, that is, unity-in-diversity. Nozick tentatively (p. 73) allows a loving couple as a novel unity with its own intrinsic value. Larger groups with distinctive cultures, such as tribes and nations, probably have less unity but much greater diversity, and so some degree of intrinsic value. Nozick (pp. 166–168) relates meaning to value: “Value involves something’s being integrated within its own boundaries, while meaning involves its having some connection beyond those boundaries . . . Meaning can be gained by linking with something of value”. Thus symbols and practices that link the cultural group have meaning to that group, and by enhancing its unity, enhance the intrinsic value of the group.

Klamer (1997) relates how windmills came to be identified with Dutch national culture, and how this change in the anthropological or popular culture of Dutch people was associated with the rise of Dutch nationalism. He writes (1997, p. 82): “Whether a windmill is exemplary of Dutch cultural heritage depends on the common values that people share, on their culture” [Klamer (1997, p. 75)]. Accordingly, it seems appropriate

to consider windmills as “cultural” goods, in some sense we have yet to define. Many of the same things can be said about covered bridges in North America.<sup>6</sup>

Some cultural economists and others have argued that no attempt should be made to justify cultural policy by an appeal to “economic value” alone [Throsby (2001, pp. 31–34 et seq.; 2003, p. 282)]. Throsby draws on concepts from economic development and argues that investment in “cultural capital” may be necessary for the sustainability of a culture [Throsby (2001, Chapter 3)]. But is this feasible? Ideas like investment and the rate of return to cultural capital presuppose partibility and additivity, which, as we have seen, cannot be assumed for intrinsic value.<sup>7</sup> Klamer (2003) adopts a pragmatic view, drawing on the ideas of Dewey<sup>8</sup> to indicate that there may be distinct realms of value. But pragmatism *per se* takes the problems as being given, and so provides us with no guidance as how to distinguish these different realms. By offering some such guidance, and raising important questions about the applicability of arithmetic methods to cultural value, Nozick’s intrinsic value conception may provide an important complement to the pragmatist’s problem-orientation, and thus a basis for formal definition.

On this view, then, objects of art may have intrinsic value (as they successfully realize a novel diversity-in-unity), cultural value (as symbols of some cultural unity), and economic value (in that some individual is willing to pay for them). Objects that carry cultural heritage may have cultural value and meaning as such. Cultural value may be correlated with economic value only if some people prefer objects with cultural value to objects that lack it. But having granted as much, what progress have we made toward a

<sup>6</sup> Popular attitudes toward artifacts such as windmills and covered bridges can often be documented by picture postcards; see McCain (2002b).

<sup>7</sup> Throsby concedes that “a single measure is very difficult to specify, given the multi-dimensional nature of cultural value” (2001, p. 84), but regards such a measure as theoretically possible and suggests that the measure might be used in cost–benefit analysis (p. 83). The implication suggested here is that such a measure, and such an exercise in cultural cost–benefit analysis, is impossible even in principle. Non-partibility means that an object of cultural value cannot be treated as an aggregate of parts, so that marginal concepts are inapplicable. This goes beyond indivisibility. Rose Tree Tavern is a historically important building near my home, which has recently been moved a few hundred feet to allow a road-widening project. But the historic significance of the building is not simply a sum of the structure and its site, so we may say that only the site has been sacrificed. Rather, arguably, the building at its original site is simply a different cultural object, with an *incommensurably* different cultural value, than the building at its new location. Similarly, that intrinsic values are non-additive means both that the value of the Rose Tree Tavern cannot be considered as a sum of the value of the structure and that of the site, and that future cultural benefits from its preservation cannot be accumulated and discounted to present value to be considered as an offset against the cultural loss of moving it from its original site (rather than demolishing it). On the other hand, recognition of the non-partibility and non-additivity of cultural and some other intrinsic values gives us an answer to a neoclassical criticism. The neoclassical criticism is that non-economic values must be reducible to economic values, since people do in fact make choices that trade off one kind of value against another, and these tradeoffs give us the terms of equivalence for the reduction. But this criticism too presumes that both kinds of values are partible and additive and fails when we realize that cultural values do not have these arithmetic properties.

<sup>8</sup> While pragmatism is also the philosophical standpoint of American Institutionalism, Klamer does not cite the works of economists and philosophers such as Veblen, Ayers and Dugger who write in that tradition.

definition of cultural goods? If the definition is to be helpful, it should allow us to make some connection to recognized aspects of cultural goods. One widely recognized aspect of cultural goods is the economic value of provenance.

#### 2.4. Provenance

Consider the following conundrum. We suppose that two pictures are put on sale at the same time: an authentic Rembrandt and a perfect duplicate of it. We suppose that the duplicate has been created by means of the newly invented “Molecular Duplicating Device” (MDD) which places each molecule of the duplicate in the exact relative position of a corresponding molecule of the original, so that the duplicate cannot be distinguished from the original by any ordinary means. Common sense tells us that the market value of the authentic picture will be much greater than that of the duplicate. Indeed, something of the kind can occur in real life when the attribution of a work of art to a famous artist is rediscovered. A Raphael, worth £8000 when it was thought to be a copy, commanded an offer of £35,000,000 after its attribution to Raphael was rediscovered and clarified [Spanier (2003); Jeromack (2002)]. A painting that had not seemed worth selling when attributed to Jan van den Hoecke was estimated at about £6,000,000, but sold for £49.5 million when reattributed to Rubens [Moncrieff (2002a, 2002b)]. Similarly, a Paul Revere silver porringer might sell for ten times the price of a contemporary porringer of equally fine workmanship, because of “the patriot factor”. What does the authentic picture or porringer have that the duplicate lacks? It is easy to give a name to it: provenance.

People are willing to pay for items with provenance. In antiques markets, for example, a weapon known to have been used in war will generally get a higher price than an otherwise identical weapon that was never used in violence. This association of the weapon with war is an objective historical fact, as is the association of the authentic Rembrandt with the historic van Rijn. For a broad category of goods, including (but not limited to) goods that we think of as cultural or artistic goods, *as a matter of fact* the willingness of people to pay for them is dependent on their history. The Revere porringer’s provenance makes it valuable partly because it is symbolic of the American struggle for independence; covered bridges are considered worthy of preservation because they are symbolic of the idealized rural North America of the 19th century; and windmills symbolic of a Netherlands in some similar idealized time. The porringer may also have intrinsic value as a fine item of craft, but, as we have seen, the value of provenance goes beyond that.

Tentatively, then, we define “cultural goods” as goods that carry cultural value, in that they derive their meaning from the unity-in-diversity of some specific cultural group and from the fact that they symbolize, through their provenance, the unity and distinctness of that group.

## 2.5. *Artistic value*

We have speculated with Nozick that artistic value is yet another distinct realm of intrinsic value. However, an art historian<sup>9</sup> writes, “I don’t think ‘unity in diversity’ is the essence of value in art. For one thing, there are many things, like airplanes and computers, which are marvelous examples of unity in diversity, but they are not art, and even if they have aesthetic value, that is not the same as the value that is in art”. This is a useful but not a decisive counterargument. It has not been asserted that value as unity in diversity is special to art, but the contrary, that it is the basis of intrinsic value in non-art as well as artistic cases. That, however, leads to the question: what particular unity-in-diversity may we associate with artistic value?

In fine craft, of course, unity of “form and function” may itself be a value. Similarly, the unity-in-diversity of an airplane has much to do with its function as a flying machine, and is largely obvious on the basis of that function, while the unity-in-diversity of the Greek Tragedy (on Nietzsche’s account) has little to do utilitarian function,<sup>10</sup> and is far from obvious on any basis. Mossetto (1993, p. 19) goes still further “The absence of ‘interest’ or ‘aim’ is a permanent feature of aesthetic judgments . . .” As an interim conclusion we may say that while Nozick’s conceptualization of value allows us coherently to assert a distinction between cultural and economic (and other) values, it does not tell us under what circumstances unity-in-diversity defines artistic rather than other sorts of values.

What can we now judge about the relation of artistic and cultural goods? In discussions consistent with UNESCO’S official position, Throsby (2001, p. 4) conceptualizes artistic goods as a subset of cultural goods and defines cultural goods by three characteristics: that creativity is (especially) involved in their production, that “they are concerned with the generation and communication of symbolic meaning”, and that they are potentially intellectual property. However, in the perspective of this essay, this seems to go too far. Goods that carry artistic value may also carry cultural value, so that the categories can have an important overlap, but it is clearly logically possible that goods may carry one sort of value and not the other. Not all cultural goods are artistic: Klamer’s windmills (and McCain’s covered bridges) may have involved no more creativity in their production than does any engineering work, have acquired but did not generate and are not “concerned with . . . communication” of symbolic values, and are perfectly ordinary property but not potentially intellectual property. Even some art works such as sculptures can hardly be identified as potential intellectual property, although they can be quite ordinary property. The Revere porringer may have been a highly creative product at its origin, since Revere was a fine silversmith and a creative man, but its cultural value has nothing to do with that, and it is ordinary, not intellectual property. A sword

<sup>9</sup> Charles Morscheck, Drexel University, personal communication, 2003.

<sup>10</sup> On the other hand, the social distinction of art from craft seems to encourage “artists” to avoid any interest in either form or function. The late romantic idea that this devalues “pure” art relative to fine craft expresses a particular aesthetic position consistent with, but not entailed by, Nozick’s conception of intrinsic value.

that happens to have been used in combat in the American Civil War almost certainly does not satisfy the first or the third of Throsby's list and bears the same relation to symbolic value as do the windmills and covered bridges. To an American it may be a very important cultural good. On the other side, artistic goods are not of cultural value in all cultures. Not all cultures value creativity as modern European-derived cultures do. In some such cultures, High Culture may be identified with athletic prowess, or with the faithful repetition of the tradition, rather than with creativity. In the face of these examples, it seems that the relationship of cultural and artistic goods is better represented by a ballentine than a Venn diagram. Nevertheless, Throsby's triad provides us with a key point to refine our understanding of artistic value both in itself and in its overlap with cultural value. For this we need a clear concept of creativity. That is the next task of the essay.

### 3. Creativity

#### 3.1. *Simon on creativity*

Creativity is two-sided. In *Simon's* (2001) words "We judge thought to be creative when it produces something that is both novel and interesting or valuable" (p. 208). In the words of *Amabile and Tighe* (1993, p. 9), "... [M]ost researchers accept a conceptual definition that includes two elements: novelty and appropriateness". For *Radford* (2004, p. 56), "In order to be creative it may be argued that it is insufficient to draw attention to a dissonance or controversy, but rather the artist must offer a way of addressing it. Jerome Bruner has said that the creative act should bring about a 'shock of recognition', a sense that the act tells us something that we already half knew". *Bruner's* (1979) "shock of recognition" points up the tension between these two aspects of creativity, even at the definitional level.

The novelty and seeming freedom of creativity suggests that it is spontaneous, independent of preparation. But that seems to be something of a romantic fallacy. As *Cohen* (2002) writes: "If we survey the work of any major artist, we get the distinct impression of someone who knew exactly what he or she was doing and knew exactly where he or she was going. Mozart always sounds like Mozart. Matisse did not produce a Picasso on Monday and a Miró on Thursday, he produced Matisses every day". Moreover, "Mozart began to compose at age four or five; until he was at least seventeen he composed no music that, however remarkable for a youngster, could be regarded as world class" [*Simon* (2001)]. Furthermore, "Most creators do not function in isolation from other creators, but rather their creativity takes place within a particular artistic, scientific, or intellectual discipline" [*Simonton* (2001)].

These facts are stressed by Simon in support of his interpretation of creativity. For Simon, creativity is nothing more than expert problem solving. "In fact, we can describe in considerable detail the fundamental processes that creative activities – in common with other human mental activities – employ ..." (p. 205). "The memory of the expert,

then, is like an indexed encyclopedia, where the index entries are recognizable patterns, each of which points to a body of organized relevant knowledge . . . The empirical evidence suggests that a world-class expert has a quarter million or half million patterns, with associated information, about the expert domain” (p. 207). On a widely-held alternative view, [Ansburg and Hill \(2003, p. 1143\)](#) argue that “Creative thinking produces innovative solutions, whereas analytic thinking evaluates and tests existing ideas”.

### 3.2. Generative linguistics

There is another formal model that has been perhaps even more influential in the writing on creativity. This is generative linguistics.<sup>11</sup> The formal modeling of this sort of creativity begins with the work of [Chomsky \(1972\)](#). In Chomskian linguistics, “. . . a speaker’s linguistic ability must be characterized in terms of a generative grammar, a system of combinatorial rules or principles that ‘generate’ or ‘derive’ an infinite set of possible sentences from a finite vocabulary” [[Jackendoff \(1999, p. 7\)](#)]. Thus, in generative linguistics, we have an approach comprised of formal rules that are creative in that they can generate an unlimited array of novel, grammatically valid expressions.

In accepting this view of linguistic creativity, we need not accept the idea that linguistic expression is always creative. [MacKenzie \(2000, p. 173\)](#) is critical of Chomsky’s minimalism: “Not unlike the oral-traditional poets of Homer’s day, we routinely rely on a vast store of fixed, prepatterned phrases, which we use more often than we generate locutions entirely from scratch”. Nevertheless, he goes on (p. 174): “Obviously, no one would deny that there *is* [emphasis in the original] a generative element to language acquisition, as it is this that enables us to be wholly novel and innovative, or more frequently, to produce slightly novel and unexpected variations on familiar usage”. On this synthetic view, expert behavior *à la* Simon facilitates, but is not sufficient for, linguistic creativity, and the same point may be applied to creativity in general.

In recent years, formal generative linguistic models have been used in studies of creativity in musical composition [[Pearce and Wiggins \(2002\)](#)], visual composition [[Stebbing \(2004\)](#)], and creative computer programs [[Cohen \(2002\)](#)]. However, the more established literature on creativity uses ideas from generative linguistics informally, with “generative rules” as a key concept. Here, the work of Margaret Boden is widely recognized as central. She writes (1991, p. 40): “A merely novel idea is one which can be described and/or produced by the same set of generative rules as are other, familiar ideas. A genuinely original, or creative, idea is one which cannot”. Thus, creative expressions are expressions that change the rules (in more Chomskian language, that change the surface structure)<sup>12</sup> of the system. This key insight leads on to important

<sup>11</sup> Yet another no less scientific approach is found in the broadly evolutionary view of Campbell and Simonton; see [Simonton \(2001\)](#). While this view is valuable especially for its insights about the way that novelty arises, it is less helpful in understanding novelty *per se* and thus is not used further in this discussion.

<sup>12</sup> In the words of [Jackendoff \(1999, p. 8\)](#) “The fact that the same semantic relation can be expressed by different syntactic means (e.g., active and passive sentences) is a consequence of moving constituents in the

conclusions for economics, especially for the study of the economics of the arts and innovation.

While "... few theorists hold the strong position that a creative idea must be completely *unique*",<sup>13</sup> we may "... contrast between 'little C' creativity – the sort which all of us evince in our daily lives – and 'big C' creativity – the kind of breakthrough that occurs only occasionally" [Gardner (1993, p. 29)]. In the case of "big C" creativity, novelty or innovation is particularly apparent. At the same time, the creative product must be appropriate or adequate according to some external criterion. In music, for example, there is "the need to compose music whose structure may be perceived by the listener: there must be some kind of alignment between the compositional mechanisms of the composer and the perceptual mechanisms of the listener" [Pearce and Wiggins (2002, p. 4)]. "To a large degree such criteria are culturally determined; we do agree on most issues, and it is rare for the work of a single individual to enforce a major shift of criteria for the entire culture. At the same time, creative behavior must involve an increasing differentiation, in whatever degree, of the individual's criteria from those of the culture at large" [Cohen (2002, p. 61)].

All the same, novelty and appropriateness are alike a matter of subjective judgment, and the judgment is specific to a domain. "... creativity occurs in domains. That is, a creative individual is never creative across the board. Rather, creative individuals display their creativity in disciplines or crafts; usually one domain, though occasionally, as in the case of Leonardo da Vinci, in two or even three domains"<sup>14</sup> [Gardner (1993, p. 32)]. Thus, domain-relevant skill is first among the skill components required for creativity [Amabile and Tighe (1993, pp. 14–15)]. Gardner goes further: "... a creative individual is one who regularly solves problems, fashions products, and/or poses new questions in a domain in a way which is initially considered novel but which is ultimately accepted in at least one cultural setting" (p. 32).

According to Boden, creative ideas are surprising. Gardner's distinction of "big C" and "little c" creativity corresponds roughly to Boden's "P-creative" (psychologically creative) and "H-creative" (historically creative) ideas. P-creative ideas "are fundamentally novel with respect to *the individual mind* which had the idea. If Mary Smith has an

course of a syntactic derivation, creating a disparity between "Deep" and "Surface" structure ... " This is part of Chomsky's original view, and Jackendoff questions it, but some such hierarchy of rules is essential for creativity studies, as we shall see.

<sup>13</sup> Amabile and Tighe (1993, p. 7). They add that for their theory, a third characteristic is required: "the task must have been heuristic for the individual, rather than algorithmic. That is, the task as presented must have been somehow open-ended, with no clear and straightforward path to a single solution". But this seems to be another aspect of innovation.

<sup>14</sup> Indeed one of the *prima facie* exceptions, Herbert Simon, himself disavowed that he worked in multiple realms. Citing a personal communication, Dasgupta (2003, p. 686) quotes Simon as follows: "... the 'Renaissance Mind' is not broader than other intelligent minds but happens to cover a narrow swathe across the multi-dimensional space of knowledge that happens to cut across many disciplines which have divided up the space in other ways. My own narrow swathe happens to be the process of human problem solving and decision making, and almost everything I have done lies in that quite narrow band".

idea she could not have had before, her idea is P-creative – no matter how many people have had the same idea already. The historical sense applies to ideas that are fundamentally novel with respect to *the whole of human history*. Mary Smith’s surprising idea is H-creative only if nobody ever had it before” [Boden (1991, p. 32)]. Both categories of ideas are surprising in a deep sense. A parallel, but distinct, dichotomy distinguishes exploratory from transformational creativity. “The process of generating ‘merely novel’ artifacts is described as exploratory creativity, while the generation of ‘genuinely original’ artifacts is described as transformational creativity” [Pearce and Wiggins (2002)]. Once again, the latter category is surprising. “Where creativity is concerned, we have to do with expectations not about probabilities, but about possibilities. Our surprise at a creative idea recognizes that the world has turned out differently, not just from the way we thought it *would*, but even from the way it *could*” [Boden (1991, pp. 30–31; emphasis in the original)].

However, there seems to be an inconsistency here. In generative linguistics, the novelities that occur are not themselves generative rules. Rather, the generative rules generate novel utterances. Conversely, the generative rules themselves are universal, and so unchanging – at least on any timeframe less than that of human evolution. Thus, Boden’s formulation seems to contain an ambiguity: on the one hand, the generative rules make creativity possible, but on the other hand, the creative product cannot be a result of the previously existing generative rules. We might resolve it this way: the ambiguity is between the production system (if–then rules as envisioned by Simon and MacKenzie) and the underlying generative rules. Objects of art (and technology and science) are indeed outputs of a production or expert system of if–then rules. But this system of if–then rules is not itself given for all time. Rather, it is a product of a system of generative rules which is capable of generating an unlimited number of potential if–then rules. When Boden (1991, p. 40) says “A genuinely original, or creative, idea . . . cannot . . . be described and/or produced by the same set of generative rules as are other, familiar ideas”, she might instead have said that a genuinely original, or creative, idea cannot be produced by the same set of if–then production system rules as are other, familiar ideas. Instead, it is the product of a new set of if–then rules, which are themselves novel products of the unchanged underlying generative system. In any case, that will be the position of this essay. Indeed, it is an extension to creative activity in general of MacKenzie’s understanding of creativity in language.

The situation is probably still a little more complex. In addition to the fundamental and unchanging system that generates novel if–then rules, and the if–then rules an expert uses directly to create a new work of art or econometric model, there will be a middle stratum of rules that are products and are also open as generative rules are, capable of producing an unlimited range of if–then rules to handle specific circumstances. Most likely the scientific method, theories of aesthetics, and engineering disciplines belong to this middle stratum. When Boden speaks of generative rules, we should (I suggest) interpret her comments as applicable not to the fundamental generative rules that do not change, but to this middle stratum. In what follows I will use the broader term

“subjective knowledge structures”<sup>15</sup> to encompass all three. In any case, we will need both (unchanging) generative rules and (changing and expanding) production systems to understand creativity.

Boden’s formulation can serve to pull some of the threads of this discussion together. The domain-relevant skill (Amabile and Tighe) or cultural setting (Gardner) required to judge creativity supply the knowledge of pre-existing subjective knowledge structures. The subjective knowledge structures themselves define the discipline or craft (Gardner) in which creativity takes place. The necessary knowledge of the craft and its subjective knowledge structures define the domain-relevant skills required of the creative person herself (Amabile and Tighe). In some fields, such as the simpler technologies, the appropriateness of the creative product may be obvious – measurable, perhaps, by a change in labor productivity [McCain (1981b)] – but in other cases judgments of appropriateness are themselves products of the subjective knowledge structures shared by the community skilled in the pre-existing domain. Indeed we may say that judgments of appropriateness are themselves products of the rules.<sup>16</sup> Note that the creative production is *impossible* on the basis of the pre-existing subjective knowledge structures, so it can only be that the creative act has given rise to new rules of production or of judging appropriateness, or, perhaps in most cases, both. Thus, even in fields such as art, knowledge is accumulative, and for this reason the H-creative act will influence subsequent work.

Indeed it is H-creative *because* it influences further work. As McCain (1981b) observes, tradition and innovation are interdependent: we recognize the innovation in that it contributes to the tradition. It is this historic association that gives the great work of art its special provenance. As McCain also points out, there are many failed innovations for every successful one, and there is no possibility of predicting which innovations will succeed, since the subjective knowledge structures necessary to judge them do not exist until after the successful innovation has been produced and recognized as such. This leads naturally to the “nobody knows property” and the crucial role of intermediaries and buffs with particular skill in the domain in markets for art [Caves (2000, p. 3 et seq., p. 185)]. The knowledge of the intermediaries and buffs cannot eliminate, but does reduce, uncertainty about the historic quality of an innovation.

### 3.3. Creativity in consumption

Turning now to consumers, we note that new works especially will not be successful without interpretation. In Moseotto’s words, “Interpretation is characterized by the same features of creativity . . .” (1993, p. 73). For works of art, then, it is not only the artist whose creativity is engaged. Being a spectator or consumer (interpreter) of art calls on

<sup>15</sup> This precise phrase is due to Boulding (1956), but the term “knowledge structures” is widely used in cognitive science; see, e.g., Mandler (1985), McCain (1992).

<sup>16</sup> Formally, a rule for judging appropriateness takes a product as its argument and generates a judgment as its dependent variable. This is the form of a linguistic generative rule.

the skills and mental processes characteristic of the artist herself, though, to be sure, in lesser ways. The creativity of the art consumer is P-creativity, not H-creativity, in Boden's terminology. Nevertheless, the creation and consumption of art links the artist and the consumer in a unity of interrelated creative action. This sort of linkage through a shared experience does not depend on just what this joint creativity of artist and interpreter creates. The "what is created" may be an emotional mood, an arousal of the senses [Shanahan et al. (1978, p. 16)], an image, a story, or all of those and more. It is the linkage through shared creativity that counts.

This provides an answer to Bentham's (1843) famous view that the game of push-pin is of equal value with the arts and sciences of music and poetry. Art is about ideas, doctrines, poetry, rhetoric and wisdom. It is about expression and affecting the emotions of the viewer, reader or hearer.<sup>17</sup> But many things that are not art are also about those things. What makes the emotional mood or the wisdom art rather than something else is that its full appreciation engages the consumer's creativity in a joint act of creation with the artist. This joint creativity defines a new unity-in-diversity, a new intrinsic value, which I submit is the distinctive intrinsic value of art.<sup>18</sup>

Thus, it seems that creativity is (*pace* Caves) the key aspect of artistic goods and services. Further, cognitive-scientific study of creativity can both rationalize many aspects of art markets and can explain the connection of important art products to provenance, that is, the tendency of buyers to assign value to the item on the basis of its historical associations. Tentatively, then, we define "artistic goods" as goods that carry non-economic value, in that they create a novel unity-in-diversity by calling forth a common creativity of the artist and the consumer of art.

#### 4. Implications for consumers of art

Once again, if the proposed definitions are to meet Malthus' criterion, they will underscore the connections we expect to find with other phenomena in markets for art. In this section we consider learning-by-consuming and artistic goods as stimulus goods and (in a negative sense) intellectual property.

##### 4.1. *Learning-by-consuming*

The domain-specific knowledge and skills necessary for creative consumption of art are together known as "taste", and are something not given but acquired. One cannot be a productive consumer of creative work without at least some knowledge of the generative

<sup>17</sup> Charles Morscheck, personal communication, cited above (Footnote 9).

<sup>18</sup> Bryant and Throsby (2006) (Chapter 16 of this volume) focus mainly on the conflict of interest between the artist, who is assumed to value creativity, and the marketer. The conflict of interest would follow from the "nobody knows" property as more experimental work is likely to fail and, even if successful, to appeal in the marketplace to a narrower expert market. Thus their view would be consistent with the view sketched here.

rules that produced it and determine its evaluation, and that knowledge is gained in part by the experience of consuming the artistic product. Caves (2000, pp. 175–178) observes that creative industries rely on tastes that are to some extent cultivated, and cultivation of taste has been modeled in economics as “rational addiction”. As he notes, the basic tools for such a model come from Stigler and Becker (1977), but as McCain has argued, the Stigler–Becker model does not account for the observed multimodal distribution of cultivation of taste without non-linearity and some other element, such as bounded rationality, hysteresis, or some game-theoretic coordination failure.<sup>19</sup>

This idea lends itself to modeling in nearly conventional terms, if the cognitive details are kept ruthlessly in the background. Let  $\{x, y\}$  be the quantities respectively of an artistic and an ordinary good consumed in some particular market. Then let  $z = kx$  be the “sensation” derived from consuming  $x$  units of the artistic good, and  $U = f(kx, y)$  the utility function of a representative consumer. Then we let  $\dot{k} = g(x, k)$ , with  $g$  an increasing function over at least part of its range and a decreasing function of  $k$  over at least some part of its range. Positive values of  $g(x, k)$  correspond to ongoing cultivation of taste.

This schema lends itself to the formulation of a dynamic optimization problem. The variables  $x$ ,  $y$  and  $k$  will then be functions of time and  $x$ ,  $y$  are subject to an income constraint. Let  $m$  be income, a function of time, and  $p_x$  and  $p_y$  the prices of  $x$  and  $y$ , respectively, which may be constants or functions of time. Then the problem is

$$\text{Max} \int_0^T f(kx, y) dt \quad \text{subject to } \dot{k} = g(x, k)$$

and

$$\int_0^T (p_x x + p_y y) dt \leq \int_0^T m dt.$$

The solution to this problem would give a path of “rational addiction” to the arts. Over this path, the rational agent trades off a rate of expenditure on the arts now (which might not maximize instantaneous utility) against increased pleasure from the arts, at the same cost, in the future [McCain (1981a)]. There could be multiple equilibria and initialization effects. For some agents who begin with relatively large “arts capital”  $k$ , perhaps because of exposure to the arts in childhood, it might be optimal to become highly cultivated, whereas for others who begin with lesser  $k$ , the optimal path would be one of rational philistinism and minimal cultivation. This multiplicity of equilibria, depending on initial conditions, could explain a bimodal distribution of degrees of cultivation of taste, as agents tend (depending on their initial conditions) to cluster in the neighborhoods of two or more distinct “basins of attraction” (to use the jargon of mathematical dynamics). The welfare economic implications of such a schema do not seem to have been investigated.

<sup>19</sup> References for McCain are: (1) non-linearity [McCain (1979)]; (2) hysteresis [McCain (1981a)]; (3) bounded rationality [McCain (1995a, 1995b)]; (4) game theory [McCain (1986)].

Another possibility, however, is that people are shortsighted, in that at each moment of time they

$$\text{Max} \int_0^T f(kx, y) dt \quad \text{subject to} \quad \int_0^T p_x x + p_y y dt \leq \int_0^T m dt$$

ignoring the future benefits of cultivated tastes. In such a case cultivation of taste enters the model as an externality as would be the case in a more conventional welfare economic model [McCain (1979, 1982, 2002a); Stevens (1985)]. Moreover, this may not be a failure of rationality, since there is a coordination problem among the agents. Unless a sufficiently large proportion of them cultivate tastes for the arts, there will not be enough demand for the arts to pay the fixed costs of an artistic infrastructure, and in that case, those who do cultivate a taste for the arts may be worse off rather than better off [McCain (1986)]. Moreover, real people are boundedly rational learners, and computer simulations suggest that in a population of agents who learn by experience with bounded rationality, only a portion of the population becomes cultivated even though the cultivated are unambiguously better off than the uncultivated. Furthermore, the proportion and other details are highly sensitive to the initial conditions and random disturbances of the simulation [McCain (1995a, 1995b)].

By keeping the value issues, creativity issues, and cognitive issues off the table, this approach enables us to model the demand for arts in ways that are consistent both with the importance of learned, domain-specific consumer knowledge (indicated by the creativity approach) and with the economics of social behavior. Nevertheless these reflections do not contribute toward a definition of cultural or artistic goods, because the role of cultivated taste is not limited to the economics of the arts. Indeed, McCain's empirical demonstration of it was a study of the demand for wine [McCain (1979)] and he observes that Scotch whiskey is no less subject to cultivation of taste than wine or grand opera. The same comments could be applied to sports and a wide range of hobbies. If we were to define artistic or cultural goods simply as goods whose productive consumption requires cultivation of taste, then we would be admitting whiskey and soccer as forms of high culture! That will not do. However, our discussion of cultivation of taste does at least extend our understanding of the role of creativity in markets.

#### 4.2. Artistic goods as stimulus goods

Scitovsky (1972, 1976) has proposed an alternative economic psychology in which there is an innate human need for stimulus. He suggests that individual decisions may be biased away from stimulus goods, and artistic goods are seen as stimulus goods that may be underconsumed. Scitovsky reasons that artistic goods are pattern-complex, so that they are able to hold our attention on repeated exposure; but this same pattern-complexity requires effort (and perhaps cultivation) that may deter individuals from making the commitment necessary to meet their (hypothetical) need for stimulus. These ideas are consistent with the literature on creativity, where domain-specific knowledge of complicated generative rules (and, indeed, the consumer's own creativity) is seen

as necessary for full *appreciation* of the creative product. We can accept the idea that artistic products are stimulus goods whether or not we endorse Scitovsky's hypotheses of an innate need for stimulus. It is also possible that Scitovsky's approach can support a model of market failure through asymmetric information<sup>20</sup> [McCain (1980)]. Like cultivation of taste, however, stimulus and engaging complexity are not unique to artistic goods. Here again, sports and such games as bridge and chess share the fascination Scitovsky attributes to art, and for many people politics, religion, and fighting are the stimulus goods of choice. As with cultivation of taste, the discussion of stimulus goods contributes to the definition of artistic goods in so far as it extends our understanding of the implications of creativity.

#### 4.3. *Intellectual property*

Many artistic goods may be copyrighted. However, many works may be copyrighted that we would not ordinarily think of as artistic. Consider, for example, a textbook of economics. Such a work is eligible for copyright if it is original in expression. I can say from experience that some P-creativity is necessary to write a text; but if the text were H-creative it would fail as a textbook. Indeed, the standard for eligibility for copyright seems explicitly to allow work that is not H-creative, by contrast with the requirement for patentability, which specifies that the invention to be patented must be an advance on products already in existence. Artistic creativity then is at most a sufficient but not a necessary condition for the work to be eligible for copyright. Like cultivation of taste and stimulus, the importance of copyright in the artistic world follows from the key role of creativity, but is not by itself definitional of artistic goods.

### 5. Conclusion

The ultimate justification for distinguishing artistic and cultural goods from other goods is pragmatic. Problems of the artistic industries or of cultural sustainability may not be adequately understood, and therefore not solved nor ameliorated, if artistic and cultural goods cannot be adequately defined. But appeals to pragmatism are not conclusive. Problem recognition is itself an aspect of creativity, dependent on domain-specific knowledge, but reflective also of preferences and prejudices. Put otherwise, one person's problems may not be problems from the point of view of another. This chapter has suggested a broader conception of value, that allows distinction among economic, cultural, artistic and aesthetic values, and has proposed definitions of cultural and artistic goods and services in terms of those categories of values. These concepts of value allow

<sup>20</sup> But McCain's (1980) model fails empirically in that it predicts a chronic shortage of artists, whereas the evidence, as reported by Alper and Wassall (2006) in Chapter 23 of this volume, indicates that artists are disproportionately affected by structural unemployment.

us to recognize cultural value in artifacts that are symbolic of the diversity-in-unity of particular cultural groups, and to recognize artistic value in the experience of shared creativity on the part of the consumer and producer of art. This recognition leads us to incorporate learning on creativity from cognitive science in cultural economics. This chapter has reviewed the learning on creativity and given examples of its use as a tool for the economic understanding of those industries. The hope that motivates this exercise is the hope that reason may yet arbitrate our differences of opinion about culture, art and public policy.

**Abstract**

Artistic value played a minor role in classical philosophy, but moved to center stage in 18th century aesthetic theory and also played a role in moral philosophy. The value of Art and the process of its valuation has remained an indispensable subject of modern aesthetics, while economists have excluded these topics from consideration. Recent attention to “external effects” has opened new ways of interpreting artistic value in a manner consistent with economic theory. Sections 1–5 narrate historical positions in both disciplines, many of which have left their imprint on current analysis. Sections 6–8 focus on the contemporary discussion of artistic values and their logic of evaluation in economics and in aesthetics.

**Keywords**

artistic valuation, consumption skills, tastes, use value

## 1. Premodern theories

Both economic and aesthetic theory, in the most strict and technical sense, are a product of modernity. Both theories have been very powerfully shaped by Greek philosophy, particularly by the works of Plato and Aristotle. Therefore we must begin our study with ancient theories of economics and aesthetics ‘*avant la lettre*’.

Plato (427?–347 BC) [see Plato (1997)] provides what is generally regarded as the first substantial theory of art. Though the value of art and beauty are usually closely related, Plato treats them very differently. Beauty plays an extremely positive role in his philosophy, serving as an exemplar of the very highest level of the ideal Forms and associated with truth and the good. Moreover, beauty is seen as the inspiration and goal of philosophy itself. Plato’s *Phaedrus* characterizes beauty as the clearest, most understandable Form and his *Symposium* describes the philosophical quest as an ascent from the love of beautiful bodies to the love of beautiful deeds, discourses and thoughts, and finally to a vision of Beauty itself from which the philosopher can give birth to the beautiful.

In contrast, art – in our modern sense of the fine Arts – fares miserably. Plato’s *Republic* defines such arts in terms of “mimesis” (typically translated as imitation though sometimes also as representation), while the general Greek term for art (*techne*) had a much wider meaning, denoting any systematic skill or form of knowledge. Plato denounces the mimetic arts, such as poetry, drama, painting and sculpture, as an imperfect imitation of the forms of the phenomenal world, which for him are themselves but a distorted imitation of the ideal rational Forms that constitute true reality. Art is thus condemned both ontologically and epistemologically as an imitation of an imitation that distorts the truth it pretends to present. Plato further condemns mimetic art on psychological, ethical, and political grounds. By appealing to the lower, emotional part of the soul and inciting it with passions, art disrupts the rational psychological order that should prevail and thus corrupts character and leads to improper behavior. Since political order and justice are intimately interdependent with the order of proper moral psychology, mimetic art – at least the popular genres criticized by Plato – represents a grave political danger; the vivid depiction of war’s horrors and of love’s delights could, for example, sway soldiers from their duties.

Plato never really considered art’s value on aesthetic grounds for to do so would establish criteria that might give it more autonomy, and art’s autonomy and social prestige were exactly what Plato wanted to undermine in order to establish the hegemony of philosophy. This deprecatory strategy was useful because the nascent and still fragile discipline of philosophy, in order to establish its authority, needed to struggle against the cultural prestige of the artists, particularly the poets, who were recognized as repositories of ancient wisdom. Defining art as an imperfect imitation not only helped to demean art but also to conceal the fact that Plato’s philosophy itself imitated many aspects of art – the concern for rational form and coherence, the satisfactions of imagination and contemplation of form, and the interpretation of the meaning of experience and events [see Dewey (1987); Shusterman (1992)].

Plato's political philosophy includes a similarly detailed discussion of economic theory and practice. The art of managing a household or the economic affairs of a city-state ranks among the more highly valued theoretical arts.<sup>1</sup> Among the lower practical arts, there are the skills of producing or building objects, the skills of applying them, and the skills of acquiring them, either by conquest or by exchange. While all these skills are necessary for the maintenance of the city-state, they do not contain much of the quality of the ideal, divine Form. But, at least, they do not disrupt the political natural order.

Aristotle (384–322 BC), who had been Plato's disciple for two decades, maintained the Platonic notion of an ideal, divinely inspired state of human behavior and political organization. With his works, the proportion between the different arts which make up the city-state gained in prominence. All human action contributes to the realization of that state of the community which corresponds to the divine and, thus, to natural order. Ideal wisdom may be perfect self-reflection. But humans need a balance between theoretical (gnostiké) and practical (praktiké) wisdom. "Oikonomía", the art of managing a public household, qualifies as a theoretical art. Among the practical arts, there is a distinction between actions and occupations that generate some external result (poietiké) and actions which employ these results. Only the latter are truly practical and ethical because they have their end and value in themselves.

Aristotle recognized the Platonic distinction between the employment and the acquisition of material objects. He transformed it in a way which remained paradigmatic for the next two millennia: the "natural" use of objects is their immediate employment. The "unnatural" use of objects is their exchange. Unnatural uses are legitimate for a community since resources are distributed unevenly throughout a territory. But since they do not follow natural proportion, they are limitless, lead to excess and thus to disorder. "Value in exchange", then, is interpreted as a limit to the natural "values in use". Beyond that limit, the accumulation of treasure, measured in a money commodity, becomes an end in itself. The lending of money sums against interest is an example of economic activity with negative value.

If practical arts are exercised with virtue (areté), i.e. in accordance with the divine laws of ethical and political order, they contribute to the well-being of the city-state. Yet, they remain far from those activities which lead to immediate experiences of "eudaimonía", i.e. the ability of humans to make their souls the receptacle of divine wisdom. In the case of the Arts (in the modern sense), the judgment is more favorable. In general, the "kátharsis" induced by them is valuable for both the individual and society, because it allows such negative emotions as pity and fear to be stirred up and then expurgated within the protected context of art's experience rather than having them spill over into real life where they could wreak psychological, ethical, social, and political havoc. If art's most obvious, general, and traditionally affirmed values can be summed up under the categories of pleasure and use, Plato recognized the pleasures but deemed them

<sup>1</sup> The term "techné" is used for any skill, be it technical, artistic or theoretical. The arts as discussed above – tragedy, music, sculpture – are dealt with as phenomena *sui generis*.

base and corruptively dangerous, just as he argued that art had negative utility in the cognitive, psychological, ethical, and socio-political spheres, while Aristotle defended the legitimacy of art's pleasures and their positive value.

Beyond catharsis, Aristotle argued for both the cognitive value of mimesis and the psychological, ethical, and social value of art's emotional arousal. Claiming that imitation was a natural and primary means of human learning and also a natural source of human delight, he further argued that art had important cognitive value because it imitated the essential and universal rather than mere contingent superficialities. That is why he described poetry as being more philosophical than history (*Poetics*, 1448b, 1151b) [see Aristotle (1947)]. He singles out music as a core discipline of education. Music, moreover, generates images (*homíoma*) that come close to "true nature" and thus succeeds in moving the soul (*Politics*, 1340a). Therefore, music is an activity which is able to combine banal pleasure with blissful happiness, a feeling of a higher order.

Aristotle's explicitly introduced formalistic or compositional principles for the analysis and evaluation of artworks, most notably for works of tragedy. More than merely advocating a general idea of organic unity (the need for a satisfying whole to "present a certain order in its arrangements of parts" and be of an appropriate "magnitude"), Aristotle's compositional principles refer to the various elements that form the artwork, classifying them in terms of whether these elements pertain to the object represented (plot, character, thought), the means of representation (diction and melody), or the manner of representation (spectacle and narrative versus dramatic role playing) (*Poetics*, 1447a–1450b). These elements are differentially valued. For example, in tragedy, the element of plot is clearly asserted as the most important. The different elements can be used to evaluate different genres. Tragedy is valued as nobler than comedy since tragedy represents nobler plots and characters and has consequently less vulgar diction as well. Aristotle evaluated tragedy as a higher mimetic form than the epic, which also had nobility of action, plot, and diction, because it had more positive elements, such as music and spectacle, as well as more unity through its narrower focus or scope. More important than any specific list of formal elements and their evaluative import was, in the long run, Aristotle's suggestion that there exist criteria for evaluating art in terms of its formal composition and that they are not reducible to ontology, epistemology, psychology, morality, or politics. The belief in such criteria – significantly linked to properties of form, expression, and quality – played an important role in the modern theories of the aesthetic that began to be formulated in the late 17th century.<sup>2</sup>

Despite the recognition of the values of poetry, music and tragedy, Aristotle continued the Platonic strategy of subordinating art to philosophy. Although art affords pleasure through cognition, philosophy's truths and pleasures are clearly asserted as superior and

<sup>2</sup> A prominent example for a frequent practice in the period is Roger de Piles (1635–1709) who suggested in his *Cours de Peinture par Principes* (1709) to decompose paintings into four fundamental characteristics and rate them each on a scale between zero and twenty [de Piles (1743)]. See Ginsburgh and Weyers (2003) and De Marchi (2006).

more rewarding, its contemplative activity of “theoria” being the “summum bonum” of human life. Just as the theory of catharsis emphasized that art’s passions are aroused in a special artworld context so that they can be harmlessly purged without harming real-life character or society, so Aristotle’s continued to interpret art as “poiesis” as contrasted with “praxis”. Thus, he further isolated art from the sphere of ethics and social and political practice. Art as “poiesis” means external making, the creation of objects outside the self. The end and value of the making is in the objects made. In contrast, praxis or ethical action have their ends and values in themselves and in their agents. They both derive from the agent’s character and reciprocally help shape it (*Nichomachean Ethics*, 1140a1–1140b25).

## 2. Art in early subjectivist theories

Two thousand years later, the terminology of philosophical thought was essentially the same. But the interpretation of the basic assumptions had changed radically. In ancient philosophical theories, properties of value like beauty or utility were conceived as objectively inhering in the objects of which they were predicated. Beauty and utility were considered real properties of things rather than a transactional product that essentially depended on the subjective experience of the beholder. This so-called “realist” view of value continued to be used in medieval and Renaissance philosophies of beauty and of states craft. Earlier works were based on Aristotelian thought, while later texts emphasize abstract measurement, following the rediscovery of Plato’s treatises in Western Europe. Since about 1500, the “nominalist” counter current of Humanist thought began to question the objective existence of ideal Forms, culminating in the strictly empiricist epistemology of John Locke (1632–1704). According to Locke, the mind is a clean slate which is filled with the sensory impressions of the outside world. This is in contrast to Descartes (1596–1650) who, inspired by the scientific advances of Galileo and others, reinterpreted the material world and its objects in essentially physical terms of mathematically measurable extension as could be mathematically measured. As such measurable physical properties became the paradigm of the real, sensory properties such as color, taste, and texture came to be regarded as secondary, less objective properties, while aesthetic properties seemed even more subjective.

Such was the intellectual setting in which a specific theory of taste as an explanation of aesthetic value and a specific theory of self-interest as an explanation of economic value emerged.

For aesthetic theory, Anthony Ashley Cooper, 3rd Earl of Shaftesbury (1671–1713), a student of Locke, was a pivotal figure. As part of his generally Platonic stance, he held a realist theory of beauty. But his Lockean convictions about cognition led him to advance the idea of a special faculty of taste that made moral judgments and aesthetic judgments by respectively discerning the Forms of Good and Beauty. This special mental attitude allows man to properly grasp and appreciate beauty in a disinterested

manner, without the desire to possess or control it. We should not, for example, in contemplating the beauty of a human form allow erotic interest to intervene, since such “desires, wishes, and hopes . . . are . . . no way suitable . . . to your rational and refined contemplation of beauty” [Shaftesbury (1711/1964, p. 126)]. It follows that a connoisseur desirous of acquiring a beautiful painting does not have the right attitude to properly judge its beauty. Shaftesbury’s notion of disinterestedness, in the versions developed by Kant and Schopenhauer, became one of the most influential ideas of modern aesthetics.

The concept of taste had also undergone a switch from external, realist meaning – as in the taste or manner of an artist or a style-period – to the internal, subjectivist meaning of taste as a sensory or perceptual competence. As an individual skill, taste could be conceived as something that is brought to excellence by one class, namely Shaftesbury’s own class of landed gentry. The members of this class had the means to develop their sense of taste for the beautiful. More importantly, they fulfilled one condition which practitioners of all trades and other commercial occupations did not fulfill: they could afford disinterested contemplation. Shaftesbury’s firm Platonic assertion of art’s value, and beauty in general, continued to resist the increasingly empiricist tendencies of British thought.<sup>3</sup>

Early modern economic thought was already deeply suspicious of such hierarchical constructions. Economic pamphlets were published in immediate response to Shaftesbury’s aesthetic theory. Prime example is Bernard Mandeville’s (1670–1733) *Fable of the Bees: Or, Private Vices, Publick Benefits* [Mandeville (1714/1988)], where the model of a state in which everyone consumes in appropriate measure, thus increasing the total volume of blissful happiness experienced in contemplating “real” beauty or moral action is rejected and replaced with a model in which all individuals seek to maximize their pleasures without regard to virtue, and yet the state prospers and grows, as does a bee-hive, filled with creatures that lack the slightest idea of virtue. Nineteen years later, Mandeville (1670–1733) published a second volume called *Fable of the Bees*, in which he continued his attack on Shaftesburian theory, this time in immediate aesthetic terms. The volume contains six conversations between three spectators of paintings of

<sup>3</sup> Shaftesbury was also responsible for introducing to British aesthetic theory the evaluative property of sublimity, first developed by an ancient unknown author (thought to have lived in the first century A.D.) who is known as Longinus [Longinus (1992)]. Shaftesbury regards the sublime as a kind of beauty, but later theorists, treated the sublime as an alternative value to beauty and in some ways more powerful or higher than it. Burke (1998) regards the sublime as “the strongest emotion which the mind is capable of feeling” because it is based on the “passions which concern self-preservation” (pp. 86, 97), while Kant describes it as “arising from a higher intellectual feeling” than the beautiful (p. 33).

Edmund Burke (1729–1797), who rejects the doctrine of a distinct internal faculty of taste, explains our judgments of taste through our ordinary sensory and mental capacities and in terms of our experiences of pleasure and pain. Burke (1757/1998) distinguishes between positive pleasure which engenders the feeling of beauty and the pleasure of delight (deriving from the removal of pain or danger, i.e., the threat of pain) which inspires the experience of the sublime. In contrast to Shaftesbury and later idealist aestheticians, Burke has a distinctly embodied approach to aesthetic value.

Christ's birth. They discuss the merits of works done in Italian and in Dutch style, and they do so in a way which discredits the Shaftesburian valuation of features that cater to artificial taste and which favors the valuation of features that render sensory impressions and thus cater to common sense.<sup>4</sup>

Mandeville was able to make contributions to an emerging political economy as well as to an emerging aesthetic philosophy, but that accomplishment is outdistanced by the works of David Hume (1711–1776). Hume's *Political Discourses* [Hume (1752)] contain essays with significant contributions to theoretical economics, most notably *Of Money*, *Of Interest*, *Of Commerce* and *Of the Balance of Trade*. At the same time, Hume's *Of the Standard of Taste* [Hume (1757/1963)] provides the most important British text on the evaluation of art.

Hume aimed to determine an objective standard for what he regards as the clearly subjective judgment of taste, which as a judgment of "sentiment" rather than "fact" admits of no objectively "true and decisive standard", even if there are objective properties in artworks that tend to elicit taste's sentiments. "Beauty is no quality in things themselves; it exists merely in the mind which contemplates them" (p. 234). While Hume recognized the diversity of evaluative judgments, he insisted, on the other hand, that some judgments (e.g., Milton's superiority to Ogilby) are undeniably true and that some individuals are better than others at evaluating art. Hume's strategy for defining a standard of taste is to link judgments of taste to judgments which do have a determinate standard "in real existence and matter of fact", and his crucial device for this linkage is the consensus of good critics – "arbiters acknowledged by universal assent to have a preference above others" [Hume (1963, p. 248)]. The standard of taste for establishing the value of an artwork is thus determined by the consensus of sentiment of good critics regarding that work, and, for Hume, the questions of who these critics are and what qualities they must have "are questions of fact, not of sentiment".

The five requisites Hume lists for good critics are "delicacy of imagination" (essentially a matter of perceptual acuity and sensibility to fine discriminations), "practice in appreciating good artworks", "experience in their comparative assessment", a "mind free from all prejudice", and "good sense" (pp. 239–246). Hume's evaluative theory reflects the liberal dilemma of wanting to guarantee both freedom of taste and an authoritative standard to ensure cultural coherence and stability [Shusterman (2002, pp. 93–107)]. Personal freedom of sentiment in evaluation is at least preserved in one's free decision to submit one's judgment to the authoritative standard set by those recognized as superior judges, the good critics. The parallel of this solution to the political solution of representative democracy with only a partial franchisement of the electorate, which was the political system of Hume's Britain, should be obvious.

Given the empiricist and subjectivist premises of Hume's philosophy, a remarkable similarity between aesthetic and economic valuation comes to light. As Schumpeter (1883–1953) has noted, the aesthetic theory in question can be seen to explain the objective fact that a work of art is considered as "beautiful" by the subjective valuations

<sup>4</sup> See Solkin (1993, pp. 13–19).

of the members of a given social group, much as the “analogous economic theory” explains the fact of market prices by subjective valuations of the individuals participating in a market: “In both cases subjective valuation creates the objective value” [Schumpeter (1954, p. 127)].

A third figure of transition is Francis Hutcheson (1694–1746). His early fame was based on *An Inquiry into the Origin of our Ideas of Beauty and Virtue* [Hutcheson (1725/1971)]. His main work, *A System of Moral Philosophy*, appeared posthumously in Hutcheson (1755/2005). Hutcheson picked up where Shaftesbury had left off.<sup>5</sup> Shaftesbury had been able to turn the ancient Platonic notion harmony and equilibrium of the soul into a modern, Christian notion of benevolent love. The principal virtue in man’s dealing with others is no longer justice and temperance but benevolence. Thus, “the motive of benevolence becomes the key to goodness” [Taylor (1989, p. 258)].

Hutcheson proposed that society is held together by two “moral principles”, namely “moral sense” and “self-love”. Two sentiments, benevolence towards others and self-interest, correspond to the two principles. They compete with one another and constitute an equilibrium. Furthermore, they form a hierarchy: moral sense generates more intensive pleasure than self-love. Hutcheson’s construct of “moral principles” bridges the gap between the two widely distinct sensations of blissful happiness and common pleasure. Benevolence is motivated through religion and thus linked to God. Through benevolence, “we participate in god’s plan through re-engagement” [Taylor (1989, p. 265)]. Such participation can take the traditional form of philosophical contemplation, but also the form of aesthetic contemplation.

Benevolence competes with self-love as a source of pleasure. Thus, in the final analysis, self-love does not differ from benevolence in its basic ability to contribute to pleasure (or happiness). To exemplify the operation of the moral sentiment of pleasure, the valuation of art is invoked: beauty is an expression of divine order. Beauty, just as virtue, triggers a particular sensation of joy or bliss, different from the everyday pleasure reached by the satisfaction of self-love. Thus, the subjectivist notion of taste connects with the sentiment of benevolence.

Hutcheson deploys the idea of taste, which he ascribes to a specific internal sense of beauty, in a thoroughly empiricist fashion. Beauty is not inherently in the object through its participation in a Platonic Form, it instead resides in the empirical experience of a subject’s mind: it is an “idea rais’d in us” [Hutcheson (1726/1971, p. 7)], an experienced feeling of pleasure that is caused by properties of a contemplated object and that arises in an essentially passive, automatic reaction just as our external senses automatically generate ideas in us from the properties they perceive. The appreciation of beauty thus requires no specially acquired knowledge or attitude, and, since it is grounded wholly in our shared internal sense of beauty and shared sensory faculties, our judgments of beauty should be shared. This means that though beauty is subjective in the sense of

<sup>5</sup> In fact, the subtitle to his *Inquiry* reads: “. . . in which the Principles of the late Earl of Shaftesbury are Explain’d and Defended, against the Author of the *Fable of the Bees*”.

existing in subjective experience, it can be objective in the sense of being widely shared rather than individualistic. For Hutcheson, the valuable triggering property of our experience of beauty is unity in variety, and he explains different judgments of taste in terms of differences or defects in people's sensory acuity and in terms of association of ideas that can distract an individual from what the object actually presents to his or her internal sense of beauty.

Self-love does not differ from benevolence in its basic ability to contribute to pleasure. In Hutcheson's *A System of Moral Philosophy* [Hutcheson (1755/2005)], the "public good" of society is attained as the sum of the pleasures attained by the members of the society. Given these conditions, it is the duty of a government to promote the common good with the aim of creating the greatest happiness for the greatest number.<sup>6</sup>

Individual ethical action takes a surprising turn in Hutcheson's interpretation: costly and beautiful commodities lay the grounds for a sense of community by stimulating the same feelings in others. By proposing aesthetic delight as the central force responsible for social cohesion, Hutcheson found a way of defending luxury, or any other kind of conspicuous consumption: it is not vice but the Ideas "of Friendship, of Love, of communicating Pleasure to others" which motivate such expenses and thus contribute to the public good [Solkin (1993, p. 83)].

The next generation of authors was not engaged in both strands of theory anymore. The "separation at birth" [Guillory (1993, p. 303)] had taken place. Both economic and aesthetic theory continued to assume a strictly subjectivist epistemology, but economic theory focused on self-interested action while aesthetic theory focused in its complement, disinterested contemplation. The process of separation can be observed particularly well on the side of economic theory. We have the unusual case of two theories, written by one author within the time span of two decades.

Adam Smith (1723–1790), student of Hutcheson and successor to his chair in Glasgow, published his *Theory of Moral Sentiments* [Smith (1759/1982)] in 1759. Following Hutcheson as well as Hume, two basic human propensities are assumed: "fellow-feeling" and "self-love". Man's disposition for sympathy comes under strict subjectivist scrutiny. Humans are limited to their own impressions and imaginations in feeling the distress or the happiness of their fellows. Mutual sympathy is a result of mutual inaccessibility. Humans also need to gain sympathy from others. The rules of propriety grow out of the need for mutual respect. Moreover, the need to secure an adequate measure of fellow-feeling in others is interpreted as a major motive of individual action [Agnew (1986, pp. 177–181)].

Self-love leads to pleasure in activities that are immediately useful for oneself. Smith identifies – as he believes, for the first time – a kind of pleasure that is distinct from mere physical satisfaction. Such pleasure is associated with the principles of beauty

<sup>6</sup> Hutcheson proposes mathematical formulae with which to calculate this quantity, but omits these in the fourth edition of *Inquiry* [Hutcheson (1738/1971)] because, as he states in the preface, "they have proved to be useless".

and elegance. Beauty and elegance, in turn, are gained through form and color on the level of perception, and through variety, fitness and imitation on a higher level of interpretation. Fitness, for instance, leads to an aesthetic appeal in objects of ingenuity and utility. The source of additional value lies in the degree of an object's fitness for the divine plan which is manifest in every natural and social event. Fitness reflects "the regular and harmonious movement of the system, the machine or oeconomy by which it is produced" (p. 183). Objects that display such values of form or design "strike the imagination as something grand and beautiful and noble" (p. 183), and that is what makes them precious. Imitation generates the pleasure of beauty in a similar manner. Smith notes that we experience amazement in seeing an object of one kind represent an object of a different kind. Such imitation requires artifice, ingenuity and imagination. He cites the example of a Dutch still life which is valued more highly than the carpet which is represented in the painting.<sup>7</sup>

The additional value thus identified plays a central role in explaining the force which drives the economic process: according to Smith, the rich "select from the heap what is most precious and agreeable" (p.184). In order to attain the grand, beautiful and noble objects which will secure them the attention and approbation of their fellows, they not only employ those who labor to provide the means for such purchases, they also make improvements in the production processes in order to increase their own buying power. The increase in productivity leads to further growth. The quest for beauty is turned into an explanation of wealth [Guillory (1993, p. 312)].

Seventeen years later, Smith published his second model of explanation, *An Inquiry into the Nature and Causes of the Wealth of Nations* [Smith (1776/1976)]. In the meantime, he had been exposed to another explanation for fueling the machine of commerce: Physiocratic French authors like Francois Quesnay (1694–1774) and Anne Robert Jacques Turgot (1727–1781) assumed that the produce of nature, standardizable in units of "wheat", constitutes the primary, external source of an economy's wealth. Smith adopted the approach of using the measurability of production input factors to establish a firm link with market value. But he extended the source of value beyond the "produce of land" and ultimately shifted it to human labor. Labor is a factor whose external nature remains ambiguous. It consists in the observable exertion of human force for periods of time, but it also consists in the mental opposite of pleasure, namely pain. Labor thus fulfills four requirements: it is, at least in principle, measurable, it legitimizes property, its "toil and trouble" mirror the pleasure enjoyed in consumption, and it contains a moral quality because work is a virtue. Smith has not abandoned his older belief in the propriety of a society founded on sympathy, but he has identified a separate realm, the realm of commercial society. Commercial society is organized around the valuations of the market. The quantity of labor is an "analogue of the standard of taste, a standard which is both transcendent and immanent" [Caygill (1989, p. 95)]. This absolute standard is exposed to the fluctuations of market valuation. The notions of "real"

<sup>7</sup> See Berg (2002) and De Marchi and Van Mignoet (1999).

and “nominal” price correspond to the distinction between the impartial spectator and the sum of empirical spectators already proposed in the *Theory of Moral Sentiments*. The gravity of “natural price” corresponds to Hume’s “mark of conformity”.<sup>8</sup> The separation of the aesthetic and the economic realm is completed, but the mode of analyzing the latter is still shaped by the mode developed for the former.

The literature of classical English economic theory that followed Smith did not retain the ambivalent connotations of Smithian labor, and the references to a society connected by mutual attention and attraction. The idea of differently valued kinds of pleasure is abandoned. New value is generated on the production side by harvesting a life-form, while the demand side of the market is assumed to remain basically passive. David Ricardo’s (1772–1823) *Principles of Political Economy and Taxation* [Ricardo (1817)] completed the formulation of a theory that was based on the absolute value of human labor. Ricardo explicitly excluded objects like “rare statues and pictures, scarce books and coins, wines of a peculiar quality” whose value depends solely on “the varying wealth and inclination of those who are desirous to possess them” (1973, p. 6).

In aesthetic philosophy, the positions of Hume and Immanuel Kant (1724–1804) mark the shift from empirical subjectivism towards analytical idealism. Kant responded to Hume’s empiricist skepticism that held there are no objective truths beyond the consensus of one’s fellows and that most values are held not rationally but because of habit or custom. He split the perception of phenomena into two levels: on a secondary level, sensations caused by the object are perceived. On a primary level, our subjective apparatus, the mind, is capable of ordering the perceived phenomenon in certain relations. Space and time are such “forms of intuition” (Formen der Anschauung), and so are 12 priori concepts. These forms cannot exist apart from human experience because they take place in the minds of the individual in a society. But, under favorable conditions, they can be recognized among members in the society, leading to “subjective universality”. Judgments of taste provide a particularly good example of universal consent because they take place under conditions of disinterestedness, unperturbed by the distortions of profit and desire.

Kant’s aesthetic theory is worthy of especially extended attention, not only because it has been historically so influential but also because it remains the dominant orientation (for better and for worse) of most contemporary philosophy of art. Kant’s pivotal position derives in part from the way he builds on insights from both the empiricist British philosophers and the rationalist continental philosophers that preceded him. He develops ideas of disinterestedness, sublimity, and correctness of taste that Shaftesbury, Burke, and Hume brought to the fore, but he also builds on the rationalist tradition of Leibniz (1616–1716), as applied to aesthetics by Alexander Baumgarten (1714–1762) who coined the term “aesthetics” and essentially founded it as a distinct philosophical “subdiscipline”.

Alexander Baumgarten (1714–1762), a disciple of Leibniz and Wolff (1679–1754), defined it in very broad terms as a science of sensory perception that would parallel

<sup>8</sup> See Caygill (1989, pp. 85–97).

logic's science of conceptual thought: "Aesthetics (as the theory of the liberal arts, the science of lower cognition, the art of beautiful thinking, and the art of analogical thought) is the science of sensory cognition". "The end of aesthetics", he continues, "is the perfection of sensory cognition as such, this implying beauty" [Baumgarten (1750–1758, §§1, 14)]. Artworks, as objects purposefully and carefully crafted to achieve beauty – which was associated at that time with harmonious, rationally proportioned form – seem paradigmatically suitable for sensory cognition. This general meaning of aesthetics as the theory of sensible cognition as well as the narrower study of beauty, sublimity, and arts remains saliently present in Kant. Much later, aesthetics became restricted to its contemporary meaning as the philosophy of art, beauty and related aesthetic concepts.

Kant's *Theory of Aesthetic Judgment* [Kant (1790/1986)] provides a solution to the evaluative problem of holding that aesthetic judgments are essentially subjective yet nonetheless can command, in a necessary way, universal assent. "The judgment of taste . . . denotes nothing in the object, but is a feeling [of pleasure or displeasure] which the Subject has of itself and of the manner in which it is affected by the representation" of the judged object (1986, pp. 41–42). Yet such judgment displays "the necessity" of "universal assent like an objective principle" (pp. 41–42, 84–85). Rather than rely on a group of good critics, Kant argues that anyone can in principle perform an accurate pure aesthetic judgment by exercising the proper aesthetic attitude. This attitude requires disinterestedness, which Kant (p. 43) describes as "indifference" or lack of concern for "the real existence of the thing" judged. For example, we should not care whether we are observing a real landscape or a mere illusory appearance of one. Aesthetic pleasure is thus distinguished from pleasure in the good and in the agreeable because these latter involve interest and desire. A pure aesthetic judgment also requires refraining from the use of concepts and functionality as determining grounds for one's evaluation. Instead one's attention should be directed exclusively to the form of the aesthetic object in terms of its presentation of finality, without regard to any function.

Pure aesthetic judgments are always particular and cannot be rule governed. This is why Kant treats aesthetics as critique rather than science: a science needs to introduce general concepts, while a critique leaves the determining ground of the judgment to the pleasure of the subject who contemplates – with the proper attitude – the object of taste. Diverse concepts and interests can lead to disagreement in judgments of taste, but if we detach our perception from concepts and interests, we can affirm that pure aesthetic judgments claim a necessary "subjective universality" since they rely on the "mere nature" of "the Subject's faculties" that is shared by all humans (pp. 51, 212–223). Kant argues that when properly contemplating the form of a good aesthetic object without concepts or interests and without any regard to "charm or emotion" (p. 64), any person should necessarily get pleasure from the enjoyable "free play" (pp. 86, 88) of the cognitive faculties, in which one's imaginative experience freely con-forms (through form) to the rationality of the understanding without being "forced" to conform in terms of a specific prescribed concept of understanding.

Kant's model objects for pure aesthetic judgment belong to nature whose beauty and sublimity he valued higher than art. Judgments of taste regarding art cannot be absolutely pure and free from concepts, since they always involve the concept of art (pp. 34, 166–167). To properly judge a landscape painting we need to consider it as an artwork and not simply as the appearance of landscape. The introduction of conceptual knowledge for art means that we can also no longer expect universal convergence, since some individuals might lack the requisite knowledge. Kant held the appreciation of nature to be also morally more beneficial, because art, unless “brought into combination with moral ideas”, tends to degenerate into mere “diversion” that “renders the soul dull and the mind dissatisfied with itself” (p. 191).

Kant also ranked the different arts, unequivocally giving poetry the highest place by all important criteria. When considered with respect to “charm and mental stimulation”, music would rank next. But Kant goes on to argue that music's value is much diminished when “we estimate the fine arts by the culture they supply to the mind”. Here, “since it plays merely with sensations”, music has the lowest place among the fine arts (pp. 193–195). The formative or plastic arts, with painting judged foremost among them because of its formal and ideational power, thus can ultimately be ranked higher than music because they not only please but promote “the urbanity of the higher powers of cognition”. Moreover, “music has a certain lack of urbanity” because “its intrusive loudness forces itself on free subjects who would prefer not to hear it” (pp. 194–196).

Though Kant seemed to give primacy to the aesthetic experience of nature – both beautiful and sublime – over art, he nonetheless had a very high regard for fine art, whose creation, he insisted, “needs genius”, an ability to create something original and exemplary rather than merely producing something mechanically according to a given rule (p. 172). A true work of fine art, he explains, requires “Soul (Geist) in an aesthetical sense, [which] signifies the animating principle in the mind [. . . and] this principle is nothing else than the faculty of presenting aesthetic ideas”. Kant defines an aesthetic idea as a “representation of the imagination which induces much thought, yet without the possibility of any definite thought whatever, i.e. “concept”, being adequate to it, and which language, consequently, can never get quite on level terms with or render completely intelligible” (pp. 175–176). Kant's account of art as requiring the creativity of genius whose aesthetic ideas resisted conceptual formulation yet stirred up deep and fruitful thought was very influential to the romantic movement and contributed to elevating the status of the artist and his work. Art and artist were regarded as belonging to a realm of genius and value that transcended conceptual definition and could not be reduced numerical reckonings.

The Kantian world of aesthetic philosophy is already far away from the Smithian world of political economy. Kant perceived order in the immutable intuitions and concepts that govern the perceptions and thus the actions of all members of society. Smith perceived an additional kind of order in commercial society, where the consensus of evaluating participants leads to the measurable result of prices. Kant bypassed the transitory and accidental level of commercial activity to reach the level of common understanding, Smith added the organizing power of the market to explain the coordi-

nation of those who follow their separate and antagonistic interests. Both of them treated beauty as a special source of pleasure, but Smith accorded little attention to artworks in *Wealth of Nations*, and Kant considered natural beauty and sublimity in important ways superior.

Since the beginning of the 19th century, aesthetic philosophy and political economy have moved along different paths. The separation of the narratives in the following sections reflects that separation.

### 3. Art in 19th century economics and aesthetics

The dominating current in political economy continued to be British in the 19th century. The influence of empirical subjectivism in general and of Hutcheson's maximization of collective pleasure in particular remained strong. Thus, we find a remarkable split in the contributions to political economy: one strand, exemplified by Ricardo, developed a theory of production cost, ultimately based on human labor, but principally concerned with objectively measurable cost. The other strand, exemplified by Jeremy Bentham (1748–1832), James Mill (1773–1836) and John Stuart Mill (1806–1873), developed a normative theory of maximizing the “summum bonum”, modeled as the measurable sum of the pleasures experienced by the members of a society. This Utilitarian credo has a reformist and educational dimension: every person can better his capacity for receiving pleasure, and the state can promote the appropriate institutions and initiate actions that raise aggregate well-being. It also has, at least in Mill's version, an evolutionist dimension, as an endstate of society which is compatible with the stationary equilibrium of society's productive, value-generating factors.

The consumption-oriented strand of theory moved to the center of the literature after the second half of the 19th century, when William S. Jevons (1835–1882) proposed a way to measure the utility contained in objects. The measure relies on new scientific ways of registering physiological sensations, and on the fundamental observation that such sensations decrease in intensity with their time of duration. In consequence, there is no need to measure all of the potential pleasure or pain that flows from an object. It is sufficient to measure the intensity at the margin, i.e. at the point where a specific quantity of that object is exchanged for a sum of money or for a quantity of another object rendering more pleasure. Given such a measure, states of consumption equilibrium can be calculated with techniques of constrained maximization, just as in problems of energy conservation and transformation [Mirowski (1989)], and such states are in fact calculated in markets. There is no need to rely on estimates of cost, or even on metaphysical ideals, because the subjective, physiological effects of pleasure can be measured directly.

Jevons applied his measurement of commodity utility through human physical sensations to the “lowest rank of feelings”. He was interested in connecting the traditional utilitarian discourse around pleasure and pain with a modern reading of utility as an analogue of energy, the fundamental force in the world of nature. He was quite aware

of the effects of aesthetic experiences, but he positioned them in the realm of “sympathy”, where the peculiar conditions of commercial society do not hold. In a manuscript “On the Functions of Music”, he described his own response to music as similar to “the contemplation of subjects of Interest, Beauty or Sublimity . . . a general removal of the mind from its ordinary course of duties and frailties, and its continual mixture of slight pleasures and pains”.<sup>9</sup> He believed that the fine arts are capable of enriching the lives of the members of the working class, but this experience cannot be anticipated and would therefore not sell well. There is a vague link between base utilitarian pleasure and sublime aesthetic enjoyment because social progress might lead to an upgrading from satisfactions of physical need to satisfactions “derived from the beauties of nature and art”.

Jevons’ admiration for the Arts is typical for the English academic tradition of late 19th and early 20th century. Alfred Marshall (1842–1924), for instance, explicitly recommended in his *Principles of Economics* (1890) that one should increase the beauty of things in one’s possession, once the necessities of life are provided: “an improvement in the artistic character of furniture and clothing trains the higher faculties of those who make them and is a course of higher happiness to those who use them” (p. 113). But neither Jevons nor any of the major authors of the following generations gave artistic value a special role in the use or utility value of the consumed set of commodities.

The increasing admiration of the Arts was a result of their increasing relevance in aesthetic philosophy, which will be reported below. That change in attitude toward the Arts was even more pronounced on the Continent. It is therefore instructive to contrast the treatment of marginal utility value in English Political Economy with that in the other two centers of the emerging paradigm of Economics, Vienna and Lausanne.

Carl Menger (1840–1925) contributed a long chapter in *Grundzüge der Volkswirtschaftslehre* [Menger (1871/1968)] to commodity value (Güterwerth). In his construction, the source of value is squarely placed in a psychological dimension. Pleasure value is determined along a subjective ordinal scale of relevance. At the limit, that measure is precise enough to determine the exchange value in the market for a given commodity quantity. He clearly interprets desires (Bedürfnisse) as a purely mental activity. The value of commodities lies in their relative ability to satisfaction a desire (Bedürfnisbefriedigung). The satisfaction of commodities is determined by their position on a scale of importance from vital to trivial, from necessities like eating bread to fancies like tobacco, hunting castles and artificial duck ponds (1968, p. 111). The value of the “commodities of lower order” (Güter niedrigerer Ordnung) determines the value of “commodities of higher order” (Güter höherer Ordnung). But “higher” simply means “earlier”: the final consumption value determines the value of the inputs used in earlier stages of the process leading up to the purchase of the end product. Mental consumption value determines material production value. Art plays no particular role among the examples its objects clearly rank among those of lesser importance, although their rarity might secure them a somewhat higher market price.

<sup>9</sup> See Goodwin, Chapter 2 in this volume.

Léon Walras (1834–1910) taught in Lausanne, but was strongly shaped by French philosophical and economic tradition. In his youth, he showed a strong interest in the Arts. He wrote a novel and an essay on *Philosophie de l'Art*. In this essay, he reduces aesthetic phenomena to ontological causes, namely substance, matter and force. In his *Eléments d'économie politique pure* [Walras (1874)], the problem of value origin recedes into the background. Some kind of sensation motivates consumers to demand limited quantities of commodities at certain prices, but the focus is on the mechanics of states of multiple market equilibria. Markets, equipped with imaginary auctioneers, provide a stable and unique solution to the problem of adoption to changes in productive and consumptive conditions. Artworks may be among the commodities that motivate acts of consumption, but they play no special role in the theory.

As we now turn to the development in aesthetic philosophy, we can easily see how the neglect for the sphere of Beauty and its claims of higher satisfaction is reciprocated with neglect for the sphere of commercial activity.

The Idealist strand of philosophical thought found its most successful continuation in the works of Friedrich Hegel (1770–1831). With respect to aesthetics, his contribution marks a turning point because art supplants nature as the paradigm object of aesthetics. As an expression – along with religion and philosophy – of absolute spirit, art, unlike natural beauty, “is capable of truth”. Therefore, it admits of clearer criteria for erecting aesthetics into a science, which is Hegel’s aim in limiting aesthetics to the philosophy of fine art (Schöne Künste).

Fine art, he argues, proves its “worthiness” for scientific study by distinguishing itself as “free” in contrast to arts “that serve the ends of pleasure and entertainment”. Hegel grounds art’s value in other ends: “its highest task . . . is revealing to consciousness and bringing to utterance the Divine Nature, the deepest interests of humanity, and the most comprehensive truths of the mind. It is in works of art that nations have deposited the profoundest intuitions and ideas of their hearts” [Hegel (1835/1993, p. 9)]. Fine art is thus valued and comparatively ranked in terms of the success of its sensuous representation of worthy collective ideas, both according to the quality of the representation and to the idea represented. The idea has greater importance, since the clarity and well-formed character of the idea is a condition for a clear, well-structured representation.

Hegel has a complex ranking of artistic forms and genres. The lowest form of the hierarchy, which he calls symbolic art, is exemplified by “the primitive artistic pantheism of the East”. In such art, the idea still exists in too much “indistinctness and obscurity” for it to have a fittingly determinate form. Hence it is typically rendered in objects that “exaggerate the natural shapes and phenomena of reality into indefiniteness and disproportion”. The next stage in the historical process is “the classical form of art” exemplified by Greek anthropomorphic sculpture whose sensuous human forms express and fully coincide with the rationality of human mind. Their perfect balance of idea and sensuous representation generates the greatest beauty. But though classical art “attained the highest excellence, of which the sensuous embodiment of art is capable”, Hegel points to a more recent and still higher “romantic form of art”. Romantic art shows the inability of the sensuous to fully capture the Idea in its ideal form which is beyond the

realm of the sensuous. Christian art exemplifies this form in which sensuous images are used to point to a realm of spirit. Hegel, thus ultimately found art's highest value in its promotion of the spiritual truth of the Idea rather than in the mere experience of beauty (pp. 82–87).

Hegel also ranks the genres of art in terms of their potential to serve the Idea and spiritually transcend materiality. Architecture lies at the bottom, followed by sculpture, painting, and music in ascending rank, with poetry at the very top. "Poetry is the universal art of the mind which has become free in its own nature, and which is not tied to find its realization in external sensuous matter, but expatiates exclusively in the inner space and inner time of the ideas and feelings. Yet just in this its highest phase art ends by transcending itself, in as much as it abandons the medium of a harmonious embodiment of mind in sensuous form, and passes from the poetry of imagination into the prose of thought" (p. 96). This is one expression of Hegel's famous thesis of the end of art. In earlier times, man needed art to advance spiritual expression since thought was not advanced enough to express the spiritual without the sensuous. But in the more philosophical "reflective culture" of modernity, art "has lost for us its genuine truth and life" and serves largely for "our immediate enjoyment". Therefore Hegel thinks a science of aesthetics necessary to continue to link art to truth and thus save art from having its value reduced to entertainment (pp. 12–13).

Arthur Schopenhauer (1788–1860) develops another variation of Kantian thought. He rejected Hegel's view of art's historically passing truth, but he introduced human will as a subjective force behind cognition. Materiality is the appearance while will is the fundamental reality, objectified into Ideas. Art's supreme value is in revealing human Will. The Ideas that art expresses, Schopenhauer argues in *Die Welt als Wille und Vorstellung* [Schopenhauer (1819/1966)], are not historical concepts but eternal Ideas, even if art's expression is naïve and provides but a fleeting image, not a permanent universal knowledge for which philosophical reflection is ultimately needed. Aesthetic experience offers a special penetration into reality, because its disinterested, "will-less" contemplation allows art's Ideas to shine forth in themselves rather than being distorted by the practical interests that normally guide our perception. The various arts are ranked on levels of Ideas: architecture ranks lower than the plastic arts of sculpture and painting, and they rank lower than poetry. The highest rank goes to music, "Because music does not, like all the other arts, exhibit the Ideas or grades of the will's objectification, but directly the will itself, . . . it is the most powerful of all the arts" (1966, p. 448).

Sharing Schopenhauer's extremely high valorization of art, Friedrich Nietzsche (1844–1900) strongly contested his predecessors's thesis of art's will-less disinterested contemplation, mordantly mocking the dogma of disinterestedness as an expression of philosophers' prudishness, innocence, and their second-hand, spectators' view of art which he contrasts to the creative experience of the artist. The power of art and beauty, Nietzsche argues in *The Birth of Tragedy* [Nietzsche (1872/1956, p. 239–240)], derives not from disinterest but rather from "the excitement of the will, of 'interest' ". "When our estheticians tirelessly rehearse, in support of Kant's view, that the spell of beauty en-

ables us to view even nude female statues ‘disinterestedly’ we may be allowed to laugh a little at their expense. The experiences of artists in this delicate matter are rather more ‘interesting’; certainly Pygmalion was not entirely devoid of esthetic feeling.” Art’s great value, for Nietzsche, is in its service to life, not in the sense of menial practical utility but as providing the heights of beauty, meaning, and pleasure that justifies existence. Though it relies on appearance, true art celebrates through its “esthetic delight” the principle of “eternal life . . . beyond all appearance and in spite of destruction”. It is through art that “this world can be justified only as an esthetic phenomenon” (pp. 55–58, 101–102, 143). Contesting Schopenhauer’s view that art reveals truth in the form of Platonic Ideas, Nietzsche argues that art provides not only beautiful life-serving illusions – the Apollonian dream-world of clear and perfect forms – but also a penetrating glimpse into a deeper Dionysian reality of frenzied will and flux that defies our principles of order and individuation. Art, “that sorceress expert in healing”, enables us to face and recover from such terrifying visions: “the spirit of the sublime . . . subjugates terror by means of art” (p. 52). But art also offers escape from the distressing or hideous truth. “Truth is ugly”, Nietzsche concludes, “We possess art lest we perish of the truth” [Nietzsche (1901/1968, p. 822)].

Hegelian philosophy was radically reinterpreted by Karl Marx (1818–1883). Marx adopts the notion of an inevitable, scientifically provable progress of society, but he replaces historical spirit with matter, or rather man’s relation to matter, as the driving force. Thus he blends Hegelian historicity with the mechanical inevitability of British political economy. In consequence, all “institutions” of human culture, including the arts, are determined by a society’s production relations. Production determines the creation of value and it shapes the intellectual superstructure to which the Arts belong. New production relations will lead to new forms of art. Therefore, a separate recognition of artistic value is not necessary. Yet, Marx’ influence on continental aesthetic philosophers, for instance, Adorno and Benjamin, was considerable.

#### 4. Art in economic theory until the 1970s

Vilfredo Pareto (1848–1923), Walras’ successor in Lausanne, made a number of contributions that helped to give greater analytical precision to economic models. In *Manuel d’Economie politique* (1909), Pareto pitches the obstacles of production against the tastes (goûts) of consumption [Pareto (1909)]. Taste, in this interpretation, is not a faculty to be developed and improved. It is any kind of predilection the user of a commodity might have and which he or she is able to rank in their order of preference. The notion of preference proved helpful for the development of English economic theory which took a formal analytical turn after the First World War.

London, the center of global finance, had become merely another European capital. The shock led to a boom in philosophical discourse. Epistemological positions were radicalized, and these positions were soon to characterize the most influential works in economic science. Intellectual circles included both economists and philosophers. The

philosophical tenor of all these circles was one of a complete separation from metaphysics. Philosophy turned towards itself – towards the observation of the way in which observing statements are made. In London, intellectual discourse liberated itself from the dominance of the “Cambridge Circles” with their strongly literary and philosophical flavor.<sup>10</sup> The circle of economists formed by Lionel Robbins (1898–2004) at the London School of Economics was, compared to Cambridge, less bound by tradition, more cosmopolitan in outlook, and more interested in applying the newly found laws of logic to one’s own methods. Such were the conditions under which John Hicks (1904–1989) presented *Value and Capital* (1939), a model of the economy where consumption value is the undisputed driver of economic action.

Following Pareto, Hicks makes tastes and preference orderings part of the formal foundation upon which the edifice of general equilibrium theory is erected. Along ordinal scales of preferences, the points of consumption equilibrium between various commodities at given budgets are determined. Without having to measure utility in cardinal units, the “value equilibrium” of every individual can be measured in money units “with respect to a system of market prices” [Hicks (1939, p. 20)], and that determination is deemed fully sufficient.

It was a small step from Hicks’ version of value determination to the version published by Gérard Debreu (1921–2004) [Debreu (1959)]. Debreu calls his contribution *Theory of Value*. In his model the need for the term is eliminated. “Value” is used synonymously with “market price times commodity volume”. Use or consumption value is still assumed to drive the economy. But it has been reduced to the subjective and impermeable preferences/tastes of individual agents. “Value . . . became whatever the individual globule of desire made it out to be, a gravitational attraction ‘sui generis’, and therefore was not something over which one should have a rational dispute . . .” [Mirowski (1989, p. 25)]. A neat division of research is thus established: economics deals with the properties of interdependent markets, while the formation of taste for art, as any other process leading to a change of preferences, is the business of other disciplines, like psychology, art history or aesthetic philosophy.

When the stability of tastes or preferences as a basis for economic modeling came under attack, George Stigler and Gary Becker developed a variation of the human capital approach, with explicit reference to artistic appreciation. In a paper titled *De gustibus non est Disputandum* (1977), Stigler and Becker do recognize that there are cases where additional exposure leads to a growth in consumption of the particular commodity. Heroin consumption is cited as an example for harmful, music consumption as an example for beneficial “addictive” effects. Rather than to postulate a change in taste, the authors suggest that the effect can be more fruitfully explained through changes in the shadow prices which govern the household production function: in order to consume

<sup>10</sup> An example is the Conversation Society of the “Apostles”, whose membership included Bertrand Russell, J.M. Keynes, E.M. Forster and Lytton Strachey. The latter were also members of the “Cranium Club”, founded in 1924, which was one of the London offshoots of pre-war Bloomsbury. See Skidelski (1992, p. 13).

music, not only market goods are needed, but also time and “music capital”. Accumulated knowledge and skill reduce the cost of future consumption and thus account for the observed increase in marginal utility.

## 5. Art in aesthetics until the 1990s

Aesthetic theory in the twentieth century displays considerable diversity, including some skepticism with respect to the possibility of universal theories of aesthetics because of the worry that “art” named a historically constructed concept of rather ambiguous, contested, and shifting boundaries rather than signifying a natural kind with a common essence. This skepticism extends to criteria for artistic valuation. At the turn of the century already we find such anti-essentialist positions.

Leo Tolstoy (1828–1910) was a vehement advocate for art’s communicative value. He defined art as the communication or contagion of feelings. “Art is a human activity, consisting in this, that one man consciously by means of external signs, hands on to others feelings he has lived through, and that others are infected by these feelings and also experience them” [Tolstoy (1896/1997, p. 681)]. From this definition of art, he derived evaluative criteria of two kinds. First in terms of efficacy of communication, “The stronger the infection the better is the art, as art, speaking of it now apart from its subject matter – that is not considering the value of the feelings it transmits”. The degree of the infectiousness depends on three conditions: “the individuality of the feeling transmitted”, the “clearness” of transmission, and “the sincerity of the artist” understood in terms of “the force with which the artist himself feels the emotion he transmits” (1997, p. 685). The condition of sincerity, Tolstoy argued, is the most important and in fact includes the others. With respect to subject matter, Tolstoy adopted a religiously Christian and democratic perspective, arguing that good art should express feelings that “unite all men” and construing this as comprising only two kinds of feeling: “first, feelings flowing from a perception of our sonship to God and of the brotherhood of man; and next, the simple feelings of common life accessible to everyone without exception, such as feelings of merriment, of pity, of cheerfulness, of tranquility, and so forth” (p. 689). One obvious (and awkward) consequence of Tolstoy’s theory is his devaluation of partisan, patriotic, difficult, or elitist art, which includes a shocking condemnation of Beethoven’s *Ninth Symphony*.

Benedetto Croce (1860–1952) offered a theory of art as intuition-expression that contained some striking views on evaluation. A true or successful artistic intuition, he argued, implied its active expression, though such intuition-expression did not need to be externalized in a physical object. Technical skill was thus excluded from artistic value. Moreover, as every intuition-expression was a unique product, there were no degrees of beauty or positive artistic value. Artistic value, for Croce, means adequate intuition-expression of its content, and if a work adequately intuits-expresses this, then nothing could be more expressive or beautiful. “The beautiful does not possess degrees, for there is no conceiving a more beautiful, that is, an expressive that is more expressive,

an adequate that is more than adequate. Ugliness [as unsuccessful expression], on the other hand, does possess degrees” [Croce (1901/1970, p. 79)]. Croce’s insistence on the uniqueness of each artwork as intuition-expression entailed rejecting all general principles of art evaluation such as those based on definitions of genres; he regarded genres as arbitrary conventions or illusions.

Most of continental, particularly German philosophy of art in the twentieth century reflected the enduring influence of Hegel by being very critical of identifying art’s value in the intrinsic pleasures of immediate experience of beauty, emphasizing instead the more than aesthetic ideals of truth and understanding. Heidegger (1889–1976), for instance, affirms art as “a distinctive way in which truth comes into being” (1975, p. 78). Hans-Georg Gadamer (1900–2002) similarly stresses the cognitive dimension in claiming that the pleasure of art’s play is “the joy of knowledge” [Gadamer (1982)]. Theodor Adorno (1903–1969) shares this philosophical bias for truth over beauty as art’s most essential value, arguing that art’s production of beauty, in our modern world that has witnessed such horrors as Auschwitz, seems too deceitfully affirmative of the world. Adorno thus can explain the way modernist art has eschewed the simple goal of beauty and instead pursued other expressive ends: “Great works of art are unable to lie” [Adorno (1973/1984, p. 188)]. In the contest of artistic values, Adorno clearly affirms that pleasures of beauty must be sacrificed to truth. “In a false world, all hedone is false. This goes for artistic pleasure too . . . In short, the very idea that enjoyment is of the essence of art needs to be thrown overboard . . . What works of art really demand from us is knowledge or, better, a cognitive faculty of judging justly” (pp. 18–21). Moreover, though Adorno recognizes that art has always had social and practical uses, he rejects the idea of understanding art’s value in terms of functionality. Instead he paradoxically maintains that “if any social function can be ascribed to art at all, it is the function to have no function” and thus offer an alternative to the “ungodly reality” of ordinary practical existence and utilitarian thinking (p. 322). Hannah Arendt (1906–1975) similarly argues that, in contrast to ordinary commodities, the value of artworks “is the very opposite of functionality” or use in the consumptive process of life. Artworks are pure ends, things of “intrinsic, independent worth”, “things which exist independently of all utilitarian and functional references, and whose quality remains always the same” and thus displays the value of “imperishability” [Arendt (1961, pp. 208–218)].

Walter Benjamin (1892–1940), who was closely associated with Adorno and much admired by Arendt, offered a more nuanced, balanced view of art’s value, by recognizing its functionality and distinguishing between varieties of its use value (1969). Benjamin’s key distinction here is the opposition between the artwork’s cult value and its exhibition value. The former is connected with art’s auratic quality, its prehistory in magic, its use in ritual, its sense of authentic uniqueness and its special connection with genius and the distant past. Part of the value here is the esoteric value connected with the artwork being not easily accessible or readily and widely seen. In contrast, exhibition value concerns the value obtained from the perceptual experience or enjoyable consumption of art. Though loss of cult aura has in some way diminished art’s power,

Benjamin recognized the valuable democratic potential of art's move toward exhibition value as some compensation for such loss.

By the turn of the century, Cambridge had become a center not only for general analytical philosophy, but for aesthetic philosophy as well. A dominating figure was George Edward Moore (1873–1958). He claimed that beautiful artworks had objective, indeed intrinsic value, but that such value could never be captured by a definition or criteria based on natural properties [Moore (1959)]. The ethically good and the aesthetically beautiful, he argued, were non-natural values that could not be analyzed in terms of criteria or standards. The aesthetic value of each artwork must be judged, as Kant and Croce had earlier argued, through a particular judgment or intuition, rather than being derivable from a general definition or principle. And to intuit the artwork properly, one had to consider it in terms of its organic unities while isolating it from its external uses. Moore's theory was not purely formalist since he thought that the truth of an artwork added to its value. But his emphasis on organic unities helped inspire the more distinctively formalist theories that Roger Fry (1866–1934) and Clive Bell (1881–1964) applied to the plastic arts, since these art theorists, as well as the J.M. Keynes and other Bloomsbury intellectuals, were avowedly influenced by Moore's philosophy.

Ludwig Wittgenstein (1889–1951), a Viennese philosopher at Cambridge who at times worked closely with Moore but soon succeeded him in philosophical influence, introduced even more particularity and variability to the evaluation of artworks. Wittgenstein argued that the concepts of aesthetics, such as art and beauty, were especially vague and ambiguous. There was no single essence of art or beauty on which we could ground our value judgments, but these concepts did not require essences for us to use them validly in evaluations. Opposing Moore's concentration on beauty and his assumption that it had a common essence (albeit one that could not be reduced to natural properties or captured by definitional criteria), Wittgenstein (1970) argued that our aesthetic evaluations were of significantly different kinds that could not be reduced to a single form. In his terminology, there are a number of different language games with respect to art: evaluating a sonnet as properly formed or a performance as technically flawless virtuosity is different from judging a portrait as luminously subtle or a novel as deep or great. Outside the plastic arts and music, he pointed out, the predicate "beauty" is not frequently used in our aesthetically evaluative language games, and these language games are practiced with somewhat flexible rules. Moreover, Wittgenstein noted that some of aesthetic evaluations are expressed as much in our behavior as in our linguistic statements. Despite such fuzziness and openness, Wittgenstein recognized that there must be significant convergence in our aesthetic evaluations since they are embedded in shared ways of life that give our evaluative terms their meaning. Though we require no essence of the beautiful for the term "beautiful" to have an understandable and shared meaning, we do need some convergence on its use and applications.

Moore and Wittgenstein were founders of analytic philosophy that largely dominated Anglo-American philosophy in the twentieth century. Pragmatism, however, has also been an influential philosophy in the United States and increasingly elsewhere. John Dewey (1859–1952), its major exponent, offered a comprehensive aesthetic theory in

*Art as Experience* [Dewey (1934/1987)]. Rejecting the Kantian ideas of disinterestedness and purposelessness, Dewey argued for art's wide-ranging functionality. Not only do artworks serve a variety of instrumental functions (entertainment, edification, religious inspiration, decoration, personal and social expression, etc.), but art is also enjoyed intrinsically for the sake of the "consummatory" experience that it provides, an experienced fulfillment that is valued for its own sake but that also, through its vividness and vitality, functions to enhance life in a general way by making it more satisfying and by stimulating the energy and intelligence of the individuals and groups who participate in art's aesthetic experience. Art's value, Dewey argued, is not in artworks as mere physical objects but in the lived experience that those objects serve, whether this is the creative experience of the artist or the appreciative experience of the audience. Because art provides enhanced experience that can be powerfully and widely shared, it has an important function of forming and expressing community, constituting "a remaking of the experience of the community in the direction of greater order and unity" (1987, p. 87). Art's imaginative power, moreover, can improve our ethical sensibility. Dewey makes the important point that instrumentality is not inconsistent with intrinsic value when the latter is construed as valuing something for its own sake rather than 'only' for its instrumental uses. We can enjoy art's aesthetic experience for its own sake while also appreciating its non-aesthetic functions.

While analytic philosophers often shied away from both the issue of aesthetic evaluation and the concept of aesthetic experience, fearing that both were too problematically subjective, Monroe C. Beardsley (1915–1985) developed Dewey's idea of aesthetic experience into a distinctive theory of evaluation [Beardsley (1958)]. The value of an artwork is defined in terms of its ability to create an aesthetic experience of a certain magnitude, such experience being presumed to have value; the larger the experiential magnitude, the higher the value. Beardsley combined this approach with three largely formalist criteria of value: the artwork should display unity, complexity, and intensity – these attributes being conducive to the production of strong aesthetic experiences. Suspicious of the notion of intrinsic value and insufficiently attentive to Dewey's harmonizing of intrinsic and instrumental value, Beardsley held that aesthetic experience was valuable, but not intrinsically; its value rather derived from the valuable role or consequences that aesthetic experiences had in the life of individuals and of society as a whole. Nonetheless, Beardsley conceived aesthetic experience as essentially compartmentalized from ordinary life, so that artworks should be interpreted in terms of their immediate perception and not in terms of their wide-ranging referential relations to real world contexts. Such views made Beardsley an important theorist for the New Criticism.

In sharp contrast to Beardsley, Nelson Goodman (1906–1998) insisted on art's referential or symbolic functioning. Goodman (1969) criticizes traditional aesthetic theory for having devoted too much attention to questions of artistic value, which he argued has obscured our understanding of art's modes of meaning and thus diminished the value of aesthetic theory itself. However, based on his analysis of art as symbol, Goodman boldly proposed "the subsumption of aesthetic under cognitive excellence" (1969,

p. 259) a remote echo of the familiar strategy of defining art's value in terms of truth or knowledge.

George Dickie, who skeptically criticized Beardsley's notion of aesthetic experience as a metaphysical phantom (1965), later affirmed experience as essential to explaining art's value: art is valuable as instrumental to the production of "the experience of aesthetic qualities" (for example, unity, complexity, intensity) such experience having intrinsic value (1997, p. 158). Recognizing that not all artworks display the same sort of valuable properties, Dickie argued that we cannot provide a single universal matrix for ranking the values of all different artworks, though we can compare artworks in terms of how many valuable aesthetic properties they display and the degree to which they display them.

Pierre Bourdieu (1930–2002) has contributed works as a philosopher and as an economic sociologist. He argues (1996) that art's value is socially and historically constructed and is thus ultimately grounded in the social structures of cultural hierarchy and hegemony. Artworks that have been admired for centuries become established as icons of culture and genius whose worth cannot be easily contested because they are so deeply socio-culturally entrenched. Not merely items possessing symbolic capital, artworks are also markers of cultured taste that bestow symbolic capital on those classes and individuals who know the right artworks to appreciate and the right ways to appreciate them. Though taste may seem spontaneous and individual, Bourdieu maintains it is the product of pervasive, extended (though typically informal and implicit) social training. Art's value is objective but only as a social fact not as an independent ontological given.

Niklas Luhmann (1927–1998) placed the social construction of artistic value in the context of an encompassing theory of society. In his view [Luhmann (1995/2000)], art theory's connection with philosophy has encumbered it with constraints in theory design which do not have their origin in the Arts themselves. A theory adequate to the unique qualities of Art must account for the simultaneous presence of surprise and recognition which characterizes the experience of works of Art. The special reality communicated by such events is an intentionally fabricated duplication of common reality, a performance of "a world within a world" (p. 241). The theorist and other observers are at liberty to apply the communicative power of Art in an idealizing, critical, affirmative or exploratory manner. But all liberties, as well as all constraints, are the result (Eigenprodukt) of decisions which have been taken within the works themselves.

## 6. Varieties of artistic external effects in contemporary economics

Since the 1970s, economic theory has expanded to explanations of institutional change. Rights to natural and intellectual property are interpreted as part of a social contract that underlies economic action. Implicit constraints on individual behavior can be explained as the stable solutions of non-cooperative strategic games: it pays off to respect the rights

accorded to others. Apart from the rights, rules are reached that reduce the damage done by negative external effects and capture a share of the possible positive external effects.

The concept of “external economies”, originally suggested by Alfred Marshall, has experienced a remarkable rise to prominence in the past thirty years. Marshall had employed it to identify deviations from constant returns to scale in production within an industry. Examples for positive external economies are education and skills, examples for external diseconomies are environmental pollution and political instability. The price system does not reflect the positive or negative “value” of such activities. The lessons of this discovery have been applied to the economics of developing countries, to the economics of education and research, and to environmental economics. They have also been applied to the role of the Arts.

The following section presents three examples of “external effects” which came into view when markets for cultural goods were investigated. The three cases are not exhaustive. They are selected because they bring the valuation of art into play.

Tibor Scitovsky (1910–2002) had participated prominently in the discussion of technological external effects in the 1950’s. In *The Joyless Economy* (1976), his scope is larger: he investigates the “value of consumption skills”. He starts from the notion that subjective value is pure mental value. In consequence, psychological research should yield insights into the process of attaining pleasure. Reviewing the literature, he arrives at a distinction between pleasures of arousal and pleasures of stimulation. The former evoke comfort, the latter evoke a sensation of novelty and discovery. Individuals choose the two varieties in changing proportion, a fact that can be measured through sociological statistics. The data show that the “growth rate” of stimulation pleasure far exceeds that of comfort pleasure. Stimulation is often supported by purchased goods and services. In many cases, it is attained in non-market contexts. Scitovsky discusses self-stimulation, mutual stimulation, non-market goods and external economies. He concludes that the welfare of the community is significantly determined by “the economy’s ability to produce the economic product with a maximum of beneficial and minimum of harmful accompanying effects” (p. 105).

Cultural experiences are singled out as activities leading to beneficial side effects. Culture is defined as “that part of knowledge which provides the redundancy needed to render stimulation enjoyable” (p. 226). Consumption skills are the means, which turn further stimulation into enjoyment, into the source of subjective value. Consumption skills rely on personal practice, on acquired taste and on critical judgment. They are, at base, information differentiation skills: out of the constant flow of new information, a very few items are selected to become the source of common enjoyment in a community or civil society.

Amongst the cultural consumption skills, the skills necessary to exercise and understand the valuation of art objects and performances are central. Scitovsky uses the example of music composition and of painting to illustrate the skill of assembling new works with sufficient degree of redundancy and novelty (pp. 48 and ff.). They are practiced by artists, by experts and by amateurs.

Just as production skills are observed to increase yield per input, consumption skills are able to increase “consumptivity”, or consumptive yield. Scitovsky observes that in the course of the past 300 years of industrial development, production skills have progressively crowded out consumption skills. He suggests several reasons for that phenomenon. Firstly, the value of consumption skills is underestimated for reasons that echo the moral principles of Hutcheson’s age: skills for enjoying leisure are frowned upon in societies which distinguish between activities elevating the soul to bliss, and activities endangering such elevation by stimulating selfish pleasure (p. 228). Secondly, measures of increases in earnings are more precise than measures of the value of skills for the enjoyment of concerts or ballets. Such skills might open “a large reservoir of novelty and years of enjoyment” (p. 235), but the results are uncertain and therefore discounted heavily. Thirdly, the exercise of consumption skills is seen as a threat to currently produced goods: the skills provide access to pleasures of self-discovery and novelty. The pleasure can even be generated out of the process of the activity itself. In consequence, certain cultural commodities and service become superfluous. Once a person has learned to write, for instance, she does not need the services of a scribe or a reader anymore. It is overlooked that new commodities which were beyond the horizon of the old preference ordering begin to be valued: a person who knows how to read develops a taste for books and newspapers.

William Baumol (1986) presented a ground-breaking study on the rates of return from the resale of paintings since 1652. According to his results, returns follow a random pattern. The average return lies at 0.55%, well below average return rates of alternative assets. Since then, an entire subdiscipline has set out to test and expand the Baumol results.<sup>11</sup> The majority of studies confirm the result of below average returns, while the random walk result is not confirmed. The explanations for the “anomaly” point consistently to “psychic returns”, and to the “social benefits” of signals that indicate a specific status or position in society. Psychic pleasure can be triggered by the subject matter of a painting (arousal) or by knowledge of a painting’s history and its position in the world of taste (stimulation). Social benefits flow from being able to signal one’s income level, cultural erudition or attitude to novelty and risk. The value for the owners of artworks lies in the improvement of their negotiating position, on the assumption that negotiating partners are able to read the signals which are brought into the medium of a private collection or a national museum. Expensive materials are easy to read, while the subtleties of a particular style, like black-ground Greek vases or “Arte povera” objects, demand the operation of elaborate standards of aesthetic discrimination. Thus, the successful operation of standards of critical taste exerts positive external effects on the consumption value of an individual.

Furthermore, standards of taste make art objects suitable for value storage and potential value increase. The decisions of investors follow the quality judgments of professional experts. The stability of these judgments has made it possible that art values

<sup>11</sup> See Ginsburgh, Mei and Moses, Chapter 27 in this volume.

maintain their resale value for longer periods of time than bonds and obligations, and that the risk of “bets” on the success of contemporary works can be significantly reduced by following the advice of gallerists and critics who are skilled in aesthetic valuation.

One of the methods developed in the extensive discussion on the value of portions of the natural environment is the “Contingent Valuation Method” [Noonan (2003)]. Environmental benefits are sometimes enjoyed by individuals, but markets for generating such effects cannot be installed. The standard institutional response to this problem is a transfer to the political agenda: taxes or transfers are executed through public households, rules and regulations are put into effect. It is difficult for political agendas to reflect individual preferences adequately. Contingent Valuation is a survey technique that helps to solve the problem by gathering information about exchange values in imaginary markets. The respondents are asked to reveal their willingness to pay for the source of non-market beneficial effects – the survival of an animal species, the designation of a nature preserve and, by extension to the cultural field, the preservation of a historical monument.

Responses to survey questions are radically different from the actual reduction of buying power in a market transaction. Still, the results consistently indicate a positive willingness to pay for artistic works and institutions, and for monuments of cultural heritage. Particularly noteworthy is the observation of option values. Cultural option values are opportunity values attached to places, objects and events which are known to the individual, but not experienced by the individual. The individual “consumes” the ability to express the identity, the history and the ideas and aspirations of a “culture” [Throsby (2001)]. A culture may have the size of a town, a region, a nation or even a network connected by a common belief or life-style. “Cultural value” is a club good for the members of such communities. They benefit from being informed about their common heritage. Cultural symbols provide common themes for conversation and they facilitate the formation of expectations about negotiation partners. For non-members, artworks inform about fundamental issues and perceptions that characterize that other culture. Beyond this instrumental dimension, members reap immediate intrinsic benefits because they take pride and pleasure in artifacts and events that are representative of their community and its “canon” of excellence.

In consequence, the particular method of valuation of art matters for the economic outcome: only autonomous processes of aesthetic valuation can credibly select those artifacts, stories and compositions which are to be regarded as the height of taste. In that process, the set of currently canonical works is formed and constantly contested. It is this set of selected works and performances which serves as a source of value to individuals within and outside of the cultural boundaries of that canon.

## 7. Varieties of artistic value in contemporary aesthetics, and their economic valuation

In the vague concept of artistic value, different kinds of value seem to be nested. We distinguish ten kinds which have been to some extent suggested in the aesthetic theories so far sketched. They are conceived as heuristic distinctions to illuminate the concept of artistic value rather than as ontologically distinct categories of value. The forms of artistic value do not include art's economic value as understood in monetary terms. This form is discussed, as a distinct category, below. It is hard to imagine how all these types of value could be organized into one accepted calculus for ranking the value of all works of art, not least because the relative weighting of these different types would be much contested. Yet, to distinguish them could enable us to be more precise about what we are in fact valuing when, with respect to particular artworks, we speak of artistic value.

(1) Art's *moral or religious vision*, its power to edify and spiritually uplift, can still form part of a work's artistic value, while the appeal to low human drives and the toleration of morally condemned behavior diminishes the value of an artwork. Form cannot be adequately isolated from content. The moral or religious vision expressed in a work forms part of the work's content and structure, and as such its valuation can be legitimately included in our appraisal of the work's value. This is not to say that the moral vision must be true or fully acceptable to the appraiser, but it must at least be regarded as reasonable, mature, and coherent. Art has traditionally been valued for its religious uses, as in altar pieces, poetry and music of prayer. Positive moral effects have been ascribed to literature, to musical education and to visual works, while others have been condemned for irreligious and moral corruption. Art can improve our character by its harmonizing of our psyche, as Aristotle and, in more individualistic terms, Schiller have suggested through their ideas of catharsis and play. The education of moral sensibility through artworks that portray fine subtleties of ethical behavior and character expression has been considered a source of value since Shaftesbury.

(2) Art has long been valued for its deep *expressiveness*. Expression, it is argued, requires a medium through which the self can be expressed, and the various media of art, rich with perceptual and semantic potential, provide a superb matrix for such expression. Advocates of expression theories of art, such as Croce (1970) and Collingwood (1958), argue that the artist begins with an unclear feeling or sense of what she wishes to express, and it is only through art that the expression acquires clarity and distinction. Apart from this transitive sense of expression, where an artwork's expression is the expression of something anterior – a specific emotion, idea, etc. – there is an intransitive sense of artistic expressiveness that is valued. It makes sense to say of a painting or a piece of music that it is expressive without our being able to specify what exactly it expresses. Here expressiveness connotes the degree of power and impact which is suggestive of artistic value.

(3) Art's *communicative power* for the sharing of feelings and ideas between artists and their public is part of artistic value. Art's emotional quality, direct experiential appeal, and link to pleasure give it a penetrating, pervasive infectiousness that promotes

easy, rapid, powerful, and widespread communication. Kant located the grounds of aesthetic judgment in the “*sensus communis*” of human nature, Schiller argued that “only the aesthetic mode of communication unites society because it relates that which is common to all” [Schiller (1986, p. 217)]. In Dewey’s words: “Art breaks through barriers that divide human beings, which are impermeable in ordinary association” [Dewey (1987, p. 249)].

(4) Communicative power is also essential to art’s *social and political* value. Artworks typically embody the meanings and ideals of the society in which they are created; even works that have a revolutionary message must rely to some extent on shared meanings and values or else they would be unintelligible and totally rejected. Art thus provides an attractive repository of ideas and ideals that build social unity and stability, while enabling their transmission over generations. Through its imaginative dimension, works of art can also inspire new visions of social and political order. The social and political import of an artwork cannot be neatly isolated from its directly experiential artistic value. Our aesthetic experience of listening to an anti-war protest song from the sixties or a politically charged rap song from the eighties derives added enjoyment and meaning from recognizing the socio-political motives and roles such artworks have played.

(5) Plato’s condemnation of art as a deceptive purveyor of falsehood has been frequently countered by affirming art’s *cognitive* value. Even if we dismiss the notion of a special form of truth that is accessible only through artistic means, art has undeniable value in effectively communicating a wide variety of truths and in honing our symbolic skills of conveying and processing very subtle forms of information. Because emotion has a strong bodily dimension, art’s emotional power makes the truths it expresses more powerful and convincing, because as emotionally grasped truths they become more deeply embodied and impressed in our consciousness and memory. The very appreciation of form and meaning is an exercise whose practice enhances our cognitive skills and our proficiency in symbolic processing.

(6) Many theorists, as do most other people, locate art’s value largely in the special, directly satisfying or pleasurable experience it gives. We call this art’s *experiential* value. It includes art’s entertainment value – the entertaining pleasure and distraction it provides as a pastime. But art also has experiential rewards that are not primarily pleasurable. Avant-garde works, for example, may produce experiences of shock, intensity or outrage that we recognize as valuable without their being pleasant or enjoyable. The central role of aesthetic experience in art’s value has been reaffirmed in recent years in rather different ways. Budd (1995) insists, contrary to Beardsley, that such experience has intrinsic value in some meaningful sense. Therefore, Budd argues, art’s value as art should be confined to purely aesthetic dimensions of art’s immediate intrinsic experience. Shusterman (1992, 2000) allows that art’s value also should include the instrumental effects or consequences of an artwork’s aesthetic experience, including the truths, insights, and uses the work provides.

(7) Aesthetics has long emphasized certain formal or design values embodied in art: unity, harmony, complexity, balance, intensity, dramatic tension, etc. Such formal values

are sometimes distinguished by philosophers as distinctively *aesthetic* values in contrast to artistic values. This is because these formal values clearly seem applicable to objects other than artworks (a flower or sunset or ocean storm) and do not seem to require historical knowledge of art in the ways demanded by assessments of art-historical value, art-technical value, or cult value. Nor do these values demand for their appreciation the sort of external, non-aesthetic knowledge we need for assessing the cognitive, moral, religious, or communicative value of artworks. Experiential value might be considered along with formal values in this group of distinctively aesthetic values of art since the dimensions of experienced value do not make essential reference to art-historical knowledge or standards outside the immediate experience of the artwork.

Expressiveness, in the intransitive sense of evocative suggestiveness, can also be included under specifically aesthetic properties of artworks. We can appreciate an artwork as expressive without external art-historical knowledge about what its creator wanted to express and without even assuming that there was a distinct idea the work aims to express. Indeed, we can even speak of a natural scene – such as a rock formation or a gnarled tree – as aesthetically expressive without implying that it expresses a prior identifiably intention by its creator. A clear distinction between artistic and aesthetic value has been hard, however, to maintain, because the term “aesthetic” is so commonly associated with the artistic and because it can be argued that even judgments of unity, intensity, complexity, etc. in artworks implicitly rely on some basic art-historical knowledge.

(8) A specific kind of artistic value could be called *art-technical* value. Such value relates to the skill, technique, or technical innovation displayed by an artwork. We can, for example, regard the content or form of an artwork as not particularly worthy of appreciation but still value the virtuosity of technique or invention that the work or its performance displays.

(9) *Art-historical* value concerns the value an artwork has for art’s history, either by its providing evidence of historical innovation or influence, whether technical, stylistic, or in terms of new content, or by simply being a crucial historical artifact for art history. Though some viewers find Picasso’s *Desmoiselles d’Avignon* a very unattractive painting, its artistic value in terms of art-historical value (as the harbinger of cubism) cannot be denied. Physical rarity, because very few other surviving exemplars of its period or style have been found, adds to appreciation.

(10) Related to art-historical value is *artistic cult* value. Through a history of appreciation and dissemination, a particular artwork, for example, Leonardo da Vinci’s *La Gioconda*, becomes identified as a hallowed locus of artistic genius and a paradigm of self-representation. The strength of the aura, to which Benjamin refers, gives value to the reproduced versions of the image, and the volume of reproductions, in turn, increases the cult value of the original.

Some of the works of art created also have economic value. Economic value is a property which all works can attain, irrespective of the kind of artistic value attributed to a particular work. Money is paid in exchange for original works, copies of originals (books, prints and disks), and performances of musical or theatrical scores. Certain

patterns of demand and supply are directly connected to some of the artistic values sketched above.

The ability of public expression has made artworks a valuable resource for the institutions of power and their public households. When religious institutions controlled a large portion of social power, their demand for works which could transport their messages and rules was high (1). It has dwindled since, to be replaced by political institutions (4), educational institutions (3) and by a recognition that the expressive power of art makes it a legitimate candidate for public financial support (2).

Art's cognitive value (5) communicates a "wide variety of truths" and it trains "symbolic skills". An economically relevant truth is social status, transported with symbolic skills. Individuals and communities know how to represent their status through the purchase of art works, through buying the right to attendance and through the acquisition of decorating items that are associable with artworks. High market values signal high social status, and therefore the prices of certain works may be bid up without any change in the artistic value of the works. While cognition is directed outward, pleasurable experiences (6) are directed inward. The desire to make time pass pleasantly is a powerful motive for spending income. The share of entertainment goods and services in total expenditure increases over time, as more immediate pleasures of "arousal" are saturated, to use Scitovsky's term. Since stimulation produces constantly new variations, works of art become a valuable source of inspiration for authors, and they attain, due to the media attention, widespread popularity among consumers which steps up demand for originals and copies.

Artworks achieve part of their impact because of the pleasure gained in experiencing virtuosity. Artworks are judged by the degree to which they satisfy formal qualities (7). The technical challenges contained in the execution of an artwork are mastered by only a few (8). Excellence implies scarcity. Kinds of works which are in shorter supply can command higher prices. Rarity is also a key factor in art-historical value (9). The economic value of a historical item, like a book from the first edition of a successful novel, also increases with a decrease in specimens available. Finally, the paradigmatic uniqueness of works that have been attributed "cult value" (10) increases the demand for copies, for travels to the location of the cult work or cult event and for other works associated with an "icon".

Economic value increases when several varieties of artistic value are combined in a single work. The highest prices are attained for rare works or performances by most highly ranked masters that combine emotional impact with status and entertainment value. In contrast to ordinary consumption goods, the value of physical artworks is sustained or even increased over time, making such works effective stores of economic value.

## 8. The logic of aesthetic and economic evaluation

Philosophical theories concerning the logic of evaluating art are focused on three related topics: the logical status of evaluative judgments, the role of reasons in evaluation, and the general structure of evaluative argument [see Shusterman (1980, 1981)].

(1) The *logical status of evaluative judgments* concerns the question of whether they are propositions that have descriptive truth value, are prescriptive expressions of feeling or of recommended decisions to take a particular attitude to the artwork or, finally, are neither descriptions nor prescriptions but rather performative verdicts that themselves establish the evaluation they make. These different options are respectively advanced by descriptivist, prescriptivist, and performativist theories of evaluation. Descriptivist theories can be divided further into subjectivist, relativist, or absolutist theories according to whether the alleged descriptively true statement of value refers only to a particular subject, or is relative only to particular criteria of evaluation, or is meant to have absolute or universal reference. The subjectivist descriptivist construes the assertion that “artwork W is valuable” as meaning “artwork W is valuable to me”. Literary masters such as D.H. Lawrence and Walter Pater argued for this position, Lawrence (1936, p. 539) claiming that “literary criticism can be no more than a reasoned account of the feeling produced in the critic by the book he is criticizing.” In contrast, absolutist (or objectivist) descriptivists – such as the renowned critics Matthew Arnold, the early T.S. Eliot, and Yvor Winters – claim that evaluative judgment is about the artwork itself “as it really is”. Though the subjectivist position may seem overly personal and impressionistic, Pater (1912, p. 10) shrewdly defends such evaluation by arguing that “in aesthetic criticism, the first step to seeing the object as it really is, is to know one’s own impression as it really is”. The relativist occupies an intermediate position of evaluative descriptivism. He admits that some evaluations are better than others and that some are plainly wrong. But recognizing that there are often conflicting evaluations of an artwork that seem well-reasoned and adequate, he rejects the absolutist assumption that there must be only one true evaluation and that all others must be regarded as false. The relativist therefore construes evaluative judgments as true or objective relative to some standard that is deemed adequate. Among the many theorists and critics who advocate forms of relativism, E.D. Hirsch (1969, p. 33) clearly formulates the key idea that though “there is no privilege [of a particular evaluative standard] in literary evaluation, there is nevertheless objectivity and accuracy, and these reside entirely in the judged relationship between the literature and the criteria we choose to apply to it”.

Other theorists construe evaluative statements not as descriptive propositions at all. For an emotivist–prescriptivist, such as A.J. Ayer (1971), critical judgments “are pure expressions of feeling and as such do not come under the category of truth and falsehood” but are instead meant to make us share the feelings and attitude expressed in the evaluation. To lack truth status does not entail lacking efficacy in communicating a work’s felt value and convincing others of it. An alternative position, performativism builds on J.L. Austin’s theory of performative utterances. It argues that evaluative judgments do not describe the work’s value in itself or for the subject who judges, but instead

display or create the work's value. As Margaret MacDonald (1954, pp. 121–122) formulates it, “to affirm a work good is more like bestowing a medal than naming any feature of it or of the status of its creators or audience. Verdicts and awards are not true or false. They may be reversed but not disproved. But they can be justified and unjustified”. To give some common examples, when an important book reviewer writes in his review that a book is highly recommended, he institutionally renders it such, thus augmenting the value it is critically accorded. The same goes for the nominations and awarding of artistic prizes.

With respect to these different theories of evaluative judgment, one is led to conclude that none is entirely acceptable because each has more than a grain of truth. Evaluative judgments are in fact diverse in form and function; descriptivism, prescriptivism, and performativism can all find some evaluative judgments that support their different analyses.

(2) Critics and art lovers do not simply offer evaluative judgments, they give reasons for them. What role do these *evaluative reasons* play? Some theorists argue that evaluative reasons play a logical role of evidence or validating principles. Monroe Beardsley, for example, views the reason “this work is unified” as providing some evidential confirmation that the given artwork has value because it provides inductive evidence that the work is likely to produce an aesthetic experience (which has value). Beardsley argues that the logical relation of unity to aesthetic value is similar to that between “The food is dangerous” and “It is crawling with salmonella bacteria”. Reasons relating to complexity and intensity are likewise evidence, though not necessary or sufficient conditions, for affirmations of aesthetic value, since objects possessing those qualities tend to produce aesthetic experiences [Beardsley (1958, pp. 533, 535)]. Similarly, when critics appeal to the fact that a classic work has passed “the test of time” or that a work has been historically very influential, they are arguing for its value on the basis of evidence from the strength of its positive past valuation. As Samuel Johnson (1709–1784) classically formulated this empirical position: “to works not raised upon principles demonstrative and scientific [e.g., mathematical or deductive], but speaking wholly to observation and experience, no other test can be applied but length of duration and continuance of esteem” [Johnson (1957, p. 9)]. This evidential approach is still widely used in contemporary evaluations of art. Lionel Trilling, for example, in advocating the aesthetic value of *The Great Gatsby*, notes that the book has “gained in weight and relevance over time” and then reasons that “this could not have happened had the book's form and style not been right as they are” [Trilling (1950, pp. 251–252)]. Another critic, Graham Hough, argues that the value of Dante's work is not logically challengeable, since “it would be a very strange position to hold that Dante's fame and influence were no evidence of literary merit” [Hough (1966, p. 76)]. Indeed, to say that an artwork has been influential and important is already to make a claim about its art-historical value.

In contrast to these logical theories of evaluative reasons, Charles Stevenson (1855–1950) offers (1957) a causal theory, urging that such reasons refer to the causes or motives that determine the critic's attitude to the work and are expressed by the critic in order to recommend those motives and attitude to the public. This sort of reasoning

can be found in a famous essay by T.S. Eliot that savagely criticized Milton's poetry, arguing that although "great" in its way, it was a grave danger and bad influence for contemporary poets because it emphasized qualities such as grandiloquence, sonority, lack of visual concreteness that were opposed to the sort of poetry that Eliot and his cohorts were trying to establish and that was exemplified by the seventeenth-century "Metaphysical Poets". Once Eliot's poetic revolution was successfully achieved, he wrote more positively about Milton while defending his earlier negative evaluation as right because of its justifiable motives in revolutionizing English poetry: "poets engaged in such a revolution will exalt the virtues of those poets of the past who offer them example and stimulation, and cry down the merits of those poets who do not stand for qualities they are zealous to realize. This is not only inevitable, it is right" [Eliot (1975, pp. 272–273)].

A third position, perceptualism, claims that reasons in artistic evaluation function as rhetorical devices for focusing attention on the work in such a way that the affirmed value will be directly perceived. The reasons do not function as logical evidence but rather as instruments of perceptual persuasion which lead the critic's readers or audience to see or experience the value the critic perceives in the work and thus to share the critic's evaluative verdict. For example, in justifying a positive evaluation of a painting, a critic may point to a particular line or feature of the work. This particular feature can lead an observer to see the work in the way the critic does and thus be perceptually convinced of the critic's evaluative verdict. Wittgenstein (1970) and many of his followers have propounded this perceptualist view of critical reasoning, and many examples of such reasoning can be found. Thus, with respect to the logical role of reasons in aesthetic evaluation, we again find that none of the major theories is entirely right or wrong, since the arguments of critics partially fit each of these theories.

(3) Closely related to the role of evaluative reasons is the issue of the general *logical form of evaluative argument*: is it inductive, deductive, or something altogether different. Beardsley (1958, pp. 471–472) argues that evaluative argument is "elliptical induction", since he denies there are any universal, absolute criteria from which we could deductively derive a true evaluative verdict.<sup>12</sup> However, Beardsley maintains that there are nonetheless criteria such as unity, complexity, and intensity that provide inductive evidence that an artwork which possesses them will be good. We have already noted that arguments relating to the test of time or historical influence are also inductive. Such arguments have themselves stood the test of time, extending from Longinus in antiquity to contemporary advocates [Savile (1984)].

In contrast, other authors claim that evaluative arguments should be deductive, based on the critic's clearly formulated norms of judgment and her description of the work in question. When we look at the practice of evaluating critics we can sometimes find arguments that look deductive in general form. Johnson and Coleridge argue deductively for the greatness of Shakespeare's dramas by trying to show these plays display the

<sup>12</sup> An example of such a universal criterion would be "all works having unity must be valuable".

essential principles of dramatic greatness. Evaluative arguments that are based on genre rules seem to have an overarching general deductive structure, where one proves the excellence of the work by showing that it meets all the necessary rules of excellence or properties of value of the esteemed genre. Joseph Addison, for example, argues for the excellence of *Paradise Lost* by demonstrating it satisfies Aristotle's "rules" for epic poetry and has all "the beauties which are essential" to that genre [Addison (1943, p. 280)]. Harold Osborne's declared norm of artistic judgment is that a work of art should be "an organic whole of interlocking organic wholes", and he maintains that any work that truly meets that description would have artistic value. However, Osborne admits that to demonstrate that a work indeed has this organic nature requires reasons that operate perceptually rather than deductively or inductively [Osborne (1952, p. 203; 1955)].

Some evaluative arguments about art do not display a clear inductive or deductive form but instead consist of a complex arrangement of focusing remarks, analogies, contrasts, leading questions, and suggested responses that attempt to bring the reader to a particular desired conclusion. Such arguments, which rely very much on the perceptualist role of reasons, have been described as dialectical or rhetorical [Shusterman (1980); Wisdom (1957)]. This style of reasoning is very salient and self-conscious in the influential English critic Frank Raymond Leavis (1845–1978) who characterizes his evaluative argument as not "measuring with a norm" but as convincing through a collaborative-persuasive appeal to the reader "in terms of concrete judgments and particular analyses: 'This – doesn't it? – bears such a relation to that; this kind of thing – don't you find it so? – wears better than that' etc." [Leavis (1976, p. 115)].

There is thus not one general logical form of argument in evaluative reasoning about art. This should not surprise us, since we saw similar plurality with respect to the logical role of evaluative reasons and the logical status of evaluative statements. Evaluative logic, to conclude, is clearly pluralistic. This need not be seen as a weakness. The different logics of aesthetic evaluation reflect the different motives, aims, and contexts that we have in evaluating art as well as the different competing values that art embodies and promotes.

Analytical philosophy clarifies the rich variety of aesthetic argument. It locates the source of value in subjective, yet communicable perceptions of truth, emotion and honor, it reveals that motives of artistic or academic recognition lead to the development of reasons in order to persuade others, and it demonstrates how the full range of heuristic devices is employed, from persuasive induction to stringent deduction, and from simple analogies to complex rhetorical patterns. Most importantly, it demonstrates that artistic valuation is a constantly shifting, competitive process. This process is played out in a variety of arenas. It takes place before festival juries, prize committees and journal editors. It generates evaluative rankings, both of the artistic value of the works and of the judgmental skill of the juries.

Economic theory is concerned with an entirely different mode of evaluation. In this mode, evaluation does not take place through judgment but through actual exchange: the buyer gives up a sum of money and gets control over the item bought. All relevant

information has been obtained and all the arguments have been delivered when the exchange takes place. Therefore, the economic value of a work is contained in the price last paid, or in the sum of the prices paid for copies or performances of an artwork.

The simplicity and unambiguity of the market mode has been identified as one of the reasons for its success. However, economic theory is well aware that the emergence and the successful performance of actual market institutions is the exception rather than the rule under conditions which deviate as far from the standard commodity assumptions as artworks do. Art works are typical “information goods”: they are uncertain in their effects, they are public in nature and their cost of multiplication has steadily decreased since the invention of print with movable letters. Under such conditions, market valuation is improbable. There may well be heated debate and exchange of words, but why should money equivalents be offered if the effect of a good is uncertain, access to it is free, and imitations are cheap?

Following recent institutionalist theory, behavioral arrangements and rules should emerge which effectively decrease uncertainty, reduce access and discriminate against imitations. In fact, a vast volume of market valuations for art works does take place in contemporary economies. Specialized professions, like agents, dealers, fair organizers and art critics, have established themselves. Special laws protect the rights of artists and performers to the commercial use of their works. Finally, the judgments of experts for rankings of artistic value provide stability for expectations of future value. There are still cases of grave impediments to exchange, like Land Art works which lack transportability and durability, but artists have shown that even such ephemeral projects can be financed through the sophisticated sale of reproductions. For the most part, artistic expression has accepted formats which improve marketability, like transportable framed canvases, or music pieces of supportable length, or gripping narratives.

While the valuation processes observed by aesthetic philosophy and by economics remain logically distinct, their performative interdependence in real life has grown. In consequence, the academic disciplines observing them gain insights by taking each other's results into consideration.

**Abstract**

This paper surveys from an economic standpoint a number of important legal issues that influence the market for art, which include the creation, sale, valuation, maintenance and, in some instances, the destruction of works of art. We show that the important legal doctrines that bear on the visual arts can best be understood as rough efforts to promote efficiency in the art market. The paper focuses on U.S. legal doctrines and only occasionally mentions foreign law. Among the legal topics we consider are the following: copyright and trademark issues; moral rights which cover the right of an artist to prevent the mutilation and destruction of his work; resale royalties; rules governing ownership disputes between innocent parties such as a good faith purchaser and an earlier owner of the work of art; disputes over the authenticity of a work of art which cause material changes in the market value of the work; and the valuation of art-rich estates.

**Keywords**

art law, visual arts, copyright, trademark law, moral rights, resale rights, ownership disputes, authenticity issues, estate valuation issues

## 1. Introduction

This chapter surveys from an economic standpoint a number of important issues in the field of art law. We focus exclusively on the visual arts – by which we mean painting, photography, sculpture and prints – and do not discuss issues specific to other art forms such as music, dance, movies and theater. We approach the subject from a positive rather than normative standpoint. We analyze the economic implications of legal rules that influence the market for art, which include the creation, sale, valuation, maintenance and, in some instances, the destruction of works of art. We also show that a number of important legal doctrines that bear on the visual arts can best be understood as rough efforts to promote efficiency in the art market. The chapter focuses on U.S. legal doctrines and only occasionally mentions foreign law. Perhaps this limitation can be partially justified from data showing the U.S. domination of the art market.<sup>1</sup> Three broad areas we do not discuss in the chapter are illicit international trade of art, public funding for the arts and government censorship of art.<sup>2</sup>

The chapter is organized as follows. Section 2 discusses copyright and trademark issues. Section 3 examines moral rights and Section 4 briefly examines resale royalties. Section 5 looks at legal rules governing disputes over ownership of art. Section 6 examines legal questions that arise in connection with disputes over the authenticity of a work of art. Finally, Section 7 examines legal issues that arise in connection with the valuation and disposition of art-rich estates.

## 2. Copyright and trademark issues<sup>3</sup>

### 2.1. *The basic law and economics of copyright*

Copyright protects original works of authorship that are fixed in a tangible form. A copyright covers not just unauthorized copying but also includes rights over the distribution of copies, derivative works (called adaptation rights), and public performance and display. “Originality” and “fixation” are threshold questions that help economize on administrative and enforcement costs. “Originality” does *not* mean novel or creative but simply that the work originates with the author – i.e., the author did not copy it from another person – and has a minimal level of creativity. Its purpose is to save administrative and enforcement costs by screening out works that probably would be created even without copyright protection. “Fixation” also saves enforcement costs because it would be more burdensome for a court to decide, for example, if an alleged infringer had copied a verbal description of a not yet executed painting than the painting itself [see Lichtman (2003)].

<sup>1</sup> See Table 2 in Ginsburgh (2005).

<sup>2</sup> See Chiang and Posner (2003).

<sup>3</sup> This section draws heavily on Landes (2000, 2003) and Landes and Posner (2003, Chapters 2–6).

A basic principle of copyright is that ownership of the physical object is distinct from ownership of the copyright, and either can be transferred without the other. Thus, the purchaser of a painting acquires the physical object but not the copyright, which is typically held by the artist or his estate.<sup>4</sup> To be sure, the purchaser could also acquire the copyright but that would require a written transaction.

Copyrightable works have in common what economists call a “public goods aspect” to them. Creating these works involves significant expenditures of money, time and effort (sometimes called the “cost of expression”) while the cost of reproducing a work is typically very low or negligible. Since each copy embodies the “cost of expression”, additional users can be added at the small cost of making a copy. In the absence of copyright protection, therefore, unauthorized copying of the work would drive down the price of copies to marginal cost. This would reduce the incentives to create the work in the first place because the creator would be unable to recover his initial cost (i.e., the cost of expression). To be sure, some original works will still be created even in the absence of copyright protection. There may be substantial benefits from being recognized as the creator or from being first in the market or the copies may be of “inferior” quality. Creators may also use contract law or other private enforcement means to discourage unauthorized copying. Finally, the creator may be able to capture some of the value of copies made by others by charging a higher price for the copies he makes.

Unlike most ordinary goods, copyright protection generates access costs because the price charged for copies will be greater than the marginal costs of making and distributing copies. Access costs fall on both consumers and creators of subsequent works who substitute other inputs that cost society more to produce or are of lower quality, assuming (realistically) that copyright holders cannot perfectly price discriminate. As a result, some creators may be deterred from building upon prior works because they are unwilling to pay the price the copyright holder demands. Paradoxically, too much copyright protection can reduce the number of new works created by making it more costly for creators to build on prior works.

Another major cost of a copyright system is administrative and enforcement costs. These include the cost of setting up boundaries or erecting imaginary fences that separate protected and unprotected elements of a work; the cost of excluding trespassers; and the costs of proving infringement and sanctioning copyright violators. Unlike real property, these costs tend to be more costly for intellectual property because of the greater difficulty in defining and enforcing the boundaries of a copyrighted work.

Because the costs of establishing and administering property rights are greater for intellectual than real property, we expect and find that property rights are more limited for intellectual than real property. In this regard, several important limitations on copyright protection are worth noting.

(i) Copyright protects expression but not ideas, concepts, principles, techniques or processes (“ideas” for short). While distinguishing the two may occasionally prove

<sup>4</sup> See Landes and Posner (2003, pp. 126–128), for a general discussion of why separation of ownership of the thing and the copyright lowers transaction costs and promotes economic efficiency.

challenging, the economic justification for doing so is clear. The evidentiary costs of proving appropriation of ideas could be excessive, and the potential benefits of doing so – enjoining the production of works that wouldn't already be captured by protecting expression – could be relatively minor.

(ii) Copyright protects against unauthorized copying but not independent duplication. The likelihood that a second author might independently create a similar work to another is relatively low unless the work contains a negligible amount of original expression (in which case it will fail the originality requirement). Nonetheless, if independent duplication were actionable, authors would spend less time creating new works and more time checking prior works in order to avoid copyright liability.

(iii) The “first sale doctrine” and “right of public display” limit the copyright owner's distribution and display rights. Under the first sale doctrine, the owner of a work can resell or lease or otherwise dispose of the work without violating the distribution right (17 U.S.C. §109(b)(1)(A)).<sup>5</sup> Similarly, the owner of the work can display the work publicly or loan it to a museum for public display without infringing the copyright owner's display right.

(iv) The most important limitation on copyright protection is the doctrine of fair use, which allows unauthorized copying or adaptation of a work in circumstances that are roughly consistent with economic efficiency. These circumstances include:

- (1) high transaction cost cases in which the benefits to the copier are greater than the costs involved in locating and negotiating with the copyright holder;
- (2) implied consent, in which unauthorized copying tends to benefit the copyright holder; and
- (3) transformative uses, where the benefits from unauthorized copying are greater than the harm done.

In case (1), unauthorized copying yields net benefits but zero (or negligible) harm to the copyright holder. Case (2) involves unauthorized quotes from the copyright work in a book review or the reproduction of an artist's work in a catalog or magazine article about the artist. While it is possible that negative reviews will reduce the artist's sales, we expect that overall artists will benefit from the information art critics provide to consumers. A more subtle point is that although transaction costs between the artist and the reviewer would not prevent the latter from negotiating to copy the former's work, reviews in general are more informative and valuable if the reviewer does not have to pay or get permission from the artist in order reproduce a small amount of copyrighted material. Category (3) is limited to productive as opposed to reproductive uses of an artist's work. A parody or appropriation art are examples of productive uses while photocopying an artist's work is a reproductive use. This category invites a cost/benefit analysis in which the benefits from unauthorized copying are weighed against the harm to the copyright holder. Fair use will be found when the benefits are greater than the harm from unauthorized copying.

