Humans are prone to aggregation bias, but the stable probabilities in the movies compound the difficulties. I think this is because it is difficult to see that the odds that the sum of random variables will be equal to some amount are no different from the odds that a random variable will be equal to that sum. The odds of making two movies whose revenues sum to \$100 million are the same as the odds of making one movie that grosses \$100 million. Most people would see the former event as less likely than the latter. This is an aggregation bias, but it is only a bias because movie grosses are stable-distributed, which makes the odds of these two events the same.<sup>24</sup>

<sup>24</sup> See Appendix A.

*Ambiguous probabilities and sure things*

Another source of difficulties occurs when probabilities are ambiguous. They always are in the movies, but here is the issue. An executive must always make some assessment of the odds in choosing movies. This is harder to do when the movie or the actors or producers are unknown entities. A known entity gives more assurance that the odds can be estimated. At least there is some experience to rely on in estimating the probabilities so they seem to be less ambiguous and the known entity is more likely to be chosen.

But, what is the meaning of ambiguity when we have distributions with infinite variance and where the mean depends so heavily on extreme events in the upper tail? Since movie outcomes are so scattered over the whole space of possibilities, there is no typical movie or representative type. If the studio were to treat both prospects as having Pareto distributions, then more ambiguous probabilities of the lesser known entity would be captured by the spread between the least outcome and the best outcome. Pareto distributions reach an upper value of infinity, no matter what parameter values they have. So one Pareto distribution can only be more diffuse than another if it has a lower minimum value. This argument would suggest that ambiguous probability distributions might be evaluated as having worse worst outcomes (lower lower bounds in the support of the distribution). It is surely easier for an executive to conjecture as the worst outcome than to estimate the parameters of the Pareto distributions and they are likely to be unduly pessimistic when unknown artists are involved. This is where good statistical modeling might make a big difference in the quality of decisions.

*Inside and outside odds*

These decision paradoxes suggest that good statistical modeling might improve Hollywood's decision making. I think all I have said in this review of research points to a conclusion that Hollywood should compare the inside against the outside odds when they choose movies. Outside odds are objective odds given by careful statistical modeling of the data. Inside odds are part of the arguments, stories, and forecasts that people tell each other in meetings when they choose the studio's production slate. Overly optimistic forecasts, known artists, big projects, and "sure things" tend to carry the argument in this setting, even when they do not square with the real odds outside the studio.

**5. Conclusion**

How durable are the methods and results that I have described here? Will the rise of DVDs and the international market and the declining share of domestic theatrical revenue in total gross change matters? I think not because this research has looked for deeper patterns that have a universal order. We know that international revenues, and revenues in many foreign countries, follow the same Paretian pattern (even with the same tail weight). Thus, culture and local arrangements in specific countries do not

alter the universal pattern. In each country where a film plays, its revenues follow a similar dynamic where choice, mixture and aggregation are the stable operators. Necessarily, they will result in a stable distribution of box office revenues. The same points hold for DVD sales. The timing of these sales does help in resolving the nobody knows problem for the later markets. If foreign theatrical distribution is later than domestic release, then the foreign film buyers have prior information on which to condition their estimates. The same point holds for DVDs; the theatrical run reveals prior information not available at the initial opening. And, we should be able to do better in predicting revenues.<sup>25</sup>

Nothing I have said changes when we open the analysis to include these markets. All the results and techniques apply to them. But, prior information, garnered from the North American theatrical run, lets us to make better estimates of outcomes in the downstream markets (just as the second and third run theaters had prior information from the first run theaters in the days before the *Paramount* decision). This prior information can be incorporated by conditioning the probability estimates of the stable distributions of foreign and DVD markets on the North American grosses. Lastly, just to show that things never change, piracy is pushing the studios to release films simultaneously in all markets, domestic, foreign, and DVD. Thus, the prior information revealed in the North American run is gradually washing away in the battle against piracy. And we shall then once again be up against the full force of the nobody knows principle.

The research reported here shows clearly that anyone who thinks he knows how much a movie will gross doesn't know what he is doing. He would have to have a model and we have seen there isn't one. If there were a model, making movies would be easy and no one would ever lose money. Movies are prospects, probability distributions as ephemeral as the images on the screen. It has to be this way because movies are creative products – they are pure information and the revenue they might earn is just a number – pure information – with no natural scale or limit.

I hope I have shown there are powerful ideas and tools that we can use to reveal the deeper order of this seemingly chaotic, challenging, and endlessly fascinating business of the movies. I believe these tools can be a constructive basis of a new economics of art and culture.