<sup>5</sup> There are exceptions for renting and leasing of sound recordings (CDs, tapes) and computer programs without the copyright owner's authorization.

## 2.2. Copyright protection for visual art

In the case of a unique work, such as a painting, the case for copyright protection is weakened because the main source of the artist's income and that of intermediaries, such as dealers, typically comes from the sale of the work itself rather than from the sale of copies. The opposite is true of most copyrightable works, such as books, movies, software, musical works, and, in the visual-arts domain, works of graphic art. That said, unauthorized copying of unique works will reduce an increasingly important source of income an artist receives from posters, note cards, puzzles, coffee mugs, mouse pads, t-shirts and other derivative works or adaptations that incorporate images from the original work. Without such income, some of which flows directly to artists and other indirectly by increasing the resources that museums and galleries have for acquiring art, there will be less incentive to create unique works. How much less? Perhaps not much since there also are substantial pecuniary and non-pecuniary benefits from recognition as an original artist and even unauthorized reproductions that appear on merchandise call attention to the original work, enhancing the artist's reputation and increasing the value of his works. Still, the prospect of future ancillary income will have a positive though possibly small influence on the incentive to create new works.

It is worth mentioning that copies of works of art often are viewed as greatly inferior in quality to the original, which in turn tends to reduce the economic impact of copying. When a painting attributed to Vermeer or Van Gogh is discovered to be a forgery, however skillful, its price nosedives. To take another example, vintage photographs (prints made at the time the photograph was taken) command a substantially higher price than the identical photograph printed later from the same negative.<sup>6</sup> Another possible reason for the great disparity in price between originals and copies is that the latter, because producible in essentially unlimited quantities, sell at a price equal to their (low) cost of production, whereas the supply of originals is fixed at a low level, so if originals are valued for their scarcity, copies are poor substitutes even at very low prices [Becker, Landes and Murphy (2000)]. But whatever the reasons, the important point for our purposes is simply that copying is a much smaller threat to the ability of artists to recover their fixed costs of expression than it is to the ability of writers and composers to do so.

There is also a transaction cost argument for vesting control over derivative works in the creator of the original. For example, there are several hundred ancillary products ranging from umbrellas to condoms that incorporate images from works of art created by Andy Warhol.<sup>7</sup> By concentrating the copyrights in the Warhol Foundation rather

<sup>6</sup> Consider two examples. Dorothea Lange's widely reproduced 1930s vintage photograph known as "Migrant Mother" sold at a Sotheby's photography auction October 7, 1998, for \$244,500, while an exhibition-quality print of "Migrant Mother" can be obtained for under \$50 from the Library of Congress Photoduplication Service. Edward Weston's vintage photograph from the 1929 entitled "Pepper" was sold at a Christie's photography auction in 1997 for \$74,000, while a print from the same negative, printed later by the photographer's son, had been sold at an auction eighteen months earlier for only \$1840.

<sup>7</sup> See "The Warhol Store" on the website of the Andy Warhol Museum, at <http://www.clpgh.org/warhol>.

than letting each creator of a derivative work own a separate copyright, the law avoids infringement suits involving multiple plaintiffs in which a court might have to decide which of many similar and widely accessible works the defendant had copied. Licensing costs would also rise because a potential licensee would be well advised to seek licenses from all owners of copyrights on derivative works, as well as from the owner of the copyright on the original, in order to avert the risk of being sued by one of them. The copyright on the original Warhol image is sufficient to prevent unauthorized copying of the various derivative works, since a derivative work will infringe the copyright on the original work.

Of course an alternate solution would be to deny copyright protection to works of art and their derivative works, given that the overall case for copyright protection of works of art is weaker than that for copyright protection of most other expressive works. This point should be kept in mind in deciding how the law ought to resolve close questions relating to art copyrights.

### 2.3. *Appropriation art*

Appropriation Art borrows images from popular culture, advertising, the mass media, and other artists and incorporates them into new works of art. Often the artist's technical skills are less important than his conceptual ability to place images in different settings and thereby alter their meaning. Appropriation Art has been described "as getting the hand out of art and putting the brain in". It is legally unproblematic when it copies works that are in the public domain. For example, Marcel Duchamp, an important precursor of Appropriation Art as well as of Pop Art, exhibited ready-made objects such as a urinal, bicycle wheel, and snow shovel as works of art. But when the copied image is copyrighted, the risk of a suit for copyright infringement looms.

Artists and judges tend to have different views about how the law should treat Appropriation Art. The artist perceives legal restraints on borrowing as a threat to artistic freedom:

Whenever people's response is "how dare you!" I consider that a high compliment. First of all, taking from other artists is not illegal in the art world, as it is in the music industry, and second, it is a direct acknowledgment of how we work in painting. Everything you do is based on what came before and what is happening concurrently. I don't see history as monolithic. I feel very free to take and change whatever I want, and that includes borrowing from my contemporaries. If some people are upset because my work has similarities to what they're doing, that's their problem. And if they take from me, that's great! I don't respect these artificial boundaries that artists and people around artists erect to keep you in a certain category [Rubinstein (1994, p. 103), quoting the artist Richmond Burton].<sup>8</sup>

<sup>8</sup> Another prominent member of the art community has been quoted as saying that "if these copyright laws had been applied from 1905 to 1975, we would not have modern art as we know it" [Norman (1996, p. 125), quoting art dealer Jeffrey Deitch].

Yet from the perspective of copyright law, “appropriation” of protected work connotes stealing. And so, rejecting the defense of fair use, *Rogers v. Koons* (960 F.2d 301 (2nd Cir. 1992)) held that Jeff Koons’s well-known sculpture of puppies infringed the plaintiff’s copyrighted black and white photograph, which Koons had transformed into a large, colored sculpture that arguably had little or no new expression since a black and white photograph of the sculpture looked nearly identical to the plaintiff’s photograph. The court said that “the essence of Rogers’ photograph was copied nearly in toto, much more than would have been necessary even if the sculpture had been a parody of plaintiff’s work. In short, it is not really the parody flag that [Koons is] sailing under, but rather the flag of piracy” (Id. at 310).<sup>9</sup>

We approach the copyright issues presented by Appropriation Art by way of six examples. The examples are:

- (1) *A* creates a unique collage that includes *B*’s copyrighted photograph;
- (2) *A* creates a limited edition series of prints that incorporates *B*’s copyrighted photograph;
- (3) the same, plus reproductions of *A*’s prints appear on posters, calendars, and other mass produced merchandise;
- (4) *A* creates a work that copies the outline of a nude from *B*’s photograph, the distinctive color from *C*’s monochromatic painting, and a miniature yellow square from *D*’s painting;
- (5) *A* constructs several identical sculptural works based on *B*’s copyrighted photograph or comic book character;
- (6) *A* creates a work that contains elements substantially similar to one of his earlier works owned by *B*, who also happens to own the copyright in that work.<sup>10</sup>

We begin with the examples in the first group.

1. *Creating a unique work.* Suppose an artist incorporates a copyrighted photograph from a popular magazine into a collage by cutting the photograph out of the magazine, affixing it to a board, and adding other objects, colors, and original images. No copy

<sup>9</sup> Koons’s sculpture had been prepared for a 1988 exhibition entitled “The Banality Show”. Copyright infringement suits were also brought successfully against two other Koons sculptures from the show. See *Campbell v. Koons*, No. 91 CIV.6055, 1993 WL 97381, at \*1 (S.D.N.Y. Apr. 1, 1993) (involving a copyrighted photograph of two boys and a pig); *United Feature Syndicate, Inc. v. Koons*, 817 F.Supp. 370 (S.D.N.Y. 1993) (involving the character “Odie” from the Garfield comic strip).

<sup>10</sup> The first three examples are based upon lawsuits brought by photographers against, among others, Robert Rauschenberg and Andy Warhol for using copyrighted photographs in their works. Both Warhol and Rauschenberg settled out of court. Warhol paid \$6000 in cash and royalties on the print edition of *Flowers* to the photographer Patricia Caulfield, who had threatened to sue Warhol over his flower paintings. Rauschenberg gave the photographer Richard Beebe \$3000 and a copy of the allegedly infringing work worth about \$10,000. These cases and others involving the artists Sherrie Levine, David Salle, and Susan Pitt are discussed in Ames (1993, pp. 1484–1485). Example 4 is based on a lawsuit in Germany brought by the well-known photographer Helmut Newton against the artist George Pusenkov, who claimed that his paintings “quote” rather than borrow from other artists. See Norman (1996, p. 123). Example 5 is based on the Koons litigation. Example 6, the case of an artist borrowing from his own works, is based on *Franklin Mint Corp. v. National Wildlife Art Exchange, Inc.*, 575 F.2d 62 (3d Cir. 1978).

of the photograph is made, and the photograph itself may constitute only a small part of the collage. This should be an easy case against a finding of copyright infringement. Since the publisher has paid the photographer for his work and charged consumers for copies of its magazine, allowing the photograph to be used in the collage will have no significant impact on incentives to create new commercial photographs or to publish magazines, but it will reduce access and transaction costs.

2. *Creating multiple copies.* Henri Dauman, a French photographer, sued Andy Warhol's estate over Warhol's "Jackie" series of silkscreen prints that incorporated a copyrighted photograph by Dauman of Jacqueline Kennedy that had appeared in *Life Magazine* in 1963 [see King (1997)].<sup>11</sup> Dauman also sued the estate for reproducing the silkscreen images on calendars, posters, and other widely distributed merchandise. We are more sympathetic to the copyright claim here. It might seem arbitrary to draw a bright line between a one-time use of an image lawfully acquired and reproducing that same lawfully-acquired image in multiple copies, but the distinction goes to the heart of the economic rationale for copyright. Commercial photographers are in the business of licensing reproduction rights for a variety of unanticipated uses. Without copyright protection the price of copies would be driven down to the cost of copying, leaving nothing to cover the cost of creating the work. Allowing an artist to make multiple copies without authorization poses a more substantial threat to the incentive to create new works than the one-time unauthorized copy, as in our first example. To be sure, Warhol had added substantial original expression to the original image, and his silk-screens, one of which sold in 1992 at Sotheby's for more than \$400,000, were not likely to cut into the market for the photograph. But remember that Warhol reproduced the silk-screens on posters, calendars, and other merchandise, and these *were* likely to cut into Dauman's market.

3. *Appropriating from multiple sources.* The Russian painter George Pusenkoff included in one of his paintings the outline of a nude from a Helmut Newton photograph, a distinctive bright blue background from an Yves Klein monochromatic painting, and a small yellow square from a painting by the late Russian artist Casimir Malevich [see Norman (1996, p. 123)]. Neither Klein nor Malevich's estate objected to Pusenkoff's borrowing, but Newton did and sought to have the painting destroyed. Pusenkoff's defense was that he had created a unique work rather than made multiple copies, that he had borrowed only the outline of a photograph and not the entire photograph, and that he had transformed the photograph by adding public domain material and altering the medium. But he clearly copied Newton's well-known image without paying for it and indeed his stated purpose was to copy recognizable elements from other artists – "to make canvases buzz with cultural associations by 'quoting' from other artists – a perfectly respectable post-modernist approach to picture-making" (Ibid., p. 123).

The German court in which Newton's case was brought held that Pusenkoff's painting was a "free adaptation" rather than a reworking and therefore did not infringe New-

<sup>11</sup> The case was settled.

ton's copyright (Ibid., p. 125).<sup>12</sup> Ordinarily an adaptation would be a derivative work and thus infringing if made without the authorization of the owner of the copyright on the original work, and the fact that Pusenkoff's adaptation did not substitute for the original photograph would be irrelevant. The impact of Pusenkoff's appropriation on Newton's income was surely minute and Pusenkoff unlike Warhol did not create posters and other merchandise but a unique work; but again that is not the sort of consideration that entitles the making of a derivative work without the authorization of the owner of the copyright on the original. However, Pusenkoff's adaptation was sufficiently transformative that it should be considered a fair use. This suggestion is supported by the fact that Pusenkoff's work borrowed (or "quoted") from more than one previous work. Transaction costs are likely to be high if the law requires artists to obtain permission to appropriate from multiple sources. And a work that copies from several sources is much less likely to be a substitute for any one of them. Other things being equal, therefore, the law should be more sympathetic to the artist whose work borrows from multiple copyrighted sources rather than from a single copyrighted source.

4. *Creating sculptures from a single copyrighted source.* This is *Rogers v. Koons* (1992). Koons bought a note card displaying a photograph of a group of puppies with their owners, tore off the copyright notice from the card, and hired an Italian firm to make four large sculptures called *A String of Puppies* based on the photograph. Koons's role was strictly conceptual. He did not make the sculptures himself, although he chose the subject matter, medium, size, materials, and colors. And he did not design the sculptures, at least in the usual sense, for he instructed the studio that they "must be just like photo – features of photo must be captured" (Id. at 305, quoting Koons). Altering the image to avoid a copyright lawsuit would have defeated his purpose of showing that meaning depends on context.

In rejecting the fair use defense, the court emphasized the commercial nature of the copying; the fact (the same point, really) that Koons had earned a substantial sum from the sculptures (three of the four sculptures sold for a total of almost \$400,000); that he had faithfully copied the original image; and that the sculptures were likely to impair the market for the copyrighted photograph. Although the copies and the original were sold in different markets, the court believed that Koons's type of appropriation could potentially eliminate an important source of licensing revenues for photographers.

Koons' main argument was that his work should be privileged as a satirical comment or parody. He claimed that by placing the image of the puppies and their owners in a different context from that of the original photograph, he was commenting critically on a political and economic system that overvalues mass-produced commodities and media images. Copyright law, however, requires that a privileged parody must "target" the original work rather than use the original as a "weapon" to comment on society in

<sup>12</sup> Newton was not happy with the German court's decision, and remarked: "Poor fellow, he hasn't got an idea of his own, so he has to use other people's" [Norman (1996, p. 125)]. But copyright law does not protect ideas.

general. The economic reason for this is clear. When the parody targets the plaintiff's work, the parties are unlikely to be able to agree on a price that allows the defendant to make fun of, embarrass, or even humiliate the plaintiff. (Of course, the photographer might not have realized that Koons's sculptural version of the photograph *was* parodic.) If the parodist wants to use the parodied work as a weapon to batter society rather than the work, he should have less trouble obtaining a license. But Koons wanted both to comment on the vacuity of modern American culture and – as the court failed to note – to do so by offering the copied work as an *example* of that fatuity. This makes us doubt that the case was correctly decided. There was no chance that Koons's costly sculptures would be substitutes in the market for the plaintiff's note cards. Nor was Koons planning to do Warhol-like reproductions – that would have been inconsistent with the critical message of his parodic copies.

5. *Borrowing from one's own earlier work.* Artists often return to themes they had used earlier in their careers and even copy from their earlier works. Gilbert Stuart is reported to have painted some 75 substantially similar portraits of George Washington [see Grampp (1989, p. 6)]; and Giorgio de Chirico made numerous copies of many of his best-known early Surrealist works [see Levin (1988, pp. 251–253)]. An issue of unlawful appropriation arises only if the artist no longer owns the copyright on the earlier work, which likely will occur less often today than prior to 1976.<sup>13</sup> Yet when an artist does part with his copyright, should the law allow him a fair use defense to produce derivative works?

Such a rule would spare the courts from having to determine whether a new work by the artist was a copy of the earlier work by him (whose copyright he had transferred) or an independently-created work substantially similar to the earlier one only because it was created by the same person. “If Cézanne painted two pictures of Mont St. Victoire, we should expect them to look more alike than if Matisse had painted the second, even if Cézanne painted the second painting from life rather than from the first painting” (*Schiller & Schmidt, Inc. v. Nordisco Corp.*, 969 F.2d 410, 414 (7th Cir. 1992)).

Against this evidentiary point in favor of an expanded fair use privilege is the harm likely to accrue to the artists themselves from retention of a right to make derivative works. The transfer of a copyright is of little value if the transferor retains the right to make a derivative work that may destroy the market for the transferred work.

#### 2.4. What is an unlawful adaptation of a work of art?

The contrast of two similar cases illustrates the difficulty of defining what it means to create an unauthorized derivative work of a work of art. In *Lee v. A.R.T. Co.* (125 F.3d 580 (7th Cir. 1997)), the defendant purchased note cards from the plaintiff, affixed them

<sup>13</sup> Section 202 of the 1976 Act reverses the common law “*Pushman* presumption”, after *Pushman v. New York Graphic Society*, 39 N.E.2d 249 (N.Y. 1942), that copyright automatically transfers to the purchaser of a physical work. Under the 1976 Act, transfers are only valid if made in writing and signed by the owner or his agent. See 17 U.S.C. §§202, 204(a).

to tiles, and sold the tiles at retail. Since copying was not involved, the plaintiff only claimed that A.R.T. had infringed its right to prepare a derivative work. The copyright statute defines a derivative work broadly to include “any other form in which a work may be recast, transformed or adapted”. But we noted that the “first sale” provision of the statute entitles the owner of a lawfully-acquired copy to sell or otherwise dispose of the copy without the copyright owner’s consent (17 U.S.C. §109(b)(1)(A)). Applying this “first sale” rule, the court held that A.R.T. had merely placed the equivalent of a mat or frame on the work it had purchased, and then resold the composite piece. The decision makes economic sense, as the defendant’s activity most likely benefited the plaintiff. The more tiled cards the defendant sold, the more cards he would have to buy from the plaintiff. The plaintiff’s position if accepted would give an artist the right to block any minor alteration in a work of his of which he disapproved. This would harm artists in the long run. Costs of contracting over art would rise as galleries, museums, and collectors, in order to avoid copyright liability, sought permission from copyright owners to mat and frame works of art they acquired.

So why would a plaintiff sue to stop an activity that benefits him? Maybe it doesn’t; maybe his reputation will be damaged by the alteration in his work. That is the basis of the moral rights doctrine, discussed shortly. But it is unlikely that mounting note cards on tiles would have tarnished the artist’s reputation. A more plausible explanation is price discrimination. Lee might want to charge higher prices for note cards to firms that affix them to tiles for resale to consumers. Arbitrage would make this discrimination infeasible unless the law forbade affixing cards to tiles, or selling the tiles, without the plaintiff’s consent. But it is doubtful that enabling artists to engage in this form of price discrimination is needed to give artists adequate incentives. There is no indication that Lee ever contemplated producing tiled note cards or licensing others to do so.

In the second case, *Peker v. Masters Collection* (96 F.Supp.2d 216 (E.D.N.Y. 2000)), the defendant lawfully purchased inexpensive poster-reproductions of original paintings, transferred the images from the posters to canvas, added paint to the images to replicate the original paintings, and sold the replicas for up to several hundred dollars. Here the court held that the replicas were unauthorized copies or derivative works. In both *Peker* and *A.R.T.*, each additional reproduction required the purchase of another copy of the original (either a note card or a poster) but in *Peker* the “derivative work” would compete with the original and thus undermine the incentive to create the work in the first place. Put differently, if the copier’s gains begin to eat into the market for the original work – and those gains cannot be captured through the initial sale of the poster – the first-sale doctrine becomes a drag on copyright protection.

### 2.5. *The appropriation of style and trade dress*

So far our examples have involved the appropriation of easily describable features of an original work. But what if all that can be said of the alleged copy is that it appropriates the *style* of the original work? What if the alleged copy does not appropriate the style of a single work, but rather an artist’s style in general [see Ginsburg (1995)]?

Two cases illustrate the challenges presented by the alleged appropriation of style. In *Steinberg v. Columbia Pictures Industries, Inc.* (663 F.Supp. 706 (S.D.N.Y. 1987)), the artist Saul Steinberg created a well-known *New Yorker* magazine cover depicting in the foreground several blocks of Manhattan's West Side and in the background the rest of the world beyond the Hudson River in formless obscurity. Steinberg accused Columbia of appropriating this image on a poster promoting its film, *Moscow on the Hudson*, starring Robin Williams. The poster, facing east rather than west, depicted Manhattan in the foreground and Moscow distantly in the back with only insignificant references to the Atlantic Ocean, London, Paris, and Rome in between. Superimposed on the bottom of the poster was a drawing of Williams and two of his co-stars.

The court held that the poster had impermissibly appropriated Steinberg's original style. Both works were "executed in the sketchy, whimsical style" for which Steinberg was well known. Both featured "a bird's eye view across the edge of Manhattan and a river bordering New York City to the world beyond". And "[b]oth depict[ed] approximately four city blocks in detail and [became] increasingly minimalist as the design recede[d] into the background" (Id. at 712). Although the case was probably decided correctly because the defendant had copied a number of Steinberg's expressive features that were not essential to working in his style, copyright protection of an artist's style (like protection of ideas) would impose significant access costs on other artists that probably would offset any incremental incentive benefits for artists to develop new styles. These benefits are likely to be negligible because an artist whose style attracts followers is very likely to be successful and highly compensated. Put differently, the value of a well-known artist's work inheres not in the physical object but in the artist's identity, and so is not impaired by copying.

It is worth noting that an artist's style may be protected as "trade dress" under trademark law, but protection is subject to several important limitations. First, the style in question must be so closely associated with the particular artist that it serves to identify and distinguish his work from other artists – i.e., the style functions as a brand name identifying the source of the work or in trademark lingo has acquired "secondary meaning". Second, an artist copying that style must cause a likelihood of confusion between his and the originator's work (i.e., the similarity of styles leads consumers to believe that the originator is the source or connected in some way to the copier's work or the reverse). Finally, the trade dress must be non-functional, in the sense that artists do not need to copy the originator's style in order to compete effectively in the marketplace. Since nothing in a painting could properly be categorized as functional (except, perhaps, the paint and the canvas), this constraint appears to be non-binding. In contrast, the other constraints will result in very weak trademark protection for style. Consider the Abstract Expressionist paintings of Jackson Pollock and Ad Reinhardt. Any painter who adopts Pollock's stylistic technique of splashing paint on large canvases spread horizontally on the floor, or who copies Reinhardt's style (or idea) of painting the surfaces entirely black, will produce paintings that look quite similar to Pollock's or Reinhardt's, respectively. Even if these styles had acquired secondary meaning, the copier can avoid trademark infringement by adding his signature or other identifying material that, in

effect, acts as a disclaimer of any connection with Pollock or Reinhardt. If the rule were otherwise, what would have stopped Braque or Picasso from acquiring trademark rights to cubism?

The case of *Romm Art Creations Ltd. v. Simcha Intern., Inc.* (786 F.Supp. 1126 (E.D.N.Y. 1992)) applied the concept of trade dress to the copying of an artist's style. In *Romm*, the plaintiff published posters of works by the Israeli artist Tarkay, including a "Women and Cafes" series of paintings for which the artist was well known. Simcha published posters of works by the artist Patricia that, in a fashion similar to Tarkay's, depicted women seated in various cafes. Romm sued Simcha for trade dress infringement, alleging that the similarities of the works would cause consumer confusion and enable Simcha to capitalize on the public's positive association with Tarkay's works. The court sided with the plaintiff because his style had acquired trademark significance, and there was the distinct possibility of consumer confusion, given the similarity of the works and the "lack of deliberate and measured product selection by consumers in a gallery or poster shop" (Id. at 1140, internal quotation removed). A key factor in the court's decision was that the works were inexpensive posters, for which signatures or other disclaimers were not likely to eliminate consumer confusion.

### 3. Moral rights<sup>14</sup>

In 1990 Congress enacted the Visual Artists Rights Act (VARA), which amended the Copyright Act to confer attribution and integrity rights, commonly called moral rights, on authors of works of visual art (see 17 U.S.C. §106A). Attribution rights entitle the artist to claim authorship of a work he created and to disclaim authorship if his work is altered in a manner "prejudicial to his honor or reputation" or incorrectly attributed to him. Integrity rights prohibit the intentional distortion, mutilation, or other alteration of the artist's work that injures his honor or reputation, and makes the intentional or grossly negligent destruction of a work of recognized stature actionable.

In contrast to the United States, most countries in Western Europe have a long tradition of recognizing moral rights. France recognized moral rights in the nineteenth century, and since 1928 they have been codified in the Berne Convention, to which the United States became a party in 1989. Before then several states, beginning with California in 1979, had enacted moral rights laws and the Copyright Act itself had occasionally been interpreted to confer analogous protections.

#### 3.1. *The statute*

VARA protects works of "visual art" narrowly defined as a unique work or a print, sculpture, or photograph produced in an edition of no more than 200 copies that are signed

<sup>14</sup> This section draws on Landes (2001) and Landes and Posner (2003, Chapter 10).

and consecutively numbered. Unlike the other rights conferred by the Copyright Act, the rights conferred by VARA are enforceable only during the artist's lifetime. There are other limitations as well. The artist may not transfer or assign his rights, though he may waive them in a signed document. The alteration, mutilation, or destruction of a work as a result of negligence, the passage of time, the nature of the materials used in the work, or failed conservation efforts does not violate VARA. VARA also provides no remedy for injuries to an artist's reputation caused by the presentation, display or reproduction of his work; he cannot complain that a dimly lit exhibition or a poor-quality reproduction in a pamphlet or website violates his integrity or attribution right.

VARA does not create any rights in works for hire – i.e., works prepared by an employee within the scope of his employment.<sup>15</sup> The works for hire exemption is a way of economizing on transaction costs: if the individual employee's creative contribution were protected by VARA, then since the employer's use of his contribution might alter, mutilate, or even destroy the work, the employer would insist on a waiver – the execution of which is costly. Or suppose a developer commissioned a large sculptural work as part of a building project and, after the work was completed and installed, decorated it with Christmas or Easter decorations that the artist regarded as degrading. Anticipating such possibilities the developer would require a waiver of VARA rights when he commissioned the sculpture. Excluding this type of commissioned work from VARA coverage saves the transaction costs that waivers impose.

Another important limitation of VARA coverage involves installed works that are likely to be mutilated or destroyed if they are ever removed. VARA provides that there is no integrity right for a work installed after the statute's effective date of July 1, 1991, provided the artist consented in writing to both its installation and the possibility that removal might mutilate or destroy the work, or, in the case of a work installed prior to the effective date, provided the artist consented to its installation. If an installed work can be removed without being mutilated or destroyed, the artist retains his integrity right unless the building owner notifies him that he intends to remove the work and gives the artist a reasonable opportunity to remove it at his own expense.

Consider a building owner who hires an artist to create a site-specific sculptural work for the building's entrance plaza. Their contract is silent on the artist's rights if the sculpture is ever removed, though removal would destroy the sculpture. A new owner acquires the building and wants to tear it down and build a modern office building in its place. Never having consented to the possible destruction of his work, the sculptor would be in a position, given VARA, to extract a substantial payment from the new owner for allowing the project to go forward. The owner might argue that the sculpture

<sup>15</sup> A work created pursuant to a formal employment relationship (as when Disney hires an animation artist who is paid a regular wage, receives fringe benefits, and can be assigned to work on different projects) is an unambiguous example of a work for hire. But a commissioned work executed by an independent artist may also be a work for hire if, for example, the commissioning party pays a monthly stipend, pays health and other fringe benefits during the time the artist works on the project, defrays the cost of materials, and exercises overall though not necessarily daily supervision.

was a work for hire, but commissioning a work does not necessarily turn it into one. So building owners would demand written waivers of VARA rights at the time works such as we are discussing were commissioned. If they proved difficult to obtain, building owners might forgo installing artwork in buildings for fear of future legal problems.

VARA's integrity right protects an artist against alterations that injure his "honor or reputation" and against the destruction of his work if it is of "recognized stature". The terms "honor" and "reputation" were borrowed without attempt at definition from moral rights laws in European countries, but the intended meanings are reasonably clear. Reputation is a matter of what other people think of one, and an artist's reputation is primarily a matter of what art lovers think of the artist's work. An injury to an artist's reputation is likely to affect the prices of his artworks and thus, if he is still active or has retained copyright or ownership of some of his works, his income. Honor is a related concept but includes self-esteem and need have no pecuniary implications. Someone might intentionally mutilate the work of an unknown artist, injuring the artist's self-esteem yet inflicting no financial injury on him because the work had no market value. Finally, the statutory term "work of recognized stature" has been interpreted to require only minimum public acknowledgment of a work's quality or significance (see *Martin v. City of Indianapolis*, 192 F.3d 608 (7th Cir. 1999); *Carter v. Helmsley-Spear, Inc.*, 861 F.Supp. 303 (S.D.N.Y. 1994), reversed on other grounds, 71 F.3d 77 (2nd Cir. 1995)).

### 3.2. *The economics of moral rights*

Attribution rights are closely related to rights against fraud and trademark infringement (and also to the norm against plagiarism), so that much of what they seek to prevent is already unlawful. For example, the laws against fraud would forbid someone who was not Jasper Johns to paint a picture in Johns' style, sign it "Jasper Johns", and attempt to pass it off in the market as Johns' work. And removing Johns' signature from an original Jasper Johns painting and selling it under one's own name would violate trademark and unfair competition law, although such a forgery is unlikely because it would reduce the painting's market value. Not only does VARA add little if anything to the rights that an artist already has in such cases; but those rights, unlike the rights created by VARA, do not expire with the artist's death. For these reasons we are not surprised to have found no cases in which a plaintiff sought to enforce an attribution right.

The picture is different when we turn to integrity rights. It is true that, just as with attribution rights, even if there were no moral rights law there would be alternative methods for securing protection of the artist's integrity rights – most obviously contract law (though also copyright law, as we shall note shortly). An artist concerned with the possible future alteration of his work could add a term to the original sales contract giving him the right to approve or veto future modifications of the work. But there would be two drawbacks. First, most sales contracts in the art world are oral rather than written,<sup>16</sup> so to protect integrity rights the parties would have to incur the added costs of

<sup>16</sup> Sixty-one percent of the respondents to a survey conducted by the Copyright Office stated that oral contracts are more common than written ones in the art world [U.S. Copyright Office (1996, Table 3-2)].

a written contract. Second, a moral rights provision would not be enforceable against subsequent purchasers of the work unless the original purchaser included it in his contract with the subsequent purchaser and the latter, if he resold it, did likewise. It should also be noted an artist can protect the integrity-rights component of moral rights law simply by enforcing his copyright. Because copyright embraces the exclusive right to make and authorize others to make derivative works, any significant distortion, mutilation, or modification of an expressive work without the artist's consent would infringe his copyright as an unauthorized creation of a derivative work [see, for example, *Ty, Inc. v. GMA Accessories, Inc.*, 132 F.3d 1167, 1173 (7th Cir. 1997); *WGN Continental Broadcasting Co. v. United Video, Inc.*, 693 F.2d 622, 626 (7th Cir. 1982); cf. *Gilliam v. American Broadcasting Cos.*, 538 F.2d 14 (2nd Cir. 1976); but see *McCartney* (1998, pp. 43–52), expressing skepticism]. And unlike VARA rights, copyright does not expire with the death of the copyright holder; indeed, under current law, the death of the author of the copyrighted work triggers a 70-year extension of copyright protection.

VARA retains significance in cases in which the copyright to the artwork is transferred along with the work itself. And the derivative-works provision of the Copyright Act would not prevent the intentional destruction of a work of visual art, as VARA does for works of recognized stature – though it is a little hard to see how this can matter very much. The owner of a work of “recognized stature” would rarely want to destroy it, though this depends on how low the “recognized stature” threshold is set, and we’ll see shortly that the tendency of the courts has been to set it very low.

*Hansmann and Santilli* (1997) have offered the following economic argument in favor of moral rights that cannot be subsumed, as we have just been suggesting, under conventional copyright law. The value of a work of art depends in part on the artist's reputation, which is embodied in the entire stock of his works, with each piece acting in effect as an advertisement for the others. Mutilating (or destroying) any one of them thus imposes a cost on the artist that is external to the mutilator (assuming he has acquired the work lawfully and so could not be punished for theft or malicious mischief). A moral rights law causes this cost to be internalized. Yet, cutting the other way, the destruction or mutilation of a single work will reduce the effective supply of the artist's works and by doing so increase rather than decrease the value of the remaining works plus any works that he creates in the future. And as long as it was known that the artist had not committed or condoned the mutilation, all the mutilation would demonstrate was that one person disliked the artist's work intensely or wanted to subject it to ridicule – and to prevent such a mutilation would be like forbidding a parody.<sup>17</sup> Given the point noted earlier that copyright law's derivative work provision itself provides some protection against mutilation (but not destruction); it is doubtful that the incremental protection

<sup>17</sup> It is true that the parody does not alter the parodied work and the mutilation does. But why should artists be immunized from this form of criticism, when persons who want to criticize the United States by burning the American flag have a constitutional right to do so? It seems, if anything, particularly fitting that criticism of a visual work should take the form of altering its appearance. A verbal work invites a verbal parody, a visual work a visual one.

added by VARA can be cost justified. We are not surprised that in the end Hansmann and Santilli draw back from claiming that moral rights are, on balance, efficient.

### 3.3. *The cases*

The paucity of litigation under VARA suggests that moral rights have little value for most artists. The evidence is not conclusive, if only because most cases are settled. But the settlement rate is unlikely to be very high in a new area of law, where there are no precedents to guide the parties in predicting the outcome of litigation if it is not settled. Nor have we been able to find more than a handful of newsworthy disputes involving moral rights (other than those in the decided cases), and most of these antedate the enactment of moral rights laws in the United States.<sup>18</sup> The infrequency of such disputes is not surprising since self-interest provides a powerful incentive for owners of art not to mutilate or destroy it.

All but one of the decided cases involved disputes between property owners and sculptors. And in only one did the artist prevail. All involve relatively unknown artists who had created (with two exceptions) large-scale sculptural or site-specific works that would have been or were substantially damaged or even destroyed as a result of new construction or renovation. The better known an artist is, the more valuable his work is likely to be and therefore the less likely it is that destroying or mutilating it would be an attractive option for its owner. And paintings and other smaller works are likely to be more valuable than the cost of moving them out of the way of whatever activity endangers them.

*Carter v. Helmsley-Spear, Inc.* (71 F.3d 77 (2d Cir. 1995)) is the best known of the cases. Artists known as the “Three-Js” created a vast lobby sculpture, using more than 50 tons of recycled materials including a school bus, in a commercial building

<sup>18</sup> Prior to the enactment of VARA, the principal disputes were the following:

- (1) A massive black and white Calder mobile installed in the rotunda of the Pittsburgh International Airport from 1958 to 1978 was repainted green and gold, the colors of Allegheny County, and motorized to turn at regular intervals.
- (2) Clement Greenberg, the distinguished art critic and trustee of the David Smith estate, stripped the paint from six of Smith’s sculptures after Smith’s death because he believed it would improve their aesthetic and market values.
- (3) A sculpture by Isamo Noguchi that had been displayed in the lobby of the Bank of Tokyo Trust Company in New York was removed, cut into pieces, and destroyed in 1980.
- (4) Diego Rivera painted a large wall mural in Rockefeller Center in 1933 that included a portrait of Lenin near the center and people marching with red flags past Lenin’s tomb – elements that were not part of Rivera’s original proposal. Rivera refused a request to replace Lenin’s head with Abraham Lincoln’s (!). The owners temporarily covered the mural and then destroyed it.
- (5) Richard Serra’s site-specific sculpture “Tilted Arc” was removed from the Federal Plaza in lower Manhattan after complaints that the sculpture was a safety hazard and prevented the public from using the space for recreation.

Examples 1 through 3 are taken from U.S. Copyright Office (1996, Chapter 2). Example 4 comes from Robinson (1983, p. 9), and example 5 from *Serra v. U.S. General Services Admin.*, 847 F.2d. 1045 (2nd Cir. 1988).

in Queens. The work was never completed, although the artists had worked at it for more than three years. A default by the original owner of the building led to a change in management, and the new management evicted the artists. Fearing that the management would destroy the sculpture, they sought an injunction under VARA. The district court ruled in their favor but the court of appeals reversed, holding that the sculpture was a work for hire. Although the artists had full authority in matters of design, color, and style, while the building management retained authority over the location and installation of the work, the artists had received a weekly salary, based on a 40-hour work week, for three years; they had received employee benefits including unemployment and health benefits (two of the artists filed for unemployment benefits after the new managers fired them); and payroll and social security taxes had been deducted from their weekly salary checks. Nevertheless the result is questionable. The contract between the Three-Js and the building's original owner stipulated that the artists retained the copyright to the work, implying that the parties did not envisage the sculpture as a typical work for hire (on which the employer owns the copyright and can therefore do with the copyrighted work what he wants). The plaintiffs had no copyright remedy because copyright does not confer a right to prevent the physical destruction of the copyrighted work by its owner.

*English v. BFC&R East 11th Street LLC* (1997 U.S. Dist. LEXIS 19137 (S.D.N.Y. 1997)) involved a group of related artworks, including both sculpture and murals, installed in a community garden on East 11th Street in New York City. A development was planned that required moving the sculptures but leaving the murals intact, though it would obstruct the view of the murals. The artists claimed that their work had been conceived as a unity, which the planned development would mutilate. Without deciding whether it was either a single work or one of recognized stature, the court held VARA inapplicable because the artwork had been placed on the property illegally. The previous owner (New York City) had never authorized the artists to put their work on the site, although it had remained there for many years without the City's trying to remove it. The court worried that a ruling for the plaintiffs would entitle artists to freeze real estate development by affixing graffiti<sup>19</sup> to construction sites. The court also noted that to accept the plaintiff's argument would force the City either to incur prohibitive costs of continually patrolling its many vacant lots or to acknowledge a "squatters rights" limitation on its property rights. It was more efficient to place the burden on the artists of obtaining the City's explicit consent to their use of the property.

In *Pavia v. 1120 Ave. of the Americas Associates* (901 F.Supp. 620 (S.D.N.Y. 1995)), the plaintiff's large bronze sculpture, comprising four standing forms, had been on display in the lobby of the Hilton Hotel in New York City from 1963 to 1988. The plaintiff had retained the title to and copyright in the work. In 1988 the owner of the hotel removed the sculpture, placing two of the four pieces in storage and displaying

<sup>19</sup> At least graffiti that are not purely verbal, in which event, as we shall see shortly, they may not be visual works and therefore may be outside the scope of VARA.

the remaining two in a parking garage. Since the artist had retained title to the work, the court held that he had rights under VARA even though the work had been created before the Act's effective date. Nonetheless, the court rejected the plaintiff's claim because the mutilation had also occurred prior to that date. This left only the plaintiff's claim of injury due to the unfavorable display of his mutilated work. VARA does not cover display rights, but New York's moral rights law does, and the court held that the plaintiff had a valid claim under that law that was not preempted by the federal statute.<sup>20</sup>

In *Martin v. City of Indianapolis* (1999), the defendant city had destroyed the plaintiff's 40-foot outdoor sculpture as part of an urban renewal project. When installed in 1986 the sculpture had been engineered in such a way that it could be disassembled and removed. Remember that VARA provides that a work created before the Act's effective date may not be destroyed unless the artist is given notice of the impending destruction and an opportunity to remove the work at his own expense. Through a bureaucratic foul-up the artist was notified but not given sufficient time to remove the work. Liability also depended on the work's being of recognized stature, but as to this the court held that the plaintiff satisfied his burden of proof by submitting local newspaper and magazine articles describing the work. No expert witness testified and there were no critical writings on the work or the sculptor. The dissent argued that more evidence of "recognized stature" should be required since otherwise buyers of works of art would be required in virtually all cases to obtain VARA waivers at the outset or face a risk of violating the statute in the future because the work, obscure when commissioned, later attained the requisite recognition.<sup>21</sup>

In *Flack v. Friends of Queen Catherine Inc.* (139 F.Supp.2d 526 (S.D.N.Y. 2001)), still another New York City sculpture case, the sculptor Flack was commissioned by a group of local boosters, the Friends of Queen Catherine (referred to in the opinion as "FQC"), to design a monumental statue of Catherine of Breganza (a seventeenth-century princess of Portugal and queen of England) for installation in the New York borough of Queens, for which Queen Catherine has some unexplained significance. The project was abandoned when it was discovered that Catherine and her family had profited from the slave trade. Flack had created a 35-inch clay model of the statue, and in the commotion attending the abandonment of the project the head of the model had been placed outdoors and suffered damage. FQC, which owned the statue and still wanted it cast in bronze, hired another sculptor to resculpt the face. Flack charged that this sculptor was grossly negligent and had produced "'a distorted, mutilated model' in which . . . the nose, nostrils, eyes and lips [were] uneven and the wrong size" (Id. at 530).

<sup>20</sup> There is an interesting addendum to the case. Three of four 3000-pound Pavia bronzes disappeared from Manhattan storage facilities in early 2005. Shortly thereafter, a scrap dealer returned the bronzes. The four pieces are being sent to the museum at Hofstra University in New York.

<sup>21</sup> Compare *Carter*, where Hilton Kramer testified for the defense and claimed that the work had no merit and no recognized stature. He based his argument of the fact that there was no literature on either the artists or the sculpture. The judge rejected Kramer's testimony on the ground that Kramer is hostile to all modern art!

The court, denying summary judgment for FQC, ruled that if Flack could prove that the substitute sculptor had been grossly negligent he was entitled to prevent FQC from casting the altered head in bronze. As a preliminary to this ruling the court held that the clay model was a work of art in its own right even though it had been intended to be only the mold for casting the bronze statue. Clay models made by recognized sculptors are accepted in the art world as works of art, as the court pointed out. But a more straightforward point is that the bronze casting, though it would not be done by Flack personally, would nevertheless be “her” creation within the most sensible reading of VARA. She would own the copyright in it and the mutilation would violate her integrity right.

Finally, *Pollara v. Seymour* (206 F.Supp.2d 333 (N.D.N.Y. 2002)) involved a large “protest mural” (actually a painting – it was not painted on a wall) that in the words of the court “depicted stylized figures of various races and socio-economic situations standing on line outside closed doors to legal offices. The mural also contained the phrases “Executive Budget Threatens the Right To Counsel” and “Preserve the Right To Counsel” (Id. at 335). The mural was installed in a state government building in Albany without authorization and the same evening was removed by government employees; in the course of removal, the mural was badly damaged. The court held that because the work “was intended solely as a display piece for a one-time event” and “there was never any intent to preserve [the] work for future display”, the work lacked the statutorily-required “stature” (Id. at 336). Stated more simply, since the artist herself had not intended the work to endure, the damaging of it inflicted no harm on her. It was not as if the defendant intended to exhibit the mural in its damaged form. It gave it back to her after removing it.

One of the cases in which a violation of VARA was alleged but not ruled on involved an assault claim by the artist Moncada against gallery owner Lynn Rubin. Moncada had painted a mural containing only the words, “I am the best artist, Rene”, on a building opposite Rubin’s Soho gallery; Rubin allegedly assaulted Moncada when she discovered the artist videotaping her attempt to remove the mural (*Moncada v. Rubin-Spangle Gallery, Inc.*, 835 F. Supp. 747 (S.D.N.Y. 1993)). The only question before the court was whether the defendant’s liability insurance policy covered an intentional tort, but the facts of the case bring to light interesting questions that may arise in future VARA disputes. First is whether the mural was a work of visual art; unlike Pollara’s mural it consisted entirely of the plaintiff’s signature and a single sentence proclaiming his artistic skill. If this is a work of visual art, how are other writings, such as a student’s homework or poem, that obviously are not protected under VARA, to be distinguished from it? This is not to deny that in some cases words can be an integral and therefore protected part of a visual work; moreover, we regard the only test of what is art to be what is accepted as art and maybe Moncada’s mural passed that test.

Second, although a tenant may have authorized Moncada to paint the mural, there is no indication that the building owner had authorized it. If a tenant’s authorization were sufficient to establish VARA rights (which it surely should not be), VARA might protect an unlimited number of graffiti artists and doodlers who decorate the outside walls of

their apartments; so cleaning and repainting walls throughout New York City would risk violating VARA.

Third, even if the plaintiff could show that the mural was a legally-authorized work of visual art, he would have to show that it was of recognized stature, which, given its purely verbal character, might have been difficult. (Of course the *Martin* case above suggested this test to be quite loose.) Note that this was not an issue in *Pollara*, because, as the court noted in an earlier opinion in the case, the complaint was not the removal of the mural from the government building but the damaging of it in the course of removal, and it could have been removed without being damaged, for it was not, despite being called a “mural”, built in (*Pollara v. Seymour*, 150 F.Supp.2d 393 (N.D.N.Y. 2001), at 396, n.4).

Our sample of VARA cases is small, but informative. They suggest that VARA disputes are likely to be limited to works of visual art that cannot be moved without damaging or destroying them; that the works are unlikely to be valuable works by well-known artists; and that judges are reluctant to preserve art at the cost of hampering development. Conceivably, too, the cost of obtaining waivers from artists may deter museums and galleries from exhibiting installation art that cannot be removed without destroying it and may deter property owners from commissioning works for installation in open spaces, lobbies, and buildings. The sheer paucity of cases, moreover, suggests that VARA did not fill some yawning gap in liability space. It is not as if the statute were so clear, or the penalties for its violation so draconian, that full compliance could be expected to be achieved immediately, obviating litigation.<sup>22</sup>

#### 4. Resale royalties

Resale rights on art, commonly known as *droit de suite*, provide an artist or his heirs a small royalty (usually less than 5 percent) each time the artist’s work is sold at auction and sometimes by a dealer. Eleven EU countries currently levy resale rights of various magnitudes and all must provide resale rights by 2006 according to a recent Directive of the European Parliament [[Ginsburgh \(1996, 2005\)](#)]. There is no federal resale royalty law in the United States although California has one for works resold in that state.

The basic argument in favor of resale rights is that they enable artists or their heirs to capture some of the increase in the value of their work after the initial sale. Proponents of resale rights often invoke the example of Van Gogh who, despite his paintings selling for millions today, sold only a couple works during his lifetime and died in poverty.<sup>23</sup> Resale rights, it is argued, would have prevented that and similar injustices.

<sup>22</sup> The inference from the paucity of VARA cases is reinforced by the extraordinary paucity of cases under state moral rights laws.

<sup>23</sup> It is far from clear whether the Van Gogh example supports the claim made by proponents of resale royalties. Van Gogh committed suicide at age 37 after an intense period of painting in the South of France. Since many of Van Gogh works were widely exhibited shortly after his death, it seems likely that he would have achieved critical and financial success at a relatively young age had he not committed suicide.

The economic case for resale rights is very weak. Resale rights are merely an interest in a future stream of cash flows. In a world with no transactions costs, the value to the artist of retaining that interest (as in a resale rights regime) should equal the value realizable from selling it (as in a regime without resale rights). In other words, first purchasers will discount the price that they pay for an artwork by the entire value of the resale right. Once you add in the costs necessary to administer a resale rights system, the simpler alternative of paying an artist upfront for the entire value of his work wins hands down.<sup>24</sup> Another disadvantage of resale royalties is it prevents artists from fully shifting the risk of future price declines to the original purchaser. And if an artist is more optimistic than the market is about future price increases of his work, he can always retain in his inventory a few paintings for future sale that will provide him an amount equivalent to what he might receive in resale royalties.

Worse yet are the distributional effects of resale rights. Art purchasers will lower the prices they pay for art that is subject to resale rights. But artists (or their heirs) only receive payments if their works sell at a price above the initial sale price. Thus artists whose works do not sell or do not increase in value – “the vast majority” (Ibid., p. 4)<sup>25</sup> – will only experience the downside of resale rights legislation. They will in effect subsidize the more successful artists and the buyers.

Not surprisingly, many artists oppose resale rights legislation “on the grounds that it damages the market for their work and the art trade in general” [*The Art Newspaper* (January 2000)]. Resale rights, they assert, are a “[restraint] on testamentary freedom” (Ibid.) because they force living artists to bear a burden today for benefits which most likely will be reaped if at all by their heirs.<sup>26</sup> Another strike against resale rights regimes is the prospect that they will drive auction business to countries without resale rights [*Wall Street Journal* (April 6, 2000)]. Harder times for auction houses in resale rights countries could further depress art prices and undermine the incentive for artistic production. Resale rights may result in less art being produced, sold, and enjoyed.

<sup>24</sup> The situation would be slightly different if artists systematically valued their expected resale rights payments more highly than did the buyers of their art – perhaps because, being confident in their abilities, they discounted them at a lower rate (less of a discount). Putting aside administrative costs, a resale rights system would enable artists to unbundle the portion of their product that was profitable to sell from that which was not. The opposite would be true if, being risk-averse, they applied a higher discount rate to the stream of payments than do buyers.

<sup>25</sup> In France, between 1993 and 1995, 2–3% of the 2000 artists who benefited from resale rights received 43% of the payments collected [*The Art Newspaper* (January 2000)].

<sup>26</sup> In Germany, for example, only 274 of 7454 artists registered with the resale rights agency were eligible for payment (Ibid.).

## 5. Resolving disputes over ownership of art

### 5.1. Introduction

Ownership disputes are more likely to occur if an object is valuable, mobile, relatively easy to hide, but still traceable – conditions frequently satisfied in the case of works of art. First, because a valuable work of art is likely to appreciate rather than depreciate over time, a search even for a work that has been missing for many years may be profitable. Second, the same characteristics, as well as durability and ease of concealment increase the possibility that works of art will resurface, often by chance, after many years of being thought destroyed or otherwise gone for good.<sup>27</sup>

Uniqueness facilitates recollection and thereby increases the possibility of tracing a lost work: the few people who have seen the work will remember having seen it and can provide valuable information to the searcher. Tracing is also facilitated by the fact that the value of a work depends on its provenance (ownership and exhibition history) and the work being preserved in its original form. The more that is known about a work, and the less the work has been altered, the easier it will be to find.

Although a registry for art – similar to a land registry – would eliminate many ownership disputes, it is probably not feasible. Most art is mobile (unlike land), so a comprehensive registry would have to be global in scope and encompass millions of works. The feasible alternative to a comprehensive registry is a registry limited to missing works of art, such as the Art Loss Register (ALR) (<http://www.artloss.com>), since works that are both missing and sufficiently valuable for owners to search for them are a tiny subset of all works of art. The ALR lists over 100,000 lost or stolen works, to which it adds approximately 10,000 new listings annually [*The Art Newspaper* (March 1998)] and it has become the standard for auction house due diligence. Each year, ALR checks 400,000 lots slated for auction against the database (*Ibid.*).<sup>28</sup> A registry limited to missing art will be valuable, as there will usually be sufficient time between the theft or loss of a work (assuming the owner discovers and reports it missing) and its resale for auction houses, galleries, or buyers to check the registry to determine its provenance.

A final explanation for why the chain of ownership of a long-lost work of art can often be traced has to do with why people own art. Economists since Veblen have described art as a prestige good that enables the collector to signal to others that he is a person of both wealth and good taste. The collector gets utility not only from admiring the work hanging in his living room but also from believing that other people envy or admire him because he owns it. To obtain this additional utility, people who buy art don't want to keep it hidden away. They brag about owning it, show it to friends, and lend it to

<sup>27</sup> This section is based on Landes and Posner (1996).

<sup>28</sup> Object ID, a uniform registration protocol for detailing lost or stolen works developed by the Getty Information Institute has further augmented effectiveness of the ALR. See <http://www.artloss.com/>.

museums and galleries for exhibitions. Art's signaling value makes it more likely that the rightful owner will eventually find his long-lost work.<sup>29</sup>

## 5.2. *The disputes*

We are interested here in ownership disputes involving “innocent” persons. But we use the term in a very broad sense, excluding – besides thieves – only persons who know they are buying a stolen work of art as opposed to buyers who fail to take proper precautions against the possibility that the work is stolen. The “good faith” purchaser, roughly one who both believes that the work he is buying is not stolen and takes optimal precautions against a mistake about title (which nonetheless fail to reveal the work is stolen), is thus a type of an innocent purchaser.

The choice of what legal rule to apply to ownership disputes over art requires taking into account the actions of three parties: rightful or original owners (owners, for short), innocent purchasers, and thieves.<sup>30</sup> Our aim here is to identify the issues that should be considered in an economic approach to this problem. Dispute resolution rules directly affect owners and buyers, as each is aware of the possibility that any particular work either will be or has been lost or stolen and thus become the subject of an ownership dispute. They indirectly affect thieves by having an impact on the market for stolen works.<sup>31</sup>

Dispute resolution rules influence the level of precautions that a buyer takes to prevent loss or theft and also what resources he expends to recover a work that has been lost or stolen. In equilibrium he will take just enough precautions such that the marginal cost of additional precautions equals the marginal value of such precautions (the decrease in the probability of loss or theft multiplied by the value of retaining the work). If a work is lost or stolen, he will expend just enough resources searching for it such that an additional dollar of searching will yield an additional dollar in expected return (equal to the increase in the probability of finding the work multiplied by the time-adjusted value of regaining the work *and* discounted by the possibility that the legal rule will not award the found work to him). The more the legal rule favors previous owners over innocent purchasers (e.g., by extending the time period an owner has to find the lost work and demand its recovery or, equivalently, by tolling the statute of limitations until the owner locates the lost work), the less an owner will spend to prevent a work's loss or theft, and the more he will spend to recover a work that is lost or stolen.

<sup>29</sup> This suggests that the high bidders for known stolen art will be art lovers rather than status seekers because the former group are more likely to be willing to conceal their ownership.

<sup>30</sup> Since each owner (other than a work's creator) is a buyer himself, it may seem erroneous to consider the two as separate parties. Here we consider separately persons *in their capacities* as buyers or owners. The costs and benefits of their actions are thus additive.

<sup>31</sup> We ignore the interests of other (fourth) parties in how ownership disputes are resolved. These interests include loss of secondary enjoyment of a work (if the legal rule forces the work underground) and pity at either a previous owner or an innocent purchaser losing out in an ownership dispute. (Such pity could be a significant consideration in disputes over Holocaust Art.)

We suspect that the effect of making a legal rule more owner-friendly will be smaller on the level of an owner's precautions than on his search expenditures. Owners already have a significant incentive to prevent a work from being lost or stolen; given that the prospect of recovering a work is small to begin with, a slightly more or less owner-friendly rule for dispute resolutions should only have a small impact on the owner's precautions in preventing theft. On the other hand, once a work disappears, the calculus changes significantly. The only reason to spend money looking for a work is if finding it will result in its return.

Innocent purchasers believe there is some possibility that works they own have defective titles. This risk will justify some amount of precautions to avoid ownership disputes with rightful owners; such precautions may include not displaying a work publicly or not publicizing one's ownership of it – a cost in the form of lost prestige value. An owner will conceal his ownership of a work just enough such that the marginal loss in the owner's prestige is equal to the risk mitigation of keeping a work out of the public's eye (the decrease in the likelihood the work is discovered times the value of the work and discounted by the likelihood that the legal rule will not return the work to the original owner). The equilibrium investment in such precautions increases as dispute resolution rules become more owner-friendly.

What sort of dispute resolution rule (owner- or innocent purchaser-friendly) will minimize theft (and thus the costs of theft) is unclear. Owner-friendly rules will decrease both the level of precautions that owners take (good for thieves) and also the prices that innocent purchasers are willing to pay for potentially stolen art (bad for thieves). Buyer-friendly rules will do the opposite. We suspect however that the net effect of an owner-friendly rule is a decrease in theft. Owners take fewer precautions in response to more owner-friendly rules in part because the decline in the price of stolen works will directly decrease theft rates. The theft-increasing effect of lower precautions is thus moderated by the theft-decreasing effect of lower prices for stolen works. Moreover, as noted earlier, the change in precautions due to changes in legal rules is likely to be small to begin with; thus the increase in the amount of theft due to the decrease in precaution spending is unlikely to drown out the direct decrease in theft caused by a decline in prices associated with a more owner-friendly rule.

The fact that owner-friendly dispute resolution rules may decrease theft does not indicate whether they are socially efficient; for that analysis, one must estimate the aggregate costs across society of the behavioral responses described above. The simplest analysis would compare two extreme legal rules: one that always returned a disputed work to the original owner (call it Rule O), and one that never did (Rule P). From what we've already said above, the costs associated with moving from Rule O to Rule P would be increased precautions and increased theft costs; the benefits would be the elimination of search costs (there being no reason for an owner to recover his work) and concealment costs (there being no reason for the subsequent purchaser to prevent the original owner's discovery of the work).

We expect the search and concealment costs under Rule O (and thus the cost savings associated with choosing Rule P) to be low relative to their benefits. Beyond the small

cost of registering the lost work (about \$65 for posting notice of a stolen work on the Art Loss Register), the marginal productivity of search is likely to diminish very rapidly. Except in extreme circumstances, dispossessed owners are more likely to “wait-and-see” if a work resurfaces than to expend further resources searching fruitlessly. Secondly, if a purchaser has acted in good faith, he will think it quite unlikely that the work has a defective title and will lower his concealment expenditures (by displaying the work) accordingly. On the other hand, the likely benefits of choosing Rule O versus Rule P, lower precautions and lower theft costs aggregated across society, are not insignificant. We noted earlier that owners always have an incentive to protect their art, but that incentive is certainly greater when there is *no possibility* of recovery from innocent purchasers, as under Rule P. And unlike expenditures on search costs, there is no obvious drop-off in the return available for precautionary expenditures.

All this yields a conclusion that rules that favor owners over innocent purchasers are more socially efficient than those that favor innocent purchasers. Such a finding is consistent with the practice of most societies around the world [see [Levmore \(1987\)](#)]. The question then becomes why statutes of limitation should exist at all, or for that matter, any limitations on the rights of owners. Most likely, there is a turning point where the error costs associated with enforcing dated causes of action overcome the benefits of an owner-friendly system.<sup>32</sup> However, when error is unlikely, for example, when a plaintiff can present reliable records or testimony evidencing his ownership of a work, we should expect courts to stretch statutes of limitation for the owner’s benefit. The cases we discuss below confirm this intuition.

### 5.3. *The cases*

In *O’Keeffe v. Snyder* (416 A.2d 862 (N.J. 1980)), the artist Georgia O’Keeffe sued a good faith purchaser for the return of paintings she contended had been stolen from her in 1946. O’Keeffe had waited until 1972 to report the disappearance of the paintings, learned of the location of the paintings in 1975, and discovered the identity of their current possessor (Snyder) in early 1976. When Snyder rejected her demand to return the paintings, O’Keeffe sued for their return.

The key issue in the case was whether a six-year statute of limitations period barred O’Keeffe’s action. In remanding the case for further considerations, the court held that the lower court should apply the “discovery rule” to determine when the six-year limitation period began to run. Under the discovery rule, the limitation period does not start until the injured party discovers, or by exercise of reasonable diligence and intelligence should have discovered the whereabouts of the missing painting.

The discovery rule is roughly consistent with our conclusions above. According to the rule, ownership rights will not be diminished by the passage of time so long as an

<sup>32</sup> Since owners (except for the artists) are themselves buyers, there is a point where statutes of limitation are in their interests as well. This idea echoes in the field of copyright law, where even copyright owners would, *ex ante*, prefer a finite to an infinite period of copyright protection. See [Landes and Posner \(1989\)](#).

owner takes reasonable efforts to search for the work. Until the identity of the current possessor is known, the marginal productivity of search expenditures is likely low; thus only the bare minimum of expenditures should be required of an owner. Today, these expenditures would involve reporting the missing painting to the Art Loss Register and (possibly) checking recent art publications, such as a catalogue raisonne, that contain information on the artist.

An alternative approach, known as the “demand and refusal” rule, avoids the administrative difficulty of determining the reasonableness of an owner’s search efforts. Under this rule, the statute of limitations does not begin to run until the current possessor rejects the original owner’s demand for a work’s return. Of course, this cannot happen until the original owner discovers the location of the work. *DeWeerth v. Baldinger* (836 F.2d 103 (2nd Cir. 1987)), which involved a dispute over a Monet landscape stolen from a German castle in 1945, illustrates the rule’s application. Baldinger acquired the painting in 1957 from the Wildenstein Gallery, which had previously purchased it from a Swiss dealer. The painting hung in Baldinger’s Park Avenue apartment for twenty-five years before DeWeerth’s nephew discovered its location from an entry in a catalogue raisonne. DeWeerth demanded the return of the painting even though New York had a three year statute of limitation. The Second Circuit applied a demand and refusal rule as New York law, distinguishing it from New Jersey’s discovery rule in the O’Keeffe case. The court however imposed on owners a duty to employ reasonable diligence in searching for the work, in addition to a duty not to unreasonably delay one’s demand for the work once it is found. It found against the plaintiff on the grounds that her search efforts (which were non-existent between 1957 until 1981) were insufficient. In *Solomon R. Guggenheim Foundation v. Lubell* (569 N.E.2d 426 (N.Y. 1991)), the highest state appellate court in New York explicitly rejected the duty of reasonable diligence expressed in *DeWeerth*. By its own account, the Guggenheim museum had lost track of a Chagall gouache “sometime in the late 1960s” (Id. at 427). After confirming it missing between 1969 and 1970, the Guggenheim notified no museums, galleries, artistic or law enforcement organizations of its loss. In 1985, the museum learned of the work’s location and demanded its return. When the then possessor refused to turn it over, the museum sued and won. The court noted both the administrative complexity of a requirement of reasonable diligence and as well the ambiguity in what amount of diligence would be reasonable.

The *Guggenheim* case illustrates another interesting point. The museum argued that publicizing the work’s disappearance would have “expose[d] gaps in security” (perhaps leading to more thefts) and “pushe[d] . . . the missing painting further underground”. The Guggenheim’s position hints of a collective action problem. All art owners would prefer a world in which stolen works were well-publicized, but no owner has the private incentive to publicize its own loss. One way to address this coordination problem is to lower the costs and raise the effectiveness of publicizing lost works. This is accomplished by lost art registries, such as the Art Loss Register (ALR), mentioned above.

Disputes over the ownership of Holocaust Art also raise a rich set of issues. One well-publicized dispute concerned two Egon Schiele paintings that had been “Aryanized” by

the Nazis in 1938 (*People v. Museum of Modern Art (In re Grand Jury Subpoena Duces Tecum*, 93 N.Y.2d 729 (N.Y. 1999)); *United States v. Portrait of Wally*, 2002 U.S. Dist. LEXIS 6445 (S.D.N.Y. 2002)). The State of New York moved to seize the works while they were on loan to the Museum of Modern Art. MoMA joined the party that had lent the works (the Leopold Foundation of Vienna) in resisting the seizure, arguing that the threat of such state action would discourage foreign collectors from loaning their works to the museum – thus preventing the museum from “mak[ing] works of art from all over the world available to New Yorkers” (*People v. Museum of Modern Art*, 1999, p. 742). The museum prevailed in the state case but was forced to forfeit one of the works in later civil proceedings initiated by the United States.

Fifty-seven delegations participated in the Washington Conference on Holocaust-Era Assets held at the U.S. State Department November 30–December 3, 1998 [[United States Department of State \(1998\)](#)]. The parties agreed upon eleven non-binding principles to assist in resolving issues relating to Aryanized art – including commitments to identify and publicize stolen works, to open archives to researchers, to establish registries, and to expedite the fair and just resolution of disputes. In “establishing that a work had been confiscated by the Nazis”, the delegations promised to consider the “unavoidable gaps or ambiguities in the provenance in light of . . . the circumstances of the Holocaust era” (*Ibid.*). Nations were further encouraged to develop alternative dispute resolution mechanisms, including mediation and arbitration. Today, most art museums in the United States post notice on their websites of works acquired after World War II that have gaps in their provenances in the 1930s and 1940s. The postings should aid owners and their heirs in identifying stolen works and facilitate their return.

## **6. Art market: Contract and authenticity issues**

### *6.1. Introduction*

The market attaches great value to the identity of the author of a work of fine art. If doubt develops that a work attributed to Rembrandt is not authentic, its market value will plunge. Indeed, if the work turns out to be a modern forgery, it may be worthless. Conversely, if scholars now believe that Rembrandt painted a work formerly attributed to a lesser artist living at the time of Rembrandt, its value will skyrocket. In each case, the physical object stays the same, yet changes in attribution substantially affect the value. One observes a similar phenomenon in the market for collectibles. Here it is not authorship but rather a work’s provenance or history that matters. For example, the dress worn by Marilyn Monroe when she sang “Happy Birthday” to President Kennedy at Madison Square Garden recently sold for \$1.15 million at auction. But the “same” dress without the Monroe/Kennedy association would sell for very little at a resale shop. To take another example, an imitation pearl necklace belonging to Jackie Kennedy Onassis sold for \$211,500 at Sotheby’s, yet an identical necklace could be bought for several

hundred dollars at a jewelry store.<sup>33</sup> These examples illustrate that the market value of a work of art or collectible consists of two components: the value of the physical object itself plus the value of intangibles embodied in the object, such as the work's author and provenance.<sup>34</sup> And it is the value of the intangibles rather than the physical object that primarily determines the value of the work. Understanding why this is so is beyond the scope of the paper.<sup>35</sup> Here we consider legal issues that arise in connection with authenticity disputes.

At the outset, it is useful to distinguish between two categories of authenticity disputes. One involves fraud in which the offending party (e.g., an artist or dealer) attempts to pass off fake or copy as an original work.<sup>36</sup> Successful art fraud exploits imperfect information and the premiums the market assigns to original works. Like theft, such fraud is a socially harmful activity because its cost (the time and effort in perpetrating the fraud) exceeds its benefit (the value of the fake); it is thus subject to criminal and civil penalties. The second category involves genuine uncertainty because of imperfect information. Here the question of authorship can only be answered with a probability, rather than a certainty, because of incomplete documentation on the history of the work. Fraud is not involved but questions arise concerning the interpretation of the contract between the parties and the costs and benefits of acquiring authorship information prior to the sale of the work. We focus below on this type of dispute.

## 6.2. *Authenticity and the law*

Parties to authenticity disputes employ a variety of methods to attack or defend the authorship of works of visual art. At one end of the spectrum is the "high-handed, note-the-weak-contours-on-the-vase-at-left ... old-fashioned connoisseurship" [Gopnik (1997, p. 36)]. At the other are highly technical scientific techniques such as X-radiography, pigment analysis, and canvas thread counting [see Schwartz (1995)].<sup>37</sup>

<sup>33</sup> Provenance also matters for works of art (even if authenticity is not an issue) because of the absence of clear standards for what constitutes good art. If an important collector has owned the work or the work has been exhibited at prestigious museums, a buyer will have greater confidence in the work's quality, which in turn will increase the value of the work.

<sup>34</sup> Intangible factors also include the intellectual property rights of copyright and trademark. Because these rights are often more valuable than the physical object itself, the value of an artwork will be substantially affected by whether these rights are sold along with the object or retained by the author. In this paper, we put to one side the intangible factors of intellectual property rights and instead focus on authorship and provenance questions.

<sup>35</sup> William Grampp (1989, Chapter 10) systematically addresses this question in *Pricing the Priceless*. See also Becker, Landes and Murphy (2000) (applying the notion of consumption externalities to explain why originals sell for much more than copies and why authorship and provenance changes can lead to large differences in price).

<sup>36</sup> Fakes are often not copies. A skillful forger may create a fake by creating a work that attempts to fill in a gap in the original artist's work. To be sure, the forger attempts to pass off the fake as a work by the original artist but the work itself need not be a copy nor closely related to a work executed by the original artist.

<sup>37</sup> X-radiography sends x-rays through a painting and onto a film to reveal overpainted areas of the work not visible to the naked eye. In autoradiography, the painting itself is made lightly radioactive. Different

Lying somewhere between the two, the provenance of a work will often weigh heavily on authenticity assessments. Scientific examination can establish the age and condition of a work; iconographic and stylistic comparison can place it in a national or regional school; art-historical scholarship can relate it to a given studio or master; connoisseurship can assign to it a certain level of quality by defined standards; the history of reception can tell us which attributions are controversial and which not; and provenance documentation (in particular, a clear ownership history without gaps that traces the work back to the artist's studio) reduces the likelihood that the work is a forgery or incorrectly attributed to a great artist.

In *Greenberg Gallery, Inc. v. Bauman* (817 F.Supp. 167 (D.D.C. 1993)), a group of four galleries claimed that a mobile they had jointly purchased for \$500,000 was not the Andrew Calder work "Rio Nero" they had thought it to be. They sought rescission of the sale on theories of fraud, breach of express warranty, and mutual mistake of fact. The previous owner had inherited the work from her father who had acquired it from the Perls Galleries who had represented Calder. The work's provenance, therefore, was impeccable.

The plaintiff's expert Klaus Perls, who had seen and photographed the actual Rio Nero twenty-three years before and had sold the work to the defendant's father, asserted that the work was "an exact copy" of the original (Id. at 171).<sup>38</sup> But comparing the questioned work to the archival photo, Perls argued that "the relative length of the rods was not the same" as in the original. Perls's reputation as a Calder expert was such that, according to other witnesses, his denial of the work's authenticity would significantly reduce or even destroy the work's value in the art market (Id. at 174, n.8). Defendants presented expert testimony questioning Perls's authentication methodology. Archival photos were unreliable, they argued, "since the lighting, camera angle, distance, and movement affect the shape of the work" (Id. at 172). Moreover, the defendant argued (plausibly) that any problems with the work were the result of damage in handling and lack of expertise in setting up the work – both brought about by the plaintiff's actions. The court found that the plaintiffs failed to prove that the work was not the original Rio Nero; in part, because it doubted the existence of another "'authentic' Rio Nero (whereabouts unknown)" (Id. at 175). In short, the record, in spite of Perls's testimony, was "too inconclusive to support [plaintiffs'] preponderance burden" (Id. at 175).

The case raises the difficult question of whether a court should substitute its judgment for that of the market. The *Greenberg* court was clear: "This is not the market . . . but

combinations of elements emit different levels of radiation onto films that are laid upon the work. In infrared reflectography, a film is bathed in light just beyond the range normally visible to the eye. The work is then videotaped with a camera designed to pick up carbon levels in the underdrawing. Pigment analysis samples a cross-section of a painting. While it captures all the materials in the painting in the proper sequence, it is destructive to the work and can only sample a small area. Finally, dendrochronology and canvas thread counting attempt to date the material on which a painting was created.

<sup>38</sup> Presumably, plaintiff's position was that the true Rio Nero had been sold to defendant's father, after which point the supposed copy was created.

a court of law, in which the trier of fact must make a decision based upon a preponderance of the evidence” (Id. at 174). The court thus treated the issue of authenticity as susceptible to a “yes” or “no” answer, rather than as an analysis yielding results along a continuum. The latter approach would focus a court’s inquiry on whether doubts about authorship caused a material decline in the work’s market value – analogous to how commercial contracts are scrutinized; whether the seller had failed to disclose material information about authenticity that he possessed (or should have reasonably possessed) at the time of sale; and whether the buyer’s behavior may have caused the decline in market value by altering or damaging the work. In *Greenberg*, the decline in the mobile’s value occurred only after the plaintiffs – knowledgeable art dealers – had accepted delivery and then shipped the work to different locations, which, as noted, may have damaged the work and led to doubts about its authenticity. In the absence of fraud, such inspection and definitive acceptance is usually sufficient to limit the seller’s liability. Thus the court may have reached the right decision for the wrong reasons.<sup>39</sup>

Consider an extreme version of the Calder case: both buyer and seller initially believe that a work is by X; yet after the sale it becomes clear that the work is not by X. Suppose further that the change in authorship leads to a substantial change in the value of the work (either up, if the work turns out to be by a more famous artist than X, or down, if the reverse is true). Should the buyer or seller bear the risk of mutual mistake? The standard law and economics response allocates the risk to the party who is able to bear the risk, or acquire information about it, most cheaply. This implies that in art transactions between sophisticated dealers and unsophisticated buyers, the seller should bear any authenticity risk that leads to a material decrease (or increase) in value, unless in the bargain the seller makes clear that there is some doubt as to whom the artist is. In the *Greenberg* case, where sophisticated parties were on both sides, the optimal rule may be the opposite because that would avoid expensive litigation in all cases except where the seller drafts an express warranty. Consider a different example. Suppose an unsophisticated person discovers a painting in his attic and sells it for \$60 to an art dealer who believes it is by a famous artist. The work turns out to be worth \$1 million. Can the seller claim he was duped and rescind the sale? The answer is no and this makes good economic sense. First, if a court held the sale invalid, it would mean that buyers would have to disclose private information about the work’s value. Such disclosure would probably defeat the transaction and, in general, discourage knowledgeable persons from searching for valuable art. Second, a seller can protect himself from selling a work that later turns out to be very valuable by hiring an appraiser. And, if the appraiser undervalues the work in his review, the former owner may have an action in negligence against him.

<sup>39</sup> Fraud requires knowing or intentional deceit (a so-called scienter requirement). Since the *Greenberg* court found insufficient evidence to doubt the work’s authenticity, it never reached the question of whether defendants had knowingly or intentionally misled the plaintiffs. We doubt that the record would have supported such a conclusion.

Rather than leave the rule-setting entirely to the courts, auction houses draft extensive sales documents to define the circumstances when authenticity disputes will justify rescission. In *De Balkany v. Christie Manson and Woods* (Queen's Bench Division, 11 January 1995), the buyer of what was described as an Egon Schiele painting in the auction catalogue claimed that the work was a forgery within the meaning of Christie's terms and conditions of sale. Although Schiele originally painted the work, the buyer claimed it was no longer a Schiele because 94% of the painting had been painted over by an unknown party after the original paint had flaked off. In response, Christie's argued that the work was an authentic Schiele and the overpainting was a question of the condition of the work, which the contract did not guarantee. The Christie's contract provided that works found to be forgeries could be returned within five years of a sale unless

(1) the catalogue description at the date of the auction was in accordance with the then generally accepted opinion of scholars . . . ; or (2) it can be established that the Lot is a Forgery only by means of a scientific process not generally accepted for use until after publication of the catalogue . . . or by means of a process which at the date of the auction was unreasonably expensive or impractical or likely to have caused damage to the Lot; (Id.).

The court found that the painting was a forgery (not, as Christie's claimed, an authentic Schiele in bad condition) and that Christie's could not avail itself of exceptions (1) or (2) above. Moreover, since the restorer had added Schiele's initials to the lower corners of the work, the court held that the overpainting was "made with an intention to deceive" and was not accurately described in the auction catalog as being "by" Egon Schiele.

The court found that Christie's could not avail itself of the exception clause above for two reasons. First, Christie's had not relied upon the "generally accepted opinion of scholars" in attributing the work to Schiele. Second, it had failed to investigate reasonably the extent of the work's overpainting, and any careful viewing of the painting would have led Christie's to describe the work as a painting "attributed to" Schiele, rather than painted by him (Id.). The court also noted that Christie's actions would have supported a tort claim for negligence since the painting's value had declined over 90% from its purchase price, an injury the buyer would not have suffered were it not for Christie's failure to take reasonable precautions in identifying the work.

Courts also become embroiled in authenticity disputes when an owner of a work claims to have been injured by another party's denial of the work's authenticity. In *Hahn v. Duveen* (234 N.Y.S. 185 (N.Y.Sup. 1929)), the plaintiff sued the well-known art dealer Sir Joseph Duveen for stating that a painting owned by the plaintiff was not a true da Vinci, but rather a copy of one displayed in the Louvre. In effect, the plaintiff claimed that Duveen had disparaged its product by making a false claim about its authenticity. To succeed in its lawsuit, the plaintiff had to show that Duveen's comment was false, misleading, and material, and that it had caused the work's value to decline. In spite of

a parade of connoisseurs (including Bernard Berenson) in near unanimous support of Duveen's position, Duveen lost the initial case and settled out of court before a retrial.

## 7. Estate issues

### 7.1. Introduction

This section examines two problems concerning the judicial treatment of art-rich estates. The first considers how courts value art-rich estates for tax and related purposes; the second concerns when trustees of charitable trusts comprising valuable art (e.g., the Barnes Foundation) should be allowed to depart from terms of the trust when it becomes impracticable, impossible or illegal to carry out these terms.

### 7.2. Estate valuation

When Andy Warhol died unexpectedly in 1987, his estate included a substantial body of his works – around 4000 paintings, 5000 drawings, 19,000 prints and 66,000 photographs. In litigation that followed, a court was asked to assess the monetary or “fair market” value of these works (*In re Determination of Legal Fees Payable by the Estate of Warhol*, 1994 N.Y. Misc. LEXIS 687 (N.Y. Misc. 1994)).<sup>40</sup> The court followed what has become a standard methodology – by first estimating the market prices of the individual items, usually from data on recent auction and private sales, and then by applying a “blockage discount” to the individual items or groups of items to arrive at an overall value. The rationale for the blockage discount is the belief that a large number of an artist's works could not be sold immediately without significantly depressing the market for the works. In determining the size of the blockage discount, courts consider such factors as the type of work; the number of works in the estate relative to the number sold in recent years; the artist's reputation; the likely future appreciation in prices; and the time and cost necessary to liquidate the estate in small lots. So, in the Warhol litigation, the court initially valued Warhol's art at \$506 million and then applied blockage discounts ranging from 20 to 35 percent to reach a final value of \$391 million (*Id.*). In another well-known case, the court valued the estate of the artist Georgia O'Keeffe at \$36 million after applying an average blockage discount of 50 percent to over 400 works initially valued at \$73 million (*Estate of O'Keeffe v. C.I.R.*, T.C. Memo. 1992-210 (U.S. Tax Ct. 1992)). And in the case of the sculptor David Smith, the individual items were initially valued at \$4.3 million and \$2.7 million after discounting (*Estate of Smith v. Commissioner*, 57 T.C. 650 (U.S. Tax Ct. 1972)).

<sup>40</sup> The case involved a dispute between the lawyer (Hayes) for the executor of the estate and the Andy Warhol Foundation for the Visual Arts (the main beneficiary of the estate). Hayes's contract called for a fee based on roughly 2 percent of the value of the estate. Hayes valued the estate at over \$700 million while the Foundation valued the estate at about \$100 million.

Valuing the estate of an artist who has retained a significant number of his own works raises interesting economic questions concerning the pricing of a durable good. Like other durable goods, art has a long life, yields a (non-monetary) return each period, requires carrying costs, and often has significant resale value. Art is also a risky asset. Not only are there wide swings in overall art prices but also the risks are even greater for individual artists who may be in fashion one period and out the next.

These risks justify employing a heightened discount rate to calculate the value today of the estimated proceeds from future sales. Why must future sales be estimated? Because, as the reasoning goes, a sale of all of an artist's works today will saturate the market for the works and will not maximize the value of the estate. A quick sale will not allow the estate time to promote the late artist's work, to locate new buyers, or to persuade collectors to increase their holdings of a single artist. Courts thus assume that value-maximizing estate will liquidate their holdings over a number of years. The problem is that by applying a heightened discount rate (in excess of the works' estimated rate of appreciation) to these future sales, the present value of future sales will be less than the estimated value of the works today – thus, the “blockage discount”.

This justification, however, is at odds with economic theory. In a rational expectations model, issues of the expected appreciation of art, the risk of holding an undiversified portfolio of art, projections on the number of future sales, aesthetic returns from owning art and discount rates are tangential to estimating the value of an artist's estate. As it turns out, the problem is much simpler than might appear. All one requires for valuation is current prices on actual sales, even assuming that it takes many years to liquidate the holdings in the estate.<sup>41</sup> Current prices capture all relevant information about future prices, risk and discount rates.

First consider the value of a single work, say a Warhol painting. Let  $P_0$  denote the monetary value of the work today. It follows that in equilibrium,

$$P_0 = P_n e^{-rn} \tag{1}$$

where  $P_n$  is the price of the work in  $n$  years, and  $r$  denotes the market discount rate. The discount rate is a composite of several factors as in

$$r = i + m - a \tag{2}$$

where  $i$  equals the one-period risk adjusted discount rate,  $m$  is the insurance, storage and other carrying costs (expressed as a percentage of the value of the work), and  $a$  is the aesthetic dividend per period from holding the work. Observe that Equation (1) is an equilibrium condition.<sup>42</sup> It is the outcome of individuals bidding for works in the art

<sup>41</sup> We are indebted to Casey Mulligan and William Grampp for helpful discussions on this point.

<sup>42</sup> If individuals receive different benefits from owning art, then the individual with the highest net benefit determines  $P_0$  in Equation (1) in the case of a single unique work. If we switch to valuing a large number of equivalent works that are fixed in supply, the net benefit of the marginal individual (the party just induced to buy the work) determines  $P_0$ .

market today and in the future. In equilibrium, the expected rate of growth of prices will equal the discount rate  $r$ . To see this, suppose  $P_0$  is less than  $P_n e^{-rn}$  say because  $P_0$  is expected to grow at a faster rate than  $r$ . Then buyers will bid up the current price until Equation (1) holds. Alternatively, if today's price exceeds the discounted value of the future resale price, today's owner will attempt to sell the work driving its price down until Equation (1) holds.

Observe that if art is a very risky investment,  $i$  and hence  $r$  will tend to be relatively high. The expected equilibrium rate of growth of art will also be high; and, taking as given the expected future price of the work, today's price will be lower the greater the risk of holding art. In short, today's price incorporates information about expected future prices and the discount rate. To continue our example, imagine that Warhol's estate contains a large number of his paintings. Assume further that we can convert these works into equivalent quality units. That is, let the price of a Warhol painting depend on various characteristics such as size, subject matter, date of execution, exhibition history, type of materials, etc. Suppose one can estimate a hedonic index relating these characteristics to prices. We can then take a group of diverse Warhol pictures and convert them into a stock of equivalent Warhol paintings. Let  $K$  denote the physical stock of these homogeneous paintings (or, equivalently, the stock of a durable good) and assume the estate plans to sell some paintings today, some next year and so on until no paintings are left in the estate.

Without any loss of generality assume that the estate plans to sell its entire stock of paintings within  $n$  years ( $n$  may be a very large number but knowing  $n$  is not essential to the solution below). Assume further that  $K$  is large relative to the total stock of Warhol paintings (which must be greater than  $K$  since Warhol sold many paintings before his death). The assumption that the estate holds a relatively large number of works raises two related questions. One is whether the estate's decision to vary the number of paintings it sells in any year will affect price. The other is whether the estate may face credibility or commitment problems because prospective buyers might be worried that if the estate sells a few paintings today at a high price, it will then dump the rest at lower prices in the future. As it turns out, none of these details matter to the problem at hand.

In valuing the estate, we assume its objective is to maximize the present value  $V$  of its sales of works over time. This holds whether the beneficiaries of the estate are individuals or a charitable foundation created by the artist. Let

$$V = \int_0^n k(t)P(t, k(t), Z)e^{-rt} dt \quad (3)$$

where  $k(t)$  denotes the number of works sold each period and  $P(t, k(t), Z)$  denotes the expected future price in period  $t$  which, in turn, may depend on the number of works sold in that period plus other factors such as the total stock of Warhol works and the number of works by other artists that are substitutable for Warhol's paintings. These factors are exogenous to the estate and represented by the variable  $Z$ .

Let  $V^*$  denote the maximum value of  $V$ . To achieve  $V^*$ , the estate might dispose of a few paintings each year, sell its entire holdings this year or hold off selling any works for

a number of years.<sup>43</sup> Again it turns out that we need not consider the details of how the estate disposes of its works in order to estimate  $V^*$ . Recall the equilibrium condition in Equation (1) relating the current to future price of a painting. This condition must hold for all  $t$  periods. That is, today's price must equal the discounted price one year from today, two years from today and so forth. Substituting Equation (1) into Equation (3) and noting that

$$K = \int k(t) dt$$

yields

$$V^* = P_0 \int_0^n k(t) dt = P_0 K. \quad (4)$$

In other words, the value of the works in the estate is simply equal to today's price times the total stock of equivalent works. Since in equilibrium future prices are expected to grow at a rate of  $r$  per period, we only need to observe a small amount of art auctioned off today ( $P_0$ ) in order to value the proceeds the estate will receive from future sales. This is a remarkable result because we do not need to know the details of how the estate disposes of its holdings in order to estimate its value.

We note several additional points.

1. In an important sense, nothing fundamentally changes when the artist dies. To be sure, no new works will be created and that may alter current and future prices. But the same number of works that existed the day before the artist's death exists after his death. Moreover, the concentration of holdings is the same. Before his death, the artist held  $K$ . Now the estate holds  $K$ . Hence any market power the estate might be able to exercise because  $K$  is relatively large could have been exercised by the artist himself.<sup>44</sup> Thus, as a first approximation,  $V^*$  is the same whether the artist or his estate holds  $K$ . We say "as a first approximation" because supply is fixed after the artist's death so prices may increase. A possible offset, however, is that the dealers may have less incentive to promote the artist's works after his death. Prices may also fall because promotional efforts by the artist himself will end. These are relatively minor points and, in any event, will be captured (in an expected sense) by current prices following the artist's death.

<sup>43</sup> The typical argument advanced against selling off works immediately is that such a "fire sale" would significantly depress prices. But the problem turns out to be more subtle. On the one hand, inter-temporal substitution may limit or eliminate the negative effects of selling a large number of works in any period. On the other, a "fire sale" by the estate may signal that the estate has private information that Warhol's standing in the art market is likely to diminish in the future and this, in turn, may lead collectors to revise downward their estimates of Warhol's stature. And since art prices are largely determined by demand (since supply is fixed), small shifts in demand may induce large changes in prices. For the moment we put off consideration of these issues.

<sup>44</sup> One difference, of course, is that the living artist also controls the rate at which the stock expands whereas the estate holds a fixed stock.

The essential point is that the artist's death does not fundamentally alter the valuation question.

2. We have been able to determine the value of the estate without making any assumption about the number of works that the estate will sell each period. All we require is the assumption that the estate's objective is to maximize the value of its assets. From this it follows that it will dispose of works in a way to maintain the equality between current prices and the present value of future sales. Given this outcome, we can use today's prices from a small number of sales (relative to  $K$ ) to value a large number of future sales.

3. Imagine that the estate must sell a large number of works today to satisfy tax obligations. Does this "forced sale" lower the value of the estate? To see that it doesn't, consider what would happen if selling a large number of works depressed current prices. Current prices would be less than the discounted value of future prices. Hence a buyer (or buyers) would step in and bid up today's price to restore the equilibrium between current and future prices. The buyer would probably be a dealer who would acquire the works to sell in the future.<sup>45</sup>

4. As mentioned earlier, if the estate sells a large number of works immediately, this may signal their belief that an artist's works are overvalued and future prices are likely to be lower than Equation (1) implies. Assuming that other participants in the art market believe the estate has some informational advantage evaluating the artist's future reputation, the net effect of the estate dumping works on the market will be that both present and expected future prices will fall. The equilibrium relationship between current and future prices will still be maintained though at lower prices. The estate may try to conceal these sales by selling through third parties. But this is not likely to be successful. Combining points (3) and (4) implies that dumping a large number of works on the market lowers price because demand shifts downward with a fixed supply. Note also that price is not declining because of a movement along the demand curve for the sale of works changes the identity of owners but not total supply.

### 7.3. Estate management: The doctrine of *cy pres* and administrative deviation

Albert C. Barnes, a self-made chemist who died in 1951, assembled one of the world's greatest art collections. The collection, now the property of a charitable trust (the Barnes Foundation), contains over 700 Impressionist works, including 181 Renoirs, 69 Cezannes, 60 Matisses, 44 Picassos, 18 Rousseaus and 14 Modiglianis. Barnes reportedly detested the elitism of the museum culture in high-society Philadelphia. Thus

<sup>45</sup> This raises the issue of whether the appropriate prices in Equations (1)–(4) are dealer or wholesale (often equated with auction) prices or a blend of the two. This turns out not to be a problem provided one is consistent. In a competitive art market, the difference between retail and wholesale reflects the cost of selling goods. These costs may be substantial because of the time and effort required to persuade buyers to purchase a work. Whether one uses wholesale or dealer prices depend on whether one wants to know the net or gross value of the estate. In the former case, one uses wholesale (auction) prices; in the latter, retail prices.

in setting up the Foundation, Barnes stipulated that the Foundation was to be an educational institution and not a public museum; public access was to be allowed only on Saturdays between September and June; no paintings were to be removed from the gallery nor moved from where he had placed them (the particular arrangement was part of his philosophy of art appreciation); no entrance fees could be charged; no loans or sales of paintings were to be allowed; and all of the Foundation's funds were to be invested in low-yielding Government securities. Most importantly, Barnes specifically provided that in no event should these terms be modified. If the Foundation did not have the resources to continue, Barnes specified that the art works were to be donated to a group of museums and other institutions [Abbinante (1997)].

Notwithstanding Barnes's testamentary clarity, as the financial situation of the Foundation has become increasingly strained in recent years, courts have sanctioned numerous deviations from these specific terms under the legal doctrines of *cy pres* and "administrative deviation". These doctrines are typically applied when the terms of a charitable trust become impossible or impractical to carry out: administrative deviation usually concerns minor changes regarding how the trust is managed (e.g., number of trustees, tuition charge, or mortgaging of property) whereas *cy pres* concerns more major changes necessary to carry out the general purpose of charitable foundation (e.g., redirecting foundation funds towards basic medical research when the foundation was set up to provide research funds to combat a particular disease that has been eliminated).

In 1995, the Montgomery County Court of Common Pleas and the Pennsylvania Superior Court granted the trustees of the Foundation greater flexibility in the management of Foundation funds. The courts allowed the Foundation to open the collection to public viewing three-and-a-half days a week, to charge an admission fee of five dollars, and to use the gallery for fundraising purposes. Perhaps most remarkably, the courts allowed the Foundation to conduct a world tour of the collection to raise money for the improvement of the Foundation's facilities. All of these modifications, against Barnes' specified intent for the collection, were defended as administrative in nature.

More recently, several foundations have offered to donate \$150 million to the Barnes Foundation if it moves the entire collection to a new facility in the museum district in Downtown Philadelphia. The Foundation insisted and the court subsequently agreed that such funds were necessary for the Foundation's continued viability, and that moving the collection was consistent with Barnes' desire that the collection be displayed so as to promote educational goals.

What is puzzling about the recent Barnes decision is that Barnes explicitly provided for the contingency that if the Foundation failed, its works were to be distributed to various museums. Rather than disposing of the collection as Barnes had provided, the courts have supported the Foundation in altering the terms of the charitable trust to bring about the outcome that Barnes had most explicitly sought to avoid – the creation of a new museum in Philadelphia to house his art. There is an economic downside when a court departs from the text of a will or a trust indenture. It undermines the incentive for charitable giving and the establishment of charitable foundations to promote the educational goals of the donor. To be sure, it might appear socially beneficial to depart from

the terms of the trust when circumstances arise that were not anticipated by the donor. But this comes at a price – namely, the reduced incentive to set up a charitable foundation in the first place. In some cases, the benefit from altering the trust may outweigh the cost, particularly, if the donor has not made any provision for dealing with these unanticipated changes. Then there is a strong argument that these changes would have to be approved by the donor if “transaction costs” had not made it impossible to discuss these modifications with him. But in the Barnes case, the argument for modifying the trust is much weaker; Barnes considered and provided for the contingency that the Foundation would no longer have the resources to continue its educational mission.

We wonder whether an alternative approach may better serve the interests of present and future generations. The value today of the right to control what happens 50 or 100 years in the future is likely a small fraction of purchase price for art. It may also be a relatively small fraction of the incentive to engage in charitable giving. Were the law to offer the right to control testamentary estates for only 50 or 100 years (rather than in perpetuity), and were courts to scrupulously respect those conditions for that term, testators and courts would have greater clarity regarding the proper time for pragmatism. Some courts may still be persuaded to allow significant deviations over the course of that term; but no longer would slippery-slope arguments for administrative deviation – i.e., that deviation is appropriate since the current situation may eventually prove unsustainable – hold water. Improved certainty may encourage charitable giving beyond today’s baseline.

## Abstract

In his essay on imitation in the arts, Adam Smith considers that the exact copy of an artwork always deserves less merit than the original. But the hierarchy between copies and originals has changed over time. So has the perception of copies by lawyers, philosophers, art historians and curators. The development of a market for copies is part of a wider contemporary questioning of the boundaries between originality and copy. We analyze whether and how the various actors in the art market (artists, collectors, lawyers, curators, art historians and philosophers) contribute to valuing and creating or, at times, to killing copies. Artists and collectors have never belittled copies. Art historians think that copies have an important role in preserving the memory of lost artworks, and in educating young artists, but nevertheless consider copies better left to the reserves of museums. Lawyers are ambivalent and judicial precedents bear testimony to the ambiguous legal status of copies. Contemporary art historians and art philosophers have influenced curators and museums to organize exhibitions that make use of copies, giving them a new life.

“We use copies to certify originals, originals to certify copies, then we stand bewildered.”

Hillel Schwartz

## 1. Introduction

Research on copies is essentially focused on industrial activities (books, records, fashion, protection of patents) and on the incentives or disincentives to creativity resulting from copyright.<sup>1</sup> But copies are also linked to questions concerned with value, the allocation of property rights, and regulation, three central questions in economics.

In his essay on imitation in the arts, *Adam Smith (1795)* considers that the exact copy of an artwork always deserves less merit than the original.<sup>2</sup> But the hierarchy between copies and originals has changed over time. So has the perception of copies by lawyers, philosophers, art historians and curators. The observation of these changes can be used to analyze art tastes and practices. The development of a market for copies is part of a wider contemporary questioning the boundaries between originality and copy.

In this chapter, we analyze whether and how the various actors in the art market (artists, collectors, lawyers, curators, art historians and philosophers) contribute to valuing and creating or, at times, to killing copies. Artists and collectors have never belittled copies. Art historians think that copies have an important role in preserving the memory of lost artworks, and in educating young artists, but nevertheless consider copies better left to the reserves of museums. Lawyers are ambivalent and judicial precedents bear testimony to the ambiguous legal status of copies. Contemporary art historians and art philosophers have influenced curators and museums to organize exhibitions that make use of copies, giving them a new life.

In Section 2 we define copies, contrasting them with forgeries, and reproductions. Section 3 deals with the permanent role of copies over time. Sections 4 and 5 give some insights into the price of copies (relative to originals). Sections 6 and 7 are devoted to the changing views held by art historians, philosophers and law-makers. Section 8 concludes.

<sup>1</sup> See, for example, *Johnson (1985)*, *Grossman and Shapiro (1988a, 1988b)*.

<sup>2</sup> Smith is just stating a view that was common in his time (and even before).

## 2. Forgeries, copies, and reproductions. Definitions and boundaries

### 2.1. Copies and fakes

Copies or reproductions differ from fakes since only the latter are produced to deceive<sup>3</sup> but it is often difficult to detect whether a work was made with the intention to deceive. Hoving (1996, p. 32) considers fakes those thousands of Roman sculptures of the archaizing style, produced between 100 B.C. and 100 A.D., which are copies of Greek marbles from the sixth century B.C. The fact that even Greek sculptors produced copies long before the first century B.C. makes it highly doubtful that these were intentional forgeries.<sup>4</sup> Arnheim (1983) holds the view that we should be “grateful to get an idea of the lost Greek sculpture through Roman copies”.<sup>5</sup> After all, the celebrated *Venus of Milo* is also a Roman copy.<sup>6</sup>

Copies pay tribute to the original, recognize its value and draw their own value from it. Forgeries deny the aesthetic superiority of the original. Acknowledged copies are cheaper than originals. As long as they are not detected as such, fakes are as expensive as originals, and their number usually increases with the fame of the artist. Good forgers often have an extraordinary knowledge of the work of an artist and of what art history has to say about him, as was the case with Van Meegeren, the forger of Vermeer. According to Werness (1983, pp. 33–34), “the excitement with which [Van Meegeren’s] *Emmaus* was received was partly due to this very practice [of sifting] through the art historical literature. Again, the resemblance to Caravaggio’s painting of the same subject ‘proved’ Vermeer at least knew the painting and had possibly traveled to Italy”. In short, Van Meegeren “proved” what Vermeer experts wanted to hear. Forgers exploit assumed “holes” in the work of an artist and fill them.<sup>7</sup> Catalogues raisonnés are a tool for limiting the production of fakes. They began to appear during the nineteenth century, to “close” the oeuvre of an artist, at the very moment when the standard practice of copying in the same medium started to compete with other means such as photography [Castelnuovo (1987)].

<sup>3</sup> It is well known and documented that even masters seem to have produced forgeries. Lucky he who, today, is the owner of the “Roman” sleeping cupid carved by Michelangelo. See Hoving (1996, p. 55).

<sup>4</sup> Chamoux et al. (1973) give the example of the Thessalian prince Daochos who, in 335–330 B.C., preferred to order marble copies of existing bronze sculptures, rather than original marbles.

<sup>5</sup> See the Exhibition Catalog *La fascination de l’Antique, Rome 1700–1770*, Lyon: Musée de la Civilisation Gallo-Romaine, 1999.

<sup>6</sup> See Hol (2004).

<sup>7</sup> Recall also the enormous influence the Ossianic epics, attributed to the third-century Celtic bard Ossian, had on late eighteenth-century European literature. The poems were later found to be a forgery due to Macpherson, an eighteenth-century poet. This does not prevent the *Encyclopedia Britannica* to sum up Macpherson’s work as follows: “The varied sources of his work and its worthlessness as a transcript of actual Celtic poems do not alter the fact that he produced a work of art which did more than any single work to bring about the romantic movement in European, and especially in German literature. Herder and Goethe were among its profound admirers.” See Koestler (1989, pp. 402–403).

## 2.2. Copies and originals

There is an imperceptible transition from “original” to “copy”, and copies of paintings may be considered as satisfying substitutes for originals. Multiples cause even greater confusion than paintings. Man Ray photographs shot, developed, and printed by him in one or several copies are considered “vintage” photographs. Such works cease to be called “vintage” if Man Ray did not print the photographs himself. The case is much more ambiguous if the photographs are printed by another photographer, under Man Ray’s supervision, or without such supervision, but with his permission, or by Man Ray himself, but twenty years after the picture was shot. A print of a negative by Man Ray that the artist did not find interesting enough to print is not original. A photograph printed in 1990 by a collector who happened to possess a genuine negative by Man Ray is not a Man Ray. The one printed by the Centre Pompidou for an exhibition devoted to the artist is not an original either. Therefore, for photographs, the definition of originals and copies is rather arbitrary. The same applies to engravings and lithographs. These are obviously copies<sup>8</sup> because, like photographs, they are not unique.<sup>9</sup> Such prints are obviously “right” if the artist did the original engraving on the copper plate or the drawing on the stone, produced each copy in his atelier or on his own printing machine, and signed each copy. If all of these characteristics apply, but the print is not signed,<sup>10</sup> or if the artist had the prints done by someone else but verified and signed each one, the definition of originality becomes as ambiguous as in the case of photographs.<sup>11</sup> When the artist only did the drawing and had it copied on a copper plate by a good professional engraver, the engraving is no longer an original. The market considers that when the artist does nothing at all, but just signs the copies, as Salvador Dali did, the engraving is not an original.<sup>12</sup>

The Rodin museum in Paris is authorized to produce up to eight copies of every piece of plaster that was left by Rodin in his atelier after his death but that he did not wish to

<sup>8</sup> This vocabulary is not unanimously accepted. Griffiths, the keeper of the Department of Prints and Drawings at the British Museum, suggests that “the word [copy] is dangerously ambiguous . . . [and that] the term impression should be used of a print. The term copy in prints should be strictly reserved for a redrawing of an original by another hand. If done by the original designer, such a copy is referred to as a replica”. See Griffiths (1996, p. 139).

<sup>9</sup> For multiples, the definition of original and copy is complex, leading Melot (1985) to formulate “the curious theorem that for objects of art, multiples can also be unique”.

<sup>10</sup> Note that signing of prints was occasional during the eighteenth century and became more systematic after 1850 only. See Griffiths (1996, pp. 152–153). Signature is not considered necessary for prints in French decrees that define works of art. See Melot (1995).

<sup>11</sup> This is obviously a widely accepted practice for lithographs: “Once the drawing is finished the artist’s task is done. The rest is the province of the printer, whose operations are complicated enough to make it unusual for the artist to do his own printing”. See Griffiths (1996, p. 102).

<sup>12</sup> Imagination is without limits. Architect Richard Meier’s luxuriously designed New York apartments are now being sold as limited editions, numbered and signed by the designer. *The Art Newspaper* 146, April 2004, p. 2.

be cast in bronze. The museum sells them as genuine Rodins. The same is true for works by Arp that can be reproduced by the Fondation Arp in Rolandseck. Jewels drawn by Verdura fifty years ago are produced today and sold as genuine Verduras. Living artists may be very opposed to such actions. Donald Judd, for example, rejected a copy of one of his installations, though its owner had given permission to a Los Angeles gallery to erect a copy in an exhibition they were mounting of Judd's works.<sup>13</sup>

Posthumous editions of prints, modestly called "later states", are sold under the names of the artists who created the originals.<sup>14</sup> An unsigned poster is not an original work. But posters by celebrated artists are almost considered artwork. The Musée d'Ixelles in Brussels claims to be the only museum to possess the complete collection of Lautrec's posters and exhibits all of them in one of the best rooms of the museum. As we shall see later, the price of prints by Rembrandt himself is not more than three times larger than the price of posthumous prints, even from a transformed original plate.

These cases show that the definition is ambiguous, and essentially depends on norms and conventions. In some cases a copy is accepted as "right", even if it is copied long after the artist died. In other cases arbitrary barriers help building a separation between originals and copies.<sup>15</sup>

### 2.3. Copies and reproductions

There are also significant differences between copies and reproductions. Copies are made to reproduce as perfectly as possible the original work, but the copier may also be tempted to copy because he thinks that he can mimic the process of creation itself. Copiers use, in most cases, the same technique as the original artist, though there are many instances of drawings or paintings made after sculptures, and vice-versa.<sup>16</sup> The objective of reproductions is to give by any possible technical means, including digitalization, the very feeling and illusion of the original with little or no artistic intention. Copies can only be imperfect, because there is mediation and there may be interpretation. Van Gogh's Milletts can hardly be considered perfect copies. Reproductions

<sup>13</sup> *The Art Newspaper* 143, January 2004, p. 32. The author of the article (A.C. Grayling from Birkbeck College) wonders why "questions about the nature of art [are] still so intimately connected with questions of authorship in this age where the artist's hand is deliberately kept out of the work".

<sup>14</sup> It is interesting to note that Lessing (1983, p. 73) describes "modern prints from old litho stones [as] forgeries, though, assuming no deception is involved, forgeries of a peculiarly amoral, non-offensive sort".

<sup>15</sup> Alan Peacock made us aware of a contemporary Scottish artist, Jack Vettriano, who sells at auction at very high prices. One of his paintings, *Mad Dogs*, was sold for £140,000 on May 28, 2004. He became famous, at least in Scotland, through prints and postcards. This is what *The Scotsman*, 29 May 2004 writes about him: "Few artists have divided the art world as deeply as Vettriano. He is regularly slated by art critics who deem his work lacking in detail, subtlety and painterly technique. In the early 1990s, his work was turned down by the Royal Scottish Academy and the Scottish Arts Council, and he is still not represented in any major public collection. However, prints and posters have made him the best-selling artist in Britain, earning an estimated £500,000 a year in royalties." No need for originals!

<sup>16</sup> Henry Moore, for instance, produced sculptures "copied" from Masaccio's frescoes of the Carmine in Florence. See *Maison* (1960).

should be perfect and not aim at interpreting, although, as noted by Focillon (1919), photographs of the Mona Lisa can be unfaithful.

An interesting issue is coming up with color photographs and videos that both have a finite life and may fade. Research is going on at the Cesar Foundation in Basel to try to reverse this deterioration. The suggested solution consists in storing photographs in digital form and reprinting them in such a way that the original color is restored when the original fades. This is a perfect solution, except that it is an infringement of the 1976 American Copyright Act which protects against duplication “in any tangible medium of expression now known or later developed”.<sup>17</sup>

It is, however, doubtful that the difference between the terms “copy” and “reproduction” should be taken too seriously. They are very often used interchangeably. The *Oxford Advanced Learner’s Dictionary*, for instance, defines “to reproduce” as “to make a copy of a picture”, and in their *Dictionnaire de la Peinture*, Laclotte and Cuzin (1991) define copies as “imitations or reproductions” of a work, but consider repetition, replica, reduction, and facsimile as different categories of copies. The blurred boundaries between copies and other kinds of reproductions justify the relatively broad definition of copies that we adopt in our study of prices, which includes “copies”, “attributions”, “manner of”, “after”, “school of”, etc. These various qualifications are used in the special sales of copies organized by Christie’s in Amsterdam.<sup>18</sup>

### 3. Artists and their patrons

The boundaries between copies, reproductions and originals were far from being obvious during the Roman Empire. As noted earlier, the Roman Empire was full (and fond) of copies. According to Holtzmann (1996, pp. 846–849), copying was essential to artistic activity at that time, and was considered a way of recognizing the artistic talent of a master. The idea that the concrete reference to a model confers value to creation became even more important during the Middle Ages, as exemplified by the history of illuminated manuscripts.

During the Renaissance, copies and replicas (that is, copies by an artist of his own work) were produced in large numbers as well: imitation became almost a necessary activity. Michelangelo substituted his own drawings for older ones. Hans Holbein copied Flemish painters, but hid the fact [Martens (2001)]. Rubens modified old drawings. Pieter Bruegel left only 45 paintings, but these became so famous that they generated a large number of copies. We know of 123 versions of *Winter Landscape with Birdtrap*. The eldest son of Bruegel, Pieter the Younger, was very fond of exploiting this vein, almost inventing the idea of multiples; he produced several dozens of *Returning from*

<sup>17</sup> See *The Art Newspaper* 139, September 2003, p. 21.

<sup>18</sup> Christie’s October 7, 1995 sales catalog of copies in Amsterdam gives a glossary of words they use, and which have different meanings: replica, variant, version, copy, quotation, pastiche, paraphrase, parody, and persiflage.

*the Country Fair* and *25 St. John the Baptist Preaching* [Francastel (1995)]. Hoving (1996, p. 57) notes that inventories made after El Greco's death "list as many as five or six versions of the most noteworthy originals, all made in differing sizes, all of which the master could not have painted himself. They sold and still sell today as originals". Martens (2004) suggests that while Italian art had its theorists (Vasari, of course, during the 16th century, but also, Ghiberti, Alberti and Filarete, during the 15th century) the Flemish used copies to transmit their knowledge and discoveries.

All masters had ateliers where pupils specialized in certain items and worked for the master. According to de Saint-Simon (1996, pp. 339–344), in Rigaud's atelier, artisans produced portraits the prices of which varied with dimensions and according to how much had been corrected by the master.<sup>19</sup>

Copying went on during the 17th century. Rubens copied Leonardo, Michelangelo, Mantegna, and Raphaël. Greco copied Corregio, Michelangelo, and Titian.<sup>20</sup> Watteau copied Rubens.

Manet is said to have executed 400 copies from 290 sources. Van Gogh produced 520 copies [Schwartz (1996, p. 248)]. Bacon copied Velazquez and Van Gogh. Picasso copied Manet, Delacroix and others. Painters copy other painters, but they also copy their own works. Ingres copied himself, executing, for instance, *Paolo and Francesca* eighteen times, and writing very proudly that "the majority of those works of mine whose subjects I like have seemed worth the trouble of being perfected through repetition and retouching".<sup>21</sup> Gerôme, a "pompiers" painter successful during the 1850s, produces so many copies of his own work that Zola felt he had to write a satirical tract against him: "Mr. Gerôme . . . paints canvases and these are reproduced or printed in thousands of copies. The subject is everything, and the painting is nothing. Copies are worth more than the original".<sup>22</sup> Later in his life De Chirico used to copy his older style which had made him famous, but got into trouble because he antedated the paintings. Jasper Johns painted several versions of *Flag*, *Numbers*, and *Target*. And who knows how many *Marilyns*, *Maos*, and *Mona Lisas* Andy Warhol, the very king of copyists, did produce.

### 3.1. *The demand for copies*

Growing demand for paintings is probably at the root of the growing production of copies. During the Renaissance, art lovers welcomed exact copies that could be substituted for originals. Chamoux et al. (1973, p. 15) write that "the proof of talent is in the ability to produce a copy that can mislead the viewer". The Renaissance Italian poet

<sup>19</sup> Rembrandt's atelier differed from others and can be considered the first "academy" because he organized sessions during which he asked his pupils to draw and paint from living models.

<sup>20</sup> See, for example, Alpers (1988) on Rembrandt, or Montias (1982) on the atmosphere in the Low Countries in general.

<sup>21</sup> Ingres, *Ecrits sur l'art*, quoted by Schwartz (1996, p. 248).

<sup>22</sup> Quoted by Lafont-Couturier (1998, p. 37).

Petrarch purchased copies when he could not find the original of a painting he wanted for his collection [Dubus (1992)].

De Marchi and Van Miegroet (1996, p. 62) note that during the Renaissance, the “terminology original/copy was more fluid, [and that] it is not clear from observed practices that transactors in paintings (makers, dealers, buyers) thought in terms of a sharp distinction between the two. Confusion about the economic status of the original was, moreover, deliberately maintained by the workshops of leading masters in the fifteenth and sixteenth centuries”. However, as Martens (2001) points out, originality was the valued default option since without specific instructions to produce a copy, the painter was expected to be creative.

In the early 17th century, collecting became a fashionable activity among kings, noblemen, and even simple connoisseurs. Some collectors patiently assembled carefully chosen works; others took shortcuts. For example, the Duke of Lerma acquired 1431 paintings between 1599 and 1606; to achieve this, he bought series of works, such as 240 portraits of popes and 153 heads of Roman emperors [Brown (1995, p. 111)]. Others purchased copies which, though “recognized as inferior to the original, [were] considered as valuable record[s] of admirable composition[s] or invention[s]. Even so discerning a connoisseur as Charles I sent the copyist Michael Cross to Spain to copy the works by Titian” [Brown (1995, p. 111)]. Louis XIV bought copies. One of the Medici (Ottaviano) offered to Frederic the Second, duke of Mantua, a copy by del Sarto of a painting by Raphaël. When the king heard of the substitution, he became enthusiastic about the gift produced by a painter who was able to reproduce with such perfection the work of a great master. Colbert asked French artists to make as many copies as possible of paintings they could see in Rome.<sup>23</sup> Montias (1996, p. 24) estimates that “the proportion of copies among landscapes and still-lives in randomly selected inventories [in Amsterdam, during the years 1650 to 1669] may [have been] as high as one half to three quarters”. The demand for copies had a twofold purpose: training for artists and complementing collections. Creators and artists, as well as art amateurs and collectors, considered copies as valuable works of art. They were a way for artists (and connoisseurs) to get close to works that they would otherwise be unable to see, and are still a means for artists to train. Ayrton (1960, pp. 16–17) reminds us that “until recently even the wealthiest, most traveled and most studious of artists (for example, a Dürer or a Rubens) could only see in his entire lifetime the quantity of material now displayed to the casual visitor who spends one day in the Louvre or the Metropolitan museum”.

### 3.2. *A change in the status of copies*

It is not easy to pin down even the approximate time at which the quest for “originals only” decreased the relative prices of copies. In the mid-18th century, imitation loses ground.<sup>24</sup> The emergence of public museums in the late 18th century certainly

<sup>23</sup> Letter of 23 July 1672, quoted in Karpinski (1989, p. 105).

<sup>24</sup> This is particularly so in literature. See Mortier (1982).

played a role, as did at the same time, Winckelmann (1768) who was the first to point out that most of the antique marbles were Roman copies.<sup>25</sup> The romantic belief in the isolated artist with genius, which became dominant during the nineteenth century, also contributed to the decline in the appreciation of copies.

The decline of the status of copies is also the consequence of technical progress (photographs as substitutes for copies), and of legal intervention (the extension of property right laws). The invention of color photography obviated one of the major functions of copying: Copies progressively ceased to be a means for artists and connoisseurs to get close to works that they would otherwise be unable to see. The quality of mechanical reproductions improved so much that most customers found them good enough and stopped ordering manual copies,<sup>26</sup> except to complement collections.<sup>27</sup>

In the late nineteenth century, a *Musée des Copies*, also called *Musée Européen*, opened in Paris. A document introduced in the French Parliament clearly states the reasons for this: “Nobody thinks that only originals should be exhibited. If this were the case, there would exist only eight to ten cities with museums exhibiting original paintings, and only there would it be possible to educate the public”.<sup>28</sup> Charles Blanc, then Directeur des Beaux-Arts, commissioned copies from living French artists and tried to gather older copies exhibited in other museums. Blanc’s successor, Philippe de Chennevières, decided to close the museum a mere nine months after its opening; its exhibits (paintings and sculptures) were returned to the Ecole des Beaux-Arts, where they are probably still used for teaching and copying.<sup>29</sup> Those who were opposed to the museum suggested opening a photographic library showing expensive “hand made” copies. According to Chamoux et al. (1973, p. 29), this is the time at which forgeries started proliferating, and experts and “attributors” emerged.

But copies were still traded during the end of the 19th century. A lag is often observed between new ideas and their effect on markets. In the late 20th century, copies seem to raise renewed interest. Museums organize exhibitions of copies and use copies even in exhibitions devoted to originals. This development had some influence on the art market, which in turn had effects on copies.

<sup>25</sup> See also Ginzburg (1989).

<sup>26</sup> Ayrton (1960, p. 7) shares this viewpoint and adds that “the status of copies has fallen in proportion to the rise of reproduction”, as the quality of reproductions has increased. Copies were less useful to keep a trace of works of art whose state was deteriorating. The political function of copying disappeared during the same period: Copies were no longer useful for displaying the portraits of kings and emperors in public spaces.

<sup>27</sup> The German collector Fiedrich von Schack, for example, used to purchase masterpieces as well as copies between 1860 and 1880. He bought 55 copies of Venetian paintings in order to complement his collection.

<sup>28</sup> See *Annales de l’Assemblée Nationale* XIV, 11 November–21 December 1872, pp. 479–481.

<sup>29</sup> Details can be found in Chamoux et al. (1973) and in Cuzin (1993).

#### 4. Markets for prints

Prints are an excellent example of works that exist in multiple, but identical, “copies”. Prices give an insight on how markets create artificial scarcity [Melot (1973)] and generate a hierarchy that depends on the degree of “originality”.

It is useful to recall that prints are produced from engraved plates (copper or other metals).<sup>30</sup> Such plates may be reworked by the artist, leading to prints produced from each reworked plate, which differ from each other, though often not greatly, since corrections on copper plates and lithographic stones are difficult. Therefore, several consecutive “states” of the same work, printed from plates that have undergone several transformations, may coexist on the market. Some artists produce their own prints, others do not.<sup>31</sup> Some plates may survive the master and may be used, without transformation, to print so-called “late prints”. These are identical to the ones that are produced from the last state of the plate by the artist himself, but differ since he did not print them. Finally, some plates may be reworked after the artist’s death and lead to “posthumous” prints. In short, markets may be faced with three types of works:

- (a) original prints, produced by the artist during his lifetime, from plates that may have undergone transformations (states);
- (b) late prints, produced after the artist’s death, using his plates in the (last) state in which he left them; and
- (c) posthumous prints, also produced after the artist’s death, but from a plate that was transformed after his death.

Intuitively, there is less and less originality when going from (a) to (c). Type (a) prints can be considered to be fully by the master himself. Type (b) prints differ from the first ones, since they were not printed during the master’s lifetime, but use the original plate. Finally, type (c) prints are printed from a transformed plate, and not by the master. One may thus expect prices to decrease between (a), (b) and (c).

Lazzaro (2006) collected 4700 observations of Rembrandt prints sold at auction between 1985 and 1998, and runs regressions of prices on dummy variables describing the “state” of each print sold,<sup>32</sup> controlling for many other characteristics, including degree of rarity, technique used (etching, drypoint, etc.), subject matter (portraits, landscapes, etc.), experts’ appraisal (very fine, good, etc.), quality of impression, quality of paper (including special features such as watermark, etc.), conservation status, as described in the sales catalog (quality of margins, stains, other defects, etc.), salesroom, year of sale. Her observations include original prints by Rembrandt, late prints and posthumous prints. She also includes dummy variables which describe whether a specific state, original or not, was followed by other states, and if so, by which types of states (other

<sup>30</sup> Or drawings on a specific surface such as a lithographic stone. We simplify very much here. See Griffiths (1996) for details.

<sup>31</sup> Modern techniques, such as lithography, are very elaborate and it has become unusual for the artist to do his own printing, though he may supervise it. See Griffiths (1996, p. 102).

<sup>32</sup> Salesrooms consider states to be an important characteristic and document these in their sales catalogs.

Table 1  
Prices of prints by Rembrandt (second and further posthumous state = 100)

The print sold is a	Only one state by R. exists	Two states by R. exist	Three states by R. exist
First state by R., possibly followed by original states only	319	327	n
First state by R., followed by late prints	321	632*	n
First state by R., followed by posthumous states	319	537	799*
Second state by R., possibly followed by original states only	–	336	209*
Second state by R., followed by late prints	–	344	626*
Second state, followed by posthumous states	–	284	422
Third state by R., possibly followed by original states only	–	–	351
Third state by R., followed by late prints	–	–	219
Third state by R., followed by posthumous states	–	–	268
Late print, possibly followed by late prints only	180*	n	n
Late prints, followed by posthumous states	80	146	150
Posthumous state no. 1 (only one state exists)	141	160	167
Posthumous state (other than first)	100	100	100
No. of observations	1673	1633	818

Notes: “n” means that there were not enough observations to include a dummy in the regression; \* means that the regression coefficient is based on less than 30 observations. Results on the many other control variables are not reported. They are detailed in Lazzaro (2006).

original, late, posthumous). Since the results in which she included all the 4700 observations were difficult to interpret, she runs three different regressions, according to how many states of each specific work Rembrandt produced during his lifetime.

Her results, summarized in Table 1, show that original prints by Rembrandt are only two to three times more expensive than late prints by other printers. Thus a late print from an untouched plate does quite well, though it can be considered a copy. But what is more surprising is that prints obtained from plates that have been reworked after Rembrandt’s death fetch prices that are similar to those of late prints. It therefore seems that copies are still considered worthy, maybe because Rembrandt’s hand is “present”

in each print, making the distinction between originals and “copies” rather fuzzy. This is not the case for copies of paintings: the hand of the master is not present.<sup>33</sup>

It is also worth pointing out that prices of a state by Rembrandt do not seem to be influenced very much by the events that followed. Consider, for instance, the case where only one state by Rembrandt exists, and the following three possibilities: only original states exist, late prints followed original ones (the plate was not reworked), late prints and posthumous states printed from the reworked plate followed. One could assume that if late, and even worse, if posthumous prints exist, the price of original prints would be affected. By and large, this does not seem to be the case, and results from effects that, according to Lazzaro, go in opposite directions. Late and posthumous prints suggest a good and thus much demanded work, with the consequence of increasing the price of originals. But they may also depress the price, since they affect rarity, and make the sorting between originals and late or posthumous prints more difficult.

## 5. Markets for paintings

The case of paintings is quite different. The separation between copies and originals is clearer, though incomplete. De Marchi and Van Miegroet (1996) analyze the market for originals and copies in the Netherlands during the seventeenth century. Their research is based on a few cases for which they could compare the value of a specific original with the value of the copy, often made by the painter who produced the original. They found that originals are roughly three times more expensive than copies even if produced by the same painter, as was often the case in the past. They attribute this difference to the innovative character of the original, which is no longer present in the copy. It is very difficult to gather good data on transactions of copies, and we know of no other case than the one by De Marchi and Van Miegroet who were able to collect prices of paired works.

We collected data from auctions (often the only part of the market for which observations are available) organized during four periods separated from each other by some hundred years: 1684–1725 [mainly Amsterdam, Hoet (1752)], 1801–1810 [France, Peronnet and Fredericksen (1998)], 1890–1900 [Europe, but mainly France, Mireur (1901–1912)] and 1976–1999 (World, *The Art Sales Index*).<sup>34</sup> The data at hand do not make it possible to compare the prices of originals with those of copies made after these originals. But the number of observations is hopefully large enough to make comparisons of average prices between originals and copies meaningful.

<sup>33</sup> While art galleries and salesrooms do sell late prints by Rembrandt, they are more careful with photographs and avoid selling non-vintages photographs, though the “hand of the artist” may be considered to be as much (or little) present as for late prints. Another circumstance may have played a role also. The market for photographs started in the early 1980s, while art markets for paintings and sculpture were getting highly speculative. It may thus have been necessary to build trust for a newly developing medium, and impose the notion of “vintage photographs”.

<sup>34</sup> See Appendix A for a short description of the data.

Unfortunately, salesrooms are quite evasive in describing such works. Authors of the copies are usually not known, and only rarely are they by a “master”. The date at which the copy was made is very seldom given, which is of course unfortunate since a copy of Rubens made in 1650 even by an unknown artist, is worth more than a copy made in 1850. Even nowadays, copies sell at auction, but salesrooms, at least Christie’s and Sotheby’s, draw a distinction between those produced before and after 1800. The former are usually offered at regular Old Master sales and are therefore almost considered Old Masters. Later copies are also auctioned by international salesrooms, but during non-specialized sales of *varia*.<sup>35</sup> Contemporary copies of Old Masters are usually not sold at auction but by specialized galleries. There is thus a distinction to be drawn, not only between old and more recent copies after Old Masters, but also between copies after Old Masters and copies after artists who were active later.

Table 2 reports on our findings for the four periods. It provides the number of copies,<sup>36</sup> and the average relative price of copies.<sup>37</sup> Number of copies and relative prices are disaggregated by “type” of copy, period and country in which the painter after whom the copy was made was active.<sup>38</sup> Even if it is far from obvious that the data are homogeneous over time, we can draw some conclusions. Copies were reasonably well-priced (a copy was worth 30 to 50 percent of an original) until 1900, but there is a very sharp drop sometime afterwards, since the best copies (that is, those that are worthy enough to be sold at auction) are worth 35 times less than originals in the late 20th century.

Neil De Marchi (2004) suggests that this relative price effect for Old Masters may be the outcome of two factors. Due to their short supply (compounded by the increasing wealth of buyers) Old Masters paintings may have undergone an absolute increase of prices. Simultaneously, the technical possibilities that made detection of copies much easier may have prevented collectors to sell works that they had acquired as originals in the past, so that only the ones that were known to be copies would reach the market (an Akerlof effect) and depress prices of copies. From there follows an obvious decrease of the relative prices of copies with respect to originals.

<sup>35</sup> Christie’s considers that “the irruption of photography and graphical reproduction techniques in the beginning of World War II, has made all of this obsolete. For these reasons, we do not include copies made after 1940 in our sales”. See Christie’s press release for its 29 September 1998 Amsterdam sale. According to Ms. Aarts from Christie’s Amsterdam, this decision is also made to avoid selling copies that could have been considered as fakes at a certain moment, without the salesroom being aware of it.

<sup>36</sup> Replicas that salesrooms as well as art historians consider as originals, are not included.

<sup>37</sup> The relative price of a copy is the ratio between its hammer price and the median price of originals by the painter who is copied. The median price was chosen since in some cases, the number of originals was small. The median also excludes extreme prices which can just be due to mistakes.

<sup>38</sup> For the first three periods, the search was made on copies, and not on painters. Given the nature of the most recent database (Art Sales Index), the search was made on painters for whom it was known that many copies existed (Boucher, Hals, Raphael, Rembrandt, Rubens, Van Dyck and Watteau). For these data, it was impossible to separate copies according to whether they were “attributions”, “school of”, “copies” and “other”.

essentially interested in the coefficients picked by the “type of copy” dummies, and expect that attributions (normalized to zero) will fetch the largest relative price, and will be followed by “school of”, “copy” and finally, “other”. As expected, attributions fetch higher relative prices than other types of copies in each time period, but significantly so only between 1801 and 1810. Prices for attributions are relatively close to those of originals, since often, a mere missing signature raises doubt. The drop in the relative price for copies after Italian, Dutch and Flemish masters may be due to a change in tastes, but more careful research may be needed to confirm this conclusion.<sup>39</sup>

<sup>39</sup> It would be interesting to check whether relative prices changed significantly over the three first periods. This could be tested by running a regression in which the three sets of data are pooled, dummies for periods are introduced, and a test is run which checks whether the coefficients picked by these period dummies are significantly different or not. Unfortunately, there are two difficulties here. First, definitions of types of copies

Table 4  
Christie's Amsterdam specialized sales of copies

	1994	1995	1996	1997	1998
Total number of works	50	52	51	71	73
Number of works unsold	8	9	11	1	11
Number of works sold at a price above the upper limit of the pre-sale estimate	15	17	15	47	23

Notes: in the 1994, 1995 and 1996 sales, paintings were followed by other works; in 1997 and 1998, the sale consisted of paintings only.

Since 1994, Christie's organizes special sales of copies in Amsterdam,<sup>40</sup> at which copies after Old Master pictures are auctioned. The first three sales consisted of some fifty paintings and drawings, followed by a mixed bag of various objects (glass, ceramics, silver, jewelry, furniture and other works of art) obviously designed to fill the session. These sales were organized on Saturdays to attract "young" buyers who were interested in art but unable to afford originals. Christie's then changed the concept, and since 1997 the sales consist of paintings only and are held during the week, like most other sales. This change suggests that both supply and demand increased and that markets have become more active. To check for the validity of this assumption, we looked at some characteristics of the sales, such as the number of unsold works, the number of works sold at more than the upper limit of the pre-sale estimate range, and prices.<sup>41</sup> Those data may be considered as an indication of tensions on the market. Table 4 summarizes our findings, and shows that there is an upward trend.<sup>42</sup>

Most interesting is that, according to Christie's Amsterdam specialists, these sales are the firm's (that is, the Amsterdam subsidiary) most internationally attended auctions. For example, the ten most expensive items sold at the 1998 auction went to American, Italian, Belgian, German, and Dutch traders and to German, Taiwanese, Dutch, and Irish collectors.<sup>43</sup> Of course, Christie's holds only one such specialized sale per year,

may have changed over time and second, later periods may include old copies and more recent copies, that fetch different prices. Since copies are only rarely dated, or attributed to specific artists (and salesrooms do not find it worth to spend time on finding the date), we could not introduce production dates among the explanatory variables.

<sup>40</sup> It is not clear whether the sale is organized in Amsterdam to keep London and New York "clean", or whether this is due to many copies being after Dutch and Flemish artists. Note that such copies are also sold in Christie's South Kensington rooms, but together with sales of other objects.

<sup>41</sup> Increasing average prices do not necessarily indicate that prices increase, since the increase could simply be due to larger dimensions, or better quality. This is implicitly taken into account in the pre-sale estimates by the salesroom. Therefore, works that are sold at more than the pre-sale estimate are, we think, a better indicator of increasing demand.

<sup>42</sup> Moulin (1992) reports on a large increase of the demand for copies by the new Canadian bourgeoisie.

<sup>43</sup> According to the after-sale press release.

but as was already mentioned, every Old Master sale, whether in London, New York, or Amsterdam (by both Christie's and Sotheby's), contains works that are "attributed to", from the "circle of", in the "manner of", "after", "with signature", "with seal", or by a "follower of".<sup>44</sup>

Contemporary copies, including after Old Masters, are produced and traded by specialized galleries. Donors often have copies made of the works they offer to museums. Bikauer, an American collector, offered a very large canvas by Delaroche (a French painter [1797–1856]) to the Louvre and ordered a copy of the painting to keep as a "souvenir" of the original one. The owners of the château de Vaux-le-Vicomte near Paris had copies made of most of the paintings that were once hanging in the castle but were sold, lost, or stolen. Guardis and Canaletto were also copied and sold by the Parisian Galerie Delamarre to complement incomplete collections elsewhere.

All these signs bear testimony to the constitution and vitality of a market for copies, though as we shall see in the next section, lawyers make their status ambiguous. The law is, as it should be, opposed to fakes, but is unclear about copies. Legal decisions are often inconsistent and scare away buyers and sellers.<sup>45</sup> Curators and art historians are taking timid steps to recognize the value of copies. Although they still do not admit that copies can be included in the collection of a museum, they organize exhibitions devoted to copies or in which both originals and copies are displayed. Of course, the accent is still put on originals. In this respect, the case of the *Madonna of the Pinks* is remarkable. Until its attribution to Raphael in 1991, the painting was worth a very small amount, possibly as little as £8000.<sup>46</sup> It was paid £22 million by the National Gallery in 2004.

## 6. Copies and art historians. A renewal of interest?

The attitude of art historians towards copies has also undergone changes. Contemporary art historians consider copies as one of the means to study tastes and norms over time.

<sup>44</sup> This is extracted from Christie's sale catalogs, which describe the various cautious denominations as follows. "Attributed to" means "In our opinion probably a work by the artist or maker in whole or part". "Circle of" means "In our opinion a work of the period of the artist or maker and showing his influence". "Manner of" means "In our opinion a work executed in the style of the artist or maker but of a later date". "After" means "In our opinion a copy of any date of a work of the artist or maker". "With signature/seal" means "Has signature/seal which in our opinion is not that of the artist". Finally, "follower of" means "In our opinion a work executed in the artist's style but not necessarily by one of his pupils". Very similar words and descriptions appear in Sotheby's sale catalogs. Note that in 1882 already, Burckhardt had suggested such distinctions, based on the works by Rubens and his workshop. See Burckhardt (1882).

<sup>45</sup> Justice Laddie (1996), one of the best known British experts on copyright law holds the view that "these detailed and pedantic exceptions to copyright protection are not only difficult to understand in some cases, but they also reinforce the perception that virtually all reproductions of copyright works, no matter how innocuous, are infringements".

<sup>46</sup> See *The Art Newspaper*, September 2003, p. 9.

In particular, they suggest that in the past copies may have been used as “textbooks”, especially in Northern Europe [Martens (2004)]. Lobstein (2002) studies paintings that were copied in France at the end of the 19th century, and uses the information to understand how collections were constructed.<sup>47</sup> The large number of copies after Goya in Aquitaine in the middle of the 19th century is closely linked to the influence of Spanish culture in this southern region of France. This was also a time at which the French State ordered copies of Spanish masters (Murillo, Ribera, Velasquez and others). Fashion changed after 1870 as shown by copies after Italian painters who have crowded out Spanish artists.

Contemporary art historians are also less fascinated by the romantic idea that has given so much importance to the concept of originality, and take into account the legacy left by Marcel Duchamp or Andy Warhol, that originality is nonsense. Warhol tried to turn things around with his prints of the Mona Lisa, claiming that it is the multiplicity of reproductions that made a star out of her. After all, everybody “knows” a well-known movie star, though very few know her personally. She only exists through the attention given to her in the media. Therefore, and contrary to the predictions made by Benjamin (1971), copies and reproductions do not destroy the aura of the original, but contribute to its value [Hughes and Ranfft (1997) and Seguy Duclot (1998)]. This is probably what Warhol meant with his silkscreen *Thirty Are Better Than One*. Copies and reproductions are the best testimony to the value of originals [Belting (1998)], and a work that does not inspire copies is a dead work [Pastoureau (1991)].

Art philosophers are often even more positive and consider that the borderline between copies and originals should be revised. Caillois' (1975) praise of the creative nature of copies is becoming more and more influential. Goodman (1983, p. 100) prefers a good copy of Lastman by Rembrandt to the original Lastman.<sup>48</sup> Meiland (1983, pp. 122–123) claims that “if what a great work of art does is to present us with a new vision of the world, then an exact copy can perform exactly the same function”. Originality, he writes, should not be praised *per se*, but matters only if the work is good. He goes as far as writing that “though there are many situations in which an original has or would have greater total aesthetic value than an exact copy . . . there may also be situations in which an exact copy has at least as much aesthetic value – primary and derivative – as the original. And this should not be surprising since an exact copy expresses exactly the same work of art as the original” [Meiland (1983, p. 130)]. Therefore, it does not matter whether the original of a self-portrait by Rembrandt hangs in The Hague, as was thought until recently, or in Nuremberg, as was discovered a few years ago.<sup>49</sup> Nor does it if the Louvre *Madona of the Rocks* was painted by Leonardo before or after the one that hangs in the National Gallery.

Curators who devote more and more exhibition space to copies also share this view. The Paris *Musée des Copies* opened in 1872 failed, but a “museum” of copies recently

<sup>47</sup> He especially stresses the role of the Galerie espagnole in the Musée du Louvre.

<sup>48</sup> See also Foucart (1973) who discusses copies that Jordaens made after paintings by Rubens.

<sup>49</sup> See *Le Monde*, 10 December 1998.

opened in Naruto, Japan. Its more than one thousand exhibits consist of copies of some of the most celebrated European works of art, including life-size reproductions of the Sistine Chapel, Giotto's frescoes in Padova, and Pompeian villas. The copies were produced with authorizations from important museums, including the Metropolitan, the Louvre, and the National Gallery. Whether the final products are copies or reproductions is unclear. The technology used is kept secret. It starts from slides copied onto enameled panels,<sup>50</sup> during the last stage, some depth and relief are added, which according to the curator adds to the impression that it is the "real thing".<sup>51</sup> Lascaux consists of "five hundred tons of modeled concrete reproducing every little bump and hollow of the original, with a precision of a few centimeters . . . [and including] the patina of time".<sup>52</sup> And visitors come in droves to see the copy, since the original is reserved for a happy few. Schwartz (1996, p. 249) notes that the Diaspora Museum in Tel Aviv (Beth Hatfoutsoth) which illustrates Jewish life across centuries "is all copies and makes no bones about it".

The Georges de La Tour exhibition in Paris in 1997–1998 displayed many copies, because originals are lost. One of the rooms was devoted to eight copies of de La Tour's *Saint Sebastien soigné par Irène*, of which no original is available. The Millet–Van Gogh exhibition in Paris in 1998, made clear that "copies" of Millet by Van Gogh may even become more valuable and expensive than originals.<sup>53</sup>

Borges (1944) provides a beautiful illustration of this paradoxical situation. In his short story *Pierre Menard*, he "describes two fragments of works, one of which is part

<sup>50</sup> Perhaps the technology is not that new after all. Stendhal in his *Voyage en France*, published in 1837, writes: "J'ai vu chez M. Bonnard plusieurs magnifiques tableaux en porcelaine de M. Constantin. Dans deux siècles, on ne connaîtra plus les fresques de Raphaël que par les tableaux de M. Constantin". Constantin's short-lived success was due to his talent as a copyist. He even required that the copies be lit so as to reproduce the conditions in which the original is exhibited.

<sup>51</sup> See its flier *What Is the Otsuka Museum?* Naruto: Otsuka Museum of Arts, 1998.

<sup>52</sup> Delluc and Delluc (1984), quoted by Schwartz (1996, p. 249).

<sup>53</sup> In recent years, such exhibitions were organized in Dresden in 1970 (Exhibition Catalog by W. Schmidt et al., *Dialogue-Kopie, Variation und Metamorphose alter Kunst in Graphik und Zeichnung vom 15. Jahrhundert bis zur Gegenwart*, Dresden: Kupferstichkabinett, 1970), in Münster in 1976 (Exhibition Catalog by G. Langemeyer and R. Schleier, *Bilder nach Bildern, Druckgraphie und die Vermittlung von Kunst*, Münster: Westfälisches Landesmuseum für Kunst und Kulturgeschichte, 1976), at Sotheby's London in 1977 (Exhibition Catalog by B. Nicolson, *Art into Art, Works of Art as a Source of Inspiration*, London: Sotheby's), in Vienna in 1980 (Exhibition Catalog by H. Hutter, *Kopie-Replik-Paraphrase*, Vienna: Academie der Bildende Kunst, 1980), in New York in 1988 (Exhibition Catalog by E. Haverkamp Begemann, *Creative Copies, Interpretative Drawings from Michelangelo to Picasso*, New York: The Drawing Center, 1988), at the National Library in Paris in 1991 (Exhibition Catalog by M. Pastoreau, *Vrai ou faux? Copier, imiter falsifier*, Paris: Bibliothèque Nationale, 1991), at the Louvre in 1993 (Exhibition Catalog *Copier et créer. De Turner à Picasso: 300 oeuvres inspirées par les maîtres du Louvre*, Paris: Musée du Louvre, 1993), in Delft in 1995 (Exhibition Catalog *Schone Kopieën, gerestaureerde Kopieën naar Oude Meesters door Paul Tetar van Elven*, Delft: Museum van Elven), in Geneva in 1997 (Exhibition Catalog *L'art d'imiter. Falsifications, manipulations, pastiches. Images de la Renaissance italienne*, Genève: Musée d'Art et d'Histoire de Genève, 1997), in Paris in 2000 (Exhibition Catalog *Monter/Sampler*, Paris: RMN, 1990) and in Paris in 2002 (Exhibition Catalog *Manet-Velazquez, la manière espagnole au 19ème siècle*, Paris: RMN, 2002).

of *Don Quixote* by Cervantes, and the other, like it in every graphic respect – like it, indeed, as much as two copies of the fragment by Cervantes could be – which happens to be by Pierre Menard<sup>54</sup> and not by Cervantes”. Nevertheless, “Borges tells us that the *Quixote* by Menard is infinitely more subtle than that of Cervantes, while that of Cervantes is immeasurably more coarse than its counterpart even though every word contained in the Menard version can be found in Cervantes”.<sup>55</sup> To make things even more difficult, Danto adds that “it is a fact that the two works identified by Borges, that of Cervantes and that of Menard, would generate classes of indiscernible copies, the one class copies of the work of Cervantes, the other copies of that of Menard: but these would be copies of different, even importantly different, works, though nothing would be easier than to mistake a copy of Cervantes for a copy of Menard”.

## 7. Regulating the market for copies

Copies are often considered “the first degree of fakes” [Chamoux et al. (1973)]. One of the main reasons for their low status is their possible illegal use. A well-known case illustrates this assumption. Nelson Rockefeller decided to have copies made of 118 works from his private collection and of works he had donated to museums. Copies of Rodin were stamped on their base with a copyright symbol, a copy number, and a date. In 1980, a gallery offered one as an authentic work: the stamps had been covered with shoe polish!<sup>56</sup> Accordingly, as Merryman and Elsen (1987, p. 61) point out, “exact reproductions of works of art, like exact reproductions of money, postage stamps, or other objects whose value inheres in their authenticity, easily lend themselves to misuse by the unscrupulous, who may misrepresent them as originals rather than as reproductions . . . Exact reproductions of works of art devalue original works by creating confusion between originals and reproductions. The more exact the reproduction, the greater the potential confusion and the consequent devaluing effect”.

Regulations by museums and intellectual property laws organize and limit the production of copies. The question is whether this helps clarifying their status or whether, on the contrary, regulatory and legal restrictions increase the degree of uncertainty.<sup>57</sup>

### 7.1. An unstable regulatory framework in museums. The case of the Louvre

The Louvre began to organize (and limit) copying at a very early stage. When the museum was created in November 1793 (as the Musée National des Arts), its 538 paintings

<sup>54</sup> Pierre Menard is supposed to have written his *Quixote* in 1899, while Cervantes’ *Quixote* was written in the 16th century.

<sup>55</sup> Danto (1981, pp. 33–36).

<sup>56</sup> See Merryman and Elsen (1987).

<sup>57</sup> See also Chapter 7 by Landes and Levine in this volume, especially the sections on copyright and trademark issues, and on authenticity and the law.

were accessible to artists during five, then seven days out of ten (the “revolutionary decade”). The general public came to the museum to order copies [Schaer (1993)], and copying was free. A first restriction was imposed in 1797: Copyists had to register and a master or a school had to provide a certificate.<sup>58</sup> The only constraint was that the works could not be moved while copying was going on. The 1824 regulation did not change much, with the exception of the days reserved for artists (Tuesday to Friday) and some rules concerning silence and health issues. Important sales of copies were organized during this period: in 1809, for example, Le Brun organized the sale of the Van Hoorn collection, an important Dutch collector of copies.

The 1848 regulation was still favorable to copyists, who could work every day. The crowd of artists executing copies to order became so large that the Louvre was forced to adopt the rule that only one copyist was allowed to copy a specific painting. In 1865 a new concern appeared in the “Règlement des musées impériaux”, concerning copyists who used to work in the Musée du Luxembourg, dedicated to contemporary art. They had to apply for an authorization from the Sénateur Surintendant des Beaux-Arts (and not from the artist of the original painting). An important sale of copies painted by Colin, a well-known copyist at the time, was organized in Paris in 1860. It contained copies of paintings by 71 artists.

Additional restrictions were imposed in 1872, 1875, 1893, 1903, and 1907, but with no important consequences. In 1908, the concern for living artists became stronger: Copyists of works “whose rights to be reproduced [were] ‘reserved’ could do so but not sell their work without being authorized”.<sup>59</sup> In 1913 a rule stipulated that there could be no more than one copyist in some of the rooms (especially the Dutch Cabinets). In 1927 and 1932, new restrictions appeared that could be interpreted as the first attempt to limit the number and even the value of copies: A copyist was not allowed to work during more than two months on the same painting; copyists could not negotiate the sale of their work in the museum; copies had to be stamped before the copyist could move them from the museum.<sup>60</sup> In 1946, the Règlement des musées nationaux added that copies could not be of the same size as originals, whatever the date of the original.<sup>61</sup> Copying in museums became therefore a totally regulated activity.

Several European museums followed with similar rules. Between 1852 and 1856, the Rijksmuseum in Amsterdam allowed copying sessions from Monday to Wednesday only.<sup>62</sup>

In the beginning of the 20th century, all the elements that draw a clear distinction between originals and copies and suggest a definitive hierarchy were there. This slow

<sup>58</sup> See *Rapport du Conservatoire du Musée national des Arts au Comité d'instruction publique*, Paris: Musée du Louvre, 1797.

<sup>59</sup> Article 8 concerning the Musée du Luxembourg.

<sup>60</sup> See *Règlement des conditions de travail des copistes et photographes dans les salles et galeries des musées nationaux*, Paris: Archives du Musée du Louvre, 1932.

<sup>61</sup> This is still so nowadays.

<sup>62</sup> See the Introduction to the *Christie's Amsterdam sale Catalog of copies*, 4 October 1994.

but inevitable construction of rules went together with the development of a speculative modern art market, and an increasingly elaborated legislative framework to protect artists' intellectual property rights. However, the distinction between copies and originals is not always as clear as it should be.

## 7.2. The legal definition of originality

A few years ago Christie's sold a painting by Egon Schiele that the buyer later found to be heavily restored. A judgment directed the auction house to reimburse the buyer because, with 90 percent of the work repainted, it could no longer be considered by Schiele. The judgment did not discuss the fact that the original painting was by Schiele, nor did it discuss at what point the restoration rendered the work not by Schiele. One can wonder whether the court's judgment would have been different if only 80 percent had been repainted. Meanwhile, a completely repainted Barnett Newman *Who Is Afraid of Red, Yellow and Blue?* which was badly damaged by a vandal, hangs in the Stedelijk Museum in Amsterdam as if nothing had ever happened. The painting is hardly an original by the artist, but is displayed as if it were an original.<sup>63</sup>

According to Mund (1983, p. 128), copies may be exact (similar to the original, but produced at a later date) or interpretative (freely transforming the original work, and adopting the style of the copyist). This twofold definition is consistent with the legislation that defines counterfeiting as a non-authorized borrowing of part or the entire original work. In *Steinberg vs. Columbia Pictures Industries, Inc.* (663 F. Supp.706, S.D.N.Y. 1987), Saul Steinberg, the well-known *New Yorker* cartoonist, sued the producers, promoters, distributors and advertisers of the movie *Moscow on the Hudson*. He alleged that the promotional poster for *Moscow* infringed his copyright on an illustration that he had produced for *The New Yorker*. The court recognized that the original and the copy were "substantially similar", though not all the details were identical. As Stanton (2002) notes, it is now admitted that "the copying need not be of every detail so long as the copy is substantially similar to the copyrighted work". Substantial similarity does not require identity, and "duplication or near identity is not necessary to establish infringement".<sup>64</sup> As Judge Learned Hand wrote for the *Krofft* case, "no plagiarist can excuse the wrong by showing how much of his work he did not pirate".

Originality is the central notion that separates originals from copies, but defining what is lost or gained in duplicating is not easy.<sup>65</sup> Legal texts on the issue are elusive:

<sup>63</sup> Some years ago, one of us walked into the room where it is exhibited, and asked the warden whether he knew when the painting came back to Amsterdam after its restoration in the United States. The answer was that it had never left the room where it hangs.

<sup>64</sup> Stanton (2002) also cites other such cases: *Comptone Co. v. Rayex Corp.*, 251 F.2d 487, 488 (2d Cir. 1958); *Krofft*, 562 F.2d at 1167; *Sheldon v. Metro-Goldwyn Pictures Corp.*, 81 F.2d 49, 56 (2d Cir.); *cert. denied*, 298 U.S. 669, 80 L. Ed. 1392, 56 S. Ct. 835 (1936).

<sup>65</sup> For Arnheim (1983, p. 237), "it is not sensible to accept only original works as art and dismiss all reproductions as nonart".

“All that is needed [...] is that the ‘author’ contributed something more than a ‘merely trivial’ variation, something recognizably ‘his own’”.<sup>66</sup>

In the case of multiples, the notion of originality is bound to remain confused. Artists such as Whistler, Degas, or Picasso signed their prints as evidence of their authenticity. Merryman and Elsen (1987, p. 526) distinguish between

- (a) prints by well-known artists that are merely reproductions of original works, even though they may be well printed on fine paper in limited editions and signed by artists; and
- (b) lithographs, etchings, woodcuts, or other print media that are a primary form of art-making as is the case with Jasper Johns.

Originality and uniqueness are often associated with scarcity,<sup>67</sup> obtained by limiting the number of copies.<sup>68</sup> In the case of Rodin’s work, for example, a decree sets the number of authorized *post-mortem* originals [Gautier (1991)]. By analogy, uniqueness is, still today, a central argument.

Legal precedents reveal large variations in the definition of copy. First, the law permits copying of manner, technique, and style. Desbois (1978) observes that one “can oppose to counterfeiting a slavish copy or adaptation, but the imitation of genre, or artist’s manner, cannot be prosecuted”.<sup>69</sup>

Second, originality is frequently associated with quality. In the case of a painting by Braque, reproduced as a print, a Paris court detected the “skill and sensitivity of the engraver” and authorized copying without compensating the heirs of the artist (December 19, 1992). In the American *Hand of God* case, in which an artist had produced a scale reduction of a sculpture by Rodin (entitled *Hand of God*), a district court found that the originality was due to the fact that “it takes an extremely skilled sculptor many hours working directly in front of the original” to make an exact copy.<sup>70</sup> This case resembles the one brought by the buyer of a Dürer against an art dealer during the 1650s, when the buyer realized that the Dürer was a copy by Luca Giordano, who had hidden his own signature on the back of the wooden panel. The quality of the copy was so good that Giordano won the case.<sup>71</sup>

Third, a copy may include the signature of the original artist. In 1992, legal action was brought against the Parisian Galerie Delamarre for reproducing and selling copies

<sup>66</sup> Merryman and Elsen (1987, pp. 183–184).

<sup>67</sup> Melot (1994) devotes a whole chapter to the different techniques used to create scarcity, such as numbering of the prints, adding colors, or the autograph signature.

<sup>68</sup> Degas usually controlled the production of prints, making each of them unique. He refused to produce industrial reproductions, though he had a real passion for engravings, prints, and so on. Melot (1994) explains how Degas or Pissarro tried to make each print unique: “The very definition of a work of art can only be in opposition with a series. Quality is incompatible with quantity”.

<sup>69</sup> See also Colombet (1997).

<sup>70</sup> *Alva Studios, Inc. vs. Winninger*, quoted in Merryman and Elsen (1987, p. 184).

<sup>71</sup> This is also reminiscent of the story told by Koestler (1989, p. 402) of the competition held to choose among a dozen guests imitating Charlie Chaplin, to decide who came the closest to the original: “Chaplin himself happened to be among them – and got only the third prize”.

of masterpieces that included the painter's signature. Whereas the initial judges found the gallery guilty of infringement on the grounds that the right to copy does not include the right to copy the author's signature, the French High Court rejected the judgment (June 11, 1997, confirmed by the Paris Court of Appeals, October 13, 1999). The court argued that "reproducing, on a copy of a work in the public domain, the signature of the author does not infringe upon the author's moral rights when there is no risk of confusion between the original and the copy".<sup>72</sup> The court added that there was no risk of confusion since the dimensions of the painting were different and the word "copy" was marked indelibly on the back and the edges of the canvas.

Fourth, the definition of originality varies according to which judicial authority or administration is in charge of the evaluation. Post-mortem works produced by the Musée Rodin are considered originals by the French fiscal administration but as non-originals by intellectual property laws, and are, therefore not liable to resale rights.<sup>73</sup>

### 7.3. Public and non-public domain

A work enters the public domain seventy years after the death of its author and becomes freely available for copying, advertising, and publishing.<sup>74</sup> Copiers of a work that belongs to the public domain are not subject to copyright. Other works occupy a legal gray area: neither the American nor the French law clearly defines the terms "copy" and "reproduction". A copy is assimilated to a photograph; the signature is an element of the painting, and changing the size is a way of escaping counterfeiting laws.

There is no definition of a "work of art" in the law, either. For inheritance taxes on works of art, the French administration bases the levy on the opinion of an ad hoc committee of experts.<sup>75</sup> Until 1994, the French definition of "original print" included the terms "executed by the artist" and excluded mechanical procedures; under such a definition, Rauschenberg's or Ernst's best engravings would not be originals [Melot (1973)]. The American Print Council excludes post-mortem editions (but the date of the edition is sometimes rather difficult to discover) and defines three conditions for a print to be original:

<sup>72</sup> *Le Journal des Arts*, 95, December 18, 1999, p. 44.

<sup>73</sup> *Le Journal des Arts*, 5, July 1994.

<sup>74</sup> Note that not even this view is universally accepted, as is illustrated by the conflict between the Bridgeman Art Library (which grants licenses to reproduce works of art belonging to European and American museums) and the Canadian firm Corel (publisher of Professional Photos CD-Rom Masters, containing reproductions made without the consent of Bridgeman). The lawyer of Corel holds the opinion that "Bridgeman's ektachromes are not originals and are therefore, not submitted to copyright" to which the lawyer of Bridgeman reacts by claiming that "the skills of the photographer who creates a large ektachrome and digitalizes it possess all the characteristics of a creation on a new support". See *Le Journal des Arts* 68, 9 October 1998. The case was judged in a New York court. The federal judge accepted Corel's arguments and ruled that the photographs were "slavish copies" that required both skill and effort but were not original enough to benefit from copyright protection (*Bridgeman Art Library, LTD. v. Corel Corporation*, 36F. Supp. 2d191, S.D.N.Y. 1999).

<sup>75</sup> Bourdon, Pontier and Ricci (1996).

- (a) the artist alone has created the master image in or upon the plate, stone, wood-block or other material, for the purpose of making the print,
- (b) the print is made from the announced material by the artist or according to his directions, and
- (c) the finished print is approved by the artist.<sup>76</sup>

In the European Union, a law passed in 1994 defines works of art to which a lower rate of value-added tax is applicable. Under this law, for a photograph to be a work of art, it must be made by the artist, printed by him or under his supervision, signed and numbered with a limit of thirty prints, regardless of dimension or medium. More generally, European regulations define the two characteristics that define a work of art: It has to be unique (or exist in a limited number of copies) and it has to be produced by the artist himself or under his strict supervision [Melot (1995)].

#### 7.4. Copies as copyrightable goods?

Copies are both subproducts and works by themselves. A copy remains a “second best”, an imperfect substitute for the original, but may also be considered a work of art, as are the copies of Old Masters auctioned by Christie’s or Sotheby’s. That is why the law protects copies<sup>77</sup> and recognizes their status as works of art. A copy may itself be copyrightable if it contains “an original contribution not present in the underlying work” [Merryman and Elsen (1987, p. 184)]. The law states that originality – the very foundation of the notion of a work of art – results only from the execution. Legally, a copy is thus an original work of art, because the personality of the copying artist leaves traces, even if the copy is close to the original. This can be considered the “legal transposition” of a remark by Theo Van Gogh to his brother Vincent, who, while at the St. Remy hospital in 1890, made copies of paintings by Millet: “Your copies of Millet are perhaps the best you have ever produced” (letter 848/733), and “copies as you do them are not copies anymore” (letter 840/T23).<sup>78</sup> One of the legal consequences is that the material execution itself justifies copyright royalties for copyists. There is no difference between copying nature – landscapes, still lifes or portraits without specific additions – and copying preexisting works of art.

Therefore, for the lawyer, the personality of the creator is the main criterion for the justification of copyright royalties. The following case illustrates this position. Some time ago, the owner of a castle in France ordered sculptures for the façade of his castle. When the chateau was opened to the public, the artist asked to be protected by a copyright. The Court of Appeals refused to compensate the sculptor, considering that “the sculptures resulted from a mere repetition and accumulation of decorative designs” and because “the quality of the execution was weak and lacking any global vision”

<sup>76</sup> See *What Is an Original Print?* London: Lumley-Cazalet, 1967, quoted by Melot (1973).

<sup>77</sup> One of the consequences is the difficulty for an artist to copy freely and resell his own work, once the “original” has been sold. This is what the law defines as self-plagiarizing.

<sup>78</sup> Van Gogh also produced copies after Rembrandt, Delacroix, and Gauguin. See Van Tilborgh (1998).

[Colombet (1997)]. The French High Court (Cour de Cassation) reviewed this judgment (November 9, 1993) and determined that the traces of the hand of the copyist were sufficient for the sculptures to be works of art. In this case the copies are seen as originals, and are entitled to royalties. These cases show that judges are supposed to assess the “originality of a copy”, but judgments are not always consistent, and do hardly provide a stable economic foundation to a copyright for copies.

Nevertheless, if originality is assimilated to invention – as opposed to imitation, which characterizes copies [Holtzmann (1996)] – then originality becomes a risky business and should be rewarded by a copyright in the same way as a patent rewards invention. As Meyer (1983) points out, “the great artist has dared to risk failure in order to reveal a new aspect of the universe for us”. This is also what De Marchi and Van Miegroet (1996) found for the 17th century.

## 8. Concluding comments

Copies have always been present, often only marginally but sometimes at the core of the art market in the past. Copies served to convey information to artists and collectors. When this function disappeared, the relative price of copies decreased, copies became aesthetically less valued, but the market did not disappear. Many signs point to their recent revival. Copies are substituted for originals that could be destroyed by bad weather and pollution: 230 sculptures of the façade of the Louvre are replaced by copies. So are the bronze horses atop St. Mark’s in Venice, and the statue of Marcus Aurelius in the Campidoglio in Rome.<sup>79</sup> The Lascaux cave that tourists can visit is a copy. Copies are used to restore originals,<sup>80</sup> and artists keep producing them. There are permanently 84 copyists in the Louvre. Half of them are artists, 25% art students and 25% amateurs. As noted by Muller (1989, p. 147), “copies augment the small and often inaccessible supply of excellent pictures”. Galleries (Troubetskoy in Paris or True Fakes Ltd. in New York) sell freshly-made copies. Museums of copies are being born, and art historians or museum keepers display copies for the purpose of illustrating concepts. There are now specialized auctions at which only copies are sold. The market wants copies, old and new; after Old Masters or Impressionists, after Modern and Contemporary painters.

<sup>79</sup> Sénéchal (1998) discusses the example of the paintings that were hanging in St. Peter’s in Rome and were suffering from humidity. They were replaced by copies on canvas during the 18th century, and later, by mosaic copies.

<sup>80</sup> Copies have contributed in preserving the appearance of lost originals. For example, during a restoration of a painting, a *repentir* by Titian was discovered and authenticated by its copy [Volle (1998)]. Likewise, the restoration of Veronese’s *Pilgrims of Emmaüs* was made possible thanks to the copy that showed that two columns were present in the original painting. There are many cases in which the original is known through copies only. Titian’s *Martyrdom of St. Peter*, lost during the fire that destroyed the San Giovanni e Paolo church in Venice in 1866 is known through a copy by a pupil of Ingres. The practice to replace paintings in churches by copies became frequent during the 18th century.

The market wants exact copies and also interpretative copies. To celebrate the Millennium, Neil Mac Gregor, director of London's National Gallery, chose well-known living painters (Lucian Freud, David Hockney and Jasper Johns, among others) and asked them to produce an interpretative copy of works kept in the museum.

Reviving copies is harmless as long as copies are not sold as originals. Preventing this from happening is made easier since there exist modern techniques for marking artworks as copies. Attention to this issue could prove more fruitful than the current haggling over whether a photograph of the Mona Lisa gives copyright to the Louvre or to the photographer, though the painting belongs to the public domain for centuries. Copying seems to be unavoidable with the rise of digitization that brings about new ways of producing copies, since the virtual is also naturally multiple [Queau (1998)]. Digitization leads to new ways of making copies, authorizing duplication in endless numbers, as well as manipulations and interpretations. This may eventually prove to be very positive by making works much better known and even lead art lovers to order old-fashioned handmade copies.

## Appendix A: Copies and originals sold at auction 1684–1999

This appendix lists painters whose copies (and originals) were sold at different times, and on whom our calculations are based. The first and second numbers that appear after each name refer to number of copies and originals sold during the period.

### A.1. Period 1684–1725

Bambouts (2, 12), Breugel (10, 62), Brouwer (2, 23), Caravaggio (2, 4), Douw (5, 27), Hondokoeter (2, 16), Jordaens (2, 13), Lairese (2, 48), Netscher (2, 20), Ostade (3, 56), Poelenburg (7, 71), Poussin (7, 16), Raphael (9, 4), Reni (3, 11), Rottenhamer (3, 10), Rubens (7, 61), Terburgh (2, 5), Tiziano (6, 23), Van der Werf (2, 13), van Schalke (2, 10), Wouverman (4, 95).

Source: Hoet (1752).

### A.2. Period 1801–1810

Albani (12, 12), Barocci (6, 18), Bassano (7, 9), Berchem (23, 77), Both (7, 32), Bourdon (6, 103), Brouwer (7, 26), Brueghel Jan the Eldest (4, 61), Caracci (31, 3), Caravaggio (9, 25), De Champaigne (12, 48), Corregio (30, 16), Cuyp (11, 64), Domenico (22, 31), Dou (16, 34), Dujardin (13, 38), Dürer (7, 15), Greuze (8, 32), Guercino (13, 40), Laer (6, 18), Le Brun (12, 27), Le Sueur (20, 41), Lingelbach (3, 32), Lorrain, Claude (8, 34), Maratti (9, 45), Metsu (3, 38), Michelangelo (10, 1), Mignard (6, 25), Murillo (11, 46), Ostade (16, 5), Ostade, Isaac (3, 50), Panini (6, 47), Pietro da Cortona (5, 25), Poelenburgh (7, 80), Potter, Paulus (11, 15), Potter, Pieter (1, 3), Poussin (36, 38), Raffaello (79, 8), Rembrandt (27, 65), Reni (43, 45), Ruisdael (4, 14), Rubens

(34, 49), Santerre (4, 19), Solario (5, 8), Subleyras (4, 17), Teniers (50, 210), Terboch (3, 33), Tintoretto (4, 29), Tiziano (20, 34), Valentin de Boulogne (3, 12), Van Dyck (10, 12), Vouet (6, 12), Wouwerman Phillips (9, 70), Wouwerman (14, 7).

**Abstract**

The new technologies of digitalization and the Internet threaten the market positions of artists and intermediaries. Artists because the technology of production of works may be readily accessible and craftsmanship may no longer be a defining characteristic of art. Intermediaries because their rents are linked to entry barriers in the distribution market. This curse of new technologies may be a blessing in disguise since it also increases the possibilities of production, of distribution and the emergence of new works of art. The system of intellectual protection gives market power to artists and the economic literature has analyzed the tradeoff between the dynamic inefficiency generated by this market power and the need to preserve the incentives for creation. We review this literature and some of its recent applications to artistic, and more generally intellectual, creation. Even if artists can capture perfectly the market value of the future home production by consumers, they may favor a strong copyright regime that prevents consumers from using their home production. Intermediaries and artists may want to limit competition in order to increase the rents brought by the indivisibility of creative ideas. The preferences of artists for strong or weaker form (e.g., licensing of rights for home production) of copyright may be related to their creativity.

Beauty, however, in its general aspect, is the inseparable characteristic of the idea when it has become known. In other words, everything is beautiful in which an idea is revealed; for to be beautiful means no more than clearly to express an idea.

Schopenhauer (2004-eBook edition)

In the last analysis, the artist may shout from all the rooftops that he is a genius: he will have to wait for the verdict of the spectator in order that his declarations take a social value and that, finally, posterity includes him in the primers of Artist History.

Marcel Duchamp (1966)

## 1. Introduction

At the time photography was invented, the technology was expensive, difficult to use and required specialized skills and craftsmanship. Because many painters at the time were doing portraits, they saw the danger of the new technology for their activity. The folk history credits the painter Paul Delaroche to have said after seeing the Daguerreotype “from today, painting is dead”.<sup>1</sup> Other artists embraced the opportunity to use the new medium and indeed, a movement developed quickly that defined photography as art. When George Eastman invented the “clic-clac Kodak” in 1868, photography became widely accessible; while there were some issues of craftsmanship, the act of taking a picture became trivial enough that it took effort by photographic artists to preserve their identity. Some have argued that the *pictorial movement* emerged in response to this democratization of the access to the technology. The recent emergence of digital photography has made the marginal cost of taking and viewing pictures rather trivial; despite this democratization of the technology, photography as an art form is still alive, present in large museums and taught in art departments in prestigious universities.

Before the Gutenberg press, the church had a monopoly on the stock of original writings and monks were the main artisans for reproducing these works, often by using techniques and crafts that required years of training. The Gutenberg press rendered this craftsmanship unnecessary for copying or for production of new books.<sup>2</sup>

The emergence of new technologies is therefore both a blessing and a curse for art. The blessing is that more opportunities for artistic creation are available. The curse is that more people have access to it. It is a curse because issues of craftsmanship tend to be less important, and a work of art may now have to be distinguished from its look

<sup>1</sup> Some historians of photography like Robert Leggat (1999) claim that in fact Delaroche was a supporter of photography. He had been commissioned by the French government to present a report on the Daguerreotype where he wrote “Daguerre’s process completely satisfies all the demands of art, carrying essential principles of art to such perfection that it must become a subject of observation and study even to the most accomplished painters.”

<sup>2</sup> See Chapter 8 by Benhamou and Ginsburgh in this volume.

alike by another dimension than craftsmanship. That aesthetics or craftsmanship is not a necessary characteristic of a work of art is well espoused by philosophers and artists.<sup>3</sup> Duchamp's Readymades are an extreme illustration of this since common objects like a urinal, a bicycle wheel or a snow shovel can become works of art. When art is not necessarily linked to aesthetics, the definition of art becomes somewhat of a challenge.

While economists are ill equipped to philosophize on art, they and scientists in general are also in the business of creating ideas, and transmitting these ideas to peers and the public at large. In a modest, or probably immodest way, this activity is sometimes compared to that of artists. As producers, most of us recognize the difficulties to come up with truly original ideas, to write these ideas in a way that will be transparent and convincing to our readers. As consumers we sit through seminars, read working papers or published papers and we hope that these activities will give us some insights into the message that the author wants to convey. Sometimes, we enjoy a speaker's charisma, sometimes we enjoy the writing of a paper, but eventually we are interested in the underlying idea. We train students for many years hoping that one day they will be able to read and understand our papers or that they will themselves be able to contribute to the production of ideas. In the process, we try to make a living and get credit for our contributions to the field.

Scientists are different from artists however, both on the demand side and the supply side for their creations. On the demand side their "natural" markets differ: new working papers are in general consumed by scientists and researchers in the field, but new paintings are bought and appreciated by non-painters. On the supply side, there is an intentionality behind scientific production: scientists try to communicate precise ideas, results and they follow well established methodologies for doing so; there is not necessarily intentionality for artistic creation. As [Duchamp \(1959\)](#) notes

In the creative act, the artist goes from intention to realization through a chain of totally subjective reactions. His struggle toward the realization is a series of efforts, pains, satisfaction, refusals, decisions, which also cannot and must not be fully self-conscious, at least on the esthetic plane.

Hence, while both scientific and artistic communications are imperfect and require interpretation, in art this interpretation is complicated by the heterogeneity of the potential consumers and the sometimes fuzzy knowledge that the artist has about his or her motives for creation. [Danto \(1986\)](#) views this as the main hurdle in defining art:

There are two sorts of mistakes the concept of art gives rise to, one of which is philosophical and the other merely critical. The first is to interpret something which is not in candidacy for art, and the second consists in giving the wrong interpretation of the right sort of thing.

Artists and philosophers refer to a "missing dimension" – the "idea" in Schopenhauer's opening quote – to explain the imperfect communication between the artist and

<sup>3</sup> I refer the reader to [Chapter 5](#) by Roger McCain in this volume and to [Danto \(1986\)](#).

the difficulty for outsiders to interpret artistic creation. Duchamp (1966) has even defined an “art coefficient” to capture the level of imperfection in artistic communication

The result of this struggle is a difference between the intention and its realization, a difference which the artist is not aware of. Consequently, in the chain of reactions accompanying the creative act, a link is missing. This gap, representing the inability of the artist to express fully his intention, this difference between what he intended to realize and did realize, is the personal ‘art coefficient’ contained in the work. In other words, the personal ‘art coefficient’ is like an arithmetical relation between the unexpressed but intended and the unintentionally expressed.

Because interpretations become so important, some have argued that they are themselves works of art [Danto (1986)]; we should not be surprised since common parlance refers to singers or pianists as *interpreters*!<sup>4</sup> Achieving the interpretation of a work of art requires knowledge, appreciation of the historical context in which the work was created. And here the Internet’s curse that more people use the same technology as the artists can be also a blessing because Internet may facilitate the diffusion of the knowledge needed for interpretation.

Hence, markets in which ideas are valued, either directly, like in research, because they contribute to the stock of knowledge and facilitate the production of new ideas, or indirectly, like in art, because they change our perception of the world, have two characteristics that distinguish them from other markets:<sup>5</sup>

- H. The consumer values the work of art, that is the physical or digital good by which the “idea” is embodied, both for its aesthetics and for the message it brings about the idea;
- I. The transmission of the idea from the creator to the consumer is not immediate, is subject to noise both during the process of creation and during the process of interpretation; furthermore interpretation requires in general effort on the part of the consumer.

There are other characteristics that are not specific to art markets. Many of them are covered in this Handbook: the rise of superstars, the use of auctions as allocation mechanisms, the two-sided nature of the market and the gatekeeper role of intermediaries, the difficulty to specify complete contracts. The Internet and the possibility of digitalization of works of art have magnified some of these aspects, in particular the possibility to distribute at a rapid pace digital works, to reproduce or even modify existing works, and for artists to bypass current gatekeepers.

<sup>4</sup> There is a famous quote on the pianist Glenn Gould: at the end of a dispute with a fellow pianist about a piece by Bach, Gould is credited to have said “Ok you will do it your way, I will do it *his* way”.

<sup>5</sup> See also Chapter 5 by Roger McCain and Chapter 16 by Tony Bryant and David Throsby in this volume. Properties H and I are actually reasonable assumptions for most processes of communication; language is inherently ambiguous and skilled speakers use rhetoric to present facts or events in a new light. Despite the importance of information in today’s economic analysis, most of it continues to assume that communication is a frictionless process, not subject to interpretation, interference or noise. Recent exceptions are Legros and Newman (1999, 2002), Dewatripont and Tirole (2005).

This chapter is by necessity incomplete. As George Stigler had noted for the theory of regulation in the 70s, the proper time to survey a literature is after the subject is developed and a consensus is reached in the field. The theory of regulation did not achieve this in the 70s. We are far from this goal for art and Internet; the Internet is in its teens, and research on its economic and cultural effects is still in its infancy.<sup>6</sup> I take the view here that it is because the Internet makes entry easier for artists and consumers that economists should be interested in its effects. I will therefore focus on the tradeoffs between the blessing (a larger market and more possibilities for creating works of art) and the curse (more competition) of the Internet for art.

Most of the discussion in the media and in the academic literature on this topic has been about the *appropriability* by artists and intermediaries of the revenues generated from creative ideas. The curse of the Internet and the new technologies is the ease with which some digital works can be replicated and distributed. Many like the monks a long time ago or the painters more recently fear that this will eliminate incentives for creation or distribution of art. The leading example has been copyright infringements for digital music and software. I review this case in Section 2. Music is obviously only used as an example of art form making use of the Internet; digital painting, poetry, photography, video are other prominent examples of works of art being distributed or created on the Internet. The issues of copyright protection, incentives for creation, the tradeoff between market expansion versus competition effects are common to all these works of art. In Section 3, I will then take a more abstract approach and use a model based on Boldrin and Levine (2002a, 2002b) and Quah (2002a) to argue that preferences of different participants in the market for strong copyright may have little to do with social efficiency, including incentive provision for new creative ideas. I continue in Section 4 with a faster tour on other issues linked to the market expansion effect of the Internet and a conclusion.

## 2. The example of MP3s and software

Traditional gatekeepers, the music majors, are fighting for strict copyright laws, by which consumers are not allowed to replicate, distribute, and much less modify a work, unless it is for “fair use”. This fight takes the form of legal battles, like against NAPSTER and other peer-to-peer networks where individuals exchange freely MP3s or videos. The software and music industries claim large losses from copyright infringement – or piracy as it is called in the media.<sup>7</sup> Some economists question the magnitude

<sup>6</sup> See however Brynjolfsson (2002), Kahin and Varian (2000), Peitz and Waelbroeck (2003b), Quah (2002b, 2003).

<sup>7</sup> Most of the empirical work is preliminary and the magnitude of the measured effect of piracy sometimes contradictory. Peitz and Waelbroeck (2003a) find a decrease of 1.76% in CD sales worldwide and that MP3 account for 25% of the decrease in CD sales in the top ten markets between 2000–2001. Hui and Png (2003) find that CD loss may be 15% higher than the 1999 industry estimate (software and music industry estimated

of these losses arguing that if copyright laws were perfectly enforced, many users would decide not to consume [Gayer and Shy (2001a, 2001b)], or that downturns in CD sales correspond to normal cycles or substitution to other types of entertainment [Liebowitz (2002)].<sup>8</sup>

The legal battle is on-going. For instance, the maker of iMesh file-sharing software agreed to pay \$4.1 million to the recording industry for copyright infringement. On August 20, 2004, a U.S. federal appeals court ruled that makers of two leading file-sharing programs (Grokster and StreamCast) are not legally liable for copyright infringement by the users of their software. This may force the music industry to fight directly against the users. And they have some successes on this front; for instance, on August 26, 2004, the FBI seized for the first time software and computers of users of a P2P network in Texas. According to an article of August 25, 2004 in the *Financial Times*, record companies have also launched legal actions against karaoke bars in big Chinese cities, demanding damages for the infringement of their licensing rights.<sup>9</sup> But many see this legal fight as hopeless.<sup>10</sup>

The industry is also fighting in more intrusive forms. For instance, by uploading bad quality MP3s on peer-to-peer networks in order to decrease the benefits of using these networks, or even – as in a recent proposal – by using software agents to sabotage the computers of the users of these networks [Corbett (2003)]. Given the wealth of information stored on computers and their other uses, the social cost of this interference may be a magnitude greater than the cost to the music industry of copyright infringement.

In parallel, the music industry uses the Internet to develop new distribution systems; the entry of Apple Computer on the online market (iTunes), where songs are sold for 99¢, has been quickly followed by other recording companies like Sony but also non-recording companies like Wal-Mart Stores, or firms engaged in delivering media software like RealNetworks and Microsoft.<sup>11</sup> MP3s have given rise to complementary hardware manufactured by some of the very firms – like Sony – fighting copyright infringement.<sup>12</sup> Software solutions, The Digital Rights Management (DRM),

its loss from piracy at \$16 billion for 1999). It is not clear how these studies control for substitution effects with other types of entertainment or correct for business cycles.

<sup>8</sup> A 2002 study by Jupiter Media Metrix found that people who download intensively from the Internet has 75% chances to have spent more on CDs than others.

<sup>9</sup> Background information, new legal actions and history of legal cases are available, for instance, on the site of the Recording Industry Association of America, [www.riaa.com](http://www.riaa.com).

<sup>10</sup> For instance, following NAPSTER's legal death, the number of P2P networks has multiplied.

<sup>11</sup> By all accounts, this market is quite small (accounting for less than 2% of all music sales in the U.S.) but is quite competitive; for instance, RealNetworks cut recently the price of its downloads to 49¢ in anticipation of Microsoft's entry (New York Times, August 30, 2004).

<sup>12</sup> This has led to proposals to tax hardware, like MP3 players or blank CDs and DVDs in order to capture some of the losses from copyright infringement (for instance, a tax of the order of 60¢ is levied in France that is put in a fund for artists). Gayer and Shy (2001a, 2001b) offer a model along these lines; they show within their model that such taxation will be ineffective.

limit copying and sharing by users.<sup>13</sup> A literature has developed the idea that illegal copying may increase the demand for complementary software or hardware<sup>14</sup> or that the industry may in fact benefit from copying because of network effects.<sup>15</sup> While suggestive, the effects are probably weak if we refer to a “revealed preference argument”: the resources spent by recording firms in fighting piracy.

Artists are quite divided on the issue of strong copyright. Some artists have organized themselves to fight against copyright infringement (e.g., *Artists coalition against piracy*, <http://welcome.to/acap>, signatories include Elton John). Others embrace the new technology. Some see an opportunity to become known and eventually sign a contract with one of the majors (examples abound of unknown artists who were able to sign their first major contract after having distributed for free their work).<sup>16</sup> This phenomenon is not limited to new artists, since well established artists, and sometimes stars, also distribute their work on the Internet under weak copyright form.<sup>17</sup>

That established firms and some artists want to use the legal system and the new technologies at their advantage, preserve their rents, is easy to understand. That the legal system should follow their lead is another issue. Proponents of strong copyright laws claim that without them there will be significantly less artistic creation or distribution. Economists are familiar with the precept that strong property rights are needed for inducing innovation: otherwise the innovator is not able to collect enough revenues ex-post to cover his ex-ante investment. There is then a tradeoff between ex-ante and ex-post efficiency [Nordhaus (1969)]: giving monopoly rights ex-post creates inefficiencies but is needed in order to provide (efficient) ex-ante incentives to invest.<sup>18</sup> This tradeoff is similar to the tradeoff in industries that exhibit increasing returns to scale.<sup>19</sup> firms cannot make positive profits when pricing at marginal cost and therefore pricing above

<sup>13</sup> Not surprisingly, DRM has become the target of hackers. See, for instance, DRM Watch Staff (2004) documenting recent successes in cracking DRM protection in Apple iTunes.

<sup>14</sup> Conner and Rumelt (1991), Shy and Thisse (1999) give theoretical arguments; Givon, Givon and Muller (1995) provide an empirical analysis of this effect and find that software piracy may boost demand for the legal software. The effect may also go in the other direction. For instance, in the January 7, 2005, issue of the *Financial Times*, Peter Jamieson, chairman of the British Phonographic Industry – representing leading labels and music distributors in England – is cited as noting a “strong move in the digital market” coinciding with strong sales of the Apple iPod and other MP3 players.

<sup>15</sup> Takeyama (1994, 1997), Shy and Thisse (1999).

<sup>16</sup> In France, the most famous example is the singer Lorie, who signed a contract with Sony Music under the label EGP after having been known through Internet downloads. In the US, the pop band Fisher signed a contract with Farmclub and Interscope after having had more than a million downloads of their album on MP3.com.

<sup>17</sup> David Bowie may have been the first to distribute the music of a new CD “Hours . . .” on the Internet before it was even made available in stores; see *The Economist*, September 9, 1999.

<sup>18</sup> See Landes and Posner (2004) and Scotchmer (2004) for state of the art economics approach to intellectual property protection.

<sup>19</sup> The parallel is not quite fair since as noted by Boldrin and Levine (2002a) the production of MP3s does not exhibit increasing returns: the cost of creation of the song by the artist is sunk rather than fixed at the time a CD or an MP3 is distributed.

marginal cost is needed. But the usual response to the problem in these industries is to *regulate* – or give subsidies to the industry – rather than to give total and uncontrolled monopoly power to one firm.<sup>20</sup>

While it may be difficult to assess the Nordhaus effect for artists, we can turn to recent studies on patents. [Lerner \(2003\)](#) analyzes patent protection over 150 years and 177 policy changes. He shows that stronger patent protection has few positive effects on patent applications by applicants from the country in which the change was made (he found in fact a negative relationship after correcting for aggregate effects), which suggests that the Nordhaus effect is not operative. Cross-section effects are consistent with the theory, however, since there is a more important effect of shifting to stricter patent policies when starting from weaker patent protection or greater development.<sup>21</sup>

Closer to our topic, two studies analyze the effect of the change in patent protection for software in the 1980's. [Bessen and Maskin \(2000\)](#) present a theoretical argument to show that if innovation is sequential and complementary, patent protection may reduce overall innovation and that the more competitive the market, the more inefficient patenting is.<sup>22</sup> Using as a natural experiment the extension of patent protection to software in the 1980's, Bessen and Maskin show that while the “Nordhaus effect” would suggest that R&D intensity and productivity should have increased among patenting firms, they did not. [Bessen and Hunt \(2004\)](#) argue that the significant increase in software patenting after the 1980's (software patents representing now 15% of all patents) is mainly due to large manufacturing companies since only 5% of these patents belong to software publishers. This suggests a strategic motive for patenting and Bessen and Hunt find evidence that software patents and R&D at the firm level are substitutes. [The methodology and results in [Bessen and Hunt \(2004\)](#) are criticized by [Hahn and Wallsten \(2003\)](#).]

One interpretation of these two studies is that stricter property right laws rather than inducing more innovation may in fact enable firms with market power to substitute patenting for R&D in order to generate rents. By most accounts software is not art,<sup>23</sup> but these studies put into question the claim that strong copyright laws are needed for artistic production. They also suggest that the social problem of providing incentives

<sup>20</sup> [Romer \(2002\)](#) proposes government direct funding, [Shavell and van Ypersele \(2001\)](#) propose the use of rewards based on realized sales as alternative means for incentive provision.

<sup>21</sup> Lerner notes that he is not able to capture the potential impact of other policy tools used in parallel to patent policy, like offering prizes for discoveries.

<sup>22</sup> A key assumption of the model is that only firms that are active in the market can copy. See [Green and Scotchmer \(1995\)](#) for the question of surplus division when there is sequential innovation. A related issue is the possibility for artists to cooperate in the creation of works of art; the Internet allows the multiplication of such cooperative efforts – as the open source movement has illustrated. Economic issues linked to patenting in cooperative production are analyzed in [Scotchmer and Green \(1990\)](#).

<sup>23</sup> However, consider the experiment suggested by Jean-Luc Moulène, a French photographer: use a digital camera to take a picture of a green pad on a red background, and take another picture of the same pad on a background of a different color. The color of the pad will not be the same in the two pictures; this is because the digital process functions on the basis of harmonic equilibrium controlled by the software. This leads Moulène to conclude that the true creative process in digital picture taking is the software.

for innovation should not be confused with the protection of rents of intermediaries, or rents of established artists. And there are reasons to believe that the discussion in the literature and the media on the costs and benefits of piracy contributes to the confusion.

First, there is a focus on the profit losses of record companies or established artists. There are analyses of the potential loss of recording companies due to piracy, but I do not know of studies evaluating the minimum future revenue needed for artists to be induced to create. We have no appreciation of the cost of copyright infringement on artistic creation.

Second, most of the debate about copying and copyright infringement assumes that CDs and MP3s are the only works of art embodying the creative idea of the artist. However, different works of art change the proportion of revenues going to the artist versus the recording company, or outside financiers. It would be interesting to analyze whether MP3 copying has positive effects for attendance at public concerts, or for viewer interest in TV shows, video clips, since these are also significant sources of revenue for the artist.

Third, the possibility for the artist to appropriate the gains from online diffusion, whether legal or not, in a non-monetary way is generally ignored, at least in empirical work. For instance, since attendance at public concerts is a function of the artist's reputation, online distribution, whether controlled or not by the artist, will contribute to this reputation. Hence even if the artist cannot appropriate the monetary gains from the distribution of MP3s he or she may appropriate the reputational gains (that may eventually turn into monetary benefits). The "revealed preference" argument we used earlier that recording companies do not favor weak copyright cannot be applied to dismiss this possibility. Indeed, for public concerts, revenues are often captured directly by the author, while in the case of CD sales, a large proportion of the revenues is captured by the recording company. Hence there is no contradiction in having recording companies oppose weak copyright – to preserve their revenues from CD sales, while artists may favor weak copyright – in order to benefit from reputational effects of online diffusion, and increase their revenues from other works of art. This is an empirical issue.

Non-monetary incentives may matter as much as direct monetary incentives for artistic creation.<sup>24</sup> What is puzzling in a world where only monetary incentives are at stake, becomes relatively clear when other motives, like reputation building and career concerns complement monetary incentives. For instance, in their study of the open source software movement [Lerner and Tirole \(2002a, 2002b\)](#) point to career concerns as a motive for cooperation among developers. Their empirical analysis of 40,000 open source projects suggests that those that are consumer oriented have restrictive licenses, while those that are developers oriented (or commercial operating systems) have less restrictive licenses. These results are consistent with developers trading off the benefits of being recognized for having contributed significantly to a project (the career concern) versus the risk that someone will appropriate the collective work (that they dub "hijacking").

<sup>24</sup> See [Chapter 16](#) by Bryant and Throsby in this volume.

Recent initiatives for distribution of software and artistic or intellectual work weaken the copyright restrictions while also preventing (or trying to prevent) hijacking. The *GNU General Public License* allows users to copy, modify, create and sell derivative products on the condition that these derivatives acknowledge their origin – give credit to the previous code writers – and contain the same licensing terms. *The creative commons license* for intellectual work is in spirit similar but can be made more restrictive, for instance, concerning remixing or changes of original songs, or commercialization of derivative works.<sup>25</sup> The main restriction in both cases is the obligation to acknowledge the original creator in any derivative work or in any use of the original work. Violations of these licenses are not documented yet, which may indicate that the stakes involved by infringing on these licenses are for the moment weak.<sup>26</sup> These licenses show the possibility for artists to appropriate credit for their work – at least in the non-monetary sphere – even if it is made widely available and if the possibilities of replication or modification are not costly.

On Magnatune.com it is possible to download MP3s for direct consumption,<sup>27</sup> but also to buy different types of licenses: some are for corporate use, some are for remix and derivative works.<sup>28</sup> On Digital Art Auction (<http://www.digitalartauction.com>), the business model is similar to a subscription system. The artist auctions the master copy of his work of art. Bidders propose in the form of a pledge or bid a retail price they'd be willing to pay, and once the maximum revenue available from these bids meets the artist's requirements, the artist chooses the price, receives the revenue from all successful bidders who then receive a copy of the artwork. Another example of innovative financing is the "Bowie bonds". In 1997, David Bowie issued \$55 million worth of bonds that were bought by Prudential Insurance Co. The bonds were backed by future royalty payments on the publishing rights and master recordings of some of Bowie's tunes.<sup>29</sup>

Whether these alternative business models will succeed is still unclear, but they suggest that ease of copying and weak copyright may not prevent an artist from collecting

<sup>25</sup> See the description of these licenses for "artists" – musicians, writers, filmmakers, photographers and (!) scholars – at <http://creativecommons.org/learn/artistscorners/>. See also Lessig (2004).

<sup>26</sup> The technology also allows some protection against infringement. For instance, Commons licensed works have software tags attached to them and these tags will be present in derivative works. If the stakes for infringing are high enough someone will probably find a program to remove the tag [see Legros and Newman (1999) for related ideas in a contract environment].

<sup>27</sup> Interestingly the price is between \$5 and \$18 and the consumer chooses how much to pay; the average price paid is around \$8. This may comfort some economists' view, e.g., De Long and Froomkin (1999), that tomorrow's economy will be based on gift exchange or that business models will be similar to fund raising campaigns.

<sup>28</sup> Example: "This license permits you to use any number of audio samples from a single song by "American Baroque", to create a single song of your own. You can also make remixes or other derivative works. If you make several songs with our samples, you will need a separate license for each song you create (note that alternate versions [i.e. remixes] of your song are considered one song).

<sup>29</sup> The bonds had an average life of 10 years, and were priced to pay investors 7.9 percent interest (*Bloomberg News*, March 2, 1997).

revenues. This point has been made in the literature on copying [Besen and Kirby (1989), Liebowitz (1985), Johnson (1985), Novos and Waldman (1984)], and sharing [Ordober and Willig (1978), Bakos, Brynjolfsson and Lichtman (1999), Varian (2000), Klein, Lerner and Murphy (2002)].<sup>30</sup> Copying may be beneficial to producers because while it creates more competition, it also increases the willingness to pay of users who anticipate the benefits of copying and sharing. In these models the technologies of production and of distribution are fixed and exhibit increasing returns; it is then cumbersome to capture the market expansion effect of the Internet. A model developed by Boldrin and Levine (2002a) is better fit for capturing the two effects.<sup>31</sup> Legros (2005) uses their approach to formalize a market for intellectual creations and to analyze who among the market participants will “bless the curse”. I turn to this model now.

### 3. A market for works of art

There are two periods and a representative consumer with a subjective discount rate  $\delta \in (0, 1]$  and a concave and increasing utility  $u(c)$  for consumption (assume the Inada condition  $u'(0) = +\infty$ ). If the price of consumption is  $p$ , the consumer consumes  $p = u'(c)$ , and the demand function is given by the solution  $c = D(p)$  to this equation; the elasticity of demand is  $\varepsilon = -1/r(c)$ , where  $r(c) = -c \frac{u''}{u'}$  is the index of relative risk aversion; demand is elastic when  $r(c) \leq 1$ . I assume that  $u$  exhibits increasing relative risk aversion, that is

$$r(c) = -c \frac{u''(c)}{u'(c)} \text{ is increasing in } c. \quad (1)$$

In the first period an artist creates  $s_1$  works of art. These are distributed and sold by firms at zero cost; the asset price of works is  $q_1$  in the first period and therefore the artist has revenue  $q_1 s_1$ . Consumers choose how much to consume ( $c_1$ ) in the first period and pay a price  $p_1$  for consumption; the works  $s_1 - c_1$  that are unsold are used by firms to create in period 2 other works of art at a rate  $\beta$ . Consumers have access to a “home production” technology that transforms one work into  $\alpha$  units; hence home production does not conflict with the act of consumption: if  $c$  units are consumed, the consumer has utility  $u(c)$  and obtains  $\alpha c$  units in period 2. I will make the reasonable assumption that  $\beta \geq \alpha \geq 1$ .<sup>32</sup> When  $\alpha$  increases, consumers have access to a technology that becomes

<sup>30</sup> For instance, Varian (2000) analyzes the incentives of a producer to rent or to sell information goods when sharing is facilitated by the formation of “clubs”, that is groups of agents who agree to share any good purchased or rented by one of the members. Libraries, video clubs are such instances of clubs. He shows that profits can increase with sharing when the transaction cost of sharing is small and when the content is viewed a few times only. Varian focuses on monopoly providers while Ordober and Willig (1978) consider Ramsey prices.

<sup>31</sup> See also Hellwig and Irmen (2001).

<sup>32</sup> Note that there is limited rivalry in the sense that once a firm sells consumption flow  $c$ , it cannot use the  $c$  units to create copies. See Quah (2002a, 2002b) for a non-rivalry example where he assumes  $\alpha > \beta$  in order to capture the idea that reproduction is faster with dissemination.

similar to that of firms: at the time of the Daguerreotype,  $\alpha$  was small and probably equal to zero, at the time of digital photography,  $\alpha$  is large.

A strong copyright regime is one in which the firm can prevent, via legal or technical constraints, consumers to use their home technology. A weak copyright regime is one in which the firm cannot – or does not want to – prevent consumers from using that technology.

Note the two main assumptions until now:

- (i) The cost of innovation (coming up with the creative idea) is sunk rather than fixed, i.e., there are constant returns to scale rather than increasing returns in the production of works of art.
- (ii) Works of art are not divisible and the “creative idea” is embodied into a medium that can be replicated only if the medium is made available; moreover producing additional works of art on the basis of existing ones requires time and the rate of production is finite. While finite, this rate can be made arbitrary large; finiteness corresponds to the concept of *finite expansibility* in David (1992) [see also Quah (2002a, 2002b)].

Assumption (i) is a significant departure from the usual assumption of increasing returns made in the literature on innovation [see however Chapter 11 by Baumol in this volume and Sutton (1991)]. Assumption (ii) captures the view that the creative ideas, and later their interpretation, have to be embodied into a support before being replicated or used to produce other works of art. Since there must be a productive activity for replicating, this activity comes at a cost, modeled here in terms of time.

Following the discussion leading to conditions H and I, let us define a work of art by a two-dimensional point  $(x, y)$ .<sup>33</sup> The first component  $x$  is never observed and corresponds to the underlying creative idea. The second component  $y$  is the observable part and corresponds to the physical or digital properties of the work (e.g., painting, recording on a CD, working paper of an economic model). Interpreting a set of  $m$  works of art  $\{(x, y_i); i = 1, \dots, m\}$  that are known to be based on the same creative idea (e.g., Duchamp’s Readymades, or a research question in science) amounts to inferring the non-observable component  $x$  from the observable components  $\{y_i\}$ .

Artists are distinguished by the number of creative ideas that they have: an artist with a large (small) number of creative ideas will be able to create only a small (large) number of works of art per creative idea. Hence if John has  $n$  creative ideas  $(x = 1, \dots, n)$  and a production capacity of  $k$ , he will have  $s_1 = k/n$  works of art  $(x, y_{xi}), i = 1, \dots, k/n$ , produced on each of these ideas where I assume that the artist never produces twice the same work of art, that is  $y_{xi} \neq y_{\hat{x}j}$  for all  $xi \neq \hat{x}j$ . Interpretation is facilitated the larger  $s_1$ : observing more works of art that are distinct in their observable components improves interpretation and inference of the underlying idea. In the words of Duchamp (1966),  $s_1$  is an index of the “art coefficient” that can be associated with the production

<sup>33</sup> Our view that consumers value the characteristics of the object and their use for home production is in the spirit of the work of Lancaster (1966) or Becker (1976).

of the artist. Because  $s_1$  is also an index of the number of creative ideas, larger values of  $s_1$  are associated with less creative artists.

For low values of  $s_1$ , interpretation is difficult but once obtained, it is easy to create new works; as  $s_1$  increases, interpretation is easier, but it becomes more difficult to create new works. Therefore, the rate  $\beta(s_1)$  available to firms for producing new works is an inverted U-shaped technology: increasing for low values of  $s_1$  and decreasing for high values of  $s_1$ . I assume throughout that the replication rate in the home production technology is bounded above by the rate available to artists:  $\alpha \leq \beta(s_1)$ . Until necessary I simply write  $\beta$  instead of  $\beta(s_1)$ .

Once interpretation is achieved, technology (or craftsmanship) can be used to produce additional works based on the same creative idea  $x$ . Each such idea creates its own market, with consumers having utility  $u(c)$  for consuming  $c$  different works: a new work has value for consumers only in that its observable component is different from existing observable components. This is obviously an extreme view; it would be the case if aesthetics has no value for consumers who care only about understanding the creative idea. The qualitative results will not change as long as the value that consumers put on new works of art is larger than for exact copies.

Artists are “driven” in the sense that they always produce initially (that is in period 1) the maximum number of works.<sup>34</sup> The distribution of these works is done by firms which may decide not to distribute all works, to smooth consumption over periods or to keep prices high if they have monopoly power.

Assumptions (i) and (ii) are sufficient for the artist to appropriate positive revenues even if there is competition on the market for works of art, and even if the home technology becomes as good as the firm technology (that is  $\beta - \alpha$  gets small), or if the firm technology improves (that is  $\beta$  gets large). The assumption of a competitive market is obviously extreme: having a new idea suggests indeed that there are few immediate substitute ideas and works embodying a similar idea in the market. Since under conditions (i) and (ii) the inventor will not be expropriated, it is fair to wonder why the holder of such innovation would behave competitively. The competitive benchmark is however useful because if the artist can have revenues large enough to induce creative activity under competition, this makes the case for weak copyright laws even stronger when there is market power. But considering the monopoly assumption provides additional insights into the reasons for an artist or a firm to favor weak rather than strong copyright.

<sup>34</sup> While we allow for strategic release to the market by the firm distributing the works of art of the artist, strategic release by the artist himself may be important to model. For instance, Duchamp (1966) writes “I realized very soon the danger of repeating indiscriminately this form of expression and decided to limit the production of “Readymades” to a small number yearly. I was aware at that time, that for the spectator even more for the artist, art is a habit forming drug and I wanted to protect my “Readymades” against such a contamination. Another aspect of the “Readymade” is its lack of uniqueness . . . the replica of the “Readymade” delivering the same message, in fact nearly every one of the “Readymades” existing today is not an original in the conventional sense.”

### 3.1. Appropriability: Competition

The representative agent's welfare maximization problem is

$$\max_{c_1} u(c_1) + \delta u(\beta(s_1 - c_1) + \alpha c_1), \quad c_1 \in [0, s_1],$$

where  $s_1$  is the initial asset holding in the economy and  $s_2 = \beta(s_1 - c_1) + \alpha c_1$ , and  $\delta$  is the subjective discount rate of consumers.

There exists a unique rate of copying above which it is optimal for the consumer to consume all works at  $t = 1$ . At this cutoff value  $\hat{\alpha}(s_1)$  the marginal utility from consumption in the first period equals the discounted expected marginal utility in the second period, that is it solves the equation  $u'(s_1) = \delta(\beta - \alpha)u'(\alpha s_1)$  and satisfies  $\hat{\alpha}(s_1) \in (0, \beta)$ . For increasing relative risk aversion utility functions, this cutoff value  $\hat{\alpha}(s_1)$  is an increasing function of  $s_1$ , that is as the number of works available in the first period increases, the home technology must be good enough for the firm to sell all units in the first period. When  $\alpha < \hat{\alpha}(s_1)$  welfare maximization requires  $c_1^* < s_1$  solving  $u'(c_1) = \delta(\beta - \alpha)u'(\beta s_1 - (\beta - \alpha)c_1)$  while when  $\alpha > \hat{\alpha}(s_1)$  the solution is  $c_1^* = s_1$ . Hence, as  $\alpha$  increases, consumers are good substitute for firms for producing the works of art, and the opportunity cost of not consuming today increases.

On a competitive market, the first period asset value  $q_1$  of the works will be equal to the expected revenue from consumption in the two periods, and the artist will have revenue of  $q_1 s_1$ . Our previous discussion suggests that we may want to distinguish between monetary and non-monetary benefits of the artists, but for simplification, we do not. The business model of *Digital Art Auction* we described above fits a monetary interpretation since the artist gets revenues by having agents subscribe (pay the asset price) for obtaining copies from a master.

Asset prices are  $q_t$  and consumption prices are  $p_t$ . Feasibility conditions are  $c_t \leq s_t$ ,  $t = 1, 2$ . Asset prices satisfy  $q_1 s_1 = p_1 c_1 + p_2 c_2$  and  $q_2 s_2 = p_2 c_2$ . Because  $t = 2$  is the last period, there is no value of saving assets and  $c_2 = s_2$  and  $q_2 = p_2$ .

The competitive consumer's problem is then under prices  $p_t, q_t$ :

$$\begin{cases} \max_{c_1, c_2, s_2} u(c_1) + \delta u(c_2), \\ p_1 c_1 + q_2 s_2 \leq q_1 s_1, \\ p_2 c_2 \leq q_2 s_2 \end{cases} \quad (2)$$

for given prices  $p_t, q_t$ . For an interior solution we have

$$\frac{u'(c_1)}{\delta u'(c_2)} = \frac{p_1}{p_2}$$

and demand functions are defined implicitly by  $u'(c_1) = \mu p_1$ ,  $\delta u'(c_2) = \mu p_2$ , where  $\mu$  is the Lagrange multiplier of the first period budget constraint.

The firm's problem is

$$\begin{cases} \max_{y_1, y_2, s_2} q_1 s_1 = p_1 y_1 + p_2 y_2, & y_t \leq s_t, \\ s_2 = \beta(s_1 - y_1) + \alpha y_1, \end{cases}$$

where  $y_t$  is supply at  $t$ . Equilibrium conditions are that  $y_t = c_t$  for  $t = 1, 2$ . Profit maximization yields

$$c_1 \leq s_1 \quad \text{if} \quad \frac{p_1}{p_2} = \beta - \alpha.$$

The welfare maximizing allocation  $(c_1^*, c_2^*)$  is then decentralized by prices  $p_1, p_2$  satisfying<sup>35</sup>

$$\begin{aligned} p_1 &= u'(c_1^*), \\ p_2 &= \delta u'(c_2^*). \end{aligned}$$

If the rate of home production is low enough ( $\alpha \leq \hat{\alpha}(s_1)$ ) the market value of the initial assets is

$$\begin{aligned} q_1 s_1 &= p_1 c_1^* + p_2 c_2^* \\ &= u'(c_1^*) c_1^* + \frac{u'(c_1^*)}{\beta - \alpha} (\beta s_1 - (\beta - \alpha) c_1^*) \\ &= \frac{\beta}{\beta - \alpha} u'(c_1^*) s_1. \end{aligned} \quad (3)$$

While if the rate of home production is high enough ( $\alpha > \hat{\alpha}(s_1)$ ), all initial works are sold in the first period and the market value is

$$q_1 s_1 = (u'(s_1) + \delta \alpha u'(\alpha s_1)) s_1. \quad (4)$$

Therefore, the minimum revenue of the artist is bounded below by  $u'(s_1) s_1$ , independently of the rates  $\alpha$  and  $\beta$ . Moreover, this bound is independent of  $\delta$ ,  $\delta$  being also an index of appropriability of second period industry profits by the artist. This is the main result in [Boldrin and Levine \(2002a\)](#): as long as there is indivisibility in the provision of ideas, a competitive market will give a positive rent to the fixed factor (the artist). Hence, innovation is compatible with competition.

As  $\alpha$  increases, for given first period consumption, tomorrow's price will be lower since there will be more works available on the market; this is the curse or the competitive effect. As  $\alpha$  increases however, consumers value more first period consumption since increasing first period consumption does not go against smoothing intertemporal utility. The fact that home production improves means that there are more potential

<sup>35</sup> Indeed when  $\alpha \leq \hat{\alpha}(s_1)$ , in an interior solution, consumer's optimization yields  $u'(c_1)/\delta u'(c_2) = p_1/p_2 = u'(c_1^*)/\delta u'(c_2^*)$  which implies that  $c_t = c_t^*$  for  $t = 1, 2$ . At the price ratio  $p_1/p_2 = \beta - \alpha$ , the firm is indifferent between all combinations of  $y_1$  and  $y_2$  since its profit is  $p_2((\beta - \alpha)y_1 + y_2)$  while the resource constraint can be written  $(\beta - \alpha)y_1 + s_2 = \beta s_1$ ; since  $c_2 = s_2$  the result follows.

If  $\alpha > \hat{\alpha}(s_1)$ , the optimal allocation is  $c_1 = s_1$  and by definition  $\frac{u'(s_1)}{\delta u'(\alpha s_1)} > \beta - \alpha$ . Consumer maximization implies  $c_1 = s_1$ . Since  $u'(s_1) - \delta(\beta - \alpha)u'(\alpha s_1) > 0$ , firm's profit function  $u'(s_1)c_1 + \delta u'(\alpha s_1)(\beta s_1 - (\beta - \alpha)y_1)$  is increasing in  $y_1$  and therefore  $y_1 = s_1$  is optimum for the firm.

works of art available in the market; this is the blessing or the market expansion effect. The net effect of a small change in  $\alpha$  on the asset value is ambiguous and depends on the elasticity of demand. For a fixed value of  $\beta$ , it is clear from Equations (3) and (4) that the maximum value of the initial assets is attained at  $\alpha^*(s_1) > \hat{\alpha}(s_1)$ . This implies that all authors prefer a weak to a strong copyright regime; when  $\alpha$  is larger than  $\alpha^*(s_1)$ , however, authors may value the imposition of some restrictions on home production.

Consider the special case of constant demand elasticity, that is when the utility function is  $u(c) = c^{1-R}/(1-R)$ , where  $R \geq 0$ . Elasticity of demand is  $-1/R$  and demand is elastic when  $R \in (0, 1)$ . In this case the cutoff value  $\hat{\alpha}(s_1)$  is independent of  $s_1$ ;  $\hat{\alpha}(s_1) = \hat{\alpha}$  solving  $\hat{\alpha}^R = \delta(\beta - \hat{\alpha})$ . When  $\alpha \geq \hat{\alpha}$ ,  $c_1^* = s_1$ ,  $p_1 = s_1^{-R}$  and  $q_1 s_1 = s_1^{1-R}(1 + \delta\alpha^{1-R})$  which is increasing in  $\alpha$  since  $R \in (0, 1)$ ; therefore the market value of the assets increases as home production becomes as good as the firm's technology or as  $\beta$  increases. When  $\alpha \leq \hat{\alpha}$ ,

$$c_1 = \frac{\beta s_1}{\beta - \alpha + (\delta(\beta - \alpha))^{1/R}},$$

$$q_1 s_1 = \beta^{1-R} \left( \delta^{\frac{1}{R}} + (\beta - \alpha)^{\frac{R-1}{R}} \right)^R s_1,$$

and are increasing with  $\alpha$  (for a fixed  $\beta$ ) and increasing in  $\beta$  (for a fixed  $\alpha$ ). Therefore when demand has constant elasticity, the market value of the asset increases when home production improves, and in this case all authors strictly prefer the weak regime, independently of  $\alpha$ .

### 3.2. Appropriability: Market power

Consider now an extension of this basic model in which the artist, or the firm distributing his initial works, has market power. The market unfolds like in the competitive case. The monopoly firm decides to sell  $c_1$  works at time 1. Consumers become sellers at time 2 and behave competitively, that is take the price  $p_2$  as given; the quantity they will be able to offer on the market depends upon the copyright regime put in place.

The static profit function is  $\pi(c) = cu'(c)$  and the marginal profit function is  $\pi'(c) = u'(c)(1 - r(c))$ . Under Equation (1)  $\pi$  is single peaked. Let  $c^M$  be the unique maximizer of the profit function and write,

$$\pi^M \stackrel{\text{def}}{=} c^M u'(c^M).$$

I assume to simplify that the monopoly can commit to a production plan (or alternatively to prices).

In the *strong copyright regime*, the monopoly can prevent consumers to use their home technology. This could be because of a legal constraint or technical protection (like DRM); while there is some doubt on the ability to suppress *all* possibility of production by consumers, it seems hard to dispute the fact that this will lead to a lower value of  $\alpha$ . We consider here the extreme case where the strong copyright protection can be perfectly enforced and lead to  $\alpha = 0$ . Consumers solve Equation (2) and the

monopoly solves

$$\begin{cases} \max_{c_1, c_2, s_2} \pi(c_1) + \delta\pi(c_2), & c_2 \leq s_2, \\ s_2 = \beta(s_1 - c_1). \end{cases} \quad (5)$$

When the constraint  $c_2 \leq s_2$  binds – which is typically the case when  $s_1 < c^M$  – the solution to Equation (5) is  $\phi(s_1, \beta) = \max_{0 \leq c \leq s_1} \pi(c) + \delta\pi(\beta(s_1 - c))$ .

In the *weak copyright regime*, consumers can use their home production technology that enables them to create new works of art at a rate  $\alpha$ . Home production creates unwanted competition to the monopoly, and this effect is magnified when consumers behave competitively when selling their home production on the market. Because the production of consumers satisfies constant return to scale, it is convenient to think of a competitive firm having capacity  $\alpha c_1$  on the market in the second period, the monopoly firm having capacity  $\beta(s_1 - c_1)$ .

The representative consumer receives dividends from the monopoly firm and the competitive firm.<sup>36</sup> At time 1, the monopoly anticipates the behavior of the consumer and the competitive firm, and acts as a monopoly on the residual demand  $p_1 = u'(c_1)$ ,  $p_2 = \delta u'(c_2 + \alpha c_1)$ . The consumer takes as given the prices on the market for consumption and for the assets and has a consumption plan  $(c_1, c_2, s_2)$  solving Equation (2). Demand functions are given by  $p_1 = u'(c_1)$  and  $p_2 = \delta u'(c_2)$ . At the optimum both constraints bind and we have  $q_1 s_1 = p_1 c_1 + p_2 c_2$ . The competitive firm is present only at time 2, and its supply is  $\alpha c_1$ . Anticipating this second period supply, the monopoly solves then

$$\begin{cases} \max_{c_1, c_2, s_2} q_1 s_1 = \pi(c_1) + \delta\pi(c_2), & c_2 \leq s_2 + \alpha c_1, \quad c_2 \geq \alpha c_1, \\ s_2 = \beta(s_1 - c_1). \end{cases} \quad (6)$$

Note that the second period profit of the monopoly from the sale of consumption good is  $\delta(c_2 - \alpha c_1)u'(c_2)$  but that the total industry profit  $\delta c_2 u'(c_2)$  is incorporated in the initial asset value. The market internalizes the externality that period 1 consumption brings in terms of home production and the price of the assets  $q_1 s_1$  is strictly greater than the profit the monopoly firm makes from its sales.

There are therefore two effects of home production from the point of view of the monopoly. There is first the *market capacity expansion* effect illustrated by the constraint  $c_2 \leq s_2 + \alpha c_1$ , or  $c_2 \leq \beta(s_1 - c_1) + \alpha c_1$ : even if the monopoly sells all assets at time 1 ( $c_1 = s_1$ ), consumers can still consume in the second period since there is home production; this effect is positive since it is a source of extra profit. There is also the *competitive effect*, illustrated by the constraint  $c_2 \geq \alpha c_1$ , suggesting that the second period capacity may be too large from the point of view of profit maximization, i.e., the monopoly is now limited to choose second period prices greater than  $\delta u'(\alpha c_1)$ .

<sup>36</sup> There is a potential benefit for the monopoly to buy some of the works of the competitive firm at  $t = 2$ : doing so will increase second period profits since the monopoly would face a larger residual demand. However, the asset price  $\hat{q}_2$  should adjust. To simplify I ignore this possibility.

Figure 1. Case  $\alpha = \beta$ .

Figure 1 illustrates the market expansion and competition effects generated by the weak copyright regime in the case  $\alpha = \beta$ , that is when consumers have access to the same production technology as firms. With the strong copyright regime, the set of feasible second period industry sales ( $c_2$ ) is given by the triangle  $ab0$ , that is the area bounded by the production frontier  $\beta(s_1 - c_1)$  and the two axes. With the weak copyright regime the feasible set is given by the triangle  $ac0$ , that is the area bounded by the production frontier  $\beta s_1$ , the lower bound on second period consumption  $\beta c_1$  and the two axes.

Consider a value of  $c^M$  as in the figure, that is  $s_1 < 2c^M/\beta$ . In the strong copyright regime, first period consumption is greater than  $\underline{c}^S$ : if  $c_1 < \underline{c}^S$ , the monopoly will choose to set  $c_2 = c^M < \beta c_1$  which is not profit maximizing since by increasing

$c_1$  first period will increase without distorting second period profits. Similar reasoning shows that in the weak copyright regime first period consumption is greater than  $\underline{c}^W$ . It is then immediate that the strong copyright regime can dominate the weak copyright regime only if first period consumption is greater than  $\underline{c}^W$ . For any level of first period consumption  $c_1$  greater than  $\underline{c}^W$ , the strong regime puts an upper bound on second period consumption that is strictly lower than the monopoly quantity (underconsumption  $\Delta^W$ ) while the weak regime puts a lower bound on second period consumption that is strictly greater than the monopoly quantity (overconsumption  $\Delta^S$ ). As long as the profit function is symmetric around  $c^M$ , the resulting loss in profits is greater for  $\Delta^S$  than for  $\Delta^W$ . Hence, when  $s_1 < 2c^M/\beta$ , artists favor the weak copyright regime. Using a similar reasoning, when  $s_1 > 2c^M/\beta$ , artists favor the strong regime.

Since  $\beta(s_1)$  is U-shaped, both highly creative artists ( $s_1$  small) and poorly creative artists ( $s_1$  large) favor weak copyright laws; only “average” artists favor strong copyright laws. Highly and poorly creative artists are indirectly protected from the competitive effect: for highly creative artists interpretation is difficult while for poorly creative artists interpretation is easier but it is difficult to create new works of art.

This simple model therefore suggests that artists at the two extreme of the creativity scale benefit from market expansion: the most creative because market expansion facilitates interpretation of their work, the least creative because they have already “cornered” the market on their creative idea. This non-convexity resonates well with the variety of opinions of artists on the issue of copyright enforcement and on other protective measures such as resale rights.

#### 4. Issues and conclusion

Like photography and the invention of the printing press a few centuries ago, the new technologies of digitalization and the Internet threaten the market positions of artists and intermediaries. Artists because the technology of production of works may be readily accessible and craftsmanship may no longer be a defining characteristic of art. Intermediaries because their rents were linked to entry barriers in the distribution market. This curse of new technologies may be a blessing in disguise since it also increases the possibilities of production, of distribution and the emergence of new works of art.

Thinking of works of art as multi-dimensional goods with consumers valuing all dimensions but being able to observe only a subset of these permits a simple answer to Arrow’s (1962) problem: how could a creative idea yield revenues on a market if valuation requires disclosure of the idea and if the idea can be appropriated at no cost? As long as interpretation is needed for works of art, and consumers value this dimension, artists can obtain revenues from their creative ideas even if consumers have access to a production technology that makes some of the observable dimensions of the work easy to replicate or produce. Copyright may complement this effect, but the preferences of different participants in the market for strong copyright reflect a basic tradeoff between market expansion and competitive effects and have little to do with social efficiency,

including incentive provision for new creative ideas. Appropriability per-se is indeed not enough for market participants to favor weak copyright, that is to allow consumers to use to its full extent the new productive opportunities of the Internet. Intermediaries and artists may want to limit competition in order to increase the rents brought by the indivisibility of creative ideas.

Legal licenses like those proposed by Common Creative License facilitate the emergence of new business models that allow artists to bypass current gatekeepers while still providing appropriability, whether monetary or non-monetary. Whether or not the artist will obtain enough revenues to cover the costs of creation is really an empirical issue, but the current support of some artists for weak copyright is an indication that this is the case.

I warned the reader that this chapter will be incomplete. There are other effects of the Internet that deserve further study. Some are already analyzed in chapters of this handbook. Others are less studied and may prove important; one leading question is the relationship between ease of entry and the “quality” of the offerings on the art market.

In a world where information is complete, entry should lead to social gains; but this is not necessarily the case for the art market. For instance, there is a tension between the desire for a “global” presence and the desire to fit local tastes and culture. The media have coined the term “glocal” for expressing this tension. While there is some work on this topic<sup>37</sup> it is still unclear how facility of access to knowledge and need to interpret works from other cultures will affect the offerings on the art market.

If we abandon the fiction of a representative consumer, and if consumers have different abilities to interpret works of art or even to identify them, a need for certification arises: either to prevent fraud,<sup>38</sup> or to facilitate the interpretation of the work, e.g., by certifying the origin and therefore the historical context during which the work was created.<sup>39</sup> Who should provide this certification? Certification is often provided after a selection process, a screening process. Traditional gatekeepers (recording studios, galleries) play the role of screening and filter works of art that will be offered on the market; then as in the quote from Duchamp the artist “will have to wait for the verdict of the spectator” – critics, buyers, and historians build his reputation. The Internet by facilitating entry of artists shifts the role of screening to the market; it is not clear at this point whether this shift will improve on the previous system.<sup>40</sup> An indirect consequence of the difficulty to provide certification and screening on the Internet is that there are rents

<sup>37</sup> For instance, Legros and Stahl (2002) provide a theoretical argument showing how the number of varieties offered locally is affected by global competition and how the local market structure may alleviate this variety loss. There is a large “business economics” literature on these glocal strategies, see, for instance, Ghemawat (2001).

<sup>38</sup> For instance, during the inaugural auction of Nart.com, an online auction company, a Picasso drawing had to be withdrawn because of fears that it might be a forgery (*Economist*, January 27, 2000).

<sup>39</sup> Duchamp’s Fountain would have probably not made an impact on art if Duchamp had not been a certified artist.

<sup>40</sup> For instance, as is known from search theory, lowering of search costs may lead to less search by consumers because firms adapt their pricing strategy in equilibrium and may increase the equilibrium opportunity cost

to be gained by offering such services to consumers; this should affect the market for the distribution of works of art, possibly leading to more rather than less concentration.<sup>41</sup>

of search. The documented search behavior of consumers on the Internet is an indication that this is not merely a theoretical argument, e.g., Brynjolfsson (2002). Search may also become less efficient, for instance, if producers adjust their offering and try to manipulate the search of consumers, see Ellison (2003).

## Abstract

Whether in ancient Rome or in the modern United States, censorship has existed in every society at every age. Art that challenges the strongly held beliefs of any society – whether those be political, ideological, religious, or otherwise – causes offense and creates pressure for censorship. At the same time, almost every society has found value in the existence of visual art. What limitations on censorship should be made for the sake of artist value, or more broadly freedom of expression? “Artistic merit” and “offensiveness” are nebulous concepts lacking in objectivity, shifting with the tastes of society at any given time. Yet the value of art to society, both positive and negative, cannot be doubted. In modern American society, with its heterogeneous tastes, the tension between the two concepts becomes especially vivid. Given the divergent and unpredictable tastes of society, the fact that destroying a work permanently removes it from future generations, and considering censorship’s dreadful history, the decision to censor is one appropriately made with caution. But neither can it be said that a work should never be censored, for art can and does cause offense, and even a society as diverse as ours will find consensus at the extremes. Rather, striking the appropriate balance calls ultimately for good judgment. In making this judgment, what is the appropriate role of the law and the courts? Those who think of the law as purely objective will desire the courts to either forbid all governmental interference with art, or to themselves abstain from interfering with political decisions on art. But these approaches place legal purity above reality, and make the impossible attempt to divorce law from its social context. The problem of relativism that inheres in the balance between artistic merit and offensiveness in fact exists in every legal controversy. The necessary public respect for our courts is unlikely to be undermined by a cautious display of good judgment, even if the judgment is inherently subjective and involves art causing offense to elements of our society.

censorship, visual art, first amendment, offensiveness, pragmatism

*JEL classification:* K10

## 1. Introduction

Our subject is the limitations that the concept of freedom of expression, including the legal embodiment of that concept in the First Amendment to the Constitution of the United States, places on the censorship of visual art (paintings, statuary, plays, opera librettos, movies, television programs, and so forth), when the censor's emphasis is on the visual rather than the verbal content of the art. We first sketch the history of such censorship and then try to explain the current position of (mainly) U.S. law with respect to it.

## 2. History

### 2.1. *Censorship in ancient times*

Ancient Egyptian civilization seems not to have had any “art” as understood in the modern sense. Workmanship, not creativity, characterized visual representation, and artists followed rigidly a set of prescribed conventions concerning color and proportion. While there are no records of individual artists being censored, the strict adherence to the conventions over a period of three millennia suggests that individual artistic freedom was highly limited to the point of being non-existent [Clapp (1972, p. 15)]. Not that subversive exercises of that freedom could be prevented entirely; satiric paintings, such as one depicting a mouse being fanned and fawned on by a cat, have been discovered [Jackson (2002)].

Plato praised Egyptian art precisely because “modification and innovation outside [the] traditional framework was prohibited” [Plato (1970, II, pp. 656–657)]. Plato was one of the earliest recorded advocates of rigorous censorship. His imagined utopian state imposed strict censorship in order to promote virtue and good morals in the young [Plato (1978, III, p. 401)]. Although he focused his criticisms more on heretical poetry and music than on the visual arts, he also disapproved of painting [Plato (1980, X, p. 603)] and sculpture [Plato (1993, pp. 235–236)] and argued that they should be submitted to state censorship so that their moral content could be monitored and if necessary corrected.

The draconian censorship envisioned by Plato was never fully realized in Greece. Sparta had some censorship relating to sculpture and music [Chambers (1928)], but the general attitude seems to have been liberal. Thus, although much Greek art was religious, the gods were portrayed in human form [Gage (1992)]. Greek vases even depicted the gods engaged in sexual acts – a depiction that would surely engender fierce controversy today if currently esteemed deities were the subject. Depictions of nudity of both men and women were acceptable. But the Greek tolerance for art was limited. Phidias, among the greatest of Greek sculptors, was tried in Athens in 438 B.C. and convicted of sacrilege for placing his own likeness on the shield of Athena. Historical sources disagree on whether he was exiled or imprisoned [Clapp (1972)].

Freedom of speech in ancient Rome depended on one's social rank, and in the republican era many poets were exiled for their writings. The Romans established the office of Censor as early as 443 B.C. [Riley (1998)], and though initially the only function of the office was to make a census of citizens and assess their wealth and taxes, the censors eventually acquired the power of *regimen morum*, or general control over the morals of citizens to determine their fitness for office. Romans occasionally associated art with decadence and corruption of morals. The Roman general Sulla was accused of corrupting his soldiers in foreign lands through art: "for there it was that the army of the Roman people first learned to indulge in women and drink, to admire statues, paintings and chased vases" [Chambers (1928, p. 55)].

We have found no instance in which an individual Roman artist was censored for his work; but then few names of Roman artists have survived. Even if there was no retribution against individual artists, their artwork received official scrutiny. Augustus displayed his displeasure upon seeing a statue of Marcus Brutus in Cisalpine Gaul, accusing the town of harboring a public enemy [Jones (2001, p. 2055)]. And a Roman administrator named Marcus Granius Marcellus was indicted for treason in 15 A.D. after elevating his own statue above those of the Caesars and mutilating the statue of Augustus [Jones (2001, p. 2055)].

Roman attitudes toward sexual representation may have shifted with time. Roman statues include many sculptures of naked male athletes; but in the Republican era naked statues of the gods were rare, and may even have been viewed as a sign of decadence. Naked depictions of the gods became more popular during the late Republic, though not without limits: Arellius was reportedly criticized for painting goddesses in the likeness of his mistresses [Jones (2001)].

Political factors were a frequent cause of censorship in ancient times (as in all subsequent times, for that matter). The destruction of a person's image after his or her downfall was a common act of retribution. When Thutmose III became Pharaoh of Egypt around 1481 B.C., he ordered the destruction of all statues and images of his aunt Hatshepsut erected during the period in which he had been forced to share power with her [Clapp (1972, p. 16)]. Similarly, the statues of Sejanus, chief minister to the Roman emperor Tiberius, were destroyed after Sejanus's downfall in 31 A.D. [Jones (2001)].

## 2.2. *Censorship in Christian Europe*

### 2.2.1. *The Middle Ages – the iconoclast controversy*

The historical relationship between artists and Christianity was complex. The Church (both its eastern and western divisions) was the most important patron of the arts for more than a thousand years, but also the greatest censor. Possessing both the carrot of patronage and the stick of excommunication, as well as other powers of persuasion and intimidation, the Church exercised enormous influence over artistic development.

The early Christians encountered, and were horrified by, the nudity and (as it seemed to them) the idolatry rife in the Hellenistic world. The Council of Elvira in 306 decided

that it should be permissible to exhibit paintings on only the outside walls of a church; and those who worshiped idols could not receive communion [Clapp (1972); Carmilly-Weinberger (1986)]. The Church became more accommodating towards artists after it discovered that art was a convenient way of spreading Christianity among the poor and the illiterate. The Edict of Milan in 367 allowed paintings to be displayed inside a church, but the order of the saints, the use of color and symbols, and other details of the paintings were all specified by church officials [Clapp (1972); Carmilly-Weinberger (1986)].

The most significant debate within Christianity about art during the middle ages was the iconoclast controversy. Nudity and sexual representation also posed problems, but the censorship of nudity was not important until the revival of classicism in the Renaissance revived artistic interest in the nude.

Idolatry is forbidden by the Second Commandment. Saint Clement of Alexandria, an early Christian thinker on art, wrote against art in general and graven images in particular [Carmilly-Weinberger (1986, p. 10)]. But the Church gradually incorporated some pagan traditions, and icons (paintings on wood) came to decorate many churches in both the East and the West [Jones (2001, vol. 1, p. 103, vol. 2, p. 1141)]. When the Bishop of Marseilles removed such images from churches, he received a gentle reprimand from Pope Gregory I, who hoped to enhance the influence of Christianity by means of art [Jones (1977)]. In furtherance of this effort Gregory I had Roman statues destroyed so that the images of saints that remained would be free from heathen competition.

The debate over the propriety of icons exploded into all-out war in the late seventh century. In 692, the Trullan Council prohibited representing Christ symbolically as a lamb and required that He be portrayed in human form [Alexander (1958)]. The Byzantine emperor Leo III went further but in the opposite direction in about 726, forbidding the making of icons and ordering the existing ones to be destroyed [Mango (1977, pp. 1–2)]. Leo's successor, Constantine V, intensified the crackdown on icons. Many churches were redecorated with landscapes depicting trees and animals [Jones (2001)].

Incidents of iconoclasm in the West were sporadic [Gimpel (1969, p. 14)]. Pope Gregory II opposed Leo III's decree, and his successor Gregory III declared that anyone who destroyed pictures of Christ or the Virgin Mary would be excommunicated [Alexander (1958)]. Charlemagne was also more liberal than his counterparts in the East, opposing the worship of images but endorsing their use as decorations in churches [Gimpel (1969)]. Many artists and sculptors fled Constantinople for Italy.

Iconoclasm declined with the accession of Leo IV to the Byzantine throne in 775, and his moderation was continued by Empress Irene after his death [Carmilly-Weinberger (1986, p. 12)]. Decrees of the Second Council of Nicaea ratified by both the western and eastern churches allowed icons to be venerated within broad limits. The Council also prescribed rules on how holy images were to be presented. The order of saints was determined; Jesus had to be on the right side of a painting, St. John on the left; the feet of Jesus, of the apostles, and of the angels could be painted bare but not the feet of the Virgin Mary and the saints. Manuals were distributed in the East informing artists of these rules [Gimpel (1969)].

Iconoclasm returned once more in 813, when Emperor Leo V renewed the prohibition on images. Soldiers destroyed them throughout the Byzantine Empire. This second iconoclast phase lasted until the death of Emperor Theophilus in 842. The Council of Constantinople brought the iconoclast movement to a final end the following year by reverting to the decrees of the Second Council of Nicaea [Clapp (1972)].

### 2.2.2. Reformation – heresy and nudity

The Reformation revived iconoclasm. Martin Luther strongly condemned the idolatry of the Catholic church, and his followers forbade religious paintings [Clapp (1972, p. 55)].<sup>1</sup> Though the reformers were enthusiastic in their destruction of idols, they had little problem with printed images depicting scenes from the Bible, or paintings denouncing the Catholic church. Indeed, they used satirical images to mock the Pope and denounce Catholic practices, and images of Luther were distributed in order to spread the Reformist message [Andersson (1997)]. In response, the Catholic church issued the Edict of Worms in 1521, decreeing that all printed, including pictorial, material contrary to Catholic belief be suppressed.

Censorship of Reformist teachings and propaganda was not the only example of an altered relation between the Catholic church and the art world. The rise of capitalism in Europe created new markets for art and thus eroded the ability of the Church to use its patronage to dictate artistic standards [see Clapp (1972, pp. 63, 65)]. One of the first paintings to cause scandal in this era was the *Sacra Conversazione* by Giovanni Battista Rosso, painted in 1518. The painting was a departure from the serenity of the classical style; and the Santa Maria Novella in Florence, for which the painting was made, refused to accept it [Bazin (1969)]. The sculptor Pietro Torrigiano was brought before the Inquisition in 1522 for sacrilege after smashing a statue of the Virgin Mary in protest against the small payment offered for the work. He starved himself to death before he could be executed [Clapp (1972)].

The depiction of nudity had been a problem for the Church from its earliest days, when Christians had denounced the “decadence” of Greek and Roman art. The Second Council of Nicaea required all adult persons depicted in pictures to be clothed, with limited exceptions for Jesus, the apostles, and angels [Carmilly-Weinberger (1986)]. During the Renaissance, admiration of classical civilization led to increased depiction of nudity in art, placing art on a collision course with Church doctrine. The Council of Trent in 1563 decreed that nudity in religious art was to be avoided in all cases, even where nude depiction was consistent with the Biblical record. Under the direction of Girolamo Savonarola in 1498, the “Bonfire of Vanities” in Florence consumed many paintings and sculptures [Carmilly-Weinberger (1986)]. Other incidents in this

<sup>1</sup> Luther’s own views were more moderate than some of his followers. When supporters were destroying paintings in Wittenberg, Luther stopped them with the statement, “Do not suppose that abuses are eliminated by destroying the object that is abused” [Carmilly-Weinberger (1986, p. 20)].

period included papal condemnation of *Sonetti Lussuriosi*, illustrated copies of which showed various positions for engaging in sexual intercourse [Clapp (1972)]. Controversy erupted even over Michelangelo's *Last Judgment*, the fresco in the Sistine Chapel above the altar, completed in 1541. Michelangelo's previous use of nudity in such works as *David* was accepted as representing heroism, but the nudity in the *Last Judgment* was described by a papal official as "shameless" and "better suited to a bathroom" [Clapp (1972, p. 60)]. In 1558 Pope Paul IV ordered that draperies be painted over portions of the *Last Judgment* [Clapp (1972)]. Even fellow artists joined in the censure; Pietro Aretino, the very author whose *Sonetti Lussuriosi* had been censored by the Church, wrote Michelangelo that the "licentiousness" of the *Last Judgment* made him blush [Clapp (1972, p. 61)]. Several years later El Greco recommended to the Pope that the work be destroyed [Bazin (1969, p. 145)]. Although the Pope did not accept the recommendation, he did order that more draperies be painted over the nude figures in the painting [Clapp (1972); Bazin (1969)]. Many other paintings and sculptures also suffered the indignity of having genitalia concealed by fig leaves [Jones (2001, vol. 3, p. 2059)].

Nudity to one side, the Inquisition kept a watchful eye over signs of heresy in art, though the actual prosecution of painters by the Inquisition was rare [Kaplan (1997)]. Andrea Gilio da Fabriano in his book *Dialogo Degli Errori Dei Pittori* criticized Michelangelo's *Last Judgment* for non-conformity with church regulations because, among other departures from orthodoxy, Jesus was depicted as unbearded and standing, instead of sitting on his throne; angels were represented without wings; and the Apocalypse angels were shown standing next to each other instead of at the four corners of the picture. In 1573 Paolo Veronese was summoned before the Inquisition in Venice for his painting *The Last Supper in the House of Simon* because he had added uncanonical details to a theologically sensitive subject. The inquisitor Aurelio Schellini was especially critical of the figure of a servant with a bloody nose, which he thought made light of the Eucharist [Bazin (1969); Kaplan (1997)]. The inclusion of German soldiers and a dwarf in the painting also drew the inquisitor's ire [Kaplan (1997)]. Yet the Inquisition was satisfied by Veronese's merely changing the title of the painting to *Feast in the House of Levi* [Jones (2001); Kaplan (1997)].

### 2.2.3. The censorship of music

Censorship of instrumental (non-vocal) music is rare, though not, as one might suppose, non-existent. Plato urged that music that appealed to the baser instincts should be censored. Centuries later, this view would be adopted by the Christians. St. Clement of Alexandria wrote against pagan music: "It must be banned, this artificial music which injures souls and draws them into feelings sniveling, impure and sensual . . . One must not expose oneself to the powerful influence of exciting and languorous modes, which, by the curve of their melodies, lead to effeminacy and infirmity of purpose" [Jones (2001, vol. 3, p. 1654)]. The association of pagan music with decadence was reflected

at the Second Council of Nicaea, which warned: “Woe on those who drink their wine to the sound of lyre and harp.”

After Christianity became the official religion of the Roman Empire, musical instruments were banned in worship. Saint Augustine of Hippo explained this ban as distancing Christianity from the “sensual heathen cults . . . and shameless performances of the degenerate theatre and circus” [Jones (2001, vol. 3, p. 1654)]. The ban persisted until 670, when the organ was permitted to be played at the Eucharist. But in the Eastern Orthodox church the ban persists to this day.

### 2.3. *Censorship in the East*

#### 2.3.1. *Islam – painting as blasphemy*

Islam was and still is far more hostile than Judaism and Christianity to artistic freedom, though there is variation within different branches of Islam. In addition to the prohibition of idolatry, Islam prohibits the representation of the human figure. The human form is regarded as the creation of Allah, and the depiction of it is therefore considered a divine prerogative [Arnold (1965)]. *Traditions of the Prophet* quotes Mohammed as saying “those who will be most severely punished by Allah on the Day of Judgment are the painters” [Clapp (1972, p. 33)].

Given such strict prohibitions, portrait and other painting in Islamic countries were and remain rare. Islamic artists focused their creative energies on calligraphy and ornamentation, where they faced few constraints [Papadopoulo (1979)]. Arabesque ornamentation, where human and animal figures are blended into the designs, was generally acceptable to religious authorities.

Art in defiance of religious teachings existed surreptitiously, aided by the lack of a central religious authority to dictate and enforce religious orthodoxy. Emperors and sultans had portraits and murals painted in the privacy of their palaces [Arnold (1965)]. Such art was sometimes destroyed by their successors. In about 869 the Caliph Al-Muhtadi ordered all paintings in his palace to be destroyed [Arnold (1965)]. Later, Sultan Firuz Shah issued an order to destroy not just paintings, but all ornaments, including those on the smallest objects, such as cups and curtains [Carmilly-Weinberger (1986)].

#### 2.3.2. *China*

The Chinese seem not to have been overly concerned with pictures; the written word was considered far more important in a society where literary skills were the key to high office. Art was influenced by Imperial tastes, because various emperors were great patrons of art, especially during the Han, Tang, and Sung dynasties [Carmilly-Weinberger (1986)]. Emperor Hui-Tsung of the Sung dynasty, himself a painter, assembled an art collection of more than 6000 pieces, with Buddhist themes especially prominent. He kept tight control over the painters at Court, dictating the subjects to be painted and

even giving artists examinations. The Emperor especially disliked the landscapes of Mi Fei, a master whose specialty was using blobs of ink in place of drawn lines. This radical technique was banned at the Court [Sullivan (1967)].

By the Ming dynasty, political concerns had found their way into visual art. The use of certain colors was proscribed to ordinary artists, being reserved for the Imperial Court. Painters were executed for insulting the emperor in their art, or dismissed from the Court for lesser offenses [Carmilly-Weinberger (1986)].

Comparatively few pieces of Chinese art have survived. Frequent wars took their toll, such as the Civil War of 190 A.D. that destroyed the collection of the Han emperors, and the Mongol conquest of 1279 that destroyed Hui-Tsung's collection [Carmilly-Weinberger (1986)]. Also, the materials used for Chinese art, such as bamboo, silk, and paper, failed to withstand the ravages of time.

### 2.3.3. Japan

The Tokugawa shogunate, which came to power in 1603, enacted strict censorship laws and exercised considerable control over the production of both woodblock prints and printed books. In Japan during this period the government's emphasis on education led to a dramatic rise in literacy, but woodblock prints remained a powerful instrument of mass communication that was believed to require rigid state control.

The Neo-Confucian ideology of the shogunate insisted upon a plain, strictly moral lifestyle. Though individual members of the ruling warrior class failed to satisfy these lofty aspirations, it was the self-indulgent consumption of the merchant class, whose economic power was steadily growing, that was seen as a threat to the established order. Tokugawa regulation of woodblock prints kept a watchful eye for political subversion and also censured sexual impropriety and excessive luxury.

The sensitivity of political subjects in art was reflected in the prohibition on portraying the Tokugawa family, the hereditary dictatorship that ruled in the name of the emperor, even in the most flattering terms [Thompson (1991, pp. 32–33)]. Sexual and sumptuary restrictions were more loosely enforced. Edicts in the 1720s banning erotic prints, a popular form of woodblock print, were ineffective; erotic prints continued to circulate, although without the signatures of the artist and printer [Thompson (1991, pp. 44–45)]. The banned picture book *Hyakunin Joro Shinasadame* showed streetwalkers, but it was not the streetwalkers *per se* that caused the ban; rather it was depictions of the Empress in the same volume as the prostitutes [Thompson (1991)].

## 2.4. Morality and art in the nineteenth century

### 2.4.1. Victorian England

The Society for the Suppression of Vice, formed in 1802, was expressive of the religious morality of the period. Partly as a result of the Society's efforts, the Obscene Publications Act was passed in 1857 by Parliament, authorizing magistrates to confiscate any articles considered indecent or obscene.

During the same period photography was invented and soon there was pornographic photography. The Obscene Publications Act was used to attempt to suppress this development; a police raid in 1874 reportedly seized over 100,000 obscene photos. Because “obscenity” was not defined, the magistrates were left to exercise their individual judgment. Challenged to produce the confiscated “abominations” for inspection, the Chief Justice of England, the leading proponent of the Act, excused his refusal on the ground that they would shock the modesty of England’s peers [Paul and Schwartz (1961)]. Even those photos with acknowledged artistic merit could cause controversy. One photograph by the well known artist O.G. Rejlander had to be covered by a black drape when it was exhibited in Edinburgh because it depicted gamblers and prostitutes [Jones (2001)].

More traditional media were also subject to scrutiny. In *Du Bost v. Beresford* (1810), the court found the painting *Beauty and the Beast* libelous. This was followed in 1868 by the case of *Regina v. Hickland* (1868), which defined obscenity by reference to its likely effects on the imagination of the intended audience of the work.

The English theater, censored since its earliest days, remained under censorship until well into the twentieth century. Under the Licensing Act of 1937, the Lord Chamberlain was authorized to deny licenses to plays “as often as he shall think fit”, a standard that did not invite consistency.

#### 2.4.2. France

Censorship in art was commonplace in France from before the Revolution. Louis XVI had suppressed various works, such as Beaumarchais’ *Marriage of Figaro* and erotic paintings by Francois Boucher. During the nineteenth century, theater and printed images continued to be heavily regulated; prior authorization was required. The Cour Royale de Paris and the Tribunal d’Assises de la Seine destroyed more than 232 prints, engravings, and drawings deemed immoral or obscene [Carmilly-Weinberger (1986)]. But because the audience for paintings as distinct from prints was overwhelmingly the middle and upper classes, self-regulation of painting was permitted: the artists themselves were the censors. Their instrument was the artists’ jury of the Paris Salon. Though the first jurors were appointed by the government in 1800, after 1830 they were appointed by the Academie des Beaux Arts. Rejection of the work by the Salon jury was not final, however, because after 1863 the work could still be displayed in the Salon des Refusés. It is a testament to the artistic judgment or authority of the Salon juries that the stigma of rejection by the jury would often lead artists to withdraw their works from the market rather than display them in the Salon des Refusés.

One artist who had consistent difficulty with the jury was Auguste Rodin; he struggled with criticism and rejection of his “impressionist” sculpture. Another and greater artist repeatedly rejected by the Salon jury was Edouard Manet. Political considerations were no doubt predominant in the suppression of his *The Execution of the Emperor Maximilian* in 1869, Maximilian having been installed as Emperor of Mexico at the behest of Napoleon III. But other paintings of his, such as *Nana*, were rejected for their supposed sexual content. Manet’s greatest painting, *Déjeuner sur l’herbe*, was not only

rejected by the Salon jury but also caused a furor among viewers and critics when it was displayed in the Salon des Refusés in 1863, and fellow artist Odilon Redon recorded his private disapproval [Clapp (1972)]. Remarkably, Manet's *Olympia* was accepted by the Salon jury, but it had to be guarded by two policemen, and subsequently removed to a remote location, because of popular fury at its style and nudity. The objection, as to *Déjeuner sur l'herbe*, was not to nudity as such, but to the fact that Manet's nudes looked like prostitutes, yet were inserted in classical settings; for example, *Olympia* was a pastiche of Titian's *Venus of Urbino* – but Manet's "Venus" was depicted as a whore [Needham (1972)].

Rodin and Manet were of course not the only victims of Salon rejection. Gustave Courbet's *The Return from the Meeting*, a painting depicting drunken priests, caused such outrage that it was rejected on the order of the government despite Courbet's exemption from jury scrutiny as a past winner [Carmilly-Weinberger (1986)]. A devout Catholic later bought the painting just so that he could destroy it [House (1997)]. Similarly, Courbet's *Venus Pursuing Psyche in Her Jealousy* was rejected by the Paris Salon the next year because of its lesbian theme.

#### 2.4.3. Comstockery in the United States

Puritan morality had a strong impact on life in the United States from its earliest days. One of the first cases to involve obscene art was *Commonwealth v. Sharpless* (1815). The Supreme Court of Pennsylvania found the display of an obscene painting offensive to the morals and dignity of the community, and levied a fine.

Federal legislative efforts to stamp out immorality in art began with the Tariff Act of 1842, in which Congress authorized customs officials to seize and destroy imported "indecent, obscene prints, paintings, engravings, lithographs and transparencies".<sup>2</sup> The first case under this statute was brought the next year and resulted in the seizure of three paintings along with a shipment of snuff boxes [United States v. Three Cases of Toys (1843)].

The prohibition was strengthened in 1865, when mailing obscene books and pictures was made a criminal offense. The passage in 1873 of the "Comstock Act" [An Act for the Suppression of Trade (1873)] increased the penalties and extended the list of prohibited materials. Under this Act, Anthony Comstock became a special agent of the Post Office. A zealot for puritan morality and the suppression of vice, Comstock claimed to have destroyed nearly four million obscene pictures during his career [Cooper, Stark and Zaleski (1994)]. He founded the New York Society for the Suppression of Vice in 1873, which the New York Legislature empowered to search, seize, and arrest for the purpose of eradicating vice.

In one of the many cases in which he was involved, *People v. Muller* (1884), Comstock secured the conviction of August Muller for selling obscene photos; the court

<sup>2</sup> Prior to this, only Vermont had enacted an anti-obscenity statute [Brockwell (1994)].

ruled that a painting is obscene if it “is naturally calculated to excite in a spectator impure imaginations”. He was less successful in an 1888 case against the Knoedler gallery. Four days after Comstock raided the gallery to seize 117 pictures and engravings replicating works of French art, the *New York Telegram* displayed the seized pictures on its front page as a brazen challenge to Comstock. In the eventual court case against 37 of the seized pictures, the judge found that only two were objectionable [Clapp (1972)].

## 2.5. *Censorship in the twentieth century*

### 2.5.1. *Art in the Soviet Union*

At the time of the Communist Revolution in 1917, the exciting development in the Russian art world was futurism, a movement with political undertones and industrial themes. Russian futurists believed that industrialization would be the bedrock of a new social order and vowed to “fight with all our might the fanatical, senseless, and snobbish religion of the past” [Carmilly-Weinberger (1986, p. 121)].

Before the revolution, Communists had supported the futurist and cubist movements on the theory that these movements were a challenge to the bourgeois establishment. But after the Communist Party took power, their attitude changed. Art was reconceived as a method of bringing Communism to the masses. Lenin dismissed modernist art with a simple statement, “I have the courage to declare myself a ‘barbarian’. I am unable to consider the works of Expressionism, Futurism, Cubism and other ‘isms’ as the highest manifestation of artistic genius. I don’t understand them. I experience no joy from them” [Carmilly-Weinberger (1986)]. In order that art should serve Communism, works that did not further that aim had to be destroyed and new ones created. Many monuments honoring Tsar Alexander and others were destroyed during this period.

After Stalin took control of the Communist Party in 1924, the Soviet government tightened its grip on the art world. In 1934 Andrei A. Zhdanov, Secretary of the Central Committee of the All-Union Communist Party, declared that the Central Committee would henceforth promote the “exclusive practice of socialism realism . . . the depiction of reality in its revolutionary development”, i.e. Communist propaganda [Carmilly-Weinberger (1986, pp. 133–134)]. Artists who failed to comply with the dictates of socialist realism were persecuted and their works destroyed.

### 2.5.2. *Public funding of art in the United States*

The Works Progress Administration (WPA) inaugurated significant federal funding for the arts in the United States. The WPA’s Federal Art Project supported many artists during the Great Depression, funding more than 2500 murals, 18,000 sculptures, and 100,000 paintings. But government funding came with strings attached, and works promoting Communist ideology were censored under the program. Even without official censorship, individuals would censor their own art to fit the politics of the time. In

1933, Nelson Rockefeller had Diego Rivera's mural in Rockefeller Center destroyed because Rivera had refused to remove an image of Lenin from it.

As anticommunist emotion gripped the nation in the 1950s, the United States Information Agency canceled two government-sponsored art shows because some of the artists involved were pro-communist [Cooper, Stark and Zaleski (1994, p. 32)].<sup>3</sup> The State Department also canceled a traveling art exhibition organized under a cultural exchange program after conservative organizations denounced the exhibits as Communist propaganda. A leading force behind the State Department's action, Congressman George A. Dondero, urged artists' organizations to expel Communists and reward patriotic painters.

In recent decades, political controversy surrounding the arts have been rare.<sup>4</sup> Notable were the controversies that embroiled the National Endowment for the Arts (NEA) in 1989 over works of two photographers whom the NEA had funded, Robert Mapplethorpe and Andres Serrano.

Robert Mapplethorpe's photographic exhibition *The Perfect Moment* was accused of being obscene after the Corcoran Gallery of Art in Washington canceled the planned exhibition of his pictures shortly after the artist's death. When the collection was eventually moved to the Contemporary Arts Center (CAC) in Cincinnati, the Director of the Center was indicted on charges of promoting obscenity and using a minor in nude materials. The Mapplethorpe photos contained graphic depictions of homosexual and sadomasochistic acts and images of nude children. Among the photographs was one that showed a black man urinating into the mouth of a white man. Nonetheless, the defense of the CAC lined up an impressive array of artists and curators who testified to the artistic merits of Mapplethorpe's photography, and the defendants were acquitted.

Andres Serrano's *Piss Christ*, a photograph of a plastic crucifix immersed in a bottle of the artist's urine, caused even more controversy than the Mapplethorpe exhibition, and was eventually destroyed by a vandal in Melbourne, Australia in 1997. While no legal retribution befell the artist, the political fallout was considerable. Under the leadership of Senator Jesse Helms, Congress passed an Act to bar use of NEA funds to "promote, disseminate or produce materials . . . which may be considered obscene". When a court struck down this law as unconstitutional, Congress passed another law that required the NEA to consider "general standards of decency". Controversy briefly surrounded the NEA once more when artist Karen Finley challenged the constitutionality of the amended decency clause, but subsided after the Supreme Court upheld the statute [National Endowment for the Arts v. Finley (1998)].

<sup>3</sup> The two exhibitions were "Sports in Art" and "100 American Artists of the Twentieth Century".

<sup>4</sup> Though certainly not non-existent. Two well-known incidents in Chicago during the 1980s demonstrate the sensitivity of some political subjects. David Nelson's *Mirth and Girth*, an unflattering painting of former Chicago mayor Harold Washington, was carried off by a hostile alderman [Nelson v. Farrey (1989)]. A display by Scott Tyler at the School of the Art Institute of Chicago inviting visitors to walk on the American flag caused the Illinois legislature to cut the school's funding to \$1.

A recent funding controversy illustrates the difference between attitudes to art in the United States and those of continental Europe. The exhibit *Sensation*, a tour of the collection of Charles Saatchi, traveled from London's Royal Academy, to Berlin, then to New York in 1999. The collection has no shortage of controversial pieces, from a sculpture made from frozen blood to a shark preserved in formaldehyde [Needle (1999)]. But what caused a storm in London was a painting by Marcus Harvey, made up of prints from a plaster cast of a child's hand, depicting the child murderer Myra Hindley. The British tabloids roundly criticized the work, members of the Royal Academy resigned in protest, and it was damaged twice by vandals throwing ink and eggs. After restoration it had to be protected behind a layer of glass.

In Germany, the exhibit attracted some isolated protests [Art and offense (1999)], but there were no violent outbreaks or significant controversy [Fitzpatrick (2002)].<sup>5</sup> Its popularity proved such that the museum extended the exhibition for one month [Steiner (1999)]. When the exhibit came to New York, the Harvey painting attracted little notice. However, the Catholic League condemned a work by Chris Ofili, titled *The Holy Virgin Mary*, that depicted a black Madonna, surrounded by images of buttocks, with the addition of elephant dung. Mayor Rudolph Giuliani threatened to cut funding to the Brooklyn Museum over the matter, but was prevented from doing so by a court decision [Brooklyn Institute of Arts & Sciences v. City of New York (1999)]. A devout 72-year-old Catholic later breached security and smeared white paint over the Ofili work [Richards and Calvert (2000)].

The New York controversy had lasting ripple effects. The National Gallery of Australia canceled its planned exhibition of *Sensation* [National Gallery of Australia (1999)], and plans for a possible tour in Tokyo never materialized.

## 2.6. *Censorship of film*

### 2.6.1. *United States*

The motion picture was invented in the late nineteenth century but not developed until the twentieth. "Nickelodeons", stores where short films could be seen for a nickel, spread across the United States. Like photography before it, pornography quickly followed the development of the new medium and censorship followed closely behind. To forestall official censorship, the industry in 1909 formed the New York Board of Censors to evaluate films before public release. In 1915 this became the National Board of Censorship of Motion Pictures.

Though political censorship in the United States has historically been rare compared to censorship for reasons of morality, the development of film in the first half of the

<sup>5</sup> Not that Germans are unconditionally accepting of all art, a Berlin exhibit showing photographs of "chopped-up tin soldiers in SS uniforms who are being castrated by skinhead mutations" caused some visitors to walk out and others to vomit [Vallely (2000)].

twentieth century happened to coincide with a period of political turmoil. D.W. Griffiths' *Birth of a Nation*, an early film that featured many cinematic innovations, was highly controversial because of its sympathetic portrayal of the Ku Klux Klan. The failure of the National Board of Censorship to ban the film undermined the authority of that body. Some local censors, such as the Kansas State Board of Review, refused to approve the film, and the mayor of Minneapolis threatened to revoke the license of any theater that showed it. The Supreme Court of Minnesota upheld the ban [*Bainbridge v. Minneapolis* (1915)].

War also led to heightened political sensitivity. *The Spirit of '76* was censored in 1917, at the height of World War I, for its negative portrayal of the British during the Revolutionary War. The judge in the case wrote:

History is history, and fact is fact . . . At the present time, however, the United States is confronted with what I conceive to be the greatest emergency we have ever been confronted with at any time in our history. There is now required of us the greatest amount of devotion to a common cause . . . , and as a necessary consequence no man should be permitted . . . to do that which will in any way detract from the efforts which the United States is putting forth. [*United States v. Motion Picture Film "The Spirit of '76'"* (1917)]

After the end of the war, the nation's focus returned once more to morality in film. The Production Code was adopted in 1930. Initially it was administered by the Studio Relations Committee of the Motion Picture Producers and Distributors of America (MPPDA), which allowed filmmakers a fair degree of flexibility. But in 1933 the Catholic Legion of Decency led a nationwide boycott, and the film industry capitulated and appointed a Catholic layperson, Joseph Breen, to head the Production Code Administration (PCA) and enforce the Code strictly. Breen maintained an iron grip over the industry for the next ten years [*Jones* (2001)].

The PCA's authority was undermined in 1946 when after a dispute with the PCA over the amount of cleavage that could be shown *The Outlaw* was released without a PCA seal of approval but nevertheless enjoyed tremendous success at the box office. This story was repeated with *The Moon Is Blue* in 1953, when Breen refused to approve the film's sexual innuendo but audiences apparently didn't mind. The influence of the Catholic Church also waned. Since 1933, a condemnation from the Catholic League of Decency had spelled certain disaster [*Phelps* (1975)] – until 1953, when *From Here to Eternity* received a condemned rating from the Catholic Legion of Decency yet was approved by the PCA, won eight Academy Awards, and was a box-office success.

Competition from television put pressure on the movie industry to show what audiences could not see at home [*Asimow* (2000)], and the MPPDA lost some control over theaters after losing the antitrust case *United States v. Paramount Pictures* (1948). After successive changes to the Code, each more liberal than its predecessor, the PCA was abandoned in 1968 in favor of the new Film Code and Ratings Administration with a suggested rating system, shifting the burden of enforcement from the industry to theaters and individuals.

In addition to the self-censorship of the movie industry, the law of obscenity remains as a mechanism of official censorship.<sup>6</sup> In the early twentieth century movies were a constitutionally unprotected medium [*Mutual Film Corp. v. Industrial Commission of Ohio* (1915)]. Many cities and states maintained local censorship boards [see *Vieira* (1999)]. The Supreme Court reversed course in 1952 by ruling that movies were protected by the First Amendment [*Joseph Burstyn Inc. v. Wilson* (1952)]. Obscene movies, like other categories of obscene speech, remain unprotected. The debate has since been about what constitutes the obscene.

In 1957, the Supreme Court first announced a test for obscene speech; it was whether the dominant theme of the material appeals to the prurient interest of the average person applying community standards [*Roth v. United States* (1957)]. The Court replaced the Roth test in 1966 with a three-part test that involved asking whether the material

- (1) appealed to a prurient interest in sex,
- (2) was patently offensive because it affronted contemporary community standards, and
- (3) was utterly without redeeming social value [*A Book Named 'John Cleland's Memoirs of a Woman of Pleasure' v. Massachusetts* (1966)].

The issue whether a particular work was obscene returned again and again to the Court, which eventually began avoiding the issue. Between 1967 and 1973 the court reversed thirty-one obscenity convictions without opinion [*Curtis* (1986)]. During this period the lower courts became ever more permissive, as few works could be deemed to be “utterly” without redeeming social value.

The Supreme Court revisited the issue in 1973. In *Miller v. California* (1973) it articulated a subtly modified three-part test. The issues are now:

- (1) whether the average person, applying contemporary community standards, would find that the work appeals to the prurient interest,
- (2) whether the work depicts or describes, in a patently offensive way, sexual conduct specifically defined by state law, and
- (3) whether the work, taken as a whole, lacks serious literary, artistic, political or scientific value [*Miller v. California* (1973)].

This test remains the framework for testing obscenity under the First Amendment. As a practical matter, however, only child pornography is suppressed in the United States today, other than on radio and television (other than pay-TV).

### 2.6.2. *Europe*

In Britain, the British Board of Film Censors (BBFC) was formed in 1912 by the Kinetograph Manufacturers Association to preempt official censorship. Local authorities have given the BBFC's classifications legal force by conditioning cinema licenses upon

<sup>6</sup> Prohibitions against sedition and blasphemy are generally acknowledged as unconstitutional, given the Supreme Court decisions in *New York Times Co v. Sullivan* (1964) and *Joseph Burstyn Inc. v. Wilson* (1952).

a theater's agreeing to show only BBFC-certified films. Local authorities retain the power to accept or reject any BBFC classification or establish other conditions [Phelps (1975)].

Layered over this quasi-official regulation of films is the Obscene Publications Act, which in 1977 was amended to clarify that it covered the distribution of films. A jury now decides whether material is obscene under the Act as tending to deprave and corrupt. Thus a film may be banned from Britain by either failing to qualify for a certificate from the BBFC or by offending the Obscene Publications Act.

The German constitution contains a free-speech clause declaring that there shall be no censorship, but there is an exception for the protection of youth. And despite the constitutional right of free expression, the penal code retains the offenses of blasphemy and dissemination of obscenity [The German Penal Code (2002, 106, pp. 118–120)]. In practice, however, the only limits on pornography in Germany are for the protection of children [Jones (2001)]. An industry organization, the Spitzenorganisation der Filmwirtschaft (SPIO), operates like the MPAA in the United States as industry self-censor. Any film not certified by the SPIO is likely to be boycotted. Attitudes, however, vary greatly from the U.S., for the SPIO is tolerant of depictions of sex but prohibits anything that might offend diplomatic or religious sensibilities [Phelps (1975)].

The open display of pornography is technically illegal in the Netherlands, but such restrictions are widely ignored by both police and consumers, resulting in the ready availability of hard-core pornography [see “Controlling pornography” (1998)]. Belgium has never had an official censorship body [Phelps (1975, p. 242)], but unlike other northern European countries has a prudish culture that underwrites a great deal of de facto censorship. Danish film censorship for adults was abolished in 1969 [Media Council for Children and Young People (n.d.)]. Sweden has the oldest film censorship body in existence, the National Board of Film Censors (Statens Biografbyrå), established in 1911, but though the Board has the power to ban films, the power is rarely exercised [see Furhammar (2001, p. 5)]. In contrast to the UK and the U.S., the focus of the Board is on psychological damage to children from violence [see Furhammar (2001)]. Curiously, the film industry in Sweden has been among the defenders of the Board's continued role, citing the uncertainty that would arise from the abolition of censorship [see Furhammar (2001)].

Despite the generally liberal attitudes toward pornography on the continent, there have been movements to curtail pornography in both France and Poland, the latter of course a highly Catholic, conservative nation. In France, where television stations air a large number of hardcore films, the legislature recently raised the tax on pornographic films to 93 percent [Henley (2002)], and there are calls for banning pornography on television completely. In Poland, a sweeping antipornography bill was passed by the Parliament but vetoed by the president [Polish Porn (2000)].

### 2.6.3. Asia

The Japanese Criminal Code prohibits the sale of obscene materials. Primary enforcement has devolved onto the industry's self-governing body, Eirin, as well as customs officials in the case of foreign films [Alexander (2003)]. The censorship system is rigid but seemingly rather futile. The entertainment media in Japan are well known for sexual and violent content, including particularly graphic images of sado-masochism. However, until recently, all displays of the genital area of either sex in film were prohibited, and even today Eirin allows only limited display of genitalia [Pitman (1995)]. For example, Nagisa Oshima's film *In the Realm of the Senses* was explicitly pornographic, and though it was shown at the Cannes Film Festival the director was tried in Japan for obscenity although eventually acquitted. The rereleased version of the film restores scenes cut by the censor but still digitally scrambles images of genitalia [Alexander (2003)].

China has a strict censorship system, the ideological foundation of being the subordination of art to politics, as in Plato's Republic and the Soviet Union. A complex web of government agencies is involved in the regulation of film, including the Ministry of Culture, the Ministry of Propaganda, and the Ministry of Radio, Film, and Television. On its face, Article 35 of the Chinese Constitution confers an extremely broad right of free speech, but in practice this is extremely limited [Calkins (1999)]. Until 1996 individual censors had broad discretion to censor as they wished, resulting in such erratic decisions that film-makers agitated for a law that would clarify standards. The resulting law appears to have achieved little clarification, and films are banned for such vague crimes as depicting "low-class" themes or "bad ideas" [Korski (1996)].

Politics remains the paramount consideration in Chinese film censorship. *Temptress Moon*, a film with no shortage of sexuality and drug use, was banned primarily because the censors associated one character with President Jiang Zemin [Tung (1998)]. Popular Hollywood films such as *Independence Day* are banned because of their "American spirit" [Brent (1999)]. The strict censorship regime also, however, results in the suppression of depictions of nudity and vice in films.

## 3. Analysis: Offensiveness, artistic merit, and the law of freedom of expression

### 3.1. The problem of objectivity

As our historical account, sketchy as it is because of the vastness of the subject, should have made clear, the common element in the censorship of art is perceived offensiveness: when art challenges strongly held beliefs, usually of a political, ideological, moral, or religious character, there is pressure for censorship. Broader generalizations regarding the political economy of censorship of the arts are elusive. Reliable correlates of such censorship are difficult to identify. There is no robust correlation between democracy and censorship, or even between censorship and religion, since not all religions

are as prudish as Judaism, Christianity, and Islam, and there are considerable variations regarding the concept of the obscene in those religions. Moreover, sexual explicitness is only one of the grounds of censorship. About all that can be ventured with confidence concerning the causality of censorship is that the more offensive to the public at large or influential segments of the public an artistic depiction is, the more likely it is to be suppressed either by government or by public opinion inducing self-censorship. To dig deeper into the causality of censorship would require considering the social sources of concepts of offensiveness. Probably those sources can be traced to differences in the status of women, the role of the family, the political structure, and the regnant religion, but we have not tried to conduct such an analysis.

We emphasize “offensiveness” rather than “harm” because censorship of art is rarely based on a plausible causal linkage viewing a work of art, whether highbrow or popular, and engaging in antisocial behavior. The analytical and regulatory problem is that in a democratic, culturally and morally heterogeneous, society such as that of the contemporary United States, there is little agreement on what is offensive, and efforts to suppress offensive work are therefore strongly resisted by those who derive pleasure from it that is not overborne by a sense of its offensiveness and who consider it their right to pursue leisure activities that do not cause demonstrable harm to other people. We need to consider whether, if this is right, it implies that offensive art should get a lot or a little – or even no – protection from governmental interference, however that interference should be defined in this setting.

That the concept of offensiveness is not objective in a strong sense of the word has been illustrated throughout our historical narrative of censorship in Section 2 of this chapter, which demonstrated that concepts of the offensive are culturally specific rather than universal. That doesn’t mean that they are arbitrary, even though they vary not only across countries but also within the same country in different periods. They can probably, as we have said, be traced to social factors. At any given time in any given place, there might be such general agreement on what is offensive that there would be no issue of lack of objectivity. That lack becomes perspicuous only when, a culturally heterogeneous society such as that of the modern United States, one attempts to classify particular works as being “offensive” or when, conceding offensiveness, one claims that it is redeemed by artistic distinction – a move that anyway is convincing only to those who regard offensiveness and artistic distinction as compatible; “moralistic” critics of the arts do not.

Let us try to explore this idea of “objectivity” a little further, beginning with the question of “objective” artistic merit and moving from there to offensiveness. When one says that lead is heavier than aluminum or that an automobile is faster than a rickshaw, one is making a statement that can be verified by methods independent of the tastes or personal values of the people doing the verifying. A Communist, a nudist, a Jehovah’s Witness, and a follower of Ayn Rand will all agree on how to test such propositions and on how to interpret the test results. Such “observer independence” gives the propositions about lead and automobiles truth value. It is quite otherwise if we say that *Piss Christ*

has, or does not have, artistic value in the context of modern American (or, more broadly, Western) values.

The problem is not that artistic value is not a thing which a work either has or has not, for in this respect artistic value is no different from weight or speed, being like them an attribute or property rather than a thing. You don't take apart a Maserati and announce, "This is the carburetor and that is the speed". Similarly, *Piss Christ* is not a composite of urine, a bottle, a crucifix, a photograph, and artistic value. But while it is possible to make objective measurements of physical properties such as weight and speed, it is not possible to make such measurements of artistic value, because people having different values and preferences do not agree and cannot be brought to agree on how to determine the presence of that attribute or even how to define it. A moralistic critic such as Tolstoy might think that the most important question about *Piss Christ* from an artistic standpoint is its likely effect on belief in Christianity. A Marxist critic might agree, and might further agree with Tolstoy that *Piss Christ* would undermine that belief, yet they would disagree about whether this made the work good or bad. Even if everyone to whom judges are willing to listen agrees that a work has no artistic value, we know from historical experience that later generations may find such value in the work even though the artist's contemporaries did not. Conversely, a work highly valued in its time, or for that matter in later times, may eventually come to seem thoroughly meretricious.

Artistic value is something an audience invests a work with, and as the tastes of audiences change, so do judgments of artistic value. About all that can be said in a positive vein is that the longer a work is held in high repute the likelier it is to continue to be held in high repute. This is the "test of time" that Samuel Johnson, David Hume, and George Orwell thought the only objective test of artistic merit.<sup>7</sup> If, to take a concrete example, the Homeric epics are still being read more than twenty-five hundred years after they were composed, then chances are they will continue to be highly regarded for some time; their appeal is robust and resists cultural change.

So far, though, all we have established is an inductive generalization, not an explanation. We could try to figure out what such durable works as the *Iliad* and *Hamlet* and Raphael's Madonnas and *The Marriage of Figaro* and the "Ode on a Grecian Urn" and the Louvre's "Winged Victory of Samothrace" have in common and call that the key to artistic value. But this sort of thing has been attempted for millennia without success, and it now seems clear that the quest is a snipe hunt, so diverse are the durable works of the Western tradition. Conceivably we might identify a *necessary* condition of artistic survival – that a work have a certain "omnificance" or, less portentously, a certain ambiguity or generality that enables it to be taken in different ways in different times and places. But the distinction between a necessary and a sufficient condition is critical here, for we would not concede artistic value to every work that crossed some

<sup>7</sup> With special reference to the visual arts, see Ginsburgh and Weyers (2003). On the failure of other "objective" tests of artistic merit, see Victor Ginsburgh (2003).

threshold of ambiguity or generality. *Piss Christ* deals with a fundamental concern of humankind, religion, and does so in a distinctly ambiguous way, Serrano denied harboring any blasphemous intent and indeed claimed that the work is a Christian commentary on the debasement of religion in modern America. The work may have artistic or even moral value, and then again it may not; it may soon come to be thought a worthless bit of trash, though, since it no longer exists, the issue may have become quite academic. Yet if *Piss Christ*, existent or not, seems altogether too slight and ephemeral a work to have any chance of winning a secure niche in art history, let us remind ourselves that the common urinal that Marcel Duchamp exhibited, one of the *objets trouvés* of the Dadaist movement, has won such a niche along with Aretino's *Sonetti Lussuriosi* and Utamaro's erotic prints.

The conclusion to which we are driven is that ascriptions of artistic value or valuelessness to "works of art" – especially to contemporary works of art – are arbitrary. And likewise with offensiveness, another property of, rather than a thing found in, a work. *Piss Christ* is no more a compound of urine, a bottle, a crucifix, and offensiveness than it is a compound of urine, a bottle, a crucifix, a photograph, and artistic value. Again this property, offensiveness, is largely, perhaps entirely, a matter of public opinion rather than of correspondence to or causation by something that is observer independent, something akin to the forces that determine weight and speed in accordance with the laws of physics.

As we pointed out earlier, this is not a problem when public opinion is united, as perhaps it is over the offensiveness of certain particularly graphic or degrading types of visual obscenity. With specific reference to *Piss Christ* one might be tempted to argue that, while there may be no consensus on what is art, there is a consensus, in Western societies anyway, that the public display of excreta is offensive. Consensus is a highly fallible warrant of truth, yet we might grant it provisionally objective status, even when it is local and temporary – a consensus in our society today, although not in all others and perhaps not in ours tomorrow. But it is a mistake to suppose that there is a consensus concerning the offensiveness of public displays of excreta. If samples of diabetics' or addicts' urine, or the feces of sufferers from Crohn's disease or cancer of the colon were displayed at a medical convention, we would not think the display offensive, it is all a matter of context and purpose. The question of the offensiveness of *Piss Christ* is therefore connected to the question of its artistic value. Those who find the work artistically valuable will not be offended by the (photographic) presence of urine, which they will consider integral to the work's value, just as a display of excreta might be integral to medical training. Those who find the work blasphemous and barren of artistic value will consider the display of urine gratuitous and hence, given our culture's feelings about excreta, offensive. A few people may find the work both offensive and aesthetic, as many probably found Michelangelo's *Last Judgment*. Their judgment on whether *Piss Christ* should be suppressed will depend on how offensive, and on how aesthetic, they find it, and on their personal sense of the proper balance between art and insult.

### 3.2. The law

All our discussion of the difficulty of balancing the offensiveness of a work of (purported) art against its artistic merit would have little or nothing to do with law if law had its own values, if it were morally autonomous. But for the most part it does not and is not. The law that entitles the victim of negligence to collect damages from the injurer is parasitic on – has no life apart from – social norms concerning what is careful and what is careless behavior. The prohibition in the First Amendment against government's abridging freedom of speech and freedom of the press, these freedoms being broadly conceived to include artistic as well as political and scientific expression, is parasitic in the same sense on social norms concerning artistic as well as other "speech" values and offensiveness and other speech harms such as violence. A speaker who urges a mob to lynch a prisoner because his guilt is so plain that a trial would be a waste of time and money will be punishable for incitement to violence because the danger of the speech will be felt to outweigh its value in drawing attention to the problematic character of due process. But if instead he writes a book urging the masses to rise up and liquidate the bosses, he will not be punishable, because such books are thought to have some value and not to be very dangerous, although citizens of Communist states may want to dispute both points. If our society thought such books were dangerous, they would be suppressed. Practical considerations, rather than the text or the eighteenth-century background of the First Amendment, guide the application of the amendment to today's problems.