## Appendix A

What is the role of stability in the movies? Theoretically, if the random revenues of movies aggregated over choices, theaters, weeks, and movies are stable, then the distributions of these sums all will be similar. The concept of stability means that the distribution of sums of random variables is similar to the distribution of the random variables (this is defined more precisely below). This implies that each observed sequence

<sup>25</sup> I am told that the price charged for a foreign release is conditioned on its domestic revenues, meaning the latter are a good predictor of foreign revenue.

of random variables or sums of random variables of a stream of box office revenues has the same distribution and is only a different view of the underlying process. The concept of similarity, or self-similarity, is used extensively in this chapter and leads to deep insights about the movie business.

The other important property for motion pictures of stable or self-similar processes is that they have limiting distributions. This means that the distributional dynamics will converge on a stable distribution and the distribution will be relatively unaffected by the initial conditions. Despite all the uncertainty about where motion picture revenues may go, they will converge on a statistical attractor. Consequently, the statistical attractors and the underlying dynamics have a deep property: they are stable and convergent. Finally, self-similar, stable processes need not have a finite mean or variance, a very important property of the movies.

Taken together, the properties of stable aggregation, non-finite variance, and self-similarity give us a way of coming to grips with the “wild” uncertainty in the movies. They make the probability distributions of outcomes central to the study of this industry. Let me briefly discuss stable distributions and their properties. I highly recommend [G. Samorodnitsky and M.S. Taqqu \(1994\)](#) as an authoritative text on stable processes and stable distributions.

Most readers know that the Central Limit Theorem states that the sum of a large number of iid random variables with finite variance converges to a Normal distribution. What they may not know is that if the finite variance assumption does not hold true of the random variables, then the Generalized Central Limit Theorem states that the limiting distribution must be a member of the stable class. Informally, the term ‘stable’ is used because when iid members of a stable family are added the shape of the distribution does not change. The distribution obtained by adding random variables is equivalent to convolving their probabilities. If the “shape” of the convolved distribution of sums is similar to the distributions of the random variables, the distribution is stable. A random variable is stable if  $\sum_{i=1}^n Y_i \simeq^D Y$  for any  $n$  where the symbol  $\simeq^D$  means equal in distribution. The distribution of stable random variables and their sums is similar. Remarkably, a random variable is stable as soon as the equality is true for  $n = 2$  and  $3$ . Surprisingly, this implies that the sum of revenues of two or three small budget movies have the same probability of hitting a revenue of, say,  $X$  as a large budget movie. An equivalent way to define stability is in linear transformations of the probability distribution. Two random variables are similar in distribution if there exist constants  $a$  and  $b > 0$  such that  $Y \simeq^D a + bX$ . That is,  $Y$  and  $X$  are similar in distribution if the distribution of  $Y$  is a linear transformation of the distribution of  $X$ .

Stability means that the dynamics lead to a stable attractor since the sequence of sums of a stable random variable is stable or self-similar. A stronger statement is this: the distribution function  $F$  possesses a domain of attraction if and only if it is stable. The limiting distribution function  $F_X$  of independent r.v.’s  $X_k$  belongs to the domain of attraction of  $F$  if there exist normalizing constants  $a_n, b_n > 0$  such that the distribution of  $(\sum_{i=1}^n X_i - a_n)/b_n \rightarrow F$ . The Normal (Gaussian) distribution is stable, but it is the only stable distribution with a finite variance. The Pareto, Lévy and Cauchy

distributions are the other (named) stable distributions. But, there are many other members of the stable class, whose functional forms cannot be given. Lévy characterized the class of stable distributions through their characteristic function. A stable distribution  $X \sim \mathbf{S}(\alpha, \beta, \gamma, \delta)$  is a four-parameter distribution with characteristic function given by

$$C(t) = \begin{cases} \exp(-\gamma^\alpha |t|^\alpha [1 + i\beta (\tan \frac{\pi\alpha}{2}) (\text{sign } t) ((\gamma|t|)^{1-\alpha} - 1)]) & \text{if } \alpha \neq 1, \\ \exp(-\gamma |t| [1 + i\beta \frac{2}{\pi} (\text{sign } t) (\ln |t| + \ln \gamma)]) & \text{if } \alpha = 1. \end{cases}$$

The exponent  $\alpha$  is a measure of the probability weight in the upper and lower tails of the distribution; it has a range of  $0 < \alpha \leq 2$  and the variance of the stable distribution is infinite when  $\alpha < 2$ . The basin of attraction is characterized by the tail weight of the distribution ( $\alpha$ ). This remarkable feature tells us that the weight assigned to extreme events is the key distinguishing property of a stable probability distribution. The skewness coefficient  $-1 \leq \beta \leq 1$  is a measure of the asymmetry of the distribution. Stable distributions need not be symmetric; they may be skewed more in their upper tail than in their lower tail. The scale parameter  $\gamma$  must be positive. It expands or contracts the distribution in a non-linear way about the location parameter  $\delta$  which is the center of the distribution.