Certain forms of obscenity are considered by virtually everyone in our society (including many of the consumers of obscene works) to be completely worthless and highly offensive, and they are suppressed without much ado, although, it must be added, also without much success. But the consensus that condemns the extremely obscene does not extend to the class of works illustrated by *Piss Christ*, which are thought valuable and non-offensive by some, worthless and offensive by others, and worthwhile but offensive by a handful. If there is no objective way to arbitrate such a disagreement, what should the courts do? More broadly, what are the implications for law of the kind of cultural relativism that we are describing?

There are three possibilities, of which the first two reflect a desire to secure the certainty of the law at any price. The first is to forbid *any* governmental interference with "art", no matter how offensive the "art" is. This approach does not escape subjectivity entirely; rather, it pushes inquiry back a stage, to the question of whether the work in question *is* art (and also to what counts as governmental "interference"). If a work is sufficiently offensive, it is classified as obscene, and therefore as non-art. At the other extreme is the judicial-hands-off approach: Courts are the forum of principle, there are no principles to apply to questions of aesthetic merit and offensiveness, so let the political branches do what they want with these questions. Such an approach is likely to appeal to those who are especially protective of courts – who want the judges to shine and believe that the judicial escutcheon is tarnished when the judges mess with indeterminate questions such as artistic value and offensiveness.

The third possible approach, the intermediate or pragmatic, is to acknowledge that the problem of relativism, moral as well as aesthetic, is a general feature of American, and perhaps of any, legal controversy. Judges need not feel that they must shy off from judgment merely because the issues raised by offensive art are spongy. That's just the way things are in law; the nature of the legal enterprise ensures that judges will frequently find themselves wrestling with indeterminate questions because those are the questions least likely to be settled without recourse to lawsuits that have to be pressed all the way to the Supreme Court or to another high appellate court before the question can be answered. Judges struggle with such questions all the time yet somehow manage to retain that minimum of public respect which is indispensable to the effectiveness of a court system. They are unlikely to forfeit it if they venture – with appropriate caution – into the controversy that eddies around issues of value and taste in purported works of art.

The first thing to note about this venture is that although artistic value is largely, perhaps entirely, unknowable, there is little doubt that art is valuable. If this seems a paradox, consider: the lesson of history is that many of the scientific theories in which we firmly believe today are almost certainly false, just as Euclidean geometry as a theory of spatial relations, the geocentric theory of the solar system, the luminiferous ether, the spontaneous generation of bacteria, and Newton's laws of motion are now known to be false after having been believed by the scientific community for centuries to be true. Yet the fallibility of scientific theory does not lead a sensible person to doubt the existence, growth, or value of scientific knowledge. Even if every current scientific theory is someday falsified, we will still be able to make atomic bombs, fly airplanes, and immunize people against polio. Likewise it is a fact that art museums are thronged, that works of art command huge prices, that some people devote a lifetime to the study of art, and – more to the point – that many people would feel a profound sense of deprivation had the nineteenth-century French artistic establishment succeeded in suppressing Impressionist art, just as they feel that the world is a poorer place because so little classical Greek sculpture has survived.

If we grant that art has value and add that the censorship of art has a dreadful historical record, we can derive, in order to guide judicial review of controversies over offensive art, a presumption in favor of letting the stuff be produced and exhibited to whoever is willing to pay the price of admission. The Supreme Court's decisions affirming the constitutional right to burn the American flag as a form of political expression is illustrative here. Burning a nation's flag is an offensive, inarticulate, and immature mode of political communication, but as long as one is burning a flag that one bought and paid for, and burning it before a willing audience, the burning contributes, however feebly, to the marketplace of ideas without impairing anybody's property rights – though many people will be offended.

We can bolster the presumption in favor of a permissive judicial attitude toward offensive art by noting that the “test of time”, which is the closest we seem able to get to an “objective” measure of artistic merit, presupposes, like natural selection in the theory of biological evolution (which the test of time resembles), the existence of variety,

from which history makes its selections. The thrust of censorship is to reduce variety, to suppress outliers, and by doing so to disrupt the test of time and impoverish art's legacy to the future.

Consider now a case in which the presumption in favor of freedom of artistic expression was successfully rebutted. *Piarowski v. Illinois Community College* (1985) involved a small junior college near Chicago that, being public, was subject to constitutional limitations on restricting free expression. The artist in the case, who was the chairman of the college's art department, made an improbable effort to fuse his two loves – the making of stained-glass windows and the art of Aubrey Beardsley – by creating stained-glass versions of some of Beardsley's illustrations from Aristophanes' comedy *Lysistrata*. The illustrations, like the comedy, are bawdy even by today's standards (how fitting that they should be on public display in the Victoria and Albert Museum in London). They are, of course, line drawings of white men and women – Greeks. But to transpose the drawings to the stained-glass medium the artist used pieces of colored glass for each of the figures, and the colors had to contrast, and he made the innocent but, as it turned out, unfortunate choice of amber glass for the women and white glass for the men. As a result, one of the stained-glass windows depicts a brown woman, naked except for stockings, on her knees, embracing in an attitude of veneration the huge white phallus of a robed man. The other two stained-glass windows depict brown women passing wind and masturbating, respectively.

The artist displayed the stained-glass windows in the art department's annual exhibition of faculty work, held in an alcove (the "gallery") off the main corridor of the college (the "mall", as it is called), on the ground floor. As the college had only one building, the exhibition was visible to all students, faculty, and visitors, whether or not they wanted to see it – there was no wall between the gallery and the mall. The first group to complain was the cleaning staff, which was black. Most of the students in the college are black, and they, too, were offended by the stained-glass windows and complained to the president of the college, who ordered the artist to shift the display from the first floor corridor to a smaller exhibition room on the fourth floor, a room normally used for exhibiting photographs but suitable for exhibiting other works of art as well. When the artist refused, the president took down the stained-glass windows and placed them in his office. The artist sued the college, charging a violation of the First Amendment.

The stained-glass pastiches seem largely free of both artistic value and offensiveness. On the one hand, Beardsley's charm is in the line, and it is lost when lines give way to chunks of colored glass. On the other hand, there was no contention that the artist was attempting a commentary on race or sex; he was merely trying to use different colors, vaguely human, to distinguish the figures in the windows from one another. The very crudeness of the windows, moreover, neutralizes any obscene impact. A "hands-off relativist" might take the position that since issues of artistic and moral taste are not objective, the artist should have lost his suit even if the college had refused to allow him to exhibit his stained-glass windows anywhere on (or for that matter off) the campus. This was not the court's view, but neither did the court think the Constitution *entitled*

Piarowski to exhibit his stained-glass windows in the most public place in the college. The college's president had offered an alternative place of exhibition that while indeed less conspicuous was by the same token less offensive. Consider how many great works of art, such as Manet's *Olympia* and *Déjeuner sur l'herbe*, survive today probably only because they were denied the most conspicuous places of exhibition. Racial sensitivities are a fact in our society, and if offensiveness ultimately is no more objective than artistic value, neither is it less so.

The college president's action seemed a reasonable compromise, and the court gave judgment for the college. In so doing, the court affirmed that "academic freedom" is a two-way street. It is the freedom of a college to manage its affairs without undue judicial interference no less than it is the freedom of the teacher or scholar to teach or write or, in this case, create works of art without undue interference by the state (for remember that this was a public college, and hence an arm of the state). A further point is that the power of a single junior college to affect the art scene by shunting offensive works to less conspicuous places of exhibition is distinctly limited. But the example might prove catching.

So particularistic and fact-specific – so pragmatic – a mode of adjudication that led to the judgment for the college, and one that implies that the scope of First Amendment protection may be different for works of art than for political or scientific works, is not to everyone's taste. Lawyers have a predilection for rules, and there are many situations in which hard-edged rules are indeed preferable to fuzzy standards. But controversies over offensive art may not be one of them. It is not even clear that art would be helped rather than hindered by a rule that forbade any and all public regulation of offensive art. Such a rule – a rule that gave privileged status to the flaunting of offensive art – might engender public hostility to art that would be out of all proportion to the benefits in artistic freedom gained. At the same time, a rule that gave government carte blanche to suppress art deemed offensive by any vocal, assertive, politically influential group in a diverse, teeming, and rather philistine modern society, such as that of the United States, could impair the future of art, a costly consequence. Perhaps, therefore, the watchword in the legal regulation of offensive art should be caution.

\* With deep thanks to my colleague, Sue Anne Batey Blackman, for her contributions to this chapter. When the editors of this volume invited me to prepare this piece, they suggested a grand evaluation of what the field of arts economics had accomplished, what work was currently under way and what most urgently still needed to be done. Though my longevity in the field appears to make this an appropriate assignment for me, the work has already been carried out with exemplary competence, notably in a well-known piece by David Throsby (1994), in a more recent article by Mark Blaug (2001), and, by implication, in the superb compendia edited by Ruth Towse (notably 1997), as well as the writings of Alan Peacock (e.g., 1992), and Bruno Frey and Werner Pommerehne (e.g., 1989). Evidently, the ground is well covered and there is no urgent need for yet another entry.

**Abstract**

The revolutionary growth in economic prosperity and technological change that underlie the “new economy” have profoundly affected the arts. They have evidently contributed new and previously unimaginable methods of dissemination and preservation. But they have even had revolutionary effects on goals and standards. They have substantially affected training. These developments also raise profound problems for financial support and pricing. The paper characterizes these developments and suggests the nature of the relationships. It also provides a brief discussion of relevant pricing principles dealing with the trade-off between encouragement of creativity and facilitation of dissemination.

## 1. Introduction

The “new economy” – whose hallmark is extraordinary technological change – is a very real phenomenon, one whose manifestations and consequences are so mind-boggling that we have had to readjust ourselves to it by a complete revision of expectations. As a consequence, we have simply grown to take it for granted. But in my view it is not something that began only in the second half of the twentieth century. Rather, the unprecedented world of the new economy emerged perhaps some two centuries earlier and has since been accelerating at a dizzying pace. The available historical statistics, such as they are, suggest that by the eighteenth century real per-capita incomes barely exceeded those of Imperial Rome, which translates on average into more than 1500 years of near-zero growth. Then in the 18th century per-capita incomes in England rose some twenty or thirty percent. Nineteenth century incomes increased 100 to 200 percent in much of Western Europe and the US. As for the 20th century, it has been argued by knowledgeable observers that the oft-suggested 600 or 700 percent rise is a gross *underestimate*.

What has this extraordinary growth in economic wealth to do with the arts? The answer is that it has brought with it opportunities, capacities and *problems* that our ancestors could never have imagined. One writer on the accomplishments of the “new economy” (in my broad, longer-period connotation) has cited as a characteristic example the fact that before the 18th century no one had ever dreamed that a person could travel faster than on horseback, much less communicate across oceans instantaneously.<sup>1</sup> For the arts, it is easy to provide examples of comparable wonders: Today we can readily experience (somewhat imperfectly) a performance by Caruso, and I have heard the voice of Johannes Brahms.

Thus, economic circumstances powerfully influence both innovation and the arts. The state of the economy cannot produce creativity, but it can stimulate the exercise of creativity and facilitate dissemination and utilization of its products. On the other side, economic conditions can starve and otherwise handicap creative activity and condemn its products either to very limited use or even to oblivion. Clearly in the case of innovation – interpreted in Joseph Schumpeter’s sense to encompass the entire innovative process from the birth of new ideas to the full utilization of their products – the market economy has produced an outpouring of novel products and processes not remotely paralleled in any other form of economic organization.<sup>2</sup> And the new economy has undoubtedly affected the arts by stimulating technological developments that have even served to create new art forms. But it has also revolutionized the means of dissemination

<sup>1</sup> This is not quite true. There were dreamers who went beyond what was known. As early as the 13th century Roger Bacon, in a remarkable and much quoted passage, had foreseen a future that provided ships and wagons driven by machines that would move “. . . with incredible speed and without aid of beast, flying machines . . . [and machines that] make it possible to go to the bottom of seas and rivers” [quoted in White (1962, p. 130)].

<sup>2</sup> See further in Baumol (2002).

and the options for preservation and has influenced the amounts and sources of funding of the arts. Most obviously, the new economy has surely freed artists from dependence on royal and noble patronage and led them to turn for funding to perhaps equally risky new sources, including the marketplace.

I will focus here on two general subjects: the influence of technical innovation on the arts, and the consequences – actual and prospective – for the arts' ability to obtain funding in the marketplace. In particular, I will deal with several themes, including changes in the general orientation of the arts, their dissemination and preservation, and the compensation of artists. My discussion of the last of these topics will perhaps be the most substantive. That is because funding, pricing and other associated matters are most squarely in the terrain of the dismal science, and so lend themselves most easily to its analytic ministrations.

## 2. Technical innovation and its effects on the arts

### 2.1. Artistic creation and "modern art"

Patently, the attributes that most fundamentally characterize developments in the arts that have accompanied the new economy are exploration of the abstract and pursuit of the unconventional. And though some may consider the hypothesis outrageously philistine, it is at least plausible that these reorientations were initially stimulated to a considerable degree by technological developments. Is it so plainly untrue that the introduction of photography helped to undermine the pursuit of accurate or at least persuasive representation of reality in the visual arts? Even if the availability of photographic images did not lead artists directly into seeking other directions, surely the market must have driven them to new orientations by depriving them of purchasers – those clients who were no longer so anxious to pay for handmade and reasonably accurate depictions of reality, notably in portraiture.

Developments in other art forms such as discordant and atonal music, unconventional writings like those of James Joyce or Gertrude Stein, and modern dance forms introduced by Isadora Duncan and Martha Graham surely only followed in the wake of the first radical departures in the visual arts – the Impressionists, *les fauves*, the secessionists and their ilk – whose success in *épatant le bourgeoisie* must certainly have served to invite the practitioners of the other arts to follow. Evidently these remarks are a vast oversimplification; yet it surely cannot be a pure coincidence that the determined effort of creative artists to break so radically with their past seems totally unprecedented. There is apparently no parallel before the industrial age, which heralded the beginnings of the new economy. Of course, much of what I have said so far rests purely on conjecture and casual observation. This means that it merits no more than acceptance as a hypothesis that can serve as a subject for research by cultural economists. Technology's stimulus of artistic reorientation can probably never be determined by formal research methods and objective evidence, though there is much here that can be studied and

tested. And the subject is surely significant, for what is at issue is what may well prove to be the most dramatic example of the influence of economics on the orientation of the artist.

But there are other forms of reorientation in the artistic media themselves. The new economy has provided artistic creation with new tools, some of them already profoundly affecting what artists can do, some offering promise for the future. The introduction of motion pictures, for example, has played a significant role in the creative process, in addition to its enormous contribution to dissemination and preservation. As is widely recognized, a screen performance has fundamental differences from a performance on the stage. A straightforward film of a staged play usually constitutes uninspired cinematography. Moreover, film provides a rich menu of possible new approaches, and the history of the cinema provides a multitude of well-recognized examples. The cinema really is a new art form that had to be thought through and mastered. Arguably, many decades of cinematic creation were required before those engaged in the activity began to see its possibilities clearly and learned how to act on them. Television was a clear runner-up.

And there are more-radical breaks. Composers such as Milton Babbitt now regularly create works to be performed by electronic instruments such as the synthesizer guided by the computer. Indeed, there have even been experiments in composition using computers as the composers. Painting in which the computer serves as the medium is now widely available and promises to open roads to new directions. Computer painting and graphics open up vast possibilities, though it may be argued that up to now these media have exercised rather more control of the artist than the artist has been able to exercise over the media. Computers can now also be used to compose and guide the performance of intricate lighting design for the dance. Choreographer Mimi Garrard and visual artist James Seawright, for example, have created a powerful program for this purpose. Undoubtedly, all these are only beginnings, and there are in prospect artistic instruments and art forms that we have not yet imagined.

## 2.2. *Dissemination*

### 2.2.1. *Availability of the arts to consumers*

Printing with movable type (as invented belatedly in Europe) is generally recognized as a revolution in the dissemination of ideas and ultimately of literature. But while it has been credited with having become in relatively short order a stimulus for upheaval in religion and politics, its speed in making reading matter widely available was considerably less than is generally realized. The early books produced with movable type were hardly inexpensive, and since the vast bulk of the population was illiterate, printing's initial role in the spreading of writings was severely circumscribed. In any event, the printed page was not inherently different from the page produced by a medieval scribe. The difference was only (!) that once one produced a single printed page, it became

relatively easy to provide many others (and to do so without a successive accumulation of copying errors).

But from the 19th century on, there have been revolutions in artistic dissemination that faced far fewer constraints and that, in terms of their break with the past, were even more dramatic. Recordings, film, radio, television, and now the Internet, have produced magical change – total breaks with anything known in the past. Yet the speed with which we have come to take almost for granted these mass media and the new means of communications is itself impressive. Of course, many people do not yet have access to the Internet, but even in remote villages in inaccessible geographic locations movies are shown and people gather round the community's television set. Telephone service, too, has penetrated widely, and machines for the playing of recorded music are available. This evidently means that music and drama are obtainable as never before, and in ways that constitute a complete change from past experience.

When a Renaissance monarch was negotiating for a bride, he could demand a likeness prepared by a painter, and would obtain one that had taken weeks to produce, perhaps weeks to transport, and was probably an idealized version of the subject. Today, the ways around these difficulties are many and obvious. As one economist has remarked as an illustration of the point, "Could Thomas Aquinas have . . . dispatched [a letter] to 1000 recipients with the touch of a key, and begun to receive replies within the hour?"<sup>3</sup> These new means of communication are not only able to transmit the written word. They bring music, paintings and photographs to particular intended recipients or they can be broadcast to the world. Not only are announcements of art exhibits in distant places readily available, the Internet user may be able to download reproductions of some of the exhibited items. And, from anywhere in the world, the armchair art enthusiast may now view art collections like the Tate Gallery (<http://www.tate.org.uk>), and even take a virtual tour of the Louvre Museum (<http://www.louvre.fr>). A personal example is constituted by my own recent paintings, executed entirely on the computer and posted on my web page, which regularly elicit comments from China and elsewhere from people I do not know.<sup>4</sup>

Why spell out these observations, when I am well aware that any reader of this piece will already know all this? There are two reasons. First is the fact that these incredible developments have become so commonplace, if not quite totally banal. Second is the more obvious observation that the new economy has, indeed, made all forms of art accessible to a degree beyond anything previously experienced. This is clearly a benefit to the creative artists, who surely do not want have their works ". . . born to blush unseen and waste [their] sweetness on the desert air".<sup>5</sup> But at the same time the explosion in the dissemination of the arts is the source of serious difficulties that threaten to exacerbate significantly the unceasing economic problems of the arts, as I will discuss later.

### 2.2.2. *Artistic products in international trade*

Not only do economic and technical influences affect the arts, but the arts have achieved a new and expanded role in the economy – the relationship has become a two-way street. Rather than being the almost exclusive preserve of a narrow privileged group, the arts have expanded in the consumption patterns of society as a whole. Their contribution to GDP and to employment has evolved, and their role in other arenas has evidently changed as well, sometimes markedly. The dissemination revolution has been one of the foundations of these developments, most strikingly shown by the emergence of artistic products as significant elements in international trade. It used to be understood with good reason that only agricultural and manufactured products lent themselves readily to international exchange. An artistic activity such as the performance of drama or orchestral music is neither a manufactured nor an agricultural product. Neither medical examinations nor haircuts supplied in the UK are readily consumed by the inhabitants of Los Angeles, and so for a similar reason it used to be true in the nineteenth century that the New York Philharmonic Orchestra felt itself under little competitive threat by an orchestra whose home base was Berlin.<sup>6</sup>

Matters have now changed for many of the services. For example, engineers in Seattle may now email the specifications for a new product part to New Delhi, where the blueprints will be drawn up within 24 hours and transmitted instantly, again via e-mail, to a manufacturing plant in Ireland. But it is in the popular art forms that the most dramatic manifestation of this change is to be found. Though these activities could surely have been no more than a flyspeck in the national economic accounts of the US in the 19th century, nowadays via the vast “entertainment” universe – including movies, videos, television programs, sound recordings, computer software, and the publishing industry – the popular art forms constitute an important economic activity. They are now a principal US export – with revenues from foreign sales reported to be somewhere between about \$25 billion [US Census Bureau (2003)] and \$85 billion [International Intellectual Property Alliance (2002)], depending on the definition of the scope of this sector. Indeed, the very substantial competitive incursions made possible by easy dissemination of these art forms have become a contentious and much publicized political issue in a number of countries. It is felt that cultural exports, particularly from the US, threaten native artistic activities and undermine distinctive local culture and its traditions. The response has sometimes been the adoption of quotas that affect both performance and imports.<sup>7</sup> But for the issue under discussion here, these competitive incursions constitute clear testimony to the degree to which the new economy has been able to modify the role of the arts in the economy.

<sup>6</sup> Still, one must make such statements cautiously. It is noteworthy that what has been described as the worst riot in the history of New York City occurred in 1849 in Astor Place near Broadway and caused widespread injury and property damage. It involved a battle between the partisans of two popular actors, one American, the other British, performing in theaters located near one another.

<sup>7</sup> See further in Chapter 33 by Acheson and Maule in this volume.

### 2.3. *Preservation*

The broadly interpreted “new economy” has evidently also changed preservation of the arts beyond anything previously experienced and probably beyond anything previously anticipated. This was in fact brought out by the example mentioned earlier: the revolutionary role of sound recording. We presumably never will have any clear idea of what medieval song really sounded like, and can only make surmises about some of the improvisation and ornamentation in 18th century musical performance. We do not know how Elizabethans pronounced the English language, despite clever conjectures from what must ultimately be shaky evidence such as rhyme in 16th and 17th century English poetry and current speech patterns in relatively isolated communities. Certainly, we have little idea about how a contemporary performance of *Macbeth* would have sounded.

Worse yet, there were creative products that were rendered completely ephemeral by the absence of means of preservation. The works of 19th century choreographers clearly do not survive except via tradition whose modifications and evolution one cannot readily evaluate. Film and the invention of dance notation have since changed all that. There are, of course, limits to what film can describe of an activity in which three dimensions are so fundamental. But if the new forms of preservation cannot tell us everything, they can at least give the viewer a good idea of earlier practices, and can offer enough information to later choreographers to permit them to do a reasonably good job in reconstructing the work of their predecessors.

The computer and the accompanying developments of storage capacity have done far more. There is now virtually no effective limit to what can be taken into the world’s collective cultural memory. The contents of entire libraries can be transferred to minuscule recording media. More and more works of art are preserved in some image form, so that nowadays when a painting turns out to be missing, its likeness is nevertheless apt to be readily available. The Mellon Foundation, under the leadership of William Bowen, is engaged in a major digitization project in remote areas of China, partly to preserve their inaccessible art works, partly as a demonstration project for others to undertake.<sup>8</sup> In sum, future “Seven Wonders of the World” will not be so readily lost, their configurations available only to frustrated conjecture as has been the case in the past.

### 2.4. *Funding problems and the cost disease*

The last of the influences of the new economy on the arts that will be discussed here is financial. Growing wealth in the industrialized nations may have facilitated the financing of the arts, but other influences have made it more difficult. For example, ease of

<sup>8</sup> However, the declaration of victory may be premature. Programmers have indeed invented fantastic methods that can store works enduringly in binary code. But computer programs are replaced and superseded with remarkable rapidity. It is not clear that in 50 years anyone will be able to read what we painstakingly store today. Specialists are deeply concerned about this problem, and have not yet provided a solution.

copying has made it harder in many artistic fields to recover costs and earn a living in the marketplace. Furthermore, given what I and my associates have perpetrated in the past in our writings on cultural economics, I will no doubt be expected to argue that it is primarily through the “cost disease of personal services” that the new economy creates financial problems for the arts. Taken at face value, this is indeed true; the cost disease asserts that, at least for live performance,<sup>9</sup> costs are expected to rise cumulatively and almost constantly, and surely that is the *bête noir* of the impresario and the producer. Yet, as will be argued below, the new economy brings both the disease and the means that enable society to deal with it. In other words, the cost disease is, and yet need not be, a primary concern for funding of the arts.

First, a few words on the relation of the new economy to the cost disease are called for. It is easily argued that without the advent of the new economy, in the broader sense in which I am using the term here, there would be no cost disease. It may be recalled that the explanation of this phenomenon lies in the pattern of productivity growth; the reason live artistic performance – like health care, education and other activities with handicraft attributes – suffers from the cost disease is simply that the growth in their productivities, i.e., their rate of labor saving, inherently tends to be markedly less rapid than that of other products in the economy. With their productivity falling behind, it is mere tautology that their relative real cost – that is, the relative input quantities they require – must be rising. If input prices throughout the economy are determined in markets that are at least moderately competitive, the relative monetary costs of those outputs must rise as well. Before the advent of the new economy, when productivity growth was truly negligible in virtually every economic activity, the differences in these growth rates hardly mattered. Thus, if there were any cost disease, it would have been a very minor disturbance that hardly merited attention. It is in the new economy with its unprecedented and accelerating growth that the issue becomes significant.

Happily, the nature of the source of the problem brings with it the means by which the effects of the disease can be dealt with. Even the activities that are beset by the disease generally benefit from *some* productivity growth, however modest. But if even these, along with most of society’s other economic activities, are experiencing productivity growth, it follows that the community *can* afford more of each and every one of its outputs, if it chooses to allocate its purchasing power appropriately. With more output per hour of labor in every field of endeavor, there is no necessity to cut back on the consumption of *any* of the products. It is only a sort of money illusion that tells us we must cut back on the arts (or health care or education). Thus, it is the new economy and its sensational productivity growth that presents us with the cost disease problem, and it is that very productivity growth that provides us with the means to cope with its consequences.

<sup>9</sup> It will also be recalled that the mass media are not generally immune from the disease, because the handicraft components of the activities entailed in their operation tend asymptotically to dominate their budgets. On this see, e.g., Baumol, Blackman and Wolff (1989, Chapter 6).

### 3. Pricing issues for the arts in the new economy

The profound upheavals in the circumstances of the arts under the influence of the new economy have to a substantial degree been favorable, making the arts easier to create, to disseminate and to preserve. But some of these developments also have another side that threatens to handicap rather than help the arts. These issues have been recognized and analyzed by economists, but there is an underlying structure to these problems that seems not to be universally recognized. It is best brought out by analogy with another side of the new economy: the important role of innovation and the problems of its financing.

It is not without reason that the term “innovative” is often used to describe a new piece of music, a recently published novel, or some other product of artistic endeavor. In music or dance or literature, a creative contribution has one inviolate attribute – it cannot replicate some previous work. Unlike the production of automobiles or shoes, in which identical products can be turned out in apparently endless succession, the choreographer’s efforts (like the research and development division of a firm) must provide creations, each of which differs significantly from each and every one of the other products in the arena. “Innovation is a heterogeneous product”, runs Baumol’s third tautology, and the tautology is evidently applicable to artistic production. Now, this requirement of heterogeneity is the source of a number of problems both for practice and for analysis. We are all aware of the complications it poses for value theory particularly in general equilibrium form, problems that have only begun to be dealt with in recent years. And it may be that such problems help to explain the paucity of formal theoretical analysis of pricing in the arts. Perhaps cultural economists working on these problems may conceivably find it helpful to turn for guidance to the growing literature on general equilibrium analysis of monopolistically competitive markets and the equally valuable literature in the theory of technical innovation.

#### *3.1. Repeatedly sunk costs and pricing problems*

But that is not the issue here, since my concern is more with practice than with theory. And from this point of view there are at least two critical issues. One is the public-good property of information, a property shared with many outputs in the arts, and the second is the role of sunk investment of a special sort – not the kind of once-and-for-all sunk outlay that economists quite rightly tend to ignore as irrelevant ancient history once it has been incurred. For in technical innovation as in artistic creation, the need never to replicate, or at least not to do so precisely, means that investment is required each time an output emerges. That investment is sunk in the production of that novel item. Thus in both fields the need to sink costs is inescapably a frequently repeated if not continual phenomenon. Moreover, it is a phenomenon that appears to have grown in magnitude in the new economy. The investments that are routinely incurred in the production of a new film or in preparation to launch a new television series dwarf anything previously experienced in live theater, at least in absolute magnitude. In the launching of a popular

song via CD, the size of the advertising outlay can also be staggering; the CD manufacturers and distributors complain that the production of a brief video publicizing the piece becomes a major cost component.

For the economics of these activities, repeatedly sunk costs are fundamentally different from the sunk costs more usually mentioned in the literature – those that are incurred only once, as, for instance, in the purchase of a license required to open a business enterprise. The economic literature stresses that such costs once incurred are irrelevant for current pricing decisions because by their nature it is now too late to do anything about them, even if management feels it has made a mistake in undertaking the outlays in the first place. If the firm does not subsequently earn the amounts required for recoupment, that is the investors' hard luck. But when sunk costs must constantly be repeated, they must be covered by current prices or by some other means – otherwise a profit-seeking firm will refuse to repeat the outlay when the time for it comes, and a non-profit enterprise will not be able to do so.

This normally means that prices in these fields can be expected to exceed marginal costs because, as will be noted again in the next section, neither increased use by current users nor an increase in the number of users requires any increase in the sunk outlays; that is, these outlays constitute no part of the marginal cost figures.<sup>10</sup> Even in the non-profit arts organizations we find that prices do often exceed marginal costs; for example, the price of a ticket to concerts by a performing group whose auditoriums are not filled to capacity will usually substantially exceed the virtually-zero cost of admission of another attendee. Indeed, in such circumstances discriminatory prices are frequently required to make ends meet. In the arts, such pricing typically takes the form of discounts to students, the elderly and other special groups, last-minute price reductions, and other familiar variants.

Of critical importance here is the relative magnitude of the sunk cost in comparison with the other costs. This is so because of the public-good property, which means that the sunk costs are not increased by additional use or additional users; in dance, for example, the effort that went into choreographing and rehearsing are not increased either by a rise in the number of attendees at a particular performance or by an increase in the number of performances. Hence, if the repeatedly sunk costs are very substantial relative to other costs, their recoupment will require prices that are well above the marginal costs.

<sup>10</sup> Clearly, repeatedly sunk costs are generally not considered by firms to be the same as costs sunk once and for all, but rather as costs of operation of the firm. That is, they cannot simply be disregarded by a profit-maximizing firm on the usual argument that they are no more than a piece of unchangeable and therefore irrelevant ancient history. Nevertheless, repeatedly sunk costs do not enter marginal costs, because they are not a function either of scale of output nor of number of customers. Thus, the cost of producing the sets of a stage play do not rise with an increase in attendance, at least up to the capacity of the theater, nor with the number of performances per week nor even in the number of performances in total (at least until replacement is needed).

This, in turn, gives rise to two other difficulties. The first is the classical problem of public goods: Even if such higher prices were feasible in the market, their welfare consequences are questionable at best. Higher prices discourage use – that is the economic role they serve in the presence of scarcity. But in goods with public-goods properties, the standard form of scarcity vanishes. A public good has the property of a Hanukkah oil lamp, kept continuously alight without depleting the fuel supply. Additional attendees in a half-filled auditorium do not increase production costs, so why ration attendance with prices that exceed the marginal costs that an added attendee imposes? That is one part of the normative side of covering the sunk costs, even if they are regularly replicated. But of course if there is inadequate recovery of costs that must be repeatedly sunk, will not the supply process be undermined, with all potential attendees the losers?

In practice, there is another problem that often can prove even more urgent. The need to sink costs repeatedly threatens survival of firms if competition drives prices towards marginal costs. Fortunately, the market mechanism will generally permit recoupment even where entry costs are the same for all entrants, because no prospective entrant will be willing to begin operations in an arena where the prospects for recovery of sunk outlays are dim. Hence, contrary to the standard conclusion, here the threat of entry will not preclude either prices that exceed marginal costs or even prices that are markedly discriminatory.

But where all firms are not created equal, low marginal costs when combined with substantial sunk costs are an irresistible temptation to entry. However, the entrants do not seek to operate on the same terms as those of the already incumbent suppliers. The entrants brought in by the cost disparities are those who seek to profit by covering the marginal costs and escaping the sunk investments. In short, they are the “pirates”, those who hope to prosper parasitically from the sunk investments repeatedly incurred by the providers of innovations and artistic creations.

In technical innovation, the problems just described are often rendered acute by great disparity in the magnitudes of the two pertinent types of costs. In computer software, for example, estimates are that even the most successful firms’ annual expenditures on R&D can amount to something like 20 percent of revenues. But the marginal cost of supplying a copy of a new computer program to an additional user is negligible – it can amount to a fraction of a dollar. In some of the arts, such disparities can also be large. For instance, in the theater the cost of mounting a new production can equal a substantial proportion of the running costs for a year of performances. But in other art forms, partly because the creative artists traditionally often bear much of the sunk cost themselves, the monetary portion of the costs that need to be repeatedly sunk may not be so substantial.

Here, yet another feature of the supply process becomes critical. In a number of art-forms the middleman plays an important, often an indispensable, role, and it is from the sunk costs incurred by the middleman that the financial issue just discussed takes its most acute form. This is most obviously so in the mass media. The firms that make and distribute musical recordings are a clear example. In popular music, just the investment in the video to publicize a new recording, as already suggested, can be very large – it

can run upwards of a million dollars. And the bulk of the real remaining costs, including the efforts of the performing artist, are incurred in the production of the recording, all adding up to a substantial sunk cost that needs to be repeated each time an additional recording is turned out. Indeed, since both musical performances and computer programs are distributed on CDs, the reasons for the comparably negligible marginal cost should be equally obvious here. Similar relationships now hold in movies, where expenditure of many tens of millions of dollars per production is common and well recognized. But the creation of a tape of a movie that can be played on the home VCR is, once again, negligible.

Even if the financial problems stemming from the difference between sunk outlays and marginal costs are not of very direct importance for the creative artists themselves, they are generally urgent for the middleman enterprises. Furthermore, the significant role of the intermediary firms in many of the arts means that when the problems affect the one type of enterprise, they must ultimately have a reflection upon all. Financial pressures that fall initially upon the middlemen will not remain confined to them alone; ultimately, they will be shared by others – composers, choreographers and most severely by those in the weakest position to defend their interests. I will return to this part of the story presently.

### *3.2. Pricing under copyright and compensation of creative activity*

Copyright is, of course, the instrument that has been invented to protect the rights of creative artists and to stimulate the creative process. In practice, it is directly helpful primarily to those who work in the “popular arts”, since the market for the work of artists in less popular venues is, as we know, generally quite limited. But even the latter are affected indirectly by the support they receive from the mass media. Script writing, composition of background music for film and television, and classical music recordings do at least help to finance activity in what may dispassionately be referred to as the “elite art forms”. But the amounts that the mass media are willing and able to pay out in these ways is dependent on what they are able to earn from their activities in the more popular art forms and the degree of protection of those earnings that is contributed by the copyright laws.

Recent developments in the new economy have put enormous strains on these protective powers. Among the accomplishments of the new economy that have already been stressed is the remarkable progress in ease of reproduction, including the reduction of its costs to negligible levels, and the ease and speed of transmission of the reproduced material. The photocopier has already caused great difficulties for publishers, as has the Internet for the producers of recorded music. There is very likely to be a race between the design of means to prevent illicit reproduction and the instruments the reproducers have at their disposal. The outcome is unpredictable, but the relative position of the two groups may well oscillate with the advantage going from one to the other and then back as time passes.

One extreme outcome may be partial collapse of current commercial institutions and invasion of the fields by amateurs who undertake the activities out of dedication and personal interest rather than pursuit of gain. The free software (“shareware”) movement, most notably the development of the Linux operating system, may be a foretaste of such a future. So far the prosperity of firms such as Microsoft, some of the film studios and the recording industry indicates that the prospect is not yet imminent, and shows that some such enterprises have managed via technical devices and with the support of the courts to stay one step ahead of the pirates. But where such protection of the financial interests of the major suppliers is effective, there is the danger that matters may swing too far in the other direction. A copyright, after all, is nothing else than a grant of monopoly power, however virtuous its purpose. The question as usual comes down to a matter of pricing. What price ideally should the copyright holder be permitted to charge?

If the issue is a mere matter of recoument of sunk costs and efficiency of resource allocation in the standard sense, economic analysis provides a solution which is now well known: the Ramsey price, which is the second-best price consistent with a given revenue requirement constraint. In the simplest case in which the cross elasticities of demands are all zero, the supplier’s socially-ideal product prices will exactly exceed marginal costs in inverse proportion to the demand elasticities of the products, up to the point where the resulting rise in revenues is just sufficient to recoup the sunk costs. For middleman firms this may be the right solution, though as we will soon see, here ideal pricing policy runs into another fundamental complication.

But before getting to this, a bit more can usefully be said about the Ramsey price of an artwork with public-good properties. In the extreme case of the ideally-pure public good, the marginal cost of increased usage will be zero, as in the case of an added audience member in an uncrowded theater or an additional reader of a poem or viewer of a painting. Then, the second-best pricing solution to the simplest Ramsey model clearly becomes

$$\frac{P - MC}{P} = \frac{P}{P} = 1 = \frac{1}{E} = E = -\frac{\frac{dQ}{dP}}{\frac{P}{Q}}, \quad \text{or} \quad \frac{Q}{P} = -\frac{dQ}{dP}. \quad (1)$$

That is, in this case the second-best welfare solution is to set price so that the quantity of sales elicited is that at which demand is unit-elastic. This means that the more responsive the quantity demanded of the product in question is in absolute terms to changes in price, i.e., the greater the value of  $-dQ/dP$ , the lower the price should be relative to the quantity sold. The intuitive explanation is that the objective here is to raise prices above their first-best levels sufficiently to increase revenues so as to cover the unavoidable costs, but to do so with minimum distortion of quantities demanded from their first-best magnitudes, the magnitudes that would be elicited by zero prices. This means that prices should be positive<sup>11</sup> but lowest for those items whose demand quantities are most substantially modified from their first-best magnitudes.

<sup>11</sup> Price evidently should be zero for any good for which the demand elasticity is infinite; for more on Ramsey pricing of pure public goods, see Baumol and Ordover (1977).

On the other hand, where the objective of price setting is not recoupment of some determinate sum but stimulation of creativity, we do not know the answer. Partisans of the arts will be tempted to say "the more the better", and in practice one may well argue that the typical compensation of the creative artist is sufficiently niggardly as to leave us in the range where this answer is valid. But it is conceivable that the allocation of talent to creative activity will be excessive. This is an obvious possibility in the case of technical innovation where the greater part of the labor force still must be engaged in production for the present rather than for the future, for the future is what invention primarily serves. But there are economists who argue that even now the pressures of the new economy are apt to result in excessive allocation of resources to innovation, because the loss of value of still-usable but obsolescent assets is what creative destruction entails. *A*'s innovation is likely to render obsolete an asset that is not her own, but rather belongs to other individuals, *B*, *C*, and *D*, who have no role in *A*'s activities. Thus, creative destruction is a detrimental externality and like other such externalities in a free market it is likely to lead to excessive output of the externality-creating product.<sup>12</sup>

In the arts, it can also be argued that there is no shortage of creative activity. There is a profuse stream of plays written without let-up, and paintings (albeit of uneven quality) are produced in vast numbers. The problem, apparently, is not further stimulation of the supply but creation of venues in which the products of creative activity in the arts will be seen and appreciated. In short, not only are we unsure of the effectiveness of copyright in benefiting the creative artists but, particularly in the new economy where creative artists are so dependent on market forces, it is not clear what prices it is desirable for copyright to yield.

### 3.3. *Efficient component-pricing*

It should be clear from the above that the determination of appropriate prices for output supplied under copyright is not really the critical issue in relation to compensation of the individual creative artist. Rather it is the giant middlemen – the film studios, the television broadcasters and the producers and distributors of musical recordings – where the matter is of substantial interest. But even here it may well be argued that the issue is not one of exploitation of monopoly power, because competition can still be a force sufficiently powerful to drive profits down toward the competitive level in the economy, even though the products are markedly heterogeneous. However, in the new economy, given the critical role of the mass media, there is an additional complication that besets the pricing issue. Others engaged in cultural activities will want permission to reuse material covered by copyright for employment in their own pursuit of profit. For example, films and recorded television programs are often replayed and rebroadcast by others than their proprietors, and recordings of music are played by broadcasters all the time. In some cases, the users are direct competitors of the owners of the copyright.

<sup>12</sup> On this see, notably, [Aghion and Howitt \(1998\)](#).

The question is whether there exists an economically efficient price for such access to copyright material.

The answer is that there does indeed exist such an efficient price. Though it will not be derived here,<sup>13</sup> it seems worthwhile to describe the efficiency consequences that are at issue. From the point of view of abstract economics, a piece of intellectual property such as a technical invention or a musical composition is interpretable as just another input into some production process where the final output is a product that incorporates the invention, or a concert or a film in which the music is played. Now, it is clear that the firm that invested in the R&D that produced the invention is not necessarily the invention's most efficient user in the production of the final product, just as the composer of the music is not necessarily the music's most gifted performer. The price that the holder of the copyright charges others for use of a musical recording or rebroadcast of a TV performance determines whether or not that activity will devolve upon the most efficient user. For example, the composer who demands a prohibitive price may end up as the sole performer of his piece, even if he is far from the ideal person for the task.

The theory of economic regulation provides a formula for the efficient price for access to such proprietary intellectual property. The formula is called the "efficient component-pricing rule" (ECPR), and yields what has come to be called the "parity price". This rule has elicited considerable discussion in the literature on economic regulation, and has been adopted by a number of courts and regulatory agencies in several countries, though other legal opinions have rejected it. But it is an issue of some importance for the economics of the arts, and it is one that yet again arises primarily in the new economy. Specifically, ECPR requires that the license price must equal the copyright owner's final-product price minus the copyright owner's incremental cost of remaining inputs, i.e., that the licensing price satisfy the following rule:

$$P_i = P_{f,i} - IC_{r,i}, \quad (2)$$

where:

$P_{f,i}$  = the copyright owner,  $I$ 's, given price per unit of final product;

$\min P_{f,c}$  = the competitor,  $C$ 's, minimum viable price of final product;

$P_i$  = price charged for a license to use the copyright, per unit of final product;

$IC_{r,i}$  = the incremental cost to the copyright owner of the remaining final-product inputs, per unit of final product;

$IC_{r,c}$  = the corresponding figure for the competitor; and

$IC_i$  = the incremental cost to the copyright owner of use of the copyright by itself or by others.

Equation (2) establishes a tight link between the price  $P_{f,i}$  that the copyright owner charges for its final product and the ECPR price  $P_i$  that it charges its rivals for the license to use the copyright. If incremental production costs do not change, efficiency requires that a rise in one of these prices must be matched dollar for dollar by a rise in the other.

<sup>13</sup> For a full exposition, see Baumol (2003).

It is trivial to prove the efficiency property of the rule via the Level Playing Field Theorem, which is stated as follows: The parity price as given by Equation (2) for use of material covered by copyright is both necessary and sufficient in order for the “playing field” to be level as between the copyright owner and any licensee. This means that the maximum difference between the remunerative prices of the perfect-substitute final-products of the two firms, the copyright owner ( $I$ ) and its final-product competitor ( $C$ ), is exactly equal to the difference in the firms’ remaining incremental costs (other than the license fees). That is,

$$\min P_{f,c} - P_{f,i} = IC_{r,c} - IC_{r,i}. \quad (3)$$

In other words, an ECPR price is necessary and sufficient for the lowest compensatory price the competitor can afford to charge in order to differ from the copyright owner’s exactly by the amount (positive or negative) that the former’s remaining costs are below the latter’s. This means that the competitor will (will not) be able to take over the use of the licensed product and the market for the resulting output if and only if it is the more (less) efficient user of the licensed item for the purpose. This clearly illustrates how the standard approaches of economic analysis can be used to solve one of the efficiency problems in the arts that the new economy has brought to the fore.

#### 4. Other problems contributed by the mass media

Through the creation of the mass media, the new economy has contributed other problems for the arts that have already received considerable discussion in the literature. Because they have been analyzed by others, I will limit my discussion to two issues here. The first is the exacerbated “star” system and its influence on the distribution of income in the arts,<sup>14</sup> and the second is the contraction and partial disappearance of secondary performance venues that served (like the minor leagues in sports activity) as training grounds for creative artists and performers.

##### 4.1. Superstars

Of course, there is nothing new about the existence of stars in the arts, star performers, star composers, and so forth. What the new economy has created is the prospectively vast audience that these stars can now draw, an audience that would not exist without the mass media. It used to be that an audience numbering in the lower thousands was considered sensational. With the mass media, millions are now the relevant order of magnitude. This means that the marginal revenue product of the stars may perhaps have been multiplied a thousand-fold, a fact that is often reflected in the remuneration they command. The lesser mortals among creative artists and performers can be expected

<sup>14</sup> See further [Chapter 25](#) by Adler in this volume.

to receive a much more modest multiplication of their fees, since viable substitutes for their services are far more readily available. The consequence has been an enormous increase in disparity of income between stars and lower-ranking performers and, often along with it, some increase in the power of the stars to command their conditions of employment, as well as the artistic uses to which their work will be put. Whether the effect of this development on artistic quality has been advantageous or disadvantageous is difficult to say, however.

#### 4.2. *Contraction of secondary performance venues*

Somewhat more easily assessed, though probably no more easily documented, is the implication for artistic quality of the second consequence of the advent of the mass media mentioned above. Because mass media enable star performances to reach such vast audiences, in many venues the demand for second-tier performances has dried up. For example, vaudeville stage entertainment used to be a pervasive activity, with live performance interspersed with film performances in theaters throughout the land and with performers constantly traveling in great numbers from one city or smaller community to another. Today the vaudeville theater is dead. Even more striking is the disappearance of live amateur concerts in private homes. A century ago in many a middle-class household several members of the family could play musical instruments with tolerable skill. Today children still take music lessons, but often their performances are listened to primarily to shore up egos, while it is the CD player that provides the musical performances that are really wanted by the listeners.<sup>15</sup> One consequence is the shrinking of a critical training ground. Another example is the effect on comic performances. The fabled comedians of the mid 20th century – the Marx Brothers, W.C. Fields, Jimmy Durante, Burns and Allen and many others – had their training on the road, and they refined their acts through much repetition, and through constant interaction with their audiences. The result was a product whose polish is considered by some observers not to be approximated by more recent performers. There are now other venues for budding comics: local comedy clubs, the *Comedy Central* cable channel, even *Saturday Night Live*, a television show from which quite a few unknowns have gone on to stardom. While one may well question whether this is enough to sustain the old level of professional polish, it may persuasively be argued that quality here is strictly a matter of taste.

Yet a suggestive analogy comes to mind. Elsewhere, my wife and I [Baumol and Baumol (1994)] have surmised that the extraordinary riches of the composers' activities in 18th century Vienna and much of Germany and the Austro-Hungarian empire was at least in part attributable to political fragmentation, with the multitude of courts of minor royalties providing jobs that attracted people into careers (sometimes menial jobs)

<sup>15</sup> Schools have made up for some of this loss, often providing significant alternative venues for young amateur musicians. It is not unusual for school-based choral and orchestral groups to perform in local communities, go on international tours, and produce CDs.

as composers, served as training grounds and as sorting instruments that could identify those who had special ability or promise.<sup>16</sup> This suggests that with the unification of Germany, the disappearance of this multiplicity of employment opportunities tended to circumscribe the country’s advantages as a location for the work of composers. The hypothesis I am proposing here is that the new dominance of the mass media in dissemination of the arts may have similar consequences.

## 5. Concluding comment

The central point of this chapter is that the new economy – the one that had its origins in the Industrial Revolution at the end of the 18th century – has indeed affected the arts and has not done so only marginally. In a variety of ways it has changed their circumstances beyond anything that humans living earlier could have recognized or imagined. The new economy has led to total upheaval in the technology of distribution, communication and preservation in the arts. It has given rise to profound and novel financial pressures. Arguably it has even had a major influence on the standards and goals of those engaged in creative activity in the arts. And, indirectly, in the new economy, the arts have had new effects on the structure of the economy. But what has been pointed out here has largely been impressionistic and discursive, entailing little data or formal analysis. I suggest that there are many elements in the relation between the arts and the new economy that merit considerably more serious exploration than is offered here. I hope that others will be tempted into following these leads.

**Abstract**

Culture, defined as shared values and beliefs, can influence the performance of an economy in many ways. The culture of a group, whether national, regional or ethnic, may be regarded as a particular type of intangible public good. The chapter summarizes and critiques a positive theory of inter-cultural competition. According to this theory, culture is created by leaders, who specialize in the production of culture, and is shared by their followers. Leaders compete for followers in order to increase the rents that they can extract from their groups. Whilst some of these rents may be pecuniary, most are non-pecuniary, such as the enjoyment of pursuing a public project which glorifies the leader and their group. There are four main dimensions of culture which influence performance, and there are trade-offs between them which are governed by the environment of the social group. The positive theory is useful in interpreting historical evidence on the rise and decline of societies, institutions, and organizations of various kinds.

## 1. Introduction

It is popularly believed that culture has a significant effect on economic performance [Buruna (1999)]. Whilst some economic historians are sympathetic to this hypothesis [Landes (1998)], most economists are skeptical. They question the intellectual rigor of the underlying theory, and the objectivity of the evidence. In *The Wealth of Nations*, Adam Smith downgraded cultural factors from the prominent position they had occupied in his previous work, and subsequent economists have largely followed his lead [Macfie (1967)]. Recently, however, theoretical interest in the economics of culture has revived [Olson (2000)]. This chapter reviews attempts to bring greater rigor to the subject. It is argued that models of rational action, on which conventional neoclassical economics is based, can be extended to allow for cultural influences. Such models suggest that certain cultures promote economic performance better than others.

Culture may be regarded as an economic asset – a form of cultural capital. It is an intangible public good, shared by the members of a social group. The analysis below identifies four major dimensions of culture which influence the performance of a group:

- individualism versus collectivism,
- pragmatism versus proceduralism,
- the degree of trust, and
- the level of tension.

Individualism emphasizes personal autonomy, and echoes the former UK Prime Minister Mrs. Thatcher's dictum that 'there is no such thing as society', whilst collectivism asserts that it is natural for people to be socially embedded in a larger group. Pragmatism favors improvisation and flair in taking decisions, whilst proceduralism emphasizes reliance on rules. High trust reflects a belief that other people are honest and hard-working, whether they are supervised or not, whilst low-trust reflects a belief that people will take every profitable opportunity to shirk and cheat. The level of tension reflects the level of achievement to which people aspire, and their determination to succeed.

The analysis distinguishes between economic performance in a material sense, and overall quality of life. Quality of life depends on emotional as well as material rewards. Culture is not merely instrumental in the pursuit of material rewards, but is a direct source of emotional rewards as well. Boosting emotional rewards can also boost material rewards – as in highly-motivated teams – but there are trade-offs too: for example, a religion that encourages prayer and fasting may reduce material performance even though it improves quality of life. Bias in the measurement of the material living standards adds a further complication. A market economy may appear to out-perform a non-market economy in material terms simply because a higher proportion of its output is recorded in the national income statistics.

It is relatively easy to show that culture can have a positive effect on quality of life. Quality of life depends heavily on the provision of intangible public goods such as visual amenity, safety on the streets, and so on. Culture is not only a public good itself, but is instrumental in creating popular support for investment in other public goods. It is more challenging, however, to show that culture can improve the material output

of private goods, and it is this challenge that is therefore the focus of attention in this chapter. Furthermore, since material performance is easier to measure than quality of life, hypotheses linking culture to material performance are in principle easier to test.

Modern neoclassical economics implicitly endorses a Western culture of 'competitive individualism', which is individualistic and low trust. The collapse of Soviet communism and the 'triumph of the market' was widely interpreted as demonstrating the advantages of an individualistic culture over a collectivist culture. However it said nothing about the advantages or disadvantages of high trust. Until the 1970s, the justification for markets was seen mainly in their ability to adjust to incremental change. Globalization, however, precipitated major changes, and led to the growth of 'enterprise culture', which emphasized the value of pragmatic improvisation over routine procedure when taking key decisions. At the same time, Soviet communism remained wedded to procedural decision-making. Thus Western capitalism was not only individualistic but pragmatic, whilst Soviet communism was both collective and procedural. It is therefore unclear whether the superiority of individualism over collectivism, or pragmatism over proceduralism, was mainly responsible for the revealed superiority of the West.

The success of many newly industrializing countries in pursuing state-led export programs suggests that where government has been pragmatic rather than procedural it has sometimes been able to achieve remarkable results. It may therefore be that excessive reliance on procedure, rather than collectivism *per se*, caused the collapse of communism.

Western capitalism and Soviet communism were both high-tension cultures, whilst developing countries, on the whole, exhibit low-tension cultures. In the third world, high-trust culture seems to perform better than low-trust culture [Sherman (1997)]. Combining the lessons from these various comparisons therefore suggests that the most promising culture is individualistic, pragmatic, high-trust and high-tension. This is entrepreneurial associationism – a culture which encourages people to freely commit themselves to ambitious pragmatic team-based projects. It differs from competitive individualism in having a high level of trust. No country has been able to sustain associationism for very long, however, and so competitive individualism has emerged as a 'second best' solution.

High tension stimulates competition, which tends to undermine trust. It is sometimes suggested that trust arises naturally, through repeated interaction, but it remains the case that selfish individuals have a strong incentive to cheat in the final play of any 'repeated game'. If trust is to prevail generally, it cannot be regarded as natural, but must be engineered [Casson (1991)]. This is achieved by moral leadership, as explained below. From this perspective, lack of trust reflects a scarcity of leadership – indeed, there are grounds for believing that there is a systematic shortage of suitable leaders in most countries. An unfortunate legacy of inter-war Fascism is that the very concept of moral leadership has fallen into disrepute. This has discouraged the systematic production of moral leaders through education. Families and local communities have under-invested in the supply of leaders for future generations. Furthermore, it is argued below that the growth of mass media has distorted competition between potential leaders to favor those who appeal to

narrow self-interest. It is suggested that ineffective moral leadership has impaired the performance of Western economies over the last twenty years. Individualism and high-tension have been pursued to the point where they undermine trust, creating a consumer society marred by crime and anti-social behavior. Undermining trust has raised the costs of coordination, eroded material performance, and caused serious detriment to quality of life.

If this economic theory of culture is correct, and its diagnosis of events is sound, then the policy implication is that nations must improve the supply of moral leadership. Intellectual leaders such as priests, politicians, philosophers and artists all have an important role to play in stimulating the imagination of political and business leaders; in a successful society such intellectual leaders will tend to embrace a high-trust high-tension culture.

The chapter is organized in four sections. Section 2 introduces basic concepts and definitions; Section 3 outlines an economic theory of culture, concerned with competition between groups; Section 4 discusses the key dimensions of culture, whilst the final section examines broader methodological and historical issues.

## 2. Basic concepts and definitions

### 2.1. The definition of culture: Culture as a public good

There are many important contemporary economic issues in which culture is a significant factor, such as

- Is a common European currency a symbol of political unification?
- Will contracting out public services such as health to private firms undermine the public service ethic?
- What exactly is 'consumerism'? Do heavily advertised 'lifestyle' consumer brands delude consumers with false hopes, and does it matter if they do?

It is necessary to define culture in a way that captures the common elements in these questions. For the purposes of this chapter, therefore, culture is defined as *shared values and beliefs relating to fundamental issues, together with the forms in which they are expressed*. This suggests that there are three main aspects to culture:

- values, which represent the moral aspect of culture,
- beliefs, which represent the technical aspects, and
- forms of expression, which represent the symbolic and artistic aspects.

These values, beliefs and forms of expression are shared within a social group.

It can be seen that this approach to culture is more general than that employed in the economics of the arts. Arts tend to be identified with 'high culture', involving the expression of emotion through artifacts (e.g., paintings, books) and performances (e.g., drama, ritual). Culture, as defined above, relates not only to emotional responses, but to quite detached views connected, for example, with scientific topics. Furthermore, it

encompasses more than just expression – it includes the formation and dissemination of views as well.

Culture is an intangible good. Cultural values and beliefs can be shared, which indicates that culture, like knowledge, has the property of a public good [Reisman (1990)]. The fact that one person holds certain beliefs, for example, does not preclude another person from holding these same beliefs too. Thus there is no rivalry in the consumption of culture. Culture may be a good because it has intrinsic value, or because it is instrumental towards some other purpose. People may value certain beliefs because holding these beliefs makes them happy [Layard (1980); Easterlin (1998, Chapter 10, 2001)]. They may value other beliefs because they are purely instrumental – for example, holding correct beliefs eliminates mistakes and so reduces waste, thereby improving the material standard of living. It follows that culture can also be a ‘bad’. Some beliefs make people unhappy – for example, the belief that nobody likes them. Other beliefs may be damaging because they are wrong – mistakes are made when acting on these beliefs, and resources are wasted as a result. From an economic perspective, therefore, the elimination of cultural bads is just as important as investment in cultural goods.

## 2.2. *Cultural diversity*

Cultural diversity is a topic which generates considerable controversy. Conventional economic theory suggests that culture is simply a set of beliefs which will ultimately converge on correct beliefs as a result of learning. According to this theory there is a unique set of correct beliefs on which everyone will eventually agree; groups that refuse to learn will fail to survive. The only cultural guarantor of economic success is a correct economic theory and the implementation of policies derived from it. Some economists seem to believe that convergence on the correct theory is almost instantaneous. Adherents of rational expectations theory, for example, maintain that everyone holds correct beliefs because they already know the true model of the economy [Lucas (1981)]. Others allow the process of adjustment to take a little longer; they concede, for example, that the final collapse of authoritarian socialism in the 1990s occurred only after a century of institutional experimentation.

Simple economic models such as rational expectations, assume that information is costless to collect and communicate, and easy to verify. These assumptions about costless information are critical to the prediction that incorrect beliefs will be eliminated, and only correct beliefs survive.<sup>1</sup> However, any plausible economic theory of culture must recognize the significance of information costs. Whilst knowledge is a public good, it is costly to share. No one has complete access to all available knowledge. Costs of collecting information mean that everyone bases their beliefs on only a limited amount of information. Optimal search theory shows that once a certain amount of

<sup>1</sup> The rational expectations approach to economics is a recent innovation which is very much at odds with traditional mainstream writing, even in the Chicago School; see, e.g., Leacock (1998) and Viner (1972, 1978).

information has been collected, it is no longer cost-effective for an individual to refine their beliefs by collecting more. Beliefs are therefore based on a very limited amount of information.<sup>2</sup> Access to information can be improved by pooling information, but this requires communication between people, which is costly too. It is often more efficient to leave someone to discover something for themselves rather than incur the costs of telling them about it. Information sources are typically localized, which means that when people rely upon their own resources, different groups of people in different localities have different sets of information. Each group generates beliefs on fundamental issues by generalizing from its own experience. This leads to different sets of beliefs, and so to cultural diversity.

Cultural diversity is likely to diminish over time. Much information is a by-product of action – it is acquired through ‘learning by doing’ – and so accumulates over time. Additional information can be captured through scientific experiment. As a result, the information available to each group is likely to become more and more the same. Groups can also compare beliefs, and refine them through a process of criticism. In this way the accumulation of knowledge, combined with critical debate, encourages the emergence of consensus. Diversity cannot be eliminated, however, because there is a lack of decisive information on certain crucial issues. Evidence is decisive when it convinces not only believers but also skeptics. Much of the evidence used in social science is difficult to replicate because it cannot be collected under fully controlled conditions. It therefore lacks the ‘objectivity’ that would convince a skeptic. Lack of objectivity is particularly problematic in the investigation of fundamental issues such as the origin of consciousness, inequality of intelligence, and the relative importance of ‘nature’ and ‘nurture’. Lack of objectivity allows people to remain attached to beliefs which explain their own experience but not the experiences of others.

Disagreements are even more difficult to resolve in the field of values. Some value systems can be criticized for lack of consistency, although not everyone would accept that logical consistency is a requirement of a value system. Religious value systems often appeal to revelation and sacred texts as a source of authority, but secular critics deny their validity. Diversity in values therefore tends to be not only greater, but also more enduring, than diversity in beliefs.<sup>3</sup>

Overall therefore, fundamental problems in assuring the quality of information mean that despite the increased quantity of information that flows within the world economy, cultural convergence on a true model is unlikely to be attained. The spread of the internet, for example, may well promote convergence on relatively superficial issues such as the consumption of heavily advertised brands, but it is unlikely to promote convergence on more fundamental issues. Indeed, the proliferation of special issue lobbies such as

<sup>2</sup> Indeed, it is interesting to note that recent research has introduced costs of rationality into rational expectations modeling, which has aligned the approach more closely with that set out in this chapter; see, e.g., Ginsburgh and Michel (1997).

<sup>3</sup> For further discussion of the influence of diversity in values see Baxter (1988), Hahnel and Albert (1990) and O’Brien (1988).

anti-globalization protest groups coordinated through the internet suggests that increasing skepticism about the quality and integrity of 'official' information is generating new sources of cultural diversity. Thus while cultural diversity in international consumption patterns may be reduced through greater quantities of information flow, the limitations on information quality mean that intra-national diversity in political and religious beliefs may well increase.

### 2.3. *Stereotypes*

There is considerable popular awareness of differences between the cultures of particular groups of the same type. These differences are usually expressed in terms of stereotypes. A stereotype is an oversimplified characterization of a social group that ignores diversity within the group. It is a form of group reputation. The members of a group generally view their own group more favorably than do outsiders (which partly explains why they are happy to remain within the group). Indeed, competing groups often adopt negative stereotypes of each other in order to justify their antagonism. For this reason stereotypes are often condemned for promoting distrust between groups. However, different outside groups often hold rather similar views of any given group, which lends support to the idea that there is an objective kernel to the outsider's view. Thus although stereotypes ignore internal diversity and are often hostile, they are still useful because they usually contain significant insights too.<sup>4</sup>

### 2.4. *Culture as an asset*

Culture is a durable asset: values and beliefs are memorized by individuals, and are transmitted to the next generation through parenting and education. Education is strengthened when culture is recorded in books, embodied in art and artifacts, and embedded in rituals and routines. The durability of culture has encouraged some writers to see it as the 'dead hand of the past'. Culture is acquired from early childhood when critical faculties are undeveloped. People become very attached to their early beliefs for emotional reasons – loyalty to parents, a concern for their 'roots', or fear of change. Beliefs are not revised in the light of new circumstances and hence there develops a disjunction between culture and the real world. This view ignores the fact that people often review their beliefs in adolescence or when they come of age. It also has the misleading implication that a very old culture is likely to be less appropriate than a newer one.

An alternative view is that culture adapts to changing circumstances, but with a lag. It is sometimes suggested that a traumatic set-back such as a military defeat is necessary to undermine confidence in a culture. Defeated groups may sometime adopt their conqueror's culture (or selected aspects of it). On this view cultures which survive do so not because of mere inertia but because the beliefs they embody are more correct or more successful than those they replace.

<sup>4</sup> For the use of national stereotypes to analyze economic performance see Casson (1990, Chapter 4).

The most efficient way for a culture to cope with change is to adapt its beliefs in an incremental fashion, up-dating them in response to significant events and new discoveries. Monitoring the environment and up-dating beliefs is a complex task, however, and benefits from specialization. It is impossible for everyone within a group to find the time to continually re-examine their beliefs for themselves. To understand how culture changes, therefore, it is necessary to understand the division of labor within social groups.

### 2.5. A typology of social groups

The basic unit of cultural analysis is the social group: it is the unit within which culture is shared [Newman (1983); Pryor (1977)]. The most significant types of group from a cultural perspective are listed in Table 1. People are born into families and the local community where they live. They also acquire nationality at birth. When they come of age they can take decisions for themselves. They can choose the firm for which they work, the profession (if any) they wish to follow, and the clubs and societies they wish to join. They can also decide whether they wish to be active members of a church or a political party. In taking these decisions they affirm certain values and beliefs they have acquired from family and friends and reject others.

In a high-tension society, belonging to a group involves significant commitments; furthermore, in a high-trust society there are significant emotional penalties for breaking such commitments – disloyalty and lack of perseverance bring guilt and shame. Within a group there are distinctive roles. Roles with greater responsibility generally carry higher

Table 1  
Typology of social groups

Type of group	Membership system
Nation state	Citizen by birth or naturalization. Tax-payer by residence.
Market	All buyers and sellers of a product are members of the relevant market – especially competing sellers who locate close to each other.
Network	Member by regular contact with other members – often met through introductions arranged by existing members.
For-profit associations: firm	Member by negotiation. Core members supply services on a regular basis: e.g., shareholders and employees. Customers may be regular, casual, or one-off purchasers.
Non-profit associations: profession, club, church, charity, political party, etc.	Member by application, invitation, qualification or election.
Local community: friends, school, etc.	Member by residential location.
Family	Member by birth or adoption.

status. High-status people can demand deference from other members of the group. In addition, there are differences in status between different groups. Some groups are task-oriented (like the firm) whilst others are support-oriented (like the family), although most types of group combine elements of the two. In a task-oriented group the clients or customers who consume the output are usually different from the workers who produce the output, whereas in a support group the consumers and producers are often the same. In a charity, for example, the donors who supply the funds are quite distinct from the beneficiaries or clients who receive them, whereas in a support group like Alcoholics Anonymous the members support each other [Bolnick (1975)].

Clients usually have low attachment to a task-oriented group. Customers may have only casual contact with a firm, for example, whereas workers are heavily involved on a daily basis. Those who provide finance usually have less attachment than those who provide labor. Shareholders in a large firm can easily sell out for speculative gain whereas employees may serve for life; similarly, donors to a charity are usually less involved than the volunteers. There are also differences amongst workers; whilst some may be permanent full-time staff, others may be casual part-time staff. In a high-trust society commitment from workers and volunteers may be readily forthcoming, but in a low-trust society people will prefer low-commitment involvement instead. People may prefer to give money rather than time to a charity and to take only casual work, while shareholders may be very concerned that their holdings are liquid.

Some groups have formal structures: these are typically large and long-lived groups. Formal structures institutionalize the division of labor, creating posts or offices to which people are appointed; some posts may be filled on a rotating basis, often by election. Other groups are informal. For example, a market consists of all the people who turn up in the market place to trade – whether the market is a physical location, a commercial publication, or a web-site. Although access to the market may be free, traders must abide by the rules for enforcing contracts. A network is even more informal – it is simply a group of people who are in regular contact with each other [Putnam (1993)]. Networks are typically governed by customs which are enforced through reputation effects. A low-trust culture requires formal rules and procedures, whereas a high-trust culture is more versatile: both formal and informal systems can be used. Networks are useful for sharing information, particularly between entrepreneurs. In a high-tension culture networks can foster innovation, but in a low-tension culture they may simply foster collusion instead.

### **3. Towards an economic theory of culture**

Up to this point, the discussion has simply taken existing insights from sociology and social anthropology and reformulated them in economic terms. Further development of an economic approach to culture requires specific analysis of competition between cultures, leading to an explanation of the competitive strategies employed by social groups. This section outlines a set of assumptions on which a formal model of cultural competition can be developed.

### 3.1. Leadership

Leadership is the most important role within a group. The leader typically manages the external relations of a group. ‘Take me to your leader’ say outsiders who need to negotiate a commitment from a group. The leader demands loyalty from the members in order to guarantee the delivery of commitments and to maintain the reputation of the group. The leader has the power to discipline or expel disloyal people.

The logic of leadership is very simple. In a highly complex and uncertain world, people cannot resolve every issue for themselves. In particular, fundamental questions about the future of the world and the destiny of the individual cannot be easily answered; the costs of collecting and processing all the relevant information would be prohibitively high. Specialist leaders such as priests and politicians are required. Even then their answers cannot be definitive. Different leaders give different answers to the same question, based on different information, and so different cultures prevail. Leaders also provide answers to more specific questions; thus the leader of a firm decides what type of product is most in demand, and the leader of a charity decides what kind of people are most in need of help. The leader is the person deemed to have a comparative advantage in processing the relevant information. He may also claim to have privileged access to information, perhaps through external contacts. Alternatively, he may claim to be able to interpret information in a better way [Casson (2000)].

Leadership styles vary. Some charismatic leaders seek publicity, whereas others are self-effacing. Some leaders even seek to disguise their identity – such as an agitator leading a demonstration or the ‘brain’ at the center of a spy-ring. The common notion that groups can achieve ‘spontaneous order’ without a leader is a myth. It is simply a consequence of failing to identify where leadership really lies.

Leadership requires very scarce talents and as a result many leaders lack appropriate qualifications for the job. Successful leaders must justify the trust that their followers place in them. A leader who has lost the trust of his or her followers is of little value to the group, since members no longer feel secure in following their orders or advice. An alternative leader may emerge ‘from the ranks’ of ordinary members and constitute a rival source of authority – the militant British shop-steward, for example. The rival leader may organize a revolution to depose the incumbent if the incumbent cannot appoint a successor first.

### 3.2. Competition between groups

In a free society people can choose which leaders they follow. At any given time rival leaders will disagree about fundamental issues and people will have to decide with whom they agree. In particular, different political parties promote different ideologies, based on different theories of the economy and different views of human nature. In principle, only one of the rival leaders can be right. Indeed, the most likely scenario is that none of the leaders is right, since each is promoting an over-simplified and somewhat distorted view of the situation. Disagreements may persist because it is impossible to

find any decisive evidence for or against a particular view. In practice most leaders do not debate upon an abstract level, but rather in terms of strategy and policy. They promote specific projects which embody the values they promote and which, it is claimed, will work because the theory on which they are based is sound. For example, a political leader may promote a project to create a Welfare State, based on the optimistic view that new technology makes 'welfare for all' an affordable proposition. A business leader may motivate their workforce by claiming that their product is the best in the world, and a great benefit to all who consume it.

An articulate leader offers their followers a vision of what the project can achieve. The leader's rhetorical skill in creating 'sound bites' and 'buzz words' may be supported symbolically – perhaps by a launch at a prestigious location. The vision typically ignores the short run constraints under which the project operates, and emphasizes its long run potential instead. A vision will often be deliberately vague. It may be expressed in an artistic form which conveys an overall impression without revealing much key detail. The rationale for this ambiguity lies in the fact that much can change before the project achieves its goal, so that it would be misleading to be too specific about the final outcome. Indeed, the more ambitious the project, the longer it is likely to take to complete and so the vaguer the final outcome will be at the initial stage.

Competition may also induce leaders to scorn their rival's visions – arguing that they represent unworkable delusions. In Western democracies, debate between party leaders sometimes degenerates into mutual scorn. The emergence of negative stereotypes, promoted by leaders who wish to discourage their members from defecting to rival groups, can be explained in similar terms. This negative strategy has its limitations, however – too much emphasis on another leader's faults may suggest to honest followers that a leader is simply distracting attention from their own defects instead.

A key feature of a vision is that it arouses an emotional response in the follower. Such emotions are often described as 'beauty' (in the discovery of a simple theory, for example), 'glory' (as in winning a great team victory) or 'awe' (as in creating a monumental piece of architecture or engineering). The follower is enthused by contemplating the vision; by assessing their own emotional response to the vision, the follower can assess the magnitude of the emotional rewards that they will obtain through participation in the project.

Participation in each project involves a contract – usually an implicit contract assured through trust, but sometimes also a formal contract too, which is backed by law. There is an important psychological dimension to this contract. The leader emphasizes that the reward obtained by contemplating the vision will be strongest for those who make the greatest effort. Each follower will know how much effort they have committed to the project; the greater the sacrifices they have made, the greater the rewards they will obtain. These rewards come from two main sources. The first is the satisfaction from being absorbed in a worthwhile project to the point where the worker is unaware of their surroundings or of the passage of time. The second is a sense of pride and contentment when they rest from their work and reflect not only on what they have already achieved but also on what will be achieved when the project is complete. Followers who

know they have made little effort will experience little reward, whilst those who have deliberately shirked will experience guilt and wish that they had never joined.

An effective leader will show appreciation of followers' efforts. But the leader cannot always monitor individual effort with great accuracy. In certain types of work this agency problem may be overcome by basing rewards on measured output. But output may be only weakly correlated with individual effort, particularly in large teams. The 'psychological contract' is particularly valuable, therefore, in motivating effort in teams. However, team-work is not just a matter of effort. Loyalty is important in any project, and particularly so in teams, where the loss of a member can be very disruptive. Every new member has to learn their role, and the cost of training usually falls on the leader. Loyalty is thus an important element in the psychological contract. The stronger a person's emotional attachment to the project at the outset, the greater their sense of guilt when quitting.

When an individual is deciding whether to follow a particular leader, therefore, they will need to know both how they are likely to respond to the vision, and how they will actually perform. They therefore need to know their own competencies and their own emotional characteristics. If these characteristics are incorrectly assessed then a mis-match will occur between the individual and the project, and thus between the individual and the group. This will in turn lead to a waste of resources, in both material and emotional terms. It is typically assumed in economics that individuals possess full information on their own personal characteristics. In practice, however, it can be argued that they do not. In neoclassical economic theory, asymmetric information is usually construed as meaning that an individual knows their own characteristics, but others do not. It is possible, however, to construe the concept differently, and to suppose that other people know a person's characteristics better than they do themselves. Focusing on emotional characteristics highlights this point. Most parents have a better understanding of their children's emotions than the children do themselves. Many people remain 'child-like' (or even 'childish') in their emotions when grown up, and so not only family but also friends may be better aware of a person's emotional characteristics than the person themselves. Indeed, using biological evidence Frank (1985) has argued that people signal their own emotions to others unselfconsciously through facial expression and posture, and that their inability to control these emotional signals gives a credibility to their statements that they would otherwise lack. In a similar vein Freudian psychoanalysts have argued that people sublimate their emotions in order to disguise their feelings from themselves. People not merely lack self-knowledge and self-awareness – they are also systematically deny the existence of certain emotions too.

It is unnecessary to accept all of these claims in order to agree that many followers may be unaware of their emotional characteristics at the time they take a decision to join a group. Joining a group is therefore not only risky because of uncertainty about the leader and about the behavior of other members of the group, but because of uncertainty about one's own characteristics too. People's uncertainties about their own characteristics provide a significant opportunity for plausible leaders who are a good judge of character. The leader can invite people who in their judgment have the cor-

rect characteristics to join their group. People who feel very uncertain about their own characteristics are likely to respond in a positive fashion to such an invitation. Trusting people are also likely to respond, as they are more likely to accept the leader's judgment. An honest leader pursuing a socially worthwhile project can turn such mechanisms to good advantage, but it is equally obvious that an unscrupulous leader can take advantage of vulnerable followers. The most vulnerable people are those who are unaware that their own uncertainties and trusting nature are very obvious to others. Those whose competencies are obviously limited are particularly vulnerable, because it is obvious that they will receive few offers from other leaders. They may however receive some offers from honest but highly altruistic leaders, who wish to save them from falling under the influence of unscrupulous leaders instead.

### 3.3. *The changing nature of competition between leaders*

The nature of competition between leaders has been changed fundamentally by the growth of the communications and media industries – from the growth of print journalism in the eighteenth century to the spread of cinema, radio and television in the twentieth. The lower cost of mass communication has intensified competition between the leaders of high-level groups, especially political parties. Most significantly, the technologies of photography, film and video have reduced the cost of pictures relative to words, giving pictorial images an increasing role in propaganda and persuasion. Images liberate arguments from the requirement of a literate readership. They make use of a natural visual language which transcends any specific written language, and therefore reaches a mass multi-lingual audience.<sup>5</sup>

Certain images elicit strong emotional reactions. These reactions are almost instantaneous and are therefore invaluable to leaders in gaining attention for their messages. Indeed these reactions are so strong that the image itself may become the argument. Pictures of starving children or police brutality, for example, make their own political points without any need for verbal interpretation. Competition between leaders for visual attention encourages the pursuit of the outrageous. In any collection of competing images the most outrageous is likely to win. People may be attracted by beauty but surprise and horror have an even greater fascination.

The abstract nature of competition between ideologies does not lend itself readily to visual expression. The loss of media space to more visual subjects may be one reason why vigorous political debate appears to have declined as consumption of media services has increased. Social projects are easier to promote, as visions of better houses, schools and hospitals are easy to project. This encourages politicians to argue less about ideology and more about specific projects – a strategy recently adopted by New Labour in the UK [Protherough and Pick (2002)].

Consumer products are remarkably easy to promote by picturing the consumer as relaxed and self-assured; this works particularly well for simple products which provide

<sup>5</sup> The links between culture and language are explored further from an economic perspective in Jones (2000).

emotional benefits of a social nature – cosmetics and alcoholic beverages, for example. The multi-lingual nature of a visual proposition benefits multinational consumer brands. Faces attract attention – particularly faces that are instantly recognized. This favors the promotion of ideas through celebrity endorsement. Since sportsmen and entertainers are not generally noted for their political wisdom, celebrity endorsement works best in product promotion, although it has been used with some success in politics too.

Commercial advertisers are unlikely to increase their sales if consumers give money to good causes instead of spending it on themselves. The implicit message of a typical product advertisement is therefore that low-trust is the norm. Similarly, many products are advertised as impulse purchases, which allow the consumer to show off in a social setting. This promotes a low-tension spontaneous lifestyle as the norm, rather than a single-minded high-tension lifestyle which would produce better long-term results.

The optimization of visual image for persuasive purposes requires very scarce skills. Creative workers in advertising and public relations can command substantial economic rents. The financial requirements of major promotional campaigns constitute a significant barrier to entry for many types of leader. A highly visual political campaign may require powerful industry backers who expect rewards if their candidate is elected to office. Thus leadership becomes more like commercial entrepreneurship as the economic requirements converge on the funding of media campaigns.

In most modern societies newspapers, magazines, radio and television rely heavily on advertising revenues rather than sales and subscriptions. They have a strong financial incentive to attract an audience that is susceptible to advertisers' messages. This can induce the 'dumbing down' of content in order to attract the people most likely to be influenced by the visual message that the advertiser plans to use. Some messages are easier to dumb down than others – for example, a blatant appeal to short-term self-interest is easier to communicate than a sophisticated appeal to long-term social concerns.

To summarize, there are many reasons why in a modern society characterized by competitive individualism the role of moral leadership is difficult to carry out. Whilst the power of visual imagery favors the promotion of certain types of charitable project such as child poverty or animal welfare, it discriminates against the promotion of high-trust high-tension political values. Competition for attention in the visual media is on average biased against the promotion of high-trust cultural values.

## **4. Key dimensions of culture**

### *4.1. Four main dimensions of cultural variation*

There are many fundamental issues which cultures must address. Some are very general, such as 'What are people really like?', whilst others are more specific such as 'Whom can you trust?' and 'How do you motivate people?' Other issues include 'What forms of organization are natural?' and 'How far can technological progress advance?' Describing a culture in full can therefore be a very complex task.

A parsimonious theory of culture must identify just a small number of dimensions along which cultures vary. By focusing on those aspects of culture which are likely to influence economic performance, four main dimensions of culture can be derived. These dimensions were introduced at the outset, and are summarized in the first two columns of Table 2. The first column of the table identifies the end of the dimension which is found in a typical Western competitive individualistic society, whilst the second column indicates the dimension which corresponds to ‘Utopian solidarity’ – the kind of culture that would be found in an idyllic closed society of the kind visualized by Rousseau. This four-way classification is a refinement of a classification proposed in Casson (1993).

- (i) *Individualism versus collectivism*: An *individualist* believes that people are autonomous. Everyone is different and each person values personal ‘lifestyle’ projects above others [Earl (1986)]. The information required for coordination is widely distributed – shocks are individual-specific. Ownership and control of resources should be vested in individuals, since only individuals have the information required to take decisions that affect themselves. A *collectivist* believes that we are all part of the community into which we were born. Even as adults we remain dependent on others for our survival. A collectivist also believes in uniformity – everyone is the same, and everyone values large awesome projects. Information required for coordination is centralized – shocks have collective impact. Collectivists believe that ownership and control of resources should be vested in the group [Ekelund and Tollison (1997)].
- (ii) *Pragmatism versus proceduralism*: *Pragmatists* believe that intuitive judgments based on wide personal experience hold the key to successful decisions. Hunches can also be tested through informal conversation with other people. The best de-

Table 2  
Four dimensions of culture

Limit of dimension corresponding to competitive individualism	Limit of dimension corresponding to Utopian solidarity	Corresponding dimension in Hofstede	Optimal combination
Individualism	Collectivism	Individualism–collectivism	Voluntarism
Pragmatism	Proceduralism	Low–high uncertainty avoidance	Good judgment
Low-trust	High-trust		Warranted trust
High-tension	Low-tension	Femininity–masculinity	Warranted self-confidence

Note: Only three of the four dimensions identified by Hofstede appear in the table. The missing power–distance dimension in the Hofstede classification may be loosely construed as a hybrid which combines elements of individualism–collectivism with elements of low-trust–high-trust.

cisions are made promptly. A single individual should be ultimately responsible for each decision. *Proceduralists* believe that good decisions are generated by closely following formal procedures, whose design is underpinned by theory, and which involve the systematic collection of objective information. The use of committees may delay decisions, but it is better to ‘get it right’ than to do it quickly.

- (iii) *Low-trust versus high-trust: High-trust* individuals believe that others will be honest, work hard, be loyal, and generally keep their promises even when they have little material incentive to do so. *Low-trust* individuals believe that others are guided by material incentives, and will therefore often lie, cheat or shirk. High-trust is particularly important in an individualistic society, because individuals do not have the same power of enforcement as a collective body [Holmes and Sunstein (1999)].
- (iv) *High-tension versus low-tension: A high-tension* person is attracted to ambitious projects, while low-tension person prefers easy projects. The high-tension person is stressed because they are aiming high, and will be ashamed of failure.<sup>6</sup> Conversely, a *low-tension* person is relaxed, because they are aiming low, and they will blame any failure on factors outside their control. Low-tension people like to behave in a spontaneous manner, which often has anti-social consequences [Casson (2002)], although it is a manner of which some economists approve [Scitovsky (1976)].

There are many other classifications of culture which have been devised for a variety of purposes, but there is one particular classification, due to Hofstede, which has been particularly influential in management and organizational studies and is particularly relevant to performance issues [Hofstede (1980); Graham (2001)]. Hofstede’s classification was arrived at empirically by applying factor analysis to a large-scale cross-national study of the employees of a multinational firm. Unlike the classification used here, Hofstede did not deduce his classification from first principles, but nevertheless a comparison is useful. It is interesting that he also focused on four dimensions, some (though not all) of which correspond to the theoretical classification as noted in the third column of Table 2.

Taking the two limits of each of the four key dimensions described above identifies 16 ideal types of culture which are presented in Table 3. Some of these are particularly interesting, especially the high-trust analogues of competitive individualism. These embody the principle of voluntary association for the purpose of pursuing ambitious projects but add the notion that the aims of the project may be altruistic, that competition between the projects is orderly rather than aggressive, and that coordination of projects relies heavy on trust between members of a team. It is known as associationism.

To keep the theory really simple it would be nice to identify just one of these 16 cultures as the best from a performance point of view. It would then be possible to compare

<sup>6</sup> For an excellent discussion of high-tension in the context of fundamentalist religious sects see Stark and Bainbridge (1987).

Table 3  
Typology of cultures

	HG High-tension pragmatic (judgmental)	HD High-tension procedural (administrative)	LG Low-tension pragmatic (spontaneous)	LD Low-tension procedural (bureaucratic)
IS Individualistic low-trust (competitive individualism)	<i>Enterprise culture:</i> Aggressive competition between highly entrepreneurial selfish people.	<i>Big business culture:</i> Aggressive competition between selfish, ambitious but unimaginative people controlling formal organizations.	<i>Libertarianism:</i> Social anarchy constrained only by legal enforcement of market contracts.	<i>Play-the-system culture:</i> Unprincipled competition between formal organizations regulated unsuccessfully by weak and corrupt bureaucracy.
IH Individualistic high-trust (associationism)	<i>Entrepreneurial associationism:</i> Orderly markets allocate resources between ambitious altruistic projects.	<i>Administrative associationism:</i> Orderly competition between ambitious altruistic people running professional organizations.	<i>Good neighbor culture:</i> Social ambitions are limited to relief of current problems such as poverty. Individuals act on impulse to help the needy who are known to them.	<i>Charity culture:</i> Compassionate leaders set up formal organizations to help the needy, and recruit volunteers.
CS Collectivistic low-trust (coercive collectivism)	<i>Revolutionary state:</i> Totalitarian dictator personally promotes prestige projects in which people are forced to participate.	<i>Soviet-style planning:</i> Professional government planners implement ambitious projects using conscripted workers.	<i>Arbitrary dictatorship:</i> Dictator with ambition simply to survive in power improvises strategies to defeat rival bids for power.	<i>Conformist culture:</i> Coercive bureaucracy resists change and demands conformity from apathetic people.
CT Collectivistic high-trust (paternalism)	<i>Charismatic leadership:</i> Paternalistic leader with Utopian vision enthruses population.	<i>Welfare state:</i> Ambitious altruistic programs are devised by a paternalistic leader and administered using public service ethic.	<i>Familism:</i> Paternalistic leader presides over low-productivity economy where socialization is more important than work.	<i>Utopian solitariness:</i> Low-productivity economy is coordinated through compulsory participation in traditional rituals presided over by leader.

the actual culture of any social group with the ideal culture, and measure how many dimensions were in agreement: the closer the actual culture to the ideal culture, the better the economy would perform. Given the advantages of a high-trust culture in reducing agency costs and transaction costs, some form of associationism would be a natural

choice. The form that is closest to classic Western individualism is entrepreneurial associationism, and so this appears to be the natural choice as the ideal.

#### 4.2. Trade-offs involved in a high-performance culture

There are three difficulties associated with identifying entrepreneurial associationism as the unique high-performance culture, however. The first is that a combination of four extreme values is rarely an optimal choice in any problem. There are strong grounds for believing that along each of the four dimensions there is scope for a trade-off.<sup>7</sup> Typical results of the trade-offs are listed in the right-hand column of Table 2. They may be summarized as follows, taking each dimension in turn:

- (i) *Voluntarism*: Individuals are encouraged to transfer their resources to institutions on a voluntary basis. They are encouraged to identify opportunities for projects which these institutions can carry out. Individuals like group projects, but prefer to choose the type of project with which they are involved
- (ii) *Good judgment*: Procedures work well in dealing with frequent minor shocks of a transitory nature. Improvisation is required in dealing with intermittent major shocks of a persistent nature. Successful improvisation requires good judgment, which is based on wide experience.
- (iii) *Selective warranted trust*: Whilst trust reduces coordination costs, naïve trust is of little value, since naïve people provide easy pickings for cheats. A high-trust equilibrium is what counts, in which the majority of people (who are trustworthy) can identify each other and transact with each other, whilst the minority of people (who are untrustworthy) cannot transact at all. Trust is engineered through moral leadership. Leaders demand loyalty and hard work from those who join their teams.
- (iv) *Warranted self-confidence*: High tension delivers results in task-oriented projects. But high-tension cannot be sustained indefinitely. A high-tension person relaxes in a secure environment where they reflect on their performance and learn from their mistakes. The low-tension person likes to mess around at work, and have lots of fun when relaxing.

A combination of voluntarism, good judgment, selective warranted trust and warranted self-confidence may be termed refined associationism, and may be taken as the most accurate characterization of optimal culture from a performance point of view.

The second difficulty with this choice is that none of the forms of associationism discussed above correspond to the cultures of the most successful Western economies. These tend to be much lower-trust than associationism would imply. It could therefore be argued that the entire theory is a predictive failure. This leads on to the third point, however, which is that the exact position of the trade-off will reflect the local

<sup>7</sup> The importance of trade-offs in culture is recognized by many writers on culture; see, e.g., Hampden-Turner and Trompenaars (1997).

circumstances with which a culture has to contend. Thus a very large, transient and widely-dispersed group may have to reconcile itself to lower levels of trust than a small, stable and compact group. It is therefore unrealistic to expect every group to conform to the same ideal. In another case, one group may have an outstanding moral leader – a ‘man of the moment’, say – who intervenes at a critical moment when change is required, whereas another group may have to cope without such a leader. Drawing upon a larger number of less able and less trustworthy individuals to do the same job, they may institute a division of powers between the leaders and even endeavor to promote a degree of competition between them.

It is in fact possible to explain the current predominance of competitive individualism in successful Western countries such as the US in terms of adaptation to changing global conditions in the period since World War II. In the post-war period, volatility has increased as a result of accelerated technological change and the globalization of trade, driven by lower transport costs and tariffs. An increase in the volatility favors a switch from collectivism to individualism, and from proceduralism to pragmatism, because of the need for greater flexibility.<sup>8</sup> Globalization has also reduced trust between trading partners, as local networks of trade have been disrupted by the emergence of foreign competition; social trust has been eroded too, as migration has disrupted the customs of local communities. The globalization of communications has encouraged a switch from low-tension to high-tension culture as people in low-productivity economies have become aware of the opportunities presented by innovation and export-led growth. Countries across the world have therefore switched towards a specific type of competitive individualism, namely an individualistic, pragmatic, low-trust high-tension ‘enterprise culture’, as indicated in the top left-hand cell of [Table 3](#).

The economic theory of culture therefore predicts that culture will adapt to the environment, both across space and over time. This accords with basic economic intuition that despite all the qualifications noted above, a successful culture must correspond closely to the realities of a situation facing a group. As circumstances change, so the optimal culture changes too and forces of adaptation, driven by competition between rival leaders, come into play.

#### *4.3. Refining the dimensions of culture*

Sociological writers on culture have between them identified over a hundred different dimensions of culture. Furthermore, cultural analysis of cross-country differences in industrial policy has identified other dimensions besides those mentioned above [[Foreman-Peck and Federico \(1999\)](#)]. Almost all of these additional dimensions can however be subsumed under the four key dimensions; indeed, these key dimensions were developed in part as composite dimensions under which various other dimensions could be subsumed. [Table 4](#) lists 22 dimensions of culture, including many of the most

<sup>8</sup> For earlier examples of such switching see [Hirschman \(1982\)](#).

Table 4  
Sub-dimensions of culture

Characteristic favoring competitive individualism	Characteristic favoring Utopian solidarity
<i>Individualistic (I)</i>	<i>Collectivistic (C)</i>
Atomistic	Organic
Dynamic	Static
Incremental	Radical
Democratic	Elitist
Market-based	Planning-based
Efficiency-oriented	Equity-oriented
Consumer-oriented	Producer-oriented
<i>Pragmatic (G)</i>	<i>Procedural (D)</i>
Empirical	Theoretical
Outcome-based	Process-based
Risk-taking	Risk-averse
Artistic	Scientific
Personal	Impersonal
<i>Low-trust (S)</i>	<i>High-trust (T)</i>
Unprincipled (moral skepticism)	Principled (morally committed)
Secular	Religious
Selfish	Altruistic
Autocratic	Consultative
Aggressive	Orderly
<i>High-tension (H)</i>	<i>Low-tension (L)</i>
Aspirational	Complacent
Deliberative	Spontaneous
Optimistic	Pessimistic
Confident	Unsure
Progressive	Conservative

frequently cited dimensions, and attributes each of them to one of the four key categories.

Where issues relating to political constitutions and national economic policy are concerned, the sub-dimensions associated with the first dimension – individualism versus collectivism – are most important. Where issues of organisational structure and management style are concerned, the sub-dimensions associated with pragmatism versus proceduralism are most important. The quality of personal relationships within organizations, the intensity of competition between organizations, and the general quality of social life are governed by the sub-divisions of the third dimension – the degree of trust. The extent to which people are energized and inspired by visions of better life, either for themselves or others, is governed by the sub-divisions of the fourth dimen-

sion – the degree of tension. Since there is insufficient space to examine each of these sub-dimensions in detail, their principal features are summarized in Tables 5–8. The middle columns of these tables explain the nature of the variation along the dimension concerned, whilst the right-hand column considers the point along the spectrum on which the best results are likely to be obtained. This is described as the ‘high performance mix’. It is important when studying culture to remember that the dimensions of cultural variation do not normally run from ‘good’ to ‘bad’ or *vice versa* but, like ordinary economic variables, express a trade-off in which the optimum is usually at an interior point. Just as in conventional economics, extremes are rarely efficient in cultural life.

An optimum in this context represents a cultural mix which is likely to prove efficient in the long run. In modern parlance, it is ‘sustainable’. However, the optimum along any one dimension cannot be determined without reference to the other dimensions of culture. Thus a culture that promotes a distrustful attitude to other people may have an optimal degree of competitiveness which is quite high, whilst a culture which encourages people to trust each other may have an optimal degree of competitiveness which is much lower. In the long run there will be a tendency for competition between cultures to select the culture that is most efficient in overall terms. The characteristics of an optimal culture are summarized in general terms in the next section. However, as noted above, the optimal culture varies according to environmental constraints, and this means that the optimum is difficult to specify in terms of all the 22 dimensions discussed in Tables 5–8. Furthermore, the process of competition between cultures is so slow and disjointed that for the foreseeable future the detailed predictions of the theory merely identify a sub-set of viable cultures which are likely to remain in competition with each other for a considerable time to come.

Some of the dimensions described in Tables 5–8 are much more relevant at one level of leadership than another. Individualism versus collectivism and the sub-dimensions associated with it are particularly important for high-level leaders of large groups such as the nation state. They influence their attitude to the decentralization of power. A high-level leader must decide how far his or her followers should be allowed to form lower-level groups on their own initiative. Should the emergence of lower leaders be encouraged, as a welcome display of initiative, or discouraged as a potential threat to the leader’s power? Other dimensions apply at every level. The issue of trust, for example, is fundamental at every level. A high-level leader who does not trust lower-level leaders will either discourage the formation of low-level groups or will promote aggressive competition between them, whereas a trusting leader may encourage low-level groups and promote co-operation and orderly competition between them [Knight (1935)]. At the same time leaders of lower level groups must decide whether to monitor their members and offer material rewards for good behavior, or whether to trust the members to monitor themselves and to reward themselves emotionally for good behavior.

Table 5  
Detailed analysis of individualism *versus* collectivism

Characteristic:	Commentary	High-performance mix
Individualist/ collectivist		
Atomistic/ organic	An atomist believes that individuals are autonomous and independent of society. Their personal rewards derive from their own activities and their attitude to others is purely instrumental. Atomists play down emotions as a source of utility and emphasize pleasure from material consumption instead. Organists believe that the most important rewards are emotional and derive from participation in social activity. Activities devoted to improving and strengthening society generate especially large rewards. The more sacrificial effort people put in, the greater the emotional rewards they get out.	Atomism is bad psychology since it underestimates the importance of emotional rewards, particularly those derive from harmonious social interaction. The atomist is correct, however, that ultimately it is individuals that take decisions. A high-performance culture recognizes that economic performance depends on the interaction of numerous individual decisions – decisions taken by people with real concerns about the society in which they live.
Dynamic/ static	A dynamic culture regards the environment as highly volatile. Change is endemic and it is necessary to adapt and evolve in order to survive. Change is exciting and people can thrive on it. A static culture believes that the environment is stable. Change can be neutralized in order to preserve the status quo. Homeostasis provides much-needed security.	The environment is volatile. Major changes usually require adaptation but minor changes can sometimes be neutralized by an appropriate respond. People can only stand so much excitement from change.
Incremental/ radical	An incrementalist believes that changes are typically small and localized. They relate to particular products or places. The people close to the changes are in the best position to respond. A decentralized system that empowers individual decision-making produces the most effective responses. A radical believes that changes affect the entire economy. Radical actions are required to take advantage of new opportunities or respond to emergent threats. This requires a centralization of power.	Volatility in the environment takes different forms. Minor changes occur all the time, whilst major changes occur only intermittently. Minor changes can easily be delegated to individuals to handle; indeed, standard procedures can be developed to deal with the most common types of change. Major changes can take many different forms and require a more consultative and collective response. Leaders have an important role in building consensus where radical change is required.
Democratic/ elitist	A democrat believes that everyone has unique life experiences which make them worth consulting on how to respond to ma-	Leaders are specialists in taking complex decisions. Leaders constitute an elite – but they should be an ‘open elite’ which anyone can

(continued on next page)

Table 5  
(continued)

Characteristic: Individualist/ collectivist	Commentary	High-performance mix
	<p>major changes. So far as minor changes are concerned, they can be left to handle them themselves.</p> <p>An elitist believes that only a select group of people of high intelligence or 'good breeding', etc. have the ability to form correct opinions and to carry out the appropriate calculations.</p>	<p>attempt to join. Leaders should consult their followers, but ultimately they must act on their own judgment. Ineffective leaders should be replaced – followers should be able to replace a bad leader, or quit a badly-performing group. Leadership roles require people of exceptional ability, but this ability is difficult to identify in advance.</p>
Market-based/ planning-based	<p>The atomist recognizes that markets provide the flexibility that allows different people to respond in different ways to similar events. Market-making middlemen adjust prices to match long-run supply and demand; they also hold inventories to buffer short-run fluctuations.</p> <p>From an organic perspective, planning is the most direct means of achieving consistency between individual responses since it uses a single directing mind. A planner may administer prices or ration quantities.</p>	<p>Planning and markets need to be combined. Firms are planning units which coordinate tightly-coupled systems. Households also plan, but on a smaller scale. Markets link these different planning systems in a loosely-coupled way. Factor markets price the labor and capital employed by firms. Firms which attempt to plan activities which are better coordinated by a market will fail to break even. By allocating scarce factor supplies to the most viable firms, the factor markets determine which activities are planned and which are not.</p>
Efficiency-based/ status-based	<p>The atomist exploits market competition to eliminate waste. An inefficient producer cannot match the price of an efficient producer, and so customer switching eliminates wasteful production methods. Consumers who value products most out-bid those who value them least, so outputs are not wasted by consumers who do not value them. The organicist notes that a consumer's ability to pay depends on income. Consumption should reflect basic needs and social status. Since basic needs are similar, necessities should be allocated fairly. Luxuries should reward service to society as a whole and not just wealth derived from scarce factors of production.</p>	<p>People care both about their own consumption and about the kind of society in which they live. Market-based incentives to eliminate wealth can make everyone better off, but only if those who make the savings are prepared to share them with others. If they are forced to share them, then the incentive to make the effort to drive out waste is reduced. An ethic of community solidarity, which provides emotional rewards to those who reduce waste for the benefit of others is the best solution. Thus a market system can usefully be supplemented by a 'honors system', provided that honors are awarded for sacrificial effort and not simply sold to the highest bidder.</p>

(continued on next page)

Table 5  
(continued)

Characteristic: Individualist/collectivist	Commentary	High-performance mix
Consumer-oriented/producer-oriented	<p>The atomist believes that people derive rewards mainly from material consumption. Novelty and fashion, packaging and presentation, are not trivial matters, but sources of serious satisfaction. The proliferation of different product varieties made possible by technology and trade is to be welcomed. So too are the efficiency gains generated by specialization, even though work becomes monotonous. Services are also valuable, even though no tangible artifact is produced.</p> <p>Organicists believe that people derive rewards mainly from producing goods. They value product variation only when it arises from the use of local materials, and from the personal style of the worker. They value tangible product over intangible services, and craft work over mass production. Producer motivation is strengthened by a long-term relationship with the customer which allows the producer to witness the product in use.</p>	<p>Consumer culture promotes the development of new technology. It exploits advances in technology and communication to significantly improve the material living standards of the poor.</p> <p>However, workers ‘alienated’ by mass production will produce poor quality, so ‘job enrichment’, which limits specialization, may actually improve overall efficiency. They may also seek enrichment through trade union activism.</p> <p>Not all workers may require job satisfaction, however. Satisfactions can also be obtained from hobbies and recreations. Boring jobs may indirectly enrich cultural life by encouraging people to seek satisfaction in community activity instead.</p>

Table 6  
Detailed analysis of pragmatism *versus* proceduralism

Characteristic: Pragmatic/proceduralist	Commentary	High-performance mix
Empirical/theoretical	<p>A pragmatist believes that the response to change should be based on evidence rather than theory – it should be improvised on the basis of previous experience. Everyone has unique life experiences which help to prepare them for taking decisions. Belief in the uniqueness of personal experience links pragmatism to atomism. A proceduralist believes that decisions should be explicitly ra-</p>	<p>Theory and experience need to be combined. Neither evidence without theory, nor theory without evidence, will produce good decisions on how to respond to change. In some situations there is no relevant theory, whereas in other cases there are multiple theories, and hence confusion. Theories invariably abstract from certain factors, and may therefore distort a decision if the omitted factor is im-</p>

(continued on next page)

Table 6  
(continued)

Characteristic: Pragmatic/ proceduralist	Commentary	High-performance mix
Outcome-based/ process-based	<p>tional, in the sense of being grounded in some theory. Without the correct theory, evidence cannot be properly interpreted. Decisions should be based on calculation rather than improvisation. Since the mastery of theory often requires intellectual ability, theoretical orientation is often linked to elitism.</p> <p>Proceduralists believe that a correct theory can suggest a rational procedure which will guarantee a correct decision. A group of people (e.g., a committee) may be involved in taking the decision. Pragmatists believe that procedures normally delay a decision, and make the outcome worse. Disagreements in committees can add to delays; it is better to make one person clearly responsible for a decision, and let them 'get on with it' right away.</p>	<p>portant. On the other hand, ignoring relevant theory can mean that the significance of key evidence is not appreciated.</p> <p>Rational procedures may be useful in dealing with transitory volatility – e.g., in recording reservations or managing inventory. But there are few cases where theory is good enough to identify an optimal procedure. Procedures can also be useful in encouraging autocratic individuals to consult with knowledgeable people. Otherwise it is individual experience that is crucial. Selecting the right individual is more important than optimizing the procedure they employ.</p>
Risk-taking/ risk-averse	<p>A proceduralist believes that risk can be reduced through rational decision-making processes, whereas a pragmatist denies this. The proceduralist worries that correct procedures have not been properly followed, whereas the pragmatist, having improvised their decision, simply sits back and waits for events to unfold.</p>	<p>Large intermittent shocks cannot easily be addressed by routine procedures, and so risk is inescapable. Frequent minor shocks can often be addressed by rational procedures which involve collecting and processing information before a decision is made. The collection of information allows risk to be managed, although it cannot be eliminated altogether. People who are responsible for dealing with large intermittent shocks must be willing to take substantial risks.</p>
Artistic/ scientific	<p>Science analyzes local situations in terms of timeless universal laws, whereas the artist often expresses surprise and wonder at a situation. The scientist typically values uniformity whereas the artist values diversity. A scientific approach supports the development of a theory and the collection of evidence in a systematic way. It therefore underpins a procedural approach. Art tends to emphasize an emotional or even mystical response to a situation which is not fully un-</p>	<p>Economic theory has employed social scientific principles, such as the division of labor, specialization according to comparative advantage and global competition, with considerable success. Decision-makers who do not understand these principles are at a major disadvantage in business life.</p> <p>Economics has proved much less successful, however, in analyzing the emotional rewards that people derive from work and social activity. A combination of scientific un-</p>

(continued on next page)

Table 6  
(continued)

Characteristic: Commentary	High-performance mix
<p>Pragmatic/proceduralist</p> <p>derstood. It focuses on situations which are difficult, or impossible, to understand in purely scientific terms. It therefore supports a pragmatic approach to decision-making.</p>	<p>derstanding of the laws of markets on the one hand, and an artistic appreciation of emotional factors on the other, is therefore the appropriate combination for successful decision-making.</p>
<p>Personal/impersonal</p> <p>Pragmatists believe that people know a great deal more than they realize, and so it pays to converse with them rather than wait for them to tell what they know. People can also say more than they can write, because tone and gesture can aid expression. Pragmatists try out their ideas in conversation with other people, provoking others into revealing what they think. This helps them to arrive at a decision quickly. Proceduralists believe that written communication is superior to the spoken word because it is more precise. There is less scope for ambiguity and reason is unlikely to be clouded by emotion. Proceduralists prefer to consult through memoranda, which they study carefully before arriving at their decision.</p>	<p>Complex arguments benefit from being set out formally, but simple powerful ideas can often be expressed most vividly in conversation. Highly original ideas are difficult to articulate in a formal way. Original solutions to problems are therefore more likely to be generated through personal interaction.</p>
<p>Unprincipled/principled</p> <p>Principled persons believe that they are under moral obligation to a higher authority. They are called to play a particular role in society. They can only achieve peace of mind by doing their duty. Their higher nature (conscience, or spirit) recognizes that they need to control their lower nature (body, or passions). Self-control can be exercised through positive emotions, e.g., enthusiasm for a cause, or negative emotions, such as guilt and shame. Principles need to be based on functionally useful moral values: honesty, loyalty, hard work, and so on. These support teamwork on projects and facilitate coordination between different teams. An unprincipled person believes in satiating their biological needs. The only source of authority is their body; their objective is pleasure rather than peace of mind.</p>	<p>People need to respect their bodily requirements for physical survival, but over-indulgence can damage health. People have emotional as well as material needs, and those who realize this will be happier than those who do not. A moral framework enhances emotional rewards derived from participation in socially beneficial projects. Traditional moral principles such as honesty, loyalty and hard work facilitate coordination in complex economies by reducing transaction costs, encouraging investment, and promoting hard work. An effective leader will therefore promote traditional moral principles, even if their ambitions are purely materialistic.</p>

(continued on next page)

Table 6  
(continued)

Characteristic: Commentary	High-performance mix
Pragmatic/ proceduralist	
Secular/ religious	<p>The secular moralist expects to derive emotional benefits as part of an enhanced quality of life, whereas the religious person expects a dividend in the after-life. Religious people are therefore motivated by deferred rather than immediate emotional rewards. Their moral conduct is therefore more robust to disappointments. On the other hand, their beliefs in the after-life can prove vulnerable to attack from skeptics.</p> <p>Rivalry between religious groups can promote distrust as well as trust. Religious commitment can make religious conflict very intense. On the other hand, religious commitment can also promote extreme forms of self-sacrifice and heroism, such as those involved in fighting in defense of a country. While both secular morality and religious belief can generate emotional satisfactions (for people of good conduct), religion adds a further dimension to motivation which secularism lacks.</p>

Table 7  
Detailed analysis of degree of trust

Characteristic: Commentary	High-performance mix
Low-trust/ high-trust	
Selfish/ altruistic	<p>Selfish people cannot empathize with others. Their concerns are focused on their own consumption, work and leisure. They may be concerned with status, but only in an instrumental way – as a means of gaining privileged access to resources. They are concerned with the state of society only in so far as it impacts on their own material interests. Altruistic people empathize with others – either personally, e.g., friends – or impersonally, e.g., concern for the poor. They can derive vicarious pleasure from other people's happiness, and share their suffering too. Degrees of altruism differ depending on the weight that people place on other people's interests.</p> <p>Altruism is important in channeling high-tension people into providing support for others. Self-interested ambition can stimulate high-tension but generates external diseconomies, and leads to under-provision of emotional support. It does nothing to address the income inequality generated by competition between self-interested people, or to support the losers from the competitive process and their dependents.</p>
Autocratic/ consultative	<p>When other people are selfish and cannot be trusted, their opinions will reflect where their own interests lie. Consultation creates a risk of distorting decisions through lobbying from vested interests. If you cannot believe</p> <p>Consultation is useful not only in improving a decision but in motivating people to implement a decision through participation in the decision process. Opinions received need to be critically examined, however. Where</p>

(continued on next page)

Table 7  
(continued)

Characteristic: Commentary	High-performance mix
Low-trust/ high-trust	
	<p>what other people say, there is no point in asking their opinion. If other people are honest and their preferences are aligned with those of the decision-maker, their opinions may be valuable since they are likely to have been thinking about similar issues for themselves. Hence consultation is worthwhile.</p>
Aggressive/ orderly	<p>vested interests are important, conflicting opinions from the different interests will reveal that a problem exists.</p> <p>The high-trust view is correct. An advanced society is highly complex and the 'law of the jungle', which usually rewards aggression, does not work well. Reprisals can lead to feuds which originate with a simple misunderstanding.</p> <p>Competition is not just about challenging monopoly but about stimulating and diffusing socially useful innovations. Competitors who sabotage each other's activities do not benefit society and so 'rules of the game' are required. Competition works best when rivals can be trusted to abide by the rules.</p> <p>While aggression may sometimes motivate innovation, other motivators such as public recognition are available too. Channeling aggression into competition may be a useful way of controlling a potentially disruptive biological urge, but it still needs to be moderated through self-control.</p>

Table 8  
Detailed analysis of the degree of tension

Table 8  
(continued)

Characteristic: High-tension/ low-tension	Commentary	High-performance mix
Deliberative/ spontaneous	<p>natively, people with wide horizons may know that higher standards are being achieved elsewhere. They are dissatisfied with the status quo. They believe that it can and must be changed. Complacent people have low norms. They have narrow horizons due to a parochial outlook. They are satisfied with the status quo, and their chief ambition is to maintain it.</p>	<p>Deliberation prevents people with high norms from giving up too easily. Spontaneity undermines the value of aspirations, since the aspirations are merely fantasies.</p>
Optimistic/ pessimistic	<p>A deliberative person concentrates single-mindedly on achieving his objective. He remains focused on it until he has either achieved it or has irretrievably failed. Success is quietly satisfying but failure is mortifying. Spontaneous persons focus on whatever has caught their attention most recently. It is not necessary to finish one task before starting another. Success is a cause for celebration, however minor it may be. Failure is attributed to bad luck or blamed on others.</p> <p>An optimist believes that the environment is favorable for the successful completion of a project whereas a pessimist believes that it is unfavorable. An optimistic culture promotes general optimism through notions such as 'the time is right' and 'it's all up for grabs'. A pessimistic culture promotes the idea that if something was really a good idea then someone else would already have done it.</p>	<p>Deliberation prevents people with high norms from giving up too easily. Spontaneity undermines the value of aspirations, since the aspirations are merely fantasies.</p> <p>Optimism reduces perceived risks and thereby encourages investment and innovation. However, unwarranted optimism can lead to wasteful projects being undertaken. Where the private benefits of investment are less than its public benefits, optimism may induce investors to risk losses for the public good. If private and social benefits are aligned, realism is better than either optimism or pessimism, as it leads to better investment decisions.</p>
Confident/ unsure	<p>When an optimist is confronted by a group of pessimists they may decide that they must be wrong. They need self-confidence to believe that they can be right when everyone else is wrong. A confident culture sustains the idea that people in the group are always right, at least compared with people in other</p>	<p>Most leaders require self-confidence to take the initiative in setting up groups, and take the responsibility if things should go wrong. A combination of optimism and self-confidence is a hall-mark of an entrepreneurial culture.</p>

Progressive/ conservative	<p data-bbox="280 371 654 475">groups. It may be based on a notion of innate superiority. People who are unsure usually adapt their opinions to conform with the majority view.</p> <p data-bbox="280 498 654 811">Progressives regard change as largely benign. They believe it provides opportunities rather than threats, whereas conservatives take the opposite view. Progressives are continually raising their norms in line with new possibilities whereas conservatives are more concerning with ensuring that existing norms are maintained. Being progressive involves innovation rather than conservation. Both are demanding, but innovation tends to be more demanding because the element of novelty increases the risks.</p>	<p data-bbox="678 498 1048 651">A high-performance culture requires a combination of science-driven innovation with the maintenance of functionally useful traditional morals. It therefore requires both a progressive technical agenda and a conservative moral agenda.</p>

## 5. Method and history

### 5.1. Methodological issues in modeling culture

This third and final part of the chapter attempts to draw together the threads of the preceding discussion. It begins by summarizing the principal differences between conventional neoclassical economics and the economic theory of culture outlined above. Five main differences have been identified. Contrary to conventional neoclassical economics, the economic theory of culture put forward above asserts that:

- Information is costly, both to collect and communicate. Where fundamental issues are concerned it is often impossible to collect objective evidence that will discriminate between alternative theories: thus different systems of beliefs can co-exist almost indefinitely. Conflicts between rival value systems are even more difficult to resolve; their authority often derives from tradition or from spiritual experiences whose authenticity it is impossible to assess. Information costs help to explain uncertainty – uncertainty exists because it is prohibitively costly to collect all the relevant information before taking a decision. Many uncertainties are radical and existential, because fundamental issues are peculiarly difficult to resolve. It is not just ‘facts’ that are uncertain – theories are uncertain too.

- The economic environment is volatile. Factual information is therefore continually obsolescing. A steady flow of new information is required to permit the economy to adapt appropriately to changing circumstances. Information sources are localized, so different people have access to different information. Furthermore, since different people use different theories to interpret this information, different people will react to similar events in very different ways. An important advantage of decentralization is that it empowers people to act immediately on their judgment of a situation. Where opinions differ about the advisability of change, competition permits the optimists to bid resources away from the pessimists, and so the weight of opinion as expressed in the market determines whether how much change takes place.
- Because information is a public good, it is inefficient to replicate its collection unless communication costs are high. Furthermore, it is better to concentrate information processing on people with a comparative advantage in interpretation – i.e. those whose beliefs are closest to the truth. These will tend to be the people with a track record of successful decisions. Intermediaries therefore emerge who specialize in processing information of particular kinds. Entrepreneurs intermediate by setting up new firms to sell new products, whilst social leaders intermediate by setting up new clubs and charities.
- Each person's utility depends upon emotional as well as material rewards. Change often elicits a powerful emotional response; some people thrive on the excitement of change, while others fear its consequences. Leaders need to be calm when taking decisions – they have to be confident in their judgments. They also need to understand the anxieties of their followers and provide them with reassurance if they can.
- Emotions are morally framed. Pride and self-esteem on the one-hand, and guilt and shame on the other, are powerful emotions. Leaders can associate positive emotions with actions that promote coordination and negative emotions with actions that undermine coordination. This engenders trust and so reduces agency costs and transactions costs. Improved coordination enhances the performance of the group. The leader can recover costs from this enhanced performance by various means – taxes, membership fees, voluntary donations – depending upon the type of group involved.

These assumptions are perfectly compatible with a rational action approach to modeling. However, the detailed specification of a model is rendered difficult by the fact that both theories and facts are uncertain. Nevertheless, the basic structure of the model can be set out using three propositions:

- Leadership operates at different levels. High-level leaders control nation states, organized religions and international pressure groups. Middle-level leaders manage firms, clubs and charities, whilst low-level leaders manage families and local communities. High-level leaders set a high-level culture within which the other leaders must operate. Lower-level leaders can 'free-ride' on useful values and beliefs inculcated by the high-level leader, but if they disagree with the values promoted at

the higher level they must invest in counteracting them. This issue separates people into those who prefer to assimilate and conform, and those who oppose or resist instead [Jones (1984)].

- Followers have a choice of leader. In a democracy they are free to vote for a political party and to practice their preferred religion; they can also decide which firm to work for, which clubs to join, and which charities to support. People recognize that when they decide to follow the leader of a particular group they must adopt the leader's values and beliefs. Many key decisions regarding choice of leader are made around the time a person comes of age. Using the prior beliefs inculcated in their childhood by their family and community, people decide which leaders they will follow in their adult life. They evaluate the risk that given leader's values and beliefs will turn out to be wrong. They take account of their own personal characteristics, as they perceive them, because these will determine their emotional responses later on. The final choice that an individual makes will reflect not only their beliefs but also their preferences – whether he is selfish or altruistic, material or emotional, and so on.
- Leaders seek to optimize the values and beliefs they promote in order to fulfill their own objectives. Honest leaders will promote their true beliefs – acting on conviction – but dishonest leaders may adapt their values in order to maximize their following. Culture change will occur both through leaders modifying their values to maintain market share, and by followers switching between committed leaders who are unwilling on principle to adjust their values for the sake of expediency.

These propositions show how the basic economic principles of choice and competition can be applied to culture. The economic theory of culture subsumes standard neoclassical economics as a special case. In a simple neoclassical economic model, there is just a single culture which corresponds to the 'true' model of the economy. This 'true' model assumes that people are selfish and materialistic. It is therefore a model of a low-trust society. The high-trust alternative is excluded by assumption. It is also a model of an individualistic society, since people care nothing about the welfare of others and take a purely instrumental view of the kind of society in which they live.<sup>9</sup>

## 5.2. Historical perspectives

The empirical and historical literature linking culture to economic performance is extremely diffuse. It is possible, however, to identify three specific issues which have had a significant impact on the economic analysis of culture: the Weber thesis, obstacles to development, and the role of freedom.

Economic historians have long debated the Weber thesis that the Protestant Ethic promoted the growth of capitalism [Weber (1930)]. There is broad agreement that the spread of international commerce in Europe coincided with the Reformation (although

<sup>9</sup> For a comprehensive critique along these lines see Roberts and Holden (1972) and Schoeffer (1955).

pre-reformation origins in Italian city-states must not be overlooked). However causality has been questioned. The Protestant Ethic can also be understood as accommodating Christian beliefs to the requirements of an emerging mercantile middle-class [Schlicht (1995)]. Behind the theological revolution, therefore, a vested business interest may be detected. Protestantism 'dis-intermediated' the Papacy and gave people a direct relationship with God through prayer. It undermined the case for paying the church for indulgences and the upkeep of chantries, and for obeying prohibitions on usury – and thereby reduced the economic burdens on the middle-class.

The theological content had real effects, however. The Protestant convert accepted grace through personal salvation. The sign of grace was not monastic seclusion, as before, but spreading the Gospel through engagement with the world. Business was a 'calling' which could promote missionary work. It supported the expansion of commercial empires into the 'darker corners' of the world. Whilst the origins of Protestantism may be questioned, therefore, its effects appear to be those which Weber predicted. Protestantism replaced the collectivist and procedural culture of the Roman Catholic church with a more individualistic and pragmatic culture, which formed the foundations of the competitive individualism that characterizes the West today.

Jones (1981, 1988) examines the 'take off' of commercialism in Western Europe from a different perspective and arrives at rather similar conclusions. Jones regards entrepreneurship as a natural human behavior which supports survival by encouraging people to show initiative in meeting their material needs. However entrepreneurship can be stifled by political tyrannies, in which collectivism and proceduralism are imposed [Rosenberg and Birdzell (1986)]. The motive is to monopolize the tax-base and use its revenues to support a leisured lifestyle for the elite. From this perspective the Reformation is a protest movement which, by overthrowing a parasitic religious elite, liberates people to follow their natural entrepreneurial inclinations. China and other Asian powers have never liberated themselves in this way; when one elite is deposed, another simply takes its place. Once again, however, the explanation may be cultural – perhaps Western society is intolerant of political oppression in the way that some Asian societies are not.

Development economists have addressed similar issues but from a more secular perspective [Bardhan (2000)]. A drive to 'modernize' post-colonial societies is typically advocated [McClelland and Winter (1969)]. In the 1960s modernization became the secular equivalent of the Protestant ethic. The object was to engineer a high-tension society driven by a desire to catch up with the West, in place of a low-tension society where people are content with low living standards and high mortality. Individualism was a secondary consideration; in the 1960s planned industrialization behind protective tariffs was the recommended strategy, and it was only in the 1990s that privatization and liberalization took over.

A major obstacle to economic development in the poorest countries is weak internal communications which perpetuate a cellular social structure based on local family and tribal loyalties. High levels of local trust are combined with low levels of trust at the national level. National government is too corrupt to intermediate the flow of funds between international agencies and local people. The engineering of trust at the na-

tional level has been accomplished in a number of Asian economies but with one or two notable exceptions there has been little success in Africa. As noted earlier, creating a high-tension high-trust society has proved difficult even in prosperous Western countries.

The disintegration of Soviet communism has led to a resurgence in research dedicated to showing that 'freedom' holds the key to economic performance [Gwartney and Lawson (2003)]. The guarantor of freedom is usually said to be a US-style constitution [Scully (1992)]. A range of freedom indicators has been developed, and cross-country statistical regressions have been reported which confirm the impacts of freedom on living standards and economic growth. On the whole these regressions simply confirm that, other things being equal, Western-style competitive individualism promotes economic growth. The point is not difficult to make if a sufficient number of poor African dictatorships is included in the sample of countries. As in any cross-section regression, there are omitted variables, and much of the sample variation remains unexplained. The apparent significance of some of the variables may be due to the presence of omitted cultural variables, including the legacy of traditional religion [Kohut et al. (2000)]. Whilst these regressions are a significant advance on anecdotal evidence, the range of explanatory variables is too narrow to offer a full account of cultural factors in economic performance.

Advocates of freedom as the critical factor are usually unsympathetic to a cultural interpretation of their findings and this biases the way in which they interpret their results. They typically believe that laws, not morals, reduce agency costs and transaction costs. They believe that a written constitution enforced through impartial courts is better than an unwritten constitution enforced through social sanctions. They believe that the biological drives such as greed and aggression are better guarantors of competition than a genuine desire to benefit the customer. They therefore ignore crucial issues such as why greedy judges do not accept bribes, and how the basic needs of people with low incomes are met.

The historical significance of culture is related to the historical significance of other intangible public goods, such as technological know-how. It is therefore not surprising that modern writers on convergence of national economic growth rates have begun to develop an interest in cultural issues. The traditional way of analyzing the convergence of growth rates focuses on technological diffusion, but there is no reason why the analysis should not include cultural diffusion too. The rapid spread of free-market ideology in the 1990s, with many governments reducing tariffs and privatizing and deregulating their utilities, is a clear example of cultural diffusion. Such cultural diffusion can lead to convergence in institutions as well as in rates of growth. A particularly interesting development has been the incorporation of religion in the convergence model.<sup>10</sup> Whilst the European empires of the nineteenth century are often credited with the spread of Christianity, the US-led Western 'empire' of the late twentieth century is noted chiefly

<sup>10</sup> For a significant step in this direction see Barro and McCleary (2003).

for its spread of secularism. This raises the issue of whether religion or secularism is best for economic growth. If religion is best then the spread of secularism could lead to convergence on a sub-optimal level of growth. The analysis in this chapter suggests that it is the specific content of religious belief that is crucial in this respect, because it is the specific beliefs that determine the emotional incentive structure which motivates people. A simple distinction between religion and secularism is therefore too crude to properly identify the link between religious belief and economic performance. The impact of the spread of religion and culture on the convergence of growth rates is clearly an important topic which warrants further research.

## 6. Conclusion

This chapter has shown that the influence of culture on the economy extends well beyond the production and consumption of cultural goods in the field of media and the arts. Culture is concerned with the production and distribution of values and beliefs relating to fundamental issues. Cultural products are simply one of the means through which these values and beliefs are expressed. Identifying the fundamental issues addressed by culture is the key to analyzing its impact on economic performance. Values and beliefs of a suitable kind can improve economic performance – both materially, and by enhancing quality of life. Culture is therefore an economic asset. Culture is shared by communication between the members of a social group. It is, in fact, an intangible durable public good. Significant investment is required to create and maintain this public good. Competition between cultures, in terms of relative economic performance, is essentially competition between social groups in investing in appropriate public goods of this type.

By modifying five key assumptions of conventional neoclassical economics, and introducing a theory of leadership, it is possible not only to explain how culture influences performance but also to explain how cultures will adapt to changing local conditions. There are different levels of leadership, corresponding roughly to the size of the group that the leader controls. At any given level the nature of competition is strongly influenced by the media that leaders employ to recruit and retain their followers. The development of mass media disseminating visual images has had a profound effect on ideological competition between political leaders. Changes in the media have made the promotion of high-trust cultures extremely difficult, whilst a skeptical attitude towards leadership in general has diminished the supply of able leaders. Distorted incentives in the market for leadership mean that the most effective culture does not always prevail.

The ideal culture from an economic point of view is individualistic, pragmatic, high-trust and high-tension, though each of these attributes must be moderated to some degree by the need to adapt the culture to local requirements. A simple way of summarizing the advantages of this culture is to note that it is both entrepreneurial and moral. It is entrepreneurial because it encourages innovation and risk-taking, and it is moral because it discourages innovations or risky ventures that cause disproportionate damage to the

interests of others. It is moral because it encourages honesty and loyalty, but it is entrepreneurial because it does so without stipulating rigid conformity to specific practices.

The high-performance culture also encourages both freedom and responsibility. Freedom allows diversity of behavior and thereby facilitates innovation. It also decentralizes power: it allows decisions to be taken by people who have immediate access to relevant information, and so avoids the expense and delay of referring straightforward decisions to higher authority. However responsibility requires people to show consideration for others [Ellickson (1991)]. In respecting other people's freedoms, they accept constraints on their own. They consult with other people before acting in an unexpected way. Consultation is effected both formally and informally. A high-trust culture encourages people to honor informal agreements. A legalistic culture sets out rights and responsibilities, records them and enforces them. People are obliged to negotiate with people who hold the relevant rights before they act. Informal methods work well with members of a tightly-knit social group – friends, relatives and neighbors – whilst formal methods are more appropriate for more impersonal groups. A moral culture will rely on trust as much as possible but will underpin trust by the rule of law.

The high-performance culture respects both tradition and modernity. Embracing modernity promotes scientific research and the practical application of science in engineering and medicine. It also encourages economy through the systematic elimination of waste. Tradition on the other hand underpins many core moral values. Conflict can ensue when scientific discoveries appear to undermine traditional religious beliefs on which conventional morality is based. Some religions are more vulnerable than others on this score, however. An entrepreneurial culture is not devoid of religion, but rather involves religious beliefs which co-exist with a scientific view of the world.

**Abstract**

This chapter begins by noting that culture as an element in economic development in the Third World has been largely neglected in traditional development economics, most writers either seeing culture as an obstacle to development or ignoring it altogether. Recently a shift in thinking has occurred whereby culture is now more widely seen as being more central to the development process, especially where a human-centered rather than a goods-centered view of development is taken. A particular aspect of culture that has been seen as important has been cultural diversity; it is argued that the beneficial aspects of diversity can only be realized when they are seen within a global ethical framework. The chapter goes on to consider the destructive and constructive role of conflict in bringing about social change, and discusses the pervasive effects of globalization on the economies and cultures of the world, arguing that international integration can lead to national disintegration. Next the chapter looks at the role of tourism as a significant economic and cultural force in developing countries. Finally the essay concludes with some recommendations for policy.

## 1. Culture in development thought

The role of culture in our thinking about development has undergone a remarkable change in the last four decades. In spite of occasional declarations to the contrary such as those in the Universal Declaration of Human Rights of 1948, which states in Articles 22 and 27 that “everyone has the right to participate in the cultural life of their community, to enjoy the arts and to share in scientific advancement and its benefit” [United Nations General Assembly (1949)], most economists have either ignored culture completely or have found traditional cultural attitudes and practices obstacles to development. The neglect of culture by economists has been reflected until recently in the work of international institutions such as the World Bank.

Among those who took culture into account but saw it as a force working against development, Gunnar Myrdal (1968) is an outstanding example. In *Asian Drama*, for instance, he argued that traditional practices such as those relating to hygiene (or rather lack of hygiene), and traditional attitudes to work, leisure, saving, competition and co-operation must be eradicated before countries can embark on their modernization. He, in the company of many development experts in the 1950s and 1960s, regarded most traditional cultural “attitudes and institutions” as major obstacles to development. He thought that the people in developing countries were lethargic and work-shy, lacked habits of cleanliness and punctuality, had no desire to make money and lacked a willingness to cooperate, to experiment, to explore and to adopt a rational approach to life and work. In short, their traditional attitudes were hostile to development. The implication was that unless the people in developing countries adopted the culture, habits and customs of advanced Western countries, there was no hope of their developing. It is only a small exaggeration to say that Myrdal’s view was that not until the Indians could become like modern Swedes would successful development in India occur.

Even when some writers did not think that culture was an obstacle to development and even when they recognized it as of some value, they attached low priority to it. Culture can be taken care of, these authors thought, after more urgent needs such as food and health have been met. Others regarded some cultural features such as frugal consumption habits, an obedience to authority and a willingness to cooperate such as that displayed by the Japanese, as useful instruments of development. They advocated building modernity on features of tradition they saw as being useful for this purpose.

Since then the pendulum has swung in the opposite direction. Culture has become the fountain of progress and a key element in the development process. This change in outlook has been associated with a shift from thinking about development in purely material or commodity-centered terms to an approach orientated towards human development. The United Nations Development Strategy for the 1990s, for example, adopted human development as its key focus, reflected in the UNDP’s annual *Human Development Reports* which first appeared in 1991. It is no coincidence that the 2004 edition of the *Human Development Report* was entirely devoted to culture, under the title *Cultural Liberty in Today’s Diverse World* [UNDP (2004)].

Among those who argue that culture matters, Amartya Sen has played an outstanding part. He writes “[t]he issue is not whether culture matters . . . [t]he real issue, rather, is how culture matters. What are the different ways in which culture may influence development?” [Sen (2004)]. And in the process of exploring this question, he argues against the view that the fates of countries are effectively sealed by the nature of their respective cultures. It is wrong to see culture as independent, unchanging and unchangeable; it should be seen as non-homogeneous, non-static and interactive. We are now beginning to see that culture should neither be neglected, as it has often been in the past by economists, nor elevated to a homogeneous, stationary and deterministic force, as some models of anthropology have done.

There are two views of the relationship between development and culture. According to the first, economic growth is the objective and culture a means to promoting it. The value of culture is entirely instrumental. Protestantism and, by a later extension Confucianism and other religions, have been thought of as cultures that contribute to savings, hard work, discipline, punctuality, hygiene and healthy living habits, and are therefore to be welcomed. According to this view, as noted above, if cultural attitudes and habits hamper economic growth, they should be eradicated. This view of the relationship between culture and development is interesting and important, but one may question whether economic growth is the end.

The alternative view sees growth as the means to our freedom to live the way we value. And what we value and cherish is a matter of culture. Looked at this way, culture is the desirable end; it is what gives meaning to our existence. This dual role applies not only to growth, but also to sustaining our environment, preserving family values or protecting civil institutions. We value some cultural features as means to certain objectives. But when we ask why we value these objectives, culture enters not as a servant of ends but as the social basis of the ends themselves. Economics and politics should, ideally, not only use culture but also serve culture.

What if conflicts arise between the preservation of a culture and the attitudes and institutions that are needed for economic growth and development? Inevitably, growth and change bring with them the demise of traditional ways of life, customs, styles and artifacts. As Sen (1999) has argued, it is then for the people to decide whether to sacrifice material goods for the preservation of a culture or whether to sacrifice certain cultural features for greater prosperity. “[I]n the freedom-oriented perspective the liberty of all to participate in deciding what traditions to observe cannot be ruled out by the national or local ‘guardians’ – neither by the ayatollahs (or other religious authorities), nor by political rulers (or governmental dictators), nor by cultural ‘experts’ (domestic or foreign).” [Sen (1999, p. 32)]

## 2. Diversity

A feature of culture that has moved to center stage in recent considerations about culture in economic development is cultural diversity. Cultural differences are celebrated

not only as a means to development but also as one of the most important ends of the development process. The emergence of diversity as a focus for development thinking is reflected in the work of UNESCO. It was responsible for the World Commission on Culture and Development whose report, published in 1995, was entitled *Our Creative Diversity* [World Commission on Culture and Development (1995)]. Subsequently UNESCO formulated the *Universal Declaration on Cultural Diversity*, adopted in 2001 [UNESCO (2001)], and then initiated a process aimed at drawing up an international convention on cultural diversity which would have the effect of raising the profile of culture in national and international affairs and of locating culture as an essential element in Third World development.

The move from condemning or attaching a low priority to celebrating cultural diversity, both between and within cultures, and from considering it as an obstacle to development to regarding it as part of the end, has been an illuminating change. It reminds us that development can take many forms, that styles of development can differ and that we are not all destined to end up as uniform Californian-type mass consumers. Yet it is clear that not all traditional cultural practices are either desirable in themselves or contribute to development. For this certain universal principles are necessary. There are indeed ethical principles that are accepted by all cultures, and these can form the basis for a global ethics. They furnish the minimal standards any political community should observe; beyond them, there is scope for different political visions, influenced by different cultural heritages and historical experiences. Among these minimum ethical principles is the respect for life, the need to alleviate suffering whenever possible and to avoid inflicting unnecessary suffering, to treat others as one wants to be treated oneself, the idea of human rights, the protection of people's integrity and respect for the vulnerability of all human beings. Democratic government, respect for the rights of minorities and peaceful conflict resolution are also part of the global ethics, as is the basic principle of intergenerational equity, which calls on present generations to take care of and use the environment and cultural and natural resources for the benefit of all members of present and future generations.

In the early days of development economics it was thought that mobilizing resources, and particularly savings for investment in physical capital, was all that was needed for development. Today we know that development calls for much more: development means improving the lives of the poor by transforming societies. This inevitably means social and cultural change; differences within and between cultures mean that desirable processes of change will not be uniform but will vary from place to place and time to time depending on economic, social and cultural circumstances.

Although cultural diversity is in a sense inevitable, there is something to be said in favor of getting rid of it. For example, diversity can lead to inefficiency in the expenditure of time and effort in communication; it would be so much simpler to communicate in a world where that was only one language. Standardized, uniform methods of communicating and conducting business would save resources. Nevertheless, the weight of opinion and evidence suggest that cultural diversity is desirable and valuable, for several reasons. First, diversity is valuable in its own right as a manifestation of the creativity of

the human spirit. Second, it is required by principles of equity, freedom of choice, human rights and self-determination. Third, in analogy to biological diversity, it can help humanity to adapt to the limited environmental resources of the world. In this context diversity is linked to sustainability. Fourth, it is needed to oppose political and economic dependence and oppression. Fifth, it is aesthetically pleasing to have an array of different cultures; so, for example, people enjoy consuming cultural expressions such as music originating from cultures other than their own. Sixth, it stimulates the mind and encourages creativity. Finally, it can provide a reserve of knowledge and experience about good and useful ways of doing things.

### 3. The role of conflict

Of course diversity can give rise to conflict, as the “clash of civilizations” thesis asserts [Huntingdon (1996)]. It is readily observable that the politicized meaning of “culture”, in the sense of the lifestyle of minorities, can give rise to tension and violence. Small differences such as those between the Muslims and Christians in the old Yugoslavia or between the Albanians and the Serbs in Kosovo, or between the Protestants and Catholics in Northern Ireland, or between the descendants of the sons of Abraham – the Jews and the Arabs – in West Asia, can give rise to tensions that break out in violent conflicts. They are at heart narcissistic conflicts.

Conflict is normally viewed as destructive of the social order. But it can be argued that conflict is not necessarily an obstacle to successful development [Streeten (1953), Hirschman (1995)]. Heraclitus thought that “war is the father of everything” and Machiavelli entitled a chapter in the *Discourses* “How the Disunion between the Plebs and the Senate Made [the Roman] Republic Free and Powerful”. One may even go further. Conflict, or at least some forms of it, can also be regarded as a pillar of democratic societies, as the glue that holds them together. Conflicts can provide society with the “social capital” it needs to be kept together. Hirschman (1995) has made a beginning in distinguishing between when conflict is destructive and when constructive. He distinguishes between conflicts about more or less, such as the distribution of income, and conflicts about either/or, such as abortion. Conflict arises inevitably with change. Globalization and technical progress benefit some countries, some regions, some sectors, and some groups, and harm others. In free societies those who suffer will tend to organize themselves and attempt to regain their position. Those who agree with them from a sense of social justice or sympathy will support them. One group is motivated by self-interest, the other by solidarity or a sense of fairness or fellow feelings. The strength of democratic societies derives from this combination and from the conflicts to which it gives rise.

In poor countries, conflict arises from a number of causes. Poverty can be a significant factor contributing to conflict, especially in the competition for resources. How far inter-tribal or inter-ethnic conflicts can be explained by economic or by cultural considerations is a moot point; Collier and Hoeffler (2000) in their research for the World Bank

suggest that it is often “greed” rather than “grievance” that precipitates such conflicts, in other words that economic rather than cultural motives underlie the violence.

Paradoxically, the reduction of poverty can also lead to conflict. If poverty comprises many more dimensions than lack of income, and includes deprivation of education and health, social exclusion, lack of employment, discrimination against women, environmental degradation of soil, water, forests and climate, insecurity, violation of human rights, lack of voice in the counsels of society, and lack of cultural expression, the chances of conflict over the reduction and eradication of poverty are greatly increased. Income can be divided in different proportions and is therefore easier to negotiate and to compromise on than decisions that are subject to an either/or choice. Ethnic, linguistic, religious and gender divisions and disagreements on voting rights give rise to non-divisible conflicts. Unfortunately it seems that these types of conflict which are not readily amenable to negotiation and compromise are on the increase.

#### 4. Globalization, development and culture

It has become a cliché to say that international interdependence is great, has increased, and will continue to grow. Normally this is intended to refer to trade, foreign investment, the flow of money and capital, and the migration of people. Advances in technology such as the jet, telex, satellite TV, container ships, super tankers and super ore carriers, and technical progress in transport, travel and above all in communication and information, have shrunk the world. By reducing the cost of communication, technology has helped to globalize production and finance. Globalization, in turn, has stimulated technological progress by intensifying competition, and competition has forced the introduction of new technology. Globalization has spread its results widely through foreign direct investment. History may not have ended, but geography, if not coming to an end, certainly matters less. And the interaction of technology and globalization has presented new problems.

The international spread of ideological and cultural impulses is at least as important as that of economic impulses. Observe the young in the capitals of the world: from Ladakh to Lisbon, from Maine to Mozambique, from West Virginia to East Jerusalem, from China to Peru, in the East, West, North, and South, styles in dress, jeans, hairdos, T-shirts, jogging, eating habits, musical tunes, attitudes to homosexuality, divorce, abortion and so on have become global. Even crimes such as those relating to drugs, the abuse and rape of women and children, embezzlement and corruption have become similar everywhere. But although American cultural influences are important, there are many other influences. As *Sainath (2002)* argues, “(t)he super-rich are seceding from their nations. So what you have is not a Western or East Asian or Southeast Asian or Chinese model. We are building enclaves of super-privilege. What you’re having is not a global village but a series of global ghettos. The Western élite is not the sole villain”.

But the impression of global uniformity can be deceptive. Just as trade, foreign investment and the flow of money have affected only a few regions of the world and left

the rest comparatively untouched (except for some negative effects), so the globalization of culture is only partial. Large areas of the world do not participate in these globalizing tendencies. The effects of globalization are evident in the towns and suburbs and the more advanced countryside, but the poor in the rural hinterlands, in spite of the spread of transistors and television, have been largely bypassed. And in many lands there has been a return to tradition and tribalism. Global integration has provoked national disintegration; nations have broken up into smaller, ethnic groups. An assertion of their indigenous values is often the only thing that poor people can do. Traditional values bring identity, continuity and meaning to their lives. Between the two opposite forces, the assertion of peoples' identities on the one hand, and globalization on the other – between what Barber (1995) calls Jihad and McWorld – nation states have found their base undermined [Streeten (2001)].

There are five reasons why partial international integration can lead to national disintegration. First, downsizing, restructuring, “delaying”, and re-engineering have reduced the demand for low-skilled workers in the rich and middle-income countries and have kept the wages of those who succeeded in keeping their jobs low. This has led to growing inequalities in the rich countries. Second, preventing excessive growth in the brain drain from developing countries makes egalitarian incomes policies impossible in those countries. Third, tax revenues to pay for social services have been reduced, though the need for them has increased. Fourth, the élites in low-income countries are opting out of national commitments; this leads to the neglect of essential social services like education and health. Fifth, the culture of these élites is global and estranged from the culture of the local people. Finally, the tendency of minorities to break away from their country and to form independent states, resulting in the proliferation of states, can be explained by their desire to participate directly in the benefits of globalization.

It is therefore apparent that in the developing world, globalization makes national government more difficult. Monetary and fiscal policies run up against the impact of global tides as people, international banks and multinational corporations avoid the intended results by sending or spending their money abroad or attracting money from abroad. The obligations of extended families, government and religion disappear as people leave their rural communities to live in large cities. Recently-enriched members of the middle class with links to politicians and officials often use their newly acquired powers in corrupt ways that counteract traditional values. Impoverished, disoriented provincials overrun cities, once the seat of the privileged.

To sum up, globalization has brought benefits to some individuals or groups in the developing world, but has left out or harmed others. The same can be said of whole countries. Faced with these effects, governments may adopt one of three policy responses: they may give unqualified support to joining the global economy; they may aim for complete isolation and delinking from the global economy; or they may attempt some selective gearing into and selective delinking from the global economy. Common sense might indicate a preference for the last of these, so that the community can benefit from the good impulses propagated by the global system while excluding the bad ones.

The question is whether inadequate bureaucracies and politicians can be entrusted with this task.

## 5. Tourism and development

One aspect of the growth of the global economy that has both economic and cultural implications for developing countries is tourism. As a source of economic benefits, tourism has much to offer. Compared with agricultural commodities it is less volatile and compared with manufactured products it is less subject to import restrictions by advanced countries. It creates many jobs if the multiplier effects work; visitors to hotels create a demand for souvenirs, restaurant services, boat and taxi rides, car services, furniture for hotels, food, etc. It is a potentially large foreign exchange earner.

Furthermore, tourism raises the educational levels of the local population, encourages growth of a middle class (who will themselves become tourists) and promotes social mobility. American Indians' and Eskimos' art has been reinvigorated by tourist demand. Tourism encourages contact with the rest of the world through radio, TV, advertising and migration. It is a useful way of diversifying the economy. It is better to sell sugar, sea and sun than sugar alone and even better to sell safaris. There are thus many good arguments for encouraging tourism in developing countries, but there are also some arguments for caution in encouraging cultural tourism, especially if income disparities between tourists and the local population are large.

First, it is not entirely a play on words to say that rendering services for tourists such as waiting, hotel and restaurant services, driving, etc. tends to make for servile attitudes unless incomes per head are already quite high. For Switzerland, Bermuda, Malta and Cyprus tourism is all right because the local population has already achieved a decent standard of living, self-respect and a sense of identity. But in the Caribbean or in Africa or in the Pacific, the situation is different. Maurice Bishop, a former Prime Minister of Grenada, said, "It is important to face the fact that . . . most of the tourists who come to our country happen to be white, and this clear association of whiteness and privilege is a major problem for Caribbean people just emerging out of racist colonial history where we have been so carefully taught the superiority of things white and inferiority of things black" [quoted in [Pattullo \(1996, p. 64\)](#)].

Second, high-income tourists can corrupt a country in other ways. Cuba was used by Americans as a "playground", which was a polite word for America's brothel. The encouragement of prostitution, venereal disease and crime contributed to Castro's revolution. Third, the local population tends to want to copy the tastes of the tourists. There is a demonstration effect on consumption habits. If their incomes are low this will lead to frustration and unhappiness. Fourth, tourism can upset male-female relationships if the women get better-paid jobs in hotels. This may, of course, contribute to their libera-

tion but it will upset the domestic peace. Fifth, tourism will tend to increase crime and violence as the frustrations of the local people grow.

Finally, tourism can change or corrupt or destroy the culture tourists have come to observe. The sheer numbers of tourists destroy the very things they come for. In Egyptian sites such as the Valley of the Kings or Sakkara thousands of visitors mill about each day in cramped tombs that were designed for one occupant's afterlife. The deterioration of the paintings and reliefs on the walls is plain to see. Even the apparently indestructible pyramids of Giza are suffering. As Throsby (2001) notes: "The cultural impacts of mass tourism are well known, ranging from the physical pressures imposed by large numbers of tourists on heritage sites to the damage that may be caused to local community cultural values if an area is constantly being invaded by crass and insensitive visitors" (p. 129).

There are also economic problems with tourism. Although it is often believed that tourism is labor-intensive, it can be very capital-intensive if hotel rooms are unoccupied for long periods out of season. It can also be very import-intensive if the tourists drink imported orange juice while local fruits are available, or if money is borrowed from abroad to finance the industry, or if hotels and related businesses such as car hire and yacht chartering are owned by foreign firms. In underdeveloped small island economies a large share of tourist earnings will leak back abroad through purchases of imported goods such as food, or through dividends or interest on invested capital, expatriate employees' salary remittances, etc. Thus, whereas Kenya, for example, produces many inputs into its tourist industry itself, many small islands in the Caribbean and in the Pacific do not.

The income elasticity of demand for tourism is liable to be high. This can lead to sudden large losses when incomes drop. When rich countries are faced with balance of payments troubles, tourism tends to be the first thing that gets cut. Furthermore, a flourishing tourist industry can cause inflation, push up prices, wages and exchange rates, displacing farming and making it harder for other industries to develop.

There are also political problems with tourism. It is a highly volatile industry. It is sensitive to energy crises, to political turbulence, news of crime, and other bad news such as natural disasters or terrorism. Sri Lanka's tourism halved between 1982 and 1986 as a result of the ethnic conflict, Africa's has suffered from the AIDS scare and Egypt's from the slaughter of tourists at Luxor. An additional problem is that some critics regard tourism as a new form of colonialism.

Can tourism be conducted in a more efficient, less destructive way that at the same time does not deprive the local population of its benefits and revenues? Can tourism become "sustainable"? Codes of practice for sustainable tourism in developing countries have been promulgated, stressing the need for cultural sensitivity and respect, care for the environment, and equitable treatment of host communities. Moreover, in a reaction to the destructive aspects of mass tourism, more constructive or alternative forms have evolved such as ecotourism, agrotourism, nature tourism and cultural tourism.

## 6. Summary and conclusions

It is a truism to say that one of the principal aims of development efforts is the eradication of poverty so that all people can develop their full potential. Yet all too often in the process of development it is the poor who shoulder the heaviest burden. In the transition from subsistence-oriented agriculture to commercial agriculture, poor women and children are sometimes hit hardest. In the transition from a traditional society in which the extended family takes care of its members who suffer misfortunes, to a market society in which the community has not yet taken on responsibility for the victims of the competitive struggle, the fate of these victims can be cruel. In the transition from rural patron–client relationships to relations based on the cash nexus, the poor suffer by losing one type of support without gaining another. In the transition from an agricultural to an industrial society, the majority of the rural people are neglected by the public authorities in favor of the urban population. In the transitions that we are now witnessing from centrally planned to market-oriented economies, and from autocracies to democracies, inflation, mass unemployment, growing poverty, alienation and new crimes have to be endured. In spite of four decades of development efforts, poverty remains high in many areas of the world. Over a billion people are estimated to fall below the poverty line [World Bank (2001, p. 23)].

Globalization and growing international interdependence present new challenges and opportunities for culture and cultural policies throughout the world. These challenges are environmental, political, social, human and cultural (in the narrow sense). This chapter has suggested that the role of culture will be of increasing importance in the discussion of development policies, especially of alternative approaches to development and its different styles. Culture is often invoked to explain both the successes and failures of development. For example, some have attributed the economic miracle of the East Asian economies to Confucian culture and so-called “Asian values” and asserted that cultural diversity is not only useful but also essential for development. It has also been established beyond doubt that the Protestant ethic is not the only source of thrift and hard work and that many religions can breed economic development. At the same time, the recent turmoil in these economies has also been attributed to certain features of local cultures. Both positive and negative traits of economic development are said to be linked to culture. Neither view is persuasive. The discussion requires a deeper analysis of the links between culture and development and its crises. Cultures are not static but change all the time, adopting features from other cultures while communicating other features to them.

I conclude with several recommendations for policy. First, although it is argued that diversity contributes to creativity, it is not enough to advocate diversity in the abstract. We must show precisely how diversity enhances economic success, social opportunities, political stability and conflict resolution, as well as being valuable, beautiful and delightful in itself. In the global system of cultural exchanges some cultures are disappearing. But as some forms of culture disappear, new forms are created, and they are created locally. The disappearance of old cultural forms is entirely consistent with a

rich variety of new forms of human life. Attitudes should be encouraged and laws and institutions should be established that recognize multiple voices and actors and provide ways of handling differences and plural, partial interpretations of the world. We should learn to value the variety of human forms of social and cultural life, so long as these differences meet the principles of a universal global ethics, in particular the respect for basic human rights such as those to life, liberty, due process, free speech, free practice of religion, and so on. We should celebrate and rejoice in cultural variety.

Second, the evidence suggests that democracy is reinforced by certain cultural conditions. It is by building democratic institutions that a more participatory culture evolves which in turn strengthens democracy. The direction of causality is mainly from social and political institutions to political values and practices. The strong evidence suggesting that the existence of democratic institutions is not associated with culturally-defined differences implies a clear signal: policy makers cannot refuse democracy by claiming their own culture. In other words they cannot use cultural traditions and characteristics as an excuse for failing to institutionalize participatory and democratic political structures of decision-making, including diverse voices and interests. The countries that weathered the Asian financial storm of the late 1990s best were democracies – Taiwan, the Philippines and Japan. South Korea and Thailand have also recovered; they have got rid of their corrupt former regimes by democratic processes. The history of Indonesia's development should put to rest the myth that democracy and human rights are Western concepts hostile to Asia and economic growth. A government that is not answerable to its people is not likely to have the institutions required to impose discipline to overcome a financial crisis or to embark on successful long-term development.

Third, if national and local cultural values are to be recognized in the management of the economy, it will be necessary for cultural policies to be integrated with economic and political policies. There is much room for experiment with creative forms of conflict resolution that foster equality instead of discrimination, and conviviality instead of violence. The growing risk of violent ethnic conflicts that arises from the arrogant and intolerant assertion of cultural, indigenous, ethnic, racial, religious, linguistic, or minority rights is evident in many places. Isolating linguistic or cultural groups and “drawing the borders in blood” reflects not only a misapprehension of the nature of culture and the evolution of history, but is doomed to fail in societies that are becoming increasingly interdependent and multicultural. Indigenous and culturally distinct groups – i.e. ethnic, racial, or religious sub-groups that demand rights to express and to continue to develop their cultures – deserve to be supported, but their relationships with the wider societies, nations, and world community in which they are embedded must also be recognized in thought and action. The cure for separatist, exclusive ethnicity is multicultural ethnicity.

Fourth, policy makers have to rethink state, community and international institutions and policies to permit local populations to choose their languages, allegiances and ways of life, provided that the implementation of these choices is taken up by the local or regional communities themselves. At the same time, institutions should be created that encourage a dialog between leaders of different cultural groups to negotiate exchanges and promote a better mutual understanding. Intercultural dialog becomes a prime line

of policy action that should be implemented according to local ways of management and organization. The important thing is that local communities and their administrative arrangements – municipal, provincial, state or departmental governments – must take on the main responsibility for this dialog and ensure that no artificial walls are erected to stop the flow of discourse between cultures. This is especially relevant for the young generations who are open to many cultures from which they take symbols, icons and customs that allow them to rejuvenate their traditions, thereby making them better adapted to the changing conditions of a global and shrunken world. Policies to encourage intercultural productions in the arts, especially by the young and by women, should be given priority. Women, where they are allowed to participate fully in social and cultural life, will contribute much to creating the new societies of the 21st century.

Fifth, cultural policy should look beyond a purely national emphasis and take in addition a broader international, interregional and global perspective. New partnerships between governments, corporations, private voluntary associations and other stakeholders should be developed. The positive impact of globalization on local creativity, by opening up markets, should be identified and encouraged. The effects, both good and bad, of global markets on local cultural industries should be more clearly recognized, so that policy can protect and enhance their cultural and economic flowering.

Finally, policies that allow expression and development of cultural potential will also have repercussions on how people relate to their physical environment. Achieving environmental sustainability calls for democratization of expertise and participation of local communities. Cities, the most multicultural sites of the future, should evolve ways in which people who speak different languages and have different loyalties can live together in peace. Urban squalor, violence and crime are not the result of urbanization but of inadequate incomes, unemployment, poor education, overcrowded housing, insecure tenure, homelessness and lack of social support. City governments and municipalities can encourage peaceful and prosperous urban communities by strengthening their support for local initiatives. Apart from the necessary social services in health, education, housing, water and sanitation, they can encourage new artistic expressions that enhance the dynamics of a local–global dialog. Artists everywhere wish to express their personal and cultural identities, and in doing so they create global trends. The new site for the creation of art is the global market place. Policy makers should ensure that artists are able to participate in the expanding global markets.

In conclusion, the analysis in this chapter shows that culture goes far beyond the field traditionally assigned to Ministries of Culture. Culture is indeed concerned with artistic creation and with ethnic and indigenous issues, but culture has also social and political dimensions. It is relevant in designing and implementing models of economic development, constructing stable democracies, ensuring that diverse cultures can live together without violent conflict or war, and providing a sense of trust, partnership and solidarity that are needed in any society in which people cooperate for their well-being. For this, an education for world citizenship is needed, a citizenship that is rooted in local culture, and is directed at patriotic cosmopolitans or cosmopolitan patriots, loyal to their families, neighbors, local communities, countries and humankind. For we undermine the

case for multicultural respect by failing to make central to education a broader respect for all human beings.

### Abstract

While audience and participation surveys, as well as econometric demand studies, generally confirm that performing arts audiences are relatively elite, there are surprises. Education (despite conflicting causal interpretations) is a stronger determinant than income, but that evidence is more reliable from survey results than from econometric estimation, and arts training is often distinguished from formal education. The arts as luxury goods can only be confirmed by those rare studies controlling for the value of time, and price elasticities are often higher than expected, especially when more disaggregated data are examined. Price inelastic demand is more likely the result of low pricing strategies of non-profit arts managements rather than any inherent result of an acquired taste for the arts, while cross-price elasticity evidence is relatively weak, even within the performing arts. Arts demand cannot adequately be estimated without also considering “life-style” variables, or non-standard socioeconomic factors such as sexual orientation, gender and socialization processes, and even the role of age has been notably complex. Quality of arts performance or organization seems important, but the econometric results are mixed. Habit formation must be distinguished from learning-by-consuming and rational addiction in examining dynamic determinants. Sociologists, psychologists, and marketing specialists, as well as economists, have contributed to this literature, which remains unusually enigmatic despite about forty years of increasingly sophisticated analysis.

## 1. Introduction

When readers of *La Scena Musicale* in December 2001 were informed that “. . . the likelihood of money being spent on orchestral music is linked to consumers’ increasing age, education and income” [Ehrensaft (2001, p. 1)] they could hardly have been shocked.<sup>1</sup> The “high arts” are widely viewed as the domain of a minority of elites, long an argument used by opponents of government arts subsidization to characterize such support as regressive, and ironically also by proponents who stress the need to make culture more accessible to the general public. Furthermore, one might suspect that this consensus and conventional wisdom would render efforts to conduct empirical studies of the demand for the arts relatively useless – at best, carefully designed confirmations of the obvious.

This chapter is designed to evaluate that suspicion, and finds surprising evidence of contradictory results, personally held convictions that are inconsistent with the empirical evidence, and significant popular misconceptions about the findings in some of the most cited empirical studies. Lévy-Garboua and Montmarquette, themselves significant contributors to this literature, reflect this best when they observe: “It is likely that the demand for the arts is price-elastic and art is a luxury good. But this prediction stems more, as yet, from a theoretical conjecture than from well-replicated empirical estimates” (2003, p. 211). They also suggest that we have not yet clarified whether arts goods have close substitutes, hence suggesting that we are still “groping towards firm answers” to three of the most basic empirical questions regarding arts demand (2003, p. 201).

Corning and Levy (2002, p. 218) observe that “studies of demand for the performing arts typically take one of two basic approaches: survey studies which seek to characterize the demographics of theater [and other] patrons, and econometric studies which seek to quantify demand and income elasticities”, although it is notable that data for econometric studies are often derived, at least in part, from either audience or arts participation surveys.<sup>2</sup>

Regarding econometric studies, while “income and price elasticities . . . are the usual end-products of empirical demand analysis” [Barten (1992, p. 21)], a substantial portion of the performing arts demand literature does not derive such elasticities. For example, only 29 of the 44 regression-based studies cited in this chapter report some kind of demand elasticities; of these only 19 estimate both own-price and income elasticities, and fewer still also estimate any cross-price elasticities.<sup>3</sup> Thus, a notable part of this litera-

<sup>1</sup> Although they might have been surprised by the optimistic tone of the article, which cited demographer David Foote as demonstrating that “aging baby boomers” and the “graying of classical music audiences” will be a “valuable asset” that will ultimately lead to an increase in the classical music market [Ehrensaft (2001, p. 1)].

<sup>2</sup> For a good roundtable discussion of the difficulties in accurately conducting such surveys, see Horowitz (1985). Audience surveys are typically based on distributing questionnaires to audiences and collecting them upon departure, while participation surveys are designed to randomly sample the broader population, not limited to those who have been “self-selected” as part of an arts audiences.

<sup>3</sup> See further in Table 1.

ture is devoted instead to more broadly examining the competing determinants of arts attendance or participation patterns without any formal link to the neoclassical theory of consumer behavior and its related concerns with formal homogeneity or aggregation constraints.<sup>4</sup>

This chapter is a much shortened adaptation of Seaman (2005), focusing on the econometric literature and also briefly summarizing the results of the survey studies. The arts are defined primarily as the non-profit performing arts (orchestral and chamber music, opera, ballet and modern dance, and theater, but also including for-profit Broadway), although comparisons are made with museums and the largely for-profit media arts and other forms of recreation and entertainment, including sports.

The organization is as follows. Section 2 briefly describes performing arts audiences based on participation and audience surveys. Section 3 provides an overview of the econometric literature, while Section 4 reports on the estimation of price and income elasticities, focusing on the effects that different levels of aggregation and audience segmentation have on the empirical results. The technical challenges that have faced researchers in conducting empirical arts demand studies are addressed in Sections 5–9, while Section 10 evaluates the view held by some that “life-style” and various socialization measures are more important determinants of variation in arts consumption behavior than are the traditional socioeconomic determinants of age, income, education and occupation. “Mixed” factors such as gender, race and ethnicity, religious affiliation, and sexual orientation combine with other variables to complicate that analysis. Section 11 summarizes the data problems that have plagued economists in addressing the issues discussed in the previous sections. A concluding summary and evaluation (Section 12) focuses on an assessment of the claim that three main developments are required before more definitive answers can be given to questions about the demand for the arts:

- (1) more careful econometric work;
- (2) the increased use of large data sets; and
- (3) the “more intensive use of explicit models of the cultivation of taste” [Lévy-Garboua and Montmarquette (2003, p. 211)].

<sup>4</sup> Even studies that estimate demand elasticities are faced with sufficient data and econometric challenges such that few can afford the luxury of ensuring that estimated demand functions are homogeneous of degree zero while also meeting Engel and Cournot aggregation conditions. Pommerehne and Kirchgassner (1987) is a rare example of using almost-ideal-demand-system restrictions to estimate expenditure shares for cinema, theater and a composite good. The general absence of such restrictions can indeed complicate the interpretation of the results, especially regarding the controversial issue of price elasticities. However, many of the conclusions regarding other important issues are relatively unaffected by statistical technique (e.g., discriminant, cluster, factor or multivariate regressions) or by field of specialization (e.g., economics, sociology, arts policy, psychology, or marketing).

## 2. What do we know about arts audiences?

### 2.1. Audience profiles

Two of the earliest empirical observations in arts economics are, first, that performing arts audiences are elite in terms of income, education and profession and hence non-representative of the more general population, and second, there are only trivial differences in those audience characteristics across the various performing arts forms.<sup>5</sup> In fact, that “audiences from art form to art form are *very* similar” was viewed by Baumol and Bowen as “the most remarkable finding” of their path-breaking efforts to assemble credible data on arts consumption patterns, primarily in the United States (1966, p. 84).

Throsby and Withers (1979), evaluating 1976 Australian data, found essential similarity between Australian and American audiences, and also cited British and Canadian data. A more recent Canadian survey of theater patrons in Montreal found ongoing evidence of this elitism in that 54 percent were university graduates, 45 percent earned more than \$40,000 per year, and only 11 percent were employed in primary (manufacturing or construction) industries [Colbert and Nantel (1989)]. The most detailed ongoing source of survey data on performing arts audiences is the *Survey of Public Participation in the Arts* (SPPA), periodically published by the US National Endowment for the Arts. The most recent version applies to 2002 [National Endowment for the Arts (2004)], and continues to generally support the arts elitism hypothesis. These data have also served as the foundation for regression-based studies such as Peterson, Hull and Kern (2000) and Gray (2003).

Actually, the commonality of arts consumption patterns across many different countries, educational systems and cultures was not a universally anticipated result, as Baumol and Bowen discovered when they were told by British colleagues to anticipate much more egalitarian results in extending their survey to Great Britain [Baumol and Bowen (1966, p. 89)]. However, except for a slightly higher representation of lower middle-income groups in British audiences (p. 93), Baumol and Bowen found “remarkable” similarity in the British and American results (p. 89). Interestingly, Cwi (1985) attacked the Baumol and Bowen (1966) conclusion about arts audience elitism as fostering a “welfare economics mentality towards arts policy” that primarily serves the interests of a political agenda to justify government subsidies to bring “arts to the people” (p. 32). Cwi further argued (1985) that even if the basic audience profile were to remain relatively constant, substantial societal changes in education and occupational choice would progressively make that profile more reflective of the general population, and that the elitism of arts audiences had always been in part the result of an overly narrow definition of the arts. The evidence regarding whether the arts are becoming less elitist is decidedly mixed. For example, O’Hagan (1996) found absolutely no evidence

<sup>5</sup> Baumol and Bowen (1966); Ford Foundation (1974); Book and Globerman (1975); National Research Center of the Arts, Inc. (1976); DiMaggio and Useem (1978); Throsby and Withers (1979); West (1985).

in Irish, British and American data of any change in the access of the performing arts to a wider audience, while Heilbrun (1996), using a different measurement standard, found notable improvements in the accessibility of the arts to the general population between 1980 and 1990 in the United States.<sup>6</sup>

## 2.2. Age

Age represented the most unexpected results in the Baumol and Bowen (1966) audience survey, with those aged 20–24 the most over-represented in both American and British arts audience relative to the size of that age group in the general population, when attendance is imperfectly defined as “having attended at least one performance within the past year”. These “relative frequencies” decline systematically with age, indicating that performing arts audiences were dramatically younger than the general urban populations in both countries in the mid-1960s. However, when frequency of annual attendance is considered, the role of age in arts audiences changes. For those attending more than 10 times per year, 7.1 percent were over 60 years old compared to 2.4 percent under age 20 for Broadway Theater, with the “older age gap” a very high 17.9 percent vs. 3.9 percent for Major Orchestras, and a more moderate 7.0 percent to 5.8 percent for Regional Theater [Baumol and Bowen (1966, Appendix, Table IV-I)]. The most recent SPPA [National Endowment for the Arts (2004)] also reflects an ongoing aging of arts audiences, even though managements of many arts organizations have objected to this conclusion [Peterson, Hull and Kern (2000, p. 1)].

Japanese and German data from the early 1980s and mid-1990s reflect the surprising complexity of the role of age in performing arts audiences. Although the context of analyzing Japanese audiences regarding western classical music may influence the comparability of such results with western audiences, the Kurabayashi and Ito (1992) survey results are striking. With the sole exception of a notable trend toward older audiences for the NHK Symphony Orchestra between 1977 and 1981, these results indicate a remarkable bias toward younger audiences, especially for the Osaka Philharmonic, where fully 68.9 percent of females in the audience were younger than 30. In fact, more than 50 percent of each gender was younger than 30 for all non-NHK cases except for males attending the Tokyo Philharmonic and the Sapporo Symphony, and even in those cases the young group outweighed the older group.

Would anything approximating this youth bias be found in countries at the heart of western classical music such as Germany, where classical music is typically referred to as *ernste* or “E-Musik”, in contrast to less culturally “rich” popular or “U-Musik”? Wiesand (1995, Table 2) provides evidence of notable differences in the propensity of different age groups to consume four different types of concerts (music theater, E-concerts, U-concerts, and rock/jazz), but except for the strong youth bias for rock/jazz music, his findings show relatively similar consumption patterns among the youngest

<sup>6</sup> See Seaman (2005, Section 2.3).

age group (18–24) across the three other music types. The next youngest group (25–34) shows more variation, but has the highest propensity to experience “E-Konzerte”. The Wiesand data confirms the expected result that the youngest German age group has the highest overall participation rate in attending concerts and that the most “high-brow” music (E-concerts) is the least popular. The youngest group (18–24) is also notable for having relatively similar participation rates for all three non-Rock and Jazz music types (although lowest for the classical type E-music). The most significant result is that the second youngest age group (25–34) has the highest classical music participation rate, and the combined participation rates of the youngest groups (younger than 35) are higher than the comparable rates for the two oldest age groups (older than 50). Thus, the German evidence is also consistent with the earlier results that, at least when frequency of attendance is ignored, the performing arts should not automatically be thought of as dominated by older age groups.<sup>7</sup>

### 2.3. *Education and income*

Arts survey studies such as the [National Research Center of the Arts, Inc. \(1976\)](#), which served as the key data source for [DiMaggio and Useem \(1978\)](#) and the [Ford Foundation \(1974, Vol. II\)](#), have also contributed substantially to our understanding of the relative roles of education and income in determining performing arts attendance. While the positive causal relationship between education and income has plagued econometric efforts to separate their independent effects,<sup>8</sup> the early non-econometric literature was replete with evidence that the role of education was much stronger than that of income.<sup>9</sup> In fact, [Heilbrun and Gray \(2001\)](#) identify the [Ford Foundation \(1974, Vol. II\)](#) study as important evidence of the relative effects of education versus income, but also citing [Gray \(1998\)](#) as providing multivariate regression evidence supportive of a larger role for education than income, based on an analysis of 1997 SPPA data (Tables A17, A20 and A21).<sup>10</sup> The later National Endowment for the Arts 2002 SPPA survey [National

<sup>7</sup> This point is also consistent with the [West \(1985\)](#) Ontario, Canada audience survey finding that the same percentage of arts audience (20.1 percent) were 20–30 years old as were 40–50 years old, and those older than 50 constituted only a trivially higher 20.9 percent of audiences. The dominant age group was 30–40 (29.6 percent). He did confirm, however, the frequent finding that the under 20 age group was dramatically under-represented at only 2.6 percent of Ontario audiences in 1984–1985.

<sup>8</sup> See further in Section 6.

<sup>9</sup> [Globerman \(1989\)](#) also cites other US data from the [Association of College, University and Community Arts Administrators, Inc. \(1984–1985\)](#) as providing at least “suggestive” evidence that education is more important than income and occupation in determining arts attendance.

<sup>10</sup> Researchers who are selectively familiar with only the econometric literature seem especially prone to concluding that there is no coherent evidence of the separate roles played by these two strongly positively correlated variables. This conclusion has no doubt been reinforced by the fact that two of the best early econometric studies that did indeed confirm a relatively weak role for income, did not include education as a separate independent variable in their equations [[Moore \(1966\)](#); [Withers \(1980\)](#); with additional results also reported in [Throsby and Withers \(1979\)](#)], and the fact that an early study that did include both independent

Endowment for the Arts (2004)] continued to report that education, “more than any other demographic factor” is highly correlated with attendance at arts events and museums (p. 19). However, of more relevance to the issue of whether regression analysis has confirmed this result is the NEA sponsored study by Peterson, Hull and Kern (2000), which generally (but not universally) reported that education is the strongest predictor of arts attendance using data from the 1997 SPPA survey and basic OLS estimation.

DiMaggio and Useem (1978, Table 1) stressed the so-called education gap and the income gap in the self-reported “exposure” of various types of individuals to seven different “cultural forms”. For example, an education gap of 55 (percent) was reported for exposure to theater because the exposure rate of the most educated group (college graduates) was 73 percent while the exposure rate for the least educated group (< high school graduate) was only 18 percent (an absolute difference of 55 percent). Each “consumption gap” entry reported by DiMaggio and Useem (1978) reflected this absolute difference between the exposure rates of the most versus least educated, or the highest versus lowest income group. The most critical feature of these consumption gap data was the sizeable education gap for all seven cultural forms, even including popular music. The three high arts forms showed the greatest education gap, a result not duplicated by the income gap, which displayed the unexpected pattern of being lowest for arguably the most elitist art form (classical music), and almost as high for the more popularized cinema as it was for art museums and theaters.

However, the Ford Foundation study (especially Table 15) has been the most influential in confirming that “to a startling degree . . . it is indeed education rather than income that matters most” [Ford Foundation (1974, II, p. 16)]. For example, using theater attendance as an example, when income was held constant at either a high or low level, differences in education generated either a 21 percent differential in attendance rates (for high income), or a 25 percent differential in attendance (for low income). However, when this was reversed, and education was held constant at either a high or a low level, differences in income had much smaller effects – an attendance rate differential of only 8 percent for those with high education, and a 12 percent differential for those with low education. This pattern was also evident for symphony, opera and ballet. While much weaker, this apparent relative potency of educational differences in affecting attendance rates even extended to popular Broadway musicals, and the more contemporary music forms of jazz, rock and folk. By this measure, education only failed as the stronger factor compared to income in the case of movies, where their average “explanatory power” was equal.

We return to the question of education vs. income in our discussion of the results of econometric studies in Section 6 below.<sup>11</sup>

variables [Gruenberg (1975); see text below] was unpublished. Furthermore, similar to the case with Gray (1998), three other studies documenting some econometric support for the strength of education over income are relatively unknown [Gapinski (1981); Goudriaan and de Kam (1983); Ganzeboom (1989)].

<sup>11</sup> Other issues regarding arts audiences are discussed in Seaman (2005), including: the question of overlapping performing arts audiences (“co-patronage”); the debate regarding possible arts booms and how such

### 3. An overview of econometric performing arts demand studies

Since 1966 there have been at least 44 econometric studies of the demand for (or consumer participation in) the performing arts.<sup>12</sup> A few of these studies also included specific numerical estimates of other demand elasticities: cross price [Withers (1980); Throsby and Withers (1979); Touchstone (1980); Gapinski (1986); Bonato, Gagliardi and Gorelli (1990)]; leisure price [Withers (1980); Throsby and Withers (1979)]; donor price [Lange and Luksetich (1984)]; tourism attendance [Gapinski (1988)]; education [Globerman and Book (1977); Gapinski (1981)]; advertising [Luksetich and Lange (1995)]; “number of shows” [Moore (1966)]; and even “unpopularity of conductor” [Greckel and Felton (1987)]. Other studies derived coefficient estimates that were not translatable into elasticities, and/or evaluated a large number of additional independent variables, many of which lacked either economic or statistical significance.

Basic linear ordinary least squares (OLS), especially using the double-log form, has been the most popular primary estimation technique (used in 18 studies), but other related techniques have been used including: step-wise OLS [Globerman and Book (1977); Greckel and Felton (1987); Andreassen and Belk (1980)]; double-log weighted OLS [Felton (1992)]; two-stage least squares [Moore (1966), Lange and Luksetich (1984), Luksetich and Lange (1995), Jenkins and Austen-Smith (1987)]; conditional maximum likelihood estimation [Corning and Levy (2002)]; the almost ideal demand system [Pommerehne and Kirchgassner (1987)], Clawson–Knetsch distance modeling [Forrest, Grimes and Woods (2000)]; non-parametric linear regression [Schimmelpfennig (1997)]; and logit, tobit, or probit non-parametric estimation (eight studies).<sup>13</sup>

Of the 44 econometric studies, 22 relied upon US data. Approximately two-thirds of all studies reported time-series results (including some pooling of time series and cross-section data), but since a few of those studies also included separate cross-section analysis [Moore (1966); Goudriaan and de Kam (1983); Luksetich and Lange (1995)] about 42 percent of all studies involved cross-section estimation. Only nine demand

dynamic changes might affect the degree of audience elitism [DiMaggio and Mukhtar (2004)]; and the emerging marketing literature regarding “omnivores” (i.e., those whose music and leisure consumption is so broad and eclectic as to defy the label elitist) and “univores” (by contrast, persons with decidedly narrower favorites among music and other leisure options) as considered by Peterson (1992), Bryson (1997), van Eijck (2000), Fisher and Preece (2002, 2003), and Lopéz Sintas and García Álvarez (2004).

<sup>12</sup> Seaman (2005) further clarifies which types of studies are omitted. For example, highly specialized marketing forecasting models such as Weinberg and Shachmut (1978), whose “ARTS PLAN” model inspired some similar efforts to predict attendance at specific (usually university) performing arts events are omitted. See also Weinberg (1986) and Putler and Lele (2003).

<sup>13</sup> This choice of approaches is in no way at odds with standard practice in empirical economics. DiNardo and Tobias (2001) begin their overview of non-parametric techniques by observing: “Even a cursory look at the empirical literature in most fields of economics reveals that a majority of applications use simple parametric approaches such as ordinary least squares or two-stage least squares accompanied by simple descriptive statistics” (p. 11).

studies constituted essentially a case study of one or two specific arts firms, with the rest involving some degree of aggregation among many organizations, with seven reporting results for some version of the aggregate performing arts [although three of these also reported less aggregated results for separate art forms: Houthakker and Taylor (1970), Throsby and Withers (1979), Pommerehne and Kirchgassner (1987)]. The most popular separate art form aggregation has been theater (including a few studies of the for-profit Broadway theater), identified in 20 studies, followed by symphony orchestras, which were the primary or secondary focus of 16 studies. Separate results were reported for aggregated opera companies eight times and for dance/ballet companies seven times.

Owing to the important role played by the concepts of own price and income elasticity of demand in economic analysis generally and in discussions of the demand for the arts in particular, the next section focuses on those studies that have estimated such elasticities.

#### 4. Price and income elasticities

Table 1 more fully documents the 29 studies that have reported either own price or income elasticities, or both. Note that the table omits any regression study that does not derive elasticities, even if it includes income and/or price as variables.

A review of Table 1 confirms that the Lévy-Garboua and Montmarquette suspicion that the arts really are luxury goods with own-price elastic demands (2003, p. 211) has not yet been justified by the econometric evidence. Regarding estimates of the own-price elasticity of demand, 12 studies found that the demand for the arts is price inelastic while only four found strong evidence of price elastic demand. Krebs and Pommerehne (1995) reported low short-run but high long-run price elasticity. However, five other studies found mixed results for the price elasticity of demand, especially when data allowed a more disaggregated analysis of different price ranges, audience characteristics, or type and sizes of individual arts organizations.

Let us consider the differences among these results in more detail.

##### 4.1. Price elasticity differences by level of aggregation

In interpreting the price elasticity results reported in Table 1, we can observe that, regardless of technical sophistication, the price *inelasticity* result is much more prominent in those studies that used very aggregative data across all performing arts groups in contrast to studying individual arts organizations,<sup>14</sup> and/or that used a measure of ticket price (such as total revenue divided by attendance) that does not measure the actual

<sup>14</sup> Of course, this aggregation problem is hardly confined to the arts. The common estimation of supply and demand functions “using uniform prices and quantities across products, yielding a single industry-wide demand elasticity estimate” is criticized in a study of the personal computer market as especially misleading when firms produce differentiated rather than homogeneous goods, since “each product is likely to face

Table 1

Note: "None" indicates that no elasticities were estimated, due largely to an absence of data.

prices paid by different types of consumers. Notably, [Jenkins and Austen-Smith \(1987\)](#), one of a few studies to find statistically significant but positive own-price elasticities, explained the paradox of that finding in part by suggesting that price is serving as a proxy for quality, but also implicating their overly aggregated measure of price (i.e. an average of total box office revenues over the entire season divided by total season attendance; p. 170).<sup>15</sup>

Given the expected importance of having more disaggregated and targeted price data, what can be said about the results of studies that segmented the audience more carefully, or that focused on less aggregated measures of the performing arts? Caution is essential in making any generalizations about this literature. For example, [Moore \(1966\)](#) found consistently low own-price elasticities for Broadway theater tickets even when studying a relatively disaggregated segment of the performing arts (aggregated to be sure across seven Broadway houses and 18 performances, but at least not focusing on the overall performing arts). His somewhat unconventional use of a list price (i.e. “an average of the cost of the most expensive seats for a regular performance of each production”; p. 83) to proxy average price paid can be criticized, but may not have seriously biased his time-series results. And [Gapinski \(1986\)](#) is widely lauded for deriving separate theater, opera, symphony and dance estimates of cross-price as well as own-price elasticities using quite disaggregated data specific to thirteen individual arts companies in London. Yet he found generally low own-price elasticities for each of the individual organizations (varying from  $-0.05$  to  $-0.70$ ). However, in constructing his nominal price variables Gapinski was forced to resort to dividing attendance into box office revenues (including value-added tax), hence failing to fully capture actual transaction prices or to differentiate among consumer groups.

Less aggregated studies generally segmented audiences in various important ways that allow for a more precise examination of pricing, as well as other likely demand determining characteristics. [Pommerehne and Kirchgassner \(1987\)](#) segmented by income of consumers, with price elasticity lower for high-income than for average-income consumers (but with both being greater than one in absolute value); they also found uncommonly low own-price elasticities for cinema. Seating section was the key for [Schimmelpennig’s ballet study \(1997\)](#), which found generally elastic demand for Orchestra, Grand Tier, and Rear Amphitheater sections, with surprisingly high price elasticities even for the more expensive Orchestra seats that supposedly serve higher-income patrons. By contrast, the [Abbé-Decarroux \(1994\)](#) results for a Geneva theater were more expected, with a finding of a high price elasticity of  $-2.45$  for his “reduced price” consumer group (although not clearly statistically different from 1.0 at the 0.05 level), but inelastic (and not statistically significant) price elasticity for the “full price” group. He

a different demand elasticity”, ideally requiring a focus on “individual products’ attributes and their market position” in estimating demand elasticity [[Stavins \(1997, pp. 347–348\)](#)]. For a comprehensive review of heterogeneity and aggregation problems in economics, see [Blundell and Stoker \(2005\)](#), with applications to demand modeling (pp. 350–364).

<sup>15</sup> [Seaman \(2005\)](#) provides a detailed analysis of the various ways to measure price (Part 3.1.1).

was also unique in explicitly arguing that such results “weaken” the conclusions of other major studies that use an overly aggregated average price to derive price-inelastic results for the performing arts (p. 105).<sup>16</sup>

Felton’s (1994/1995) study of 25 large US orchestras found lower price elasticity for subscribers ( $-0.24$ ) compared to price elasticity for the combined “total attendance” (although still less than unity at  $-0.85$ ). However, that result contrasted with her pooled time-series study of 13 opera companies [Felton (1989)], where subscribers appeared more responsive to ticket-price changes than single-ticket purchasers (i.e. her only statistically significant results were for subscribers, although the magnitude of the price elasticities varied widely across organizations). Even though subscriber reactions to ticket price changes differed somewhat between her 1994/1995 orchestra and 1989 opera samples, she decided to limit her 1992 study of orchestra, opera and ballet companies to subscriber demand, basing this decision on her conclusion that her previous work with opera data had revealed “that season subscribers do react to ticket price changes while non-subscribers do not” [Felton (1992, p. 2)].

Lévy-Garboua and Montmarquette (1996) imputed rather than directly estimated price elasticities (see Section 7 below) but derived the surprising result that more experienced French theater-goers actually had higher price elasticity of demand ( $-1.47$ ) compared to those less experienced (price elasticity close to unity), inconsistent with the view that price elasticity will be low for an acquired taste like the arts.<sup>17</sup> Since the more educated typically have more arts experience, Forrest, Grimes and Woods (2000) found contrary strong evidence for price inelastic demand in those regional zones with particularly high educational levels and higher price elasticities elsewhere.<sup>18</sup>

Segmenting by organization location has also generated differing own-price elasticities, with Corning and Levy (2002) finding that a three-location Southern California theater group faced price elasticities varying from inelastic to elastic depending on the specific venue. Lange and Luksetich (1984) found higher own-price elasticities for smaller orchestras than for large budget major orchestras, but their 1995 simultaneous

<sup>16</sup> Throsby (1990) found supporting evidence in his equations estimating the consumer “valuation” of a play. These utility function estimations revealed that the strongest influence of price was on the mainly young and less affluent audience of one of his Sydney theaters, whereas his least price-sensitive group was the audience of the most conservative of his theaters (p. 79). Huntington (1991) showed a kinked demand curve based on different price points. Kirchberg (1988) found that low-income groups regarded museum entrance fees as a barrier five times as often as do those in higher income groups with education, occupation, and “lifestyle” variables further broadening this gap.

<sup>17</sup> Doubtless the most novel interpretation linked to this finding is that of Köster and Marco-Serrano (2000, p. 8, Footnote 7), who cite Lévy-Garboua and Montmarquette (1996) for the finding that “the satisfaction degree is bigger among the occasional attenders than in the frequent attenders”, suggesting to them that the satisfaction of the occasional attenders stems more from the “sensation of having completed a duty” than from any direct arts consumption “sensorial rewards”.

<sup>18</sup> Ulibarri (2005) lends further theoretical support to the idea that more experienced arts consumers should have lower price elasticities in his application of an adaptive utility choice model the arts, lending further support to the notion that markets for arts goods will be segmented (p. 140).

equation orchestra model (where they also incorporated interactions with donations) found generally low price elasticities regardless of organization size (see Section 5 below).

Thus, while it can be said that own-price elasticities estimated with more disaggregated data are more likely to be greater than one in absolute value (whereas with aggregated data they almost never are), the extent and significance of those findings have sometimes been overstated. For example, Felton (1992) is regularly cited for finding low price elasticities of demand for aggregated groups of arts organizations, but significantly higher price elasticities for individual arts organizations within those groups [e.g., Throsby (1994, p. 8)]; however, she actually found price elastic demand in only 21 percent of her orchestra sample, 7 percent of her ballet sample, and 16 percent of her opera sample. Furthermore, while that paper is sometimes portrayed as distinguishing between industry and firm price elasticities, her pooled data did not include multiple companies in any one artform in any one city,<sup>19</sup> and in some cases did not even have more than one company of any artform in any one city. So Felton (1992) is not really a study well-designed to distinguish market or industry price elasticities from firm price elasticities. Furthermore, Felton's earlier study of individual opera companies (1989) reported only three opera companies with statistically significant subscriber own-price elasticities, with one being elastic (San Francisco), one unity (San Diego), and one inelastic (Houston). So there is no unambiguous finding of price elasticity greater than one even when the focus is on individual organizations.

#### 4.2. *Conceptual issues in interpreting the price elasticity results*

Regardless of how the empirical price elasticity results vary by level of aggregation or with the sophistication and “accuracy” of econometric technique, it is surprising how little attention has been paid to interpreting these results in light of economic theory. For example, little focus has been directed to the standard argument that non-profit arts organizations often charge lower than revenue-maximizing ticket prices.<sup>20</sup> In a related literature, it has been explicitly argued that profit-maximizing sports teams strategically under-price tickets; such non-revenue-maximizing behavior has become a standard explanation for the low price elasticities frequently found in empirical studies of sports

<sup>19</sup> Admittedly not possible to do if there is only one local professional opera company or even orchestra; Gapinski (1986) is a notable exception.

<sup>20</sup> Of course, the convenient and very commonly used double-log linear equation specification generates constant elasticities that do not vary with price, in contrast to a cubic log equation that can generate price elasticities that vary with prices [for an example in sports, see García and Rodríguez (2002)]. If the range and level of available performing arts price data is “artificially low” due to either non-optimal pricing, or systematic efforts to make the arts “more accessible”, perhaps not just as a public service but as part of a longer run strategy of encouraging people (especially the young) to develop the kind of human capital that can lead to various forms of consumption addiction, we would naturally expect to find relatively low estimated constant price elasticities.

demand.<sup>21</sup> In fact, sports economists have generally refused to accept any empirical evidence of price-inelastic demand.<sup>22</sup> Even when there is dissent, the issue of the price level at which price elasticity is estimated remains critical. For example, Coates and Harrison (2005) express amazement at their finding that the demand for baseball attendance in the US is strongly price inelastic. They argue that the significant local market power of all baseball franchises should induce them to “operate on the elastic portion of the demand curve”, and consider the quest for an explanation for why teams are operating in the inelastic portion of their demand curve “an important question for future research” (p. 298).

By stark contrast, the most common reaction among arts economists has been to find econometric evidence for low price elasticities to be consistent with theoretical expectations and non-econometric survey evidence.<sup>23</sup> For example, Throsby (1994) repeats his earlier distinction between “immediately accessible” popular entertainments and the higher arts that reflect an acquired taste, in defending his view that the arts will have lower price elasticities among established consumers “for whom qualitative characteristics of performances are likely to be decisive” (pp. 3 and 7–8).<sup>24</sup> While this argument seems consistent with a view that demand for the lively arts is “inherently” price insensitive, it is important to note the Throsby reference to “established” consumers rather than all consumers.

In defense of an “inherently” low price elasticity of demand for the arts, it is universally recognized that ticket price is only one component of the explicit expense of attending a live performance, and an even smaller share of the total expense when the implicit opportunity cost of time is included in the “full price”.<sup>25</sup> Furthermore,

<sup>21</sup> See, for example, Marburger (1997), Fort (2004); see Seaman (2005, Part 3.1.2) for a detailed review.

<sup>22</sup> In a study of the Spanish Football League García and Rodríguez (2002) found confirmation of low price elasticities of demand for all league teams when using a linear model and not adjusting for the possible endogeneity of price, which is inconsistent with “clubs acting as profit maximizers and costs not depending on attendance in a standard monopolistic model” (p. 28). However, they found good evidence for their contention that econometric specification issues should play a bigger role in estimating sports demand; their cubic specification using instrumental variables to correct for price endogeneity yielded 11 teams out of 27 with average price elasticities above one in absolute value, although for all teams the null hypothesis of unitary elasticity could not be rejected.

<sup>23</sup> Examples include Globerman and Book (1977), Ryans and Weinberg (1978), Kolb (1997, 2002), and Scheff (1999).

<sup>24</sup> The presumed greater availability of effective substitutes for more accessible forms of entertainment compared to the more “esoteric” forms of the higher arts would certainly be a key factor that would suggest that demand for the performing arts would be less price elastic than the demand for, say, cinema at comparable prices or when evaluated at competitive equilibria with limited market power. The necessity of distinguishing the price elasticity of demand at *observed* prices from the price elasticity at *competitive* prices is an iconic feature of antitrust economics.

<sup>25</sup> In fact, Globerman (1989) would extend this point to popular culture as well, noting that the admittedly less consistent evidence is that demand is price inelastic for those arts as well, consistent with the idea that the opportunity cost of time is usually the largest cost of attending any live events (his Note 14). However, it is interesting that Cameron (1990) extending his similar earlier results, has found relatively high price

viewing consumers as producers would distinguish between purchasing a ticket for a performance (a market good serving as a productive input) and actually consuming the individually-produced “art appreciation”. Once that fundamental distinction is made, there is no theoretical inconsistency between finding a “shadow price-elastic demand for art appreciation” and a “market price-inelastic demand for art consumption” as revealed in ticket price data.<sup>26</sup>

Another aspect of the full price of arts consumption that can reduce the economic significance of the explicit admission price is the interaction between admission expenses and voluntary donations. The potential for price discrimination strategies in the arts is further enhanced by their non-profit status that encourages donations. As argued by Lange and Luksetich (1984), the total price of attending a symphony concert includes both the price of the ticket and any contributions of that patron to the orchestra.

Finally, it is useful to remember the textbook list of factors determining price elasticity variations across different products (always measured for the industry or market, and not for the individual firm or consumer):

- substitution possibilities;
- budget share;
- direction of income effect; and
- time.

Frank (2006) presents a comparison of empirically estimated price elasticities of demand for seven very aggregated product groupings ranging from “green peas” (elasticity of  $-2.8$ ) to “theater, opera” [ $-0.18$ , citing the short-run price elasticity from Houthakker and Taylor (1970)]. In explaining why the price elasticity of the demand for green peas is more than 14 times larger than for theater and opera performances, he cites two factors: first, the likely small real income effect that would accompany any change in price for arts consumers who are expected to have much larger than average incomes, and second, the many more close substitutes for green peas than there are for theater and opera performances [Frank (2006, p. 128)]. This explanation is consistent with the view that there is something inherent in the performing arts that would yield very low price elasticities, i.e. limited substitutes. Yet again, any such explanation ignores the question of “substitutes at what price” and the issue of localized competitive conditions [Seaman (2004)]. It also fails even to consider why such firms (assuming some market power) would choose to operate so far from the seemingly rational average price level (i.e., the one approximating unit price elasticity when marginal costs approach zero).

In summary, estimated arts price inelasticity may simply reflect pricing in the inelastic range of demand curves or, when using excessively aggregated data, the failure

elasticities of demand for cinema in the United Kingdom (in the range of  $-1.53$  to  $-1.6$ ) using pooled cross-sectional and time series data, but when later explicitly testing for rational addiction in the demand for cinema (1999), he found neither strong support for rational addiction, nor statistical significance in his price variable. Fernández-Blanco and Baños Pino (1997) estimated an even higher long-run price elasticity of demand for cinema in Spain ( $-3.51$ ), but did not address the issue of price levels.

<sup>26</sup> See Lévy-Garboua and Montmarquette (1996, p. 206) and further discussion in Section 7 below.

to capture the range of differing arts consumer segments. At the same time, theoretical clarifications as to the full price of arts consumption, either by distinguishing arts attendance from arts appreciation or by clarifying the possibly low weight that ticket price alone has relative to the full cost, could suggest that the arts do indeed have lower price elasticities than other goods and services when properly evaluated at comparable prices.<sup>27</sup>

#### 4.3. Income elasticity differences by level of aggregation

Despite the somewhat mixed results for price elasticity, the results are even more ambiguous for income elasticity. *Pommerehne and Kirchgassner (1987)* found income elasticities greater than 1.0 in German theater for both average- and high-income consumers, but with higher-income people having lower income elasticity than do average-income people. However, while they used this differential income result in their summary, they warned about the low level of statistical significance in their income results and noted “income elasticities are not much larger than one” (p. 48).

Felton’s results were more indicative of the varying income elasticities derived in more refined studies. *Felton (1989)* found no statistically significant income elasticities for her individual opera companies, and found (1992) income elasticities of either less than one or about one for her two largest orchestra groups (again, while this is still fairly aggregated, it at least distinguishes orchestra size). *Felton (1992)* did, however, find luxury good evidence for her highest and second highest budget samples of ballet companies (but nothing significant for opera). *Felton (1994/1995)* also found a higher income elasticity of 1.4 for her “total attendance” group vs. an elasticity of only 0.82 for her “subscriber” database for US orchestras. By contrast, *Luksetich and Lange (1995)* found no statistically significant income elasticities at all in their large market vs. small market study of orchestras. Unfortunately, neither *Schimmelpennig (1997)* nor *Abbé-Decarroux (1994)*, who did such useful work regarding more disaggregated price elasticities, were able to estimate any income elasticities since they lacked income data.

Superficially, the strongest evidence for income elasticity estimates being notably different when less aggregated data are utilized is *Greckel and Felton (1987)*, who derived a statistically significant income elasticity of 6.13 in their second demand equation for the Louisville Orchestra, although their other orchestra income elasticity of 2.66, as well as the 2.26 estimate for the Bach Society were not statistically significant. Furthermore, this suspiciously high income elasticity of 6.13 is derived in an equation with only ticket price and concert hall capacity as control variables. Even more importantly, that high

<sup>27</sup> However, since other forms of entertainment with lower ticket prices share these characteristics, this conclusion is not inevitable. Furthermore, a focus on the weight of the admission price relative to the full consumption price would suggest that a sport like cricket, where a match can last for up to five days, would have the lowest comparable price elasticity of demand of nearly all live entertainments; regrettably, despite their insightful analysis of county cricket, *Paton and Cooke (2005)* do not estimate price elasticities.

income elasticity estimate dropped to the 2.66 noted above and lost statistical significance when a proxy variable was added to account for a four-year period in which the conductor of the Louisville Orchestra and his successor were widely unpopular. Hence, this evidence for high income elasticities of demand when using organization-specific data is not compelling.<sup>28</sup>

Abbé-Decarroux and Grin (1992) also studied individual (Swiss) arts organizations, and estimated logit models that included pre-tax monthly personal income, but the estimated attendance probability coefficients were quite small (although statistically significant for two of three organizations). Only one of the Corning and Levy (2002) income elasticities for their target theater company across three geographical venues exceeded one while also being statistically significant. Gapinski's (1984) study of production and demand functions for the Royal Shakespeare Company (RSC) did generate a statistically significant income elasticity above one (1.33) in an equation with only price and the constant term. While he was willing to conclude that "an RSC cultural experience is a luxury good", he faced considerable difficulty in eliminating autocorrelation and heteroskedasticity problems and, even after correcting for those problems, was forced to eliminate seven of his eight demand equations "because of intercept or substitute-price insignificance" (p. 463). Thus, the evidence is mixed that estimating demand at the individual organizational level will reliably result in higher income elasticities compared to more aggregated data.

In the following sections we discuss a range of problems encountered in econometric studies of arts demand, beginning with that of model selection.

## 5. The modeling problem: Single versus simultaneous equations

Economists have wrestled with the important issue of whether to model arts demand using a single equation, i.e. by treating the performing arts market as essentially a recursive process in which supply decisions are not determined in the same time period as demand, or to model arts demand as one of several equations in which key endogenous variables are determined simultaneously, hence requiring more complex estimation techniques.<sup>29</sup> In this section we consider these measurement and modeling issues by de-

<sup>28</sup> Carson and Mobilia (1989) also found high standardized income elasticities for Broadway that were highly sensitive to seasons, with highly positive income elastic demand for the fall, winter and spring seasons, but highly negative income elastic demand during the summer season. Given the outlier nature of their estimates (+5.78 to -4.74) and the lack of any modeling foundation compared to, say, Moore (1966), who found dramatically different results (although not adjusting for seasonality), it is difficult to know how much weight to place on these income elasticity results.

<sup>29</sup> Another modeling issue that has been less prevalent in the arts demand literature, but is nevertheless important, is the functional form to choose when estimating a system of demand equations for differentiated goods so as to make parameter estimation feasible. For example, both logit and the almost-ideal-demand-system [e.g., Pommerehne and Kirchgassner (1987)] can be viewed as imposing constraints on substitution patterns so as limit the number of parameters that would have to be estimated.

scribing the key features of three representative studies: Moore (1966), Withers (1980), and Luksetich and Lange (1995).

### 5.1. Moore: "The demand for Broadway theater tickets" (1966)

Moore did not present an explicit utility maximizing framework, but focused on developing a defensible econometric model to estimate demand elasticities that may solve the puzzle of low Broadway attendance growth. Since ticket prices were fixed in any one time period, an explicit time-series model was necessary to derive price elasticity, and a more broadly defined full attendance cost elasticity of demand.<sup>30</sup> However, he also examined the determinants of the cost of an evening of entertainment per person beyond the cost of tickets by using cross-section analysis from data derived from a survey of seven Broadway houses and 18 performances. He also used the cross-section survey results to estimate an income elasticity of 1.03 based on relative frequency of attendance as a function of income.

His time-series model included three equations related to the  $i$ th time period, with  $A$  representing attendance,  $Y$  a measure of permanent income,  $C$  the cost of attending the theater,  $S$  the number of shows,  $P$  ticket prices,  $M$  a dummy variable for sound movies,  $T$  the transportation cost to the theater, and  $O$  the other costs of attending a Broadway play:

$$A_i = f(Y_i, C_i, S_i), \quad (1)$$

$$S_i = g(A_i, P_i, M_i), \quad (2)$$

$$C_i = h(P_i, T_i, O_i). \quad (3)$$

He then postulated that average attendance per show was probably a constant, so that a long run equilibrium condition could be expressed as  $A = \alpha S$ , yielding a four equation system with four endogenous variables,  $A$ ,  $S$ ,  $P$  and  $C$ . However, since it could not be assumed that the market was necessarily in long-run equilibrium, price was treated as exogenous. Furthermore, given the lack of adequate data regarding travel expenses and other expenses of attending the theater, he assumed that such costs, including those related to population movements within the New York area, had no trend over his 1928–1963 time period and were uncorrelated with the other variables, allowing him to drop Equation (3) and substitute price  $P_i$  for cost  $C_i$  in Equation (1).

These modifications allowed him to estimate three basic variations of the model:

- (1) a "naive" approach that assumed that the supply of shows was determined outside the system, estimated both as linear and multiplicative;
- (2) a simultaneous equation approach using two-stage least squares (again both linear and multiplicative); and

<sup>30</sup> Throsby and Withers (1979, p. 111) observed that time-series analysis is more appropriate "for past analysis and for prediction" since time-series data are capable of describing the effect on behavior of changes in a variable, whereas a cross-section elasticity can only describe the effects of differences in that variable.

- (3) two-stage estimation, but with the income elasticity constrained to equal its value estimated from the cross-section data (i.e. 1.03) as a way to limit the bias in the income elasticity estimate created by the absence of population and travel expense variables, which are likely to be correlated with income.<sup>31</sup>

The three most important results are:

- the price and income elasticities were less than one in absolute value, and those results were largely independent of the specific econometric specification;
- the low income elasticity results in all of the time-series estimations were surprising to Moore and prompted him to observe that he had not been capable of controlling for the opportunity cost of time; and
- despite the fact that Moore believed that it was a “dubious” assumption to consider the number of shows (his Equation (2)) as being determined “outside the system”, the fact that shifting to two-stage estimation increased the price elasticity results only trivially compared to the naive single-equation cases has led most later researchers to justify the use of single-equation recursive techniques.

5.2. *Withers: “Unbalanced growth and the demand for the performing arts: An econometric analysis” (1980)*<sup>32</sup>

The basic model was a straightforward application of theory postulating quantity demanded as a function of relative prices and income, adjusted to reflect the realities of using aggregated data applicable to the entire performing arts for the period 1929–1973 (largely from the US *Survey of Current Business*). Hence, the general estimating equation, defined for all time periods  $t$ , was:

$$(Q/\text{Pop}) = f(P_A, P_S, I, D), \quad (4)$$

where  $(Q/\text{Pop})$  is the number of attendances per capita in the population, the  $P$  terms are the price of attendance and the price of substitutes, respectively,  $I$  is income, and  $D$  is a measure of the distribution of income (defined to increase with inequality favoring the wealthy). Expected partial derivatives are positive for all variables except own-price. Withers’ normalization of the attendance dependent variable by dividing by population became conventional in many arts demand studies.

Withers’ critical contribution was to adapt the Owen (1969) approach to adjusting hourly wage rates by the unemployment rate so as to better measure leisure price, and then to utilize the Becker (1965) concept of full income (defined over all available hours, not just working hours) so as to impute leisure time as part of this full income, while incorporating the price of leisure into the consumer price index deflator. This generated

<sup>31</sup> An approach recognized as problematic by Moore and others, such as Throsby and Withers (1979, p. 111).

<sup>32</sup> Withers’ study was a development and application of a model originally proposed in Throsby and Withers (1979, Chapter 3).

the alternative “time allocation” estimating model defined for all time periods  $t$ :

$$(Q/\text{Pop}) = f(P_A, P_S, P_L, F, D) \quad (5)$$

with the new variables  $P_L$  defined as the price of leisure, and  $F$  as full income. In turn, those two variables are defined as:

$$P_L = w(1 - U_R), \quad (6)$$

where  $w$  is the hourly wage rate and  $U_R$  is the unemployment rate, and full income is the standard Becker formulation:

$$F = T_C P_L + T_W w + Y \quad (7)$$

with  $T_C$  and  $T_W$  defined as hours of consumption and hours of work ( $1 - T_C$ ), respectively, and  $Y$  defined as property income. An adjusted price index was also derived incorporating the leisure price. The expected signs on the first partial derivatives are the same as in the non-time allocation model for own-price, substitute price and income distribution ( $D$ ), and negative for the two new leisure price variable ( $P_L$ ), while positive for the full income variable ( $F$ ). The arts are considered a priori to be a “superior time-intensive good” in this formulation.

Withers utilized single-equation estimation, justified in part by the Moore (1966) results, but also by his belief that the performing arts market is inherently recursive in structure, with price in one time period affecting attendance in that same period, but any supply of new performances having an observable effect no earlier than the next time period. The latter hypothesis is attributable to the “advance planning and announcement of production and seasons and their prices that is typically required in this industry” [Withers (1980, p. 737)].<sup>33</sup> Thus, ordinary least squares was used with the double-log transformation, which he also justified by prior econometric evidence that this form is preferable for non-necessities in single good estimation (pp. 737–738).

There are two broad reasons for the popularity of the Withers (1980) results. First, the largely successful decomposition of the effect of rising income in the time allocation model into a relatively high “full-income” effect offset by a smaller real leisure price effect is consistent with a priori expectations that the arts can indeed be considered luxury goods that are time-intensive in consumption. Second, the low price elasticities in the more structurally sound time-intensive model (which increase to approximately unity or are only modestly elastic in the conventional model) are also consistent with a priori notions among many arts economists. Of course, these price elasticities are applicable to an extremely aggregated measure of the performing arts, and do not apply to specific organizations in specific product and geographic markets, nor does their interpretation

<sup>33</sup> Heilbrun (1984, 1996) stressed the difficulties in smoothly increasing the quantity supplied of arts services and emphasized the role that periodic supply shifts can play in later stimulating observed increases in arts attendance. However, that issue is never linked in the econometric literature to the choice of single or simultaneous equation methods.

reflect any sensitivity to the issue of the level of prices at which such “industry-wide” elasticities are estimated, as discussed above.

Interestingly, Withers’ (1980) cross-price elasticity results for reading and recreation are rarely cited, even though they are generally higher than the cross-price elasticities estimated by Gapinski (1986). Of course, Gapinski’s data were much more disaggregated, so that he was also able to estimate cross-price elasticities faced by individual arts organizations (three of which were indeed quite high). Furthermore, the substitute prices were much better defined as the ticket prices charged by the other art forms.<sup>34</sup> Another relatively ignored feature is Withers’ conclusion that the results potentially weaken the case of government support of the performing arts on the grounds of financial distress. That is, the high income elasticities only partially offset by the elasticity of the price of leisure together with the relatively low price elasticities of demand, suggested to Withers that “the potential for continued growth of private market support for the performing arts should be recognized” (p. 742). It is ironic that this conclusion would be downplayed inasmuch as the very title of his paper announces his interest in exploring the unbalanced growth issue in the performing arts.<sup>35</sup>

Ekelund and Ritenour (1999) represents a rare subsequent attempt to focus on this problem and isolate the effect of the time costs on US symphony concert demand using a less aggregated unit of analysis than Withers, although still an aggregation of anonymous individual orchestra data.<sup>36</sup> They estimated a single linear OLS equation, which they suggested may be even more justified for orchestras than for Broadway as studied by Moore (1966), also independently testing for possible simultaneity bias. They regressed annual per capita symphony orchestra concert attendance on average ticket price, the price of audio recordings, annual real disposable income, and their key variable, the cost of time (as measured by the annual average real hourly wage rate). Only the coefficient on the substitute price variable behaved poorly (negative in sign rather than positive, and significant at only the 0.10 level). The own-price coefficient was negative and strongly statistically significant (although low in magnitude consistent with a

<sup>34</sup> See further in Section 8. This aspect of the Gapinski (1986) results can easily be missed. For example, Fernández-Blanco and Baños Pino (1997) observe that Gapinski “shows that the best substitute for a theater play is not a film, but a different theater play” (pp. 62–63). In fact, the substitute price for the two theaters in the Gapinski database is the average of prices of opera, symphony and dance only [Gapinski (1986, p. 21)].

<sup>35</sup> Another forgotten feature of the Withers results is that when his model was applied to both Australian and Canadian data in Throsby and Withers (1979), the results were not as strong statistically. In the Australian case, while the ticket price elasticities were largely consistent with the American results, no significant income effect was found using either the conventional or the time allocation model (pp. 115–117). While Throsby and Withers attributed some of these problems to weaknesses in their Australian data, it is interesting that those data were at least less aggregated than in the US case (i.e. applying to seven major professional performance companies, although over a shorter time period of 1964–1974; p. 115). Any degrees-of-freedom and related problems were even more severe in the Canadian data, and the model could not be estimated in that case at all [Throsby and Withers (1979, p. 112)].

<sup>36</sup> Ekelund and Ritenour acknowledged this aggregation problem by noting that results may be different if city or SMSA data were to be used for specific orchestras, citing some panel data evidence supporting that possibility.

low ticket price elasticity of demand), while income had a positive effect on attendance per capita (but with a normalized coefficient suggesting less than unit elasticity), and the wage rate (value of time) had a negative coefficient.

Despite its modeling limitations and remaining aggregation problems, the Ekelund and Ritenour (1999) results are consistent with the fundamental idea that any positive income effect on arts demand will be partially counterbalanced by the time-intensive nature of live performances and the opportunity cost of that time. They were duly cautious in evaluating their findings, but interestingly tended to stress the threats to the arts resulting from their results in contrast to the more optimistic assessment provided by Withers (1980).

### 5.3. Luksetich and Lange: “A simultaneous model of nonprofit symphony orchestra behavior” (1995)

Luksetich and Lange had previously employed two-stage least squares methods to estimate orchestra demand.<sup>37</sup> Their key findings in 1984 were:

- price elasticities varied by orchestra size, becoming more elastic as the size of the orchestra fell, with major orchestra demand quite inelastic and metro orchestra demand modestly elastic;
- the price elasticities became less elastic with the inclusion of a donor price variable (measured as total donations divided by attendance), although the donor price elasticities themselves were not statistically significant;
- their total sample price elasticity estimate of about  $-0.48$  both with and without donor price was notably close to estimates from major prior studies; and
- they concluded that “in general” when comparing the OLS and the 2SLS results there was support for the latter, and the elasticities of the non-price determinants were stable regardless of procedure.<sup>38</sup>

The superior database for the 1995 paper allowed for a more thorough exploration of the relationship between factors under managerial control and various orchestra performance measures, which they modeled as a six-equation system with attendance, average price, administrative expenses, orchestra quality (using non-administrative orchestra spending as a proxy, an expansion of the “wages” variable they had used in 1984), number of concerts, and donations simultaneously determined. The model was

<sup>37</sup> See Lange and Luksetich (1984). A related paper [Lange, Luksetich and Jacobs (1986)] confirmed that equations for orchestras of different size and classification should be estimated separately; see also Luksetich and Lange (1995, p. 52).

<sup>38</sup> However, the case for the superiority of the more complex approach was not overwhelming. The authors noted that the estimated equations of “price” from the single-equation estimation of 2SLS varied widely regarding the adjusted  $R^2$  results across the orchestra sub-samples, possibly suggesting that the instrument price in the second stage was not necessary because the firms were not price takers so that no supply curve existed [Luksetich and Lange (1984, p. 43)].

estimated using 2SLS regression, the second stage being estimated using pooled cross-section, time-series techniques with estimates corrected for heteroskedasticity and serial correlation.

Luksetich and Lange (1995) is perhaps the best example of estimating arts demand as part of a multi-equation simultaneous equation system using 2SLS estimation techniques to date. Their findings are summarized here. While a surprising omission in the demand equation was any measure of regional educational level, the most important findings related to the low price elasticities of demand for each orchestral group. Although this is a familiar result with aggregated data (although here at least segmented by orchestra size), it has especially interesting implications for orchestral full-income-maximizing (ticket-plus-donation) pricing strategies and for the interpretation of price elasticity results when organizations have multiple interrelated revenue sources, as discussed in Section 4.2 above.

Regarding the individual components of the demand equation, ticket price performed well with a derived price elasticity of  $-0.33$  (p. 56). Surprisingly, quality had a negative effect on per capita attendance, although their quality proxy of artistic personnel and total concert production expenses per concert was shown by Tobias (2004) to be an unreliable predictor of *expert* opinions regarding the quality of arts organizations. The result that the number of concerts per capita in the region was a strong predictor of regional attendance per capita was consistent with arguments that variations in the sheer availability of artistic resources is critical to explaining attendance variations [Heilbrun (1984, 1996), Gold (1980), Khakee and Nilsson (1980)], but in a model expressly designed to correct for simultaneity bias, it is surprising that attendance did not also appear as an independent variable in the concert equation.

The most noteworthy results of the Luksetich and Lange (1995) analysis relate to the interaction of ticket buying and voluntary donations. Not only were the implied price elasticities low for all three orchestra types, but the interactions between the ticket price and gifts per capita further clarified the fact that orchestras have been following an excessively low price strategy. That is, even when adjusting for the possibility that higher ticket prices would induce arts patrons to partially reduce the donated portion of their “full price” of attendance, orchestras would generate more total income if they were to substantially increase average ticket prices (even ignoring more targeted price increases that might be justified if the audience could be further segmented). For major orchestras, the mean elasticity of gifts per capita to ticket price was  $-1.19$  (p. 56). But, even considering that interaction between revenue sources, the authors calculated that the major orchestras could double the average ticket price from its current mean value in order to maximize ticket revenues, but more importantly could increase ticket prices as much as 62 percent and still maximize the sum of ticket-plus-donated revenues (p. 58).

Of particular importance was their calculation that following such a ticket price increase, the resulting average-ticket-price elasticity of demand at those higher prices was still well within the inelastic range at  $-0.65$ , fully consistent with the sports literature result that the optimal price for such “performance firms” is to actively price in the

inelastic range of their demand curves, hence explaining the “paradox” of low price elasticities estimated in empirical demand studies.<sup>39</sup>

## 6. The multicollinearity problem: Education versus income

The non-econometric evidence considered in Section 2.3 above demonstrated that education is likely the most important single variable in explaining variations in performing arts attendance. However, regression-based models have not generally succeeded in confirming this result. While the typically high correlations between education and other key independent variables (class, occupation, age, and even ticket prices in some models) is a key reason, multicollinearity is not the only complication.<sup>40</sup> Competing measures of education, distinctions between arts training and general education, and conceptual conflicts regarding the underlying causal relationships are also to blame.

The issue of how to measure education and whether to distinguish it from arts specific training at home, arts specific training in school, or just from past experience is highly problematic. As McCaughey (1989) asserts, “the reasons for the positive association of general educational attainment with participation in the arts are not fully understood; and how specifically arts education fits into this association is not clear” (p. 48). For example, Orend and Keegan (1996) and Relish (1997) stress the socialization or network effects of education in affecting arts participation rates, while Globerman and Book (1977) put education into a consumer production function model, although with only limited success in isolating a unique “consumption efficiency” effect on arts demand. It is also possible that education reduces search costs and generates more accurate perceptions of performing arts prices, a possible link to attendance established by Globerman (1978).

The Globerman and Book (1977) contribution is unique. While education is most commonly cited as merely a taste-determining variable, cultural economists are perfectly comfortable with viewing education as one form of specific consumption capital affecting relative shadow prices, and hence the constraints, facing arts consumers. However, no one else has actually tested for an explicit education consumption efficiency

<sup>39</sup> Metro orchestras appeared to have come closer to their optimal pricing strategy, requiring only about a 10 percent price increase to maximize combined ticket and donation revenues (the price elasticity of gifts was quite small for those orchestras), while small market orchestras were in the unique but bizarre position of being able to maximize ticket revenues with only a 31 percent price increase, but would actually generate even higher combined ticket and gift revenues if they were to raise ticket prices by 57 percent (the result of having an estimated positive elasticity of gifts with respect to ticket prices); see Luksetich and Lange (1995, p. 60).

<sup>40</sup> For example, due to the high correlation between incomes and prices over time, Goudriaan and de Kam (1983) could not get statistically significant elasticity estimates for both in their time-series demand equations for theater and concerts without imposing a constraint on the income elasticity from their separately estimated cross-section equations. While they were aware of the weaknesses to that approach [citing Kuh and Meyer (1957) on problems with extraneous estimates], they observed that “there was no alternative to get significant results” (p. 39).

link to arts attendance. Despite its creative application of the consumer household production model [Michael (1972); Michael and Becker (1973)], the Gliberman and Book (1977) effort to isolate this effect yielded only mixed results.<sup>41</sup>

Regardless of the exact causal connection between education and arts consumption, the various classifications of formal schooling are common measures of “education” in econometric studies. The specific way such formal education enters those equations depends on the data being used and the unit of analysis being studied. In what might be called “Type A” (aggregative) studies, the aggregate attendance or participation behavior of the population is known, but the data are not based on the attendance patterns of specific individuals with known personalized demand-determining characteristics.<sup>42</sup> The dependent variable is typically some version of attendance at specific arts organizations normalized by the regional population in which they are located. Consequently, the education independent variable must reflect the aggregative characteristics of the population in that region (e.g., “percent of the population with a college degree” or “median years of schooling”, etc.). The same measurement issues arise regarding income in Type A studies (i.e. “percent of the population earning above \$30,000” or “per capita disposable income”, etc.); but some localized measures of income are typically incorporated into those demand equations. These studies sometimes also incorporate measures of local performing arts ticket prices or even prices of substitutes and organizational quality proxies.

Alternatively, in “Type P” (personalized) studies, the attendance or participation behavior of particular individuals can be matched to their unique demand-determining characteristics. Dependent variables can be continuous (e.g., “number of arts events attended”, or “number of attendances”) or binary (e.g., “1 if attended at least one time, 0 if did not attend at all”). In Type P studies a wider variety of educational variables can be included beyond the usual formal education measures, and in fact, distinctions can be made between own education, parents’ education (sometimes distinguished by gender), specific types of education (e.g., art training at home versus at school), or diverse measures of exposure to various art forms or practical training in those fields. However, they are not capable of incorporating arts organization prices or organizational quality. At best, a variable can be inserted such as “lives in city over 50,000” [Lewis and Seaman (2004)] to try to capture some of those localized “fixed effects”. In this sense, Type P studies are not estimations of well-defined demand functions.

The results of 12 econometric studies that include both income and education variables are fully documented in Seaman (2005, Table 14). Gapinski (1981) viewed

<sup>41</sup> Seaman (2005, pp. 90–94) provides the details.

<sup>42</sup> As usual, the variability in databases can create anomalies. For example, Bajic (1985) had access to subscriber lists (not audience survey data) for both the St. Lawrence Theatre and the Toronto Free Theatre. While this provided information on the residential location of individual subscribers and hence allowed the construction of an independent variable measuring commuting distance to the theaters, there was no personalized information on education or income – hence requiring the construction of an aggregated measure of education and income per “zone”.

his own elasticity estimates as only tentative, but paid homage to the Ford (1974, Vol. II) non-regression based findings by noting their general similarity to his results. More importantly, the overall results of the 12 studies provide only relatively weak confirmation that education measures reliably outweigh income measures as determinants of arts demand. Only five of the studies (41.7 percent) found evidence for the dominance of education; strong pro-education evidence is in Ganzeboom (1989) and Peterson, Hull and Kern (2000). Gapinski (1981), Gray (2003), and Lewis and Seaman (2004) provide modestly strong evidence that education outweighs income, while two studies generated opposite results favoring income [Bajic (1985); Bonato, Gagliardi and Gorelli (1990)]. Although Globerman and Book (1977) focused on the separate issue of whether the role of education is consistent with the household production model, their estimated elasticities were higher for income than for education, providing some evidence against the education dominant hypothesis.

The remaining four studies yielded ambiguous results. Goudriaan and de Kam (1983) did not calculate education elasticities, making direct comparisons difficult; however their t-statistics on the education variable were very high (but with the non-normalized coefficients, difficult to compare in economic significance across determining variables). Meanwhile their income elasticities were only high when age and education are dropped from the equations. Jenkins and Austen-Smith (1987) generated a higher education-demand elasticity in their two-stage least squares equation but a lower elasticity relative to income using OLS. But in both cases, the standard errors were quite high when both variables were included along with “social class”. The income coefficient in Dobson and West (1989) was negative, but the standard educational variable was also weak and statistically insignificant. Their strongest results were for two formal education substitutes: childhood participation in non-school theater performances as opposed to school-related performances, as well as childhood theater participation rather than just exposure to the theater, both strongly influenced adult theater attendance. Finally, Abbé-Decarroux and Grin (1992) did not utilize a formal education variable, but found similar evidence to that of Dobson and West (1989) that “arts training” variables performed well (although their variables did not distinguish between home and school exposures). But they also found fairly strong evidence for the importance of income (although less strong than for the arts training variables).

## **7. The taste cultivation problem and human capital: Habit formation, learning-by-consuming and rational addiction**

Cultural economists have always stressed that current arts demand (whether for live performing arts services or the stock of tangible art works) is especially influenced by past arts exposure, and hence that inter-temporal dynamics should be incorporated into a well-specified demand model. Nevertheless, except for indirectly addressing this issue via the inclusion of age, education, or childhood exposure [e.g., Morrison and West (1986)], explicit inclusion of lagged dependent variables as separate determinants

has been relatively rare. Only Houthakker and Taylor (1970), Goudriaan and de Kam (1983), Oteri and Trimarchi (1990), Krebs and Pommerehne (1995) and Urrutiaguer (2002) included a one-year lagged endogenous dependent variable, and in each case it was strongly positive and statistically significant.<sup>43</sup> Carson and Mobilia (1989) defined the lag differently. Their much shorter weekly lagged dependent variable had negative effects on current attendance, a result they explained as capturing the effect of infrequent arts consumption such that very recent attendance actually reduces the likelihood of attending again in the current period. With a longer lagged dependent variable of even one year, what seems to be captured is not infrequent and discrete arts consumption patterns, but a proxy for the cumulative effect of some version of what might be called the cultivation of taste. It is not always appreciated that there are multiple versions of this phenomenon, with each having somewhat different implications for our understanding of arts demand and for optimal arts marketing strategies.<sup>44</sup> In the following sections we consider three such explanations: habit formation, learning by consuming and rational addiction.

### 7.1. *Habit formation*

The most “passive” explanation for past consumption affecting current and future consumption is simple habit formation, the behavioral inertia so characteristic of much of human behavior [Houthakker and Taylor (1970); Pollak (1970)]. If habit formation is the primary reason for the strong performance of lagged dependent variables in arts demand equations, arts managers should go to great lengths to introduce the arts to young audiences with regularly scheduled targeted programs to get them into the habit of attending, regardless of any particular human capital formation effects. In fact, the

<sup>43</sup> Krebs and Pommerehne attributed the difference between their estimated low short-run price elasticity ( $-0.16$ ) and the higher long-run elasticity ( $-2.6$ ) to the stronger impact of their one-year lagged attendance variable (actually mislabeled as a lagged quality variable in their Equation (1A), p. 26). They interpreted this result, following Houthakker and Taylor (1970), as reflecting “habit formation”, although their partial adjustment model (where consumers are assumed to partially adjust to long-run equilibrium) was not identical to their predecessors’ “stock adjustment” model [see Krebs and Pommerehne (1995, p. 25, and their Note 25, p. 30)].

<sup>44</sup> Lévy-Garboua and Montmarquette (1996) emphasized the two most interesting reasons identified by Pollak (1970) for a distinction between long- and short-run demand functions, ignoring his more institutional “contractually fixed commitments” explanation [Pollak (1970, p. 745)]. Thus, while Pollak originally did have a three-fold classification scheme, only two approaches were cited by Lévy-Garboua and Montmarquette. They defined the simple “habit forming” phenomenon identified by Pollak (his third case) as a “deterministic approach”, by which any type of habit formation or the creation of consumption capital, whether myopic or farsighted, is considered an inevitable reality of the human condition (p. 28). This was contrasted with Pollak’s second approach stressing the ignorance of consumers about their own preference orderings “outside the range of . . . past consumption experience” who rely upon personal experience through “a time consuming learning process” [quotations from Pollak (1970, p. 745)]. Lévy-Garboua and Montmarquette (1996) also cited two other antecedent related approaches (Note 2), but seem to have been the first to actually use the phrase “learning-by-consuming”.

important role of specific consumption capital is closely associated with the notion of rational addiction discussed below.

Houthakker and Taylor (1970) remains the classic “state-adjustment” dynamic model linked to habit formation, estimated using OLS as part of a comprehensive study of consumer demand in the United States (reporting results for 82 separate spending categories). While they also reported results for motion pictures and spectator sports, their estimated equation for “legitimate theater and opera” is often cited, both for the specific derived short-run versus long-run “relative price” elasticities ( $-0.1827$  and  $-0.3109$ , respectively) as well as for their conclusion that while theater and opera are subject to habit formation, it “wears off quite rapidly” (p. 131). While not as frequently cited, they also derived short- and long-run elasticities with respect to total expenditures, ( $0.7407$  and  $1.2604$ , respectively). Their equations for all spending categories were estimated over the period 1929–1964 using the *Survey of Current Business* as the principal source of data.

The Globerman (1978) approach to indirectly isolating the effect of past consumption on present consumption is novel in the arts demand literature. He investigated the determinants of public perceptions about performing arts prices, including the role played by past attendance in generating more accurate price perceptions that can be viewed as stimulating attendance. His approach might be viewed as a more traditional price search model in contrast to the “utility function search” model of Lévy-Garboua and Montmarquette (1996); see also Brito and Barros (2005). Furthermore, Globerman’s finding that higher levels of formal education are at times related to lower perceived minimum arts prices is suggestive of an important and generally ignored link between education and attendance that requires neither a “taste development” explanation, nor even a beneficial productivity effect in a household production context [as in Globerman and Book (1977)].

## 7.2. Learning by consuming

Another version of taste cultivation has become known as learning-by-consuming, in which consumers are characterized as uncertain about their utility functions but learn their own subjective preference structures through a process of consumption experiences generating either positive or negative feedback [Lévy-Garboua and Montmarquette (1996); Brito and Barros (2005); Ulibarri (2005)]. Abbé-Decarroux and Grin (1992) presented a “hybrid” type of learning-by-consuming model, in which consumers already have well-defined utility functions (with older consumers being especially risk averse), but poor knowledge about the product characteristics of different suppliers which can be clarified by positive and negative feedback from a kind of “lottery” of actual consumption. These models can have implications for the programmatic choices of arts managers.<sup>45</sup> Globerman (1978) put forward a search model that has some sim-

<sup>45</sup> Usually biased toward less esoteric and less risky programming; see, for example, Abbé-Decarroux and Grin (1992).

ilarities to both passive habit formation and a broader interpretation of learning-by-consuming that relies upon a process of price discovery rather than taste discovery.

Lévy-Garboua and Montmarquette (1996) has become the most cited example of the learning-by-doing approach. Their approach to the dependence of current consumption on past consumption did not include a lagged endogenous dependent variable in their estimated equations, but focused instead on the contrast between the various predicted effects of key variables in testing their learning-by-consuming model (1996, p. 39). They confirmed the methodological challenge of how best to incorporate past consumption into studies of current consumption by observing that despite the general consensus among economists and sociologists that such effects are important for a wide variety of goods, “it is seldom possible to directly verify this assertion . . . using individual data and after controlling for many wealth, price and taste variables” (pp. 27–28).

Their approach fully accepts the non-Beckerian premise that changes/differences in behavior can be linked to taste changes/differences rather than subtle constraint variations and incorporates two key elements: first, any new experience of a good to the consumer reveals an unexpected positive or negative “increment in his taste” for the good, with this increment treated *ex ante* as a random variable with zero mean; and second, the concept of someone developing a taste for an art form such as the theater can be viewed as their having experienced repeated pleasant surprises when attending plays and hence revising expectations upward. Lévy-Garboua and Montmarquette (1996) claimed three theoretical advantages for this representation:

- it is compatible with an assumed strong heterogeneity of tastes and the independence of individual choices;
- it allows for extensive differentiation of cultural goods further magnified by the “unique nature of each ‘cultural’ experience provid[ing] new possibilities for surprises and implies long learning periods”; and
- it maintains intertemporal separability of the utility function conditional on past consumption by viewing consumers as having uncertainty regarding their preferences that prevents them from rationally anticipating the future taste (utility) that will be acquired over time (p. 28).

A full description of their quite complex model is beyond the scope of this chapter,<sup>46</sup> however, the especially important features can be identified. The utility function includes the quality-adjusted quantities for all goods  $i = (1, \dots, r)$  whose consumption “may give rise to non-systematic cultivation of taste” (1996, p. 28):

$$U = u(s_1 x_1, \dots, s_r x_r), \quad (8)$$

where  $x_i$  = the quantities consumed of market goods and the  $s_i$  weights represent “subjective qualities” anticipated before the decision is made to consume the goods; these weights depend on previous consumption experiences. A similar utility function can

<sup>46</sup> See Seaman (2005) as well as their own more concise description in Lévy-Garboua and Montmarquette (2003).

be defined for each time period. If we now define  $x_a$  as attendance at an arts performance, the effect of consumption experiences that yield additional information about the subjective quality of that good,  $s_a$ , can be represented in period  $t$  as:

$$s_t = E_{t-1}(s_t) + \gamma_t \quad \text{if } x_t > 0, \quad (9)$$

where  $E_{t-1}$  represents the expectation operator before period  $t$ 's choice, and  $\gamma_t$  is the "taste surprise" experienced in period  $t$  (i.e.  $E_{t-1}(\gamma_t) = 0$ ). This can be called the "experienced taste for arts consumption in period  $t$ ". As noted above, consumers who find themselves "developing a taste" for music (for example), will generally experience pleasant surprises, i.e.  $\gamma_t > 0$  is more common than the reverse. Consumers are viewed as basing their expectation of taste solely on their past experiences. Therefore, taste expectations are identical across all time periods (as noted, preserving the intertemporal separability of the utility function). Lévy-Garboua and Montmarquette then define a taste-constant Frisch demand function (i.e. marginal utility of income or wealth constant in contrast to Marshallian demand functions) that suggests that a good such as arts attendance that is assessed by a consumer as having a high quality will have a low "personalized price". However, analogous to the household production model of the new consumer theory when the marginal product of any unit of attendance is quite high in producing "arts appreciation", this greater potency of each unit of attendance in generating quality also implies that less quantity of the good  $x$  is required to achieve a given utility level (see Equation (8) above).

This generates a key insight from the learning-by-consuming approach, and allows Lévy-Garboua and Montmarquette to "impute" a price elasticity of demand from their empirical analysis even though they are missing a price variable in their vast database. That is, if the price elasticity of  $x$  is  $> 1$  in absolute value, the experience of consuming the arts will have a positive effect on current consumption when the good was "enjoyable overall", but a negative effect when it was not (1996, p. 30). They clarify this relationship by modifying the demand function so as to isolate the marginal effect of quality on the quantity of the arts consumed,  $\delta x / \delta s$ , which they derive after several steps to be:

$$\frac{\delta x}{\delta s} = -\frac{x}{s}(1 + e), \quad (10)$$

where  $e$  designates the price elasticity of demand for  $x$ . This directly implies that

$$\frac{\delta x}{\delta s} \frac{s}{x} = -(1 + e),$$

i.e. that the elasticity of arts attendance with respect to perceived arts quality (which they call the "taste elasticity") =  $-(1 + \text{own price elasticity of demand for arts attendance})$ . That elasticity is  $> 0$  if  $e < -1$ , i.e. if the price elasticity is elastic. If the price elasticity is inelastic ( $e > -1$ ), the quality (or taste) elasticity of the demand for the arts becomes negative, and unitary price elasticity implies a zero quality elasticity. As interpreted by Lévy-Garboua and Montmarquette, this allows them to measure the price elasticity of

demand when the model measures accumulated experience and taste for consumption (1996, p. 30). As noted above in Section 6, normally price elasticity is not capable of being estimated in Type P studies due to the absence of data on ticket prices.

Since their Ministry of Culture survey database was rich in opinion type questions, some of the key empirical results referred to those variables. For example, the authors viewed opinions referring to greater appreciation of the actors and the quality of the text of the play as indirectly measuring the taste for the theater. Two of their constructed variables, were designed to measure taste more directly. They used the “appreciation scores” from 0 to 10 that respondents had assigned to a list of 56 (23 theatrical writers and 33 actors/directors), and designated high scores of 9 and 10 as indicating “evidence of a taste for the theater” (p. 39). But they then found that writers were seemingly treated differently than actors and directors (based on the performance of these variables in their estimated tobit model), so they identified a taste for reading as a substitute for live theater among those who showed a strong preference for writers, and vice versa for those giving especially high ratings to actors and directors. They found support for this view in the negative effect of reading journals and magazines on the frequency of theater attendance.

They found that the variable measuring the percentage of actors and directors known was the best measure of “the degree of familiarity with or experience of” the theater, and they designated a person who claimed to know more than 80 percent of the names put to him or her as knowing the theater well. They found it noteworthy that the performance of their variable designating knowledge of writers performed more poorly than their variable measuring knowledge of actors and directors, and concluded that “it is necessary to have attended the theater personally in the past in order to know the actors and directors whose talent can only be appreciated on the stage and in action” (p. 39). They thus identified this variable as their prime measure of previous theater attendance and predictor of current attendance (and based on their tobit estimation the probability of someone knowing more than 80 percent of the actors and directors *not* attending the theater fell from 0.49 to 0.02).

This finding then becomes the key to their imputing price elasticity from their survey data. They estimated the price elasticity of demand (see their Note 7) for their experienced group of theater consumers as  $-1.47$  based on an application of Equation (10) above and the assumption that the average experienced consumer knows 85 percent of the actors and directors (yielding in their model an  $s$  value = 0.85), and that this type of consumer attends the theater an average of 3.87 times per year (so that  $x = 3.87$ ). These parameters along with the estimated logit coefficient of 2.1262 on their knowledge of actors and directors variable (interpreted from above to be  $\delta x / \delta s$ ), yielded the calculation (which they do not explicitly show) of  $e = -1.467$  for the more experienced consumer [see Equation (20) in Seaman (2005)] and  $-1.0$  for the less experienced theater-goer.

It is easy to question the many steps and assumptions required to impute this result. But Lévy-Garboua and Montmarquette viewed it as fully expected from their model when one views experienced theater-attenders are those who have “completed their learning process” after experiencing many cases of pleasant surprises generating high  $s$

values, high quality adjusted quantities of arts consumption and low personalized prices of consuming the arts. In their view, had theater experiences generally led to unpleasant surprises and a reduction rather than increase in the subjective quality assessments, the result would have been price inelasticity.

This approach of endogenizing the discovery of consumer utility functions via a learning-by-consuming process and testing the model without the use of a lagged consumption variable is unique, but is not the only empirical approach that might be taken. For example, Brito and Barros (2005) modeled the dynamics of demand and prices in a learning-by-consuming model and suggested that the standard empirical approach of using a lagged consumption variable is fully consistent with their version of that model. The unique finding of price-elastic demand for experienced consumers is also not an inevitable result of learning-by-consuming processes inasmuch as Brito and Barros (2005) derived the contrary expectation of both low income and own-price elasticities (p. 104) due to the way that flows of cultural good consumption interact with the decay of the stock of culture in response to an exogenous “shock” in the relative price of cultural goods in their particular dynamic model (pp. 97–98).

### 7.3. *Rational addiction*

Finally, past consumption can positively influence present and future consumption through rational addiction.<sup>47</sup> The key assumption here is consistent forward-looking behavior where consumers maximize an intertemporal utility function and are willing to sacrifice current utility for future utility by making investments in human capital (either general education, or more targeted training). The opposite of myopic habit formation, this model actually requires the least of arts managers, who in the extreme need only maintain generally high quality standards; in so doing, it is suggested, they will not endanger the perception that the arts are one of those goods capable of yielding future utility through the sacrifice of current consumption in order to invest in the creation of human consumption capital. In contrast to the learning-by-consuming approach, the rational addiction model combined with specific consumption capital in a household production framework has a different modeling setup and can generate different implications, some of which were described earlier in the Section 6 discussion of Gliberman and Book (1977).

Despite its popularity in the arts literature, attempts to verify a more technically precise version of this framework have not always succeeded. For example, while applied to cinema rather than the performing arts, Cameron (1999) found his results in testing for this phenomenon problematic and offering “little support” for the rational addiction model (p. 619). This is in large part due to the additional requirements that must be met in finding evidence for addiction in the more technical version of that model.

<sup>47</sup> See Stigler and Becker (1977), McCain (1979, 1981, 1995), Spinnewyn (1981), West and McKee (1983), Becker and Murphy (1988), Villani (1992), Cameron (1999), Lévy-Garboua and Montmarquette (2003).

That is, the household production element of the rational addiction model generates an important distinction between shadow-price elasticities linked to arts appreciation and market-price elasticities related to observed arts attendance. But the intertemporal non-separability of the utility function feature of the model stresses the rate of time preference of consumers, i.e. their ability to be far-sighted rather than short-sighted. In this context, findings of “too-high” a rate of time preference is inconsistent with the premise behind the rational addiction framework.<sup>48</sup> Tests for rational addiction also involve investigating the relationship between the interest rate and the discount rate. Lévy-Garboua and Montmarquette (2003) provided a concise description of the rational addiction perspective, and contrasted it to their own learning-by-consuming approach.<sup>49</sup> A key result derived from the formal analysis is that the “relative shadow price” of arts appreciation (as distinct from ticket purchases) will normally decline over time with the accumulation of arts-specific capital, be it from consumption or training [Smith (1998)].

There are two especially important implications of the rational addiction framework:

- While it might be thought that with a declining relative shadow price of art appreciation over time its quantity will grow as well, that will only definitely occur when the rate of time preference does not exceed the interest rate; more impatient consumers, therefore, may actually reduce their consumption of arts appreciation over time even in the face of a declining relative shadow price.
- As is true of any variation in the household-production-consumer-choice framework, even if consumption of the unobserved art appreciation ( $X$ ) rises over time, there is no guarantee that the observed attendance at arts events ( $x$ ) will similarly increase over time. As usual this is because with the cultivation of taste, increasing arts experience makes each unit of  $x$  more productive in generating a unit of  $X$ . Since less  $x$  can generate a given  $X$ , the net result is uncertain, although again  $x$  is more likely to rise the lower is the discount rate and the higher is the interest rate.

Finally, this critical distinction between arts appreciation  $X$  and arts attendance  $x$  provides one of the theoretical justifications as to why one might expect an inherent bias toward relatively low price elasticities of demand for arts attendance relative to other goods at comparable explicit prices. That is, there is a distinction between the shadow price elasticity of  $X$  in any time period ( $E$ ) and the market elasticity of arts attendance ( $e$ ). Specifically, the shadow price elasticity is always higher than the market price elasticity due to the effect of positive addiction. The key point is that there is nothing inconsistent between having a price-elastic demand for art appreciation  $X$  and a market-price-inelastic demand for arts attendance  $x$  [Lévy-Garboua and Montmarquette (2003, p. 206)].

<sup>48</sup> McCain (2003, p. 448) notes that efforts to test the rational addiction model empirically have not been “entirely satisfactory”, and that at times findings of high rates of time preference have been found to be “implausible” by advocates of the rational addiction model.

<sup>49</sup> Borrowing also from the original contributions of Spinnewyn (1981), Stigler and Becker (1977), and Becker and Murphy (1988).

In summary, while many arts demand studies have improved the performance of their estimated equations by including a one-year lagged dependent variable capturing the effect of past consumption on future consumption, that is not the only, or even necessarily the preferred, way to capture the dynamic effect of taste cultivation in arts demand analysis. Even if such a lagged variable is introduced, the underlying theoretical justification for its inclusion is a complex subject, with competing approaches having somewhat different implications, especially for arts management strategy and for the future growth of performing arts demand.

## 8. The product and geographic market problem: Substitutes and complements

In addition to the unresolved issue of whether the arts are price-inelastic luxury goods, Lévy-Garboua and Montmarquette (2003) have found no definitive evidence in the literature regarding close substitutes for the performing arts. While Withers (1980) estimated fairly strong cross-price elasticities for his “reading and recreation component of the CPI” as noted earlier, the t-statistics were not especially strong, and a time-series study of the aggregate performing arts in the United States is not well-adapted to capture localized competitive effects, or to distinguish among the sub-categories of the performing arts. Corning and Levy (2002) stated the dilemma perfectly when they observed that the most direct competitors of their three southern California theater venues are the Santa Barbara City College Theater Group, the Ensemble Theater Company, and Civic Light Opera, but “unfortunately insufficient price data were available to construct a useful variable” (Note 5, p. 234).<sup>50</sup> They were thus forced to fall back on the “recreation component of the CPI” and found that none of those variations had any “measurable effect in any configuration and was dropped” (p. 227).

Some suggestive evidence on substitutes was developed by Lévy-Garboua and Montmarquette (1996), although no variable in their vast database really captured the price of substitutes. One variable reflected the perceived quality of available substitutes, and the relatively strong negative coefficients for this variable reflected a potentially broader product market than theater alone. This conclusion is also supported by their finding of a negative effect of regular magazine and journal reading on the frequency of live theater attendance, suggesting that those two forms of intellectual stimulation and entertainment are partial substitutes. Certainly, evidence regarding substitutes and complements need not stem solely from cross-price elasticities. Available quantities of potential substitutes like television programming or proxies reflecting technical improvements in the quality of such substitutes [e.g., Bonato, Gagliardi and Gorelli (1990), Pommerehne and Kirchgassner (1987)] may be revealing indicators of substitution relationships. Heilbrun

<sup>50</sup> In a non-regression case-study of marketing strategies for the Los Angeles Music Center, Kaali-Nagy and Garrison (1972) identified eight potentially competing Southern California attractions: Marineland, Busch Gardens, Disneyland, Knott’s Berry Farm, the L.A. Zoo, the San Diego Zoo, Huntington Library and the L.A. County Museum.

(1997) found evidence that the popular arts have had notable negative effects on the high arts by examining the press coverage of both art forms over time in the *New York Times*.

Regarding cross-price evidence, it was not always presumed that arts and entertainment alternatives would be substitutes as opposed to complements for the high arts. Nevertheless, Felton's (1992) explicit expression of neutrality regarding the expected signs of such variables is rare<sup>51</sup> and most discussions of the empirical results reflect the expectation that gross substitution should dominate.<sup>52</sup> For example, Ekelund and Ritenour (1999) were troubled by the unexpected negative coefficient on their variable for price of audio recordings, and stressed that it was statistically significant at "only" the 0.10 level.

While some version of movie price is the most popular cross-price choice,<sup>53</sup> such variables have performed very poorly.<sup>54</sup> In fact, it can be safely concluded that there is little empirical evidence that movies are effective substitutes for the performing arts. Only Withers (1980) and Gapinski (1986) had any real success in capturing positive cross-price effects for the performing arts, with Withers being the only remotely successful application of an aggregated recreation or entertainment price index. However, Felton (1992) generated evidence of a positive cross-price effect of symphony prices on attendances for large-budget but not small-budget ballet companies, and Goudriaan and de Kam (1983) found evidence of a positive effect of education and recreation expenditures on symphony, but not theater, attendance in their time-series model.

While Gapinski (1986) has understandably received all of the attention regarding cross-price evidence, it is noteworthy that his earlier attempt to find cross-price effects between cinema and recreation price indices and attendance at the Royal Shakespeare Company was not successful [Gapinski (1984)]; moreover his later study of resident versus tourist demand using the same 13 arts companies as in his 1986 study (and with a more inclusive variation of his 1986 substitute-price variables) also failed to generate any significant results. It is interesting that the Gapinski substitute prices that omitted any "intra-art form" components (1986) were more successful than the versions that

<sup>51</sup> She stated that "it was deemed equally likely that the two [alternative arts] experiences would be substitutes or complements" [Felton (1992, p. 4)].

<sup>52</sup> At times, this expectation was clearly dependent on the particular measure being used. For example, in Greckel and Felton (1987) their "poor" measure of substitute prices was dropped (i.e. the entertainment component of the CPI), not only due to weak and statistically insignificant coefficients but because in most equations the "the sign of the coefficient was negative, indicating complementarity instead of substitution" (p. 64).

<sup>53</sup> The enthusiasm for cinema prices in performing arts demand equations is not reciprocated in cinema demand analysis, where performing arts prices never appear. One possible reason, beyond mere measurement problems and data availability, is that while cinema and theater may appear to be excellent substitutes, the greater availability of cinema in all parts of a country compared to the more concentrated location of theater in only the major urban centers, may reduce the practical degree of such substitutability. Fernández Blanco and Baños Pino argued this for the case of Spain (1997, p. 62).

<sup>54</sup> Only Touchstone (1980) came close to an expected result in her symphony equation and the coefficient in the opera equation was negative.

included such intra-art form prices (1988), although the two studies were not otherwise identical. Also, it is puzzling that citations of [Gapinski \(1986\)](#) almost always claim that he found strong evidence of substitution across artforms and stress the fact that his cross-price elasticities are greater than 2.0 in some cases, despite the fact that the cross-price elasticities are below 0.20 for four of his 13 companies, and 0.65 or lower for all but three of his companies (with two of the dance companies being as low as 0.21 and 0.28).<sup>55</sup>

Furthermore, [Gapinski](#) himself stressed that the two modern dance companies having those unusually high cross price elasticities were those with the lowest attendance and most “heavily contemporary” of all the companies in his study (p. 22), and that the “clearest pattern to emerge” was that “a price change by a single company alone has minor impact on a second company” and that the “greatest attendance response to a price maneuver occurs for the initiating firm itself” (p. 23), which is especially noteworthy given the quite inelastic own-price elasticities that average less than  $-0.30$  for all art forms [see [Gapinski \(1986, Table 1\)](#)]. However, among the rarely discussed results are his projections of the effects of price changes by rivals acting together rather than unilaterally (p. 24), with one of his examples being a loss of 4800 patrons annually for one of his theaters if all other non-theater companies reduced their prices by 10 percent (an attendance decline that he argued is almost twice what could be generated by own-price changes by that particular theater itself).<sup>56</sup> Nevertheless, the overall message of his path-breaking study is that price interdependencies among performing arts firms in specific geographic markets are potentially important, and that the focus should clearly be on further efforts to find evidence of the degree to which “the lively arts substitute for the lively arts”. To date, no successful replications or extensions of the [Gapinski \(1986\)](#) analysis have appeared.

There is little direct cross-price elasticity evidence regarding one aspect of complementary goods, i.e. the effect of higher prices for transportation (for given distances from the venue), parking, child care, dining and other components of the full price of an arts performance visit. The only exceptions are [Carson and Mobilia \(1989\)](#) and [Lévy-Garboua and Montmarquette \(1996\)](#), where some indirect evidence is presented that such costs (or perceived costs) can have negative effects on performing arts consumption.

The relative success of [Gapinski \(1986\)](#) in studying the particular geographic area of London raises an issue not normally addressed: what is the geographic scope of the market for the performing arts? Complementary television programming or other forms

<sup>55</sup> The rare exception of a more accurate portrayal of the [Gapinski \(1986\)](#) results is [Abbe-Decarroux \(1994\)](#), who lamented his inability to find sufficient real income and substitute price data to include in his study of Geneva theater, but noted that various studies have found that performing arts demand is income insensitive, and that [Gapinski \(1986\)](#) also found that it is substitute-price insensitive as well (Note 6, p. 103).

<sup>56</sup> It is possible, but unlikely, that all other firms would independently change price by roughly the same magnitude, and [Seaman \(2004\)](#) provides evidence that successful collusion, whether on price or other issues, has no doubt been rare in the performing arts.

of the media arts [Waterman, Schechter and Contractor (1991); Heilbrun (1993)], as well as touring arts companies [Escalera (2002)], can extend the geographic scope of the relevant market far beyond any localized geographical region.<sup>57</sup> Furthermore, while Verhoeff (1992) confirmed the negative effect of distance on performing arts attendance [see also Zuzanek and Lee (1985)], he found surprising variability in the distances that people travel to performances in the Netherlands.

Despite this potential evidence that the geographic scope of effective performing arts markets need not be as localized as is generally assumed, Forrest, Grimes and Woods (2000) provide the most sophisticated econometric evidence regarding the important negative role of distance traveled in performing arts demand. They applied a zonal travel cost model to data regarding the Royal Exchange Theater in Manchester. Their price variability was derived from the notion that all potential consumers faced different effective prices due to the varying costs of traveling to the venue. Using distance as a proxy for travel costs, they also assumed that an increase of 2.66 km is equivalent to an increase of £1 in the cost of attendance, and that symmetrically a £1 increase in ticket prices is the equivalent of shifting the population of each zone outwards from the theater by 2.66 km. They then calculated for each of 20 zones the change in total visitor numbers with respect to a change in ticket price, and derived a price elasticity of demand of  $-1.24$ , which they interpreted as being reasonably close to the revenue-maximizing pricing strategy when marginal cost in the non-capacity-constrained case is nearly zero. Interestingly, calculations of elasticity for individual zones (with prices different from the mean) showed inelastic demand in areas with the largest values for their variable controlling for educational level but elastic demand elsewhere.<sup>58</sup>

Finally, there is a small literature that addresses the substitutes/complements issue not by inserting the prices or quantities of consumption alternatives into a regression equation on arts attendance, but by examining the correlation between the estimation errors corresponding to consumers' demand equations for different types of entertainment in an effort to answer the question: "Are high arts and popular arts (or sports) consumers the same people?" These studies by Prieto-Rodríguez and Fernández-Blanco (2000) regarding classical and popular music, and Fernandez-Blanco and Prieto-Rodríguez (2000) and Montgomery and Robinson (2005) regarding live sports and the live arts, generate some evidence that the high and low arts may be complements instead of substitutes, but provide conflicting results regarding the relationship between arts and sports consumption [Seaman (2005, pp. 120–122)].

<sup>57</sup> Seaman (2004) reviews this evidence.

<sup>58</sup> They also addressed the issue of the possible endogeneity of residential location, whereby people with strong arts demands would locate in close proximity to arts venues. While it is known that arts attendance is higher for those living in urban areas or in locations with relatively large populations, that issue is rarely addressed as a simultaneity problem. Bajic (1985) also found some evidence of theater location being a factor in the housing choices of those with especially strong theater demand in Toronto, but this result is hardly typical of arts consumers, much less the general population.

## 9. The product quality problem

### 9.1. Modeling quality

Throsby's attempt to address the quality issue in arts demand studies (1990; a reprint of a 1982 paper) represented an important step in correcting a prior mis-specification of arts demand equations. He developed the distinction between an *objective* measure of individual plays (based on repertoire classification), and so-called technical variables (standards of source material, production, acting, and design) that actually depended upon the *subjective* assessments of press reviews. There is another critical distinction in the arts quality literature: whether the primary focus is on a time-series or pooled analysis of the quality of a large number of performances by a small group of arts organizations, or on the overall quality of a large number of arts organizations themselves. Two things are clear. First, the most studied artform by far has been theater [Throsby (1990), Jenkins and Austen-Smith (1987), Dobson and West (1989), Abbé-Decarroux (1994), Corning and Levy (2002), and Urrutiaguer (2002), with Krebs and Pommerehne (1995), a mixed case that primarily focused on theater but with a database that also includes opera and other art forms]. Second, the overwhelming focus has been on attendance per performance related to quality variables applied to the individual repertoire as opposed to the overall quality of arts organizations. Interestingly, the few studies that did not focus on theater [Greckel and Felton (1987), Felton (1989), and Luksetich and Lange (1995)] primarily used non-Throsby type variables that did apply to the organizations themselves (see below).

The Throsby (1990) model postulated a subsidized non-profit theater management choosing price, season length, and quality attributes of its productions, so as to maximize a managerial utility function containing those quality attributes and the percentage of seats in its venue that are filled with paying customers. Paid attendance demand is a straightforward function of average price per seat, season length, venue capacity, and an  $n$ -vector of quality characteristics. Data were available from three Sydney theater companies. The key innovations were in generating the variables to include in the quality characteristics vector. Five characteristics  $q_1, \dots, q_5$  were defined as repertoire classification, standard of source material, standard of production, standard of acting, and standard of design, respectively. The repertoire classification variable,  $q_1$  could be defined using objective criteria based on four groupings of plays that would be essentially non-controversial: A = a "classic" written before 1900; B = written after 1900 by a well-known author (from the audience perspective); C = written after 1900 by little or unknown authors (from the audience perspective); D = entertainment, revue, and musical. Class D was defined as the omitted benchmark if all three other repertoire classifications enter the equation, and a dummy variable was created for each of the A, B, and C groupings which was set = 1 if a play fell into that particular class, and 0 if it did not.

The development of variables  $q_2$  through  $q_5$  was more challenging and was based on an assessment of the "subjective" opinion of press reviews defined in terms of how

Table 2  
Demand function estimates for three Sydney companies, 1974–1978

T	Con	Price	Cap	Repertoire class			Technical standard				$\sum q_i$	$R^2$
				Cl A	Cl B	Cl C	Mat	Prod	Act	Set		
1	1.67 (3.2)	-0.41 (-0.7)			0.04 (0.7)		0.18 (0.7)	-0.09 (-0.4)	0.90 (2.2)	0.21 (0.6)		
1	1.14 (2.0)	-0.20 (-0.3)			0.03 (0.5)						0.87 (2.1)	0.21
2	-0.85 (3.3)	0.66 (1.9)	0.92 (11.4)	-0.01 (-0.1)	-0.04 (0.7)	-0.12 (2.2)	0.12 (0.8)	0.20 (1.1)	0.20 (1.1)	0.30 (1.8)		0.51
2	-1.38 (5.1)	0.58 (1.9)	0.94 (13.2)	-0.04 (0.6)	-0.05 (0.9)	-0.12 (2.3)					0.88 (4.2)	0.51
3	0.43 (1.3)	0.30 (0.8)	0.63 (5.9)	0.06 (1.2)	0.07 (1.6)		0.06 (0.4)	0.04 (0.4)	0.04 (0.4)	0.04 (0.3)		0.71
3	0.31 (0.9)	0.28 (0.8)	0.63 (6.2)	0.06 (1.7)	0.07 (1.8)						0.21 (1.3)	0.71

Source: Throsby (1990, Table 1).

Notes: Theater (T) 1 = Ensemble (180 seat theater-in-the-round in a converted boat shed in a harbor-side suburb); 2 = Nimrod (300 seat converted factory in inner suburbs); and 3 = Old Tote (principal state drama company in several venues; already was closed when the study was completed); Con = constant term; Cap = venue capacity; Cl (class) A, B and C are as defined in the text prior to the table; and the technical standards of source material (Mat), production (Prod), acting (Act) and design (Set) are the  $q_2$  through  $q_5$  variables. Absolute values of the t-statistics are in parentheses.

well any play met high standards defined over the four “technical” dimensions listed above. A cardinal scale 1 to 5 was created. Importantly, he also summed the  $q_2$  through  $q_5$  variables to obtain a single “composite standard” (p. 73). This was rationalized as an attempt to overcome some of the variability in individual assessments, but can be justified on its own merits as reflecting something akin to the overall impression that a play would make on a viewer who may not even be thinking in terms of the four separate criteria. This entirely separate variable (defined as “sum” =  $\sum q_i$ , for  $i = 2, \dots, 5$ ) was substituted for the individual  $q_2$  through  $q_5$  variables in an alternative specification of the model for each of the three theaters. The results are reported in Table 2, although coefficients are rounded to two decimals and the column headings are slightly modified compared to the original. Except for the repertoire dummies, the double-log specification was used.

Since only the Nimrod theater (theater 2) offered plays in all three of the “non-popular” (i.e. class D) repertoire classifications entered as dummies, its results regarding those three types of plays should be interpreted relative to entertainment, revue and musical plays. Its audiences revealed a strong distaste for class C plays (those by little known authors), but neither classics nor twentieth century plays by well-known authors had significant effects. The type of play also had no effect on Ensemble audiences (theater 1), but Old Tote audiences reacted favorably to both classics and well-

known plays relative to those by little-known authors (type C, the omitted base case for theater 3). Thus, there is some evidence that the type of play is an important variable to include in theater demand equations.

There were also mixed but generally supportive results regarding the more subjective rankings of the four technical performance criteria. The most noteworthy finding was that for all three theaters the aggregated quality variable generated much more statistical significance in the positive coefficient estimates than for each quality variable entered separately (although still not significant for theater 3, the Old Tote). The weak results for the Old Tote possibly reflected the high proportion of subscription seats sold by that theater, producing what Throsby called a “captive audience” effect (p. 75).<sup>59</sup> Considered individually, the standard of acting had by far the strongest effect on the Ensemble theater (theater 1), with set design dominating audience choices for the Nimrod (theater 2). Throsby found this first result fully consistent with the Ensemble’s known commitment to acting (p. 75). Taken as a whole, these “tentative and qualified” (p. 81) findings have been viewed as confirmation of the importance of controlling for quality in arts demand studies.<sup>60</sup>

Following Throsby (1990), the inclusion of some form of both objective and subjective measures of program classification into arts demand studies has become relatively common, although the results continue to be mixed. These approaches and results are reported below in the following sections.

## 9.2. Studies using objective quality criteria

We review here a number of studies that have assessed quality on the basis of objectively observable criteria, beginning with that of Jenkins and Austen-Smith (1987) who had only limited success in finding a positive effect on English provincial theater attendance of “less esoteric” programming (defined as comedies, thrillers and musicals, in contrast to so-called serious drama). While the effect was positive and statistically significant, it was not especially economically significant. They estimated that an increase in the mix of less esoteric programming from 50 percent to 60 percent would increase demand by only one percent. On the other hand Greckel and Felton (1987) did not attempt to characterize the content of programs, but included even more objective measures without success. Their dummy variable to capture the shift of the Louisville Symphony

<sup>59</sup> This is reminiscent of the Hjorth-Andersen (1992) suggestion that if subscription sales dominate total ticket sales (as he found in his forecasting equations for Danish theater), the financial success of a whole season is known before it even starts.

<sup>60</sup> In addition to the widely varying  $R^2$ s for the three equations, the primary discordant note was in the behavior of the ticket price coefficients, not statistically significant and with conflicting signs for the Ensemble and the Old Tote, but positive and significant for the Nimrod. Throsby suggested that this reflected a demand shift for the Nimrod during a time when the real price of admission was only gently rising due to the Nimrod’s policy of keeping prices low to encourage audience development rather than commercial success [Throsby (1990, p. 75)]. This justification is an extension to the positive elasticity case of the downward bias in estimated negative price elasticities created by low pricing strategies.

Orchestra to a full-time orchestra, and variables for the number of programs, and the number of performances (both intended to reflect desirable product variety) failed and were dropped from their reported equations. Two variables that did work well were idiosyncratic to the Louisville Orchestra: (1) a dummy variable to capture the effect of an “unpopular conductor” (i.e. Jorge Mester) was introduced to assess the negative impacts of the frequent absences of this primary conductor during his final two years, and the unpopularity of Akiro Endo, his successor (the authors surprisingly identify an estimated elasticity of  $-0.30$  despite this being a dummy variable); and (2) a concert hall capacity variable with the unique interpretation of capturing the positive effect of the shift of the orchestra to new and far superior facilities that also included a larger hall. In subsequent studies *Dobson and West* (1989) found no significant effect on Atlanta theater audiences of the type of play or the day of the week of the performance; similarly, *Felton* (1989) found statistical significance for her opera popularity ratings variable in only one of her opera company equations (the Kentucky Opera Association), and concluded that in other cities programmatic content had little effect on subscriber attendance. *Luksetich and Lange* (1995) had no success with their attempt to link total expenditure per symphony performance to attendance via a quality argument.

While *Abbe-Decarroux* (1994) included a variable measuring subjective press reviews, he perhaps followed *Throsby* (1990) as closely as anyone in also introducing eight quite objective dummy variables (although not aggregating them into a single variable). He also estimated his seven-year (64 productions) Geneva theater demand function for both full-price and reduced price audiences (as well as reporting the total demand equation). Some variables performed well; others did not. “Home productions” (those produced by the institution itself) had significantly negative effects on per performance admissions (explained as being due to the higher frequency of such plays being performed), while well-known authors, producers and casts had separately positive and generally statistically significant effects across all equations. But surprisingly, the fame of the play, and whether it was a classic (written before 1900) or a modern play (after 1990; deceased author) had no real effect on either audience segment, but audiences clearly rewarded novelty, with “atypical” plays (circus, revue, collection creation or other) having strongly positive effects on per performance attendance.

*Krebs and Pommerehne* (1995) considered but rejected various quality measures, and tried to capture the popularity of various arts productions by measuring the “share of productions with many performances out of all performances” (p. 25). Specifically, they constructed a proxy for highbrow versus lowbrow theater productions by measuring the “ratio of works with more than 75 performances to all works played in a season”, which they viewed as a proxy for more popular lowbrow productions that would survive longer than highbrow plays. Given the recognized weaknesses of this construction, it is remarkable that this variable performed fairly well – a positive coefficient, although not quite statistically significant (unless income is omitted from the equation). The derived “lowbrow” elasticity of arts demand implied that a 10 percent increase in the share of such works would increase paid attendance per capita of the population by one percent. This lowbrow inelasticity result is consistent with the low “less-esoteric-programming”

elasticity result in [Jenkins and Austen-Smith \(1987\)](#) and suggests that even when this dimension of repertoire quality has an effect on attendance, it is not as high as has been generally expected. However, since the [Abbé-Decarroux \(1994\)](#) definition of “atypical play” seems to include some more popular rather than eccentric content, its strong positive effect in that study is potential counter-evidence.

A large number of objective quality variables were introduced by [Corning and Levy \(2002\)](#) in their study of demand for live theater with market segmentation and seasonality. They found evidence that programmatic content had limited effects on single-ticket theater attendance, varying notably across individual theaters and strongest for the unique case of the musical *Tommy*, which in the case of one Southern California theater location would increase per performance attendance by over 200 in contrast to a performance of Shakespeare *ceteris paribus* (p. 230). They also found more evidence than did [Dobson and West \(1989\)](#) that scheduling has some effect on attendance, with the weekend dummy variable having the strongest positive effect across all venues. However, their seasonality results were generally weak. Their most fascinating objective variable is one that would seem to pre-judge the issue: “Flop” was a dummy variable = 1 when the average total attendance for a play at its first location prior to its shifting to another venue was less than 50 percent of capacity; remarkably, the coefficient on this variable was positive in two venue equations (statistically significant in one) and only negative and significant in the outdoor summer season venue. The fact that seemingly clear evidence that a play is a failure cannot reliably reveal later negative effects on attendance may be the best evidence of the challenge in capturing the effects of quality in arts demand studies.

### 9.3. *Studies using subjective quality assessments*

In contrast to the above efforts to capture objective quality effects, some subsequent studies focused on the determination of subjective perceptions of quality, typically focusing on the role that various expert critics have on the perceptions of the lay public. For example, [Abbé-Decarroux \(1994\)](#) supplemented his four repertoire and four “fame” (author, play, producer, cast) objective variables with a qualitative press review variable scaled nearly identically to [Throsby \(1990\)](#), adding a sixth category for “excellent”. This variable was positive and highly statistically significant in both full-price and reduced-price equations. [Corning and Levy \(2002\)](#) also supplemented their inventory of programmatic, scheduling and seasonal variables with a newspaper review variable on a five-point scale [adding some additional detail to the parsimonious [Throsby \(1990\)](#) ratings; their Table II, p. 227]. Due to some format changes in the two publications used in their analysis, some productions were not reviewed at all, which was registered with a “no-review” variable. The quality of such press reviews had a positive and statistically significant effect on per performance attendance in only one case (the summer outdoor festival venue). Interestingly, the total absence of any review of a production actually had a positive effect in each of the three venue equations, with reasonably high although not statistically significant t-statistics.

#### 9.4. An extended model

Urrutiaguer (2002) has provided the most important extension of the Throsby (1990) analysis. He modified the Throsby model in two ways, one somewhat technical, but the other more important conceptually. The technical adjustment was in changing the dependent variable from a measurement of seasonal attendance for each year to per performance attendance, by dividing the Throsby dependent variable by the number of performances. Urrutiaguer justified this in his case as necessary to avoid heterogeneity in the size of theatrical institutions among his much larger database of 87–104 theaters, and to reduce the risks of heteroskedasticity (p. 187). More fundamentally, he noted that when he applied his model to the demand for individual shows in 1995, the adjusted  $R^2$  was quite low (about 0.13; the Throsby  $R^2$ s ranged from 0.21 to 0.71). He suggested that the weakness of this result should not be surprising inasmuch as the theater itself rather than just individual shows is a “much more appropriate” level at which to examine variance in demand, which can be caused by an organization’s program, auditorium comfort and the overall image of an individual theater.

Urrutiaguer’s four repertoire classifications were updated variations of Throsby (1990) adapted to France. An important modification was required to make the resulting dummy variables applicable to a theater rather than an individual play. A theater-reviews variable was based on an analysis of the opinions in three publications, again aggregated to apply to an individual theater rather than just specific performances. The final step was to recognize that unambiguous reviews have more impact than those with “nuances”, and any dummy variables entered into the estimating equation should reflect this. Urrutiaguer also developed a “weak and high centrality” measure to capture the potential effects of a unique quality proxy in France: the weight in a theater’s programs of shows produced by what he calls “directors-cum-managers”. Finally, assuming that public recognition of a theater via tax-financed subsidies is a quality proxy, he specified a dummy with value = 1 if the yearly growth of subsidies was more than 8 percent, and = 0 otherwise. Two such dummies were defined, one for state and one for local subsidies.

Despite the sophisticated technical innovations in constructing the drama review and centrality dummy variables, and the important conceptual shift toward a focus on the theater rather than the individual play, Urrutiaguer (2002) originally had limited success in generating significant results for his quality variables, an outcome consistent with the frequently mixed experience of prior studies. So he went on to test the hypothesis that different portions of theater audiences have contrasting perceptions of reputation, especially in how they weigh the reputations of drama critics and those of artistic directors. Thus, the full theater sample was segmented into two groups: a Group I of 40 institutions for which the audience shares the scale of judgments of drama critics and a Group II of 47 institutions whose audience have more trust in the artistic reputation of directors-cum-managers and who either ignore or do not share the judgments of theater critics. Therefore, the signs on certain estimated quality coefficients were expected to differ between Group I and Group II regressions.

The effect of this disaggregation into two groups was dramatic. The adjusted  $R^2$  for both groups was very high ( $>0.824$ ). While the price coefficient was enigmatic, positive in both equations and strongly significant for Group I, and only one objective repertoire quality variable was significant (strongly negative for foreign contemporary plays for Group I), the other quality variables generally performed well. Also, consistent with other studies using a one-year lagged dependent variable, that effect was strongly positive in both equations, as is the venue capacity coefficient (although stronger for Group I). The regressions confirmed the expected opposition of the signs on the reputation variables for the media and art director, except for the weak centrality variable, with both groups have highly significant but opposite coefficients on the drama-reviews variables. This suggests that the effect of drama critics can be negative as well as positive, at least for some segments of the audience, which is a more encouraging result than the lack of significance that such variables have sometimes had in other studies.<sup>61</sup>

Despite the delay relative to the appearance of Throsby's work (which was first published in 1983), Urrutiaguer (2002) significantly advances our understanding of the arts quality issue, even if he did not incorporate Throsby's aggregated composite of different technical standards variable into his extensive analysis.

## 10. The role of socioeconomic factors versus life-style determinants of arts demand

### 10.1. Lifestyle determinants

Andreasen and Belk (1980, 1981) are best known for asserting that life-style factors, attitudes and socialization to the arts are more reliable predictors of attendance among "marginal attenders" (at least for theater and symphony in the southern US) than are demographic and socioeconomic variables. A notable feature of Andreasen and Belk's provocative assertion is that it was not only founded upon the derivation of statistically significant univariate correlations of 56 independent variables with the likelihood of attendance, but was further confirmed using step-wise regression analysis. As expected, multicollinearity problems were severe among their 56 independent variables that included all standard socioeconomic determinants (education, gender, income, occupation, and age), but also variables as diverse as six "general life-style" dimensions (e.g., optimism/hedonism and traditionalism), six "leisure life-style" group characterizations (e.g., passive homebody, culture patron, inner-directed self-sufficient), life-cycle variables, and various socialization proxies.<sup>62</sup> As a result, only six variables in the step-wise regressions were found to add significantly (at the 0.05 level) to the prediction of

<sup>61</sup> Including Urrutiaguer (2002) prior to segmenting the theater sample by audience reputation perceptions.

<sup>62</sup> Levantal (1989) included a related list of six "psychographic factors" including "eclecticism" and "independence of opinion" along with "determination to see a particular play".

theater attendance and five to the prediction of symphony attendance, with only modest adjusted  $R^2$  values of 0.279 and 0.289, respectively [Andreasen and Belk (1980, Table 2)].

However, despite those limitations<sup>63</sup> the essential results were striking: not one of those standard socioeconomic variables was a significant predictor of future arts attendance when controlling for attitude, and general and specific life-style factors. Instead, what mattered most as positive predictors of future attendance in the theater equation (based on the standardized beta weights) were: attitude toward attending the theater; being a “culture patron”, a leisure life-style characteristic; interest in live theater when growing up; and theater attendance during the past year. The most important negative predictors were two of the “general” life-style characteristics: “traditionalism”; and “self-confidence/opinion leadership”. There were no significant negative predictors of symphony attendance, but quite similar positive predictors: attitude toward attending the symphony; culture patron; “socially active”, a leisure life-style trait; interest in classical music when growing up; and symphony attendance during the past year. While these results again confirm the importance of previous attendance as a predictor of current attendance, the elimination of variables like education, income and age as significant independent variables was novel.

But have those findings been replicated? Some studies have cited important socialization effects within the family [e.g., Ganzeboom (1989), van Eijck (1997)], and others have carefully distinguished between childhood arts experiences with parents in contrast to those obtained in school [e.g., Abbé-Decarroux (1995), Morrison and West (1986)]. Furthermore, among the determinants used by Lévy-Garboua and Montmarquette (1996) were such attitudinal variables as “appreciates humanity” (which intriguingly had a negative effect on the probability and frequency of attending the theater, but a positive effect on the “satisfaction” derived from attending; Table 1, p. 36). And when one adds variables from non-regression based studies, the variety of such factors expands further. A mere sampling would include: the ticket purchasing habits of friends [Bamosy and Semenik (1981), Kolb (1997)]; years spent residing in the geographical area being studied [Ryans and Weinberg (1978)]; divorced versus widowed status in addition to the more standard single versus married designations, as well as who within the family makes the decision to attend various types of entertainment events [Kaali-Nagy and Garrison (1972), and Upright (2004)]; and networking among women [Kane (2004)].

However, there is no real evidence that the Andreasen and Belk (1980) conclusion regarding the dominance of the socialization “error-term” variables over the other standard demand variables has been replicated. There are three reasons. First, even Andreasen and Belk (1980) found that of their daunting list of non-traditional variables, only a very few survived the step-wise regression pruning process (as described above). Second, other studies of “socialization”-type variables have found that income,

<sup>63</sup> And more; see Seaman (2005, p. 135).

education and age are not eliminated from those equations and often perform quite well [DiMaggio and Ostrower (1990); Lewis and Seaman (2004)]. Finally, from the purely limited perspective of explaining the variance in the dependent variable, extremely parsimonious time-series or pooled studies sometimes do quite well without adding such so-called taste-adjusting variables.

### 10.2. Racial differences

While race has been a surveyed characteristic of the SPPA since 1982, race and ethnicity have been nearly absent from econometric arts demand studies, with only Dobson and West (1989), Gray (2003), and Lewis and Seaman (2004) as exceptions. It is also difficult to find examples using non-US data, with Trienekens (2002) being a rare exception (i.e. the Netherlands).

Dobson and West (1989) found “ethnic background” to have a modestly negative effect on Atlanta theater attendance; Lewis and Seaman (2004) found mixed results, with “Black” being a negative and statistically significant determinant of classical music attendance, but with competing and not statistically significant effects on arts museum (negative) and dance (positive) attendance. Gray’s (2003) logistic regression results based on the 1997 SPPA are of interest inasmuch as, after adjusting for age, income, education, gender, work hours, and music and art lessons, the “Black” variable coefficient was statistically significant and negative only for classical music, opera, and ballet, while being positive for jazz, musical theater, non-musical theater, dance, and museum. Also, he reported *ceteris paribus* positive and statistically significant coefficients for “Hispanic” across all categories, negative “Asian” coefficients for all arts categories except dance and museum, and negative “Indian” coefficients for all arts categories except opera and musical theater. While not all of those coefficients were economically significant (e.g., six coefficients were below 0.10 in absolute value), no other study incorporated that degree of ethnic variety.

The surprisingly weak and mixed performance of racial/ethnic variables in these few studies is noteworthy in light of DiMaggio and Ostrower’s (1990) conclusion that “given the degree of racial oppression and exclusion to which black Americans have been subjected, they participate in the arts at rates and in ways remarkably similar to those of white Americans”, a pattern they call “*differentiation without segmentation*” (p. 772). Utilizing the 1982 SPPA as the data source, DiMaggio and Ostrower posed the key question: since whites are more likely than blacks to exhibit key characteristics linked to demand for the performing arts (higher levels of education, income and prestigious occupations), is there really an independent role for race in explaining the lower arts participation rates of blacks that are revealed by survey data? The four major results of their empirical analysis were:<sup>64</sup>

- the unique negative effect of race on Euro-American high culture arts participation was modest, but statistically significant [roughly consistent with Gray (2003)];

<sup>64</sup> The unique methodological features of DiMaggio and Ostrower (1990) are discussed in Seaman (2005).

- race effects were stronger for arts consumption than for arts production behavior, and stronger for public arts consumption than for private arts consumption via television watching, where in fact the racial effect was nearly absent – a fascinating result consistent with their view that racial discrimination may adversely affect public but not private participation in the arts and that arts consumption but not production is affected by “status competition”;
- being black had strong positive effects on both attendance and enjoyment measures for the non-European-based artforms of jazz, soul, blues and R&B, confirming the obvious point that viewing black arts participation rates as relatively low depends in large part on one’s definition of the arts; and
- the behavior of interaction terms with race and the other control variables was complex and highly variable.

Finally, DiMaggio and Ostrower conducted a detailed analysis of two hypotheses that might explain the remaining racial differences in arts participation. These were a “cultural convergence” model by which any such differences would be expected to diminish with increased interracial peer contact, and a “cultural resistance” model by which increased black/white economic competition would create opportunities for younger, well-educated blacks to embrace minority cultural norms [e.g., (1990, p. 773)]. However, despite their best efforts, they eventually found little systematic evidence to support either of these perspectives.

### 10.3. *Sexual orientation*

The Lewis and Seaman (2004) study of the role of sexual orientation in affecting arts demand relied upon the 1993 and 1998 US General Social Survey (GSS) for data. They confronted the challenging problem of defining sexual orientation by using the self-reported number of male and female sex partners since age 18, and whether one’s recent sex partners have been male, female or both. While they experimented with a variety of definitions (all yielding similar results), they chose the one yielding the largest sample size (5 percent, or 180 of 2188 respondents) in order to reduce standard errors. They coded the LGB (lesbian, gay and bisexual) variable as 1 for those who reported at least one same-sex partner since their 18th birthday, and 0 for everyone else.

Just as a large part of racial arts consumption differences may actually reflect educational, occupational and income disparities, similar control variable problems (along with urban location factors and differential family obligations) complicate the effort to isolate a unique role for sexual orientation.<sup>65</sup> The descriptive data used by Lewis

<sup>65</sup> While there is evidence that LGB’s are more educated, urbanized, and more likely to be childless than heterosexuals, the common notion that their average incomes are also higher is due largely to non-representative samples of wealthy gay men and lesbians. In fact, controlling for education, gay men earn 15 to 30 percent less than straight men of the same age, and the evidence on lesbian versus heterosexual women is mixed. Yet, there is indeed evidence that gay male couples have higher income (especially disposable income) than married straight couples, with lesbian couple earnings the lowest of the three groups; see Lewis and Seaman (2004, p. 525 and related citations).

and Seaman yielded powerfully suggestive results. With no demographic or other controls, substantially higher percentages of LGBs compared to straight respondents had visited or attended an art museum/gallery, or ballet, dance, classical music or opera performance in the prior year, yielding attendance differentials of between 16 and 19 percentage points, with LGBs being about twice as likely to have attended a classical music or dance performance and almost three times as likely to have attended a museum, musical and dance performance, i.e. 17 percent compared to 6 percent [Lewis and Seaman (2004, p. 529)]. Even after controlling for demographic and other variables, the percentage differences between LGB and heterosexual attendance patterns dropped only to 12 (museum), 10 (dance) and 14 percent (music) from the unadjusted respective differences of 17, 16 and 19 percent, respectively (p. 531). The logistic consumption regression equations<sup>66</sup> estimated by Lewis and Seaman revealed strong and statistically significant positive effects on attendance due to being LGB, higher education, higher parents' education, higher income, and living in a city over 50,000 population, with a moderately positive effect due to being Jewish (but not statistically significant in the classical music equation). Being a fundamentalist Protestant had a modestly negative and significant effect for dance performances (and negative but not significant for museums, and almost dropping out of the classical music equation entirely).

As with DiMaggio and Ostrower (1990), after establishing the unique role of sexual orientation, Lewis and Seaman (2004) confronted a similarly frustrating problem in explaining why it exists. Little compelling evidence was found from supplemental tests for any of four explanations: pure demographics; an innate "gay affinity for the arts", tested by also examining arts production behavior such as "make art, play music, perform live or identity as a professional artist"; a reaction to the historical repression of homosexuality; and an ongoing more welcoming environment for LGBs in arts venues than in other public entertainment environments – an explanation that was at least weakly supported.

Summarizing the various studies discussed above, we can conclude that the Andersen and Belk (1980) hypothesis that "life-style" and socialization-type variables eliminate from significance the standard socioeconomic variables of education, income, age and occupation (not to mention own- and cross-price effects) has found little support from subsequent studies. However, any full understanding of the demand for the performing arts clearly cannot ignore this larger variety of complex determinants.

## 11. Data problems

One of the most common laments of researchers in the economics of art and culture deals with the inadequacies of data.<sup>67</sup> Historically, cultural economists may have had

<sup>66</sup> Their dependent variable = 1 for "attended" and 0 for "did not attend" in each of three equations for art museum, dance performance, and classical music. Results did not change using ordered logit when the three dummy variables were summed to get a proxy for "intensity of arts attendance".

<sup>67</sup> Luksetich and Lange (1995) observed that in all of their earlier work on symphony orchestras they had been severely constrained by data limitations, including an absence of usable data for more than one year.

a strong case that their job was made especially challenging by the traditional lack of business savvy among artists and arts organizations that hindered coherent data collection and reporting, together with the tedious but perennial question “what is art?”. Yet without doubt, the seminal impact of Baumol and Bown (1966) was in large part the result of their uniquely rich database in addition to the provocative quality of their analysis. Even then, empirical work in the performing arts in the US was nearly impossible prior to the Ford Foundation’s extensive survey (1974),<sup>68</sup> followed by another by the National Research Center of the Arts, Inc. (1976); their surveys stimulated efforts in other countries to further improve the quality of their own data. It is therefore not surprising that a characteristic feature of many topics in the arts economics literature has been the degree to which basic data gathering and attempts to develop consistent standards of measurement have competed for attention with modeling and analysis.

Conditions have certainly improved in terms of government-financed studies such as those done by the venerable Arts Council of Great Britain but also extending to other countries. Even in the United States the NEA Research Division, despite desperate under-funding, has frequently generated data that have become international benchmarks, as with the *Surveys of Public Participation in the Arts*. These government efforts have been supplemented by an increasingly rich array of private non-profit and university centers devoted to arts research.<sup>69</sup> Furthermore, despite the frustrations of obtaining reliable data from arts organizations, it is also common for authors of arts demand studies to cite the unusual degree of cooperation (sometimes after failed efforts) given to them by individual or groups of arts organizations. Examples include Felton (1989) paying homage to Opera America for rescuing her after receiving assistance from only five of 20 personally contacted opera companies; Schimmelpfennig (1997) getting unusual cooperation from the Royal Opera House Covent Garden; and Abbé-Decarroux and Grin (1992) working closely with three major cultural organizations in Geneva.

One dilemma that is not unique to demand studies in the arts is that a particular data set or research agenda that may overcome one type of missing information problem, or that may address one deficiency in previous research, may be incapable of incorporating other critical demand-determining variables whose exclusion is undesirable in a fully specified model. For example, Globerman and Book (1977) used audience survey data and an explicit household production model to try to improve the estimate of the income elasticity of demand by directly incorporating the role of education in increasing productivity in the consumption of arts activities. However, they lacked ticket price data and “borrowed” long-run price elasticity results from Houthakker and Taylor (1970) to draw certain inferences about the relative productive effect of education on the arts

However, owing to the generosity of the American Symphony Orchestra League in providing them with truly extensive data on a proprietary basis, they were now able to seriously address those limitations (p. 51).

<sup>68</sup> In addition to the descriptive data published by Ford Foundation (1974), more extensive Ford data were also critical for some econometric demand analysis [e.g., Touchstone (1980), Gapinski (1981)].

<sup>69</sup> This phenomenon is especially notable in the United States, where the more modest governmental role in arts financing and policy-making has created a void to be filled by such organizations.

compared to other activities in the aggregate. Lange and Luksetich (1984) obtained data that allowed them to derive price elasticities that varied across three different types of orchestras, but the lack of consumer income data in their regressions raised questions as to the reliability of those results.<sup>70</sup>

Other examples of studies affected by data limitations include:

- Throsby (1990), who addressed the absence of systematic quality variables in previous arts demand studies, but was missing income as well as education data in his analysis;
- Forrest, Grimes and Woods (2000), who effectively incorporated distance traveled into their theater demand analysis but were able to use only education and age as control variables in their equations;
- Schimmelpfennig (1997), who confronted the issue of price elasticity variations as a function of differing seating sections in a ballet theater, but had no other control variables and was forced to use a quite restrictive assumption about product homogeneity across two different ballets;<sup>71</sup>
- Lévy-Garboua and Montmarquette (1996), who provided an unusually rich analytical framework to assess “learning-by-consuming”, supplemented by a database with 58 independent variables, that did not allow the direct measurement of either consumer income or arts admission prices; and
- Lewis and Seaman (2004), who were able to use unique data from the US General Social Survey to address the previously ignored topic of sexual orientation (and religious affiliation) in arts demand controlling for many other demand determining variables, but could not incorporate any arts pricing or quality variables given that particular data source.

Thus, despite the notable improvements in data availability and quality, a weakness of empirical performing arts demand studies has been the difficulty of any one study having adequate measures of all of the critical determining variables.

## 12. Conclusions

Several reasonably clear conclusions can be drawn from the research reviewed in this chapter, including the following:

<sup>70</sup> For example, see Green, Hassan and Johnson (1992) on the bias created by omitting income in demand function estimation.

<sup>71</sup> The Royal Ballet Summer Season that was examined consisted of 16 performances (nine of which included in the estimations) of two full-length works (for 1995, Giselle and Sleeping Beauty). Schimmelpfennig used the highest prices for (eventually) three seating categories. Such prices were the same for each performance of any one ballet, but that price schedule was higher for Sleeping Beauty than for Giselle. Therefore, he was forced to assume that both ballets are homogeneous in order to get the necessary price variation across his observations, an assumption that he recognized (p. 121) was contradicted by the very existence of two different price schedules, but that he viewed as acceptable for his purposes of examining the relationship between actual prices and revenue-maximizing prices.

- Income elasticities of demand for the arts cannot be adequately estimated without separating the real income effect from the opportunity cost of leisure pure substitution effect;
- Quality matters, although the mixed results from various objective and subjective measures suggest that we are not yet sure how best to capture this important determinant of variations in arts attendance and participation;
- Some version of dynamics in consumption, be it passive inertia, learning-by-consuming, or the more complex rational addiction, should be incorporated to better understand arts demand, especially because these distinct notions have quite different implications for the optimal marketing strategies of arts managers;
- The survey study evidence favoring formal education as the most powerful determinant of variations in arts attendance has not been reliably strengthened by regression analysis.

Nevertheless is hard to dispute the [Lévy-Garboua and Montmarquette \(2003\)](#) assessment that critical issues remain unresolved in the performing arts demand literature. This is especially the case regarding the robustness and interpretation of the price inelasticity “consensus”, the limited evidence regarding substitutes and complements, and the complex relative roles of the traditional socioeconomic demand-determining variables and the vast array of specialized lifestyle and socialization factors (or non-traditional socioeconomic variables). Regarding research improvements, Lévy-Garboua’s and Montmarquette’s faith in the importance of well-defined taste cultivation models, larger databases and more sophisticated econometric modeling in improving our empirical models is understandable, but such analytical improvements to date have largely failed to generate substantial changes in the results or new insights about performing arts demand. In the case of sample sizes, for example, despite the fact that some of the studies discussed in this chapter have used very large databases,<sup>72</sup> the nature and validity of some key results in arts demand analysis do not show any systematic relationship to the sample sizes from which they were derived, *ceteris paribus*. Furthermore there is no firm evidence that more complex econometric techniques are necessary to resolve the remaining enigmas in arts demand studies especially when compared to obtaining more disaggregated data. On the other hand it is clear that applying additional theoretical structure to the derivation and interpretation of empirical results is warranted. This is especially necessary regarding the debate about the price elasticity of demand for the arts, and the choice of model specification will be particularly important in future studies exploring this issue.

More generally it can be concluded that more carefully done modeling, when combined with efforts to apply such models to less aggregated data, will doubtless be important to making further improvements in our understanding of the demand for

<sup>72</sup> For example, [Lévy-Garboua and Montmarquette \(1996\)](#) themselves used a sample of 8000 individuals; other examples include [Peterson, Hull and Kern \(2000\)](#), [Globerman and Book \(1977\)](#) and [Montgomery and Robinson \(2005\)](#) with sample sizes of 17,135; 13,750; and 8000, respectively.

the performing arts. Despite the initial suspicion that the determinants of the typical performing arts demand function are obvious, there are surprisingly few arts-demand axioms beyond

- (1) the confirmation that demand curves are negatively sloped (i.e., assuming any contrary results reflect own price being a proxy for quality),
- (2) the performing arts are normal (but not necessarily luxury) goods, and
- (3) that some positive cross-price elasticities can be identified.

As stated by *Lévy-Garboua and Montmarquette (1996, p. 26)* after noting some general limitations of past arts demand studies, “it is nevertheless known that the performing arts are not exempt from the law of demand”. Empirical performing arts demand studies remain a rich area for further sound economic analysis.

**Abstract**

The nonprofit performing arts have received substantial attention in the cultural economics literature, and represent an interesting application for many areas of economic inquiry. This chapter surveys the relevant theory and the most prominent empirical studies on performing arts nonprofits. The chapter begins with a description of the nonprofit sector – and the role of the performing arts in this sector – around the world. I then ask why performing arts nonprofits exist, taking into account the objectives of both consumers and suppliers of performing arts services. Next, I study the production and cost conditions that these firms face, paying particular attention to issues such as product quality, product cross-subsidization, and the so-called “cost disease”. The issue of revenue sources and their generation follows, with a special emphasis on earned revenues, donations, and government subsidies. This discussion includes topics such as ticket pricing strategies, fundraising innovations, and the relationship between private giving and public funding. The chapter closes with suggestions for future research on the nonprofit performing arts.

## 1. Introduction

The nonprofit sector encompasses an important portion of the world economy. In 1995, for example, it made up about 4.6 percent of the GDP of 22 industrialized and developing nations, 5 percent of total nonagricultural employment, and 10 percent of all service employment [Salamon et al. (1999)]. In the United States, the nonprofit sector had revenues in 1997 of \$665 billion, or about 6.7 percent of GDP, and represented 7.1 percent of all paid employment [Independent Sector (2001)].<sup>1</sup>

There is no uniform international legal definition of “nonprofit organization” (NPO) or “nongovernmental organization” (NGO). Organizations are subjected to different laws in different countries. In the United States, for example, there are currently 29 different types of legally-defined nonprofits in the tax code, from charities, to credit unions, to farmers’ collectives. The largest category in the tax code includes what most other countries also define as nonprofits: organizations that exist for charitable, religious, or educational purposes. The American tax code opaquely defines these organizations as

Corporations, and any community chest, fund, or foundation, organized and operated exclusively for religious, charitable, scientific, testing for public safety, literary, or educational purposes, or to foster national or international amateur sports competition (but only if no part of its activities involve the provision of athletic facilities or equipment), or for the prevention of cruelty to children or animals, no part of the net earnings of which inures to the benefit of any private shareholder or individual, no substantial part of the activities of which is carrying on propaganda, or otherwise attempting, to influence legislation . . . and which does not participate in, or intervene in (including the publishing or distributing of statements), any political campaign on behalf of (or in opposition to) any candidate for public office.<sup>2</sup>

Most nonprofit activity is dedicated to areas in which we typically find goods and services with public-goods characteristics: religion, education, health, social services, international development, the environment, and arts and culture. Nonprofit designation generally entitles organizations to public or private donations. In many countries, the revenues raised by these organizations are free from corporate taxation; in some countries, private donations are tax-deductible for the donors as well.

Functional definitions of nonprofits are more illuminating than legal definitions. Hall (1987) defines a nonprofit organization as a private group that associates in order to

- (i) undertake public tasks on behalf of the government,
- (ii) provide public goods and services for which there is a demand but no supply from either the public or for-profit sectors, or
- (iii) influence public policy.

<sup>1</sup> Arguably, these figures overestimate the true “contribution” of nonprofits to the economy, because they don’t measure the value added of these firms to GDP.

<sup>2</sup> Source: US Internal Revenue Code Title 26, Subtitle A, Chapter 1, Subchapter F, Part I, Section 501 (c) 3.

Arguably less descriptive, but more precise, is the functional definition of the nonprofit firm usually used by economists: A firm  $i$  may be defined as a nonprofit if, as an organization, it seeks to maximize some utility  $u_i(\cdot)$ , subject to the “nondistribution constraint”  $ER_i + UR_i - TC_i = 0$ , where  $ER_i$  = earned revenues,  $UR_i$  = “unearned revenues”, i.e. those donated by government and the private sector, and  $TC_i$  = the organization’s total costs. The nondistribution constraint can also be modified to the weaker assumption that economic profits sum to zero over a multi-period time horizon, to allow for such phenomena as borrowing and endowments.

The nonprofit sector in almost every country, however defined, contains firms dedicated to the arts in general, and the performing arts in particular. In the US, the National Center for Charitable Statistics (NCCS) at the Urban Institute defines 64 different categories of nonprofit arts activity, 10 of which are undertaken by performing arts organizations.<sup>3</sup> These include performing arts centers, dance ensembles, ballet ensembles, theater companies, music organizations, symphony orchestras, opera companies, choruses, and other music groups.<sup>4</sup>

Although a multi-billion dollar industry, the nonprofit performing arts still comprise only a small part of the nonprofit economy. Figure 1 illustrates this for the United States, showing that the arts and culture are about 2 percent of all nonprofit activity, and the performing arts are about a quarter of that amount. Further breakdown shows that most nonprofit performing arts activity involves performance promotion and facilities (33 percent), theater companies (24 percent), and classical music organizations (21 percent), followed by opera and dance companies (12 and 7 percent, respectively).<sup>5</sup>

The arts are a larger portion of the nonprofit sector in other parts of the world than they are in the US. For example, they comprise 7 percent of the sector in Germany, 9 percent in Italy, 21 percent in the United Kingdom, and 57 percent in Hungary [Rose-Ackerman (1996)]. In general, the arts are especially heavily represented in the nonprofit sectors of Eastern Europe: on average, 35 percent [Salamon et al. (1999)]. Part of the difference between the United States and much of the rest of the world has to do with the fact that many of the health, education, and social services that make up the largest component of the American nonprofit sector reside in the public sector in many social democracies and transition economies.

Whether a small or large part of a country’s nonprofit sector, the performing arts have played an interesting role in the development of the literature on nonprofit economics.

<sup>3</sup> See [www.urban.org](http://www.urban.org), for details on the National Taxonomy of Exempt Entities (NTEE) classification system.

<sup>4</sup> The forms of nonprofit performing arts firms are highly variegated. As DiMaggio (1987) suggests, their common legal status indicates homogeneity that does not exist. Jeffri (1980, pp. 48–49) makes this point in surveying the landscape of “dance companies”, which can range from single performers to large nonprofits managed by for-profit companies.

<sup>5</sup> The categories in Figure 1 do not correspond precisely with the NCCS taxonomy because these data were derived from the *US Census of Service Industries* (USCSI) [US Department of Commerce, Bureau of the Census (1997)], which categorizes nonprofits slightly differently.

Figure 1. The American nonprofit sector. Source: Independent Sector (2001), US Department of Commerce, Bureau of the Census (1997).

In this chapter, I follow the development of nonprofit economic theory over the past 35 years, discussing some of the most salient findings and relating them to the literature on the economics of nonprofit performing arts organizations. In so doing, I aim both to show how research on the performing arts has enriched the nonprofit field in general, and also to expose the areas of work on the performing arts that are relatively underdeveloped.

The rest of this chapter is organized in six parts. I begin with a brief survey of the facts surrounding the nonprofit performing arts sector, and then move on to ask why nonprofit performing arts firms exist (both from the perspective of consumers as well as the firms themselves). Following this, I look at production and cost, and then focus on a topic of particular interest in the performing arts, the so-called “cost disease”. I then look at the financing of performing arts nonprofits at the earned, government, and philanthropic levels. Finally, I discuss the trends and neglected areas in this literature, and suggest future work.

## 2. Nonprofit performing arts firms: Basic facts

The best data available suggest that the nonprofit arts represent about one-half of one percent of the workforces in most countries [Salamon et al. (1999)]. Figure 2 summarizes these percentages in 22 countries around the world. It is reasonable to assume that not more than half of this amount is dedicated to the performing arts. To attain much higher detail about the dimensions of the nonprofit performing arts requires looking more closely at a specific country. The United States is particularly convenient in this regard because statistics on the sector are relatively abundant.

We start by asking how many performing arts firms there are, their average size, how they break down across discipline, and whether they are organized for-profit or nonprofit. Table 1 shows that in 1997, there were more than 8000 organizations dedicated to the performance of theater, opera, dance, and music in the US. This does not include

Figure 2. Proportion of employment in the nonprofit arts, 22 countries. Source: Salamon et al. (1999).

performing arts agents, promoters, or facilities; it also excludes many companies such as circuses that are commonly listed alongside the performing arts in the *US Census of Service Industries (USCSI)*.

Theater in America is fairly evenly split between the commercial and nonprofit sectors, while opera, symphony orchestras, and chamber music are dominated by nonprofits. The average annual revenues of nonprofit opera companies are much larger than the other disciplines, at over \$4 million. The average nonprofit theater company, on the other hand, had annual revenues under \$800,000. Note that these figures almost certainly understate the number of organizations and overstate the average size, because US Census data only consider nonprofits over \$25,000 (which are required to file tax forms with the US Internal Revenue Service). Smith (1997) estimates that small, non-filing organizations outnumber filers by as many as eight to one.

The average revenues of American performing arts have been falling. The USCSI indicates, for example, that the average nonprofit performing arts firm had seven percent lower revenues (in real terms) in 1997 than in 1982. Rather than indicating a moribund performing arts market, however, this is a result of the explosion in the number of these firms, which increased 81 percent over the same period, an average annual growth rate of about 4 percent. In general, earned revenues make up the largest portion of total

Table 1  
Dimensions of the performing arts in the United States

	Number of organizations	Percentage nonprofit	Average annual revenues per nonprofit firm
Theater	3077	49%	\$788,237
Opera	170	86%	\$4,038,150
Dance	530	70%	\$871,445
Classical music	805	87%	\$1,487,401
Other music	3775	14%	\$225,743

Figure 3. Funding sources to US nonprofit performing arts firms, 1982–1997. Source: US Department of Commerce, Bureau of the Census (1997).

revenues for performing arts firms in the US, followed by donations, and then government contributions. In 1997, 59 percent of the sector’s income was earned, 29 percent was donated, 5 percent came from government, and 7 percent came from other sources [US Department of Commerce, Bureau of the Census (1997)]. We might suppose that the US is anomalous in this regard internationally, assuming that private giving and market activity are disproportionately high in cultural affairs, relative to government support. I will turn to this subject in greater detail later in this chapter.

Figure 3 illustrates that the proportions of funding changed in the US over the 15-year period ending in 1997. For firms in theater and music, earned revenues fell as

a percentage of the total, while contributions rose to fill the gap. Dance is somewhat different, in that the increase in the budget of dance companies from 1982 to 1997 came disproportionately in the form of earned revenues.

In most industries, high fixed costs lead to high firm concentration; the performing arts are no exception. In the disciplines in [Table 1](#), the firms with the highest fixed costs tend to be opera and classical music (mainly symphony orchestras), which require facilities for hundreds of employees and thousands of audience members. Measuring size in terms of revenues, the largest 20 nonprofit firms in each of these disciplines control 80 and 50 percent of their industries, respectively. Theater and dance companies, on the other hand, have more structural flexibility regarding the scale of operations, meaning that fixed costs are not necessarily so high. The market shares controlled by the top 20 nonprofit firms in these disciplines are respectively 25 and 20 percent [[McCarthy et al. \(2001\)](#)].

### 3. Why are there performing arts nonprofits?

A discussion of the economics of the nonprofit performing arts does well to include the most basic question: Why do these firms exist? This question really has two sides to it. First, we would like to know why these firms have a place in free market economies – what is the source of demand for a specifically *nonprofit* performing arts product? Second, what is the motivation of performing arts firms that are organized not-for-profit – does the nonprofit form facilitate attainment of these firms’ objectives? The literature on the theory of the nonprofit firm provides guidance on these issues, and authors on the nonprofit performing arts have enriched the discussion.

#### 3.1. The demand for nonprofit activity

The most frequent explanation for the demand for nonprofit provision of goods and services comes from the “public goods model”, developed by [Weisbrod \(1978\)](#), [Warr \(1982\)](#), [Bergstrom, Blume and Varian \(1986\)](#), [Andreoni \(1988\)](#), and others.<sup>6</sup> This model starts with the assumption that an agent  $i$  exhausts his budget  $m_i$  between purchases of a private good  $x_i$  and gifts to a public good  $d_i$ . Setting the price of a unit of each to unity,

$$x_i + d_i = m_i. \tag{1}$$

Assuming that the public good is truly nonrivalrous and nonexcludable in consumption, the total amount of resources to the good donated across the population,  $\sum_i d_i = D$ , can be enjoyed by each member of the population. Hence, the agent’s utility can be

<sup>6</sup> The particular treatment here loosely follows [Andreoni \(1998\)](#).

represented by the equation

$$u_i = u_i(x_i, D). \quad (2)$$

We assume that  $u_i$  has the standard properties. Notice that  $D$  can be redefined as  $d_i + D_{-i}$ , where  $D_{-i}$  is the contribution of the rest of the population. At the Nash equilibrium, this contribution is assumed constant by each agent, and thus can be added to each side of the budget constraint. We define the agent's problem as  $\max_{x_i, D} \{u_i(x_i, D)\}$ , subject to  $x_i + D = m_i + D_{-i}$ ,  $D \geq D_{-i}$ .

The first-order conditions for this problem will produce a private demand function for  $D$ , which can be written as<sup>7</sup>

$$D = f_i(m_i + D_{-i}). \quad (3)$$

Assuming that  $f_i(0) = 0$  and that both  $x$  and  $d$  are normal goods, we know that  $f'_i \in (0, 1)$ , and thus that if at least one agent  $i$  has  $m_i > 0$ ,  $D$  must be positive. This establishes the possible existence of private donations for a public good.<sup>8</sup> This demand can manifest itself in private donations or public subsidies for the public good.<sup>9</sup>

The nonprofit organizational form equips a firm to garner donated funds. This is often called the “subsidy theory” of why nonprofits exist [Hansmann (1987)]. West (1987, p. 39) summarizes this theory when he says that “a policy of aiding the nonprofit [performing arts] organizations . . . can easily be predicted to encourage their growth”. Nonprofits are positioned to collect donated funds for legal reasons, as well as because nonprofit status assuages fears that donated funds will simply be converted into profits [Bilodeau and Slivinski (1998)]. This constitutes the (complementary) “contract failure” explanation for nonprofits [Hansmann (1980)]: Donors cannot observe how funds are used, and insist on an institutional arrangement that prohibits the distribution of revenues for activities not involving operations. Relatively few studies on the nonprofit performing arts employ these explanations. One exception is O’Hagan and Purdy (1993), who implicitly use both subsidy theory and contract failure in study of the history and management strategies of an Irish opera festival.

Another explanation for the nonprofit form is that of “club goods” [Cornes and Sandler (1984)]. Club goods are generally exclusionary goods and services from which people derive mutual benefits from shared characteristics, or the actual exclusion of nonmembers. Nonprofit status allows member control over these types of organizations. The club goods model has received some application in the performing arts literature.

<sup>7</sup> Authors [e.g., Bergstrom, Blume and Varian (1986)] have shown that a unique Nash equilibrium of donations exists in the vector  $d = (d_1^*, \dots, d_n^*)$ .

<sup>8</sup> This model assumes that agents recognize the public value they are paying for; a common argument regarding the public good in the arts is that ordinary citizens don't understand this value and hence the choice to fund it, privately or publicly, must come from those who are better-informed. These are so-called “merit goods” [Musgrave (1959)].

<sup>9</sup> In the latter case, we would predict that public support would occur if those with above-average demand for the public good have the political influence necessary to generate the subsidy.

DiMaggio (1982) uses the basic concept to explain how performing arts organizations in the United States were protected by social elites from the aesthetic contamination of commercial markets. Kuan (2001) treats the subject theoretically, creating a model of the performing arts world in which people are either intensive or casual in their consumption, and then shows straightforwardly that the former group has an incentive to “produce” the performing arts service itself (that is, set up production as a mutually-beneficial club), as opposed to purchasing it from a for-profit. Kushner and King (1994) empirically confirm the proposition that an American choral society possesses club good characteristics by looking at the proportion of admission tickets preferentially purchased by society “members”.

Models that begin by assuming the performing arts are pure public goods may be problematic, in that the assumption of complete nonexcludability is unrealistic with respect to the private benefit that audience members derive from performing arts events. However, some authors have argued that  $D$  in Equation (2) contains a number of nonexcludable, nonuse public arts benefits as well, although very few writers have tested empirically for the existence of such benefits. For example, Frey (1997) lists the following nonuse, public values from the arts in general, which could also be argued to exist for the performing arts in particular.

- *Existence value.* Even if they don’t directly consume a particular cultural good, some people appreciate its existence.
- *Option value.* Nonusers may place a positive value on the option to become users of it in the future, and hence favor its preservation.
- *Education value.* Cultural goods might create intellectual and cultural spillovers among users and nonusers.
- *Prestige value.* Cultural goods might produce prestige for their region of origin.
- *Bequest value.* Users and nonusers may derive utility from the expected enjoyment of a cultural good by future generations.

Some authors would add the economic impact of performing arts activities to this list [Brooks and Kushner (2001)]. Others, particularly those that look at the performing arts among indigenous peoples, might add *cultural value* to this list, where “cultural” has an anthropological connotation.<sup>10</sup> For example, Mackerras (1999) studies how practice of the Tibetan performing arts helps to maintain the integrity of traditional Tibetan culture in the face of modernization.

### 3.2. *The objectives of nonprofit firms*

Given a demand for nonprofit performing arts services, what do we know about the objectives of the firms themselves? In other words, what do we know about the nature

<sup>10</sup> This anthropological sense of “culture” is in general contrast to the way the term is almost always used in the field of cultural economics. Cultural economics usually employs Matthew Arnold’s (1869, p. viii) definition: “a pursuit of our total perfection by means of getting to know, on all the matters which most concern us, the best which has been thought and said in the world”.

of  $u_i(\cdot)$  for a firm  $i$ ? The nonprofit literature has produced a limited set of theories on the topic.<sup>11</sup>

One of the most influential works on the economic objective of nonprofit firms in general came from Steinberg (1986), who suggested that, given zero economic profits, nonprofit “utility” would tend to fall along some continuum between spending on core operations and budget size. The key in his formulation was fundraising expenditures; as such, he called organizations that maximized revenues to be spent on operations (net of fundraising expenditures) *service maximizers*, while those that ignored them *budget maximizers*. Utility was defined as a linear combination of these two possibilities; that is, for an organization  $i$ ,

$$u_i = \alpha S_i + (1 - \alpha)[ER_i + D(F_i)],$$

subject to  $ER_i + D(F_i) - S_i - F_i = 0,$  (4)

where  $0 \leq \alpha \leq 1$ ,  $S_i$  = service, or expenditures on core operations;  $ER_i$  = earned revenues;  $F_i$  = fundraising expenditures; and  $D(F_i)$  = the donations that come from fundraising. Clearly, if  $\alpha = 0$ , a firm is a budget maximizer; if  $\alpha = 1$ , it is a service maximizer; if  $0 < \alpha < 1$ , the objective is mixed. We assume that  $D' \geq 0$ ,  $D'' < 0$ , and  $0 \leq F \leq ER + D$ .

Solving the firm’s problem, we see that when  $\partial u_i / \partial F_i = 0$ ,  $\partial D_i / \partial F_i = \alpha$ . That is, the value of  $\alpha$  is equivalent to the marginal impact of fundraising on donations (in the language of nonprofit managers, the “fundraising yield”). Obviously, the value of  $\alpha$  is an empirical question. Steinberg found that health nonprofits tended to be budget maximizers, while those in social welfare, education, and (most notably) the arts were service maximizers.

In the case of the performing arts, budget is easy to understand, while service is less obvious: As noted by Throsby (1994) and others, it could refer to the quantity of service, quality, or both. Hansmann (1981) distinguishes these as different maximands in his treatment of performing arts firms. He assumes that performing arts firms maximize utility with respect to audience size, quality, or budget. He then contrasts socially-optimal firm behavior (in which consumer surplus is maximized) with that predicted for audience maximizers, quality maximizers, and budget maximizers. He shows that if the firm is an audience maximizer, quality will tend to be suboptimally low; if the firm is a quality maximizer, quality will generally be suboptimally high relative to audience size. If the firm is a budget maximizer, the social optimum may be obtained, but only by coincidence.

In one empirical paper designed specifically to test Hansmann’s model, Luksetich and Lange (1995) study the objectives of American orchestras of different sizes in the 1970s

<sup>11</sup> Some sociologists have challenged the notion underlying the literature on performing arts objective functions; namely, that objectives are stationary and well-defined. DiMaggio (1987) points out that the concept of pursuing a focused strategy may be unrealistic for many arts firms. In addition, strategies may change according to the firm’s external circumstances [Salem (1984)]. Objectives may even change incoherently due to contradictory directives from funders [DiMaggio (1984)].

and 80s. They find that in general, large orchestras (in terms of budget) are primarily quality maximizers and secondarily budget maximizers. In contrast, medium-sized and small orchestras tend to be audience maximizers. Several other empirical papers, while not specifically designed to test models such as Hansmann's or Steinberg's, nevertheless provide evidence that nonprofit performing arts firms behave in one or more of the ways these models predict. In his analysis of England's Royal Shakespeare Company, for example, [Gapinski \(1985\)](#) begins with the question of whether performing arts nonprofits optimize with respect to anything at all. He concludes that theater firms do indeed optimize, maximizing output subject to the nondistribution constraint. This is consistent with Steinberg's service maximization.

Other papers have focused more specifically on quality as the maximand, generally finding that it is in decline due to adverse financial constraints faced by the organizations. For example, [Heilbrun \(2001\)](#) sees falling programmatic diversity among US opera companies as a way to lower rehearsal costs. [Throsby \(1990\)](#) finds that theater audiences in Australia don't value quality in terms of new repertoire, leading firms to sacrifice new works for higher-revenue repertoire "chestnuts". And [Peacock \(1976\)](#) finds that symphony orchestras in London have increasingly sacrificed rehearsal time for performances. While a more rigorous discussion of quality (as well as quantity) is deferred to a later section of this chapter, we might note that the literature just cited suggests a difference between the way patrons and audiences define quality, and the way *researchers* do.

#### 4. Performing arts production and cost

The foregoing discussion of performing arts nonprofits' objectives omitted the answers to several important questions: What are the inputs to production of the performing arts? How are they most appropriately defined and measured? How are they combined to produce the service? How do nonprofits compare (and compete) with each other and with for-profit performing arts organizations?

##### 4.1. *Inputs to production*

Most treatments of nonprofit production inputs focus on labor, because this is the area in which most authors feel that nonprofits differ most dramatically from the for-profit and public sectors. Specifically, just as the organizations themselves face a multidimensional utility function, so do nonprofit workers, who presumably value an organization's mission – something they believe in. The result might be the presence of volunteer labor in the sector, or persistently sub-market wages [[Handy and Katz \(1998\)](#)]. Indeed, volunteers make up between 25–40 percent of the nonprofit labor forces in the US, Western Europe, Latin America, and Central Europe [[Salamon et al. \(1999\)](#)]. And nonprofit employees in the US are paid 35–40 percent lower wages than their professional equivalents in the for-profit sector [[Weisbrod \(1983\)](#)];

Frank (1996)]. Note that volunteers are disproportionately highly represented in the arts: While arts firms are only 2 percent of the US third sector, they use 5.2 percent of American volunteers [Independent Sector (2001)].

Relative to nonprofit labor, the subjects of capital, land, and entrepreneurship have received little treatment in the nonprofit economic literature. Authors have noted that the exemption of nonprofits from corporate taxation in most countries makes the use of plant, equipment, and land relatively cheaper, which should encourage higher utilization than in the for-profit world [Brown and Slivinski (2002)], but research has not gone past this observation. The only rigorous work on nonprofit entrepreneurship is Bilodeau and Slivinski (1998), which models the decision of how and why someone would set up a nonprofit firm. They show circumstances under which an entrepreneur voluntarily adopts a budget constraint in order to collect the private gifts on offer in the public-goods model introduced earlier.

In the performing arts economics literature, no specific treatments of capital or entrepreneurship have appeared, to my knowledge. In contrast, quite a bit has been written about labor, which receives several chapters in this volume as well as a discussion later in the present chapter under the heading of the “cost disease”. Suffice it to say at this point that labor conditions for firms have been found to vary significantly from country to country in the performing arts. Specifically, it seems that rising labor cost problems plague American firms more than others. Schwarz (1992) finds that among orchestras, labor costs rose and fell in Canada more than in the US, following the financial circumstances of the firms. Rubinstein, Baumol and Baumol (1992) finds that labor costs were astronomical in the US compared to the former Soviet Union (60 percent versus 20 percent of total performing arts production costs). Benhamou (2000) finds substantial growth in performing arts employment in France and Great Britain in the 1980s.

#### 4.2. Production functions

In combining resources, there is no especially intuitive reason to believe that a nonprofit performing arts production function would vary dramatically from some traditional form in production theory. So we might begin with

$$Q = f(L, Z), \tag{5}$$

where  $L$  = labor and  $Z$  is a vector of capital, land, and entrepreneurship. We assume that  $f$  is defined only over nonnegative input values, and is a regular, strictly quasi-concave function. Without a statement of the firm’s problem, Equation (5) makes no assumptions about any organizational objective.

Equation (5) raises several questions. First of all, what exactly is  $Q$ ? A number of authors have defined it in different ways; Throsby and Withers (1979, pp. 11–12) summarize the definitions nicely along four dimensions over a given time period:

- number of works produced by a firm;
- number of performances;

- number of potential performance attendees (generally, the number of seats in a performance venue); or
- number of actual attendees.

The first two measures can give ideas of economies of scale and scope – whether, say, a theater company should perform more works less frequently, or rather have longer runs of fewer works. The third and fourth measures distinguish between quantity supplied and quantity demanded, and hence allow study of disequilibrium prices and policies.

However defined, Equation (5) will probably have to be refined to reflect the multiple output definitions. However, this still leaves out the important issue of *quality*, which enters into practically every management discussion of the performing arts. Shanahan (1978, p. 13) points out the importance of quality when he states what is probably obvious: “To properly study the markets for artistic goods, it is necessary to deal with the aesthetic nature of art”. Abbé-Decarroux (1994) underscores the importance of quality by noting that demand for the performing arts is affected by quality expectations; as such, it functions much like risk in the consumption decision.

Throsby (1990) takes on the measurement of quality, adopting (as was the case with quantity) a multidimensional approach. His taxonomy breaks performing arts quality into three parts:

- source material characteristics (such as the quality of a script or score);
- technical factors (such as performance execution); and
- benefits to audiences, society and to the art form itself.

This approach allows research to put a finer point on empirical estimations of, for example, Hansmann’s (1981) treatment of quality presented earlier.<sup>12</sup>

Given these considerations, we might redefine Equation (5) as

$$Q = f(L, m, v, Z), \quad (6)$$

where  $Q$  = performance attendees,  $m$  = the number of performances, and  $v$  = quality.

Given these inputs, modeling production is not simplified by assuming the nondistribution constraint; it is potentially complicated by the fact that nondistribution, as well as multidimensional firm objectives, may lead to output incentives that are not compatible with traditional firm theory. In other words, nonprofit firms may operate in “un-economic” regions of production. The performing arts pose the further complication that they are characterized by inputs that diverge wildly in their importance to production. For example, while some orchestras can operate at least in the short run without formal administrators, none can without musicians.

One way to examine these characteristics is by employing the transcendental production function [Halter, Carter and Hocking (1957)]. Suppose we have a performing arts firm with two inputs; for example, imagine a theater company  $i$  at time  $t$  that employs actors  $L_{it}$  and equipment  $K_{it}$ . The output  $Q_{it}$  of the organization – productions,

<sup>12</sup> To date, little work on the performing arts has tried to put such a multi-dimensional approach into practice. Rather, most papers have tended to construct one proxy for quality (such as programming diversity), and then treat the issue tangentially to quantity.

or perhaps services – is characterized by the function

$$Q = \Omega e^{\gamma t} L^\alpha e^{\beta L} e^{\theta K + \delta K^2} e^\varepsilon, \quad (7)$$

where the firm and time subscripts are dropped for ease of exposition. In Equation (7),  $\Omega$  represents a composite environment parameter to capture the firm's unique exogenous circumstances, including quality;  $\gamma$  represents the effect of time (the marginal impact of time on the log of  $Q$ ) and measures technological change; the production parameters are  $\alpha$ ,  $\beta$ ,  $\theta$ , and  $\delta$ ; and  $\varepsilon$  is a random error.

Note that  $f(0, K) = 0$ , while  $f(L, 0) > 0$  (for positive values of  $L$ ), reflecting the relative importance of the inputs. The time and production parameters may be either positive or negative, reflecting the fact that nonprofit performing arts firms may have a marginal products that are decreasing, increasing, or even negative. The output elasticities of  $L$  and  $K$  also depend on the values of the production parameters. [Gapinski \(1980\)](#) uses American data on theater, opera, orchestra, and ballet companies from the 1960s and 70s to estimate these elasticities, and found all principal inputs (artists and capital) had positive elasticities less than unity; that secondary inputs (administrators) for ballet had a negative elasticity; and that the elasticity was higher for artists than for any other input. In a later paper [[Gapinski \(1984\)](#)], he uses data on English theater to estimate labor and capital output elasticities, finding similar values (including the finding that artist elasticity is twice that of capital). [Goudriaan and Pommer \(1987\)](#) perform a similar estimation (although using a simpler Cobb–Douglas production function) on 1984 data on orchestras and theater companies in the Netherlands. While measured elasticities were positive and less than unity, it is notable that in the case of theater, the elasticity of capital (0.65) exceeded that of labor (0.50).

### 4.3. Output decisions

Obviously, performing arts firms have considerable latitude in deciding what to produce and how much. Should an orchestra perform more “pops”, contemporary music, or standard repertoire? More matinees, or night concerts? Should it go on tour? Should it put on major concerts on the same nights as performances by other entertainment organizations? Understanding of nonprofit firms' output decisions – including those of performing arts firms – was greatly enhanced by [James' \(1983\)](#) influential model of nonprofit firm behavior. The model begins by describing a nonprofit firm that produces two outputs,  $Q_1$  and  $Q_2$ . The firm's profit equation is

$$(P_1 + D_1 + G_1)Q_1 + (P_2 + D_2 + G_2)Q_2 + D + G - C(Q_1) - C(Q_2) = 0, \quad (8)$$

where  $P_i$  is the output price for  $Q_i$ ,  $D_i$  and  $G_i$  the private donations and government grants associated with each unit of  $Q_i$ ,  $D$  and  $G$  are fixed donations and grants, and  $C(Q_i)$  is the cost function for  $Q_i$ . Both cost functions are assumed identical for ease, although no important results depend on this. Cost is positive and twice-continuously

differentiable. Assume that  $dC/dQ_i > 0$  and  $d^2C/d^2Q_i > 0$ . All of the variables in Equation (8) are nonnegative.

The firm maximizes some utility function  $u = u(Q_1, Q_2)$ , subject to Equation (8). In contrast to a typical utility model, we make no assumptions on the sign of  $\partial u/\partial Q_i$ . Depending on the firm and the product, the marginal utility of  $Q_i$  may be positive, negative, or zero. However, we assume that  $\partial^2 u/\partial^2 Q_i \leq 0$ , and  $\partial^2 u/\partial Q_i \partial Q_j = 0$ .

The first-order conditions of the firm's Lagrangian function (with respect to each  $Q_i$ ) are

$$\frac{\partial L}{\partial Q_i} = \frac{\partial u}{\partial Q_i} + \lambda \left( P_i + D_i + G_i - \frac{dC}{dQ_i} \right) = 0, \quad i = 1, 2. \quad (9)$$

Solving the two equations in Equation (9) simultaneously with the zero-profit constraint yields the optimal values  $Q_1^*$  and  $Q_2^*$ . Now imagine a profit-maximizing, for-profit firm that produces the same outputs, although not necessarily at the same levels. This firm's first-order conditions are given by the two corresponding equations

$$\frac{\partial \pi}{\partial Q_i} = P_i + D_i + G_i - \frac{dC}{dQ_i} = 0, \quad i = 1, 2. \quad (10)$$

The two equations in Equation (10) yield  $\tilde{Q}_1$  and  $\tilde{Q}_2$ . Comparing Equations (9) and (10), we come to the following important conclusions:

- (i) If  $\partial u/\partial Q_i > 0$ ,  $Q_i^* > \tilde{Q}_i$ . In other words, nonprofits tend to produce more of a particular good than for-profits if they receive positive organizational utility from it. If this is a public good that is naturally underproduced by for-profits, the nonprofit may thus ameliorate a market failure. On the other hand, if there is no market failure, the nonprofit produces the good at inefficiently high levels.
- (ii) If  $\partial u/\partial Q_i < 0$ ,  $Q_i^* < \tilde{Q}_i$ . Furthermore,  $Q_i^* > 0$  only if at this point average revenues exceed average costs (that is,  $P_i + D_i + G_i > C(Q_i^*)/Q_i^*$ ). In other words, nonprofits cross-subsidize utility-enhancing activities with utility-lowering ones, as long as the latter turns a profit for the firm.

Several obvious empirical questions take shape from James' model. First of all, do the arts constitute a public good, and hence might nonprofit organizations enhance efficiency? Second, do nonprofit performing arts firms compete with for-profits? Third, what activities do performing arts firms engage in, such that cross-subsidization takes place?

The first question is somewhat outside the scope of this chapter; however, the earlier discussion of the purported nonuse, nonmarket values of the performing arts might be useful in deciding whether there is a true public-goods component to the performing arts. Throsby and Withers (1986) provide empirical evidence that people tend to believe the performing arts are public goods. Still, Netzer (1992) notes that most performing arts consumption is private and spills over relatively little onto nonpayers.

The efficiency of performing arts nonprofits was been treated earlier, in the context of production and costs. West (1987) argues that in general we will not see performing arts

nonprofits operate at minimum cost owing to the disincentives created by the nondistribution constraint, a prediction that James' model supports. And indeed, most studies suggest that performing arts firms in many countries tend to produce at suboptimal levels. For example, [Fazioli and Filippini \(1997\)](#) estimate that Italian theater companies operate at a scale that is too low to minimize cost. [Gray \(1997\)](#) uses theater data from Norway, and estimates that while large companies tend to operate beyond the point of minimum cost, small companies operate at a scale below this minimum. [Taalas \(1997\)](#) finds that Finnish theater companies tend to operate above minimum average cost due to overutilization of both labor and capital.<sup>13</sup>

Not surprisingly, the main addition to the theory of competition between nonprofits (of all types) and for-profits came from an extension to James' model. [Schiff and Weisbrod \(1991\)](#) note that (assuming for-profits rely on earned revenues), in the absence of corporate tax exemptions and donations, nonprofits would naturally be at a disadvantage compared with for-profits and thus unable to compete with them. This disadvantage would be due to inefficiently-high production levels for favored activities ( $Q_1$ ), and the disutility from unfavored activities ( $Q_2$ ). Empirical research has not looked at competition between nonprofit and for-profit performing arts firms, however. The closest treatment is probably [Gapinski \(1986\)](#), who shows that different performing disciplines (theater, opera, symphony, and dance) substitute for one another in consumers' demand decisions, and hence implicitly compete.

The idea of cross-subsidization of performing arts activities is easy to grasp intuitively. For example, symphony orchestras may perform obscure works at a loss, but make profits on "pops" concerts. The James model suggests that the former programming provides positive utility, the latter negative utility. This cross-subsidization relates closely to economies of scope: Can performing arts firms find multiple outputs that improve their financial position by more than they can by increasing the scale of their core activity? Two studies suggest that the performing arts do indeed enjoy economies of scope. [Lange and Luksetich \(1993\)](#) find that large American orchestras benefit from diverse types of performance activity. Similarly, [Fazioli and Filippini \(1997\)](#) find that Italian theaters can more efficiently provide multiple types of performances than they can just one type.

## 5. The cost disease

The discussion of performing arts production functions pointed out that the main input to the production of the performing arts is labor. The literature shows that, at least for American performing arts firms, labor costs have been rising rapidly.<sup>14</sup> This fact

<sup>13</sup> [Globerman and Book \(1974\)](#) estimate the optimal scale of services per year – where cost per performance is minimized – for Canadian orchestras and theater companies to be 115 and 210 performances, respectively. However, they do not report whether this falls below or above the actual scale of operations.

<sup>14</sup> [Faine \(1972\)](#) explains this by noting that American performing artists are heavily unionized.

broadly supports the so-called “cost disease” theory, which has been the subject of much research in cultural economics, and which deserves some special attention here. While this theory does not predict anything that is uniquely “nonprofit” – indeed, if it is valid, it should be so irrespective of sector – it is conventionally invoked in discussions of the nonprofit performing arts.

In a 1965 paper (and 1966 book), William Baumol and William Bowen (1965, 1966) argue that labor costs will plague the performing arts, for a simple reason: Real wages rise all over the economy with the increasing average levels of labor productivity; labor productivity (Baumol and Bowen assert) is largely stagnant in performing arts firms, which produce a service technologically unchanged over the past 100 years or so and thus have unchanged labor input requirements; therefore, costs will constantly rise over time to the performing arts. The implications of this argument are that these cost increases will necessitate more donated revenues, borrowing, production cuts, or all three.

Baumol and Baumol (1967) model the problem very simply as follows.<sup>15</sup> Imagine an orchestra that produces output  $Q_{1t}$  in period  $t$ , and a representative nonarts firm that produces  $Q_{2t}$ . Assume the production of each is a linear function of labor  $L$ , and the orchestra sees no labor productivity growth, while the other firm has constantly-compounded productivity growth at the rate of  $r$ . That is,

$$Q_{1t} = aL_{1t}, \quad Q_{2t} = bL_{2t}e^{rt}, \quad (11)$$

where  $a$  and  $b$  are constants. Assume that sector 2 dominates the economy, and hence the wage  $w_t$  – to which both firms are subject – also rises with productivity. Suppose, for example, that<sup>16</sup>

$$w_t = we^{rt}. \quad (12)$$

We can derive four main conclusions from this model:<sup>17</sup>

- (i) Costs for the orchestra rise over time, but do not for the other firm. Defining costs per unit of output as  $c_i = w_t L_{it} / Q_{it}$ , we see that  $c_1 = we^{rt} / a$  and  $c_2 = w / b$ .
- (ii) If labor proportions are constant between the sectors, the orchestra’s output falls over time, as a proportion of total output. Defining  $L_{1t} / L_{2t} = A$  where  $A$  is a constant, we see that  $Q_{1t} / Q_{2t} = aA / be^{rt}$ .
- (iii) On the other hand, if the output proportions are constant between the firms, labor will be systematically transferred to the orchestra. Assume that  $(b/a)(Q_{1t} / Q_{2t}) = K$ , where  $K$  is constant, and that  $L_{1t} + L_{2t} = L_t$ . Then,  $L_{1t} = L_t K e^{rt} / (1 + K e^{rt})$  and  $L_{2t} = L_t / (1 + K e^{rt})$ . As  $t$  increases,  $L_{1t}$  goes to  $L_t$  and  $L_{2t}$  goes to zero.

<sup>15</sup> For an alternative modeling approach, see Brooks (1998).

<sup>16</sup> The assumption that wages rise at the same rate as productivity is made only for modeling simplicity. It is not a necessary assumption for the conclusions that follow, only that wages rise monotonically with productivity.

<sup>17</sup> These conclusions are modified by Keren (1972) from Baumol’s original article.

(iv) Economic growth will suffer over time if the labor force does not grow, output proportions do not change, and unproductivity persists in the orchestra. Define  $q_t$  as a weighted sum of the outputs of the two firms:  $\beta_1 Q_{1t} + \beta_2 Q_{2t} = q_t$ .

From Equations (11) and the derivations above, we obtain

$$q_t = \frac{L_t(K\beta_1 a + \beta_2 b)e^{rt}}{1 + Ke^{rt}}. \quad (13)$$

Note that

$$q'_t = \frac{\partial q_t}{\partial t} = \frac{rL_t(K\beta_1 a + \beta_2 b)e^{rt}}{(1 + Ke^{rt})^2} \quad (14)$$

and thus that  $\lim_{t \rightarrow \infty} (q'_t/q_t) = 0$ .

There are two main testable hypotheses about performing arts firms that proceed from the model. The first is that the operating costs of performing arts firms rise over time because of wage increases. The second is that the performing arts sector is shrinking relative to the rest of the economy.<sup>18</sup> If these hypotheses are not supported, we may then conclude that

- (i) a force outside the model – such as rising earned or donated revenues – must be ameliorating the cost problem, or
- (ii) the cost disease theory is somehow flawed.

These hypotheses are the themes on which most of the empirical studies of cost disease have varied.

Raw data provide mixed support for these hypotheses. For example, looking at data on American performing arts nonprofits, McCarthy et al. (2001) show that over the ten-year period ending in 1997, real costs to opera and dance companies increased, but costs to theater companies and musical ensembles fell. Figure 2 above shows that from 1982–1997 donations rose as a portion of total revenues for theater and music firms, but fell for dance companies. And while Figure 4 shows that unearned revenues have indeed generally increased for performing arts firms over the 1990s, it also shows that these increases have been more-or-less proportional to increases in total revenues. Not surprisingly, then, economists have come to mixed conclusions about the degree to which cost disease has affected the performing arts, or indeed exists at all [Throsby (1994)]. Some empirical work supports the proposition, while some does not.

The work of Baumol himself consistently points to cost disease as a real and ongoing problem in the performing arts. For example, Baumol and Baumol (1980) show that costs in the performing arts have increased disproportionately to rises in the price level, except in periods of high inflation. Baumol and Oates (1972) hold that the principle also applies historically, arguing that low real wages for actors in the past are responsible for the success of, among other things, English Renaissance theater. Baumol has also extended the concept beyond the nonprofit performing arts to other labor intensive

<sup>18</sup> This hypothesis assumes the constancy of labor proportions between sectors, as opposed to the constancy of output proportions.

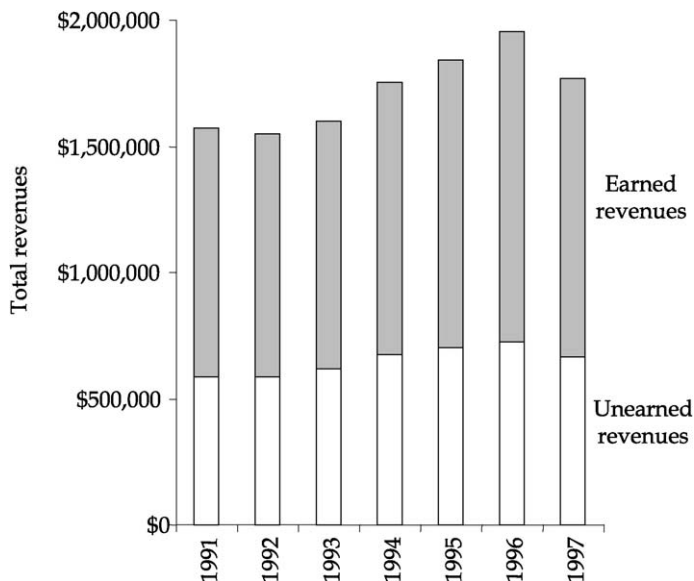

Figure 4. Total and earned average revenues of US performing arts nonprofits, 1991–1997. Source: McCarthy et al. (2001).

industries, presenting evidence of the cost disease in areas such as health care [Baumol and Baumol (1993)], education [Baumol and Baumol (1996)], and libraries [Baumol and Blackman (1983)].

Other writers have encountered some evidence of the cost disease as well. Gapinski (1984) and Fazioli and Filippini (1997) find that technological progress in English and Italian theater (respectively) is very weak, compared to other industries, validating this modeling assumption. Felton (1994) finds that rising labor costs to US orchestras have led to cheaper programming. She notes, however, that such production adjustments belie the inevitability of cost disease problems. Throsby (1996) agrees with Felton on both of these points in his study of labor costs in the Australian performing arts in the 1980s and 90s.

However, a number of writers have argued either that the cost disease does not exist, or that it does not pose a significant problem for the performing arts. For example, Cowen (1996) believes that performing arts firms should be able to greatly enhance labor productivity vis-à-vis recording technologies (that is, a single musician can reach millions of customers at once with a compact disk, as opposed to a live performance).<sup>19</sup> Baumol would not agree with the technology argument, however; they use data on

<sup>19</sup> The opposite side of this coin is that technology simply lowers the demand for labor by firms. For example, Colonna, Kerns and Anderson (1993) argue that synthesized technologies have greatly lowered the employment of certain classes of performing musicians.

American television and film to show that mass media can put off cost disease pressures, but only temporarily. Labor productivity might also be enhanced if performers and other workers can be combined in ways that lower their cost per unit of performance. For example, theater companies can employ tactics such as programming works with fewer actors, or actors in multiple roles.<sup>20</sup>

The demand side is absent from the model presented above, but some authors [e.g., Cowen (1996)] would say that this is not appropriate: Performing arts firms can generally change their revenue positions by changing programming in ways that stimulate demand, thus driving up prices and quantities. Other demand-side cost-disease strategies may exist as well. Peacock (1996) notes that income effects from general economic growth could totally swamp cost disease pressures. This would be especially likely, if, as seems probable, the performing arts have a high income elasticity. Kesenne (1994), however, notes that this would be mitigated by the so-called Linder effect [Linder (1970)]: As incomes rise, so does the opportunity cost of time-intensive leisure activities, such as attending live performing arts events. To exploit income increases optimally – even in spite of Linder effects – Brooks (1997a) suggests that performing arts firms market the luxury aspects of their products so as to maximize income elasticity.<sup>21</sup>

On balance, it seems fair to say that the cost disease is a threat to performing arts firms, but that there exist enough mitigating circumstances that these firms don't generally face any clear and present danger of extinction. Principal among these circumstances is the role of demand increases accompanying rising rates of prosperity and education. Strategies for demand stimulation represent a promising avenue for economists, managers, and policy researchers on the performing arts.

## 6. Revenues of performing arts firms

As discussed earlier, nonprofit organizations of all types receive their revenues from three sources: earned income, private donations, and government subsidies. Surveying the sector in 22 countries worldwide, Salamon et al. (1999) find that earned income makes up about half of revenues, governments underwrite another 40 percent, and private giving constitutes about 10 percent. This masks considerable variance, however. For example, earned income represents 85 percent of nonprofit revenues in Mexico, but just 16 percent in Ireland. This discrepancy is mirrored by public-sector funding of nonprofits: 77 percent of revenues in Ireland, but just 9 percent in Mexico. Private

<sup>20</sup> Certain types of firms (for example, symphony orchestras) have less recourse than others to this kind of labor flexibility, and consequently would be expected to turn to other ways of fighting off cost disease pressures, such as lobbying the government for subsidies.

<sup>21</sup> We should not overlook the fact that technology itself might impact demand for the live performing arts. Heilbrun (1993), for example, believes that technology has hurt the demand for symphony orchestra concerts by improving electronically reproduced substitutes.

philanthropy sees far more uniformity worldwide, where in most countries it makes up between 5 and 15 percent of all revenues.

For the average American nonprofit performing arts firm, 59 percent of income is earned, about 36 percent is donated, and about 5 percent comes directly from government [US Department of Commerce, Bureau of the Census (1997)]. Each of these revenue sources warrants discussion.

### 6.1. Earned revenues

Americans in 1997 spent more than \$10 billion on performing arts events, substantially more than on tickets to movies or sporting events [National Endowment for the Arts (1998)]. As already discussed, this amounts to between 50 and 60 percent of the total revenues of nonprofit performing arts firms. In some countries, the performing arts have an even higher proportion of earned revenues. In the late Soviet era, for example, musical organizations in the USSR (“nonprofits” in function, if not by legal definition) apparently earned upwards of 90 percent of their income at the box office [Rubinstein, Baumol and Baumol (1992)].

As such, discussions of earned revenues might begin by looking at demand for the performing arts. Many authors have treated this subject empirically, and it is the focus of another chapter in this volume.<sup>22</sup> Here, I simply note that equations approximating demand often take some variant of the form

$$\ln Q_{it} = \alpha + \beta_P \ln P_{it} + (\ln \bar{P}_{it})\beta_{\bar{P}} + \beta_Y \ln I_{it} + X_{it}\beta_X + \varepsilon_{it}, \quad (15)$$

where  $Q_{it}$  is the quantity demanded of performing arts firm  $i$  at time  $t$ ,  $P_{it}$ ,  $\bar{P}_{it}$  and  $I_{it}$  are own price, substitutes’ prices, and income levels, respectively; and  $X_{it}$  is a vector of other relevant variables. The coefficients are interpreted as the relevant elasticities. Unfortunately, pricing among nonprofits is general highly nonlinear, reflecting firm strategy in the face of client heterogeneity. Equation (15) estimates some notion of “average” elasticity, but such a concept may not be meaningful. Hence inquiry into earned revenues from the firm side does well to study actual pricing schemes. A number of authors have done so in the case of the performing arts. For example, Huntington (1993) shows that in the mid-1980s about half of theaters in Great Britain charged differential ticket prices based on seating and that this was generally a revenue-enhancing strategy. Seaman (1985) finds that in the US, differential pricing is most common for opera, and least for theater. Blaug (1978), looking specifically at Covent Garden, concludes that “superstar” programming explains much of the difference in prices between venues and events.

Many performing arts firms appear to bundle donations with their ticket prices, asking for voluntary payments that are higher than the minimum for event admission.<sup>23</sup>

<sup>22</sup> See Chapter 14 by Seaman in this volume.

<sup>23</sup> Some authors refer to this phenomenon as “voluntary price discrimination” [e.g., Hansmann (1981)].

O'Hagan and Purdy (1993) and Seaman (1985) provide evidence of this in Europe and the US, respectively. Luksetich and Lange (1995) come to the interesting conclusion that while smaller American orchestras frequently underprice tickets in order to solicit donations, on average this is a money-losing strategy. Kushner and Brooks (2000) extend the idea to street performance, noting that voluntary price discrimination in its purest form (i.e. where all payment is totally voluntary) characterizes support for "buskers".

Another common strategy is one of offering free admission to certain events in order to build audience bases, but this has received little attention by economists. However, given the general finding that performing arts demand is inelastic [Brooks (1997a)], we might question whether lowering prices – even to zero – would really have an effect on attendance.<sup>24</sup> Indeed, Kolb (1997) reports on a survey of students, showing that price is not the issue in performing arts attendance; the real problem seems to be that many young people simply find the performing arts boring. Globerman (1978) finds that demand elasticity can be increased – and thus pricing schemes can be more effective – through the dissemination of better price information. On the other hand, demand inelasticity may be a blessing for some firms losing donations: Touchstone (1980), for example, shows that for American performing arts organizations, a complete loss of donations would require more than doubling ticket prices. Given low demand elasticity, this would decrease audiences by less than 10 percent for theater, less than 15 percent for ballet and opera, and less than 20 percent for orchestras.

## 6.2. Donated revenues

Nonprofit economic theory has occasionally focused on philanthropic behavior. Andreoni (1989, 1990), the most prominent theorist in this area, has developed models that separate out purely altruistic giving from that which is motivated instead by a "warm glow". Other motives have been examined as well. Particularly in the case of religious giving, authors [for example, Asheim (1991)] have modeled deontological, or duty-based, altruism in which a certain giving threshold must be reached before an agent can derive utility from private consumption. And consistent with much of the sociological literature on altruism, others [for example, Rose-Ackerman (1996)] have modeled altruism related in some measure to social status. The data presented earlier suggested that private charitable giving is substantial internationally, but especially large in the United States, where it amounted to \$132 billion in 1997 [Independent Sector (2001)]. 70.1 percent of American households gave in 1998; 11.5 percent made contributions to the arts. The arts consistently represent less than 4 percent of household donations (\$4.4 billion), but a much greater part of corporate and foundation philanthropy. In 1997, private donations from all sources to the arts in the US were about \$10.6 billion [AAFRC (1998)].<sup>25</sup>

<sup>24</sup> It may be that demand is too inelastic and weak to intersect with supply at any nonnegative prices for many performing arts firms [Brooks (1997b)].

<sup>25</sup> See further Schuster's Chapter 36 in this volume.

Between the theoretical interest in philanthropy and the high stakes for nonprofits, it is not surprising that several nonprofit scholars have studied nonprofit fundraising. Among the most influential – and useful for studying performing arts firms – is [Rose-Ackerman's \(1982\)](#) model. She begins with a measure  $\bar{D}_{it}$ , which represents the average expected donation to nonprofit firm  $i$  in period  $t$ . This measure is a function of the proportion of the population (where population is  $n$  individuals) solicited for donations  $k_{it}$  (where  $0 \leq k_{it} \leq 1$ ) and the number of similar organizations  $z_t$  with which firm  $i$  competes for funding in period  $t$ . That is,

$$\bar{D}_{it} = \bar{D}_{it}(k_{it}, z_t). \quad (16)$$

Assume that those people most likely to donate are known and are solicited first, and that more competition drives down the average donation. Then,  $\partial \bar{D}_{it} / \partial k_{it} < 0$ , because wider fundraising appeals have lower average returns, and  $\partial \bar{D}_{it} / \partial z_t < 0$ . Defining the (constant) cost per fundraising contact as  $c$ , dropping subscripts, and assuming firm  $i$  has a one-year time-horizon, its problem is  $\max_k \{kn[\bar{D}(k, z) - c]\}$ . The first-order conditions yield  $k(\partial \bar{D} / \partial k) + \bar{D} = c$ . Dividing this last expression by  $\bar{D}$  yields

$$w = \mu + 1, \quad (17)$$

where  $\mu$  represents the elasticity of the average donation with respect to fundraising penetration, and  $w = c/\bar{D}$  is the budget proportion spent on fundraising.

Equation (17) leads to two main conclusions about nonprofit spending on fundraising, both of which are sensible. First, differentiating the first-order condition with respect to the elasticity gives  $\partial w / \partial \mu > 0$ . That is, as the sensitivity of the average gift to fundraising penetration decreases – for example, if more people become potential strong donors for some reason – fundraising expenditures will increase as a proportion of the nonprofit's budget. Second, differentiating  $w = c/\bar{D}$  with respect to  $z$  yields  $\partial w / \partial z = (-c/\bar{D}^2)(\partial \bar{D} / \partial z) > 0$ . That is, more competition leads to higher budget shares devoted to fundraising.<sup>26</sup>

Apart from [Baumol and Bowen's \(1966\)](#) study of the performing arts and the papers on the importance of private philanthropy in combating the cost disease, there has been relatively little empirical and theoretical economic research on fundraising specifically for the nonprofit performing arts. What little work that has appeared has generally focused on fundraising yields and funding diversification. [McCarthy et al. \(2001\)](#) show that, while arts philanthropy continues to rise, yields to fundraising are falling to performing arts firms, probably due to the explosion in the number of firms – in other words  $z$  is increasing which, consistent with Rose-Ackerman's model, should be driving up fundraising budgets. [Brooks \(1997b\)](#) looks at American symphony orchestra budgets in the 1980s and 90s, and finds that there is a significant difference between large and

<sup>26</sup> These conclusions assume that donors' utility is not affected by  $w$ . [Rose-Ackerman \(1982\)](#) also looks at cases in which donors dislike high  $w$ , and alternatively where they see a high  $w$  as a valuable investment in donor cultivation.

small orchestras: While small (in budget size) orchestras generally find fundraising to be a good investment, many large budget orchestras don't even earn back their fundraising budgets. He attributes this to the fact that large orchestras have a higher  $k$  – they have saturated a larger proportion of their potential donor pools than small orchestras. Nelson (1983) looks at ballet companies, and charts the way that funding has moved over time from box office revenues, to private giving, to greater reliance on corporate philanthropy.

### 6.3. Fundraising innovations

Fundraising and philanthropy in the performing arts are at an interesting frontier with the advent of innovations such as “venture philanthropy” and “e-philanthropy”. Both of these phenomena have received popular attention and deserve mention in the current context.

Venture philanthropy refers to foundation giving in search of large, immediate payoff outcomes across a wide variety of potential activities [Goodale (2000)]: the maximum philanthropic “bang for the buck”. The idea sounds consistent with the rising popularity of venture capital funding in the for-profit economy. In practice, however, there seems to be less here than meets the eye. In 2001, for example, there were just 42 foundations engaged in this type of giving, and they represented just 0.2 percent of all foundation giving [Venture Philanthropy Partners (2002)]. 25 percent of venture philanthropists made no grants at all, and only half made grants to nonprofit organizations, let alone performing arts nonprofits [Jana (2001)].

Broadly speaking, e-philanthropy refers to donations given over the Internet, and takes three basic forms. First, some charities set up their own systems to collect credit card donations on their websites. Second, there are *donation portals*, or Internet clearinghouses for multiple charities which administer funds and donor information for a commission. Third, there are *charity malls*, which are retail establishments that advertise on nonprofit websites and dedicate a portion (usually 5 percent) of resulting Internet sales to the charity. Hopes in the e-commerce world have been high for the future of e-philanthropy. Harvard Business School's Initiative on Social Enterprise, for example, projected that by 2010, one third of all philanthropy would take place over the Internet [Hart (2001)]. This may be a heroic projection, however, given that 1999 online giving amounted to \$10 million, or less than \$1 for every \$13,000 in traditional giving. And indeed, Feller (2001) argues that e-philanthropy firms are seeing far less growth than expected, with some e-philanthropy firms (such as former leader Charitableway) going out of business along with their for-profit e-commerce counterparts.

Economists have not yet studied these fundraising innovations in the context of the performing arts. Any work that is forthcoming would do well to begin by putting hard numbers to these mechanisms and hence to give an idea as to whether firms should invest time and resources in these areas. It may be that venture philanthropy and e-philanthropy are simply not suited to the performing arts, perhaps because donors tend also to be consumers, to whom performing arts firms already have ample exposure.

It is also possible that these organizations, like many for-profits, require closer consumer contact and information than the Internet allows. Potentially instructive for the case at hand is the failure of commercial Internet art auctions [Brooks (2003)].

#### 6.4. Government funding

The final source of funding for performing arts nonprofits is the public sector. Public sector funding comes in two main varieties: direct and indirect. Direct subsidies are payments by governments to arts organizations. Indirect subsidies are taxes forgone on private contributions to these organizations. They result from tax laws that allow charitable donations to be deducted from taxable personal or corporate income before income taxes are calculated.

Direct government subsidies are ubiquitous internationally whereas indirect subsidies are less common, for the simple reason that most countries do not have provisions in their tax laws that allow tax deductions for arts contributions [Zimmer and Toepler (1999)]. Schuster (1999) notes several exceptions, including Australia and Romania (both of which have arts deductions similar to the American system), and Chile (which has an even more generous system of tax credits – not deductions – for corporate arts support). In the United States, however, indirect funding is the primary source of government support. Indeed, indirect federal subsidies to the arts in the US in 1999 (about \$1.7 billion) outweighed direct federal subsidies by about 16-to-1.<sup>27</sup> And indirect subsidies from state and local taxes would augment this figure substantially.

The political economy of government arts funding is the subject of other chapters in this book, and represents a substantial literature in and of itself.<sup>28</sup> Two points bear making here, however, because they explicitly tie government funds to the way nonprofits function in the performing arts. First, several authors have looked at the way government funding affects management decisions. For example, Austen-Smith (1980) shows that government support for British theater companies pushes output down, but variety of repertoire up; further, he predicts that the level of government (central versus local) making grants to performing arts firms will influence output decisions [Austen-Smith (1984)]. In one of the rare looks at the privatization of cultural organizations, Klaic (1998) finds that the delinking of European performing arts organizations from the public sector has been more managerial than financial.

The second issue regards the extent to which public sector funds to performing arts nonprofits displace, or “crowd out”, private donations. One of the most provocative predictions from all of nonprofit economic theory is based on a variant of the public-goods

<sup>27</sup> These data are based on National Endowment for the Arts allocations (see [www.arts.endow.gov](http://www.arts.endow.gov)), total giving to the arts in 1999 as calculated by AAFRC in *Giving USA*, and assuming the average marginal tax rate of 14.8 percent estimated by the US Congressional Budget Office (see [www.cbo.gov](http://www.cbo.gov)). If, as seems likely, the average marginal tax rate for givers to the arts is higher than the national average, this ratio would actually be higher than 16:1.

<sup>28</sup> See further Chapter 34 by van der Ploeg and Chapter 35 by Netzer in this volume.

model outlined earlier, and can be summarized as follows. Suppose a representative agent  $i$  has utility  $u_i = u_i(x_i, D_i, G)$ , where  $D_i$  represents private donations to a public charitable good,  $G$  is the total amount of the public good provided, and  $x_i$  is a composite private good. Assume that utility is concave in all arguments, is twice-continuously differentiable in each, and that at least one argument has a nonzero second derivative. Note that  $D_i$  enters the utility function twice: once through the public good (altruism), and once for the act of giving itself (the “warm glow” from giving). Assume the agent spends all his income  $m_i$  on  $x_i$  and  $D_i$ .  $G$  is financed through government spending  $\bar{G}$  and the agent’s private donations, and is financed through a lump-sum tax  $T$ . Thus, dropping the subscripts, the agent’s problem is  $\max_{x, D} \{u(x, D, G)\}$ , subject to  $m = x + D + T$ ;  $G = \bar{G} + D$ ;  $\bar{G} = T$ ;  $x, D, G \in \Re_+$ .

Folding the constraints into the objective function, the agent’s problem can be restated as a function of  $D$ . The first-order condition is:

$$\frac{du}{dD} = u' = -u_x + u_D + u_G = 0, \quad (18)$$

where  $u_s$  is the partial derivative of  $u$  with respect to argument  $s$ . The second-order condition indicates that  $u(D^*)$  is a unique global maximum. The Implicit Function Theorem tells us that

$$\frac{\partial D}{\partial \bar{G}} = -\frac{\partial u' / \partial \bar{G}}{\partial u' / \partial D} = -\frac{u_{xx} + u_{GG}}{u_{xx} + u_{DD} + u_{GG}}. \quad (19)$$

Equation (19) makes three points:

- (i)  $-1 \leq \partial D / \partial \bar{G} \leq 0$ . That is, government grants will have a crowding-out impact on giving, if any at all.
- (ii) If  $u_{xx} \neq 0$  and/or  $u_{GG} \neq 0$ , and giving provides no “warm glow” (so  $u_D = u_{DD} = 0$ ), grants will crowd out donations dollar-for-dollar.
- (iii) If  $u_{xx} \neq 0$  and/or  $u_{GG} \neq 0$ , and  $u_{DD} < 0$ , grants will crowd out donations fractionally. Bergstrom, Blume and Varian (1986) also note that in a multi-agent model, in which not all agents give voluntarily, crowding-out will also be fractional.

In general, these predictions square with the empirical literature on nonprofits, which finds that a dollar in government grants displaces between 10 and 50 cents in private giving on average [Steinberg (1993)]. However, the few articles on performing arts nonprofits present slightly more complicated results. While Brooks (1999) finds that American orchestras tended to see no significant crowding out, he later (2000) estimated that the true effect was nonlinear; low levels of government funding crowded in donations, while high levels crowded them out. This is consistent with work on non-profit “public” radio stations [e.g., Kingma (1989)], and may be due to the prevalence of “matching grants” in the arts and culture, in which governments match private donations with government money. Note that adding the matching-grant constraint  $\bar{G} = a + bD$ , where  $a$  is a constant lump-sum grant and  $bD$  is a grant for which \$1 in  $D$  is matched

by  $b$  dollars in government money, changes Equation (19) to

$$\frac{\partial D}{\partial a} = \frac{-(1+b)(u_{xx} + u_{GG})}{(1+b)^2(u_{xx} + u_{GG}) + u_{DD}}, \quad (20)$$

and

$$\frac{\partial D}{\partial b} = \frac{-(1+b)D(u_{xx} + u_{GG}) + u_x - u_G}{(1+b)^2(u_{xx} + u_{GG}) + u_{DD}}. \quad (21)$$

Not surprisingly, Equation (20) must be negative. Equation (21), however, may be either positive or negative, suggesting that the matching mechanism may be effective for reversing the crowding out problem. Clearly, much interesting theoretical and empirical work remains to be done on how such institutional arrangements might affect the efficacy of government funding to the performing arts (as well as other parts of the nonprofit economy).

## 7. Summary and future research directions

This chapter has traced the development of the economics literature on nonprofit performing arts firms through some of the most important milestones in nonprofit economic theory. In covering more than 100 papers to date on the subject, we observe contributions to the nonprofit literature as well as an incomplete research agenda. The main areas I see for potential future work on the nonprofit performing arts – to complement and expand general knowledge of the economics of nonprofits – are in updating and expanding older studies, theory building, new empirical applications, and the development of policy and management implications.

Much of the work on performing arts cost and production is based on data from the 1970s and 80s; there appears to be a significant drop-off in empirical work focusing on the 1990s and beyond. Given the rapid changes in production conditions in other parts of the economy, simply re-estimating many of the cost and production measures in the earlier studies surveyed here would be illuminating. Indeed, given that much of the cost disease argument was predicated on resistance to change in performing arts production conditions, new studies could potentially add to the cost disease debate in addition to providing current values of measures such as input elasticities and efficient scales of production. Second, the overwhelming majority of performing arts studies have focused on the United States, Western Europe and Australia, with far less attention to the performing arts in other parts of the world. Naturally, much of this has to do with the availability of data. Nevertheless, data collection efforts and comparative studies featuring developing and transition economies would add significant value to the literature. Third, studies have focused far more on the professional performing arts than activity among amateurs, once again due almost certainly to data availability. Recent work makes it clear that amateur activity affects many more people than previously thought [Brooks (2002)]. Hence, any policy work on the importance of performing arts participation should be accompanied by inquiry into grassroots performing arts organizations.

Several areas of work stand out in the development of the theory of the nonprofit performing arts firm. First, relatively little work rigorously connects the public-goods theory of philanthropic resources to the actual emergence of performing arts nonprofits. Do high fixed costs explain why these firms require donations to survive, and do tax-deductibility and contract failure explain why these donations only flow to firms organized on a not-for-profit basis? Second, it seems reasonable on balance to conclude that the cost disease has not presented increasingly serious problems for the performing arts. Theoretical work on the cost disease could work to understand this phenomenon in more of an intertemporal general equilibrium context, such that the arts interface with education and tastes, and the supply and demand for the performing arts interact over time. Finally, more theory-building is needed on the relationship between revenue sources. Earlier, I suggested the way that just one institution – government matching grants – might defray the “crowding out” relationship between subsidies and gifts. What about other institutional mechanisms? What about the relationships between other sources of revenues? One large unanswered question, for example, involves the degree to which crowding out exists between donors themselves.

Many interesting empirical questions remain unanswered in the nonprofit performing art literature. Examples include the following:

- Tests of the public-goods theory of nonprofits might try to establish the existence of the purported “nonuse” benefits of the performing arts (existence value, bequest value, etc.). At present, these values are empirically unsubstantiated.
- Production functions in the performing arts have not generally included unpriced resources. What is the production value of, say, volunteer time?
- Quality could receive a comprehensive, empirical treatment. Taxonomies of quality such as [Throsby’s \(1990\)](#) could be subjected to scrutiny, by, for example, comparing how alternative definitions of quality relate to one another and predict firm or audience behavior.
- Competition between nonprofits and for-profits is not well understood in the performing arts. To what extent are their products substitutes? In what disciplines does the most competition exist?
- It appears that fundraising yields may vary dramatically by discipline, firm size, and other characteristics. What does this tell us about different firm objectives, within the performing arts, as per [Steinberg \(1986\)](#)?

Finally, the work on nonprofit performing arts economics could be better connected to the literature on arts management and cultural policy. For example, the work on pricing policies and demand suggests that consumers are extremely insensitive to price changes for performing arts events. This fact, as well as strategies to change it, would be invaluable to arts administrators. Second, the innovations in philanthropy reviewed earlier are the subject of much discussion among managers; they deserve some theoretical and empirical treatment by economists. Finally, specifically regarding non-US performing arts markets facing privatization movements, what can economists tell cultural policymakers about what performing arts firms can expect when public subsidies are ended, or American-style tax incentives for private charity are implemented? In all of these cases

and others, economists could take their analysis several steps forward in practicality and accessibility for more general audiences.

**Abstract**

Creativity is a basic human trait that comes into play in a variety of contexts, including the production of art. It relates to the capacity of individuals to think inventively and imaginatively and to go beyond traditional ways of solving problems. In this chapter we consider various definitions of creativity and proceed to consider theories and models of creativity that endeavor to characterize both the creative individual and creative modes of thought. Next, we examine some of the ways in which creativity has been brought into economic analysis. We then turn to the central concern of the chapter, namely modeling the creative process in the arts. Our consideration of the issue leads us to propose an approach in which the creative choice by artists is viewed as an optimization decision with respect to 'creative effort', given the artists' perceptions of what 'the market' and what 'the artworld' care about. In the penultimate section we discuss the relationship between creativity and talent in an empirical context, using recent data on artists' attitudes and behavior. The chapter ends with some conclusions and suggestions for further research.

**Keywords**

creativity, talent, artists, innovation

## 1. Introduction

The concept of creativity as a dynamic force in human behavior has long been a subject for study among philosophers, psychologists, sociologists and mathematicians. In more recent times, neurophysiologists have become interested in creativity as their understandings of the complexities of the functioning of the human brain have developed. In another sphere, the revolution in communications technology has stimulated interest in creativity as a means to finding solutions to problems in computer science. In economics, however, creativity has been of little concern, beyond some attention to its role as a precursor to innovation, following Schumpeter. By and large creativity has not been seen *per se* as a significant variable in economic models of individuals, firms, industries or economies, although the potential role of creativity as a key resource in the so-called new economy is awakening some interest amongst economists at the present time.

In the arts, of course, creativity has always been central to discussions about how art is produced, and countless studies of creativity in music, the visual arts, literature etc. have been undertaken from a variety of disciplinary standpoints. Investigations into the creative processes of the great artists, composers and writers of the past have tried to identify how they found their inspiration and how this was transformed into finished artistic product. A particular purpose of creativity research in the arts carried out by psychologists and educationists has been to determine how best to frame educational strategies to unlock the creative potential of children and young people.

In this chapter we examine the notion of creativity in the context of the economics of the arts and culture. We are motivated particularly by the following question: are there parallel processes where the economic and cultural worth of artistic goods and services are generated separately, or is the process of value creation one that could be understood only as a unitary phenomenon? Partly because of its elusiveness, but mostly because of its potential for profound and unpredictable impacts on modes of production and sources of value, the phenomenon of creativity and the behavior of artists is a matter that deserves to be given serious attention by economists.

We begin our account with definitional questions, demonstrating perhaps the validity of Shea's (1990, p. xiii) proposition that "Only a very rash person would attempt to define creativity in either the arts or science". We proceed to consider theories and models of creativity that endeavor to characterize both the creative individual and creative modes of thought. Next, we examine some of the ways in which creativity has been brought into economic analysis. We then turn to the central concern of the chapter, namely modeling the creative process in the arts. Our consideration of the issue leads us to propose an approach in which the creative choice by artists is viewed as an optimization decision with respect to 'creative effort', given the artists' perceptions of what 'the market' and what 'the artworld' care about. In the penultimate section we discuss the relationship between creativity and talent in an empirical context, using recent data on artists' attitudes and behavior. The chapter ends with some conclusions and suggestions for further research.

## 2. Definitions of creativity

Standard definitions of creativity that can be found in any dictionary emphasize the ability to produce new products or new solutions to problems, where the individual involved uses inventive means and shows imagination as well as routine skill. In general usage, creativity is seen as a capacity of individuals to go beyond traditional ways of thinking, doing, knowing and making. Thus the end result of creativity is something new and original. In this vein, an intriguing and concise definition is provided by Sanchez-Capdequi (2000) who describes creativity as a human activity “which generates a non-pre-existent human order”. Creativity can be contrasted with intelligence insofar as it is characterized by heuristic, open-ended or divergent thinking rather than by algorithmic or convergent thought processes. These characteristics of creativity imply an instability or unpredictability, suggesting that whereas intelligence is measurable (at least in principle), creativity is likely to be less amenable to standardized evaluative tests.

Apart from relying on traditional disciplinary definitions of creativity, it is useful to ask creative people themselves how they would define it. For example, Glück, Ernst and Unger (2002) surveyed artists from different domains of the pictorial arts and elicited from them their definitions of creativity. A control group of forty-seven psychology students were also asked the same question. Both groups of respondents were asked to rate the salience of product and personal attributes in their definitions of creativity. The responses showed that definitions and salience ratings differed systematically between ‘free’ artists such as painters and sculptors, artists in more constrained professions such as architects and designers, and the students of psychology. The only commonality among the groups was that it was agreed that ‘a creative person should have many ideas’. Also, the psychology students tended to emphasize positive feelings evoked by creative activities while both groups of artists often referred to creativity as ‘hard work’. Indeed the latter characteristic reflects a particular difficulty in pinning down a precise definition of creativity, i.e. the fact that it is unclear to what extent creativity comes from random processes of inspiration and to what extent it results simply from determined and purposeful thinking.<sup>1</sup>

Overall, it seems that the prospects for finding a clear-cut definition of creativity are dim. Hayes and Stratton (2003, p. 70) sum up the present state of the field from a psychological viewpoint as being one in which “we have no plausible theory of how creativity happens, no reliable way of measuring the creativity of a person, and no real idea of whether creativity happens because of characteristics of the individual, or because of particular kinds of circumstances”. Despite these problems, we turn in the next

<sup>1</sup> The poet A.E. Housman is one artist who saw his own creativity as arising from *both* sources, describing his composition of a particular poem thus: “Two of the stanzas . . . came into my head . . . while I was crossing the corner of Hampstead Heath between the Spaniard’s Inn and the footpath to Temple Fortune. A third stanza came with a little coaxing after tea. One more was needed, but it did not come: I had to turn to and compose it myself, and that was a laborious business” [Housman (1961, p. 195)].

section to a brief account of some theories and models of creativity that are currently under discussion.

### 3. Theories and models of creativity

Studies of creativity in the behavioral sciences distinguish between creativity as a *trait* of individuals and creativity as a *process* by which problems are solved or new ideas generated. In the former context, a further distinction is made between those aspects of an individual's personality and character that are intrinsic, arising, for example, as a result of genetic inheritance, and those that are acquired through the influence of external circumstances, such as education and experience.

Looking more closely at the concept of the creative individual, we can observe three characteristics that have been extensively discussed. First, there is family background, which has the capacity to influence creative development both positively and negatively. In particular there appears to be a strong tendency in people of exceptional creative ability to have come from family backgrounds in which parents and other role models have provided a climate conducive to the fullest development of creative talent [Ochse (1991); Albert (1994); Runco (1999a)]. Nevertheless there are contrary examples where other factors have had to assert themselves in order to overcome unfavorable or discouraging family circumstances.

Important amongst such other factors is the second characteristic or group of characteristics of the creative individual, namely personality traits. A large number of studies have looked at the sorts of personal qualities that facilitate creative thinking and creative behavior. Generally these qualities have been found to be distinct from high general intelligence, and more important than IQ as predictors of creative achievement. They include such traits as flexibility, freedom of thought, independent mindedness, a willingness to take risks and a tolerance of ambiguity (i.e. an ability to remain open-minded in the face of uncertainty). Other traits such as perseverance and courage have also been discussed [Dacey and Lennon (1998, Chapter 5)].

The third characteristic of creative individuals is the acquisition of cognitive skills, such as the capacity for divergent thinking, i.e. thinking 'beyond the square', where the exercise of the imagination leads to multiple possible solutions to a problem. This has proved to be a fruitful area for empirical research, and tests for divergent thinking have been devised which have been widely used in creativity research and in practical applications, for example, as indicators of potential for creative thought in areas such as management [Runco (1999b)].

Turning to creativity as a process, we note that the representation of creativity in this context has generally dissected the process into a series of stages [Gilhooly (1988); Lubart (2001)]. Typically the stages as described involve preparation or observation, followed by definition of the problem, perhaps a stage of 'incubation', and then illumination leading to a solution. A final stage may also be identified involving verification. Whilst the characterization of the creative process as one of rational decision-making

according to a logical procedure has much appeal, it seems to imply that anyone could become creative simply by following the required steps. In fact, it may well be that creativity, especially in art, is the very antithesis of a rational process. Indeed revolutionary movements in art such as dada have been explicitly aimed at subversion of the established order.

Alternatively, the staged model of rational choice could be replaced by one that recognizes creativity as a stochastic process. For example, [Simonton \(2004a, p. 84\)](#) argues that

to claim that creativity is stochastic is to assert that it entails much more uncertainty and unpredictability than would be expected from a forthright, rational process. At the same time, to hold that creativity is stochastic is not tantamount to the assertion that it is totally random, and therefore capricious and illogical. On the contrary, . . . creativity has the characteristics of *constrained* stochastic behavior. Creativity is to a certain degree predictable, but far from deterministic.

Finally, we turn to creativity specifically in the arts. During the 17th and 18th centuries there was much speculation about the nature of genius – the indefinable quality that touched certain individuals and turned them into great artists.<sup>2</sup> More recently, the existence of an absolute standard of aesthetic judgment in defining genius has been challenged. Furthermore, it is argued that the social and political context within which artists work has a profound effect on the exercise of their creativity. Indeed [Simonton \(2004b, pp. 3–12\)](#) identifies both genius and the social context amongst four explanations of creative behavior in science, the other two being logic (simply following an orderly experimental path) and chance (serendipity or the chance juxtaposition of events producing unexpected outcomes). Somewhat similar propositions could be made about the origins of creativity in the arts.<sup>3</sup>

Despite all the difficulties, efforts have continued towards understanding the workings of the mind in the making of art, with attempts to model the cognitive, affective, behavioral and contextual factors associated with the process of artistic creation. One particular line of investigation has been to analyze the evidence from artists themselves in describing how they work [[Mace \(1997\)](#); [Mace and Ward \(2002\)](#)]. Along these lines, a number of researchers have scoured the biographical records and writings of great artists of the past in an effort to identify how artists of outstanding creativity have found their inspiration [[Gedo and Gedo \(1992\)](#)]. We return to the question of modeling the creative process in the arts in later sections of this chapter.

<sup>2</sup> See [Etlin \(1996, p. 38ff\)](#); from a psychological viewpoint [Weisberg \(1993\)](#) argues that the idea of genius as deriving from some unfathomable or mystical source is unfounded, but rather that creative thinking is simply an extension of normal mental functions.

<sup>3</sup> For another comparison between creativity in art and in science, see [Rothenberg \(1979\)](#).

#### 4. Creativity in economic behavior

Although this chapter deals primarily with creativity in the economics of art and culture, it is appropriate as a prelude to our discussion of the behavior of artists to look briefly at creativity as it occurs in economics more generally, notwithstanding the fact that, as we remarked earlier, the concept of creativity has not stirred a great deal of interest amongst economists. Three approaches to this issue can be identified.

First, the phenomenon of the creative individual can be interpreted in economic terms by reference to the theory of human capital. Although [Becker \(1964\)](#) does not mention creativity in his seminal book on this subject, it is not hard to see that, in the portfolio of human characteristics that go to make up a given individual's human capital, creativity could be seen as one element.<sup>4</sup> Even if creativity as such cannot be separately identified, at least those attributes that appear to contribute to a person's creative ability – flexibility, personality traits, cognitive skills, etc. as noted above – can be interpreted as components of the human capital resource. Carrying the proposition further opens up the possibility in a given individual of improving the creative productivity of one or more of these components through investment, via the usual avenues of education, training, on-the-job experience, etc. Following this line, [Sternberg and Lubart \(1991\)](#) suggest that creative performance results from a confluence of six different individual characteristics – intellectual processes, knowledge, intellectual style, personality, motivation and the person's environmental context; investment in improving any of these could improve creativity. However, the relationships involved are not necessarily simple or linear; for instance, it is likely that creativity increases with knowledge at a decreasing rate, and that the marginal product will turn negative if, as seems plausible, “too much” knowledge actually inhibits creativity [[Lubart and Runco \(1999, p. 624\)](#)]. Moreover it may be that traditional education, including arts training, may not be the most effective human capital investment for unlocking creativity. History is replete with examples of brilliant artists who did poorly at school; D.H. Lawrence, for instance, was ranked only 13th out of 21 in his secondary school composition class, yet became a major novelist and poet [[Simonton \(1999, p. 191\)](#)]. Many artists regard experience as a better teacher.

Second, creativity in economics is implicated in the analysis of innovation, market structures and technological change, especially following the seminal contributions to thinking in this area made by Joseph Schumpeter, who challenged the proposition that competitive markets provide the strongest incentive towards innovation [[Schumpeter \(1943, Chapter 8\)](#)]. He argued on the contrary that large firms and firms with significant market power would be more likely than small ones to encourage innovative effort and that this would lead to more rapid technological progress than would occur under other structural conditions. The monopoly-competition-innovation issue has been discussed at length by a number of subsequent writers, notably [Arrow \(1962\)](#) and [Demsetz \(1969\)](#), both of whom examined the supposed underinvestment in inventive effort in a free-market competitive economy. All of this work on innovation as an element in industrial

<sup>4</sup> See also [Chapter 24](#) by Towse in this volume.

organization and as an object of public policy has made little or no reference to creativity as such, although there has been some attention paid to the invention process and the sources of scientific ideas in studies of the role of R&D in the economy [MacKinnon (1962); Hope (1988)].

There has also been some allusion to the nature of creative thought *per se* in the third line of development to which we can refer, namely the role of creativity within organizations. Indeed this is an area that has developed significantly in recent years. It extends a long way beyond simply the invention of new products to gain a competitive advantage for the firm. Certainly it has a lot to say about this matter, especially in the context of contemporary production technologies, but it also looks at creativity as a more ubiquitous resource within the firm (and other types of organization such as bureaucracies), informing processes of strategic planning, personnel management, marketing, community relations and so on. Factors that contribute to creativity in these respects may arise from personal qualities of managers and employees, or from institutional structures that deliberately encourage creative thought [Heunks (1998)].

In the end it may be that in economic terms creativity both of individuals and of organizations may spring from similar sources and hence may be able to be modeled in similar ways. Thus, for example, McCain (1992, Chapters 18–19) develops a theory of individual creativity based on the cognitive filtering of impulses which he goes on to show can be readily extended to business enterprises. Without wishing to become anthropomorphic, we might likewise extend other theories of the creative individual, enabling us to give some substance to otherwise imprecise concepts such as ‘the creative firm’, ‘the creative city’, etc.

## 5. Modeling the creative process in the arts

Given the centrality of creativity to the act of artistic production, whether by an individual artist or by groups of artists, it is difficult to imagine analyzing production decisions in the arts without at least some acknowledgment of the creative origins of artistic work. Nevertheless, much of the modeling of the production processes of arts firms – theater groups, music ensembles, opera and dance companies, etc. – has proceeded without specific reference to creativity. It should be noted however that decisions about output quality have certainly played a prominent part in such models and hence the role of creativity is at least implied if not explicitly specified as a variable. Similarly, research into the behavior of individual artists has generally adopted a labor market framework within which to analyze their working patterns, concentrating on estimating labor supply functions, earnings functions, etc. rather than looking for the creative origins of artists’ decision-making.<sup>5</sup> Nevertheless, again it must be acknowledged that in some studies the role of talent as a determinant of success in artistic labor markets has been

<sup>5</sup> See Chapter 22 by Menger and Chapter 23 by Alper and Wassall in this volume.

brought into account, and hence the possibility of a link to the 'pure' concept of creativity is established [Rosen (1981)].

One area of considerable interest in the economics of artists' behavior is the matter of motivation, interpreted in the context of a staged creative process as the stimulus towards taking the first step. Artists may be motivated by a variety of influences and desires, ranging from the pursuit of a grand artistic vision to more mundane concerns for pecuniary gain. Frey (1997; 2003, pp. 141–144) has distinguished between motivations arising from within the artist's being and those imposing themselves on the artist from outside; he identifies these as 'intrinsic' and 'extrinsic' motivations respectively. These motivations might be transformed into a desire on the part of the artist to create value, realized in either an economic or a cultural payoff [Throsby (2001, Chapter 6)]. Thus for the intrinsically motivated artist seeking purely artistic reward, a link between creativity and cultural value is established; for the commercially minded artist the extrinsic profit motive consigns creativity to a lesser role, since more routine skills of market awareness, entrepreneurial flair, etc. are likely to be implicated in the generation of economic value.

A further aspect of creativity in the arts with particular relevance to the question of motivation is the pattern of creative activity over time. Some artists are able to produce a steady stream of output over long periods; for example, Dickens and Ibsen wrote regularly for most of their working lives. Others reach a point in their career at which creativity seems to dry up – an example is the Finnish composer, Jan Sibelius. A particularly intriguing case is the artist who produces work in cycles; the output patterns of Mozart and van Gogh, for example, show clear cyclical phases of intense productivity followed by inactivity. Rinaldi, Cordone and Casagrandi (2000) model the dynamics of production in creative professions by proposing two differential equations to specify the interaction between two state variables, satisfaction (self-esteem felt on the basis of past achievements) and creativity (fluency in identifying new ideas and directions). The flow of new achievements in this model is made a function of creativity, under an assumption of diminishing returns in the output of new work. The interactions between the two state variables are specified such that satisfaction increases with the flow of achievements, and creativity is stimulated by the ups and downs of satisfaction. Rinaldi et al. show that regular output over time is likely to be produced by artists who quickly forget their past achievements and are not affected by variations in their levels of satisfaction. By contrast oscillatory behavior will be demonstrated by individuals who do not forget their past too quickly, and who are sensitive to variations in satisfaction.

The Rinaldi et al. model relies on intrinsic factors as conditioning the creative process. An alternative approach is to look to external circumstances as affecting the incentives to artistic work. There is no doubt that historical, political and social factors influence creative activity in the arts. Although some artists may be characterized as living and working entirely in an imaginative realm derived only from within themselves, it is more likely that external influences will play some role in initiating or mediating the creative process. Generally it might be thought that the role of such factors – whether they be the prevailing artistic fashion, political or social conditions, or the

demands of the marketplace<sup>6</sup> – will be positive in their influence on creativity. Alternatively, Seitz (2003) argues that political and religious censorship, corporate control and influence, copyright restrictions and other cultural and economic considerations deeply constrain creative self-expression. He suggests that creative product is most likely to emerge when individual creative abilities are exercised within a communal structure with strong associative networks and a shared sense of collective values. An example of such circumstances might be the emergence of ‘genres’ within particular artforms, such as in the music community of Nashville where country musicians live and interact with one another in the production of their music [Negus and Pickering (2004, p. 73)].

Further evidence for the effects of exogenous circumstances on artists’ creativity comes from Simonton’s (1997, pp. 29–53) analysis of the socio-cultural determinants of artistic distinction. Using data for 772 visual artists and sculptors over a 900 year period up to the beginning of the 20th century, he shows that high levels of creative achievement among these artists were positively associated with contacts with associates, challenges from rivals, guidance from an eminent predecessor (a “paragon”) and relationships with successors (apprentices, admirers, etc.).

## 6. Game theory, optimization and artistic creativity

### 6.1. *A game against financiers*

As John Nash saw it, the aim of game theory is to provide an understanding of the ‘underlying dynamics’ of human behavior, particularly in a social context. It would be surprising, therefore, if game theory could not provide a fruitful means for analyzing the creative process in the arts. Yet so far little attention has been paid to this possibility. One notable exception is the model developed by Cellini and Cuccia (2003) to represent a two-person game between an ‘artist’ and a ‘financier’, i.e. a profit-seeking individual who has to decide whether or not to finance the artist’s work. The artist’s strategies are to experiment, producing creative or innovative output, or not to experiment, producing conservative commercial work. The artist population contains an unknown proportion of innovative artists. Solving the model as a one-shot game shows that a certain number of conservative artists in the population is necessary (and sufficient in the case of a risk-neutral financier) for private financing of the arts.

If the model is analyzed as a repeated game, the opportunity arises for both players to gain information on critical parameters as the game proceeds. Cellini and Cuccia solve the model as a two-stage process, identifying the options open to both sides at each stage. The higher the probability of finding innovative artists in the second stage

<sup>6</sup> Cowen (1998), for example, argues that market incentives lead directly to the production of great works of art; since such works undoubtedly require creativity in their making, the link between financial incentives and the exercise of creativity is established, if Cowen’s argument is correct.

of the game, the lower the probability that the financier will finance an art project at this stage, and the more likely it will be that an artist, in anticipation of this outcome, will choose to experiment in the first stage. For our purposes, the interest of this model lies particularly in the way it depicts the exercise of creativity as a choice the artist makes, conditioned by the expectation of receiving funding. One of the results of this analysis is to show that the probability of creative experimentation is a continuous, non-monotonic and concave function of  $q$ , the *ex ante* probability of a financier facing an innovative artist drawn from the population; the probability of experimentation increases for low values of  $q$  and then declines. The authors interpret this result as indicating that “the presence of conservative artists is a necessary condition to guarantee the possibility of a private financing of artists who choose to experiment” (p. 32).

What this analysis reveals is that the act of being ‘truly creative’ (i.e. ‘experimental’ to use the language of the above analysis) can be understood as a strategic response to the environment in which an artist finds himself or herself, and is not something that needs to be perpetually shrouded in mystery. To carry this point further, we suggest in the following paragraphs an alternative model of the artist’s creative choice.

## 6.2. A creative optimization decision

Consider the following artistic decision,<sup>7</sup> in which a creative artist is thought of as choosing the amount of ‘creative effort’ to invest in a particular work such as a painting, a novel or a musical composition. Suppose the artist’s decision is conditioned by her beliefs about the likely reaction to her work in the domains where the work is received. The domains in which artistic work is received are assumed to be comprised of two parts: ‘the market’ and ‘the world of ideas’ (here referred to simply as ‘the artworld’).

Let  $A$  be a non-empty set of artists and let  $i \in A$  be a typical artist. Assume that there is a trait  $T$  called ‘creativity’ which is exogenously given in amount  $T_i$  to artist  $i$  and in general  $T_i \neq T_j$  if  $i$  and  $j$  are different artists. For each work of art  $w_i$  produced by  $i$  there is a production function. One of the inputs of that production function is the proportion of his or her total creative talent that  $i$  chooses to use in the production of  $w_i$ . Let  $\alpha_i$  denote the proportion of  $T_i$  that  $i$  chooses to use in the production of  $w_i$ . Clearly  $0 \leq \alpha_i \leq 1$ , and the amount of  $i$ ’s productive talent that is actually used in the production of  $w_i$  is  $\alpha_i T_i$ . So  $\alpha_i$  is the basic choice variable for artist  $i$  in the decision that she has to make. If  $i$  chooses  $\alpha_i = 1$  (‘full and free creativity’),  $w_i$  is called a ‘creative work’. If  $i$  chooses  $\alpha_i = 0$ ,  $w_i$  is called a ‘commercial work’. Works for which  $0 < \alpha_i < 1$  contain varying degrees of creative and commercial content, according to the size of  $\alpha_i$ .

<sup>7</sup> The distinction between a *game* and a *decision* may be captured as follows: “When a person . . . decides how to act in dealings with other people . . . there must be some cross-effect of their actions; what one does must affect the outcome for the other . . . For the interaction to become a strategic game, however, we need something more, namely the participants’ mutual awareness of this cross-effect” [Dixit and Skeath (1999, p. 16)].

Suppose that a work of art  $w_i$  can have ‘economic value’  $v_e$  usually conferred by ‘the market’, and ‘cultural value’  $v_c$ , usually conferred by ‘the artworld’. Then the decision problem faced by artist  $i$  can be summarized as follows:

<i>Action</i>		<i>Goods</i>	<i>Utility</i>
<i>space</i>		<i>space</i>	<i>space</i>
$\{\alpha_i: 0 \leq \alpha_i \leq 1\}$	(Production function) $\longrightarrow$	$w_i$	(World) $\longrightarrow U_i(v_e, v_c)$

Artist  $i$  aims to choose  $\alpha_i$  so as to maximize  $U_i(v_e, v_c)$  given her understanding of how  $w_i$  will be transformed into  $(v_e, v_c)$  by the market M and the artworld W.

ASSUMPTION 1. The market M cares only about the economic value of the work  $v_e$ . The artworld W cares only about the cultural value of the good  $v_c$ . The artist cares about both the economic and cultural value of the work, the relative weights assigned to each depending on her preference pattern between the two types of value (see below).

REMARK. Assumption 1 means that  $U^M(w_i) = v_e$ ,  $U^W(w_i) = v_c$  and  $U_i(w_i) = (1 - \lambda_i)v_e + \lambda_i v_c$ , with  $0 \leq \lambda_i \leq 1$ , where  $\lambda_i$  can be thought of as a ‘creative preference parameter’ of artist  $i$ . Given her preferences (i.e. the weighting  $\lambda_i$ ), artist  $i$  has to choose the type of work to produce. This decision will depend on the beliefs she has about the connection between the choice of  $\alpha_i$  (i.e. the *type* of good that  $w_i$  is), and the payoffs  $v_e$  and  $v_c$ . These beliefs may be many and varied. We suppose here that the beliefs of  $i$  are captured by the following assumption.

ASSUMPTION 2.  $v_e = v_e(\alpha_i)$  and  $v_c = v_c(\alpha_i)$  are both concave in  $\alpha_i$ . Assume also that  $v_e$  is positive for  $\alpha_i = 0$ , increasing for  $0 < \alpha_i < k$  and decreasing for  $1 > \alpha_i > k$ , where  $k$  is a “critical value” of  $\alpha$  (see below). Assume that  $v_c$  is zero for  $\alpha_i = 0$  and increasing in  $\alpha_i$  for any  $0 < \alpha_i < 1$ .

REMARK. Assumption 2 means that a “fully commercial” artwork ( $\alpha_i = 0$ ) has a moderate  $v_e$  and a zero  $v_c$ . A “fully creative” artwork ( $\alpha_i = 1$ ) has zero  $v_e$  and relatively high  $v_c$ . The assumption also holds the idea that  $v_e$  is an increasing function of  $\alpha_i$  provided that  $\alpha_i$  is in the ‘safe’ range  $0 < \alpha_i < k$ , i.e. for  $\alpha_i$  less than some critical value  $k$  (e.g.,  $k = 0.5$ ). In other words *some* creative content will contribute to raising the economic value of the work beyond that of a purely routine work with little or no creative appeal. However, the economic value of the work is then a decreasing function for a choice of  $\alpha_i$  greater than  $k$ , because such values of  $\alpha_i$  mean more ‘adventurousness’ and so less market acceptability. As far as the artworld is concerned, the artist conjectures that  $v_c$  is an increasing function of  $\alpha_i$  over the range  $0 \leq \alpha_i \leq 1$  (i.e. the more adventurousness the better in purely artistic terms). A picture of what Assumption 2 is trying to say is in Figure 1.

Figure 1.

The artist’s problem is then to choose the proportion of her talent to apply in the production of a work of art, given her preferences for economic and artistic rewards, and her conjecture about the way the market and the artworld will value the work which she produces. Specifically, the artist’s problem is to choose  $\alpha_i$  to maximize utility, i.e. to choose a level of creative effort  $\alpha_i$  that solves the following constrained optimization problem

$$\text{Max}_{\alpha_i} U_i(w(\alpha_i)) = (1 - \lambda_i)v_e(\alpha_i) + \lambda_i v_c(\alpha_i) \tag{1}$$

subject to

$$0 \leq \alpha_i \leq 1. \tag{2}$$

To see what the solution to this problem looks like and how it responds to variations in the artist's preferences, rewrite the problem as

$$\text{Max}_{\alpha_i} (1 - \lambda_i)v_e + \lambda_i v_c \tag{3}$$

subject to

$$v_e, v_c \in V \tag{4}$$

where

$$V = \{v_e, v_c \wedge v_e(\alpha_i) \geq v_e, v_c(\alpha_i) \geq v_c, 0 \leq \alpha_i \leq 1\}.$$

By virtue of **Assumption 2**,  $V$  is a convex set so the problem in Equation (1) is a convex maximization problem with a linear objective function. Since this function is maximized, it is easy to see that at the optimum the first two inequalities in  $V$  will hold as equalities.

A sketch of what is going on here is provided in **Figure 2**. In the context of this figure we can explore the consequences for the choice of creative effort in the following cases (where a star [\*] indicates optimality):

Figure 2.

*Case 1:* If the artist doesn't care at all about money, in other words is uninterested in the evaluation of the market, then  $\lambda_i = 1$  and the objective function in Figure 2 is vertical, with the implied  $\alpha_i^* = 1$ .

*Case 2:* If the artist doesn't care at all about the evaluation of the artworld, but is interested only in making money, we have  $\lambda_i = 0$ ; the objective function becomes horizontal and the implied level of creative effort is then  $\alpha_i^* = k$ .

*Case 3:* If the artist cares about both money and cultural contribution so that  $0 < \lambda_i < 1$ , the implied choice of  $\alpha_i^*$  yields values of  $v_c^*$  and  $v_c^*$  as in the example shown in Figure 2.

Consideration of these three cases and contemplation of the artist's optimization problem leads to the following summary proposition:

**PROPOSITION.** *If an artist imagines that they are in a decision context in which either or both the market and the artworld have a role in the evaluation of their work and if Assumptions 1 and 2 capture the beliefs of the artist, then  $\alpha_i$ , the level of creativity used in the production of an artwork  $w_i$ , is an increasing function of  $\lambda_i$ .*

We note that this proposition is in effect simply a logical consequence deriving from the assumptions that go to make up our model.<sup>8</sup> Nevertheless it is still useful to state it in these terms, given that our purpose in constructing the model and in investigating what it implies has been to illuminate the underlying mechanisms governing the creative choices of the artists.

There are a number of fruitful ways in which this model could be extended. One possibility would be to endogenize the creative preference parameter  $\lambda_i$ . Although it is beyond our present scope to do so here, we can at least suggest one or two comparative static results based on informal speculations about an artist's preference formation. For instance, it might be supposed that an artist who had an unexpectedly gratifying experience in the way her work was received by the artworld would subsequently change her weighting of  $v_c$  (so that  $\lambda_i$  would increase); if so, the model predicts that  $v_c^*$  would shift to the right and  $v_c^*$  would shift down in the new equilibrium. On the other hand commercial success could have differential effects on preferences depending on the initial starting position. These and other conjectures could be translated into statements about how  $\lambda_i$  changes as a result of feedback effects, and the consequent impacts on creative choices in equilibrium could be worked out.

## 7. Creativity, talent and artistic output: Some empirical evidence

We turn now to the question of incorporating creativity into empirical models of artist behavior. In doing so we note that the term 'talent' is more often used than the word

<sup>8</sup> As Suppes (1987) points out, any proposition derived in a formal axiomatic system is necessarily an expression of the axioms or assumptions that comprise the system.

'creativity' in describing an individual's capability of achieving artistic success. Is there a difference between talent and creativity? At one level a differentiation could be made between the possession of a capacity for creative work (talent) and how much of that talent is actually expended on a given work, i.e. how truly creative the final work actually is. Thus, for example, a highly talented pianist could on one occasion perform Rachmaninov's Third Piano Concerto in a technically competent way without playing any wrong notes, whereas on another occasion might offer an entirely new and creative interpretation of this work. This was how creativity was modeled in our previous theoretical section.

We also referred above to speculation about whether creativity or talent are inherited or acquired characteristics, observing that if creativity is inherited it is likely to be enhanced in an individual by a supportive family background. If it is acquired, the process of acquisition could occur in many different ways, including via an artist's education and training.<sup>9</sup> However it arises and however it might be measured, we have noted that artists are likely to possess differing levels of creativity, ranging from highly creative individuals to routine practitioners. Our model proposes that, whatever the level of creative talent an artist possesses, she faces a choice: whether to use it to produce innovative work requiring a high creative input or commercial work requiring a lower creative input.

Can these theoretical propositions be put to the empirical test? To do so requires a means of measuring creativity and a basis for distinguishing creative from commercial output. To examine these questions, we take cross-section data from a recent sample survey of Australian professional artists [Throsby and Hollister (2003)]. These data can be used to identify creativity amongst artists in different artforms by making certain assumptions as to the origins and manifestations of creative ability in the individual practitioner. The data also allow us to propose a distinction between the creative and commercial output of respondents to this survey. In the following paragraphs we construct a *creativity index* for a group of 'initial creative' artists (writers, visual artists, craftspeople, and composers),<sup>10</sup> and use the index to evaluate the importance of creativity in their production of creative and commercial artistic output.

We turn first to the derivation of the creativity index. Assessment of a person's creativity may come from their own opinions about their talent (self-assessment) or from the opinions of observers of their behavior or of their work (external assessment). The survey data do not provide any direct assessment of creativity, but they do contain some information about respondents that can be taken as indicators of or proxies for creativity which can then be aggregated into a combined index. In the survey, participating artists were asked to identify factors that they believed had contributed to their professional development as an artist. They could indicate multiple factors as having had an effect

<sup>9</sup> The growth in 'creative writing' courses in recent years would suggest that in this artform creativity can be acquired, or at least enhanced, through training.

<sup>10</sup> As distinct from performing artists (actors, dancers, musicians, etc.)

and were then asked to indicate which one of the nominated factors they regarded as having been *most* important. A range of 14 possible influences was suggested, including the artist's training, a 'lucky break', financial assistance at a critical time, etc. One of the alternatives was 'my talent' and another was 'support from family and friends'. It might be presumed that those indicating their talent as having been important would see themselves as being talented or creative, on a self-evaluative basis. Furthermore, since as discussed above it is known that creative individuals are more likely to arise from supportive family circumstances, those artists in the survey who indicated this factor as having been important might also be seen as more creative.

In addition to these self-assessments, there is also an external assessment of the artists' work in the survey data. Artists were asked about their receipt of a grant from a Federal or State government arts funding agency. These grants are subject to strict peer-assessment procedures. Hence award of such a grant might be seen as an external indication of the artist's creative achievement or potential, and might be thought of, in terms of the theoretical model in the previous section, as 'the evaluation of the artworld'.

Putting these characteristics together enables us to assemble five separate indicators that might be thought of as contributing towards an individual's creativity. They are:

- Talent considered a factor in advancing own artistic development;
- Talent considered the most important factor;
- Family support considered a factor in advancing own artistic development;
- Family support considered the most important factor;
- Peer-assessed grant received.

If for a given artist a zero-one value is attached to each factor, an unweighted sum of all five factors can be obtained, which could be called a *creativity index* for that artist<sup>11</sup> ranging from zero to 4. Of course calculating the index in this way implies a cardinal scale for measuring creativity, where each factor contributes equally in numerical terms to the aggregate assessment. While these are strong assumptions, they are not entirely implausible in the limited context in which we are applying them, especially if the index is interpreted not as a measure of intensity of creativity but simply as a count of relevant contributing factors when a higher score is a *prima facie* indication of greater creative potential.

Table 1 shows the proportions of artists in this survey sample with a positive score on each criterion, and Table 2 gives the frequency distribution of the creativity index across the whole sample. It can be seen from Table 2 that there is indeed a wide spread of artists according to the creativity measure we have derived. At one extreme these results suggest that almost 15 percent of artists have relatively low creative potential – these artists do not have confidence in their own talent, they do not appear to have come from supportive family backgrounds, and the artworld has not recognized their creative

<sup>11</sup> Note the maximum possible score is 4, not 5; only one (or none) of the second and fourth characteristics listed above could hold for any individual.

Table 1  
Proportion of artists<sup>a</sup> with various creativity attributes: Australia, 2002 (percent)

	Writers (%)	Visual artists (%)	Crafts- people (%)	Composers (%)	Total (%)
Talent: one factor advancing my professional development	74.9	69.9	71.5	92.4	74.2
Talent: most important factor advancing development	33.8	25.1	22.0	42.4	29.2
Family support: one factor advancing my professional development	48.4	48.1	53.7	59.1	50.4
Family support: most important factor advancing development	5.9	7.9	14.6	1.5	7.9
Received peer-assessed grant in last five years	13.7	23.9	18.7	33.3	20.4
<i>n</i>	219	239	123	66	647

<sup>a</sup>Writers, visual artists, craftspeople and composers.

Table 2  
Frequency distribution of creativity index for artists<sup>a</sup>: Australia, 2002

Creativity index <sup>b</sup>	Frequencies	
	no.	%
0	91	14.1
1	150	23.2
2	219	33.8
3	158	24.4
4	29	4.5
Total	647	100.00

<sup>a</sup>Writers, visual artists, craftspeople and composers.

<sup>b</sup>See text for method.

work by award of a peer-assessed grant. At the other end of the spectrum, somewhat less than 5 percent of artists achieve the maximum score.<sup>12</sup>

Using this creativity index we can proceed now to a simple indirect test of the model proposed in the previous section. Following [Throsby \(2006\)](#) we can suggest that the

<sup>12</sup> These numbers would seem to confirm the oft-expressed belief held by skeptical observers of the contemporary arts that there are more bad artists than good artists in the world.

output of artists can be represented by a production function in which labor time, working capital and human capital are the inputs. In this specific context the vector of human capital characteristics includes creativity,<sup>13</sup> in addition to the usual variables of education, training and on-the-job experience. Furthermore, the artist's total output can be divided into "creative" and "commercial" output; the former comprises the novels, the poetry, the paintings and sculptures, the original craft works, the musical compositions etc. that the artist produces, while the commercial output includes art-related activities such as teaching, arts administration etc., where production uses some artistic skills but at a more routine and commercially-oriented level.

Formally, we can define for a given time period for the  $j$ th artist ( $j = 1, \dots, n$ ):

$$y_j^{\text{cr}} = f_1(L_j^{\text{cr}}, PK_j^{\text{cr}}, HK_{ij}), \quad (5a)$$

$$y_j^{\text{co}} = f_2(L_j^{\text{co}}, PK_j^{\text{co}}, HK_{ij}), \quad (5b)$$

where

$y$  = quantity of output;

$L$  = labor input;

$PK$  = input of physical capital;

$HK_i$  = vector of human capital characteristics ( $i = 1, \dots, m$ )

and where the superscripts cr and co denote creative and commercial artistic production, respectively.

In the empirical estimation of Equations (5a) and (5b), we measure creative and commercial output in value terms as the gross revenue from the sale of goods and services of a creative or commercial (arts-related) nature respectively in the survey year (\$A'000). The labor inputs are the average hours per week worked by the artist at creative and commercial artwork, respectively. Physical capital input is measured as art-related expenses incurred in the year of the survey; note that this figure was available only for creative output, so the expenses variable is omitted from the commercial output equation. The components of  $HK_i$  ( $i = 1, \dots, 4$ ) are the artist's years of arts training; age (as a proxy for experience); level of general education (measured as a dummy variable where post-secondary education completed = 1, zero otherwise); and the creativity index as derived above.

Equations (5a) and (5b) were first estimated by OLS, but because of non-normality in residuals and the presence of heteroscedasticity they were re-estimated by generalized least squares, a satisfactory procedure given that we are interested in the relative size and significance of coefficients rather than in using the fitted equations for prediction. Table 3 gives the results. We note in passing that labor and operating capital are significant inputs in producing creative output, and that labor and to a lesser (non-significant) extent arts training have a positive effect on commercial output. However, our interest

<sup>13</sup> Note that the creativity measure used here differs slightly from that used in Throsby (2006).

Table 3  
Determinants of the creative and commercial output of Australian artists,  
2000–2001

Explanatory variable	Creative output <sup>a</sup>	Commercial output <sup>b</sup>
Constant	−0.616 (−0.53)	7.669** (5.08)
Labor time <sup>c</sup>	0.311** (3.81)	0.682** (7.56)
Operating capital <sup>c</sup>	0.814** (14.73)	–
Human capital 1: general education	−0.097 (−0.71)	0.136 (0.68)
Human capital 2: arts training <sup>c</sup>	−0.326** (−3.79)	0.194 (1.49)
Human capital 3: experience <sup>c</sup>	0.400 (1.49)	−0.225 (−0.60)
Human capital 4: creative talent	0.196** (3.06)	0.063 (0.73)
<i>n</i>	424	192
<i>F</i>	57.058	13.155
Adjusted <i>R</i> <sup>2</sup>	0.443	0.241

Artists included are writers, visual artists, craftspeople and composers; all logs are natural logs; t-statistics shown in parentheses; coefficients significantly different from zero at 1 percent (\*\*) level; both equations estimated by generalized least squares.

<sup>a</sup>Dependent variable is log of value of creative artwork produced.

<sup>b</sup>Dependent variable is log of value of commercial (art-related) work produced.

<sup>c</sup>Variable measured in logs.

here is in creativity. The creativity variable shows up as a positive and very significant influence on creative output, and is indeed the only one of the four human capital variables specified in the model to have such a positive effect.<sup>14</sup> On the other hand, creativity has a negligible and insignificant effect on the output of commercial artistic work. These results are consistent with the primary hypothesis put forward above.

Although this analysis is very crude, it does at least suggest, as we remarked earlier, that creativity in the arts, for all its elusive and protean quality, can be systematically studied and that results can be obtained which provide plausible insights into the contribution that creative talent makes to the production of artistic output.

<sup>14</sup> The negative influence of arts training on creative output is difficult to explain, even though it is more than offset in quantitative terms by the positive (though non-significant) influence of experience.

## 8. Conclusions

Creativity remains an elusive phenomenon. This chapter has pointed to some of the ways in which social scientists have attempted to pin down that elusiveness and propose testable theories about how creativity arises and how it asserts itself in decision-making. We have noted that creativity as such has not received much attention in economics; even economists working in fields such as R & D and technological change, where creativity would seem to be especially important, have tended to regard it as a 'black box' whose contents are best left undisturbed. Yet in the economics of arts and culture, the prominence of creativity as an element in artistic production would seem to suggest that ignoring it is likely to compromise the explanatory power of models purporting to represent artistic behavior.

We have suggested in this chapter that some progress can be made, both theoretically and empirically, if creativity can be brought more directly into analysis of artistic decision-making. Clearly work in this area is still at a formative stage, and many avenues exist for carrying the study of the economics of creativity in the arts forward. In this process a number of opportunities would seem to present themselves for economists to cooperate with creativity specialists in other disciplines, notably in psychology. Creativity is indeed a field which would seem to be an ideal one for cross-disciplinary research in the future.

## Abstract

The organization of the creative (arts and entertainment) industries rests on many types of contracts. These contracts govern collaborations between artists and other parties – at arm’s length, or within an enterprise. These contracts’ structures devolve from a few bedrock properties of creative work and creative products. Artists invest in developing their talents, presenting themselves before ‘gatekeepers’ who seek talents that can profitably be developed and marketed. Gatekeepers commonly function as agents for selecting artists and as match-makers between artists and complementary inputs. As an extension of the gatekeeping function, the participants in creative industries take part in a continuous ranking process that sets and revises the ranks of vertically differentiated talents. Real option contracts pervasively govern the sequential steps of developing a creative product. These can leave the artist an autonomous creative agent (pop musicians and record labels) or enclose artists’ talents in an employment relationship (classic Hollywood studios). The transformation of the movie industry to ‘flexible specialization’ illustrates how changing basic conditions can transform the dominant form of organization. The scales of enterprise in the creative industries tend to be driven by the efficient scales with which creative goods are distributed (very large for record labels and movie studios, small for art galleries), and they tend to assort themselves into those focused on the distribution of creative goods (‘promoters’) and those concerned with identifying and nurturing creative talents (‘pickers’). Large enterprises also include the ‘entertainment conglomerates’ which seek synergistic gains that depend theoretically on quite special conditions; foreclosure and its avoidance may be principal motives. Non-profit enterprises dominate a number of arts activities, apparently for two interrelated reasons. These activities incur high fixed but low marginal costs, pressing them to employ two-part prices and club arrangements to ensure fixed costs’ coverage. When product quality is endogenous, however, non-profit status may be necessary for the manager credibly to forewear degrading quality once the fixed payment is in hand. Non-profits supported by donation streams thus enjoy functional advantages.

## 1. Introduction: Organization and contracts in creative industries

The field of industrial organization is divided into two branches. The more traditional branch is concerned with how the structures of markets and the behavior conditioned by those structures affect their allocative efficiency. The second branch addresses the question of why markets are organized the way they are. This latter pathway proves highly inviting for study of the arts and entertainment industries, because they pose a richer array of questions about the logic of organizations than do most other sectors. Consider the task of explaining an industry's organization. Any unitary transaction can be carried on between independent firms, with competition among buyers and sellers determining the market's price and quantity. Or transactions can be bundled inside of firms, with quantities determined by administrative decisions. Theory identifies the strengths and weaknesses associated with each mode of organization. Empirical investigators commonly assume that the most effective mode of organization prevails by means of Darwinian survival, then test the match between theoretically predicted and empirically observed organizational choices.

This approach to the organization of industry, originated by [Ronald Coase \(1937\)](#) and [Oliver Williamson \(1985\)](#), has lately been much enriched by research on the theory of contracts. The alternative to internalizing decisions within the firm is to govern them by means of arm's-length contracts between independent agents. Williamson emphasized the hazards to which arm's-length contracts are subject as the key to understanding why decisions are internalized within the firm. Many arm's-length contracts, formal and informal, nonetheless persist. Moreover allocative decisions made within the firm do not automatically escape the shortcomings of contracts. Indeed they are governed by incentive contracts that ply various carrots and sticks in order to influence employees' actions. The firm is a "nexus of contracts", and the success of internalization depends on the performance of arm's-length contracts relative not to "administrative decisions" but rather to the efficacy of contracts drawn and implemented within the firm. In Darwinian fashion we expect the whole set of prevailing arrangements (extent of internalization, organization of firms, structures of arm's-length contracts) to reflect the relative efficiency of arm's-length and internal contractual dealings.

The arts and entertainment industries (hereafter "creative industries") provide an attractive site for applying this approach because they employ distinctive types of deals and intra-firm governance arrangements. While the volume of quantitative research on these organizational arrangements is small, a great deal of casual evidence exists, especially for the United States. When casual observation confirms the prevalence of a practice with a clear and apposite theoretical rationale, the news is worth reporting even where the niceties of controlled experiments and statistical inference remain out of reach.<sup>1</sup> Deciding when a theoretical model pertains to an empirical situation is, of

<sup>1</sup> Much of the theoretical analysis in this paper was set forth in [Caves \(2000\)](#), though some points get fuller development here. That study also assembled a good deal of diffuse empirical evidence that will not be cited or repeated here.

course, a tricky step on which judgments may differ, and researchers ought to leave their tracks uncovered. We take what can pretentiously be labeled an axiomatic approach, laying out some properties that seem common to all creative industries, or to some substantial and specific group of them. These properties were established inductively from a broad body of mostly descriptive evidence, but also with the guidance of the structure-conduct-performance paradigm that informs much empirical research on industrial organization. Thus these properties are hypothesized to be the “bedrock” elements of market structure based in tastes and technologies that determine important but endogenous aspects of structure – the organization of contracts and less formal deals, and the number, sizes, and activity sets of firms.

Creative industries combine inputs from various types of artists with other inputs to turn out some creative good or service intended for consumers’ enjoyment. This production process may involve nothing more than the marketing of the artist’s creation (the visual arts, for example), or it may entail substantial further manufacture (book publishing, music recording). Whether simple or complex, this activity is conditioned by two axiomatic properties. The first, *art for art’s sake*, holds that artists’ utility functions commonly contain two features that strongly affect their participation in contractual economic relationships. The first is a taste for undertaking artistic work for its own sake, which depresses the supply price for the artist’s services below the pecuniary compensation expected from the artist’s best alternative (non-creative) job. The second is preferences as to how the artistic task should be executed. The widely accepted nineteenth-century romantic view holds that the artist creates from inner necessity in order to realize some internal vision.<sup>2</sup> While the artist’s low supply price facilitates in an obvious sense her cooperation with other inputs in a production process, the existence of tastes defined over the mode of production complicates the artist’s contractual participation in a complex creative activity. If the exercise of preferences about the creative process were contractible, they could be traded off against pecuniary compensation in a mutually agreed manner. When they cannot be specified and contracted upon, and when the creative urge also refuses to respect time constraints or commitments, the completeness of contracts between artists and other inputs and on the subsequent governance of such contracts is substantially limited. (We refer to non-artistic inputs lacking these tastes as “humdrum”.)

Another property that we impute to products with substantial creative inputs is great uncertainty about buyers’ reservation prices for any creative output; this uncertainty persists until all costs have been incurred and the finished output placed before them. This property is widely recognized in entertainment industries, where large sunk costs give rise to highly uncertain returns, by the slogan *nobody knows anything* [Goldman (1984)]. The force of this property depends on the interaction of its two conditions – the sunkness of costs and the uncertainty of the output’s market value. When net revenue depends heavily on distinguishing good from bad projects *ex ante*, great effort is

<sup>2</sup> Studies of the training of art and music students show that these imperatives are built into the curricula and absorbed into students’ attitudes. See Getzels and Csikszentmihalyi (1976) and Kingsbury (1988).

devoted to forecasting these outcomes by decision-makers who have invested heavily in knowledge about what failed and succeeded in the past. The *nobody knows* proposition is consistent with costly investments in forecasting by decision-makers who understand the wide variance around their point forecasts: a small improvement in the likelihood of distinguishing correctly between good and bad projects is worth a lot. Also pervasive in creative industries is the property of horizontal differentiation, associated with creative goods that seek uniqueness within sets of conventions that make many of them close substitutes for one another. We can call this property *infinite variety*. The closeness of substitution as an axiomatic property pertains to potential varieties of a creative good. Where it pertains to actual varieties depends on the incidence of fixed costs per variety relative to consumers' combined willingness to pay (overall, and for preferred varieties).<sup>3</sup>

Other axiomatic properties pertain to complex creative activities that require inputs from a number of suppliers each with *art-for-art's-sake* preferences. The resistance of artists to contractual commitments specifying their creative work complicates the organization of activities that demand the collaboration of several artists' inputs (along with humdrum inputs) – a *motley crew* of creative inputs. Creative inputs of any given type are differentiated vertically, that is, all agree that one artist's talent excels another's overall, although the better talent may not be worth its higher wage in every project. Artists' rankings are determined empirically in a costly consensus-based evaluation process involving the vertically differentiated artists themselves as well as others who employ, supervise or collaborate with them. This is the *A-list/B-list* property. It is closely related to another: that the ultimately perceived quality of a complex creative good tends to depend on each creative input performing at least up to some threshold level of competence. A handy way to represent this property is by means of a multiplicative production function: the failure or substandard performance of any input renders the project's whole output valueless. This is the *O-rings* property [Kremer (1993)]. Finally, the efficient execution of complex creative activities requires the close temporal coordination of key artistic and humdrum inputs, and this requirement complicates both the initial contracting and subsequent coordination of such projects (the *time flies* property).

## 2. Simple creative goods

Simple creative activities involve a single artist (source of creative input) dealing with one agent or enterprise that combines the artist's input with humdrum inputs and distributes (perhaps through intermediaries) the creative good to consumers. This seemingly simple relationship raises several major issues of organizational choice. First, would-be artists offering their talents to the market appear to be in chronic excess supply, so that the distributor assumes the role of a gatekeeper, selecting some but turning many

<sup>3</sup> On the determinants of the equilibrium number of units of creative goods on the market, see Baker (1991).

others away. Second, creative and humdrum inputs could be combined in several organizational settings. The humdrum entrepreneur might represent the artist or take part in a joint venture to develop and distribute the artist's product (talent), or the entrepreneur might hire the artist and assume decision rights over her creative activities. Third, the physical location of creative activities is subject to agglomerative pulls that depend in turn on how the dealings between the artist and humdrum inputs are organized and governed.

### 2.1. *Supply and returns on investment*<sup>4</sup>

We suppose that the artist seeks representation and employment upon completion of training or apprenticeship. The training process itself takes the would-be artist before a series of gatekeepers. As in other tournaments, the would-be artist competes at first with a random assortment of local aspirants. Success at the first stage brings the candidate into competition with others who have survived a first round. This series of elimination rounds proceeds through elementary and advanced training and continues through apprenticeship and the quest for commercial success. For the would-be artist the pursuit involves a series of investment decisions made under great uncertainty. While positive local certification is more informative than none, its value for predicting success in subsequent rounds is very low. That is partly because the proportion of initial contestants who achieve some ultimate success is tiny, partly because a student/apprentice's ability to benefit from additional training, conditional on the certification already attained, is not accurately predictable.

The apprentice artist's investment in training eventually realizes some rate of return, which we can think of as becoming known when she faces a commercial gatekeeper. The gatekeeper seeks to judge whether suitable humdrum inputs combined with the artist's developed talent will create enough value to cover their opportunity cost. Gatekeepers will on average do no better than covering their opportunity costs if gatekeeping is a competitive trade. What reward will flow to the artist, though, depends not only on the competitiveness of gatekeepers but also on the correlation of their *ex ante* assessments of the proffered talents. The artist's gross return to her talent is learned only after a contract is reached with the gatekeeper (or other partner) and the market's ultimate assessment realized. Because training and apprenticeship costs are sunk, these realized rates of return will fall into three ranges. First, some contenders get the nod from no commercial gatekeeper; their investments are clearly lost (aside from future consumption benefits). Second, the more successful apprentices admitted by the gatekeeper find that the market's willingness to pay for their talents will yield a positive return on their investment after the competitive gatekeeping enterprise has taken its normal profit. Third, the less successful contestants realize returns that cover the gatekeeper's opportunity cost but

<sup>4</sup> For further discussion of issues raised in this section, see Chapter 22 by Menger and Chapter 24 by Towse in this volume.

yield a rent on the artist's talent insufficient to produce a positive return on her sunk investment in training.

Do all would-be artists, taking the successful and the unsuccessful together, earn a normal return on their training investments? No hard data exist, but the enormous ratios of arts students graduated from U.S. colleges to professionals entering successfully into careers in a given year make it seem highly unlikely. How should we interpret this behavior and the apparent misallocation of resources that results? A high level of expected utility from purely consumption benefits of training is one factor that helps to rationalize the pattern. Another interpretation invokes a form of risk-loving behavior embodied in the attitude that a high level of creative success yields untold riches in utility (beyond that due to the cash takings). However, the budding artist is poorly positioned to make a rational decision about expected returns to training. The romantic conception of the artist's calling encourages the student to regard talent as a god-given asset that deserves unstinting dedication and effort. Furthermore, the teacher who faces the task of sustaining the student's motivation through years of arduous training and practice has every incentive to emphasize the glory of artistic greatness once achieved, and none to mention the paltry chances of achieving it [Towse (1993)].

## 2.2. Organizing supply of creative goods

The gatekeeping process rations and allocates the humdrum resources available to supplement the artist's input, but it does not dictate the organization of the process, which can take several forms. Consider for concreteness the visual artist whose work requires humdrum assistance to distribute and promote it. The artist could become an employee in a humdrum enterprise, producing works of art at the manager's direction under a conventional employment contract. The artist could prepare works sprung from her own inspiration, to be sold (off the park fence on Sunday morning?) piecemeal to whatever dealer takes a fancy to them. Finally, the artist could be represented by a single gallery on the basis of an exclusive-dealing arrangement.

The last arrangement clearly prevails for simple creative goods – between visual artist and gallery owner, between pop musician (group) and record label, between soloist in classical music and impresario, between author and publisher. Why is this so? Continue with the visual artist. In the context of the romantic ideal, artist, consumers, and intermediaries and certifiers (teachers, critics) agree that what matters is the artist's ability to create a sustained body of work that cumulates to a lifetime career. This requires that both the artist and the distributor of her work undertake many actions that amount to investments for long-run returns. The artist develops a body of work that will sustain periodic shows in the art gallery. The gallery operator interprets the work and promotes it to collectors, museum curators, critics, and periodicals, and lends works for shows in museums and other galleries, etc. Maximizing the value of this joint venture to develop the artist's career requires each party to undertake these actions to optimal degrees. For this arrangement to beat out other ways to organize distribution of the artist's work, it must be consistent with *art-for-art's-sake* tastes, which it clearly is. Artist and dealer

must be able to govern their relationship through explicit or implicit contracts. Formally, the dice are loaded against anything approaching a complete contract, which would require long-term commitments by both parties to ideal courses of action that are largely unknown in advance (dependent on random opportunities), incapable of formal contract and not practicably monitored by the parties even if contractible.

The arrangements prevailing in practice are simple (often handshake) contracts that divide gross revenues from sale of the artist's work between the two parties after certain costs are allocated to each. This contract falls short of an ideal incentive structure, which would require that each party exert effort up to the point where the last dollar's worth of effort adds just one dollar to the joint benefit. In practice the actual incentive for effort is weaker: each party expends effort only to the point where the last dollar's worth of effort adds another dollar to its share of the joint benefit. Categories of purchased inputs that are made one party's responsibility are likewise underfunded. However, any cost that is one party's responsibility, though reimbursed before revenues are divided, will be undertaken to the optimal degree (an action that maximizes revenue net of these assigned costs also maximizes either partner's fractional share of this revenue). Lacking a specific duration, these contracts run until either party chooses to end them, for example, when the artist's style changes in a way that eludes the dealer's sympathy. Reputation plays an important role in supporting the enforcement of the implicit terms, but contract failures do occur (for example, when the artist sells directly to collectors without compensating the dealer, or the dealer fails to report sales and make the associated payment to the artist). Evidently the contracts in these joint-venture type arrangements work well enough to dominate any fundamentally different organization of the distribution of visual art.<sup>5</sup>

The joint-venture types of contracts in the creative industries bear a relationship to the theoretical literature on incomplete contracts. The alignment appears neither neat nor simple, however, so we shall only point to some promising connections.<sup>6</sup> The first of these lies in the theoretical assumption that both parties to a relationship can observe and agree on the outcome of a transaction (or the quality of an input or state of nature that is occurring), but they cannot convey their understanding to a third party such as a court enforcing a contract. The assumption comports well with *art for art's sake* and other core properties of creative activities. The conditions in question are "observable but not verifiable". Under some circumstances – such as where the parties can observe each others' investments in the joint enterprise or the quality of intermediate inputs supplied – a first-best contract can still be sustained. Under others, only second-best is sustainable. The second assumption is that no asymmetry of information exists between the primary parties to the transaction. They possess the same information about actions

<sup>5</sup> A particularly interesting historical experience with the organization of the visual arts is the transformation of the French market around the time of Impressionism. An era of state certification through official salons gave way to a "dealer-critic" system of private certification and marketing. See White and White (1993), Jensen (1994), and Wijnberg and Gemser (2000).

<sup>6</sup> For background, see Hart (1989).

(investments) that either party has taken and the resulting quality of a product or level of its variable cost. Rather paradoxically this assumption aligns with the *nobody knows* property: the uncertainty around the values each party observes is great, but there is no general reason to expect one's accuracy or bias to differ from the other's. With this set-up, the theory of incomplete contracts may prove able to explain some empirical aspects of joint ventures in the creative industries: why they might contract on one variable (for example, a movie's screenplay and key actors) rather than another (the quality of the resulting film). It may also explain why one party reserves the right to decline to purchase a creative good (for example, the studio that chooses not to release a completed film), an action that both parties recognized as a possible outcome of their contract. Finally, the literature on incomplete contracts gives much attention to the possibility of renegotiation – think of the buyer's refusal to pay the agreed price for a finished good [Hart and Moore (1999)]. The creative industries illustrate the reputation mechanisms that so often seem effective for punishing those who violate understandings even where formal contracts and courts are not involved.

### 2.3. Prevalence of option contracts

The visual art market makes clear that the viability of an organizational structure compatible with *art-for-art's-sake* preferences depends on congenial long-term contracts and mechanisms that make them sustainable with only the lightest degree of formalization. Other arts and entertainment sectors depend on more formal contracts with distinctive recurring features. As in the visual art market, the creative product originates from some talent of the individual artist. It then goes through one or more steps (processes, transactions) before reaching the final consumer. The *nobody knows* property points to the great uncertainty about the ultimate reception of this product, both early and late in this series of fabrication stages. Because the right decision about fabricating a creative product can sometimes realize so much more value than a wrong decision, the participants find it worth investigating omens of successful or failure even if their information content is small. The incentive to make this investment in information and adapt to its message is at its maximum for the party next in line in the fabrication sequence to sink still-fungible resources into the project. Another key property is that inputs incorporated at any stage in the process (whether of creative or humdrum origin) are entirely sunk. With the input sunk, its supplier generally can make no further contribution to the value of the product; she might be asked for a rewrite (or the equivalent) when a partially completed project is judged to have gone off the rails, but that entails an additional contribution of resources and any allotment of decision rights tied to it. In general, the input sequence does not “cycle back”.

To focus incentives efficiently, a contract governing such a processing sequence should allocate decision rights in a way consistent with the parties' opportunities to affect the final product's value. That is exactly the property of the real option contracts in widespread use among creative industries. Consider the deal between an artist (screenwriter with a completed script, for example) and an agent able to supply the next round

of inputs to the process (film producer). The option contract between them has these features:

- The producer gets a period of time (six months perhaps) in which to investigate the possibility of filming the writer's screenplay. This investigation period may be renewable.
- Writer and producer agree on the full terms under which the writer will be compensated if the producer decides to purchase the script and make the film. Rights to modify and adapt the screenplay now pass to the producer.
- The writer is compensated for giving the option (forgoing other opportunities until the option runs out), often receiving a fraction of the agreed purchase price (the option payment likely credits against the purchase price if the option is exercised).

This contract provides an efficient structure of incentives because it respects the sunkness of previously installed inputs in the creative good's production process and assigns decision rights to the party poised to decide whether and how to continue fabrication. However it does carry an odor of unfairness to the artist who supplies the initial and often defining input to the product, only to see decision rights about its subsequent fate pass to the hands of humdrum decision makers. This violates *art for art's sake* in the sense of putting the realization of the artist's conception in the control of other parties. The artist can bargain to retain decision rights, of course, as when a film director retains the right of "first cut" – assembling the raw film into a completed motion picture. However retaining decision rights over subsequent steps likely costs the artist dearly. That is because it conveys an unlimited opportunity to hold up collaborators deciding how to proceed subsequently with the project, unless the scope of the retained decision power can be clearly delineated (as with first cut).<sup>7</sup>

The most apposite theoretical analysis of this option contract appears to be Nöldeke and Schmidt (1998), who addressed alternative ownership arrangements for a project that involves sequential production processes undertaken in turn by parties *A* and *B*. Suppose that *B* holds an option to buy the project after *A* has sunk his investment but before the resulting surplus is realized. *B*'s reservation value for the project increases with *A*'s investment (effort). This provision strengthens *A*'s incentive to invest, because underinvestment will deter *B* from exercising his option. But *A* also does not overinvest, because *B* becomes the owner of the firm and captures most of the benefit of any excess in *A*'s investment. If *B*'s ownership is sufficient to induce efficient investment by *B*, then the overall contract is first-best.

Other terms of contracts used in creative industries have related incentive and efficiency properties. Consider the advance against royalties commonly paid by publisher

<sup>7</sup> A few demonstrations can be found of trade-off between *art-for-art's-sake* preferences and the terms of financing creative work. Fee (2002) compared films financed by the major studio distributors ("production-finance-distribution deals") to those financed independently by foreign distributors, personal funds, etc. Securing independent financing is a considerable burden for the filmmaker, but leaves her creative control intact. Fee hypothesized and confirmed that films would be financed independently when the film-maker's *art-for-art's-sake* tastes were particularly strong. This he proxied by situations in which producer, director, and screenwriter are all the same person.

to author or record label to pop musician. The royalties subject to the advance implement a sharing of expected net revenues from the project between (say) publisher and author. However the royalty is literally based on sales revenue, so the publisher faces an impaired incentive to make promotional outlays that “buy” additional sales revenue that flows partly into the author’s pocket.<sup>8</sup> A royalty is traditionally regarded as working capital to provide the impecunious author with bread while the creative throes proceed. However it has an important incentive property for the publisher. Until the advance is earned back from realized net revenue, the publisher retains the whole of the profit dollar elicited by its effort to promote the author’s work. Since the publisher’s promotional decisions typically matter more for the work’s profitability than any contribution the author can make post-publication (e.g., book-signing sessions, appearing on TV talk shows), the advance improves the efficiency of the contract.<sup>9</sup>

The advance figures distinctively in contracts between pop musicians and record labels because it not only anticipates royalties on the record but also covers the musician’s cost of recording the master tape – a substantial outlay when the musician favors elaborate electronic procedures that require costly studio facilities. The musician, prone to perfectionism (*art for art’s sake*), thereby gains a pecuniary incentive to make efficient rather than excessive use of studio time. The incentive may not work as intended, though, on a risk-loving musician prone to bet all available resources on the chance of a gigantic success.<sup>10</sup>

#### 2.4. Agents and matchmakers

The artist–gatekeeper relationship frequently involves an agent who mediates between artists and the enterprises that realize the market value of their creations. These intermediaries perform several services, depending on the creative sector. One is matchmaking between artists with heterogeneous talents and creative enterprises with diverse capabilities and input needs. Another is negotiating terms between artist and gatekeeper. As a third, the agent himself functions as a gatekeeper when he selects artists to represent.

The service ostensibly provided by the agent is to represent the artist (author, say) to enterprises that might bring her work to market (publishers). This representation function is governed by an incentive contract that compensates the agent with a share (traditionally 10 percent but with upward perturbations) of the artist’s gross earnings.

<sup>8</sup> Record labels rectify this incentive by charging some promotional expenses against the artist’s royalties, which indeed induces the label to undertake excessive promotion (the artist pays, while label and artist share the additional gross revenue).

<sup>9</sup> Hansmann and Kraakman (1992) developed some related propositions about the efficiency of contracts carrying an advance; they can deter the publisher from opportunistically declining a manuscript when (bad) fresh news arrives at a later stage in the publishing sequence.

<sup>10</sup> Another distinctive feature of popular-music contracts is the incorporation of a series of “cheats” whereby the musician’s contractual royalty percentage is nibbled away by costs (including wholly artificial ones) charged against royalties. Industry observers [Passman (1994)] conjecture that musicians gain utility from the right to brag of a high royalty rate, implicitly agreeing to its dilution.

This contract (including the 10 percent figure) was established in the nineteenth century at the inception of the agency business, quickly displacing a fee-for-services contract because of authorial poverty as well as its incentive value [Hepburn (1968)]. Besides representation, however, the agent performs a gatekeeping service that would otherwise fall entirely on the publisher. The agent can profitably undertake to represent an author only if the time (effort) devoted to seeking an outlet for her work is expected to reap sufficient compensation from the resulting royalties. The agent may also invest time (effort) in editing and improving the author's work, to the point where a publishing-house editor can appreciate its potential. Now consider the dealings that occur between established agents and editors employed by publishing houses. They interact repeatedly, which increases the editor's credence in an agent's pitch on its his author's behalf. The credence due to their repeated interactions is supported by the editor's inference that the agent will suffer a pecuniary loss from devoting effort to an author of indifferent promise – a substantial up-front opportunity cost with poor long-run prospects for compensation. For the publisher, relying on agents' representations (their gatekeeping skills and quality signals) substitutes for dependence on what can be picked from the "slush pile" of unsolicited manuscripts. That is likely a less efficient matchmaking procedure because the publisher pondering an unchaperoned manuscript lacks the information that the agent draws from personal contact with the author.

While the agent's gatekeeping and representation functions benefit the publisher, the agent's skill at negotiating on the author's behalf is adversary. Publishers offer somewhat differentiated bundles of services, but none capable of generating substantial rents. The author's unique manuscript is the one input into the publication venture with rent-yielding potential. Thus over the years the publisher's one-time share of subsidiary rights for paperback, cinema film, and other such derivative products has eroded, as the agent representing the author came to pre-empt the publisher and take over the auctioning of subsidiary rights. The publisher's gains from the agent's gatekeeping function thus trade against the publisher's reduced share of rents from subsidiary rights.<sup>11</sup>

Akin to the gatekeeping role of agents is the function of certifiers who possess or invest in skills at making fine judgments on the quality of artists or their works. Theoretical research has recently turned to characterizing the market for certifiers' services, including the vertical differentiation of their services [Hvide and Heifetz (2001)]. The critic's economic function in creative industries has not been much studied, but on casual evidence seems to possess some analytically interesting features. Major acquisitions of visual art excepted, the individual's decision to consume a creative good is too small a transaction to warrant a large outlay on an advisor's services.<sup>12</sup> So critical opinion is commonly bundled into magazines or newspapers along with complementary

<sup>11</sup> The hard-back publisher's one-time substantial share of subsidiary-rights income clearly had an incentive value for the publisher's promotional efforts. Apparently authors (and agents) have adjudged the value to them of that incentive to be less than their gains from redistributing the rent stream.

<sup>12</sup> Large investments may be made in personal search and inspection, however. It is no doubt difficult for the consumer to convey her tastes to the advisor.

sorts of information. The amount of criticism supplied then depends on its marginal attraction to consumers of the bundle relative to their marginal valuations of other content. Critical services seem subject to vertical differentiation parallel to the differentiated involvement of consumers in various arts and entertainment industries. That is, the utility one gets from consuming creative goods increases with one's accumulated "cultural consumption capital" – built up from previous experience and both specialized and general training [Stigler and Becker (1977)]. Individuals vary in both aptitude and desire for building such stocks of consumption capital. As a result they tend to distribute themselves between the poles of "buff" and "casual" in their involvement. The judgments offered by critics and certifiers tend to display a parallel vertical differentiation, with reasoned and contextualized evaluations provided for the buffs, while the critic servicing the casuals tends to internalize their standards and opine whether or not they will like the work.

### 2.5. Agency and intermediation

Several unanswered analytical questions bear on how the agent's function is organized. The agent's primary function is analogous to intermediation or job-matching. A good deal of research has been done on the theory of intermediation.<sup>13</sup> It focuses on the factors giving the intermediary a productivity advantage over search by the individual primary sellers and buyers. It also addresses the determinants of the intermediaries' price-cost margin, which include their number and mode of competition with one another. In this literature the productivity of intermediation stems from transaction-cost advantages, inventory-holding advantages, and/or advantages in ascertaining quality and warding off adverse selection [for example, Biglaiser (1993)]. Unfortunately, none of this agrees very well with what seem the basic properties of matchmaking in the creative industries. Because *nobody knows*, impacted information seems not to be a problem, although collecting information in order to match the attributes of heterogeneous buyers and sellers involves significant costs. Also, explaining the equilibrium market price of the agents' services cedes place to the problem of explaining why a long-established revenue-sharing arrangement between agent and artist-client should seem conventionalized and immune to supply and demand disturbances. Consequently the following theoretical propositions are advanced tentatively.

Suppose that authors are to be matched to publishers. Members of each group possess a given set of differentiated attributes that are objective and can be determined at a cost by another party (no hidden information). Assume that the value created by pairing any author and publisher depends on the attributes of the two together. Assume that some optimal allocation of authors to publishers exists and can be calculated by any agent who has acquired information on every candidate party's attributes. Because the parties' haggling over terms holds no special interest, we assume that each author's outside

<sup>13</sup> Spulber (1999) provided a survey.

reservation price is zero, and that matched parties always reach a Nash bargaining solution. In these conditions the agent's matchmaking advantage is a natural monopoly: the attributes of each author and publisher need be collected but once by the agent who determines the optimal allocation, while decentralized match-making requires repeated collection of the same information. The gain from a central agent might be compromised by bounded rationality or its temporal equivalent – costs of delay while a central agent collects and processes all parties' information. Any such source of diminishing returns will tend to increase the number of agents and make the equilibrium population of agents an increasing function of the numbers of authors and publishers to be matched and the cost of gathering information from each. The average quality of the matches of course declines.<sup>14</sup>

It can matter who employs the match-making agent. If authors and publishers were like right and left shoes, the agent could simply enter the market as an entrepreneur, purchasing isolated rights and lefts, matching them and reselling pairs at a profit. Where units of human capital are being matched, this procedure clearly fails, and some party must recruit the agent and serve as principal in a governance relationship. This need for governance seems to inject an intrinsic asymmetry into the agent's activities. Can the agent work at random for parties on either side of the market? At first glance that arrangement seems viable but it is probably not. The marriage broker representing both brides and grooms has an incentive to provide a groom with a bride on his representation list, which need not maximize benefit to the groom (or the couple together). The agent negotiating a dowry incurs a clear conflict of interest if he represents both parties. Even without these governance problems, economies of specialization call for the agent to work for parties on only one side of the market. That being the case, we can ask what asymmetries or differences between the types of entities to be matched affect the question as to which of them more efficiently takes on the task of employing and monitoring the agent.

Let us return this question to the context of author and publisher. Suppose that publishers' attributes and policies are readily inferred from their backlists and reputations with authors for capability and integrity; authors' qualities on the other hand are more costly to identify. If the transacting parties on one side of the deal are represented by agents who pool information and economize on its transfer to the other side, pooling the more costly assessments of authors and their manuscripts beats pooling the less costly assessments of publishers' traits on behalf of authors. The same logic applies to the differential importance or value of the information to the other side. A publisher loses heavily if a celebrity author's book flops, but the celebrity might be nearly indifferent about which of several mainline trade publishers issues the book. Intensive collection of information about authors is then more valuable and lays claim to the agent's services, and the collection of information about publishers gets left to individual authors.

<sup>14</sup> The effect of costs of gathering information should depend on whether agents can segment the market's population and avoid duplicating collection costs.

Other influences also weigh in. Suppose that it costs the same for a publisher to size up a prospective author as for the author to evaluate a prospective publisher. Even after the gatekeeping agents have swept out the losers, the authors remain more numerous than the publishers (think of each house serving as exclusive publisher to a number of authors). If agents are to pool information on one side of the market only, they should pick the more numerous authors, thereby consolidating more information than if they represented the less numerous publishers.<sup>15</sup> The agent's gatekeeping function, which excludes many authors, is really a special case of this "differential numbers" effect.

Only descriptive information is available to provide empirical evidence on these predictions. Natural-monopoly tendencies were evident long ago in the booking of variety and vaudeville acts into local theaters [Poggi (1968, pp. 11–26); Sanjek and Sanjek (1991, Chapters 2, 3)]. The booking of big bands in the United States during the 1920s through 1940s provides a particularly interesting case because it illustrates the factors that served to cast up a near-monopoly intermediary, Music Corporation of America (MCA), to undertake the matching of bands to venues. Its dominance was owed, however, not so much to scale economies in matching as to two other factors: scale economies in managing bands' travel arrangements, and the credence value of a large organization with substantial fixed assets for ensuring the intermediary's responsibility in adhering to contracts and remitting payments [Walker (1964, Section 2, Chapter 5); Stowe (1994, pp. 103–106)]. MCA may also have benefited from forcing exclusive dealing on venue operators, requiring them to book only MCA bands if they obtained any of them [McDougal (1998, pp. 108, 128, 224)]. Finally, descriptions of the internal operations of large Hollywood agencies such as Creative Artists Agency (CAA) show that their individual agents work for limited numbers of artists, consistent with the hypothesis of size limits stemming from individual agents' bounded rationality and time costs. Scale economies stem importantly from the unfettered exchange of information among agents working for the same firm and the opportunity to assemble projects as packages of the various talents represented by a given agency [Slater (1997)].

## 2.6. Internal organization of gatekeeping firms

The gatekeeping process influences the internal organization of firms in creative industries because the gatekeeper (subject to the top manager's review) selects the projects undertaken by the firm and thereby makes its fundamental investment decisions. While the gatekeeper's primary qualifications presumably lie in detecting the potential of the artist's talent and perhaps working with the artist to ripen its fruits, the task of implementing the firm's investment decisions implies a wider scope for both responsibilities and incentives. An efficient compensation scheme will reward the gatekeeper for a good pick and penalize a bad one. The decision-maker responsible for selecting a project

<sup>15</sup> We neglect the plausible outcome of specialized agents on both sides of the market: plaintiffs' attorneys and defendants' attorneys.

therefore has an interest in the proficient performance of the subsequent processing steps that will affect the venture's final profitability. The implications of this organizational logic have worked themselves out in the U.S. publishing industry in modern times. The editor who performs the gatekeeping function was once just that – the party responsible for selecting the manuscript and polishing it to lapidary perfection. Promotional campaigns for books with the potential for wide popularity (“blockbusters”) have emerged as a central function of the publishing house, so the payout of the editor's pick becomes heavily dependent on the prowess of the promotional campaign, which therefore logically displaces copy-editing as the editor's primary entrepreneurial task [Whitesides (1981)]. Editors' compensation does not seem closely related to projects' profitability (as it might be for a sales representative or securities trader). However successful editors do realize important rewards (such as boutique labels of their own), and those who pick a run of unsuccessful projects can expect to be seeking new opportunities. Their counterparts in some other creative industries – motion-picture and Broadway stage producers, for example – receive explicit profit shares of successful ventures while being largely protected from the pecuniary downside of a failed project. That asymmetrical form of incentive compensation is likely optimal when the gatekeeper is risk-averse and the project's success highly uncertain even after the gatekeeper's best entrepreneurial efforts.

The logic of the gatekeeper's function – as editor, record-label talent scout, movie producer, etc. – also implies something about the external contacts of these persons and their mobility among firms in a creative industry. These patterns were first noticed by sociologists interested in the communication that occurs among skilled project-runners employed in different firms [Rogers and Larsen (1964); Powell (1985)]. Economists commonly assume that firms vigorously protect from prying eyes all information on their internal activities. Leakage of this information presumably allows competitors to copy the secrets of the firm's productivity or forestall its strategies in the market. However, creative industries deal with vast numbers of potential projects that will ultimately not go forward (*infinite variety*), and many others that are pursued but ultimately fail. Information on what projects have failed for a given firm, and what projects look promising but are not right for the firm considering them, largely lacks this value of confidentiality. Its access by a competing firm creates potential value for that firm without imposing any direct cost on the firm that divulges it. Proprietary information therefore becomes valuable trading stock among the gatekeepers employed by competing firms, for whom a transfer of useful information today creates a claim on some reciprocal tidbit in the future.<sup>16</sup>

Parallel to this mobility of information among a creative industry's gatekeepers is mobility of the gatekeepers themselves. Their human capital is not firm-specific, in that the differences among firms lie not in systems or technologies outside the gatekeeper's

<sup>16</sup> There appears to be room for theoretical research in this area. For a possible approach, see Baron and Besanko (1999).

control or authority but in the selection strategy that the gatekeeper himself implements. The gatekeeper's personal goodwill assets arise from his recurrent dealings with agents, artists, and other gatekeepers through the informal trade in information, and mainly resist appropriation by the firm that employs him. Accordingly gatekeepers in creative industries exhibit high levels of job mobility. Among publishing houses and record labels this mobility appears as simple job-hopping. In cinema films and TV programs the gatekeeper (producer and writer-producer, respectively) is usually an independent agent or the proprietor of a small firm who may reach a housekeeping deal with a large firm such as a movie studio. Such a deal provides the agent with a base for operations and seed money for developing new projects, while the host obtains the right of first refusal over the agent's projects for a period of a few years.

### 3. Structures and contracts in complex creative industries

A useful if rough distinction can be made between creative industries that rely on the works of a single class of artist and those whose products combine several of them. Producers of diverse creative inputs may interact in complex ways that would generally not occur among humdrum inputs. Artists may have *art-for-art's-sake* tastes that embrace preferences over how the common creative task is performed. Bringing several sets of divergent preferences into consonance poses a thorny bargaining problem, as the preferences likely defy exact codification and negotiation to reach a mutually satisfactory contractual agreement. Indeed accounts of the development of cinema films and stage plays and musicals commonly refer to disputes among artistic personnel over competing visions of the end product. These get resolved through the application of "muscle", the dominance of the preferences of whichever participant would most harm the project's prospects by withdrawing. The threat value of withdrawal is likely related to the participant's track record of superior performance (success) and/or distinctive and irreplaceable skills or attributes [Rosenberg and Harburg (1993, Chapter 7)]. In a creative project a compromise among several coherent but disparate conceptions of a creative project incurs an obvious danger of becoming a failed mishmash, whereas one or more of the pre-compromise visions might have succeeded on its own.

#### 3.1. Integration and disintegration

Among creative industries the U.S. motion-picture industry in the twentieth century provides a striking example how an industry's organization can be determined by the relative feasibility of different structures of contracts interacting with consumers' valuations of various types and qualities of creative goods. The major Hollywood studios emerged in the 1920s, integrated vertically from the production of films through their distribution and exhibition, and retaining under contract or regular employment many of the creative and specialized technical skills needed to produce cinema films. The efficient deployment of these film-making inputs under contract required that films be

turned out at a regular pace in order to keep the distribution and exhibition pipeline full, and each studio's portfolio of films was composed so as to make full-time use of the costly talents under contract. This assembly line rolled out a well-defined product – films relatively standardized in quality and style, even though varying in their reception by audiences and critics. A distinction was regularly made between “A” and “B” pictures, the latter of lower quality and shorter running time, intended to play as second features on a movie house's double bill. The B pictures were made by separate units of the major studios as well as by independent studios, and they served *inter alia* as training grounds for novice movie talents.

Contracts between the studios and key actors and other artists took the option form explained in Section 2.3 above. An actor was bound to the studio for a maximum period of seven years in half-year steps, with the studio holding the option either to renew (with a salary increase) or terminate every six months. The studio was thus motivated to make a substantial investment in the career of a promising performer, as it could collect the resulting rents over what was likely to be a substantial proportion of the actor's career. The studio retained decision rights over major creative choices such as which roles the actor undertook. Apparently the actor's pay was often renegotiated prior to her contract's expiration when she rose to star status, and stars gained access to the perks for which Hollywood is legendary. However even stars got no control over what roles they undertook. A device that no doubt helped to resolve the disputes arising under these contracts was that of lending out the performer to make a single picture at another studio. For this the contracting studio collected not only the fee due the performer but also a premium for its own treasury. Beyond its use in resolving disputes and tensions due to long-term option contracts, the loan-out procedure relaxed the constraint on film quality that was inherent in the studio's presumption that each film would be made by those inputs it had under contract and currently available for work.

The studio system was transformed in the 1940s and 1950s into a completely different organizational structure bound together by different contracts. It is a striking example of how the optimal organization of an activity can make a large, discrete switch following an exogenous disturbance affecting demand for the product and/or the feasible (legal) set of contracts. Several factors precipitated this change, and their respective necessity and sufficiency are not entirely clear. One was the introduction and diffusion of television, which provided to movie-goers a low-quality but cheap and convenient substitute for cinema films. With TV entertainment available at no pecuniary or travel cost, the cinema film (especially the B picture) faced formidable competition. The industry made the theoretically predictable adjustment of reducing the quantity of cinema films produced and raising their quality in the sense of employing costly inputs and elaborate special effects that distanced the cinema film from its small-screen competitor. Another major causal factor was the antitrust case *U.S. v. Paramount Pictures* 334 U.S. 131 (1948). Its principal consequence was to terminate vertical integration of the Hollywood studios into exhibition, which had been implemented mainly through ownership of then first-run downtown movie palaces. Although no studio by any means exhibited its films only in its own cinemas, this forward integration had effectively mandated a pace of movie

production to permit regular weekly changes of bill at each theater [Conant (1960)]. Disintegration tended to reduce the optimal rate of film production by the studios, and each film came to be marketed individually for exhibition in each city.

The mandated divestiture of exhibition and vertical differentiation led to the complete reorganization of studios by means of the divorcement of film production from exhibition. The central change was that each film was now assembled *à la carte* from the most suitable inputs available anywhere in the Hollywood talent pool. This change was congenial to the vertical differentiation of films from TV fodder, because it relaxed the constraint of reliance on the single studio's talent pool, and it facilitated the production of films differing widely in scope and ambition. Numerous fixed facilities were dismantled – each studio previously had its own production lot with pre-built sets, its own symphony orchestra, etc. Now, these and many other inputs and skills were hired temporarily as needed.<sup>17</sup>

The subsequent transformation of Hollywood's organization was traced in a series of papers by Christopherson and Storper [Christopherson (1992); Christopherson and Storper (1989); Storper (1989); Storper and Christopherson (1987)]. The following changes are documented in their research unless other sources are cited. Film production shifted away from the major distributors (studios) to smaller distributors and independent firms. Different bundles of inputs tended to come together for each film, with little "repeat business" [Lazarus (1985, pp. 94–95)]. Other packagers of film inputs such as talent agencies got into the business of organizing film production [Slater (1997)]. Many specialized independent service firms arose to provide film-making services on demand, and these firms diminished in average size as they became more numerous. The great increase in the number of arm's-length transactions involved in making a film entailed transaction costs that were mitigated if the input suppliers clustered closely in the Los Angeles area, and this centripetal force was evident. Personnel came more typically to work part-time for several employers, and the craft unions that had long siphoned substantial rents from the major movie studios found themselves unable to control access to competitive supplies of skilled labor. The factors explaining the year-to-year variation of studios' profits shifted from what stars they had under contract and theaters under control to the quality of films produced [Miller and Shamsie (1996)]. Independent markets for the exhibition of completed films sprang into existence in North America (Sundance, Toronto) as well as abroad (Cannes) [Donahue (1987)].<sup>18</sup>

<sup>17</sup> Other exogenous changes played minor roles in this transformation. During World War II high personal income-tax rates encouraged individual stars to form their own production companies to rent their services to a studio on a per-picture basis, and this tax dodge became a precedent for the later regime of one-off deals. Changes in camera technology made shooting films on location much easier, reducing the usefulness of studio lots. Also, when the *Paramount* decrees expired in the 1980s, there was no substantial return to the vertical integration of distribution and exhibition. Regarding the relative importance of these exogenous changes, it is noteworthy that the British film industry underwent the same disintegration as the American; the British film-makers also faced rivalry from TV, but they encountered no *Paramount* decision, suggesting the sufficiency of competition from television as explanation of the British disintegration.

<sup>18</sup> A somewhat similar disintegration has occurred in the television programming market in Great Britain; see Starkey, Barnatt and Tempest (2000).

### 3.2. *Contracts for complex creative goods*

When a complex creative industry's organization is transformed from extensive integration to "flexible specialization", we expect that a congenial set of contractual arrangements will emerge to govern the now-independent dealings. The motion-picture industry provides an attractive case study, along with its adjunct the market for TV program series. Cinema film projects usually start from a speculative script or a literary source from which a script is to be developed. Real option contracts provide workable governance for the producer (a film's entrepreneur) who seeks to develop a script. A series of steps is defined – a treatment (synopsis), a full draft, revision, polish, and so forth – with the writer paid for each step and the producer holding the option to continue with the next step. The screenwriters' organization, the Screen Writers Guild, supervises an arbitration procedure to determine the allocation of screen credit in the common case where a script passes through the hands of several writers.

With the script developed, the producer seeks to assemble the creative and technical inputs needed to make the film and to ensure that they are available at the right times for a closely coordinated series of sequential steps. This task can encounter hold-up problems. The last input committed to the coalition acquires some hold-up power due to the sunk negotiation costs and foreclosed alternatives already incurred by the other participants. Participants with high opportunity costs may insist on play-or-pay contracts that require them to be paid for their availability at a particular time even if the film is postponed or canceled. Play-or-pay commitments, though, can be renegotiated or traded off to another producer. Films sometimes fail because of defects in this contracting process, as when the coalition is assembled before all problems with the script are resolved or a key participant obtains a commitment to gratify some whim or preference that proves fatal to the film's overall success. However the process seems about as orderly as is feasible for investment decisions about which *nobody knows*, and the Hollywood studios at any time have hundreds of projects at some stage of development, so that those actually "greenlighted" have for better or worse survived an arduous winnowing process.

Motion-picture contracts commonly specify contingent compensation for major participants, bestowing shares of gross rentals received from exhibitors, net profits, or some variant on these. The exact incentive content of these deals is the subject of controversy. Participants sometimes take revenue or profit shares rather than straight compensation in order to assert their conviction about the project's merit. Contingent pay may also serve to induce effort, for example for the principal actor in the  $n$ th film of an action-adventure series [Chisholm (1997)].<sup>19</sup> However the compensation of highly-paid participants might be contingent simply because a gigantic fixed fee (the alternative) would shift enough of the film's overall risk on the other claimants to the film's cash

<sup>19</sup> Whether or not incentives are important in contingent motion-picture contracts, they are prominent in other contracts used in the industry. Goldberg (1997) showed how various contingent contracts reflect the timing of the opportunities open to various parties that can enhance the value of a deal.

flow to drive up their reservation prices substantially [Weinstein (1998)]. Whatever reasons for its use, compensation based on net profits suffers from the fact that the studio that distributes the film keeps the books in which net profits are determined. While the elements of creative accounting that enter studios' profit determinations generally have cogent economic bases, the studio has great scope for moral hazard by inflating judgmental costs and allocations that favor its own stake and invade the stakes of other participants – the notorious Hollywood accounting. The participants seek to avoid this moral-hazard problem by pre-negotiating the definition of net profits or demanding a share of gross revenue rather than profit, but transaction costs by themselves impair the use of contingent compensation.

### 3.3. Vertically differentiated talents

Complex creative industries employ teams of functionally differentiated creative talents, but their vertical differentiation – the *A-list/B-list* property – is also important for the industry's organization. Questions arise about how entrepreneurs selecting creative inputs and outputs deal with differences in inputs' quality. The obvious assumption is that the quality of a creative good perceived by the market generally increases with the quality of its creative inputs. An input's quality is optimally raised until the expected increment to revenue from the project falls equal to the incremental cost of quality. Another production relationship encountered in creative industries is that inputs' qualities interact multiplicatively rather than additively in determining the market's expected valuation – the O-rings production function. In these circumstances the failure or substandard performance of any one of them shrivels the value of the whole project. Also a high-quality input added to a project staffed with other high-quality inputs generates more incremental value than if it were added to a low-quality project. Faulkner and Anderson (1987) provide evidence supporting one implication: that the more successful producers, directors, and cinematographers tend to work together with significantly more than random frequency.

The importance of vertical differentiation in creative inputs raises the question as to what mechanism evaluates and records quality rankings of competing creative inputs. This is not quite the question of whom the gatekeeper admits and excludes, although admitted talents (visual artists, musicians, authors) undergo a ranking by critics' and consumers' evaluations. In complex creative industries such as cinema films, an economic mechanism underlies an evaluation process that continuously ranks the members of a given creative group. They rate each other's performances on professional prowess independent of the overall success of projects in which they participate. Each talent profits from having accurate knowledge of her own position on the quality scale: it reduces transaction costs and opportunity losses associated with competing for projects slotted above her quality ranking, or accepting projects targeted below it.<sup>20</sup> Knowledge of the prevailing rankings may generate value in other ways as well. For example,

<sup>20</sup> Analogous to the profit gained by a Cournot competitor from knowing accurately its variable costs relative to those of its rivals [Shapiro (1986)].

composers providing background musical scores for films sometimes become over-committed and need to subcontract jobs to newly arrived and/or lower-ranked talents [Faulkner (1983)]; hence there is also economic value to the talent from participating in the random interchanges with peer talents in which rankings are discussed and assigned and the emerging consensus reported. Furthermore, interest in the *A-list/B-list* ranking of a given class of talents extends to other types of talents who participate in the common set of projects. Each needs to know the talent rankings in other specialties in order to infer correctly the quality ranking of the project as a whole. Thus the whole system operates to create and update a consensus judgment on creative talents' rankings that is available to producers when they select inputs for a project.

### 3.4. *Distributing complex creative goods*

Complex creative industries, like other fabricating activities, face the problem of efficiently distributing their product to ultimate consumers. Distribution here embraces informing consumers about the varieties available as well as making them physically accessible. Creative industries such as publishing and sound recordings face distinctive problems due to two underlying structural features. First, the creative product is an "experience good" that cannot be accurately evaluated by final buyers short of actually consuming it. The supplier therefore faces a problem of how to disseminate information that will hold some value for signaling a match to consumers' tastes. Second, the product line offered by an industry embraces a large number of individual differentiated goods that are bought at retail in small dollar amounts. The marketplace must solve the problem of efficiently distributing many small units and holding them in inventory to await the exercise of consumers' uncertain demands.

A distinctive factor for book publishers and record labels is that retail inventories themselves perform a promotional function, because consumers learn about potential purchases through browsing in retail outlets. The retailer captures part of the extra sales revenue generated through enlarging his inventory and makes inventory decisions in light of that partial reward. The publisher, who shares this revenue, has reason to induce the enlargement of retail inventories. The publisher could use several policies to achieve this goal, and two of them hold particular importance in practice. One, employed by U.S. publishers since the 1930s, is to allow the retailer free return of unsold books. This privilege reduces the retailer's cost of holding inventory and increases its level. The retailer still incurs the cost of packing and shipping unsold books for return, but this bite out of net revenue is likely less than the alternative of knocking down the retail price until the book is sold. The publisher incurs costs of printing and one-way shipping of returned books as well as dealing with the returns (pulsing them, or disposing of them through specialized discount booksellers). An alternative policy, common until recently in countries outside the United States, is resale price maintenance (RPM), by which the publisher's contract with the retailer requires that books not be sold below the publisher's suggested retail price. RPM increases the bookseller's gross profit margin on books that due to retail competition might otherwise be sold at a discount – presumably

“best sellers”. It thereby increases the retailer’s optimal inventory of best sellers. It could increase the equilibrium number of retail bookstores, but it does not directly promote enlarged inventories of less popular titles. Thus, free returns and RPM both rectify what are regarded as market distortions from the publisher’s point of view, but each is prone to generate further distortions of its own. From society’s viewpoint there is no presumption about which policy to prefer.

The promotional role of retail inventories holds another implication for the distribution of creative goods. The retailer’s shelf space itself holds value for the publisher or record label because of the extra profit generated by additional copies sold to customers acting on impulse. That potential profit opens an opportunity for the retailer to charge the publisher for exhibition space in highly visible locations within the store, such as tables near the front door. Such “slotting allowances”, also familiar in grocery retailing, similarly apply to other distinguishable forms of promotion that the retailer undertakes [Shaffer (1991)]. To the publisher, paying the retailer directly for the value generated by these promotional policies is a partial substitute for the free returns and RPM already mentioned.

When failures occur in contracts between producers and distributors, a classic remedy candidate is vertical integration, which substitutes administrative direction for arm’s-length dealings. Integration has seen some use in creative industries, notably between record labels and wholesale distributors during the 1970s. It apparently arose from the labels’ need to coordinate the distribution and promotion of those pop recordings with the potential for large sales. For example, when a musician tours in order to promote a new recording, large stocks of her new release and past hits need to move in timely fashion through the distribution sector and into retail stores in cities on the tour. Without integration the label cannot readily induce independent wholesalers to stock at levels that will maximize their joint profits.<sup>21</sup> The solution of vertical integration has important implications for concentration among the record companies that are discussed in the next section.

Thus, the producer of creative goods such as books and sound recordings faces inter-related problems of informing consumers and efficiently distributing many small units of differentiated creative goods. The available instruments, including free returns, resale price maintenance, slotting allowances among others, are substitutes for one another in some settings, complements in others.

### 3.5. Structures of creative industries

Many observers have noted the high concentration of sellers in several creative industries – in the United States, and also for some worldwide. Concentration has been rising

<sup>21</sup> The scope and role of independent book wholesalers has changed repeatedly, reflecting in an interesting way organizational changes in both publishing and retail bookselling, as well as underlying costs and technology; see Miller (2003).

in some sectors, long stable in others. It shows no signs of transience. In motion-picture distribution roughly five to eight major distributors have dominated the industry since the 1920s. Although the market shares of individual distributors fluctuate considerably from year to year with the success levels of their films, the group's combined share is quite stable. Sound recordings have become concentrated since the 1970s, with the largest five or six companies recently accounting for about 80 percent of shipments worldwide and with more concentration in prospect. In book publishing, once unconcentrated, the largest four U.S. publishers in 1993 accounted for 30 percent of wholesale revenue.<sup>22</sup> A common explanation for concentration lies in the scale economies and sunk costs of the physical distribution system. The evidence for sound recordings was noted in the previous section. For motion pictures the distribution system manages the promotion of new films, negotiates exhibition contracts with individual theaters and carries out the physical distribution of prints of each film. Compelling circumstantial evidence holds that distribution systems determine the concentration of these creative industries. In motion pictures the disintegration of both exhibition and production left the distribution systems in place and unchanged in their concentration. In sound recordings the concentration of production coincided with vertical integration into distribution [Belinfante and Johnson (1982)]. In book publishing physical distribution plays a less central role, but the promotion of blockbusters is a function that fosters large-scale firms [Whitesides (1981)].

This hypothesis about concentration and its roots in creative industries is usefully probed by examining the responses of these oligopolies to major disturbances. The toys and games industry, with many marks of a creative industry, shows a noteworthy contrast to films and sound recordings, with their stable populations of dominant distributors and churning fringes. Toys and games exhibit the same scale economies in the promotion of blockbuster toys, where indeed the degree of dominance of the most popular designs if anything exceeds that of other creative industries. In toys and games, however, there are no substantial sunk assets in the form of production facilities, distribution systems, or promotional organizations. Manufacturing is generally contracted out. When a toy succeeds wildly, sales of the firm that introduced it can suddenly expand greatly, but no new fixed facilities or lasting goodwill assets result. When a toy expected to be popular fails in the market, or even when the popularity of a continuing success declines unexpectedly, quite large toymakers can run losses and disappear overnight [Stern and Schoenhaus (1990)]. The record industry's responses to major stylistic shifts in popular music provide a valuable laboratory experiment. When rock 'n' roll first came on the scene, it offended the ears of the established artist and repertory (A&R) executives, who kept their companies out of the business. The result was increased churning in the weekly Top 10 records and deconcentration of the record industry. The incumbent leading firms learned a lesson, however. They became much more open, starting or acquiring new record labels to exploit new musical styles as they emerged, making use of

<sup>22</sup> *Billboard*, January 21, 1995, p. 42; *Book Industry Trends*, 1995, quoted by Greco (1997, p. 58).

the firms' distribution and promotion capacities and raising the industry's concentration to its current high level [Peterson and Berger (1975); Lopes (1992)].

This source of concentration in creative industries clearly reflects one distinctive underlying feature of their structures, the proliferation of differentiated creative goods (*infinite variety*) and the associated scale economies in their distribution. More subtly, it reflects another – the incompatibility of the romantic concept of the artist, as the autonomous creator working from inner necessity, with the requisites of collaboration in a large and hence bureaucratic business organization. The typical creative industry contains large-scale firms organized around promotion and distribution, but also a large number of small firms organized around the gatekeeping functions of selecting and nurturing promising artists. The latter activities require personal rapport and suffer diseconomies of scale in effectiveness when organized on large scales. The large firms whose sizes are driven by scale economies in promotion and distribution can be labeled *promoters*, the small firms specialized in gatekeeping and nurture are *pickers*. The advantage of their separation lies quite simply in keeping artists and bureaucrats out of each other's hair. The picker/promoter distinction clearly appears in motion pictures, TV films and programs, first-run TV syndicators, record labels, art galleries, and book publishing. Mezias and Mezias (2000) identified essentially this distinction in the early (1912–1929) motion picture industry between the generalist firms vertically integrated in production and distribution and the innovative specialist firms operating at only one of these stages. It also appears in creative industries that fail to exhibit levels of concentration that are high by common standards. Picker art galleries are typically run by individuals with strong sympathy for and involvement in creative processes in the visual arts, hence well-attuned to dealing with artists. Promoters tend to represent artists who have achieved some measure of success and can be attracted away from a picker gallery by the offer of more effective promotion on a larger scale.<sup>23</sup> Agencies representing classical musicians similarly divide into small-scale units that take a hand in their artists' personal development and large-scale units suited to the job-matching tasks of assigning the top performers.

Another factor explaining differences in the organization of creative industries is the way in which the cost of quality varies with the quantity of output produced. If quality is a variable cost, high quality will enter into marginal cost. Firms offering different quality levels at correspondingly different prices will likely survive in the market. If quality is a fixed cost, however, it does not enter into marginal cost, and a high-quality firm will tend to undercut lower-quality competitors. The market will be highly concentrated with little variation of price with quality; where quality is a variable cost, more competitors will survive, and a range of qualities will be offered at diverse prices. Berry and Waldfogel (2003) showed that this difference in the variance of prices holds between two local creative industries – restaurants (quality enters into the meal's marginal cost)

<sup>23</sup> An important feature for the viability of these two classes of enterprise is the ability of the pickers to realize capital gains on works created by successful artists before their prices were lofted by large-scale promotion.

and newspapers (tabloid and “newspapers of record” incur the same marginal printing costs). Fixed costs of quality contribute to explaining many important features of creative industries, including the “superstar effect” [Rosen (1981)] and the dominance of the United States as a supplier in the world market for cinema films [Wildman and Siwek (1988)].

### 3.6. *Multi-activity firms in creative industries*

Large firms in creative industries commonly engage in numerous activities, earning them the label of “entertainment conglomerates”. The term is deceptive, however, because their parts are assembled in ways intended to generate rents – extra net revenue over what the same activities could earn if organized as free-standing single-business firms. Synergistic gains claimed by managers bent on merger often come into question when subjected to economic analysis.<sup>24</sup> One business model of gains from diversification stems from the observation that core creative works can yield rents from their embodiment in a number of different forms. The novel that arrives on the doorstep of a trade publisher is first issued as a hard-cover book. Then it appears in paperback. It is turned into a screenplay for a motion picture. The motion picture is “novelized”, the screenplay turned into a book with still photos from the movie. The soundtrack score is issued as a recording. A television series is conceived as a spin-off from the movie. The simplistic account of organizing these transactions holds that the firm possessing a business in each product line can simply pass the core creative input along from one of its divisions to the next, with cash gushing forth at each step. The problem with that program, of course, is that the author of the primary book manuscript is the legal owner of the core intangible asset, and she (or her literary agent) can readily stage an auction of this literary property in each of the markets where rents can be generated. Standard hard-cover publishers’ contracts have sought to divide the rents from subsidiary rights evenly between author and publisher. Indeed, that distribution might be agreeable to (optimal for) a novice author whose novel lacks manifest signs of major subsidiary-rights potential, so that the value of these rights depends substantially on the publisher’s efforts to develop and promote the work. However acceptance of that arrangement is the author’s option. If the author chooses to stage her own auction of subsidiary rights, it is not obvious why bidders affiliated with the hard-cover publisher should be able to wring more value from the project than independent bidders and therefore to prevail in the bidding. An auction is a highly efficient device for extracting value from bidders and a successful conglomerate needs some special trick to generate more value than independent firms bidding in the author’s auction.

<sup>24</sup> That risk-spreading is not featured to explain the diversification of firms in creative industries may seem surprising. The case for imputing a risk-averse preference function to the publicly-traded firm is always shaky, and little empirical evidence ties the entertainment conglomerates’ behavior to risk aversion. Smaller firms in creative industries, whose uncertain cash flows directly affect the welfare of potentially risk-averse individuals, commonly behave as if they are risk-loving due to *art for art’s sake* (see Section 2.1 above).

This is not to deny synergistic gains for entertainment conglomerates, but rather to point to the stringent conditions for realizing them. When core creative elements can be embodied in many different forms, some ways to create value may not be fully exploited by sequential independent auctions. The cash-flow streams of the diverse embodiments likely are interdependent. Coordination at the outset in styling the element for its first use raises its value in subsequent uses as well. Outlays to promote one embodiment yield spillover benefits for others that must be taken into account in order to maximize value. Internalization can facilitate this coordination, which is likely difficult at arm's length.

Another feature of creative industries that promotes multi-activity firms grows from the public-good character of some core creative products. The cinema film, the television sitcom series, the pop song or recording once created can be used repeatedly at no marginal cost, or at only a small incremental cost of putting the good in another form. However the creative good must earn rents in these various uses if its original fixed cost is to be recovered. No matter how many creative goods compete for any given use, nor how closely competitive are their providers, the equilibrium price must exceed the zero marginal cost.<sup>25</sup> This property of all information-type goods creates incentives for vertical integration between businesses that provide creative content and those that distribute it. Consider one of the vertically integrated firms that account for most U.S. television networks, say, Disney and ABC. If ABC shows a film from (say) Paramount's library, the payment is a cost to ABC and a rent to Paramount. If ABC instead draws from Disney's library, any payment is purely an internal transfer, and Disney/ABC incurs no cash cost. The incentive to internalize the transaction applies to Paramount-UPN and any other integrated firm comprising a content provider and distributor. The individual firm's incentive to internalize this rent transfer might be augmented by a strategic consideration. A non-integrated firm that depends on vertically integrated rivals for content or distribution feels itself vulnerable to foreclosure by its integrated rival. Foreclosure and refusal to deal are by no means necessarily profitable to an integrated aggressor, but states of nature can occur in which they would be; in such vertically related oligopoly industries firms commonly explain their actions as if they believe that the likelihood of a costly hold-up is substantial.<sup>26</sup>

This incentive to internalize transactions and ensure against foreclosure would apply in any industry that produces information, or any other good with a fixed but no marginal cost. It holds further significance in creative industries, though, because of two of their distinctive properties: the great uncertainty about consumers' valuations of a yet-uncompleted good (*nobody knows*); and the prevalence of large numbers of products (movies, sitcoms, pop recordings) that are close but imperfect substitutes (*infinite variety*). When the ABC network restricts itself to showing Disney programs and

<sup>25</sup> If competition between vendors of creative goods drives their prices below average cost, equilibrium requires that some sellers exit until a price no less than average cost is sustainable.

<sup>26</sup> For a rigorous demonstration of how a firm could gain by vertical foreclosure, see Ordovery, Saloner and Salop (1990). A connection to incomplete contracts is made by Bolton and Whinston (1993).

movies, it narrows its choices and presumably offers viewers a less attractive menu than if ABC picked freely among all studios' offerings. This is a real cost of the internalization, though (with close substitution) likely a small offset to Disney–ABC's business-stealing gain from internalization. Another real cost arises from the internalization because the distributor of programming probably has some useful experience for assessing the prospect of new entertainment investments. Dealing at arm's-length with content providers, the distributor might create some value by occasionally warding off a turkey-in-the-making. If Disney instructs ABC to take program series produced by Disney, this critical input is stifled unless the distribution arm can preserve considerable bureaucratic autonomy in the face of the basic incentive to steal business from rival content providers.<sup>27</sup>

#### 4. Role of non-profit enterprise<sup>28</sup>

An important aspect of industrial organization in the U.S. creative industries is the incidence of non-profit organizations (NPOs). They dominate the performing arts (except for Broadway theater) and share dominance of "cultural storage" activities – museums, libraries – with public-sector firms. Substantial fringes of NPOs appear in other sectors such as publishing, music recording, and broadcasting. This pattern invites an explanation why NPOs appear where they do. Two distinctive features of creative industries, interacting with each other, seem to offer one. The first is the combination of high fixed and low marginal costs that prevails in many creative activities. The second is the prevalence of *art-for-art's-sake* tastes, particularly those pertaining to the quality and variety of creative goods.

##### 4.1. Non-profits and governance in creative industries

High fixed costs pose a problem for any industry if sellers are constrained to charging a single linear price. In order to cover average costs, the equilibrium price must substantially exceed marginal cost, even when large numbers of sellers compete. Indeed, if fixed costs are sunk at the outset in a two-stage market game, the maximum viable number of sellers may be limited to the few that can cooperate and avoid price competition in the second stage (after the fixed costs are sunk). The gap between price and marginal cost inflicts a deadweight welfare loss, and high-fixed-cost industries have an incentive to avert it by means of non-linear prices or price discrimination. Non-linear pricing involves charging each customer a combination of fixed and variable prices, with the variable component ideally equal to marginal cost and the fixed component

<sup>27</sup> See Caves (2005, Chapter 7) on the consequences of removing regulations that limited the internalized ownership of TV program series.

<sup>28</sup> For further discussion of this topic see Brooks' Chapter 15 in this volume.

high enough that total revenues cover total costs but without excluding any customer willing to buy at marginal cost. In addition, or instead, the enterprise may be able to align prices with customers' diverse levels of willingness to pay. This might be done by allowing customers to choose different bundles of services (à la carte admission fees or an annual membership – second-degree price discrimination). It might be done by charging prices aligned to individuals' differing levels of willingness to pay (discounts for seniors and students – third-degree price discrimination). All these devices of course turn up in many markets dominated by profit-seeking enterprises. What is it about creative industries that pushes them toward NPO status when high fixed costs are present?

The answer seems to lie in the difficulty in creative industries of managing the contracts that implement non-linear prices in an enterprise run by a profit-seeking manager. The fixed charge (membership fee, say) must be committed at the start of the season before the product (performance) is actually on display. The consumer's willingness to prepay depends on the expected variety and quality of performances to be offered during the coming season. The list of plays to be performed might be contractible, but not the myriad stylistic and quality-related choices involved in presenting them. What then keeps the manager from promising high quality, offering lower quality, and pocketing the profit? The manager's *art-for-art's-sake* tastes may come to the rescue, if the organization is non-profit and the manager can credibly display a preference for high-quality and innovative performances. Moral hazard is then kept at bay. This mechanism may also facilitate the contract between the manager and performing artists, whose own *art-for-art's-sake* tastes make them willing to sacrifice pecuniary compensation for the opportunity to reach for artistic innovation and excellence. Their employment precommitment may turn on the manager's shared tastes, like the audience members' season tickets.<sup>29</sup>

The NPO is thus hypothesized to succeed because the manager's publicly espoused tastes mitigate the governance problem facing consumers, when they are asked to cover the fixed cost now and enjoy the performance later. The mechanism seems even more persuasively coherent when we think of the ongoing NPO in which the manager mounts this season's performances and then passes the hat for contributions as well as requesting membership renewals. Audience members' enthusiasm for the preceding season's offerings presumably determines not only the incidence of renewal but also the generosity of donations.

#### 4.2. Two-part pricing in practice: The donor-supported non-profit organization

The specific form of organization that provides the empirical embodiment of the NPO is the donor supported NPO, characterized by a self-perpetuating board of directors.<sup>30</sup> Its

<sup>29</sup> Hansmann (1981) developed the theory behind this model. For an empirical study of the alignment between regional theater directors' values and outside interest groups, see, Voss, Cable and Voss (2000).

<sup>30</sup> Sociologists get credit for identifying this form [DiMaggio (1982, 1986)] and researching the mechanisms that make it effective [Ostrower (1996), Odendahl (1990)].

board consists chiefly of wealthy consumers of the NPO's services, whose board memberships reward past financial contributions but also carry the expectation of continuing support. These persons are not necessarily effective monitors or managers of what may be a large and complex organization, but they are strongly motivated to ensure the viability and success of the organization by a sort of "social equity" that they hold, and that yields a return of esteem when the organization performs well and loss of face when it does not. Studies of such NPO board members show that their fund-raising efforts and administrative service to the organization are important relative to their role as personal donors [Ostrower (1996)]. This institution arose in nineteenth-century America, and the symphony orchestras, museums, and other such cultural enterprises organized in this manner were markedly successful in delivering "quality" in the organization's product relative to the for-profit enterprises and cooperatives that preceded the NPOs.<sup>31</sup>

Research on the ecology of donor-supported NPOs confirms this model of governance and its implications for the population of these firms. The model implies that donations should function as a regular, planned component of the organization's resource intake, as distinguished from an emergency topping-up when the organization suffers a negative fiscal shock. Financial flows over time indeed do behave as if both direct box-office revenues and donations maintain a stable average relationship to the organization's costs, subject to random year-to-year shortfalls and surpluses. Negative shocks may well occasion special flurries of fund-raising, because the NPO generally has no equity capital to absorb such shocks (an endowment, of course, may perform this function). Other relevant research deals with variations in the population of NPOs from city to city. The weight of fixed costs for such organizations implies that no market can efficiently support a large number. When small and large metropolitan areas are compared, the number of NPOs in a given class tends to increase with city size, though less than proportionally, and where larger numbers of NPOs of a given type tend to persist, they are commonly differentiated in their functions, reflecting in turn the cultural diversity of the city in question [Blau (1986)]. Finally, the aggregate U.S. population of arts and culture NPOs has grown over time at rates responsive to major changes in tax policy and in the ecological niches opened by the growth of the national economy [Bowen et al. (1994)].

## 5. Conclusions

A standard research line in industrial economics seeks to explain the level of or changes in the number and size distribution of business units within an industry. Some of our conclusions follow in that tradition. Like others, the creative industries' structures tend

<sup>31</sup> Symphony orchestras in nineteenth-century America provide a particularly interesting case study. NPOs competed with and vanquished other organizational types, i.e. for-profit firms and cooperatives [Hart (1973); Shanet (1975)].

to be driven by the efficient scales with which creative goods are produced and distributed (very large for record labels and movie studios, small for art galleries). Firms tend to sort themselves into those focused on the distribution of creative goods (“promoters”) and those concerned with identifying and nurturing creative talents (“pickers”). Large enterprises also include the “entertainment conglomerates”, which seek synergistic gains that depend theoretically on quite special conditions; foreclosing others and avoiding foreclosure by them may be principal motives.

What distinguishes the organization of the creative industries, however, is the prevalence of distinctive types of contracts. These contracts govern collaborations between artists and other parties in arm’s-length relationships or within an enterprise. These contracts’ structures devolve from a few bedrock properties of creative work and creative products. Two broad types of contracts hold particular importance in the creative industries. Some amount to joint ventures in which artists and “humdrum” inputs (perhaps one of each, perhaps many) collaborate simultaneously to obtain some valuable output. When these production processes occur not simultaneously but in sequence, real option contracts pervasively govern the sequential steps. Option contracts can leave the artist an autonomous creative agent (pop musicians and record labels) or govern the use of their talents to an employment relationship (classic Hollywood studios).

Our interpretation of these contracts and patterns of enterprise organization invokes the self-interested economic actors adapting to the fundamental elements of tastes and technology that characterize creative industries. That statement might appear in any analysis of an industry’s organization. Indeed, it usually does. The creative industries are striking, though, for possessing specific properties of tastes and technologies – the axiomatic properties listed at the start of this chapter – that supply theoretically coherent explanations for the structures of contracts and organization of enterprises. It has not been feasible to frame these interpretations with formally testable hypotheses, but the many points of agreement between casual empirical evidence and predictions based on these basic properties are certainly encouraging.

Besides deal structures and enterprise populations, the organization of an industry also embraces the prevalent type of firm – in this case, the role of non-profit enterprises. They dominate a number of arts activities, apparently for two interrelated reasons. These activities incur high fixed but low marginal costs, pressing them to employ two-part prices and club arrangements to ensure the coverage of fixed costs. When product quality is endogenous, however, non-profit status may be necessary for the manager credibly to forswear degrading quality once the customers’ fixed payments are in hand. Non-profit organizations supported by donation streams thus enjoy functional advantages.

While the creative industries are no fecund source of data bases, they do provide many opportunities for further research. The following list is confined to points that received rather conjectural treatment in this survey – theoretical propositions that could change greatly when formally worked out, or readings of qualitative empirical evidence that might turn out to be faulty generalizations.

- The organization of agents' activities and their roles as matchmakers and intermediaries have been little studied. The existing literature on intermediation does not match up well with the empirical questions that arise in the creative industries.
- Sticky, conventionalized prices present a puzzle. Are they really sticky, or do "list" and "transaction" prices diverge? If the stickiness is real, do the theoretical conjectures offered here stand close examination?
- The recent wave of vertical integration in the "entertainment conglomerates" suggests issues of foreclosure, especially in industries with zero marginal costs, that have not been worked out.
- The talent guilds that prevail in the creative industries arose long ago in response to contract failures. However it is not clear how their objectives in the ongoing entertainment industries might be characterized.
- The literature of contract theory assigns great importance to renegotiation, and renegotiation (shading into repeated interactions) seems to play an important role in the ongoing balancing of equities in the creative industries. Can empirical evidence be developed and related to theory?

## Abstract

Media industries are important drivers of popular culture. A large fraction of leisure time is devoted to radio, magazines, newspapers, the Internet, and television (the illustrative example henceforth). Most advertising expenditures are incurred for these media. They are also mainly supported by advertising revenue. Early work stressed possible market failures in program duplication and catering to the Lowest Common Denominator, indicating lack of cultural diversity and quality. The business model for most media industries is underscored by advertisers' demand to reach prospective customers. This business model has important implications for performance in the market since viewer sovereignty is indirect. Viewers are attracted by programming, though they dislike the ads it carries, and advertisers want viewers as potential consumers. The two sides are coordinated by broadcasters (or "platforms") that choose ad levels and program types, and advertising finances the programming. Competition for viewers of the demographics most desired by advertisers implies that programming choices will be biased towards the tastes of those with such demographics. The ability to use subscription pricing may help improve performance by catering to the tastes of those otherwise under-represented, though higher full prices tend to favor broadcasters at the expense of viewers and advertisers. If advertising demand is weak, program equilibrium program selection may be too extreme as broadcasters strive to avoid ruinous subscription price competition, but strong advertising demand may lead to strong competition for viewers and hence minimum differentiation ("la pensée unique"). Markets (such as newspapers) with a high proportion of ad-lovers may be served only by monopoly due to a circulation spiral: advertisers want to place ads in the paper with most readers, but readers want to buy the paper with more ads.

## 1. Introduction

Sociologists, political scientists, lawyers, historians, and philosophers all have their views about the media. The wide scientific interest in media reflects the growing importance of entertainment and communication in today's information society. Citizens in developed countries devote the lion's share of their leisure time to consuming mass media such as television and newspapers. It may not be too large a stretch of the imagination to say that leisure time use (job satisfaction aside and ignoring eating pleasure in those cultures with fine cuisine) determines much of the quality of life: by extension, the quality of life for many people is thus underpinned by the quality of the media!<sup>1</sup> In this respect the media industries, and the broadcasting industry in particular, take on an overall importance to the national well-being far beyond the dollar or euro magnitude of the sector in the national accounts.<sup>2</sup>

Much of today's popular culture derives from television programming. Children at school copy the actions and characters of their heroes seen on TV the evening before, adults retell jokes and rehash story lines, and the hairstyle of the leading lady in *Friends* becomes a topic of national debate. Media are also the source of news of current affairs and political actions. The way the news are presented can also shape public opinion and, by influencing citizens' voting behavior, can even establish or depose governments and presidents.

Surprisingly enough, the media were long ignored by economists, despite the fact that media content cannot exist without some physical medium (TV sets, newspapers, magazines) that is produced and exchanged in a market. Yet the media are not traditional products like butter, gasoline, or sugar. First, media firms (in most cases) produce and distribute a *public good*: one person's consumption of a media product does not diminish the ability of another to consume it (non-rivalrousness).<sup>3</sup> Second, media products in many countries are viewed as *merit goods*, a category of goods where the state makes a paternalistic judgment that consumption is "good". Such consumption is often encouraged by public spending (whereas "merit bads" are discouraged by taxes or regulations and restrictions). With merit goods, "public" evaluation is seen as different from the private one, so rejecting a purely individualistic view of consumer benefits. This stance derives from the fact that media constitute a powerful instrument of education whose nature and diversity considerably shape the collective values of society. Finally, most

<sup>1</sup> The average American watches over four hours of TV per day. In Japan, the figure is three hours and thirty minutes, and in Europe only slightly more. Subtracting hours of sleep, hours worked, hours commuting, and hours eating from the daily total of 24 hours we conclude that leisure time is mostly devoted to watching TV.

<sup>2</sup> The intrusion of American cultural values and icons into European homes through the television screen is one reason why many countries (such as France with the "exception culturelle") restrict non-local content of programming.

<sup>3</sup> Some media products also share the other property common to public goods, non-excludability, like free newspapers or television broadcasting. Other media products, like cable broadcasting or magazines, are excludable, see [Samuelson \(1964\)](#) for further discussion.

media companies finance their activities (at least partially) by *advertising*. Media firms need advertisers to make the production of media content worthwhile, while advertisers need media firms to make their products known to potential consumers.<sup>4</sup> Consequently, the media industry sells a joint product to two different categories of buyers: the medium itself to advertisers, and the medium *content* to media consumers (readers, TV-watchers, web-surfers, etc.).

Media firms thereby operate in two different industries and get their profits from both. From this two-sided interest, the cultural content offered to media consumers is shaped by the desire to offer advertisers a vehicle that reaches as many prospective consumers as possible: “when news sell ‘eyeballs’ to advertisers, the question becomes what content can attract readers or viewers rather than what value will consumers place on content” [Hamilton (2004)]. This potential bias in the type of programming or reading content offered may bias popular culture as well. The ads themselves are the subject of cult followings, and characters in ads may lead fashions and fads. The dollar amount spent on ads is the tip of a larger economic iceberg: insofar as new product introduction needs or is facilitated by advertising, product turnover and product generation is determined by ads. Some might say tastes too are influenced by ads. Ads can certainly create hype and fashions. Advertising also forms and reflects popular culture. It is important economically not only because of the fraction of GDP that it represents directly (around 2%) but also because it may facilitate the introduction of new products to market and so underscore a larger fraction of GDP.

Competition for advertising revenues therefore governs market performance; commercial television needs advertising revenue to survive (subscription pricing aside). Competition for advertising revenues therefore governs market performance. The willingness to pay of advertisers to contact viewers of particular demographics thus determines the type and range of programs offered in a free market system. This is very different from a traditional market structure where the principle of consumer sovereignty governs the type and range of products offered on the market. In conventional economic markets, consumers “vote” with their dollar purchasing power for the products they want, and firms, seeking profits, have the incentive to provide what consumers want. In the commercial television context, viewer sovereignty is filtered and muted. Viewers “vote” with their eyeballs for the programs they want to watch, and broadcasters need to deliver eyeballs to advertisers. However, different eyeballs get different vote weights in the sense that advertisers care about the type of viewers who are delivered – those most inclined to change their purchase behavior and buy copious quantities of the product on display are those of most interest to the advertiser. In addition to this type of distortion (whose consequences we elaborate upon below), media market performance can be sub-optimal for more subtle reasons even when all viewers are equally weighted

<sup>4</sup> The degree of advertising in media financing varies across media and countries. Public broadcasting services financed only by public subscription exist in England or Japan, while other media are fully financed by ads, like free newspapers and commercial TV broadcasting.

by advertisers. The reason stems from the particular market interaction inherent in the commercial television market, which forms a leading example of a “two-sided market” with network externalities.<sup>5</sup> In a two-sided market, two groups interact through an intermediary, or platform, that accounts for the externalities between the groups. In the media context, the platform is the broadcast company (or companies) and the two interacting groups are advertisers and viewers. Advertisers like more viewers to receive their messages. Viewers though find advertising a nuisance insofar as it detracts from time available to watch a program. The more advertisements are carried, the more the viewers are disappointed, so the former impart a negative externality on the latter. However, the viewers do not pay a direct price for the entertainment that they receive.

A similar structure governs commercial radio. Many Internet sites are also financed solely by advertising revenues from click-throughs and pop-up ads, which are also frequently a nuisance to surfers (at least, those who do not click through!). Magazines and newspapers are founded on a similar business model, and derive much of their revenue from the advertisements they carry. However, they also typically charge a direct price to their readers. This is true now for pay-per-view television, and for premium television shows too. Cable television, which involves a local service provider bundling together selections of channels, is an intermediary type of structure insofar as it typically carries to the household many programs that do carry ads themselves. The ability to price programming alters the market outcome by drawing in some direct competition for viewers.

The business model for newspapers and magazines has similar elements, although arguably advertisements are not as much of a nuisance as they are with television, radio, or web-pages.<sup>6</sup> Readers can skip past the ads without having to pay much attention to them, while they interrupt and postpone a television program. Readers may even find a positive net benefit from ads. This is especially true for classified ads in newspapers, and for products displayed in specialist magazines (motorcycles, golf, sailing, etc.). If readers do get positive net benefits, then the market interaction may be fundamentally different. If a medium attracts more readers or viewers, the more are advertisers willing to pay to get their messages across (this is true regardless of whether the readers or viewers are attracted to the messages per se). When readers want to get ad exposure (“ad-loving” behavior), then the market may loosely be described in terms of a “positive spiral”.<sup>7</sup> That is, the more readers there are, the more advertisers want to advertise in the paper or magazine, but then the more readers want to subscribe to it. This reinforcing effect may mean that only a monopoly can survive in the market. This conclusion

<sup>5</sup> Although most two-sided markets studied in the literature involve bilateral positive externalities, broadcasting instead typically involves negative externalities to viewers from advertisers and positive externalities on advertisers from the number of viewers.

<sup>6</sup> The existence of “Infomercials” on television indicates that advertising is not a nuisance to all viewers, too.

<sup>7</sup> Modeling this can be quite intricate. Caillaud and Jullien (2001) note that they “attempt to capture a fundamentally dynamic process by way of a static model, hence some imperfection”.

though ought to be tempered if there is product differentiation (so that several different types of magazine can survive, offering different specialties, or newspapers may provide different political viewpoints). Another caveat here concerns whether advertisers can reach readers through different media, and whether advertisers tout their wares in several papers or magazines. These issues are discussed further below.

In what follows we shall refer to the television context, and speak for the most part of viewers who watch broadcasts on channels. Differences for other media are pointed out where pertinent.

## 2. Background

We first present some conceptual background, and then some statistical background. This is followed by a description of the basic two-sided market paradigm, as applied to media markets.

### 2.1. Conceptual background

Perhaps the earliest model of television program choice is due to [Steiner \(1952\)](#). Steiner assumed simply that viewers will watch the (single) program type they prefer, and that different viewers have different preferences.<sup>8</sup> To take an example, suppose that 67% of the population will only watch game shows, and the rest only will watch sports. Then if there are two channels operated by competing firms, they will both offer game shows and so divide the larger pool of viewers. This is the Principle of Duplication, and is arguably prevalent on afternoon and prime-time network television. It implies that the market system does not cater to the minority taste. A monopoly though, with two channels, would not cannibalize its own game audience by providing a second game show, but would instead provide a sports show and then cater to the whole market. Implicit in the above description is that television broadcasters wish to maximize viewers. This makes sense when viewers do not mind ads, ads are sold at a fixed price per ad per viewer, and there is a binding cap on ad levels (as in the E.U. currently). Otherwise, and as we develop in the models below, broadcasters need to worry about viewers switching over or off, and extracting advertising revenues optimally.

A similar idea to Steiner's Duplication Principle is arrived at with a different variant of the model. Suppose [following [Hotelling \(1929\)](#)] that viewers' ideal tastes are distributed along a unit interval. Each viewer watches the channel closest to her ideal taste point. There are two broadcasters who choose "locations" in the unit interval, with the objective purely of maximizing own viewership. Then the equilibrium is what [Boulding](#)

<sup>8</sup> See [Cabizza \(2004\)](#) for a model with a similar preference structure. Her paper addresses the extent that programs cater to minority tastes under private or public broadcasting, and in a mixed system. She also notes that, in addition to [Steiner \(1952\)](#), [Rothenberg \(1962\)](#) and [Wiles \(1963\)](#) indicate the tendency for duplication of program types that attract large audiences.

(1955) christened the Principle of Minimum Differentiation. Both broadcasters choose exactly the same program type and split the market, just as in Steiner's analysis.<sup>9</sup>

An alternative specification of the program scheduling problem is formulated by Cancian, Angela and Bergstrom (1995).<sup>10</sup> These authors consider two TV channels that must decide (non-cooperatively) when to broadcast their evening television news. Viewers prefer to watch the news as soon as they get home from work. The times when viewers get home are distributed on an interval of time. Broadcasters strive to maximize audience size, and each is to choose a broadcast time. This game has no pure strategy Nash equilibrium. Indeed, whenever its opponent chooses a broadcasting time past the median of the distribution, each network's best response is to broadcast its show just before its competitor's to get over half the viewers. Its best reply when its competitor's expected broadcasting time is before the median is to choose the latest possible time and so again get over half the viewers.<sup>11</sup>

A second early concept that still resonates today is that of the Lowest Common Denominator (LCD), proposed in this context by Beebe (1977). Beebe took issue with Steiner's assumption that viewers will not watch if they are not offered their most preferred program type – and hence took issue with Steiner's conclusion that monopoly outperforms competition in terms of catering to diverse tastes. Suppose for illustration that viewers have diverse first preferences, but all would watch a game show if nothing else were available. Then a monopoly would have no reason to offer more than one program, and it would air a game show. This is, by construction, the LCD program type. Competing broadcasters though would offer different program types in order to attract viewers from rivals.<sup>12</sup>

These basic analyses are important as far as they go, but they miss the crucial tension in the market. In these models, viewers are not deterred by ads, and advertisers have the same willingness to pay for communicating with viewers. The important insight from the economics of platform competition is that the platform (broadcaster) needs to get both sides of the market on board – viewers must be delivered to advertisers, and advertisers are the direct revenue. How much they are willing to pay depends on the number of viewers delivered on the other side of the market.

<sup>9</sup> See Eaton and Lipsey (1975) for an extension to many firms, a consideration of non-uniform consumer densities, and other extensions.

<sup>10</sup> See also Nilssen and Sjørgard (1998).

<sup>11</sup> Gabszewicz, Laussel and Sonnac (2004) analyze an extension of the basic Hotelling game with single-homing advertisers and competition for viewers who dislike ads. Surprisingly, this extension also leads to non-existence of a pure strategy equilibrium, albeit in a more complex (two-stage) game where firms choose broadcast times and then ad levels.

<sup>12</sup> Beebe (1977) presents several numerical examples of group sizes and preference structures to determine equilibrium offerings under competition and under multi-channel monopoly. He does so for both a fixed number of channels, and for an endogenous number of channels determined by fixed costs of airing a channel.

## 2.2. Statistical background

This sub-section substantiates the view that media consumption takes up a lot of available leisure time, by providing some data about the time spent by consumers (readers or viewers) with various media. It also indicates the economic importance of advertising in the US as a fraction of total GDP and as a function of medium type, and shows that performance concerns due to large amounts of advertising might be quite well-founded. A break-down of what advertising time on various media is worth to advertisers is given later in the text.

Table 1 shows how much time is spent by households in the US watching television. The table documents the rise in the importance of television watching over the last 50 years. The current household (not individual!) average hours watched is an astounding eight per day. Arguably this rise (from four and a half in the 1950's) is due to habit changes and technology changes (such as cheaper television sets). The 1970's and 1980's saw households owning multiple sets, as well as the advent of color televisions. In the 1990's, the set of program options (including many 24 hour programming options) increased immensely with the increased popularity of cable, satellite, etc.

Individual watching rates are quite a lot lower than the household rates, but still around 4 hours a day in the US (a detailed break-down by medium type is given in

Table 1  
Time spent viewing per household, US

Source: Corneo (2001).

Table 2). While the US rate is the highest in the world, some other countries come close. Corneo (2001) presents evidence that people spend roughly the same amount of time working as they do watching television so there is a positive correlation across countries.<sup>13</sup> Surprisingly, Norway has the lowest number of hours watching (60% of the US figure).<sup>14</sup> On average, people spend only 30% more time working than they do watching TV.

Corneo estimates an OLS regression of the correlation between hours worked per adult ( $W$ ) and hours watching television ( $TV$ ). The estimated equation is  $TV = -614 + 1.05 W$ . Both the constant and the coefficient are statistically significant, and the  $R^2$  value is .51.

Table 3 provides a breakdown across media (television, newspapers, radio, magazines, and the Internet) of time spent. The importance of demographics to advertisers is implicit in this table, given the break-out of occupations, income, and education levels.<sup>15</sup> Poorer people tend to watch more television, as do the retired. Magazine and Internet use is highest among richer individuals.

<sup>13</sup> To explain this, Corneo (2001) develops a simple model in which adults choose between 3 activities, work, TV watching, and “socially enjoyed leisure” (activities enjoyed with others). To explain the positive correlation, Corneo invokes multiplicity of (Pareto-ranked) equilibria. Given that others are working long hours, it does not pay an individual to invest greatly in social ties. In a related vein, Rogerson (2005) explains the big difference in continental European (France, Germany and Italy) hours worked as due to different tax rates: the Europeans consequently indulged in more “home production”.

<sup>14</sup> Surprising at least, because one might imagine that long winter nights would be spent watching television.

<sup>15</sup> Wildman, McCulloch and Kieshnick (2004) show empirically that implicit prices for access to different individual types in a program’s viewership have different prices. See also Goettler (1999) and Wilbur (2004b).

Source: [www.tvb.org](http://www.tvb.org), based on data from Nielsen.

To get the data in Table 3 (which pertain to January 2003), adults were asked about their prior day's usage ("yesterday"). The philosophy behind this methodology is that people remember well what they did on the previous day. Interviews were evenly conducted over a 2-week period, so that the data aggregates week-end and week-day figures (see [www.tvb.org](http://www.tvb.org) for more details on the methodology).

The cost of accessing attention differs quite substantially across media. More detailed data are given in Table 4. For instance, the current rate for a 30 second commercial on prime-time translates into a rate of 2 cents per household reached. For spot television commercials, the rate is somewhat higher, at 2.7 cents per home reached. For comparison, the newspaper rate for the year 2000 works out at nearly seven cents per home for a half-page advert. We turn now to the share of advertising expenditures in the economy, and how much of this is on TV. The share of advertising in GDP has remained roughly 2% over the last forty years.

A break-down in terms of advertising volume across media (also from [www.tvb.org](http://www.tvb.org)) is given in Table 5. The last year (2003) is broken out into shares and the percentage change over the previous year. Television (summing broadcast and cable) accounts for

Table 4  
Gross domestic product, total ad volume, and television ad volume 1960–2003

Year	GDP*	Ad volume		TV ad volume	
	\$Billions	\$Millions	GDP (%)	\$Millions	Ad volume (%)
1963	617.7	13,100	2.12	2032	15.50

\*Sources: GDP, [bea.doc.gov](http://bea.doc.gov); ad volume and TV ad volume [www.tvb.org](http://www.tvb.org), based on data from Nielsen.

about a quarter of the total spending, and, using the data from the previous table, therefore accounts for about half a percent of GDP on its own.

Finally, the amount of advertising is also a performance concern. In broadcast media, especially, ads are hard to avoid Shields (2004) reports a study by MindShare for 2003 “ad clutter” meaning non-program (commercials, promos, PSAs, etc.) minutes. The data are recorded in Table 6. ABC, NBC, and Fox all passed 15 mins./hr.; and CBS has increased its clutter, but is still below the 15-minute mark at 14:18 minutes.<sup>16</sup> All are trending upward, as are Cable networks, though they generally carry less clutter. At one extreme, MTV carries 15:25 minutes every hour, while ESPN carries “only” 11:48 minutes of non-programming. By contrast, the EU has advertising caps that restrict the level of advertising to 9 minutes per hour. This level is very similar to the 9.5 non-programming minutes per hour that were standard in the US twenty years ago. This amount was a limit on commercials that was agreed upon by the National Association of Broadcasters and maintained by a voluntary code.<sup>17</sup> There is evidence the actual programming is being subverted with messaging too.

Shields suggests that total viewer demand for TV is pretty inelastic: “overall TV viewing is not that different [over the last decade] suggesting that clutter isn’t driving viewers from the set, but may be causing them to flip [channels]” and notes that network ratings have dropped for prime time programming as fragmentation spreads viewership over hundreds of channels.

<sup>16</sup> Some popular programs are among those with the highest clutter (for the fourth quarter of 2003). These include “The Bachelor” (18:08 minutes), “My Wife and Kids” (17:40), “Everybody Loves Raymond” (16:15), “Survivor: Pearl Islands” (16:05), and “Friends” (16:06) [source: Shields (2004)]. However, daytime television carries even more clutter than prime-time. In November 2001, NBC’s “Days of our lives” carried 23:23 minutes per hour, ABC’s “All of our children” carried 22:59 minutes, and ABC’s “General hospital” had 22:31 minutes. These figures, and much further interesting data on clutter, can be found in the American Association of Advertising Agencies and the Association of National Advertisers, Inc. joint 2001 Television Commercial Monitoring Report.

<sup>17</sup> Unfortunately (and interestingly), Nielsen does not publish data on advertisement ratings (number of people watching the ads) even though it has the technology to do so.

2.3. Platform competition

The key to the basic market model is that advertisers want to reach viewers, but viewers dislike ads,<sup>18</sup> and the size of each of these two segments matters both for the equilibrium arrangement and the optimum. The platform, or intermediary, is the broadcast company (or companies) that renders the ads palatable by bundling them with programs that are the viewers’ ultimate objective. That is, entertainment is provided free of a direct price, and this sugar-coats the consumption of ads the prospective consumer would otherwise not choose to watch. However, the platform recognizes the trade-off between higher ad levels that lead to more revenue per viewer, and the loss in viewer base from ramping up ad levels too high. Thus the platform has to coordinate the two sides of the market to get them both on board in the numbers that maximize revenue, and recognizing how both sides benefit or suffer from the interaction. When the market structure has more than one platform, competition from other platforms must also be factored into each platform’s calculus.

The economics of two-sided markets was developed after researchers into credit card markets recognized that this is a market not immediately amenable to traditional analysis.<sup>19</sup> Instead, credit cards and other prominent examples are two-sided in the sense that the benefits one receives on one side of the market depend not directly on the number of other agents on one’s own side, but rather on the number of agents on the other side. Thus the benefits to a shopper from holding a card depend on the number of stores that take it, and the benefits to a store from taking a card depend on the number of

<sup>18</sup> In the ad-loving variant, they do like ads.

<sup>19</sup> Indeed, even though it was sometimes suggested that credit cards constitute a market with network externalities, the prevailing model of network externalities at the time was one in which these externalities were “one-sided”. That is, a consumer’s benefit from carrying a card depends on the number of other card holders. Some reflection suggests that this is true to the extent that more shops are likely to take a card if more prospective consumers carry it. However, this mechanism ought to be modeled directly. The one-sided prototype might fit well such networks as fax machines or computer software [see Economides (1996), for a review].

consumers who carry it. The credit card example has two-sided positive externalities. Here the card-issuing company is the platform, the intermediary that coordinates the two sides of the market.

The economics of two-sided markets were pioneered by [Caillaud and Jullien \(2001, 2003\)](#) and [Rochet and Tirole \(2003\)](#), and further synthesized and extended by [Armstrong \(2004\)](#) and [Rochet and Tirole \(2004\)](#). The latter authors address the tricky task of defining two-sided markets.<sup>20</sup> [Wright \(2003\)](#) provides a useful service in indicating several examples of fallacious reasoning that would be ill-inspired from thinking about traditional markets in a context that was actually two sided. For example, one might think pricing below marginal cost would be indicative of predatory intent. However, in a two sided market, such pricing is quite natural, and stems from the need to get one side on board in order to extract surplus from the other side. In the TV context, viewers watch for “free” but advertisers pay for access. Indeed, [Armstrong](#) suggests that creates more benefits for the other side is the one that will enjoy low prices (for joining the platform). [Wright](#) though warns against thinking of this as a cross-subsidy from one side to the other, pointing out that with traditional subsidies, the side “paying” would prefer that the other were eliminated, along with the implicit tax. In the television context, the advertisers definitely would NOT like to see the viewers barred from the market! Rather, it is the low (or zero) price that attracts the viewers and therefore provides the surplus to the advertisers.<sup>21</sup>

[Caillaud and Jullien \(2003\)](#) also allow for “multi-homing”,<sup>22</sup> meaning that sometimes agents from one side of the market may use more than one platform – men (or indeed women) could use two different dating services, say. In the television context below, [Anderson and Coate \(2005\)](#) have multi-homing by advertisers, meaning that advertisers can place ads on several channels, while [Ferrando et al. \(2004\)](#) have single-homing.<sup>23</sup>

<sup>20</sup> The typical firm must get both worker and consumer sides “on board” in the sense of coordinating different agent groups, but this should not be considered a two-sided market problem. As [Armstrong \(2004\)](#) notes, “agents from one group generally do not care how well the firm performs in the market for the other group, but only about their own terms for dealing with the platform”. Two-sided markets also involve cross-group network effects absent in the simple firm context.

<sup>21</sup> In a similar vein, the earlier papers by [Caillaud and Jullien \(2001, 2003\)](#) situate the problem as competing “cybermediaries” (internet matchmakers) that coordinate groups of agents that wish to transact. The “Chicken and Egg” problem to which they refer alludes to getting both sides on board. In the simplest variants of the models, there are just entrance fees to the parties who may then interact. In a more complex version, agents transact if they find a match (which they do with an exogenous probability), and the platform can charge a price on that transaction too. This would be analogous to a royalty on sales following an ad on TV, which is an arrangement not seen in practice in ad markets.

<sup>22</sup> The term comes from usage on the Internet, meaning to have more than one Internet Service Provider.

<sup>23</sup> [Gabszewicz and Wauthy \(2004\)](#) contribute further to the debate.

### 3. The model ingredients

Going beyond the powerful, but rather rudimentary analyses of Steiner (1952) and Beebe (1977) means getting more explicit about the tastes and objectives of the three principal groups of agents who interact in the market. For concreteness, consider the case of television. The agents are the viewers, the advertisers, and the broadcast companies who have the central role of coordinating the two sides of the market. We describe these in turn.

#### 3.1. Viewers and readers

The model is built up from the basic ingredients that form its micro underpinnings. This means describing the tastes of diverse individuals to then generate their choices. We then aggregate up over individuals to find the viewership of each program type offered.<sup>24</sup>

Viewers make a discrete choice of which station to watch. At any moment, a viewer can reasonably only watch one station. Although a viewer might switch channels over a given hour (and we describe below how to allow such behavior), our starting point is to have viewers watch a single channel. We must also modify the model in the case of newspapers for which it is conceivable that a reader may buy and read several alternative papers: a fortiori for magazines (multi-homing by readers).<sup>25</sup> Table 3 above showed a break-down across media of time spent by individuals. In parallel, Table 7 shows the fraction of adults that each medium reaches (i.e., it gives a break-down by category of how many individuals are accessing the medium).

A simple way to model tastes is to suppose that each viewer has a conditional utility function for each option  $i$ , and this utility depends on the *match value*, which is the intrinsic benefit of entertainment, and may differ across viewers. From this we subtract the full price paid for the option. The full price consists of the monetary (or subscription) price,  $s_i$ , from watching channel  $i = 1, \dots, n$ , plus any nuisance from advertising. Supposing the advertising level is  $a_i$ , the simplest way to capture the nuisance cost is to

<sup>24</sup> Of course, this is not the only way to proceed. There is a long-standing tradition in Industrial Organization (and more recently on Macroeconomics) to use representative consumer models to portray the aggregate taste. These have also been used in Media Economics: see Barros et al. (2005) for an application to the Internet and vertical integration. Cunningham and Alexander (2004) study an equilibrium model and find that greater concentration (the inverse of the number of firms broadcasting) may decrease the total amount of programming broadcast, and a decrease in consumer welfare.

<sup>25</sup> Models in which viewers are assumed to mix between channels include Gal-Or and Dukes (2003) and Peitz and Valletti (2005). Anderson and Neven (1989) analyze the welfare properties of such a set-up in the context of product differentiation. Indeed, while without mixing the socially optimal locations are the quartiles of a linear location space, with mixing the optimal locations are the extreme ones. The positive analysis is the same if there is a linear likelihood of buying a product after seeing an ad; when it comes to the pricing analysis, the analogy is to a model of pay-per-view rather than flat subscription pricing. Another interesting issue that arises is that mixing viewers may be reached on two different channels, thus eroding the monopoly bottleneck that channels have over delivering viewers.

assume it is linear in the advertising level, at a rate  $\gamma$  per ad. This nuisance rate may be constant across the population, or may differ across different viewers. We also deduct from the full price any expected surplus the consumer may expect from trades inspired from the ads seen. Loosely, such surplus serves to reduce the effective  $\gamma$ , and may even render it negative. Such might be the case with classified ads for which the consumer actively searches out information and so advertising provides a positive net benefit. In the sequel we shall assume that nuisance costs are the same for all viewers, and that viewers expect no surplus from the goods they see advertised. We denote the full price of option  $i$  as  $f_i$  and it is thus given by

$$f_i = s_i + \gamma a_i. \quad (1)$$

The match utility is inspired from the standard stable of discrete choice models of product differentiation. From models of vertical (or quality) differentiation [Mussa and Rosen (1978), Gabszewicz and Thisse (1979), Shaked and Sutton (1982)] we draw a taste for a measure of quality,  $\theta q_i$ , with  $\theta$  an individual specific marginal willingness to pay for quality, and  $q_i$  the quality of option  $i$ . From models of spatial competition we draw the distance disutility  $\tau(\cdot)$  that measures how disappointed is the consumer from

not getting her ideal horizontal product specification. This depends on the “distance” between the viewer (at  $x$ ) and the program offering (at  $x_i$ ). From models of probabilistic discrete choice, we draw an alternative way to conceptualize horizontal differentiation, via match values  $\mu\varepsilon_i$ . These are typically assumed independently and identically distributed across consumers, and so (if the other potential sources of differentiation are not present), products are symmetric substitutes and competition is “global” in the sense that each product competes symmetrically with each other one. This is to be compared to the “local” competition inherent in the spatial model: each product competes directly with only its two neighbors.

In sum, the utility of consumer with preference draws  $\{\theta, x, \varepsilon\}$  (i.e., located at  $x$  and buying from a firm “located” at  $x_i$  with quality  $q_i$  and setting price  $s_i$  with ad level  $a_i$ ) then becomes:

$$u_i = y - [s_i + \gamma a_i] + \theta q_i - \tau(|x - x_i|) + \mu\varepsilon_i, \quad i = 1, \dots, n, \quad (2)$$

where the term in square brackets is the full price (i.e.,  $f_i$ : recall Equation (1)) and  $y$  is consumer income (which we suppose is the same across all consumers since it anyway plays no role in the choice model). In the sequel, we shall typically only deal with one type of differentiation in Equation (2) at a time, and the others will be suppressed.

### 3.2. Advertisers

The Economics of Advertising are quite controversial when it comes to the normative analysis. This is because successful advertising shifts demand, and therefore (presumably) consumer surplus. A comprehensive survey of the Economics of Advertising is provided in [Bagwell \(2003\)](#), and some salient points are discussed following the presentation of the model used here.

The simplest formulation for advertiser demand is that it is perfectly elastic. This means that there is no producer surplus to worry about. This assumption was used by [Spence and Owen \(1977\)](#). These authors assume that ad demand is flat and also that broadcast firms run into regulatory caps, so effectively there is neither an ad level decision to make, nor is there any ad surplus to worry about. Many papers treat this (simple) case of perfectly elastic demand, including [Gabszewicz, Laussel and Sonnac \(2001\)](#) and [Hansen and Kyhl \(2001\)](#). Other authors treat a downward sloping ad demand but do not treat ad surplus in the welfare analysis. This makes sense if all ads are viewed as pure social waste, and just serve to reshuffle demand. Nonetheless, such analyses do impart a socially important role for advertising spending – that of financing the media. On the other hand, if ads do generate some expected surplus to consumers, this surplus ought to be added to the utility function when deciding which channel to watch.<sup>26</sup> In order to disentangle the market performance in the media market per se from that in the ad

<sup>26</sup> This rather complicates matters. [Anderson and Coate \(2005\)](#) refer to analysis of this issue.

market, we shall analyze a benchmark case in which the private and social demand for advertising coincide.

One consistent story that generates such an ad demand is as follows. Suppose all advertisers are independent producers of new goods. Ads communicate the existence of these products to prospective consumers who could not otherwise find out about these goods and so can only buy them if they see an ad. Such ads are not persuasive but informative, and so are readily amenable to welfare analysis. The independence assumption implies that there can be no business stealing. We further suppose that each good is sold at a price that extracts all consumer surplus. This therefore closes down the other possible channel for deviation of social and private advertising.<sup>27</sup> Moreover, it obviates having to deal with the consumer surplus from goods in the viewer choice model. A simple formulation that ensures there is no consumer surplus arises when viewers, if interested, buy one unit of the good up to a reservation price that is common to all consumers.<sup>28</sup>

The aggregate demand for ads is then determined as follows. Following [Anderson and Coate \(2005\)](#), assume that advertisers differ in the probability that consumers are interested in their products, but advertisers are otherwise identical. More generally, it suffices to rank advertisers by a scale of high to low profit from contacting a viewer. All viewers are the same except for their tastes for programs, so there can be no targeting of ads correlated to programs.<sup>29</sup> Then the demand for advertising is simply the mass of advertisers who find that the expected benefit from communicating with viewers exceeds the price stipulated by the channel. We also assume that viewers “single-home” (watch one channel), and that there is a single period only. A viewer only needs to see an ad once in order to be informed of the product.<sup>30</sup> Taken together, the above assumptions imply that all that matters to an advertiser is the price for contacting a viewer. If the advertiser’s demand price exceeds the price quoted, the advertiser will advertise on the

<sup>27</sup> The broad Industrial Organization principle that governs the optimality of various economic magnitudes [following [Spence \(1976\)](#)] is that the bias depends on where the balance tilts between two opposing forces. First, firms do not take into account incremental consumer surplus that they cannot capture when they decide the level of an activity. This is termed Consumer Surplus Non-Appropriability. Second, firms do not account for the fact that they reduce other firms’ profits. This effect is commonly termed Business Stealing. These principles are usually applied to entry decisions [[Spence \(1976\)](#)] but apply equally well to advertising levels. In general then we should not expect the ad level to be optimal for these reasons. [Dukes \(2004\)](#) highlights business stealing by using the framework of [Grossman and Shapiro \(1984\)](#).

A neutral benchmark case naturally arises when we close down both of these channels of discrepancy of equilibrium from optimal levels. This has the advantage that we can then concentrate directly on the distortions inherent in finance by ad support, without yet worrying about the ad benefit per se. Put another way, the backdrop is one in which the private demand for ads coincides perfectly with the social demand.

<sup>28</sup> Alternatively, we could envisage a perfectly discriminating monopoly using two-part tariffs.

<sup>29</sup> Allowing targeted ads is a potentially important extension given the importance of demographic variables in ad demand.

<sup>30</sup> [Shields \(2004\)](#) reports that less clutter (i.e., non-program material) may result in a greater impact for advertisers. Ford sponsored the season-premiere of “24” on FOX, which was otherwise commercial-free. Ford’s brand recall score was over twice the average for the time period, according to IAG’s Reward TV data.

channel and reap a surplus equal to demand price minus advertising price per viewer, all multiplied by the number of consumers reached. This also means that active advertisers will typically advertise on all channels available, in order to reach the consumers who are delivered only through those channels. Equivalently, the advertisers engage in “multi-homing”.<sup>31</sup>

Let then the inverse advertising demand be given by  $p(a)$  per viewer when a channel carries  $a$  ads. The corresponding revenue per viewer is then  $R(a) = p(a)a$ . We assume below that this revenue function is log-concave. This means that the revenue function is quite “well-behaved” (the assumption includes a concave revenue as a special case).

At this juncture, we briefly review alternative views of advertising proposed in the literature on the economics of advertising. This literature traditionally distinguishes persuasive from informative advertising. Persuasive advertising is viewed as shifting consumer tastes [see, for example, the somewhat controversial paper by [Dixit and Norman \(1978\)](#), and the comments thereon in later issues of the *Bell Journal*]. [Dixit and Norman \(1978\)](#) take an agnostic view of how advertising works, but they take as a primitive that it shifts demand. The problem then for the practitioner of welfare economics is which demand curve to take as the true one. [Dixit and Norman](#) argue that over-advertising is the norm in both cases, whether one takes the pre-advertising demand or the post-advertising demand as the “true” one. However, explaining why demand shifted frequently leads us back to the complementary goods story or the informative advertising one described in more detail below.

Informative advertising works by telling consumers something about the product that then makes them more likely to buy, or to buy at a higher price. Informative advertising can be further split into that which indirectly informs consumers, and that which directly communicates product characteristics, quality, or price. Indirect information is communicated in signaling models [such as [Milgrom and Roberts \(1986\)](#)] in which advertising allows consumers to infer high quality in an adverse selection context.<sup>32</sup>

Directly informative advertising has been the topic of many studies. A major result in this context is due to [Butters \(1977\)](#), who finds that the market provides the socially optimal amount of advertising. His model was extended by [Stegeman \(1991\)](#), who suggests that the market tends to err towards under-advertising. An important contribution by [Grossman and Shapiro \(1984\)](#) introduces product differentiation via a circle model

<sup>31</sup> We address single-homing advertisers in Section 6 below.

<sup>32</sup> The view of advertising as a signal of product quality goes back to Nelson and to Klein and Leffler. A more formal treatment was undertaken by [Milgrom and Roberts \(1986\)](#), and several subsequent papers have extended this line of inquiry. The basic view is that advertising communicates quality by the firm “putting its money where its mouth is”. A low quality producer would not conspicuously spend large sums of money in promoting a product that no consumer would ever buy again. Thus reassured, consumers buy the product knowing that it is of high quality and they will repeat their purchases. The firm recoups its advertising expenses on the profits from the repeat purchases, and the advertising, which equivalently is public “money-burning”, serves an indirectly informative role, though no direct information about the product is actually transmitted in the advertisement.

[as in Vickrey (1964) and Salop (1979)]. This formulation was used by Dukes (2004) in the broadcasting context.

Another view is associated with the Chicago School [see, for example, Stigler and Becker (1977), and Becker and Murphy (1993)], and holds that advertising can provide a complementary good to the physical product. Advertising can be seen as enhancing the perceived product quality, for example, by fostering a brand image that consumers appreciate being associated with. Stigler and Becker (1977) argue first that “persuasive” advertising can be addressed within economic models, and, further that the level of advertising is socially optimal.

Depending on which view one takes, the conclusions below as regards the optimality of industry performance need to be tempered. For example, if there is over-advertising on broadcasts in the benchmark model, and it is believed that advertising levels are themselves excessive (so that the private benefit overstates the social benefit), then a fortiori advertising is excessive. Matters become more delicate when the conclusions from the separate parts run in opposite directions.

### 3.3. Platforms

The platforms are the TV stations that intermediate between the advertisers and the viewers. They are, of course, crucial to the two-sided market because they coordinate and balance the two sides on the platform. By bundling entertainment with the ads, they sweeten the delivery of the message in order to get it across.

The platforms that are covered by the current analysis are broadcasters (television and radio), publishers (newspapers and magazines), and web portals. Each follows the basic business model of delivering prospective customers to advertisers by attracting the viewership/listenership, readership, or web-surfer with news or entertainment content that carries a set of messages, superfluous (and possibly annoying) to the person enjoying the content. The relative size of the costs and benefits to agents who participate on the platform differs across applications. With television and radio, the advertisements break into the content and supplant it. In newspapers and magazines, the reader can easily bypass the ads so that the nuisance cost per se is likely negligible. While the overall modeling framework applies to various different markets, parameter values will differ across market applications.

Table 8 gives a time series of rates for prime-time network TV.

These rates are somewhat lower than the spot television rates, which are given in Table 9.

For comparison, magazine rates and newspaper rates are given below in Section 7.

In what follows we look at several variants of the model. We first consider a short run analysis in which the number of platforms is fixed. In the long-run, the number of platforms is determined by a free entry condition. We shall also first take the product locations as fixed, then look at them as being endogenously determined.

Table 8  
Network television cost, primetime (Mon–Sun) average program\*

	Households viewing (avg. min.)	Cost per 30 sec. (\$)	Cost per 1000 homes (\$)
1965	9,968,000	19,700	1.98
1975	13,500,000	32,200	2.39
1985	14,510,000	94,700	6.52

## 4. Equilibrium

We now find the equilibrium for the model, starting with a short-run analysis (a fixed number of firms) and then moving to a zero-profit (free entry and exit) equilibrium. In the next sub-section, we consider the case when advertising is the only revenue source. We then look at subscription pricing alone, and finally at pricing and advertising together. The model below encompasses many of those used in the literature as special cases, and we derive the equilibrium values for these special cases for comparison purposes. The particular models include the duopoly at the ends of a Hotelling line with linear transport costs [Anderson and Coate (2005)]; the quadratic transport cost version [Gabszewicz, Laussel and Sonnac (1999, 2002)]; and the Vickrey–Salop circle model with linear transport costs [Choi (2003); Crampes, Haritchabalet and Jullien (2004)].

### 4.1. Short-run equilibrium with advertising

Suppose that there are  $n$  platforms and let  $K$  be the fixed cost in setting up a platform. Given the revenue per consumer,  $R(a_i)$ , the profit to broadcaster  $i$  is

$$\pi_i = R(a_i)N_i(f_i, f_{-i}) - K \quad (3)$$

where we recall that  $f_i = s_i + \gamma a_i$  denotes the full price of broadcaster  $i$ ;  $f_{-i}$  denotes the vector of full prices of all broadcasters other than  $i$ , and the viewership functions  $N_i(\cdot)$  are determined from the particular viewer model assumed (i.e., the specification of Equation (2)). We go into more detail on this below (and give derivations in [Appendix A](#)), but for the moment write the own viewership derivative with respect to full price as  $N'_i < 0$  (i.e.,  $\partial N_i(f_i, f_{-i})/\partial f_i$ ). Then, suppressing arguments, we have, for an interior solution:

$$R'(a_i)N_i + R(a_i)\gamma N'_i = 0, \quad (4)$$

or, in elasticity form:

$$\frac{R'(a_i)}{R(a_i)}a_i + \frac{\gamma N'_i}{N_i}a_i = 0.$$

As long as  $R$  is log-concave,  $R'/R$  is a decreasing function. Likewise, as long as the viewership demand function is well behaved in the sense that  $N_i$  is log-concave, then  $N'_i/N_i$  is a decreasing function. These conditions suffice to ensure a unique solution for ad levels. In the case of a symmetric demand model, the equilibrium is symmetric. Supposing that there is a unit mass of consumers, the equilibrium viewership is  $N_i = 1/n$ . Denoting the common value of the viewership derivative (with respect to full price) by  $N'$  (i.e.,  $\partial N_i(f, f)/\partial f_i$ ), the equilibrium ad level,  $a^*$ , is defined implicitly from Equation (4) as

$$\frac{R'(a^*)}{R(a^*)} + \gamma n N' = 0. \quad (5)$$

In [Appendix A](#) we derive some common solutions for the viewer demand switch-over rate,  $N'$ .

It is useful to point out the case of  $\gamma = 0$ , meaning that viewers and readers are neutral about ads. In that case, due to product differentiation, each media firm will have its own market share, and is the exclusive channel for reaching the corresponding prospective consumers. Each channel will then price ads at the point where the marginal revenue from ads is zero (which is the marginal cost to the firm of airing an ad, and corresponds to the point of unit elasticity of the ad demand function).

If  $\gamma > 0$ , then viewers or readers find ads to be a nuisance. Advertising levels are then lower than if ads are not a nuisance. The reason is that competition is in nuisance levels, and firms strive to reduce the nuisance (all the while recognizing that the “nuisance” is the source of their income). It therefore makes sense that more competition (higher  $n$ ) results in lower equilibrium nuisance, just as more competition typically leads to lower prices (also a nuisance!) in standard models of product differentiation. These conclusions are borne out in [Appendix A](#) for some standard formulations of viewer choice. This interpretation in terms of competition for nuisance is important because one might usually expect the total “output” (ad level, by analogy) to be higher when there are

more firms.<sup>33</sup> Along with a lower level of ads the more firms there are, the approach concurrently predicts that the price per ad per viewer should be higher (with fewer firms advertising, the demand price is higher). Empirical evidence presented in [Brown and Alexander \(2005\)](#) gives the opposite relation, and so disagrees with the set-up above, but is consistent with the representative consumer model presented in [Cunningham and Alexander \(2004\)](#). More work is needed here to evaluate the hypotheses of the alternative approaches.

If  $\gamma < 0$ , then viewers or readers actually appreciate ads. While this does not seem relevant for the case of television or radio for the majority of people (since ads then necessarily displace entertainment content that presumably drew the individual in the first place to watch or listen), with magazines or newspapers there is no such presumption. The value of  $\gamma$  then represents the expected (net) surplus per ad seen by the reader. If this is negative, there is a desire for ads (ad-lovers), and the intermediary (television or radio broadcaster, newspaper or magazine publisher, web-master) must take this into account when determining how many ads to run. Now, more ads will actually attract more readers or viewers, but running more ads will also bring the broadcaster or publisher into the region where marginal revenue is negative. It follows from this logic, and from the equations presented previously, that now ad levels rise with the number of firms. This at least might sound more intuitive – “output” is larger with more firms and each has less market power to keep down the advertising level and so keep up the advertising price. Then the competition among firms is not in nuisance but rather in the attractiveness that is afforded by carrying many (desirable) ads.

[Dukes \(2004\)](#) emphasizes strategic interaction among advertisers. He models the product market with a circle framework using the oligopoly informative advertising model of [Grossman and Shapiro \(1984\)](#), and so allows for an explicit business stealing effect (at the cost of assuming that one industry supports the medium). The media are modeled with the circle framework, as above. He shows that less product differentiation or more media differentiation lead to a higher market level of advertising.<sup>34</sup> His result that there are more ads per station when products are closer substitutes contrasts with the standard [Grossman and Shapiro \(1984\)](#) finding, and underscores the importance of jointly considering the advertising and product markets. In the other direction, [Dukes and Gal-Or \(2003\)](#), [Gal-Or and Dukes \(2003\)](#) and [Gal-Or and Dukes \(2006\)](#) show that several features of the media industry may be explained by the joint incentive of both

<sup>33</sup> Indeed, though, the ad level per firm is lower. These properties vis-a-vis the workhorse Cournot model were first brought out by [Masson, Ram and Reynolds \(1990\)](#).

<sup>34</sup> [Anderson and Coate \(2005\)](#) get the latter result, but cannot treat the former in their ad specification. [Dukes \(2005\)](#) assumes instead that advertising is not informative but is used to differentiate a product from competing products. As usual, lower levels of media market competition lead to more advertising. However, here more advertising leads to higher surpluses in product markets since more advertising leads to more product market differentiation.

media and advertisers to limit the extent of advertising in order to limit competitive product information from consumers.<sup>35,36</sup>

#### 4.2. Short-run equilibrium with pricing

At this point it is worthwhile deriving several results that are quite standard to the economics of product differentiation regarding the pricing of differentiated commodities. These results are useful both in their own right for describing the properties of equilibrium when there is no advertising, and as an ingredient for the analysis of the next sub-section, which treats subscription prices along with advertising.

So consider now a broadcaster's (or a newspaper's, or a magazine's) profit if it uses only subscription prices. Assuming zero marginal cost for reaching viewers or readers,<sup>37</sup> its profit is

$$\pi_i = s_i N_i - K,$$

and so the price equation (the pricing first-order condition) is

$$N_i + s_i N'_i = 0,$$

which has a similar form to the advertising Equation (4) above.<sup>38</sup>

Now, under demand symmetry,  $N_i = 1/n$ , and this pricing equation reduces to a simple form

$$s = \frac{-1}{nN'}$$

where again the notation  $N'$  denotes that the viewer share derivative is taken at a symmetric solution (recall that this is negative, and so the subscription price is positive!). The values of  $N'$  for the commonly used models of product differentiation are given in [Appendix A](#), and hence the solutions for the symmetric subscription price are readily derived.

<sup>35</sup> These results stem from the fact that informative advertising is a competitive externality for competing producers [see [Grossman and Shapiro \(1984\)](#)]. Then competing producers supply too much advertising relative to the joint profit maximization. Competitive conditions in the commercial media industry determine the extent of this externality.

<sup>36</sup> [Dukes and Gal-Or \(2003\)](#) modify the [Dukes \(2004\)](#) model to investigate the incentives for broadcasters to sign exclusive contracts with advertisers, whereby competing advertisers are excluded from advertising. While such exclusion unambiguously benefits an advertiser, certain conditions must be satisfied before a broadcaster will offer such a contract. Exclusive contracts are offered when media have sufficient power in the market for advertising vis-à-vis advertisers since they are able to capture rents from consumers who are excluded from informative advertising. Exclusive contracts are more likely to occur when media markets are less differentiated or when consumers are unlikely to be informed about products in the absence of advertising.

<sup>37</sup> Positive marginal costs are addressed below, and are given a separate development because of their importance in the analysis of pricing and ad level choice which follows.

<sup>38</sup> Equivalently, the elasticity of the own viewer demand is  $-1$ .

It is useful for the analysis of the next sub-section to now present an intermediate result, dealing with the case when the subscription revenue received by the broadcaster or publisher is augmented by a fixed sum per viewer (or listener, as the case may be) of  $\bar{R}$ . This could arise if there is a step demand for ads per viewer, but we shall see below that it belies a more general principle.

The broadcaster's (publisher's) profit then is

$$\pi_i = (\bar{R} + s_i)N_i - K,$$

and, following the same steps as above, the price equation under demand symmetry reduces to a simple form

$$\bar{R} + s = \frac{-1}{nN'}.$$

We can now re-introduce this into the profit function to give the equilibrium value of profits as

$$\pi^* = \frac{-1}{n^2N'} - K.$$

The key property here is that this profit level is independent of  $\bar{R}$ . This is because whatever extra rents may be attached to the consumer are competed away at the equilibrium pricing decision. We term this result the revenue-neutrality property.<sup>39</sup> The revenue-neutrality result arises because markets are fully covered (all consumers watch/buy a magazine) and because each reader/viewer buys one magazine or TV channel each. Note from the form of the profit function that  $\bar{R}$  enters just like a (negative) average cost per unit would. In this light, it is unsurprising that average cost levels in such models do not affect equilibrium profit levels. The pricing equation simply determines mark-ups, which are the revenues earned per reader or viewer delivered. We return below to the wider impact of the revenue-neutrality property.

#### 4.3. Short-run equilibrium with pricing and advertising

We now allow the platforms to price along with their ad levels. When both price and advertising are positive, the value of advertising,  $a_p$ , solves<sup>40</sup>

$$R'(a_p) = \gamma.$$

<sup>39</sup> This result that has been noted previously by several authors, including Armstrong (2004) and Anderson and Coate (2005). Wright (2002) gets it in the context of mobile phone telephony.

<sup>40</sup> The idea behind this result can be seen by thinking of the broadcaster as maximizing revenues per viewer for a given level of full cost per viewer. That is, recalling the full cost is  $s + \gamma a$ , a broadcaster that maximizes the revenue per viewer,  $R(a) + s$ , subject to this constraint, will optimally choose to set  $R'(a) = \gamma$ . If negative pricing is not permissible or feasible, then the price is zero (there is no subscription fee even if one is feasible), and the ad level is determined by the market interaction over ad levels alone, as per the analysis of the preceding sections.

It is noteworthy that this result is independent of market structure. The intuition behind the result is that it parlays nuisance costs into ad revenues. Indeed, suppose that  $\gamma$  were above  $R'(a)$ . Then  $a$  could be reduced by a small amount,  $da$ , while  $s$  could be raised by a small amount  $\gamma da$  so that the full price to consumers is constant. Ad revenues would go down by  $R'(a) da$ , but by supposition this is less than the rise in subscription revenues ( $\gamma da$ ).

Given that  $a_p$  is determined by  $a_p = R'^{-1}(\gamma)$ , we can substitute this relation into the profit function and write it as

$$\pi_i = (R(a_p) + s_i)N_i - K,$$

and think of the broadcasters choosing just the subscription levels (or indeed, the full prices), since  $R(a_p)$  is tied down by the above relations.<sup>41</sup> This though means that the revenue  $R(a_p)$  plays just the same role as the fixed revenue  $\bar{R}$  in the analysis of the previous sub-section. The implication is then from the revenue-neutrality property that short-run profits are independent of the strength of advertising demand as long as  $s > 0$  (so that  $R'(a_p) = \gamma$ ). They are also independent of  $\gamma$ . Note lastly that ad levels are independent of the number of firms.

We have now to determine when subscription pricing will be used in equilibrium. As we argued above, a broadcaster will monetize the nuisance if  $R'(a) < \gamma$ . Conversely then, we can say that a broadcaster will not monetize any nuisance if  $R'(a) > \gamma$ . Most importantly, if the equilibrium without subscription pricing involves  $a^* = R'^{-1}(\gamma) < a_p$ , then introducing the ability to price will not have any effect and the equilibrium will be as in the first sub-section above. That is, pricing will not be used, and the equilibrium will remain a free-to-air commercial television, free newspapers or web-sites, etc., if  $a^* < a_p$ . If though  $a^* > a_p$ , the equilibrium when pricing is feasible will have positive subscription prices and the equilibrium level of advertising  $a_p$ . Pricing has important distributional effects. First, profits rise. This can be seen from comparing profit levels with and without it. With pricing, profits are  $\pi_p^* = \frac{-1}{n^2 N'} - K$ . Without pricing, they are  $\pi_a^* = \frac{R(a^*)}{n} - K$ , with  $a^*$  determined from  $\frac{R'(a^*)}{R(a^*)} = -n\gamma N'$ . Hence  $\pi_p^* > \pi_a^*$  as  $\frac{-1}{n^2 N'} > \frac{R'(a^*)}{R(a^*)}$ . Since  $R'(a^*) < \gamma$  in order for pricing to be used, then profits are higher when pricing is chosen in equilibrium.<sup>42</sup> Advertisers lose out because the ad level is lower, and so they lose some surplus. Viewers lose out because the full price (the sum of the advertising nuisance plus subscription price) rises.

The strong conclusion above is that the properties of the market equilibrium are just the same as the subscription-price-only model when prices are positive. They therefore depend only on the product differentiation specification used to describe the consumer

<sup>41</sup> See Anderson and Coate (2005) for more details on equilibria with ads and pricing.

<sup>42</sup> It is obvious that the ability to price raises profits for a monopoly, but it is not a priori clear that this is so for oligopoly since competition might be expected to be more severe once firms compete in more dimensions.

preferences in the market.<sup>43</sup> It is important to reiterate that these properties stem from full market coverage, unit demand per consumer, and also that parameter values ensure the equilibrium is in the regime with positive subscription prices along with advertising.<sup>44</sup> The influence of the latter condition may be rather subtle. As we shall see below, the equilibrium product selection may change drastically as parameters change, and the reason revolves around this condition.

#### 4.4. *Long-run equilibrium (free entry)*

The long-run equilibrium we consider involves zero profits for all firms.<sup>45</sup> The corresponding numbers of firms are determined from setting the profit expressions in the sub-sections above equal to zero. This is straightforward for the most part, but the effects of allowing pricing (as compared to the advertising-only equilibrium) does bear comment.

As noted above, when pricing is actually used along with advertising, short-run profits are independent of the strength of advertising and the nuisance to consumers. This

<sup>43</sup> Peitz and Valletti (2005) consider a two-stage duopoly game in which location along the unit Hotelling line is chosen first, then broadcasters compete for viewers. Otherwise the set-up is the same as in Anderson and Coate (2005), so that one contribution can be seen as endogenizing locations. Peitz and Valletti (2005) consider two symmetric games; one without subscription pricing, and the other one with subscription pricing. Their objective is to analyze the welfare properties of these two formulations. With subscription pricing, the location game involves extreme differentiation. Under free-to-air broadcasting, there is always some provision of ads (unless platforms are located at the very same point, which does not happen at equilibrium). As expected, ads decrease with nuisance, and increase with transportation costs (at a given location). Candidate location equilibria go monotonically from minimal differentiation (when nuisance is zero or transportation cost is infinity) to maximal (when nuisance is high enough or transportation cost is low enough). For given locations, welfare is only affected by ads. As expected from the Anderson and Coate (2005) analysis, pay-tv is better than free-to-air when nuisance is high (since free-to-air overprovides), or when locations are sufficiently close (under such duplication, both systems underprovide, but more so with free-to-air since competition escalates in providing few ads that cannot be compensated by pricing). Finally, for endogenous content provision, pay-tv is better with high nuisance costs: both systems provide extremely differentiated content, but pay-tv offers efficient ad levels, while free-to-air overprovides. When the nuisance parameter is very small: free-to-air almost minimally differentiates content, and pay-tv maximally differentiates (but these have same welfare losses), so free-to-air is worse because it severely underprovides ads given locations are almost at the center. Similar effects arise with respect to transportation costs.

<sup>44</sup> It is possible that advertising is chosen to be zero, which will happen if  $R'(0) \leq \gamma$ , meaning that the marginal revenue from the advertising sector starts out no higher than the nuisance cost. Then advertising is so annoying that broadcasters would price it out of the market. Note then that the optimal level of ads is also zero in this case.

<sup>45</sup> Spectrum constraints limit the number of broadcasters in many markets. Even if there are no such constraints (as with newspapers and magazines) the number of firms should be an integer, so the equilibrium number is the largest number making non-negative profits (implicitly assuming profits per firm decline with firm numbers), while the optimum number is not so constrained with a floor. The integer problem is ignored below, although explicitly considered in Anderson and Coate (2005), albeit for at most two firms. We also do not consider here the possibility of equilibria with entry deterrence: see Eaton and Wooders (1985) and Anderson and Engers (2001) for a description of such possibilities.

turn means that the long-run (zero-profit) configuration of firms is independent of these variables, and indeed is just the same as when there is no advertising or only subscription prices are chosen. As compared to the equilibrium with advertising only, if then pricing is rendered feasible, the long-run equilibrium number of broadcasters will be greater because of the higher profits associated with the ability to price.

## 5. Welfare analysis

Suppose that parameters ensure that all markets are served.<sup>46</sup> Then the *optimum* advertising level,  $a_o$ , has the marginal social cost,  $\gamma \geq 0$ , equal to the marginal social benefit, which is the advertising demand price. Thus it solves

$$p(a_o) = \gamma.$$

It is therefore immediately clear that the advertising level with pricing is below what is optimal. The marginal revenue curve that determines the equilibrium level is below the demand curve that determines the optimal level.

Without pricing though, either relation is possible, as the following discussion makes clear. For low  $\gamma$ , virtually all the advertisers ought to be communicating with the viewers. The equilibrium has the ad level provided by each broadcaster bounded above by the level  $R'^{-1}(0)$ , where marginal revenue is zero. This is effectively the “competitive bottleneck” property [see [Armstrong \(2004\)](#)] that each broadcaster has a monopoly in delivering its viewers and so prices access to those viewers monopolistically.<sup>47</sup> This is a feature of two-sided markets when one side single-homes. At the other extreme, if  $\gamma \geq p(0)$ , the optimum has no advertising because the nuisance cost exceeds the demand price (social benefit) of all ads. The equilibrium though always has advertising, because ads are the only source of revenue for broadcasters.

We now look at the entry dimension of performance. We continue to suppose that subscription pricing is infeasible (or indeed that it is not used in equilibrium). It is insightful to suppose that  $\gamma = 0$  and retain the assumptions of fully covered markets and unit demands by consumers. Then there is a total disconnect between the equilibrium and the optimum. The optimum has the number of firms as described in the previous section, which depends on the product differentiation parameters. It also has a level of advertising determined by  $p(a) = 0$ : given that viewers and readers are not disturbed

<sup>46</sup> Unserved markets are addressed in [Anderson and Coate \(2005\)](#).

<sup>47</sup> This monopoly position is due to the assumption in the models described that viewers are single-homing (choosing just one channel to watch). While it is true that at any given time a viewer may only watch one program, there still may be competition in delivering viewers in a multi-period context when viewers switch channels. [Anderson and Coate \(2005\)](#) provide a preliminary analysis of two-period competition with broadcasters, while [Armstrong \(2004\)](#) analyzes (simultaneous) readership of multiple magazines along the lines of [Caillaud and Jullien \(2003\)](#).

at all, the social optimum should have all advertisers with positive demand price communicate with the prospective buyers of their products. On the other hand, if  $\gamma = 0$ , there is no conduit for competition between firms. Each will choose the level of ads such that  $R'(a) = 0$ , and so maximizes the revenue per reader or viewer delivered. Advertisers (leastwise, those with demand prices for ads above  $p(R'^{-1}(0))$ ) choose to advertise on all channels so the number of prospective buyers reached is independent of the number of broadcasters in the market. What this means is then that the total revenue,  $R(a^*)$ , is a “prize” that is fully dissipated by the  $n$  broadcasters entering the market. The equilibrium number of broadcasters is then  $R(a^*)/K$ . Hence, for example, doubling the number of advertisers (at each level of willingness to pay), will double the number of firms in the market at equilibrium. But the optimal number will remain unchanged.

In summary, the advertising level when  $\gamma = 0$  is too small at the equilibrium and advertising revenue is a pure rent split by the number of firms. Hence there are too few ads and the number of firms may bear no relation to the optimal number. A weak ad demand will mean the market cannot be served; a strong one will be massively over-served. Anderson and Coate (2005) already note that if there is little ad demand, then the free market cannot provide much programming. This is clear in a system that needs ad revenues to survive. On the other hand, the market may over-provide too. For example, Anderson and Coate (2005) show the market may be served by two firms when it is optimal to only have one. This possibility of over-entry clearly extends to circle model with free entry, as is borne out by results in Choi (2003). It is also apparent for the explicit advertising model with business stealing as used by Dukes (2004). Indeed, parallel to the finding in Anderson and Coate (2005), Dukes finds that advertising is above the optimal level when media differentiation (measured by  $\tau$ ) is high enough.

Consider briefly the case when ad demand is perfectly elastic with demand price  $\beta$  per advertiser per viewer reached. Then ads are formally like standard prices in product differentiation models. At the optimum, though, we should have no ads shown if  $\gamma > \beta$ . Conversely, if  $\gamma < \beta$ , all advertisers should be allowed to advertise. The equilibrium number of ads varies continuously with  $\gamma$  though.

Finally, we return to the case when pricing is feasible along with advertising. Then, as shown in the short-run analysis, ad levels are independent of firm numbers. Ad levels are insufficient, because the optimum under covered markets sets  $p(a) = \gamma$ .<sup>48</sup> The number of firms in the market is the same as in the model when only prices can be used, and we know that the number of firms is typically too large in models of product differentiation, and these conclusions transfer directly. These conclusions differ quite drastically from those of the equilibrium without pricing (i.e., advertising only). It is worth recalling though our earlier caveat that we have assumed that each viewer watches one program, and that parameters ensure the equilibrium is in the region with fully served markets.

<sup>48</sup> Anderson and Coate (2005) deal with uncovered markets.

## 6. Product selection: Choosing program type

We now address the issue of “breadth” provided by the market, by which we mean the horizontal differentiation between products selected. To ease readability, we develop the model from the beginning to make this section free-standing. Given the motivating example is newspapers, we refer throughout to papers and readers.

Suppose then that there are two newspapers. Each produces at unit cost  $c \geq 0$ , and each sells advertising space to advertisers. The newspapers are sold at prices  $s_i$ ,  $i = 1, 2$ , to readers. Each reader buys only one paper (“single-homing”). Readers’ political opinions range from the extreme left to the extreme right. This taste diversity is represented by the unit interval  $[0, 1]$ . In standard fashion, the further the newspaper’s stance from the reader’s ideal point, the higher the disutility of the reader. Following Gabszewicz, Laussel and Sonnac (2002), we suppose that this disutility is  $t(x - x_i)^2 + s_i$  for a reader of type  $x$  buying a newspaper offering opinion  $x_i$  (see Equation (2)).

Let  $x_1$  and  $x_2$  denote the locations of the papers. The demand functions  $N_1$  and  $N_2$  for the newspapers are then easily derived as

$$N_1(s_1, s_2) = \frac{x_1 + x_2}{2} + \frac{s_2 - s_1}{2t(x_2 - x_1)}$$

and

$$N_2(s_1, s_2) = \frac{2 - x_1 - x_2}{2} + \frac{s_1 - s_2}{2t(x_2 - x_1)}.$$

The corresponding editorial revenues are then

$$\pi_i = (s_i - c)N_i(s_1, s_2), \quad i = 1, 2.$$

This model of the press industry is the standard Hotelling location model with quadratic transportation costs, and for this problem we know that firms always locate at the two extremes of the unit interval at the unique sub-game perfect equilibrium of the game in which firms select price and location [see d’Aspremont, Gabszewicz and Thisse (1979)]. Thus, in the absence of advertising revenues, the media’s ideological messages reflect maximal political diversity at equilibrium.

We now introduce the second source for financing daily press, revenue accruing from advertising. Of course, if advertising rates and volumes are assumed to be fixed and independent of the number of readers, the above conclusion still holds and advertising revenues simply add to revenues. However, the larger the readership, the more attractive should be the newspaper to advertisers, and the more they are willing to pay for exposure to a larger block of readers. For simplicity, we suppose that the demand for advertising per reader reached is perfectly elastic, and let the demand price (per advertiser per viewer) be  $\beta$ .

Then profits accruing to paper  $i$  from newspapers’ sales to the readership and advertising space to the advertisers now amount to

$$\pi_i = (s_i - c)N_i(s_1, s_2) + \beta N_i(s_1, s_2), \quad i = 1, 2.$$

Substituting from the reader demand functions above, we get

$$\pi_1(s_1, s_2) = (s_1 + \beta - c) \left( \frac{x_1 + x_2}{2} + \frac{s_2 - s_1}{2t(x_2 - x_1)} \right)$$

and

$$\pi_2(s_1, s_2) = (s_2 + \beta - c) \left( \frac{2 - x_1 - x_2}{2} + \frac{s_1 - s_2}{2t(x_2 - x_1)} \right).$$

These revenue expressions are just the same as those obtained by the firms in a spatial competition model with quadratic transportation costs, when a constant unit subsidy equal to  $\beta - c$  is added to the newspaper's price. This subsidy is equal to the difference between the unit receipt originating from advertising sales and the unit production cost of each copy of the newspaper. We may now identify the sub-game perfect equilibrium of the sequential game in which editors select, in the first stage, their political images  $x_1$  and  $x_2$  (opinion game) and in the second stage, their newspapers' prices  $s_1$  and  $s_2$  (price game). In the price game, payoffs are given by the equations above. However, prices are constrained to be non-negative. When the price game has an interior solution with positive prices,<sup>49</sup> these are given by

$$s_1^* = c - \beta + t(x_2 - x_1) \frac{2 + x_1 + x_2}{3}$$

and

$$s_2^* = c - \beta + t(x_2 - x_1) \frac{4 - x_1 - x_2}{3}.$$

Substituting these sub-game equilibrium values of the price game back into the profit functions enables us to now solve for the equilibrium to the papers' location game. This yields the conclusion that the equilibrium outcome depends crucially on the size of  $t$  and  $\beta$  [see Gabszewicz, Laussel and Sonnac (2002), for full details]. Indeed, when political preferences are strong ( $t$  "large") and/or when advertising receipts are weak ( $\beta$  "small"), the opinion game has a unique equilibrium with maximal political diversity. This is much as the game in pure subscriptions, which might be expected with weak advertising demand.

However, with weak political preferences and/or significant advertising receipts, the opinion game has a unique equilibrium with *minimal* political diversity.<sup>50</sup> Thus, when

<sup>49</sup> This assumption simplifies the presentation of the results here. It is not true though that the price game always has an interior solution. The values for prices given in the text can become negative, for instance, when  $\beta$  is large compared with  $c$ , in which case the subscription price must be equal to zero. See Gabszewicz, Laussel and Sonnac (2002) for more details.

<sup>50</sup> There is also an overlap region where both are equilibria. Gal-Or and Dukes (2003) offer an additional explanation for duplication. By offering similar programming (i.e. duplicating) media induce stiffer competition for viewers, thus coordinating on lower levels of advertising and thereby raising advertisers' surpluses in product markets.

papers seek advertising revenue, there are considerable consequences on the equilibrium of the opinion game: the tendency to offer readers maximal political diversity is fully reversed when political preferences are weak and/or advertising receipts are sufficiently important.<sup>51</sup> This conclusion reveals that the dependence of advertising rates on the readership's size may well induce editors to influence the political content they display to their readership so as to develop higher advertising resources.

The welfare economics of the above model are quite straightforward. The social optimum locations are at the quartiles.<sup>52</sup> The equilibrium though involves either minimum differentiation, or maximum differentiation.<sup>53</sup> These locations are equally bad from the social perspective. Recall that if the subscription prices are allowed to be negative, the only equilibrium is maximal differentiation. Negative prices could be reflected in giveaways like free gifts, although in that case one might expect readers could pick up several copies of free papers along with free gifts, so rendering such negative prices infeasible.<sup>54</sup> In practice, even though there do exist newspapers that are given away free, one might expect the non-negativity constraint to be reflected in a small nominal price to obviate outright wastage.

The equilibrium determined above was derived from two specific assumptions on nuisance costs (they are zero) and advertising revenues (they are constant per viewer). We might though expect somewhat similar results with positive nuisance costs and a revenue function that exhibits decreasing average returns per ad per viewer. Indeed, as long as the subscription price is positive, newspapers carry the ad level that satisfies  $R'(a) = \gamma$ , and so profits are independent of the ad revenue and competition is effectively competition in subscription prices alone, as we have seen above. Such competition leads to maximal differentiation. However, when locations are "too close", the subscription price is capped at zero. Then the equilibrium is in ads alone. This consideration leads us to briefly consider the case of competition in ads alone.

Suppose then that  $R(a) = \beta a$ , so that the ad demand is the same as above, yet now with  $\gamma > 0$ . Then the result is maximal differentiation because the ad competition model is formally equivalent to the pure subscription price one.<sup>55</sup> This means that there

<sup>51</sup> The price floor (non-negative price) is crucial to this result. Without it, equilibrium prices can take on negative values, dissipating advertising revenues to the benefit of readers and maximum differentiation would continue to prevail. With a price floor, the editors can, beyond some point, choose a political position closer to their competitor's, without further exacerbating competition.

<sup>52</sup> These locations minimize the average distance traveled. Each location is at the mid-point of the market it serves, and market sizes are equal.

<sup>53</sup> The maximum differentiation result is rather an artifact of the assumption that firms must locate in the unit interval. If locations are unrestricted, they choose to locate at  $(-\frac{1}{4}, \frac{5}{4})$ , which locations are outside the unit interval, although not as far apart as they could possibly go. These locations are more extreme than the tastes of any reader, and are socially less desirable than minimum differentiation.

<sup>54</sup> The "free gift" could be interpreted as the comics pages, so individuals only want one copy.

<sup>55</sup> To see this, note that the ad competition profit function is  $\pi_i = \beta a_i N_i(\cdot)$  and the profit function under price competition is  $\pi_i = s_i N_i(\cdot)$ . The argument of the readership function in both cases is the full price, so the two problems give the same solutions.

is a discontinuity in behavior between the cases of  $\gamma = 0$  (minimum differentiation) and  $\gamma > 0$  (maximal differentiation).

Suppose now that  $R'(a)$  is strictly concave. Note first that if  $\gamma = 0$ , both papers carry the ad level such that  $R'(a) = 0$ , and papers just strive to maximize the number of readers. Then they minimally differentiate. The analysis is quite complex if  $\gamma > 0$ . Preliminary results suggest that the equilibrium locations may get arbitrarily close to minimal differentiation. However, verifying that the second order conditions hold for the first stage (location) game remains elusive.

An overall evaluation of the state of the art on location competition as applied to the economics of media industries is as follows. The standard specification of quadratic disutility costs and price-only competition leads to maximal differentiation. This result constrains welfare analysis because it predicts that locations are always excessively far apart, contradicting casual empiricism and flexibility of the solution. Allowing for advertising competition offers the tantalizing proposition that locations could vary between maximal and minimal differentiation (according to parameters), and so the solution is not a priori constrained by excessive diversity. However, actually proving that the candidate equilibrium is the solution to the problem is a difficult mathematical problem.

## 7. Press concentration and advertising

Specialists in media economics have often viewed the advertising market as responsible for *concentration* in the press industry. This is backed up with empirical work that relates advertising rates to the circulation of newspapers.<sup>56</sup> Earlier theoretical contributions that ascribe the growth of concentration within the press industry to the interaction between advertising and newspapers' markets are due to Furhoff (1973), Gustafsson (1978), and Engwall (1981). We now understand these interactions as those of a two-sided market. The market for printed media is a particularly significant example of this phenomenon. Newspapers sell some space to advertisers and the larger the demand for advertising, the higher the share of advertising revenues in their total profits. On the other side of the market, readers' attitudes toward printed media advertising are quite ambiguous. Although it seems generally accepted that TV-viewers dislike advertising [see Brown and Rothschild (1993), and Danaher (1995)], it seems that readers of printed media have mixed views, and some have a positive perception of press advertising while others are negative.<sup>57</sup> If we take this at face value, then the utility of the readers is related to the size of advertising demand, positively for some and negatively for others. This means there are different types of network effects at play between the printed media and the advertising markets for the readership too. Indeed, some think that advertising could foster the circulation of newspapers [see Blair and Romano (1993), Gustafsson (1978),

<sup>56</sup> See Dertouzos and Trautman (1990), Reimer (1992) and Kaitatzi-Whitlock (1996).

<sup>57</sup> In a recent opinion poll, 37% of French readers claimed to be ad-averse (*Le Monde*, November, 9, 2002).

Table 10  
Magazine advertising cost and daily newspapers, US, circulation, costs, and cost per 1000 readers

			1965	1985	1997	2000
Magazine	Combined circulation	(000)	147,080	159,978	129,623

and Rosse (1980)]. Others believe that it slows it down [see Musnick (1999) and Sonnac (2000)].

Some statistics on advertising costs through reaching readers by magazine ads and by newspapers are given in Table 10.

We now analyze the interaction between the newsprint media and advertising industries when there are readers of both stripes. Let there be two editors producing differentiated newspapers or magazines (for instance, news-magazines proposing different political opinions) that take the extreme positions on a unit segment. Readers' tastes are distributed uniformly on  $[0, 1]$ . Newspaper 1 is located on this spectrum at point 0, while newspaper 2 is located at point 1. Editors also sell some proportion of their newspaper's surface to advertisers who buy it to promote the sales of their products. At each point  $x$  of the unit interval  $[0, 1]$ , a fraction  $\lambda$  of readers are *advertising-avoiders* and a proportion  $1 - \lambda$  are *advertising-lovers*. The advertising-avoiders lose utility when there are more ads in the paper, while the advertising-lovers gain. More precisely, suppose editor  $i$  quotes a price  $s_i$  for the newspaper and sells a proportion  $a_i$  of it to advertisers. For an advertising-avoiding reader located at  $x$ , the total loss in utility when buying newspaper 1 (at 0) is

$$x^2 + \gamma a_1 + s_1, \quad \gamma > 0,$$

while the total loss in utility when buying newspaper 2 (at 1) is  $(1 - x)^2 + \gamma a_2 + s_2$ . Similarly, for one of the  $1 - \lambda$  advertising-loving readers at  $x$ , the total loss in utility when buying newspaper 0 is

$$x^2 - \gamma a_1 + s_1, \quad \gamma > 0$$

and the total loss in utility when buying newspaper 2 is  $(1 - x)^2 - \gamma a_2 + s_2$ . Note that, for simplicity, it is assumed that the ad-loving propensity on one side is exactly equal to the ad-avoiding cost on the other side.

Define  $\tilde{k} = \gamma(2\lambda - 1)$  (so that the case of all ad avoiders corresponds to  $\tilde{k} = \gamma$ ). The reader demand function for newspaper  $i$ ,  $i = 1, 2$ , is then

$$\begin{aligned} D_i(s_1, s_2, a_1, a_2) &= 0 \quad \text{for } s_i \geq 1 + s_j + \tilde{k}(a_j - a_i); \\ D_i(s_1, s_2, a_1, a_2) &= 1 \quad \text{for } s_j + \tilde{k}(a_j - a_i) - 1 \geq s_i \geq 0; \\ D_i(s_1, s_2, a_1, a_2) &= \frac{1}{2}(1 + (s_j - s_i) + \tilde{k}(a_j - a_i)) \quad \text{otherwise.} \end{aligned}$$

The difference  $(a_i - a_j)$  between the advertising volumes in the papers plays a crucial role in the demands for the newspapers. At equal prices, the paper with the more advertising benefits from a larger readership if and only if there is an ad-loving majority in the reader population ( $\lambda < \frac{1}{2}$ ).

Total revenues also include advertising revenues from sales of advertising space. We now develop a model of the advertising market to derive the demand for advertising space as a function of the advertising rates charged by the editors in this market. Let  $q_i$  denote the unit price of an ad charged to advertisers by paper  $i$ ,  $i = 1, 2$ . Advertisers are ranked in the unit interval  $[0, 1]$  by increasing willingness to pay for an ad. Assume that each advertiser  $\theta$ ,  $\theta \in [0, 1]$ , buys an ad in only one of the two newspapers, at the exclusion of the other (thus we assume single-homing for advertisers). Assume that advertiser  $\theta$ 's benefit from inserting an ad in newspaper  $i$  at a rate  $q_i$  is  $D_i\theta - q_i$ , where  $D_i$  is the readership of paper  $i$  as given above. Since  $\theta \in [0, 1]$ , the advertising market is never covered.<sup>58</sup> This representation of the advertising market sets it up as a vertically differentiated industry [Gabszewicz and Thisse (1979)]; here, the ‘‘high quality’’ product firm is the newspaper with the larger readership.

Consequently, if  $a_i$  advertisers buy their ads in newspaper  $i$ , paper  $i$ 's total profit  $\pi_i$  is

$$\pi_i(s_1, s_2, q_1, q_2) = s_i D_i(s_1, s_2, a_1, a_2) + q_i a_i, \quad i = 1, 2. \tag{6}$$

We consider a two-stage game played between the papers. At the first stage, they select newsstand prices  $s_1(a_1^a, a_2^a)$  and  $s_2(a_1^a, a_2^a)$  conditional on the expected volumes  $a_1^a$  and  $a_2^a$  of advertising which will be determined in the second stage. Payoffs in the first stage depend on the expectations of both editors and readers about the difference  $a_i^a - a_j^a$  between the advertising volumes sold by the editors in the second period. These payoffs are given by Equation (6) with  $a_i - a_j = a_i^a - a_j^a$ .

The second stage strategies are the advertising prices  $q_1$  and  $q_2$ . Entering in this stage, prices  $s_1$  and  $s_2$  have been already selected determining readerships,  $D_i(s_1, s_2) = D_i$ . Based on the above model of the advertising market, payoffs in the second stage game are derived as a function of advertising rates  $q_1$  and  $q_2$ . Denoting by  $s_i^*(a_1^a, a_2^a)$ ,

<sup>58</sup> The case of a covered market is treated in Gabszewicz, Laussel and Sonnac (2004).

$i = 1, 2$ , the equilibrium values in the first-stage game, conditional on expectations  $a_1^a$  and  $a_2^a$ , and by  $(q_1^*, q_2^*)$  the equilibrium of the second-stage game, we further require  $a_i(q_1^*, q_2^*) = a_i^a$ : the value of the demand function of each editor in the advertising market at the second-stage equilibrium is consistent with first-stage expectations on these values.<sup>59</sup>

The equilibria of the game are as follows [and broadly substantiate parallel results by [Caillaud and Jullien \(2003\)](#)]. First, whatever the value of  $\lambda \in [0, 1]$ , there always exists an equilibrium corresponding to symmetric expectations ( $a_1^a = a_2^a$ ), with prices and market shares equal in both markets. This is an equilibrium with symmetric expectations about the advertising market shares. This equilibrium leads to Bertrand competition in the advertising market and, consequently, to equal prices and market shares in the newspaper market. In the case of ad-repulsion ( $\lambda > \frac{1}{2}$ ), no other equilibrium exists than the symmetric one.

Second, consider the case of a majority of ad-lovers ( $\lambda < \frac{1}{2}$ ). Then, if ad-attraction is strong ( $-6 \geq \tilde{k} = \gamma(2\lambda - 1)$ ), there are two asymmetric equilibria. At each, one editor eliminates the rival completely, and the eliminating editor is the one who is expected to sell more advertising. If ad-attraction is weaker ( $\tilde{k} > -12$ ), there are also two asymmetric equilibria with both editors enjoying strictly positive market shares in both the readership market and in the advertising markets. The paper which is expected to sell more advertising has higher prices and larger market shares in both markets. This latter result is akin to the base intuition of [Furhoff \(1973\)](#) revealing why ad-attraction can drive concentration growth in the daily newspaper industry. This intuition was described by [Gustafsson \(1978, p. 1\)](#) in the following terms: "The larger of two competing newspapers is favoured by a process of mutual reinforcement between circulation and advertising, as a larger circulation attracts advertisements, which in turn attracts more advertising and again more readers. In contrast, the smaller of two competing newspapers is caught in a vicious circle, its circulation has less appeal for the advertisers, and it loses readers if the newspaper does not contain attractive advertising. A decreasing circulation again aggravates the problems of selling advertising space; so that finally the smaller newspaper will have to close down." The equilibria under strong advertising attraction can be viewed as the limit of the market dynamics underlying this description. The paper which is expected to sell a larger number of ads makes itself more attractive than the rival one. The more ads the former inserts, the more this reinforces the attractiveness. This strengthening finally leads to the eviction of the latter from both the press and advertising markets. There also exist other equilibria corresponding to situations of weaker ad-attraction. At these equilibria, the paper with the larger expected share in the advertising market does not completely evict its rival. Nevertheless, the initial asymmetry about expected advertising market shares makes the paper with the larger expected share the leader in both industries since it sells more in both, and at higher prices.

<sup>59</sup> For a detailed equilibrium analysis, see [Ferrando et al. \(2004\)](#).

The interaction between the reader and advertising markets is rather complex when the two-sided network effects between these two industries are explicitly taken into account. It leads however to an important conclusion: *under ad-attraction, concentration in the press industry should be expected as a direct and natural consequence of the advertising market.* Since newspapers constitute a major vehicle for spreading political and social information to citizens, it is important to recognize the shortcomings in the business model that might lead to high concentration.

## 8. Conclusions

Television indubitably drives much of popular culture today and radio, magazines, and the Internet are other important drivers. Households in the US currently watch some 8 hours of television a day. A common business model describes several media markets, including television and radio, the Internet, and newspapers and magazines. Entertainment and content are the bait to get prospective purchasers of consumer goods to be exposed to advertisements. This chapter has described the economics of this business model. What makes broadcasting different from other goods is that the broadcast delivers two goods, the program to viewers and the audience to the advertisers. This is why it is a two-sided market. Put another way, the advertising is piggy-backed onto the program that interests the viewers.

We have examined several dimensions of performance of the market. These include the range, quality, and breadth of the offerings (magazines, television programs, websites) provided. Since these are classic dimensions studied in the economics of product differentiation, we borrowed heavily from the economic theory of product differentiation. The dimension of interest may also be a political measure, such as the difference between the political stances represented in newspapers. There are other dimensions apart from the measures of the diversification of offerings that are important to the economics of media industries. All of these dimensions are important determinants of the cultural level. However, the economic models must be interpreted with care. For example, a higher “quality” in the model is one that more people choose, *ceteris paribus*. This may not correspond to some paternalistic view of what people “should” be watching, reading, or listening to.

Media industries exhibit several market imperfections. Broadcasting is a public good that is nonetheless provided by the market system, and the reason it is provided is advertising finance. But the ads are a nuisance to viewers (negative externality). Broadcast firms often historically formed a tight oligopoly. Given this knot of imperfections, one might have a poor expectation of performance in the industry. Indeed, one usually expects public goods to be under-provided, market power to also cause underproduction, and negative externalities to cause overproduction. Surprisingly then, media markets are

able to deliver optimal performance configurations. Careful empirical work is needed to determine the values of key parameters in the structural model and hence to determine how far current practice deviates from optimal, and in what direction. For valuable progress in this direction, see [Wilbur \(2004b\)](#).

There is another type of market failure inherent to the market provision of broadcasting through advertising finance. Television offerings are disciplined by indirect consumer sovereignty: viewers “vote” with their eyes, and broadcast companies want to deliver viewers – of the right demographics – to advertisers. However, there is no incentive under advertising-based finance to cater to the tastes of viewers who would not buy the products advertised. This means there will be bias even without paternalistic views of what people “ought” to be watching. This bias explains the targeting of TV programs to those demographics that deliver most expected revenues to advertisers. Loosely, one would expect these to be the twenty- and thirty-somethings with high disposable incomes. Those with as-yet unformed tastes and large discretionary spending are the most lucrative targets for advertisers. Insofar as characters in television programs often reflect their audience (people like to watch characters similar to themselves), then one can indeed see many programs with characters in the 20–50 year old range. The reason is quite straightforward: the advertising dollars are in this range. This causes quite an important cultural bias. [Goettler \(1999\)](#) finds that shows attracting more homogeneous viewerships (in terms of age and gender) elicit higher advertising prices. This makes sense because then ads may be better targeted. The concurrent bias that this effect suggests is that there is a tendency for programming to be too narrow. Second, he finds that shows watched by 35–49 year olds command higher advertising rate premia, suggesting a bias in catering to this group. Third, he finds that the advertising price increases in the size of the audience in a convex manner. The associated bias is toward programming with mass appeal, and the Lowest Common Denominator concern of [Beebe \(1977\)](#) arises from this incentive.

Of course, whenever an audience is watching or paying attention to any event, there is the incentive to try to reach them with a message. This is all the more true in the age of TiVo and other ad avoidance technologies, and ever greater demand from advertisers to get their messages across. Commercial placement is being seen increasingly in movies and programs (e.g., BMW’s in James Bond films in place of the traditional Aston Martin), and it will alter the scripts of the movies themselves, as writers have to write in the sponsoring products. One might view such placement as a Trojan Horse carrying in undesired elements. A similar phenomenon has been happening in US schools. Channel One provides programming free to schools and even pays for the hardware (televisions, satellite dishes, etc.). The Trojan Horse is the advertising that comes with the programming. The schools must guarantee 90% of students watch, and they are not allowed to turn off the supposedly educational programming. The programming is designed rather like MTV programming, and, although purportedly covering current affairs, is really de-

signed as a vehicle for advertisements.<sup>60</sup> Advertisers in turn pay high premia for slots: up to twice the amount spent to reach adults.<sup>61</sup>

Children's viewing habits are also the concern underlying the FCC's requirement (since 2001) that each new television be equipped with a V-chip (see <http://www.fcc.gov/vchip/>). The chip enables parents to block programming deemed unsuitable, as rated by the "TV Parental Guidelines", that were established by the National Association of Broadcasters, the National Cable Television Association and the Motion Picture Association of America. However, use of this blocking device does not seem to have caught on (in contrast with Internet blocking filters). As Hazlett (2004) puts it: "Perhaps parents adopted Internet filters and spurned the V-chip because watching television is generally a more public activity: It's easier to keep an ear on what your kids are watching in the living room than to keep an eye on every Web site they see."

Several recent papers have empirically investigated models of two-sided markets in various different contexts. The pioneering paper in the print area is Rosse (1970), who estimated cost curves in the newspaper industry in the context of a model that included newspapers' feedback effects between advertising and readership. Rysman (2004) considers welfare properties of various market structures in the yellow-pages market, and finds that oligopoly is preferred to monopoly. Since consumers use yellow pages to find information, his conceptual framework could be applied to a newspaper industry with ad-loving readers. Kaiser and Wright (2004) take Armstrong's (2004) model of two-sided market competition to data on the German magazine industry, assuming single-homing on the part of both advertisers and readers.

There have also been several recent empirical studies of the broadcasting industry. Berry and Waldfogel (1999a, 1999b, 2001) use data on radio listenership to look at the effects of entry and concentration in radio. Sweeting (2004) tackles the difficult problem of estimating an equilibrium model of the timing of radio stations' commercial breaks. Wilbur (2004a) uses advertising levels and ad prices and viewing data to estimate a two-sided model of the television advertising market. He finds ads cause viewing losses: preliminary estimates indicate that 30 seconds of ads on top of the current level will decrease watching by 1.1% of viewers (or 0.7% of households) per hour.

One direction for future research is to take a deeper look at actual market structures. Most systems are mixed, and include a variety of different firm types. Anderson (2003) provides a preliminary analysis in this direction by looking at the coexistence of advertising financed and subscription financed television, while Peitz and Valletti (2005) also compare these two types of regime. If we look at actual market structures there are various types operating in the market, with varying degrees of public support, regulation, advertising finance, etc. In the US, public television, supported by the Federal

<sup>60</sup> "Channel One is more commercial than network TV; its hipper, faster-moving, full of loud rock music and directly or indirectly, its always selling something." [Fox (2004)]

<sup>61</sup> "Each 30 second ad costs advertisers nearly \$160,000, more than twice the cost of a commercial on prime time television news." [Gange (2004), in a review of Fox (2004)]

Government and by private donations, coexists with commercial channels, pay channels and religious channels. In the UK, the BBC is supported by television license fees and Government grants, and is not allowed to carry ads. There are six major channels in the television market in France. These vary by the level of Government support and the number of ads they are allowed to screen, as well as by content of programming, and one is a pay channel during prime time and into the night. One thorny problem for future research concerns the appropriate modeling of the behavior and objectives of a Public Broadcaster.

On the empirical side, it is worth investigating more deeply the extent to which programming is indeed duplicated along the lines suggested by Steiner (1952), and the work on the *Pensée Unique*, or whether indeed programs are more differentiated. Very useful work in this direction is the study by Goettler and Shachar (2001). These authors suggest that broadcast firms instead differentiate their offerings quite substantially.

Another issue of cultural concern is the “quality” of programming defined from the perspective of the local community. The FCC in the US stresses concerns about “localism” in the decision to grant a license. Similarly, local content rules (as in France and Australia, among others) are designed to retain and foster national programming. These are related issues because they stress a concept of quality that reflects and bolsters community appreciation of its integrity. If an objective such as protecting community identity is valued, then it would presumably need special protection (or subsidy) when faced with a Lowest Common Denominator type programming of mass appeal (“Hollywood” to the protagonists). The appropriate policy stance in this regard remains an open research issue.

### Appendix A

Several special cases treated in the literature may be derived from a circle model with power transport costs. We therefore determine the equilibrium for that model. Assume the circle has circumference  $L$ , and the transport cost function is  $\tau(\cdot)$ . We seek a symmetric equilibrium. Let the indifferent viewer between broadcaster  $i$  (at location 0) and its clockwise neighbor (at  $L/n$ ) be at  $\hat{x}$ , so  $i$ 's viewership is simply  $2\hat{x}$ , and our task is to determine the value of  $N'$ .

If the other broadcasters all set a common ad level  $a$ , while broadcaster  $i$  sets  $a_i$ , demand satisfies equality of “full nuisance” or

$$\gamma a_i + \tau(\hat{x}) = \gamma a + \tau\left(\frac{L}{n} - \hat{x}\right).$$

Evaluating at a symmetric solution,

$$\frac{d\hat{x}}{da_i} = \frac{-\gamma}{2\tau'\left(\frac{L}{2n}\right)}.$$

For power transport costs,  $\tau(x) = tx^\alpha$ ,  $\alpha \geq 1$ , this becomes

$$\frac{d\hat{x}}{da_i} = \frac{-2^{\alpha-2}\gamma n^{\alpha-1}}{\alpha t L^{\alpha-1}}$$

so that ad levels solve (by Equation (5) and recalling that in a symmetric equilibrium,  $N_i = L/n$ , and  $N'_i = \frac{2}{\gamma} \frac{d\hat{x}}{da_i}$ )

$$\frac{R'(a^*)}{R(a^*)} = \frac{2^{\alpha-1}\gamma n^\alpha}{\alpha t L^\alpha}.$$

Since the left-hand side is falling in  $a$ , the important result here is that the equilibrium ad level is *decreasing* in the number of competing platforms. This makes sense here because competition is effectively contested over the nuisance value to consumers, and more competition means less nuisance, and so less advertising on each channel.<sup>62</sup>

There are some important special cases to this. First, suppose that ad demand is perfectly elastic. Then  $R = \beta a$ , where  $\beta$  is then the demand price for ads. Then  $\frac{R'}{R} = \frac{1}{a}$

<sup>62</sup> We assume in the main text that the strategic variable is price per ad per viewer. This is equivalent to ad levels being the strategic variables (this equivalence property follows from the feasibility of multi-homing for advertisers and the assumption that the willingness to pay for an ad is a linear function of the number viewers delivered by a channel). This strategic assumption corresponds to broadcasters that choose the size of their advertising breaks and then sell the space to prospective advertisers. An alternative strategic assumption is that broadcasters take as given the ad prices of rivals. This could be considered a Bertrand assumption where the standard one is a Cournot assumption. The implications of the alternative (Bertrand) assumption may be thought of as follows. When a broadcaster changes its price per ad, and a rival's price is assumed fixed, the rival must adjust its ad levels to keep its price per ad constant. More concretely, suppose a broadcaster raises its price per ad. Fewer advertisers want buy ads there, and so more viewers watch (which dampens the initial effect somewhat). This means that the rival needs to cut back its ad level because otherwise the rival is delivering fewer consumers per ad. It must make up for that by improving the “quality” of its ads – by delivering more viewers. This then means that the ad levels move together when broadcasters use ad price as strategies. This means more collusive behavior. Since more collusion implies MORE ads, price strategies lead to more ads, and closer to monopoly levels. It is noteworthy that Bertrand competition in standard differentiated products markets typically leads in stead to more competitive outcomes than Cournot competition. [Crampes, Haritchabalet and Jullien \(2004\)](#) also uncover such an effect. [Nilssen and Sjørgard \(2003\)](#) compare price and quantity strategies, using a representative consumer approach to advertising demand.

and we can solve for  $a^*$  directly as

$$a^* = \frac{\alpha t L^\alpha}{2^{\alpha-1} \gamma n^\alpha}. \quad (\text{A.1})$$

Ad levels rise with product differentiation ( $t$ ) and fall with the number of firms. They fall as viewers get more annoyed by them too.

The special case of  $\alpha = 1$  gives the standard Vickrey–Salop [Vickrey (1964), Salop (1979)] result of<sup>63</sup>

$$a = \frac{tL}{\gamma n}.$$

Noting that the standard duopoly line model is like  $L = 2$  (the firms are one unit distance apart), then (setting  $n = L = 2$  and  $\alpha = 1$  in Equation (A.1)) we have for that case<sup>64</sup>

$$a = \frac{t}{\gamma}.$$

In a similar fashion, for the standard version of the line model with two platforms and quadratic transport costs, set  $n = L = \alpha = 2$  in Equation (A.1) to give exactly the same result as for linear transport costs:

$$a = \frac{t}{\gamma}.$$

<sup>63</sup> Gal-Or and Dukes (2006) investigate the incentives for non-consolidating media mergers for firms on the circle, using the framework of Dukes (2004) described further below. On the one hand, a merging media firm improves its market power vis-à-vis advertisers since they now have a larger set of viewers. However, reduced competition for viewers induces higher equilibrium levels of advertising, which, in their model, lowers product market surpluses. They show that media mergers are profitable when the media market is sufficiently competitive so that, post-merger, the market power benefit exceeds the losses associated with increased advertising levels. Their results contrast with traditional product markets, where mergers are more profitable with less competition [Deneckere and Davidson (1985)]. Choi (2003) considers mergers of neighboring firms in the context of the model of this section. He shows the more familiar result [see also Eaton and Wooders (1985)] that such mergers raise the profits of all firms, and these profits are lower for firms further from those that merge.

<sup>64</sup> The monopoly case is rather interesting. Anderson and Coate (2005) show that the monopoly ad level for the Hotelling specification may be higher or lower than the duopoly one as the market is or is not served, respectively, under monopoly. This result appears quite specific to the Hotelling model with unserved markets though, as we argue below.

Rather similar qualitative results hold for the logit model of demand considered by Anderson (2000).<sup>65</sup> Here we have simply that

$$N' = \frac{1}{\mu} \frac{1}{n} \left( \frac{1}{n} - 1 \right),$$

and so the equilibrium ad level is given by

$$\frac{R'}{R} = \frac{\gamma}{\mu} \left( \frac{n-1}{n} \right).$$

With perfectly elastic ad demand, as above, this reduces to the closed form:

$$a = \frac{\mu}{\gamma} \left( \frac{n}{n-1} \right)$$

which increases with product differentiation as measured by  $\mu$  and also decreases with the number of firms.<sup>66</sup>

The logit form may also readily be extended to allow for viewers who do not watch. Then, with the logit above, and an outside option,<sup>67</sup> we get an implicit form for the equilibrium ad level of:

$$\frac{R'}{R} = \frac{\gamma}{\mu} \left( 1 - \frac{\exp(-\frac{\gamma a}{\mu})}{n \exp(-\frac{\gamma a}{\mu}) + \exp(\frac{V_0}{\mu})} \right)$$

where  $V_0$  denotes the relative quality of the outside option.

Rewriting,

$$\frac{R'}{R} = \frac{\gamma}{\mu} \left( 1 - \frac{1}{n + \exp(\frac{V_0 + \gamma a}{\mu})} \right).$$

Since the right-hand side is increasing in  $a$ , there is a unique solution; since the right-hand side is increasing in  $n$ , higher  $n$  always means lower ad levels for all  $n$ , including

<sup>65</sup> The logit model is given by assuming the  $\varepsilon_i$  terms in Equation (2) are i.i.d. double exponential. Suppressing the transport cost and quality components, the viewership demand function is

$$N_i = \frac{\exp(-\gamma a_i / \mu)}{\sum_{j=1, \dots, n} \exp(-\gamma a_j / \mu)}.$$

<sup>66</sup> These properties hold for a general class of discrete choice models with i.i.d. idiosyncratic tastes with a log-concave distribution.

<sup>67</sup> The viewership demand function is then

$$N_i = \frac{\exp(-\gamma a_i / \mu)}{\sum_{j=1, \dots, n} \exp(-\gamma a_j / \mu) + \exp(V_0 / \mu)},$$

where  $V_0$  measures the attractivity of the outside option [see Anderson, Palma and Thisse (1992) for further details].

the transition from monopoly to duopoly. The intuition follows naturally since competition over viewers involves nuisance levels (where one would normally have direct prices) higher competition implies lower prices.

**Abstract**

This chapter is an overview of a new kind of economics of the movies; it also is my attempt to lay a new foundation of the economics of art and culture. The essence of cultural goods is that they are creative goods that have no natural limit on their consumption or dissemination; they are information goods. And they are wildly uncertain. I show how this vision may be implemented in a rigorous and insightful way in the study of the movies. A centerpiece of the analysis is the stable Paretian hypothesis and its usefulness as a model of motion picture revenues, costs, and returns. The industry's organization, contracts, pricing, and compensation deals are also seen as rational adaptations to the uncertainty captured by the stable Paretian probability model.

The essence of the stable Paretian model is that the probabilities of motion picture outcomes are far from Normal. The tails of the stable Paretian distribution are "heavy" and large-scale events are far more probable in a Paretian than in a Gaussian world. The large events far out on the probability tails dominate sample statistics. The variance is infinite and, for some variables, even the mean does not exist. Movie box office revenues, therefore, have no natural size or scale and there is no typical or average movie; each is unique unto itself. Revenue and cost dynamics are complex and expectations of cost or revenue at level  $X$  are proportional to  $X$ .

## 1. Introduction

The movie business is hard to understand. It defies conventional economic models on many levels. But, this is what makes it so interesting. I see the movie business as a laboratory for developing a new kind of economics of art and culture. It is an extraordinarily well-documented business, so there is a rich data base to be exploited by researchers. Where else can you follow a product from birth to death in a matter of weeks or months? Where else can you study the evolution of its revenues and market penetration in such detail? And for so many products.

Studios get overnight reports of box office revenues. Weekly reports are available in industry trade publications, on internet sites, and on the evening news. There are at least three proprietary data sources where the researcher can follow statistics on a weekly or annual basis.<sup>1</sup> And these data sources go back for years.

Detailed filmographies exist of casts, producers, and directors for virtually every film ever released in North America. Because screen credits are so important in the movies, filmographies are highly accurate. Their accuracy is insured because craft unions have elaborate criteria for awarding screen credits. Where else can you find so widely distributed such a careful documentation of creative work and rigorous delineation of creative credits?

The industry requires all this information about box office returns and reputation in order to solve the many vexing problems the industry faces. I think the first order of business for research is to recognize that the movies are an information industry, arguably the first of the twentieth century. The industry produces information, for all that a film really is, and it lives on it. Without this elaborate reporting of film revenues and reputations, the industry could not function. The reporting is required because nobody knows what a film will gross so the industry has to have in place the instruments to adapt flexibly adjusting prices and supply to demand when the audience reveals it. Reputation is crucial when artists and creative inputs are hired for short periods of time and each can become the critical input at some stage of production.

Movies are one-off products that only go around once. You do not know if you will like a movie until you see it. If you like it, you tell your friends about it. This simple act of sharing information leaves no less of the movie for you to enjoy and may even increase your pleasure. This means information can be multiplied.

If information can be multiplied, motion pictures will have increasing returns. Movies that have many viewers will grow more rapidly than movies that have few viewers. The supply of theater seats is perfectly elastic because the run can be extended to increase supply until it equals demand. This means box office revenue is just a number, with no natural limit or scale. It turns out that scale-free distributions capture the statistics of

<sup>1</sup> A.C. Nielsen/EDI (my primary source), Exhibitor Relations, and Paul Kagen are three proprietary data sources. Industry publications, such as *Variety*, *Hollywood Reporter*, and *Box Office*, report on the industry prolifically. The Internet Movie Data Base is a good source for filmographies and various data as well.

movies with high fidelity. Because information does not obey the usual laws of production, the statistics of the movies are rather strange: distributions of variables are sharply peaked and skewed, with a long tail to the right. They are scale-free and high on kurtosis.

The need to manage and adapt to information leads to interesting business practices and contracts. The industry is filled with colorful phrases and unusual contracting practices like “four-walling”, “road shows”, “pay or play”, “house nut”, “legs”, “blind-selling”, and “block-booking”. It is an extremely hierarchical business, with a few movies, stars and directors standing far above the rest in box office grosses. It is frighteningly risky, yet the rate of return is low. Most movies lose money and a handful make nearly all the profit the industry earns.

Movies are produced in a novel way too. Producers assemble temporary teams from a large pool of artists and craftsmen to make movies. These production teams live only for the duration of the project and disband when the movie is finished. At any point in time, just a few people in the industry are actually working. But, a few well-connected actors and directors are very busy and they make most of the movies that dominate box office revenues.

Most movies take several years to produce. There are many pitfalls along the way and the final product is nothing more than a few reels of celluloid. All its production costs are sunk by the time a movie is finished and ready to be released. They may not be recoverable and a finished movie might never get a chance to be seen on a theater screen. Cost is notoriously difficult to forecast and some movies famously go far over budget. A studio can go broke if it goes just one year without a hit. And movies are financed in unusual ways.

These are hard problems, but the hardest one of all is that nobody really knows how much a movie will gross at the box office. If people in the industry did know, there would be no need for its strange practices and they would disappear. It is because “nobody knows” that the movie industry is so fascinating and so different from dentistry or warehousing. It does have analogues though in other creative activities that deal in information such as publishing, music, stage, and patents. The emphasis on complex dynamics and their statistical basin of attraction that has been the basis of a good deal of the work on the movies reviewed in this chapter would appear to have a profitable use in other industries.<sup>2</sup>

“Nobody knows” is the core problem of the movie business. This is the problem almost all of the industry’s colorful and strange practices, contracts and business organization are designed to solve. It is the source of its preoccupation with rank and power and relationships. It elevates “the deal” to its mythical status in the industry.

<sup>2</sup> For example, F.M. Scherer (2000) has used the Bose–Einstein process David Walls and I used to capture motion picture dynamics and the heavy-tailed distributions to which they are drawn to explain the dynamics and size distribution of patent royalties. D. Sornette and D. Zajdenweber (1999) have shown that the innovation time series contains the same ragged profile typical of the movies and other Levy Stable motions.

In this chapter, I shall try to use the ideas of sequential contracting and uncertainty in cost and revenue to explain the movie business. In the process, I will review some of the literature on the movies, but my intention is to reveal what light these concepts shed on these issues rather than to survey the literature. There are three bodies of research on the movie business; the old, the new, and what I call the new–new.

The old research came out of the decade of the antitrust litigation that eventually led to the dissolution of the great studios (and to much antitrust involvement in the movie business in other countries beyond the United States). The approach was to apply conventional antitrust economics to the industry, seeing virtually all its hard-to-fathom practices as attempts to exploit market power. This research is exemplified by Michael Conant's (1960) book, by the testimony in the *Paramount* litigation [Federal Trade Commission (1965) or the more recent book by Litman (1990)]. The bulk of this research did not see the movie business as an information industry and by incorrectly applying models suited to industrial products to this new industry they failed to see the efficiency of the industry's contracts and institutions. This research often confuses demand with supply, as when Seagrave (1997) says that Hollywood "dominates" the world's movie screens. Large openings may temporarily dominate theater screens, but that is supply, not demand. If demand does not fill seats, theaters quickly drop a film for something more promising.

The old motion picture research has been tested and found wanting. In a detailed analysis of the *Paramount* charges, De Vany and Eckert (1991) showed that the industry's organization and contracts were clever and necessary adaptations to the nobody knows principle. De Vany and McMillan (2004) used stock market prices to show that the forced divestment of theaters by the studios was a major financial blow to the industry and that the pattern of losses among firms was inconsistent with the idea that the industry had functioned as an implicit price-fixing cartel (the primary basis of the court's judgment). De Vany and Lee (2001) have shown that market shares are wildly volatile and unstable and that the industry is concentrated, as all information industries are, but the players at the top turnover at a high rate.

The new motion picture research is a modern variant of the old. A number of researchers have been drawn to study the industry (which is good), but have brought with them tools that are, essentially, game-theoretic versions of the old models. Papers have appeared that model the choice of opening date as a strategic game among studios,<sup>3</sup> entry and exit decisions of theaters are modeled as a location game, and rental price differentials among theaters have been described as (centralized) price discrimination (when they are determined in a completely decentralized fashion by the audience under the terms of the exhibition license). There is, of course, an element of truth in each of these points of view; studios do try to avoid opening against a blockbuster. But, no one knows half of what the models posit of the agents, which is more a criticism of the large

<sup>3</sup> See Krider and Weinberg (1998). Liran Einav (2004) has made some progress in empirically modeling motion picture release timing.

information requirements of standard models than of the research. Say, for example, you move your opening two weeks later to avoid going against *Titanic* only to find that *Titanic* is just getting its legs and completely flattens your movie. The models (at least those I have seen) do not correctly portray the uncertainty the agents face, and it can be shown that models that are faithful to the complexity of the problem are computationally intractable. I think the nobody knows principle cuts sharply against this line of research. But, this is good for economics and will eventually lead to progress.

The motion picture industry challenges equilibrium models and existing mathematics in fundamental ways that will require a new kind of modeling. The highly decentralized and adaptive mechanisms employed by the industry are difficult to model in the centralized, strategic mindset typical of optimizing models. I believe capturing the “wild” uncertainty and adaptive decision processes of creative industries provides a more rigorous and insightful basis for a new-new economics. By bringing the “wild” uncertainty of creative enterprises to the forefront, the work I report on here lays a foundation for a New Economics of Art and Culture

A hint of the formidable challenge of understanding “wild” uncertainty in motion pictures and the way the movie business relies on adaptive and decentralized mechanisms is developed in work I and colleagues have been doing. This work is a continuation of ideas originally developed by Mandelbrot (1963a, 1963b) and Simon (1955). The key ideas are that production is sequential and that there is a “wild” kind of uncertainty in cost. Motion picture revenue (nobody knows) unfolds during the run in a complex and recursive dynamic that can “go anywhere”, but the dynamics converge on a statistical attractor, the Lévy stable distributions with “heavy” (non-Gaussian) tails. These properties set the information discovery and contracting problems that are at the core of the industry’s structure, contracts, and organization.

This research is statistical in nature, emphasizing the complexity of motion picture revenue and cost dynamics and their basins of attraction. It is focused on a characterization of the sources and nature of the uncertainty which is then used to discover the problems to which the industry’s organization, contracts, and practices must be adapted. This line of inquiry was originated by De Vany and Eckert (1991) and pinned down by De Vany and Walls (1996) and famously named the “nobody knows” principle by Richard Caves (2000) in his *Creative Industries* [after screenwriter William Goldman’s line “With all due respect, nobody knows anything” in his *Adventures in the Screen Trade* (1983)]. Cassey Lee’s doctoral dissertation [Lee (1999)] was one of the first explorations of the stable Paretian hypothesis in motion pictures, which lies at the core of this line of work. Other papers have appeared in this vein recently by Chris Hand (2001), Collins, Hand and Snell (2003), and Jordi McKensie (2003). John Sedgewick’s (2001) book on British filmgoing during the 1930’s is also very much in this vein.<sup>4</sup> This is the

<sup>4</sup> In David Walls’ (2002) review of Sedgewick (2001) he shows that the distribution of Sedgewick’s index of film popularity is a Pareto law of the form found for the distribution of motion picture revenue by the above cited authors. I will show below that this is an example of the self-similarity of statistical distributions implied by the stable Paretian hypothesis.

line of research I shall emphasize in this chapter because I believe it is foundational to the development of a New Economics of Art and Culture.

In Section 2 I begin with a discussion of the essential economics of the business. This is Movie Economics 101 and its aim is to identify the main issues that confront the business and show how they are solved; you will see that the movie business shares many features and practices of other creative industries for they are all information industries. Following this, in Section 3, I apply these ideas to a brief historical analysis of the movie business. The purpose here is to show how the industry's methods of production, its structure and regional distribution, and its exotic contracts and practices evolved historically as solutions to many of its more vexing problems. You will see that the judges and lawyers relied on concepts more suited to toasters and bricks than to one of the first information industries – the movies. In this section, I also cover the Paramount antitrust cases and show how the courts reshaped this nascent information industry in the mode of the old economics of antitrust.

Section 4 covers the graduate level course in movie economics. It begins with the laws of the box office and with a discussion of the Lévy stable distribution. (Since we will often be interested in the upper or lower tails of this distribution and these tails are Pareto distributions, I shall freely interchange the terms stable Paretian distribution and Lévy stable distribution, letting the context indicate if the tail or whole distribution is at issue.) The laws of the box office are those of a winner-takes-all contest. The laws are driven by a non-linear information dynamic that takes movies that are close to one another and propels them apart at exponential speed. Under the influence of these recursive and non-linear processes, movie revenues can “go anywhere”. They may even be chaotic. The extreme skew of the revenue distribution, the influence of extreme events, and the unstable and non-finite moments provide a rigorous basis for the nobody knows principle. I show that the stable Paretian model captures with high fidelity all the essential features of the statistics of the business. I use the concept of statistical self-similarity to show the importance of extreme events in all facets of the industry from film revenues to budgets, productivity, pay, and careers. The influence of marketing and stars and the opening are discussed here in terms of the non-linearity of the revenue dynamics of motion picture information. In this section I show how pay keys on extreme events and I reveal the laws of stardom.

Other topics taken up in the graduate course are the structure of the industry implied by the stable Paretian hypothesis and the evidence for it, the pricing of talent, and the many decision problems that are engendered by the wild statistics of the movies. I introduce the concept of stochastic industry structure and use it to show that concentration measures are not well-founded in this industry. I show the industry is stochastically concentrated, but intensely competitive. Leaders turn over at a high rate and the Hershman–Hirfindahl index, a gold standard for antitrust, does not even exist. Then I discuss the difficulties of making decisions in a business where the probabilities are non-Gaussian and confound expectations. The stable Paretian probabilities lie somewhere between risk and uncertainty and they lead to many decision errors. I explain the “curse of the superstar”, the “angel’s nightmare”, the “sure thing principle”, and the

“producer’s curse” as examples of the many decision paradoxes faced by movie makers. In Section 5, I reach some conclusions.

Naturally, this chapter is a somewhat personal view of the business and what I think is interesting and important about it. Much of the material draws on my research in many articles and from my book *Hollywood Economics: How Extreme Uncertainty Shapes the Film Industry* [De Vany (2003b)]. This is not a review of research. Rather it is an exposition of a modeling strategy and a research agenda that I have found to be productive and informative. In my own work on this industry I have found that all the complexity of economics can be found there and there is much to explain that stretches the boundaries of current economic theory.

Much of economics focuses on averages, expectations, and standard deviations. Economists focus so intently on these measures that they often toss out “outliers” to eliminate their influence. This might be right for toasters or trousers, but the movies are not like that. The statistics of the movies are “wild” and utterly non-Gaussian. The outliers are the main event, not something to be tossed out, and averages are just numbers signifying nothing. Motion picture revenues are just a number – pure information – and have no natural scale or limit. Expectations and higher moments of the distribution need not even exist. One of the key lessons of trying to do science in such a non-standard industry is that we have to take the focus away from explaining particular events (why movie A did well and B did not) to understanding process and pattern; the ultimate object of a science of the movies is the probability distribution and the dynamic process that produces it.

## 2. The essential economics of motion pictures

This should go quickly as I have already alerted you to many of the key issues. On the other hand, there are some that have to wait for the graduate version of movie economics to come later.

### 2.1. *Nobody knows*

I still like the way the fundamental property of the movies was put by a wise District Court Judge (whose smart decision was overturned by the Supreme Court).

Moving picture films are a fluctuating and uncertain product. Until a film has been exhibited no one knows or can accurately estimate its value as a box-office attraction, either as a first-run exhibition or a subsequent run exhibition.<sup>5</sup>

<sup>5</sup> *United States v. Griffith Amusement Co.*, 68 F. Supp. 180, 196 [W.D. Okla (1946), cited in De Vany and Eckert (1991)].

Economists would put this by saying that movies are experience rather than inspection goods. You have to see a movie to know if you like it or not. What this means is that demand is revealed by the audience when the film opens. Audiences discover what they like, they do not reveal preferences they already have. Once demand is discovered, supply and pricing must adapt.

## 2.2. *Discovering demand*

To get the discovery process underway, films have to be exposed on screens. Throughout a film's run, audiences discover and exchange information about movies. Box office reports are signals to distributors and exhibitors about the audience's likes and dislikes.

A studio/distributor can sample this information in a variety of ways through the design of its release. A wide release on many screens simultaneously gathers a large sample of information, but leaves few degrees of freedom in responding to it. It leaves less time for word of mouth and other information to influence viewers. The film may disappear too quickly for word to spread and for audiences to find it. In a smaller release on fewer screens, a studio is sampling sequentially through the audience, discovering its demand as information flows over a longer period of time.

## 2.3. *Adapting supply*

Once demand is discovered, prices and supply adapt. There are three prices relevant to a movie: the admission price, the rental rate, and the distribution fee. The admission price does not vary much, though it may differ among theaters. The rental rate is highly variable. So is the distribution fee. These will be discussed below.

The main supply response is in extending the run, keeping the film longer in theaters. This is particularly true of a wide release. In a smaller release, prints may be ready or can be made quickly enough to expand the number of theatrical engagements; thus, both the length of the run and the number of theaters can be changed to respond to demand. The later engagements have the benefit of the demand information revealed in the earlier bookings, so the sequential sampling, smaller release reduces risk for the exhibitors who show the film later in the run. The large, wide release is more risky for exhibitors as they have no prior information to go on. The big release is likely to be more risky for the studio too because the number of prints to be made has to be decided before demand is known and because supplying more prints means more is spent before demand is known.<sup>6</sup>

So, demand is discovered and supply adapts, primarily by extending the length of the run. This goes on in real time using overnight and weekly box office reports. The decision to extend the run is a matter of contract which is delegated to the individual theater

<sup>6</sup> A print is a role of film and can cost thousands of dollars. Print and advertising costs are all expended up front and may be from 25 to 40% of a movie's costs.

under the holdover clause. The holdover clause is a contingent term of the exhibition license that specifies an amount of box office revenue which, if equaled or exceeded in the prior week, extends the run another week. The holdover amount is unique to each theater and film, negotiated as part of the license. The clause decentralizes the decision to extend the run because it relies only on local information of time and place, i.e. conditions at the theater where it is running. If box office revenue exceeds the holdover, the distributor is obligated to leave the film another week and the theater is obligated to run it another week. There is no limit to the number of times a film may be held over so a theater might run a movie for twenty or more weeks if it is grossing well.

#### 2.4. *Pricing films*

Motion pictures have three different prices. Most people think of the “price” of a movie as what they pay at the box office. But the price the theater pays for showing a movie is more important to the motion picture distributor, for this is their primary source of revenue from the film; this price is the rental rate or percentage of box office revenues paid to the distributor for the right to exhibit the film. The third “price” is what the producer of the movie pays to the distributor for placing the film in theaters and collecting film rentals. These prices are interrelated: the admission price is the source of box office revenues to the theater which pays a rental rate to the distributor, who deducts from these rental receipts a distribution fee.

Since demand must be discovered in a way that lets supply and prices adapt, three problems arise with respect to setting all three prices of the film. First, the demand signal shouldn't be noisy. Second, the demand signal should convey information about demand at the point where price is to be adjusted. Third, prices should respond in some reasonably optimal way to the demand signal. I have come over the years to admire the industry's solution to the film pricing problem.

The admission price is fixed over the duration of the run, with passes and discounts being restricted in the earliest weeks of the run. With a fixed admission price, any variations in box office revenue are due entirely to the number of admissions. The studio, therefore, receives a pure quantity signal of demand, uncontaminated by variations in the admission price. If a minimum admission price were not specified, the exhibitor could, literally, cut the price to zero and make it up on concession sales, particularly for Disney animated movies and movies that appeal to a young audience. As a protection against this, exhibition licenses prior to the *Paramount* decision usually specified either a minimum admission price, or, deferring to the local knowledge of the exhibitor, specified a “usual, or customary” price. The courts ruled this practice to be unlawful price fixing and such price clauses were expunged from exhibition contracts. Virtually all theaters in the post-*Paramount* era became first-run theaters, so the almost ancient practice of charging more for the first than for second and subsequent runs became extinct. So, we find that admission price does not vary over the course of a motion picture's run, though some theaters may charge different prices than others.

The stability of admission price among different movies and over the course of the run has puzzled economists and observers of the motion picture business. This is such a durable practice that it must have some enduring properties; if this pricing arrangement were not maximizing revenue, then it would change, according to economic principles. But, aside from its historical durability, there are economic reasons to think the practice is rational.

Consider first how one would decide how to price a studio's motion pictures. Would a Warner Brothers movie be priced differently from one produced by Twentieth Century, Paramount or Columbia? Since studios no longer produce a certain style of motion picture, there is no brand identity for differentiating their products. At one time, MGM had a brand name and its movies could command a premium price. But, that era is gone and all the studios produce a wide range of films with no evident or predictable studio style or genre; nor do they have particular stars under contract. No studio has a lock on blockbusters and they all make bombs. Moreover, every studio would strongly object to having its movies priced more cheaply than others; it would be seen as a signal of inferior quality.

But, then why not price the best movies more dearly? If only you knew ... The "nobody knows" principle, developed at some length later, says that you don't know which movies will be hits and which will be misses. You only know after a movie runs that demand is so high that a premium price could be charged. Setting a higher price before a movie is released gambles with the information dynamics. Choking off demand early in the run curtails the non-linear building of demand from week to week. You will see later that hits have distinctly different runs from conventional movies and they build demand over time. Charging a higher price in the early weeks of the run may prevent that dynamic from getting off the ground. A studio really only knows that it has a hit on its hands four or more weeks into the run, and then it is too late to change the admission price, and illegal for it to direct the exhibitor to do so. Once it is understood that supply can be expanded in a perfectly elastic way, then one sees that high demand can be fully captured by extending the run, without raising the admission price. A side benefit of an inflexible admission price is that the exhibitor cannot game the rental rate by varying his admission price.

Now that *Paramount's* restrictions have made virtually all theaters first run theaters, it is no longer possible to price the first run higher than the second and subsequent runs. Nor is it likely that limiting the film's initial run to a few theaters to give them a measure of exclusivity and pricing power would survive a legal test under *Paramount's* holding that excessively wide clearances are unreasonable restraints.

The simple answer to the question of why do prices not adjust to high demand is that they do, you just have to look at the prices that really count for the studio and the producer. The rental price adjusts almost perfectly to demand and the distribution fee does as well. The rental price depends directly on the grosses at each theater where

the film is playing.<sup>7</sup> This provision keys the price to local conditions, because the local rental rate depends wholly on the local theater's admissions. So, price is low where local conditions warrant and high otherwise; this gives a close-to-optimal spatial variation in prices that extracts more revenue from each film.

The solution to the problem of varying the rental price in accordance with demand is achieved through the contingent pricing clauses of the rental contract. The exhibition license cleverly specifies a two-part pricing rule that is adaptive and sufficient to capture most of the value of the film to the exhibitor. Note, this variable pricing component too is decentralized as the license sets a unique price to each exhibitor conditional only on her theater's grosses. The rental is determined by a formula in the contract. Let us consider the sophisticated pricing instruments contained in the motion picture rental contract and how the rental price is adjusted in accordance with demand.

### 2.5. *The rental contract*

First, there is a guarantee or fixed amount which the exhibitor must pay no matter what the film grosses. This is individually negotiated or, if the distributor awards licenses by taking bids, it will be part of the exhibitor's bid. For many films, the guarantee will be small or zero. For a number of heavily demanded films, it may be rather high (above \$100,000). We know a two-part price is sufficient to capture all the exhibitor's surplus; the guarantee is the fixed part of the two-part price.

But, neither the distributor nor the exhibitor knows what the film will gross, so the guarantee cannot be set optimally in advance. Adjusting price when demand is revealed is the task left to the variable terms of the rental contract. The rental is a percentage of the exhibitor's gross. It is reset each week according to a declining schedule. The exhibitor pays a minimum percentage of her gross each week, with the minimum declining over the course of the run. A typical example would be a four week minimum run (part of the contract) where the minimum percentages might be 70, 70, 60, 60 with any weeks beyond at the flat rate of 40 or 35 percent. This declining schedule compensates the exhibitor for the rising probability that the film will die next week [De Vany and Walls (1997)] as the run progresses.

### 2.6. *Pricing hits*

There is more. Suppose the film takes off in its fifth week and begins to gross major money. By that week, the rental rate is only 35 or 40 percent and the exhibitor is making a killing. If a film gets "legs" it is likely to occur around the fourth or fifth week [De Vany and Walls (2003b)]. And it may run 20 to 40 weeks if it is a *Star Wars* or *Forrest Gump*. Runaway hits such as these generate the bulk of revenue and profit, so the studio

<sup>7</sup> At one time there were contracts that called for the theater to pay a rental based on a national gross rather than the theater's gross. See the discussion of these "formula deals" in the historical section below.

must extract a high rent from them; otherwise profits will be left with exhibitors who had nothing to do with producing the hit.

To guard against leaving money in the exhibitor's hands, the rental contract contains a rental escalation clause. This is the 90 percent on gross above the house nut rule:  $\text{Rent} = 0.90 \times (\text{Box Office Gross} - \text{House Nut})$ . The rent will be the minimum applicable percent of gross or 90 percent of gross minus the house nut, whichever is higher. The house nut is a fixed, negotiated amount; years ago, the house nut was an approximation to the exhibitor's weekly cost of operating his theater.

How important is this rental escalation? The sort of data required to answer this question are private, but I have seen data to indicate that the clause is very important in pricing breakaway movies. An example is *Tootsie's* 23 week run in a theater. The minimum weekly percentages for the contracted six week minimum run were 70, 70, 60, 60, 50, 50, with holdover weeks at 35 percent. The house nut was \$3000. The data for this theater show that *Tootsie's* effective rental rate was 70 percent the first week. Then it jumped to 90 percent for 10 straight weeks (less the house nut), dropped to the minimum 35 percent for 5 weeks and then jumped back in the 16th and 17th weeks to 90 percent after which it ran 5 more weeks at 35 percent.

Overall, *Tootsie's* rental rate in this theater was 54.29 percent. Had the 90 percent over the house nut clause not been in the contract, *Tootsie* would have earned a rental rate of just 45.78 because it would have run 17 weeks of its 23 week run at 35 percent.

How much did the 90 percent clause add to *Tootsie's* rentals? We don't know for sure, but we can calculate an illustrative amount from the data for this theater. *Tootsie* played on 1222 screens. Its US gross was \$177.2 million. Suppose we take the difference in rental rates for this theater and apply it to *Tootsie's* national total box office revenue. Without the clause, the rental rate of 45.78 percent would have yielded total rentals of \$81.1 million. With the clause, the rental rate of 54.29 percent would have yielded total rentals of \$96.1 million, an increase of nearly 19 percent or \$15 million.

Lesson learned. *Tootsie* was the second-highest grossing film of 1982. It ran 23 weeks in the theater for which we have data and longer in other theaters. The laws of the box office, which shall see later, say that hit movies have long runs and they dominate total theatrical grosses and rentals. A distributor cannot afford to underprice the hits or leave them in theaters for long runs at the minimum rental rate. The 90 percent clause keeps this from happening, even when no one knows which movies will be hits.

## 2.7. Clearances

Distributors must give exhibitors some protection against competition. Otherwise, exhibitors will be reluctant to screen the movie. In addition, the distributor does not want the theater's box office take to be diluted among many theaters for this would lower rentals and shorten the film's run for its take would fall below the holdover. Finally, distributors would be reluctant to have exhibitors competing in admission price for that would reduce their rentals which, we have seen, depend directly on box office revenue.

The long-standing solution to most of these problems is the clearance clause of the rental contract.

A clearance is an agreement with the exhibitor that gives him a measure of exclusivity in the showing. The distributor agrees not to license the movie to specifically named competitors of the licensed exhibitor. The clearance is determined through bid or negotiation. A theater might include the clearance it wants in its bid. The bid letter might suggest a clearance. Alternatively, the clearance might be negotiated. Over time, clearances may tend to become more or less customary.

Broad or stable clearances tend to limit competition. For that reason, clearance arrangements are subject to court scrutiny. Granting a theater an exclusive franchise can be interpreted as a grant of a long-run clearance to the franchised theater against its competitors. When a distributor owns a theater the effect is to clear the territory of competing exhibitors. This is a controversial area because the Supreme Court found clearances that were too wide or routinized to be violations of the antitrust law.<sup>8</sup>

### 2.8. *The distribution fee*

This is the third of the prices we are concerned with. Here too, the nobody knows principle applies: since nobody knows how much a film will gross, it is impossible to set an optimal fee for distribution service. The distributor, a studio usually, books the film with theatrical booking agents, advertises, distributes prints to theaters and collects them after the showing for distribution to other theaters. Most importantly, the distributor collects rental payments and monitors exhibitors to verify they are showing the movies booked and at their proper times and that rental payments are properly correlated with box office revenues.<sup>9</sup>

If a movie has a long run, the distributor is continuously performing these duties over an extended time frame. No one knows how long a movie will run or what it will gross. So, it is impossible to gauge the distributor's cost or the value of the distributor's productive efforts. That is, until the film has run; after that, all these things become clear.

The industry's long-standing solution to these, and other issues, is to charge a conditional distribution fee that depends on the outcome. The typical arrangement is a fee around 30%, but the rate is negotiable. This fee not only addresses the nobody knows problem, it also better aligns the distributor's interests with those of the producer, who is really the residual claimant or owner of the movie. A proportional distribution fee gives the distributor an incentive to maximize rentals and, since rentals are the source of revenue ultimately to the producer, their interests are made more compatible. If the

<sup>8</sup> *United States v. Paramount Pictures, Inc.*, 334 U.S. 131 (1948).

<sup>9</sup> There are detective firms for hire to detect theater cheating because the theater pays rentals based on what they report their box office revenues to be. There had been in the past a good deal of underreporting, but this appears to have lessened with modern ticket machines and theater chains who have long-term relationships to preserve [see De Vany and Eckert (1991)].

distributor received a fixed fee, the incentive to maximize rental collections would be muted.

Because it is a percentage of rentals, the distribution fee varies directly with movie's success. So, the key prices are quite flexible and their levels are conditioned on the state of demand as demand is revealed over the course of the run.

### 3. A brief history of motion pictures

We have spent some time on the arrangements between distributors and theaters because they are at the heart of the industry's problem: how do you discover demand, adjust supply, and price movies when nobody knows their value? This problem is as old as the feature motion picture. And the solution to it has not changed much since the movies began. In fact, many features of the industry today resemble those at the inception of the industry. It is useful to look back briefly to see how little has changed, including nearly all the terms of the exhibition license, for it reveals those features of the industry that are deep and immutable and those that are superficial.

In the 1890s and 1900s, producers sold copies or prints of motion pictures outright to theater owners.<sup>10</sup> Exhibitors resold their prints when they no longer wished to show them. By 1903, organized film exchanges supported print trading among exhibitors and eventually the exchanges became rental agencies to reduce the cost of transferring prints. Most of these pictures were low-budget one-reelers: 10-minute comedies, 15-minute dramas, 5-minute scenic films, and 20-minute westerns. Four to eight of them comprised the typical two-hour program for which patrons paid a nickel. By 1911, about 150 exchanges supplied 11,500 theaters with enough reels to provide almost daily program changes.

Copying and bootlegging were common. The flat price that the producer received for selling a print to an exchange did not correlate with the picture's success in the market place. Revenues were too small to justify big productions. Releases had to be changed frequently to stimulate attendance. Without marketing, however, the public had scant information about which pictures to see. There were no great stars or studios in this period, and memorable pictures were rare. Exhibitors faced an unreliable stream of indifferent motion pictures by unrecognized producers and artists.

#### 3.1. *The feature motion picture*

The multi-reel feature picture, produced as early as 1907, became popular and widespread by 1913. It fundamentally changed the industry. Producers and exhibitors saw the value in moving from daily program changes to two or three features per week.

<sup>10</sup> In this section I rely on De Vany and Eckert (1991).

Demand would rise through word-of-mouth advertising, theaters could become more lavish and charge higher admission prices, and distributors could choose among better theaters. The major studios, great stars, and memorable features developed as the industry moved away from one-reelers to feature motion pictures.

Features cost more to make than one-reelers, so a nationwide distribution system was formed to lower the cost of distributing them. Higher cost productions required larger financial commitments from producers. To finance a picture, a producer had to show that a distributor would handle it and exhibitors play it. The ability to contract “forward” for the distribution and exhibition of a feature before it was produced was essential to financing. Forward contracting was also the genesis of vertical integration.

At first producers sold exclusive rights to their productions by territory. These were called “states’ rights” deals because they encompassed one or more states, although they were often for only part of a state. Copies of the motion picture were sold to a states’ rights distributor for a flat fee that was based on the territory’s population. As they gained experience, however, distributors learned that population was an unreliable estimator of demand and they began to charge a rental fee, or royalty, that was based on a percentage of the exhibitor’s box office revenue. This arrangement was also acceptable to the exhibitor since it was less risky than paying a flat rental for the feature no matter how well it did at the box office. However, for the royalty to correspond with demand, the exhibitor’s box office report had to be truthful. Anticipating vertical integration, the typical area or states’ rights distributors were exhibitors who would show the picture in their own theaters, and then lease it to other exhibitors in the allowed territory for later runs. These later runs were for designated periods and sometimes were exclusive.

By 1913–1914, producers licensed blocks of a full season’s production (perhaps thirty pictures) to a distributor in a single agreement. Paramount Pictures Corporation, formed in May 1914 by the merger of five exchanges and regional distributors, secured the franchise to distribute all the features of three of the leading production companies. The producers agreed to make a number of features each season for Paramount to distribute. In return, Paramount agreed to pay the producers 65% of the gross revenue it received from theater rentals and sub-licensing to other distributors. Paramount retained 35% as its distribution fee, an arrangement that is retained to the present day. Paramount guaranteed minimum returns to the producers and advanced cash to them on each features release date, against which film rental payments received from exhibitors were credited.

To secure exhibitors for the features they financed, distributors granted franchises to exhibitors. These franchises gradually replaced states’ rights deals. By taking a distributor’s franchise, an exhibitor agreed to show the distributor’s entire line of motion pictures. As *Cassady (1959)* noted, “this early version of block-booking developed out of the need of distributors for a more efficient method of selling films”. The franchising exhibitor also bought features “blind”, before they were seen, or before they had even been made.

### 3.2. *The emergence of vertical integration*

By 1916, features predominated over short films, and movie “palaces” had been built. But, producers and distributors wanted stable outlets and exhibitors wanted assured supplies. The contractual arrangements on which they relied were a more uncertain instrument to that end than vertical integration. Vertical integration of distribution with exhibition offered outlets for distributors, who could then guarantee play time to the producers with whom they contracted. With guaranteed distribution and exhibition, producers were better able to finance their features.

The impetus for integration came from all links of the production, distribution, and exhibition chain: distributors merged upstream and downstream; theater chains merged upstream through distribution to production; producers merged downstream through distribution to exhibition. Paramount the distributor became a producer and also built theaters. Fox and Loew’s entered production from the exhibition side of the industry. The producers Warner and Goldwyn formed theater chains and also developed distribution facilities. By 1931, Paramount owned nearly 1000 houses and its own studios, and the six largest circuits owned 2437 theaters (one-eighth of all theaters).<sup>11</sup>

The driving force behind these changes was the introduction of the high-cost feature motion picture. Within fifteen years of its introduction, the structure and controversial practices that the government would later attack had emerged: exclusive territorial licensing, a sequence of runs, block-booking, franchising, price stipulations, and vertical integration and become the industry norm.

### 3.3. *The Paramount litigation*

The five major defendants in *United States v. Paramount Pictures, Inc.*<sup>12</sup> were Loew’s (renamed MGM), Paramount, RKO, Twentieth Century-Fox, and Warner Brothers. Each of the major studios was vertically integrated from production through distribution and exhibition. The three minor studio-defendants were not fully integrated: Columbia and Universal produced and distributed motion pictures; United Artists distributed only. The court found that the defendants conspired to fix minimum theater admission prices; engaged in intertemporal price discrimination by charging higher admission prices for first-run than for later showings; conspired to fix patterns of exclusive clearances and runs for neighborhood theaters; and restrained trade by licensing motion pictures in blocks. It found that the five major defendants also operated theaters monopolistically through joint ownership or pools.

In its 1948 *Paramount* antitrust decision, the Supreme Court relied on simple measures of box office revenue concentration among the major motion picture distributors to make its finding that the studios, acting together, monopolized the market for “first

<sup>11</sup> Conant (1960).

<sup>12</sup> 66 F. Supp. 323 (S.D.N.Y. 1946).

run” motion pictures. The Court’s decision indisputably altered the studio system, forcing the divestment of studio-owned theaters and altering the contracts through which motion pictures were licensed to theaters [De Vany and Eckert (1991)]. Unfortunately, the courts got it wrong.

A central piece of evidence the courts relied on to infer market power of the defendants was the combined market shares.<sup>13</sup> It is interesting to note that during the half century following the Paramount Consent Decrees, all but one of the distributors–defendants (RKO, who exited in 1957) continue to survive. The original distributors–defendants were Loews, Paramount, RKO, Twentieth Century-Fox, Warner Brothers, Columbia, Universal and United Artists. Loews and United Artists are now part of MGM while Columbia is now part of Sony Pictures. The new entry into this upper echelon is the Disney-owned Buena Vista.

The current market share of the top five distributors (at 72 percent) is similar to that of the market share of the five major distributors–defendants during the Paramount litigation (at 73 percent in 1943–1944). The current Eight Firm Concentration level at 95 percent is the same as during the period of the litigation.<sup>14</sup> So, little has changed in terms of revenue concentration in the business, a property related to self-similarity which we discuss in the next section.

### 3.4. *Contracts and practices*

The courts challenged five practices of the defendants; each of these practices highlights the challenges of discovering demand, adapting supply, pricing movies, and structuring incentives which remain central issues in today’s motion picture industry. I will briefly discuss each the challenges to show where the court went wrong.

#### *Admission price fixing and price discrimination*

The courts found that the defendant distributors were guilty of price fixing and price discrimination. Admission price fixing was inferred from the practice of clearing a zone of competing exhibitions and a clause in the contract that stipulated the exhibitor’s admission price. Film rentals were then, as well as now, determined by box office receipts. An exclusive run limits rivalry so that the theater’s profit maximizing price will be closer to the price that will maximize rentals. The license exploited the exhibitor’s informational advantage by stipulating that the usual or customary price was to be the minimum admission price, leaving the exhibitor the (seldom exploited now, but historically important) option of raising the price for motion pictures the exhibitor thought would be in high demand.

<sup>13</sup> *United States v. Paramount Pictures, Inc.*, 85F. Supp. 881, 894 (S.D.N.Y. 1949). See Conant (1960) and De Vany and Eckert (1991). During the 1943–1944 season, the eight defendants had received 95 percent of domestic film rentals (Westerns excluded).

<sup>14</sup> Values of CR5 and CR8 for 1943–1944 are computed from *United States v. Loew’s Inc.*, 334 U.S. 131. Final Finding of Fact 100, February 8, 1950. See Conant (1960, Table 13, p. 46).

Intertemporal price discrimination may have been tempting for distributors to try and there is little to object to about it, since if it increases film rentals it will expand the supply of motion pictures. But it required information about audience preferences that could only be learned as the feature played. The best a distributor seeking to extract additional revenue from a film could do given this imperfect information would be to put it in a high-priced theater first and allow movie goers with high preference to “self-select” for that theater. Exclusive, first-run engagements followed by broader release to neighborhood theaters enabled distributors to create a system of priority among film goers that would extract more film rental if the film played well. The limited number of prints of a first-run release had to be rationed sequentially in any event.

### *Runs and clearances*

The District Court and the Supreme Court argued that the clearances of a competitive system would not be stable and might even change from one motion picture to the next. But this is not necessarily so. The exhibitors willing to pay the highest royalty on a motion picture may change little from picture to picture since this depends on the theater’s location, quality, and size which do not change from picture to picture. The courts also neglected the fact that runs are variable even within a fixed run and clearance system. Pictures that play poorly do not run the expected length of time and those that are more successful run longer than expected. The actual run and clearance period depends on how the film performs.

The stability of runs and clearances were reasonable restraints on trade because they enabled distributors and exhibitors to build trust and reputation. Longer term relations with first-run exhibitors supported demand-revealing experimentation and promoted stable expectations of product and play time on both sides. The exhibitors whose runs followed the riskier first run had more information on which to base their booking decision and could select films more carefully. Their rewards were potentially smaller, but so was their risk and the potential gross of their house. The modern analogue to this practice is following a theatrical run with videos and TV. The latter are more easily priced because of the information revealed in the former.

### *Formula deals, master agreements, and franchises*

What we now know as theater chains were at the time called circuits. Some of the most interesting deals the courts found wanting were designed to address issues involving the theater circuits that were beginning to become a major force on the exhibitor side of the industry. They can be seen as precursors to dealing with multiplex theaters and chains.<sup>15</sup>

<sup>15</sup> De Vany and Eckert (1991) argue that these practices were deemed objectionable because they were seen as favoring the circuits over the independent exhibitors. Today, even independent exhibitors are best seen as small chains.

Formula deals determined the rental price of a given feature for the circuit as a specified percentage of the feature's national box office gross receipts. All the circuit's theaters were included in the deal, and the circuit could allocate playing time and film rentals among them at its discretion. This flexibility is surely useful in today's multi-screened theater environment.

In a formula deal, a circuit paid royalties on the nationwide gross box office receipts rather than its own. Because the royalty was independent of the pattern of play chosen by the circuit, it could move a film among its theaters so as to maximize its earnings. The circuit could not decrease its rental payments by manipulating a film's play pattern among its theaters since its film rentals were tied to the national box office revenues [see [De Vany and Eckert \(1991\)](#) for a more complete discussion of this exotic deal]. A modern theorist would see this clever scheme as an asymptotically incentive compatible mechanism. Since a circuit's rentals would be a negligible portion of a movie's national gross, there is little to gain from falsely reporting its theater grosses; truthful revelation is then an asymptotically dominant strategy. This remarkable device was invented more than 50 years before [Groves \(1973\)](#) discovered his famous, truth-revealing mechanism and well before the full theoretical development of incentive-compatible mechanisms. Fact is stranger than theory.

Master agreements (or "blanket deals") licensed a feature in more than one theater (usually a circuit). In an age of multiscreen theaters operated in chains, a master agreement is simply a license that covers several screens and theaters. This seems to have an advantage over writing a contract for every screen independently. An  $n$ -screen contract is more efficient than  $n$  contracts for the same screens. One can see that this transactions-saving device presages [Coase's \(1937\)](#) theory of the firm. Again, the constraints of solving real problems in the movie business led to the development of mechanisms which economic theory had not yet imagined. The theoretical imagination pales in comparison to the "wild" uncertainty and rich complexity of the motion picture environment. Fact can inform theory in ways that are hard to imagine (see below my discussion of contracting when "nobody knows anything").

Franchises covered all of a distributor's releases for more than one season. The Department of Justice has dropped nearly all its objections to franchising and this practice has recently begun to grow.

"Moveover" clauses allowed a licensee to exhibit a given picture in a second theater as a continuation of a run in the first theater. This clearly is the precursor to permitting multiplex theaters the flexibility to move movies among screens in accordance with demand.

### 3.5. *The legacy of Paramount*

The intended beneficiary of *Paramount* was the independent exhibitor. The independent exhibitors issued a heavy volume of complaints to the Department of Justice regarding the defendants and their actions. Independent exhibitors were highly organized and resolutions adopted at their national meetings were directly communicated to the De-

partment of Justice. Not only is there evidence that the Department of Justice heard from the independent exhibitors, but there is evidence that the Department listened to them. Most Department-instigated changes favored the independent exhibitor over the theater chains and the studios.

*Paramount's* remedies did not have their intended effect, however, and they eventually harmed the independent exhibitor. They promoted wider competition for film exhibition rights and reduced production, which raised motion picture rental rates and admission prices. The higher film rental rates lowered exhibitor net profits. Distributors stiffened the terms of exhibition licenses as the less flexible licenses and licensing methods called for by *Paramount* increased their vulnerability to the decline of exhibition caused by the increased competition from television.

Perhaps the definitive test of whether *Paramount* improved the lot of the independent exhibitor is to look at their own actions. Just a few years after the studios sold their theaters, exhibitors, fearing television, called on the Department of Justice to let the studios reenter exhibition so that they might have stronger incentives to produce motion pictures. Exhibitors contended that competitive bidding did not solve any problems and increased film rentals [Federal Trade Commission (1965)]. The methods for allocating motion pictures that were devised in the *Paramount* decrees fostered an explosion of exhibitor antitrust cases against the distributors [Cassady and Cassady (1974)].

The integrated studios – Loews, RKO, Fox, Warner Brothers – lost market value in the range of from 4 to 12 percent when the Supreme Court handed down its 1948 decision [De Vany and McMillan (2004)]. But, Columbia and Universal, non-theater owning defendants, also lost market value on the order of 7 to 9 percent. This suggests the decision was more far-reaching than merely banning producer/distributors from owning theaters; it also barred franchising and other film licensing practices. These would have been more valuable to the non-integrated studio/distributors than to the integrated ones for they were the means through which they maintained vertical controls over theaters.

The evidence does not suggest that the District Court's self-acknowledged "experiment" in altering the long-standing and highly developed structure and practices in this new information industry was "ruinous". A fall in value of 5 to 12 percent is damaging, but not ruinous. But, it did not help and, in the opinion of the stock market, the Court appears to have done harm to the motion picture industry and the value of its assets. The pattern of harm is broad: the integrated and non-integrated studios were harmed and so was their major competitor who was not a defendant. Nor did the litigation seem to end the long-standing hostilities between the studios and independent exhibitors that had been the source of the litigation. The number of lawsuits brought by exhibitors over distribution practices grew rapidly after *Paramount*. Other evidence shows that neither the independent exhibitors nor the film-going public benefited from the fall in feature film production and rise in theater prices and film rental rates that followed *Paramount*.

Current antitrust decisions and policy with respect to the licensing of films and ownership of theaters by distributors have implications for what sorts of films are produced and how they are exhibited. The courts have required films to be individually licensed, theater by theater, and solely on the merits of the film and theater. This requirement has

stood in the way of ownership, franchising, or other forms of long-term contracting between exhibitors and distributors. It also has been interpreted to restrict multiple-picture licensing.

In practice, what this has meant is that it is not possible for a theater to agree with a distributor to exhibit more than one film at a time. No contracts can be made for the whole season of a distributor's releases, nor for any portion of them. This makes it impossible for a theater to be the outlet for a single distributor such as Twentieth Century-Fox or New Line Cinema or Buena Vista. Nor is it possible to license a series of films to theaters as a means of financing their production. Moreover, the inability to contract for portfolios of motion pictures restricts the means by which distributors, producers and theaters manage risk and uncertainty.

At one time, when the studios owned their own theaters and when they could contract for many productions with theaters for a period of years, the theaters were among the primary means of financing production. This was labeled "block booking" and halted by the Paramount Decrees. The licensing and ownership restrictions of the Paramount antitrust litigation have made it impossible for exhibitors to finance the production of motion pictures for release in their theaters. As a result, motion picture financing falls almost entirely on the distributors who rely on internally generated funds, the capital market, or presales of distribution rights in other countries. This, in turn, has probably been a major factor in the emergence of the concept of a "bankable" star whose participation in a project can assure its financing because the star will get it on theater screens where it has an opportunity to earn revenue.

A final irony of the *Paramount* legacy is that only the original signatories to the Decrees are bound by its restrictions. This leaves Sony and other new entrants free to own theaters while Warner Brothers, Paramount, and Twentieth Century Fox cannot.

#### **4. Graduate movie economics: The stable Paretian hypothesis**

Think about it; motion picture revenues are just information, a pure number that has no upper bound. Supply can be extended indefinitely and at constant cost. Consumption does not use up the movie, there is still as much for others to see. And, consumption may lead to an exchange of information with others, expanding the class of users. So there is no limit to what a film might earn, nor is there a natural scale to which revenues converge. Information variables can be magnified by non-linear feedback and, as a result, they can grow explosively or shrink disastrously. Thus, differences among movies can expand exponentially during the course of their runs and motion picture revenues can "go anywhere".

The ability of any model to capture these features seems unlikely, but a deeper look at the nature of the dynamics offers more hope. What we would like to find is the statistical attractor to which motion picture revenues are drawn. There is a class of distributions to which motion picture revenues are drawn; it is the stable class. Stable distributions are the attractors of dynamical processes that retain a self-similar structure

under choice, aggregation, and mixture. The generalized central limit theorem says that sums of independently distributed random variables converge in distribution to the class of stable distributions. The normal or Gaussian distribution is stable, but it is the only stable distribution with finite variance. Other distributions in the stable class are the Pareto, the Cauchy, and the Lévy distributions some un-named ones (because they do not have closed forms). See [Appendix A](#) for a more detailed discussion of the stable distribution.

A stable distribution  $S(\alpha, \beta, \gamma, \delta)$  is a 4-parameter distribution. Distributions in the stable class are characterized by their tail weights. If the tail weight,  $\alpha$ , is 2, the distribution is Gaussian and the tail decays exponentially. If  $\alpha$  is between 0 and 2, then the distribution is some other non-Gaussian member of the stable class and the tail is said to be “heavy” because it decays at less than exponential speed. Non-Gaussian stable distributions have Pareto or power law tails and their tail weight parameter lies in the interval  $(0 < \alpha < 2)$ . When  $\alpha < 2$ , the stable distributions do not have finite variances. And they may not, for  $\alpha < 1$ , have finite means.

Stable distributions, particularly their Paretian tails, give us the laws of the box office. Because they are the attractors of dynamics that are stable in form under choice (maximization), mixture (grouping) and aggregation (adding), they are the natural candidates for our laws of the box office. Motion picture revenues are the result of choices of individual movie fans, grouping of fans of diverse interests in theaters, and an adding up of revenues in individual theaters and over many theaters during the run. Motion picture revenue dynamics, therefore, should converge to stable distributions, but they needn’t be Gaussian (and are not).

With its characteristic high peak, “heavy” Paretian tails and skew, the stable distribution is a statistical monstrosity suffering from a condition called leptokurtosis. But, leptokurtosis is not something that requires mouth wash or deodorant; it is a thing of beauty. It is what makes the movies a business of the extraordinary; a kurtocracy in [Nassim Taleb’s \(2001\)](#) world of randomness. The stable distribution captures the winner-take-all nature of the movie business as well as the dominant influence of extreme events. As it is the limiting distribution of recursive, stable dynamical processes, it is relatively insensitive to initial conditions. But, the naturalness of these properties is insufficient reason to establish that the stable distributions are good descriptions of motion picture revenues. They must fit the data.

And they fit like a glove. The stable distributions and the dynamics that produce them give us the laws of the box office. There is a large and growing literature on this. To conserve space, I will just note these works here together; they are [Sornette and Zajdenweber \(1999\)](#), [De Vany and Walls \(1996, 1999, 2002\)](#), [Lee \(1999\)](#), [Walls \(1997\)](#), [Hand \(2001\)](#), [Ghosh \(2000\)](#), [McKensie \(2003\)](#), [De Vany \(2003a\)](#).<sup>16</sup>

<sup>16</sup> I must mention Art Murphy, a long-time reporter on the business with *Variety* and *The Hollywood Reporter*, who drew log-log plots of movie revenues and frequencies years ago and coined Murphy’s Law; 20% of movies earn 80% of the grosses. He discovered the Pareto law, though he did not know it as such, and his law has been pretty durable (a signature of self-similarity).

#### 4.1. Estimating stable Paretian parameters

A brief word about estimating the parameters of stable distributions. Lee (1999) in his doctoral dissertation covers five techniques for estimating the tail weight parameter  $\alpha$ : the Hill estimator, Nolan's Stable program, McCulloch's quantile estimator, and two techniques adapted from Mandelbrot's early research on cotton future's prices [Mandelbrot (1963a, 1963b)].

Mandelbrot plotted data to find linear portions in the upper tails of probability versus magnitude graphs, just as Art Murphy did in the *Hollywood Reporter*. If such portions existed, then log linear regressions of log survival probability versus log revenue could be used to estimate  $\alpha$ . The slope of this linear regression  $\text{Log}(\text{Prob}) = \text{Log}(\text{constant}) - \alpha \text{Log}(\text{Revenue})$  is the estimate.

An alternative method of estimating  $\alpha$  is to rank movies according to their grosses, from high to low. Assign rank 1 to the first, 2 to the second and on down the line. The ordered revenues are the so-called order statistics. Take the logarithms of these variables and plot them. The left-hand portion of the graph, corresponding to the top grossing movies, will be linear and well-fitted by  $\text{Log}(\text{Revenue}) = \text{Log}(\text{constant}) - \beta \text{Log}(\text{Rank})$ . The inverse of  $\beta$  is an estimate of the tail weight parameter  $\alpha$ .<sup>17</sup>

Nolan's Stable program (available at his web site) estimates the parameters of the stable distribution using maximum likelihood methods. The four parameters of the stable distribution  $\{\alpha, \beta, \gamma, \delta\}$  are interpreted as follows: The characteristic exponent  $\alpha$  is a measure of the probability weight in the upper and lower tails of the distribution; it has a range of  $0 < \alpha \leq 2$  and the variance of the stable distribution is infinite when  $\alpha < 2$ . The skewness coefficient  $\beta$  is a measure of the asymmetry of the distribution; it has a range of  $-1 \leq \beta \leq 1$ , where the sign indicates the direction of skewness. The scale parameter  $\gamma$  must be positive. It expands or contracts the distribution in a non-linear way around the location parameter  $\delta$  which indicates the center of the distribution; the scale parameter is, roughly, the "width" of the central part of the distribution.

We can illustrate these features of stable distributions in the following figures. Figure 1 from De Vany and Walls (2004) shows the stable distribution of motion picture profit as estimated by Nolan's Stable program; it also shows a normal distribution as well as the empirical data. Note how closely the stable distribution fits the data and how poorly the normal fits. The difference is even greater in the tails, but the figure cannot reveal this. A look at the upper tail of box office revenue is shown in a log-log plot of box office gross versus rank, where the top grossing film is rank 1, the next rank 2, and so on. Figure 2 from De Vany and Walls (1999) illustrates the tail linearity for star and non-star movies. The slope of the regression of the logarithm of revenue on the logarithm of rank, as stated above, is an estimate of  $1/\alpha$ . Finally, if the distributions can be shown to be a member of the stable class, De Vany and Walls (2003a) show that estimates of  $\alpha$  can be derived from the mapping of future on past revenues (see below).

<sup>17</sup> Essentially, the left-hand tail in the order statistics plot is the right hand tail in the frequency plot. Because the graphs are flipped over, the slopes are the inverses of one another.

Figure 1. The stable, normal, and empirical distributions of profit.

Figure 2. The linear upper region of the log rank versus log revenue distribution for star and non-star movies.

A further issue is the infinite variance. What does this do to regression analysis of the sort often done of the “determinants” of box office grosses or returns? The usual regression model assumes a normally distributed error term with finite variance. But if the variance is infinite, then the conditional expectation of a linear regression model has no precision – it may be useless or misleading. In their research on stars, [De Vany and Walls \(1999\)](#) use quantile estimators and probability point estimators instead of the usual linear regression. In recent work, [Walls \(2005\)](#) uses [McCulloch’s \(1998\)](#) estimator

of the stable regression model. He finds that the distribution of movie returns conditional on its attributes has infinite variance. In a related paper, he shows that the skew-t distribution is a good approximation to the more demanding stable distribution. Thus, without tackling the difficulty of stable regression, researchers can get close approximations to stable results using the skew-t distribution for the error term.

With this background, we can now turn to the laws of revenue and cost that are implied by their dynamics and their stable attractors.

#### 4.2. *Laws of the box office*

There are quite a few findings that have been replicated often enough to assume a tentative status of a law, at least of a statistical form. They relate to either the dynamics or the distribution of box office revenue. I shall be very brief in describing them since there are detailed descriptions in the literature cited above.

##### *“Winner takes all”*

Motion picture box office revenues are highly concentrated and unevenly distributed. The top 4 movies account for 20% of revenues and the top eight for nearly 30%. The Gini coefficient is 0.777, indicating a degree of inequality approaching the distribution of income in Third World countries, and just 20% of movies earn 80% of revenues.

One of the best measures of inequality is the kurtosis. This is a measure of departure from the shape of the Gaussian distribution. A leptokurtotic distribution is sharply peaked, asymmetric and skewed, just the kind of shape that tells us that movies are very different from one another. In the movies, kurtosis is high. A Gaussian distribution has a kurtosis of 3; in the movies we find kurtosis values ranging from 15 to over 100. The kurtosis of box office revenues is 45.

Another measure of inequality is the tail weight coefficient  $\alpha$ . Small values of  $\alpha$  are associated with large inequality because such values make extremely large grosses more likely. Many estimates of  $\alpha$  place it in a range of 1.3 to 1.7, with the most frequent estimate being 1.5. The movies are more unequal than a Gaussian world would ever be. This vast inequality makes Hollywood a kurtocracy. In new work [De Vany, Taleb and Spitznagle \(2005\)](#) have found that lifetime movie grosses of actors is so leptokurtotic and “wild” that the mean does not even exist ( $\alpha \simeq 0.84 < 1$ ). The kurtosis is on the order of 104, making it clear that the movies is a kurtocracy ruled by extraordinary artists and events. Yet, even these kurtocrats experience the “wild” uncertainty and cannot form even an expectation of the box office grosses of their future movies.

Finally, just in case you are an unrepentant Gaussian, you should know that *Forrest Gump* had a domestic gross revenue that was 10 standard deviations above the mean. *Titanic* was 20 standard deviations above the mean. These events would never occur in a billion reruns of history in a Gaussian world. The improbable happens in the movies and these are the main events.

*Hits have long runs*

It is impossible to find a movie that grossed \$50 million or \$100 million in real terms (relative to 1984 base) that did not have a long run. Over the past two decades only 5% of movies exceeded \$50 million and fewer than 2% exceeded \$100 million. A long run does not guarantee big revenues, but hits always have long runs. That is just what the dynamics of non-linear information flow would imply and leads to our next law.

*Non-linear information flow*

When you consume a movie you leave no less for others to see. Each viewer adds to the total without taking anything away because movies are pure information. New viewers are attracted to movies that already have many viewers; box office reports on the news and word of mouth news convey messages to prospective viewers proportional to the number who have seen the film. This non-linear growth rapidly propels film revenues apart from one another. When large revenues produce large revenue growth, the runs of the largest grossing films are extended and the result is long-running hits.<sup>18</sup>

*Opening gross does not predict total gross*

Suppose a movie dies after its first week. Its opening week gross would predict its total gross perfectly because they would be one and the same. On the other hand, opening week gross will not forecast total gross if a movie runs, say, 36 weeks. There is a high but slowly decaying auto-correlation between weekly revenues, but the correlation between opening week revenue and revenues in subsequent weeks decays rapidly. By the seventh or eighth week of the run, there is no correlation between a movie's opening revenue and weekly revenues or between its total and opening revenue. Because non-hit movies have short runs (4 to 6 weeks), their opening revenue is from 60 to 70% of their total revenue. So, for these movies, there is some correlation between opening and total revenue and it is stronger for movies whose revenues decay rapidly. Hit movies move on a different dynamic as we next will show.

*Momentum and chaos*

De Vany and Walls (2003b) offer an explanation for the sudden loss of correlation of revenues for hit movies around the fourth to fifth week of the run and this leads to another law of the box office, the law of momentum and chaos.

<sup>18</sup> Readers may think this information flow is a Gibrat process, but that is not the case. Growth rates in a pure Gibrat process are proportional to size. A Gibrat growth process predicts a linear increase of the variance with time; this is not found and the variance increases non-linearly over time. Second, the standard deviation of the growth rates does not decrease according to  $S^{1/2}$ . A Gibrat process converges on a log-Normal distribution and this is rejected in the dynamics (they do not settle down and show longer range correlations).

Momentum is a non-linear expansion or contraction of revenues, conditional on past revenues; the winners separate themselves from the losers. De Vany and Walls (2003b) show that the expectation of revenues going forward during a movie's run can be mapped on past revenues. Under the stable Paretian hypothesis, the conditional expectation forward revenue on past revenue is  $E[R_i^+ | R_i^+ \geq R_i^-] = R_i^- \alpha / (\alpha - 1)$ , where + means future and - means past. The expectation of future on past revenues is proportional to past revenue. The mapping is multifractal, meaning that  $\alpha$  changes value during the run (hence violating the Gibrat property). Though variable, a typical  $\alpha$  is about 1.5 which implies that  $\alpha / (\alpha - 1)$  is about 3.<sup>19</sup> This implies that, for a value  $\alpha = 1.5$ , a film's expected future earnings for its complete run in week  $i$  is about three times what it has earned to date. A movie that has grossed a large amount does not "use up" its revenue; it can continue to expand its gross. Big films grow faster and small differences between films can grow explosively. This is momentum.

The non-linearity of momentum opens the possibility of chaos. De Vany and Walls (2003b) did find evidence of a bifurcation in the mapping of future on past demand at the fourth or fifth week of the run; at this point hit movies rapidly diverge from the bombs and the mapping bifurcates into two branches, a hit and a non-hit branch. Bifurcation is known to be a route to chaos. De Vany and Walls do no formal tests for chaos because these tests require very long time series and most films do not run long enough to discern chaos. But, the evidence is there in the change in the form of the mapping – it becomes expansive for hits and contractive for bombs – and in the evidence of a rapid separation in the distance (measured as revenue) between hits and bombs. When two near points are propelled rapidly away from one another by a non-linear mapping, you have evidence of chaos.

### *Champions, births and deaths*

Films that attain high rank in the revenue tournament have longer runs than films that attain lesser rank. This and the following laws are from De Vany and Walls (1997) who model box office revenues as a dynamic rank tournament. Champions last longer in rank than contenders do in theirs and expected duration in rank is declining in rank. This is a law of champions that seems to hold in sports as well as in the movies.

Seen from another angle, we can say the hazard of death rises during a film's run and the hazard is everywhere greater for a film the lower is its revenue rank. The smaller hazard of successful films in successive weeks of their runs implies that they should have longer runs. And they do. The expected run life of a film is longer if, at some time during its run, it attains rank 1 and the higher is the highest rank it ever achieves during its life.

Another survival statistic that speaks to the unpredictability of films is that the distributions of deaths and new releases are Poisson. Births and deaths are pure counting

<sup>19</sup> The value of  $\alpha$  can be derived from the regression of the expectation mapping and, thus, is yet another method for estimating its value [see De Vany (2003b)].

processes and their weekly rates are equal. This implies that the intervals of time between deaths is exponentially distributed. The exponential distribution is said to be forgetful because the time to the next death is independent of the length of the interval.<sup>20</sup> So, a film in the  $n$ th week of its run has the same probability of death as one that just opened (if they are at equal rank). De Vany and Lee (2003) extend this model by estimating the Markovian transition probabilities between ranks. A descent in rank is more probable than a rise in rank, and small leaps are slightly more probable than large ones. Nonetheless, a film can transition from low to high rank – a humble beginning does not prevent a film from becoming a hit.

### *Extreme events dominate*

The sample average of motion picture revenues is strongly influenced by extreme events. Dropping just one film, *Titanic*, from a sample of 6289 movies covering twenty years of films released from 1982 through 2001 causes the mean box office revenue to fall by more than a million dollars and the maximum to fall from \$601 million to \$431 million. This single film accounts for just under 1% of the cumulative box office revenue of all the movies released in North America over the past twenty years. In the year it was released, 1997, *Titanic* earned 9% of all motion picture box office revenue that year.

The dominance of extreme events is revealed in many ways: by the rightward skew with the mean far above the mode and reaching the 75th or higher percentile. Figure 2 reveals the dominance in another way. Revenue declines rapidly with a decline in rank; a fall from rank 1 to rank 10 produces a change in revenue of nearly 2 orders of magnitude (from a power 10 to 8). The figure also reveals that extreme events are more dominant for non-star than for star movies (the flatter slope for non-star movies implies a higher value of the tail weight  $\alpha$ ). De Vany and Walls (1999, 2003a) show why this is so: stars increase the least revenue a film might earn, but do not increase the most it might earn.<sup>21</sup>

### *Volatility*

What follows from the dominance of extreme events is that aggregate box office revenues are volatile. So are the average and variance of revenues. One or a few big movies can move aggregate revenues by a lot and this pulls the average and variance along. When revenues obey a stable Paretian law, increments scale as  $(\Delta t)^{1/\alpha}$ . Put another way, the phase space is stable-distributed with parameters in the time space as  $S_\alpha(|\Delta t|^{1/\alpha}, 0, 0)$ , where  $\Delta t$  is the length of the time step.<sup>22</sup>

<sup>20</sup> So much for the motion picture release timing game discussed above. If time to death is independent of how long a film has been running, there is no way for a studio to predict when to release its film in order to avoid competition with some other film.

<sup>21</sup> This is confirmed in the stable parameter estimates in Table 1 where the estimate of  $\alpha$  is smaller for non-star than for star movies.

<sup>22</sup> This relation opens another method of estimating  $\alpha$  which has been coded in the DFA (detrended fluctuation analysis) algorithm by Peng.

Thus, if we observe the box office revenues over a period of 4 years, the maximum difference among revenues we will likely see in 4 years will be about  $4^{2/3} = 5.333$  larger than what we would see in 2 years. The largest leap or fall in revenue from one film to the next that occurs in 4 time years should be about 5 times the change that occurs in 2 years. Thus, we expect quite a bit of volatility in motion picture revenues when they are stable Paretian distributed. At times the bottom may appear to fall out and at others it may appear that the industry is on a rapid expansionary path. But, they are all part of the natural variation and do not indicate a fundamental change in market conditions or fundamentals. Things just happen.

### *Self-similarity*

Volatility is linked to the statistical self-similarity of motion picture revenues. This appears in many guises, but the operative point is this: a random variable  $X(t)$ ,  $t \in T$  is self-similar with index  $H$  if for every  $k > 0$

$$\{X(kt), t \in T\} \simeq \{k^H X(t), t \in T\}$$

where  $\simeq$  means equal in distribution. For a stable motion,  $H = 1/\alpha$  and since we know  $\alpha = 1.5$  it follows that  $H = 2/3$ . For Brownian motion,  $H = 1/2$ . Thus, movie revenues do not follow a Brownian motion. What follows is that there are longer-range correlations in motion picture revenues than in a Brownian motion. This reflects, among other things, the dependence of revenues on extreme events; such events linger in the data because of the powerful influence they exert on the statistics.

But, self-similarity may reflect other kinds of scaling beyond time. We shall see this later, but we can for now imagine that we could restrict movies according to some observable measure that, in effect, is a rescaling of the variable. What we should find is that we get back the same probability distribution once we properly rescale it. Thus, theater screens are another way to rescale revenues and we should find that a similar distribution holds for screens as for revenues, allowing for the difference in their magnitudes. And we do find this [De Vany and Lee (2001)]. Alternatively, if we group movies in budget categories, high, medium, low, we should get back a rescaled distribution of the same probability distribution in each of these classes. However we proceed to analyze the data, self-similarity suggests we may find that they are all windows of different scale onto the same underlying process. We shall encounter self-similarity again.

### *Non-finite moments*

Among the most counterintuitive properties of the stable distribution is that the variance may be infinite; even more mind-blowing is that the mean need not exist. All physical processes that can be realized in an observable world have to be finite, at least we feel that ought to be true. How then is it possible for a probability distribution that actually describes a real phenomenon to have an infinite variance or, worse, a non-finite mean?

Mathematically, this is not hard. All that is required is that probability in the outer tails, or upper tail if we are talking about box office revenue because its lower tail is bounded by zero, decays slowly. A probability distribution can be perfectly well-behaved and yet decay so slowly in the tail that the integrals of the variance or mean may not converge. For example, the variance is the expectation of  $x^2$ . In the Paretian upper tail of box office revenue, probability is of the order  $x^{-\alpha}$ . Since  $\alpha = 1.5$ , the term in the integral of the variance is, therefore, of the order  $x^2 x^{-1.5}$ . This goes to infinity as  $x$  goes to infinity and, so, the variance does not exist. If  $\alpha < 1$ , the same limit argument holds for the expected value, or mean.

There is nothing hard about that. What is hard is how to interpret a stochastic process that does not have a variance or may not have an expected value. I see these properties as a warning that our knowledge is limited and that further observation of the process will reveal novel outcomes. The process is not changing, but what it cranks out does change; some changes will appear to be so abrupt that we may feel that we are observing something entirely new. But, only the outcome of the process has revealed heretofore unseen events, the process remains stable.

Take the infinite variance. We know that our stochastic process takes leaps and falls on the order of  $\Delta t^{1/\alpha}$ . This means that, as time expands, the size of changes grows. Thus, the largest event so far observed will, eventually, be exceeded. In fact, the variance will grow as the sample grows. So, the infinite variance is just a warning that we can never see the full realization of the process which our observations can only reveal a glimpse of. The Lévy stable process unveils perpetual novelty, an attractive feature for a creative process like movie-making.

As to the possible non-existence of the expected value, a similar point is to be made. Now, most motion picture data do tend to have a finite sample mean; though there are some exceptions, notably market shares of the major distributors. But, even if the theoretical mean exists (is finite), we expect it to be variable. This follows from theory, as we know that a linear combination of stable-distributed random variables will also be stable-distributed, so the mean must be a random variable and is stable distributed (with suitable rescaling). But, it is the dependence of the mean on extreme values and the unfolding of the process generating new extreme values that makes the mean variable.

Aside from cautions against drawing inferences from finite observations of a process that can “go anywhere”, the infinite variance (and possibly infinite expected value) has a real advantage. We can forecast outside the sample; the largest box office revenue that we have so far seen does not put an upper bound on the possibilities. It would in a stochastic process that makes only finite leaps, for then the probability of an event larger than the largest event in the sample would be vanishingly small. We couldn’t forecast revenue beyond the largest in the sample. Yet, we know that the probability mass in the upper tail of an infinite variance stable-distributed variable does not vanish, even for events more than four or five standard deviations above the mean. If box office revenues were Gaussian, the chances of a movie reaching *Forrest Gump*’s or *Titanic*’s revenues would be zero since the former is 10 and the latter is 20 standard deviations

above the mean! But, box office is not Gaussian and the stable distribution tells us there are movies yet to be made that will exceed the largest grosses we have ever seen.

*“Nobody knows”*

The laws of the box office offer a foundation for Goldman’s nobody knows anything proposition [Goldman (1983)]. Sample averages and variances are unstable; they change with the sample and the variance grows with the size of the sample. The expected variance is infinite; the mean or expected value may not exist. The stochastic process unveils perpetual novelty. Leaps and falls are so large that the business may seem to have entered a new era. Forecasts of expected values have zero precision. And, yet bigger things lie out there. Put these together and you will see that nobody on Earth can forecast how much a movie will gross.

We know this has to be true anyway. If box office grosses could be forecast, then making movies would be easy. It is not and it should not be. The nobody knows principle elevates the creative process to the center of the motion picture universe. Nobody knows because movies are one-off, creative products, each one unique unto itself. And, they each play out their lives on the screens in equally unique ways. There is a hint of chaos in the dynamics which are richly complex and non-linear.

One suspects that Broadway shows, pharmaceuticals, patent royalties, records, books, and many other creative products share this property. It would be instructive to explore these industries using the models and tools that have proven so useful in motion pictures.

#### *4.3. Laws of production and cost*

Hollywood has its laws of production and cost, but I would not dream of writing down production or cost functions and estimating them. I would not know how to measure the output or the inputs. That is because movies are unique. And, they are produced in fairly unique ways. When a movie gets produced it is by a temporary assemblage of individuals, a temporary team. The producer puts the team together to make a movie and then the team members go back into the labor pool to wait for their next project. The movie can be storyboarded, scene by scene, and the requirements and shooting time can be estimated for each of them. But, shooting time does not translate linearly into frames and scenes of a finished picture. Linear feet of film do not add up to make a movie.

#### *Sequential production*

Producing a movie is a drawn-out process that unfolds in fits and starts over time. It is a recursive process with complex linkages among stages and this point of view is born out, not only by tales told by filmmakers such as Steven Bach (1986) or Mark Litwak (1986), but in the behavior of cost, as you will see. I will describe the stable law of production which says that a movie gets no closer to being finished as work progresses. This odd law of production is revealed in the behavior of expected cost in what I call the

angel's nightmare which says that the expected cost of finishing a movie is proportional to what has already been spent.

### *Production problems*

What I first wish to emphasize are the many problems that arise from the way films are produced and how they are dealt with to varying degrees of success. These problems make the transformation of inputs into output uncertain; hence the difficulty of writing down a function that represents that transformation. Broadly, there are hold up problems, sunk costs, and principal-agent problems among the many creative inputs and financial interests. And, they are solved in the usual ways, by crafting clever contracts and contingent payment schemes, by reputation, by careful monitoring, and by ultimatum.

A movie goes through many stages: the development stage where the story is crafted and tentative casting and financing are explored, to pre-production where the creative elements are cast and contracted and financing and distribution arrangements are made, to production where the scenes that make up the movie are shot, to post-production where editing and reshooting are done, to its eventual release. Money is spent at each stage so if the process fails to advance to the next stage, that money is spent to no effect. It is sunk and not recoverable. The hard lesson is that unless a film is finished and playing on theater screens, none of the money expended on it can be recovered. All the money spent on a movie is sunk at the time it is released.

### *End stage*

Naturally, this end of stage problem presents difficulties. A distributor might decide to renege on a distribution deal and leave the producer with all those sunk costs. At that point, unless there is competition for the film, the distributor might pick it up at a fraction of the cost knowing the producer has sunk his costs and has to sell the film to recover them. This end of stage problem was one of the reasons producers and distributors merged to form the studio system that governed production in the movies from about 1915 to around 1950. Now, it is settled by contract under which the distributor acquires an equity interest in the film. The distributor advances at least part of the production cost of the film in exchange for an interest in it along with the right and obligation to distribute it. With this arrangement, producer and distributor have a mutual interest in seeing the film finished and distributed and the end-stage problem is solved. We know that solving the end stage problem is crucial for, if the end stage cannot successfully be completed, then each preceding stage will come undone and the film will unravel from the end to the beginning and the movie won't get made.

### *Hold ups*

Another stage problem is the potential hold-up that any creative element can expose the whole production to. If an actor or director decides to change the terms of their deal or

insist on some change in the story or role or location or what have you, they threaten the whole project and may render sunk and non-recoverable everything that has been spent up to that point. It is very hard to fire an actor or director or cinematographer after scenes have been shot and are in the can. If they have tantrums or refuse to follow direction or conform to any of the many details that have been laid out in the story board or script, the project is in trouble. These days, when a studio only makes from five to a dozen movies, one movie can bankrupt a studio if it fails to be finished or runs far over budget (or is just expensive and lousy). Tantrums, creative conflicts, a script that falls apart as it is shot, bad weather, or a mechanical shark that breaks under the stress of being towed at high speed in the ocean, and a thousand other things can bring a movie's production to a halt.

### *Solutions*

So, these sorts of problems must be dealt with carefully and creatively and they are among the many sources of what appear to be strange business practices in the movie business. First, we know that reputation can make people act more responsibly and to more diligently pursue the common goal of all the agents involved in making a good movie that comes in on budget. Reputation is one solution. Hollywood may have the most carefully adjudicated system of reputation of any industry. You are in Hollywood what your screen credits say you are. They are out there for everyone to see. So are the box office statistics. Hollywood's many guilds carefully parcel out screen credits and they have developed detailed criteria for awarding director, screenwriter or producer credits.

Repeat dealing amplifies the effect of reputation. People who have worked together before tend to do so again, if their collaboration was a good one. One can trace networks of contacts, as in the Six Degrees of Kevin Bacon game played by devotees of the Internet Movie Data Base, and they are densely wired with a few key people at central nodes. Opportunities flow over this network and the structure of this network is the key to understanding patterns of work and productivity. The network structure of work and opportunity is known to be Pareto-distributed; a few central nodes have dense contacts while most nodes have few. This is another example of self-similarity in the movies; the contact network is Pareto-wired just as box office revenue is Pareto-distributed.

### *Contracts and roles*

Another method of reconciling the creative types and the money people is to write contracts or organize roles suitably. Thus, a director can be punished for going over budget; just reduce her fees in proportion to the amount the production is over budget. This is a common contractual remedy. An alternative is to blur the line between art and money by having talent participate in the profit a movie earns. Actors, directors, or screen writers can get a piece of the action, blunting their willingness to act contrary to the project's economic interest. Some directors or actors assume the role of producer, thus merging

the creative and money roles. Similarly, an actor or director who has agreed to make a movie must have assurances that the project will move ahead to production; his or her participation may be important to getting financing if the talent is “bankable”. So, there is a drop dead date at which the producer must be prepared to “pay or play”. If production does not commence by that date, the producer must pay the artist a fee.

Monitoring the artists is second nature to the money people in Hollywood. The story board tells scene by scene how the movie should progress and this progress is constantly monitored by the producer and a representative of the financial people. They watch the dailies, the film shot each day, and compare the dailies with the story board. If the shooting falls behind schedule, this is noticed and a work-around is discussed. If the dailies show too many reshoots another discussion takes place. And so on.

### *Final authority*

At some point, there must be a decision with whom to vest the authority to decide each problem that comes up. This is another place where reputation and authority crop up. No contract can contemplate all the contingencies that will arise or who should decide when there is disagreement. But, someone must decide when there are opposing views. Who should it be? It is here that contracts can become arcane and inscrutable to an outsider. It is in the best interests of all concerned to place the residual authority in the hands of the person best suited to choose the best action. But, this will differ; sometimes the director is the best one to decide, at other times it is the producer. A sloppy deal memo that vests all residual authority in a director may put the production in the hands of a mad genius and break the studio. If it puts creative authority in the hands of a money person, the cast may walk off.

Ultimately, someone must make the hard decisions that may be required to rein in a runaway production. The stage game is turned into an ultimatum game. That is the role of the completion guarantee, a bonding company that puts up the money to finish the movie. When a movie reaches this stage, the game is up and a third party steps in to make the final decisions. They may not be the best creative choices, but at least the movie will be completed, salvaging some of the costs now long sunk. The only hope of recouping these costs is to finish the movie, which the ones in charge have shown themselves to be incapable of doing. So, the completion guarantor steps in and finishes the job.

### *Stable Paretian costs*

Having described the tangible possibilities that a movie might go over budget or that budgets might be uncertain, a natural question is: How predictable are production budgets? There are many stories about movies famously over budget; Cleopatra, Heaven's Gate, and Titanic are examples that readily come to mind. We are asking what the probability distribution of motion picture production budgets is. There is a problem in finding

the answer to this question. We have production budgets for most movies that are produced and released. But, we don't have data on whether they are on- or over-budget. The best we can do is to estimate the distribution of production budgets, as reported by third party sources, to get a picture of the variety and possibilities. The production budget data will include movies that are over and on budget, giving us some idea of the possibilities.

In two papers, [De Vany and Walls \(2002, 2004\)](#) examine the distribution of production budgets. They find that budgets are Pareto-distributed, though they are less skewed than revenues. Mean budget is at the 62nd percentile and its standard deviation is approximately equal to the mean.

[De Vany and Walls \(2004\)](#) estimate the general stable parameter values of the profit distribution. The lower tail of the profit distribution is Paretian with a tail exponent of  $\alpha = -2.64$ . Because the estimated value of the tail coefficient exceeds 2, budgets have a finite variance. The lower tail of the profit distribution is dominated by cost and so this is a reasonable estimate of the tail weight of the cost distribution. In another paper, [De Vany and Walls \(2002\)](#) estimate the tail coefficient and test the Pareto distribution as a model of the cost data. It turns out to be is a very good model of the budget data. Interestingly, they find that the budgets of R-rated movies have heavier tails than do the distributions of the other ratings and, thus, have a higher probability of large budgets. G-rated movies have the least heavy tails, the inference being that they have a lower probability of reaching very large expenditure values.

### *Returns on budgets*

What does a higher budget buy? [De Vany and Walls \(2003a\)](#) estimate returns to production budgets. The elasticity of mean box-office gross revenue with respect to production budget is 0.54. Larger than zero, but it does show that you cannot buy box office revenue by throwing production dollars at a movie. You only get back fifty cents on the dollar. Hence, there are decreasing returns to production budgets with respect to the box office take.

The elasticity of opening box office revenue, the lowest decile, with respect to production budget is a bit higher at 0.636, but it still is not a good return. Ten percent more budget buys just six percent more opening revenue. Higher deciles show slightly lower budget elasticities: 0.56 for the median, 0.52 for the upper quartile, and just 0.44 for the top decile. To explain it in plainer terms, the top decile is the amount ninety percent of movies will fail to earn and only ten percent will equal or exceed. The estimates say you move this upper decile by just forty cents when you spend another dollar on production. Thus, you have increased the revenue by forty cents of an event that has a probability of just ten percent of occurring. You could say the expected value of the best that can happen is just four cents. Not a very good return for a dollar investment.

### *The angel's nightmare*

An “angel” in Hollywood or on Broadway is an investor who agrees to finance a production.<sup>23</sup> Having found budgets to be Pareto-distributed, we are in a position to see what sort of a nightmare is in store for an angel when a production goes over budget. The angel’s nightmare is tied to the conditional expectation of the Pareto-distributed budget. The Pareto distribution has a counter-intuitive conditional expectation: the expected budget, given that  $y_0$  has been spent, is  $y_0 \frac{\alpha}{(\alpha-1)}$ . Substituting  $\alpha = 2.64$  the expected budget, conditional on  $y_0$  having been spent, is  $y_0 \times 1.609$ . Suppose \$20 million has been spent on a movie budgeted to cost \$16 million. What is the expected cost now that it is already \$4 million over budget? It is  $20 \times 1.609$  or \$32 million. The movie is over the budget and there is no end in sight. This is the angel’s nightmare. It arises from the peculiar property of the conditional expectation of a Pareto-distributed random variable; the conditional expectation is linear in the value of the conditioning event.

### *A strange law of production*

We can infer something of the production process from the behavior of budgets. Time is money and we can invert the budget to obtain production time. This gives us a rather strange law of production. It is that the expected time to completion of a movie in production for  $t$  time periods is  $t \times 1.609$ . The time it will take to finish the project is proportional to how long the movie has been in production. This means that there really is no end in sight, which is why production schedules and completion guarantees are so important in the movie business.

### *Artist productivity*

The first thing one should know about productivity is that artists can differ in the extreme in productivity. The movies is not like washing dishes where two people cannot differ by much. Actors and directors, the two creative productive factors we will focus on, can differ enormously in their productivity, as we shall see. This is natural for several reasons. First, non-linearity can magnify small differences in talent or luck into extreme differences in box office revenues. Second, work opportunities flow over a non-linear network and densely connected artists – made so because they act or direct hit movies – get most of the opportunities and work. Third, the most successful artists tend to have long careers. These facts are implied by the high kurtosis of the stable Paretian distribution that describes the laws of production.

In spite of Rosen’s (1981) explanation of superstardom, there is not much empirical evidence about it. According to his model, small differences in talent translate into large differences in income. Hamlen (1994) presents evidence from popular music regarding

<sup>23</sup> This is drawn from De Vany and Walls (2004).

the distribution of hits. Chung and Cox (1994) show that the Yule distribution is a good model of hit movies of the top stars. The Yule distribution is a power law distribution with  $\alpha = 1$ , so their model is a variant of the stable Paretian model. Interestingly, in their model differences in success are due wholly to chance and talent need not be invoked to explain the variation in artist productivity. Ravid (1999) and De Vany and Walls (1999) examine the influence of stars on profits or revenues and find they are weak.

To shed more light on the productivity of artists, De Vany (2003a, 2003b) examined the productivity of directors and actors. Unsurprisingly, there is a high degree of self-similarity of the laws of productivity and the laws of the box office already presented. The distributions of the number of movies made by actors or by directors are leptokurtotic; kurtosis is 16 and 22, respectively.

Most actors or directors make just one movie: the mode of both distributions is one, the mean of both distributions is 2 and is located at the 75th percentile of each distribution. If we take box office revenue as a measure of productivity, things become a bit more wild. The mean cumulative gross of actors is \$32.6 million and the kurtosis is a breath-taking 104. The median is just \$1.01 million and the mean is up at the 85th percentile. In keeping with the dominance of extreme events, De Vany (2003a, 2003b) finds that the mean portion of cumulative gross due to just one picture is 22% for actors and 32% for directors.

The stable Paretian distribution fits the production data well and estimates of  $\alpha$  values are 1.5 for directors and 1.8 for actors. The form, fit, and values of the tail coefficient follow the stable Paretian property of self-similarity. We know that  $\alpha = 1.5$  for box office revenues; to find a similar value for actor and director productivity tells us that their productivity is statistically similar to box office revenues. In other words, the distribution of the number of films artists make is just another view of the distribution of box office revenues. In keeping with Chung and Cox (1994), it turns out that talent is hard to separate from luck when it comes to how many movies directors make. De Vany (2003a, 2003b) shows that it is only among the most productive directors that one finds a significant role for talent over luck in the odds ratios.

#### 4.4. *Laws of profit*

“Upfront and sunk” is the rule for costs. The rule for profits might be “way after and maybe”. You have to wait a long time for profits to accrue and it might never happen. Movies do lose money, most of them. Revenue streams in over a fairly long time period as a film makes its way through its many venues, domestic theaters, foreign markets, videos, television and so on.

And then there are portfolios to consider. Studios produce portfolios of films, most of which lose money and they have to pool profit over all the films in the portfolio. This is the so-called studio accounting problem. But, it isn’t trickery to allocate all the cost of the portfolio against all the revenue and then find that a few movies took in most of the revenue. The producer of a hit may cry “foul” but this is the way the studio has to be to manage the huge risks it is up against. All this makes accounting separately for

film profits problematic. And, on top of this, is the fact that these figures are not made public. So, one approaches the subject of film profitability with a lot of trepidation and caution.

But, economists want to know and there are ways to at least approximate film profitability in ways that get at the object of our interest; the probability distribution. If it is stable Paretian, we are in luck (it is), because bias will not change the form of the distribution, only its scale. So, our probabilistic inferences will not be that far off. Another way to get at this is to look at returns which can be approximated by the ratio of revenue to cost.

### *Dominance of extreme events*

Our first clue that profit is stable Paretian distributed is in the dominance we find of extreme events. Seventy-eight percent of movies lose money and 35% of profitable movies earn 80% of total profit. Losses are more evenly distributed, after all they are not subject to the non-linear information flow like revenues, and are generally finite; you can only lose what you spend. Fifty percent of the unprofitable movies accounted for 80% of total losses. Just 6.3% of movies earned 80% of profits earned in Hollywood over the past decade. Profits are skewed (but in surprising ways we shall see later) and the kurtosis is large, 15 for all movies in the sample, 23 for movies that do not feature a star, and a mere 5.6 for movies with stars. The mean profit is negative in each of these categories. Finally, the impact of extreme events is clearly evident in the stunning changes that occur over time in the running cumulative average profit shown in [Figure 3](#) taken from [De Vany and Walls \(2004\)](#). The rugged, fractal appearance of the graph is

Figure 3. Average cumulative profit of films by date of release.

testimony to the impact of extreme events on the running average and of the stable law of motion of profit.

### Stable profit laws

Having mentioned the stable law of motion, we should now consider the evidence that profit is a stable distributed random variable. There is no doubt profit is random, as we have seen, so how can we say it is stable-distributed? Because the stable distribution fits motion picture profit like a glove and other distributions, like the Gaussian, can be rejected with high confidence. De Vany and Walls (2004) use John Nolan's Stable program to estimate the four parameters of the general stable distribution  $S_\alpha(\alpha, \delta, \gamma, \beta)$ ; I reproduce their results in Table 1.

Note that the Normal distribution, which requires tail index  $\alpha = 2$  and skewness  $\beta = 0$ , does not fit as well (by the Log-likelihood statistic) and normality can be directly rejected by tests. The distribution is not symmetric either, as the best fitting distribution is the general stable distribution with positive skew for movies featuring stars and negative for others. Only positive skew can be accepted with high confidence for star movies; the negative skew of non-star movies and of all movies are not significant. Notice that the locations of the distributions, given by  $\delta$ , roughly corresponding to the mean, differ; the stable distributions place more probability mass on larger losses than the Gaussian.

The scale parameter,  $\gamma$ , represents the width of the central part of the distribution. In all cases, this region is narrower than a Gaussian distribution. This reflects the greater weight in the tails of the stable distribution relative to the Gaussian; the lesson is that the location statistic is a brittle estimate of the mean because probability mass spills away

Table 1  
Maximum likelihood parameter estimates

	Index $\alpha$	Location $\delta$	Scale $\gamma$	Skewness $\beta$	Log-likelihood
<i>All movies</i>					
Normal	2	-3.351	8.442	0	-7855.37
Symmetric $\alpha$ -stable	1.268	-4.079	4.032	0	-7279.87
$\alpha$ -stable	1.259	-4.042	4.020	0.043	-7279.46
<i>Movies with stars</i>					
Normal	2	-2.083	14.186	0	-1439.69
Symmetric $\alpha$ -stable	1.582	-4.568	10.555	0	-1419.16
$\alpha$ -stable	1.624	-6.385	10.805	0.768	-1410.82
<i>Movies without stars</i>					
Normal	2	-3.595	6.789	0	-6216.46
Symmetric $\alpha$ -stable	1.358	-3.932	3.507	0	-5739.47
$\alpha$ -stable	1.335	-3.827	3.441	-0.122	-5737.95

from that area, flowing rapidly into the tails; this is kurtosis – a sharp peak with heavy tails.

The prime parameter is  $\alpha$ , the tail weight coefficient that measures the probability mass that lies in the tails.  $\alpha$  is between 1 and 2, so the expected value of profit exists, but the variance is infinite.  $\alpha$  is well below 2, the tail weight of a Gaussian tail; this is the sense of saying the stable distribution has heavy tails – its probability mass decays more slowly than a Gaussian rate, 1.26 for all movies rather than 2. The star distribution is asymmetric, with a heavier upper than lower tail (this leads to the curse of the superstar, discussed below). The non-star distribution is symmetric.

### *Returns*

Returns are a bit less difficult to measure than profit. One measure of motion picture returns is given by the ratio of box office revenue to production cost. These figures omit certain details, like rentals and print and advertising cost, but they are readily measured and non-controversial. Given reasonable proportionality of these measures, which are partly assured by the way the rental rate and distribution fees are determined, this ratio mimics returns.

Using the self-similarity argument, our expectation is that the ratio of revenue to cost is a Pareto-distributed random variable, at least asymptotically in the tails. The mean return is 0.069 and the standard deviation is a large 6, evidence of a dependence on extreme events. Further evidence is that the mean is well above the 75th percentile. Kurtosis is a monstrous 940, very far from a Gaussian kurtosis of 3.

Taking a lower bound on returns of 2, to move into the tail of the return distribution, De Vany and Walls (2002) estimate the tail exponent  $\alpha$  for G-rated movies at 1.35, PG at 1.56, PG-13 at 1.78 and R at 1.48. A Kolmogorov–Smirnov test accepts the hypothesis that the data follow a Pareto distribution in this upper tail where returns exceed 2. Returns have finite expected values and infinite variance. The authors go on to show that G-rated movies stochastically dominate other ratings in returns and that, with respect to profit, movies in every rating category stochastically dominate R-rated movies.

### *4.5. Stochastic market structure*

We have already seen that motion picture revenues are unequal in the extreme. What about the market shares of firms? De Vany and Walls (1997) show that inequality among motion picture distributors exceeds the inequality of revenues. De Vany and Lee (2003) show that the concept of stochastic market structure is relevant to this industry because shares are extremely volatile. They conclude that the motion picture industry is stochastically concentrated, but enormously competitive.

Market shares are driven by successful movies and follow a stochastic Pareto motion with  $\alpha = 1.3$ . When market structure is stochastic, a stationary measure of concentration, such as the Hershman–Herfindahl Index (HHI) is a misleading index of competitiveness. One must use a stochastic measure. One such measure is the expected value of

the HHI. De Vany and Lee (2003) show that the expected value of the HHI is the second moment (variance) of market shares. Because shares are Pareto-distributed with tail index less than 2, the HHI does not exist (because the variance is infinite). The movies are so competitive that this vaunted (and much over-rated) measure of competitiveness does not exist; the measure has no measure.

#### 4.6. *Pricing talent*

If you really don't know anything, you should wait until you do know. This principle applies to determining the rental rate, as we have seen. The question now is how to price talent when you don't know how much a movie will make. The same principle, the option principle of delaying the decision until you have more information, applies. But, it only applies to the most expensive talent. There we find that prices are determined through contingent clauses in the contract that trigger adjustments to the artist's price if the movie does well. This is called a participation contract in Hollywood, meaning that the artist participates in the movie's profit or revenue. We already know that the studio portfolio problem makes individual motion picture profit somewhat arbitrary (economics says the allocation of joint costs is arbitrary). Revenue is separable from other movies in the portfolio, so participation contracts more often are contingent on revenue rather than profit.

#### *Extreme events and contracting in the tail*

The stable Paretian hypothesis says that extreme events dominate, which implies that compensation should be conditioned on extreme events because that is where the real action is. De Vany and Walls (2004) call this contracting in the tails because the extreme events are located in the upper tail of the revenue distribution, where it is Paretian. Mark Weinstein (1998) studied the evolution of profit-sharing contracts. Darlene Chisholm (1997) employs a sample of contracts to show that contingent compensation is given only to established actors. In her 1995 study [Chisholm (1995)], she analyzes actor incentives in share contracts and looks at degrees of residual claims ("points" in Hollywood). De Vany (2003a, 2003b) makes the same point about directors. Using a sample of contracts of established directors, he shows that there are break points where the percentage of gross distributor revenues paid escalates as revenues rise. He then shows the Gaussian probabilities of these break point events is essentially zero, but significant under the Pareto distribution that actually fits the data. Conclusion: the parties seem to sense they are contracting in a stable Paretian, non-Gaussian world.

Taking this point a bit further, the contracts condition on such extreme events that there can be only a modest incentive effect here. De Vany (2003a) argues that the participation contract is a dynamic decision rule that pays the conditional expectation of future revenue at discrete breakpoints along the realized revenue stream. The contract pays when you do know and its escalating terms reflect the Pareto property of a rising conditional expectation of future revenues as revenues accumulate.

A related important finding is that total director pay is dominated by contingent compensation and that the latter is dominated by one or two movies. De Vany (2003a) shows self-similarity of the revenue and compensation probability distributions for these major directors; they both are Pareto-distributed and have equal tail weights of 1.5. Director careers share the same statistics. Director careers, productivity, pay, and the revenues of their movies all are windows onto the same underlying fundamental process, one that is dominated by extreme events.

### *Stars, profits and the curse of the superstar*

There are difficulties in pricing superstars, particularly if they command a fixed, upfront fee. De Vany and Walls (2004) call it the curse of the superstar. It too, contributes to a preference for paying superstars through participation deals, as shown above.

The curse of the superstar arises because the general stable distribution of profits of superstar movies is skewed and asymmetric; it has a heavier upper than lower tail (recall our discussion of the profit distribution above). This causes the expected profit, \$7.68 million, of superstar movies to be larger than the most likely profit,  $-\$7.50$  million. You can see what would happen if the star's agent extracts the expected profit as the star's fee. The movie almost surely would lose money. Why? A single movie is a small sample (of one). In small samples, the most probable event dominates and the expectation, being a large sample statistic, is improbable. Calculations show that the probability of a loss is 0.80 if the star is paid the expected profit of her movie. This may explain why Ravid (1999) finds that star movies are not more profitable. The curse is another good reason to pay stars contingent rather than fixed fees.

### *Bidding wars and the producer's curse*

There is another reason for producers to be cautious in bidding for stars. There are about 33 big budget movies produced each year. If each of their producers tries to hire an established star, a currently active actor who has three hits in his or her filmography, there will be 33 producers chasing 18 actors. Each producer places a value on each star, known only to the producer. The producer who outbids everyone had the highest value among the 33 producers bidding. That means that 32 producers had lower values, evidence that the winning producer bid too much. This is the producer's curse. It is known as the winner's curse in private value auctions; when you win against many other bidders bidding personal values, which are unknown to you, you have a lot of evidence stacked up against you that your value was too high. Rational bidding requires that you shade your bid downward when you bid against a large number of other bidders.

### *Is an actor really worth \$20 million?*

When you combine the superstar curse and the producer's curse with the evidence that star movies are not more profitable, you begin to see that an actor might not really be

worth \$20 million. But, they will get it anyway if Hollywood fails to guard against these curses. Contingent compensation is one way to avoid these hazards. In the Epilogue to his book, *Hollywood Economics* (2003b), De Vany shows that the sure thing principle adds another layer of complexity to the problem for it leads producers to overvalue the prospects of known entities relative to lesser known ones because the latter have more ambiguous probability distributions.

#### *4.7. Decisions: Greenlighting, bias, and sure things*

There is more to tell, now that we have opened the Pandora Box of decision problems in movie making. I shall be brief because we have set out the model in enough detail to see the issues. Hollywood's decision problems stem from the counterintuitive properties of the stable probabilities and the need to treat movies as prospects, probability distributions, not sure things. Of course, executives share our human failings too, and known biases in human decision making must share the blame.

#### *Ratings and genre*

Ratings and genre predict almost nothing. The odds do differ among films rated differently, but only fairly sophisticated tools can detect this. An R-rating does narrow the audience some, but even among a smaller group of potential viewers, revenue is essentially unlimited. Self-similarity reminds us that all these categories have the same Paretian probability distribution. And, it is stochastic anyway, so there is no way to predict a movie's outcome knowing its rating or genre. Genre is a particularly weak predictor.

#### *Aggregation bias*

Aggregates of variables share the same probability distribution as the variables themselves, the essential property of stable distributed random variables. So, the aggregate returns or revenues of a collection of small budget movies have the same odds or expectations as one large movie whose budget is the sum of the small movie budgets. But, it is much harder to get a studio to finance several small movies than to get one large one for the same money. Why is this so? It is aggregation bias.