The tails of a stable distribution are Paretian and moments of order  $\geq 2$  do not exist when  $\alpha < 2$ . This is typical of motion picture revenues. Its mean need not exist for values of  $\alpha < 1$ . This is true of the cumulative grosses of movies made by actors.

The  $\alpha$ -stable distribution becomes the Cauchy distribution when  $\alpha = 1$  and  $\beta = 0$ . The stable distribution is the Lévy distribution when  $\alpha = 0.5$  and  $\beta = \pm 1$ . When  $\alpha = 2$  the skew parameter ceases to have any impact and the stable distribution has only two parameters ( $\delta, \gamma$ ) the mean and variance of the symmetric Gaussian distribution. The general stable distribution contains the Lévy, Pareto, Cauchy and Normal distributions for specific values of the parameters. It need not be symmetrical; thus, the upper and lower tails may differ. This is precisely what we would expect to find for motion picture profit because the lower tail is limited by expenditures while the upper tail is essentially unlimited.

Aside from these theoretical properties of stable-distributed random variables, the sample statistics are unusual and they befuddle standard analysis that is too often based on the Normal distribution. For one thing, the sample variance (not the theoretical variance, which is infinite) increases with the size of the sample. For another thing, the sample average is volatile. Just one movie can move the average in a dramatic way. Indeed, the sample average  $(X_1 + X_2 + \dots + X_n)/n$  has the same distribution as  $X_k n^{1/\alpha-1}$  where  $X_k$  is any term in the sum. If  $\alpha < 1$  then the maximum value contributes heavily to the average. This is true, though to a lesser extent, when  $1 < \alpha < 2$ . This is the Titanic effect wherein a single movie may contribute a large portion of the sum of movie revenues in a year. Since the average is a linear combination of stable random variables, it too is stable-distributed. This means that sample averages are unreliable and that the perils of forecasting future events from past averages are large. Forecasts have an infinite variance as well.

### **Abstract**

This chapter considers economic issues and trends in the rock and roll industry, broadly defined. The analysis focuses on concert revenues, the main source of performers' income. Issues considered include: price measurement; concert price acceleration in the 1990s; the increased concentration of revenue among performers; reasons for the secondary ticket market; methods for ranking performers; copyright protection; and technological change.

### **Keywords**

*The fact of the matter is that popular music is one of the industries of the country. It's all completely tied up with capitalism. It's stupid to separate it.*

Paul Simon

## 1. Introduction

As was highlighted by a much ridiculed box in the 2004 *Economic Report of the President* that questioned whether fast food restaurants should be classified in the manufacturing sector, defining an industry necessarily entails some arbitrariness. We seek to survey the economics of the popular music industry, a subfield of economics that we euphemistically call *Rockonomics*. But what is popular music? Where does one draw the lines? Here, we will define popular music as music that has a wide following, is produced by contemporary artists and composers, and does not require public subsidy to survive. This definition rules out classical music and publicly supported orchestras. It includes rock and roll, pop, rap, bebop, jazz, blues and many other genres. What about Pavarotti? Well, we warned you that the border of the definition can be fuzzy. If the three tenors attract a large following and are financially viable, we would include them in the popular music industry as well.

Why is popular music worthy of a *Handbook* chapter? There are several responses. First, Paul Simon's sentiment in the epigraph notwithstanding, for many fans popular music transcends usual market economics and raises spirits and aspirations. In this vein, for example, Bruce Springsteen once commented, "In some fashion, I help people hold on to their own humanity, if I'm doing my job right." Dewey Finn, the character played by Jack Black in the hit movie, *School of Rock*, went even further, immodestly claiming, "One great rock show can change the world." The rock and roll industry arguably started as a social movement intended to bring about political, economic and cultural change, as much as it did as a business. Certainly, popular music is an important cultural industry.

Second, precisely because emotion and non-traditional economic concerns loom large in popular music, the industry can be a breeding ground for new insights into economics. Social considerations are important in transactions outside the music industry; they are just magnified when it comes to a rock and roll concert.

Third, the popular music industry provides a testing ground for some important economic theories. For example, popular music is a classic superstar industry, where rewards are highly skewed. Can economic models explain the distribution of rewards? Also, despite the non-economic forces that affect the popular music industry, can basic economic factors, such as supply and demand, still provide a good explanation of many of the important developments in the industry?

Fourth, the industry is profoundly affected by technological change, such as the advent of radio, TV, record albums, cassette tapes, CDs, MP3 players, the Internet, etc. Thus, popular music provides an unusual setting to understand how rapid technological change affects an industry.

Fifth, and finally, the popular music industry is, by definition, popular. As a consequence, students are particularly motivated to learn about the industry, and examples drawn from the industry thus provide good material for teaching economics.

To help guide our coverage, [Table 1](#) provides a summary of the main income sources for the top 35 popular music performers who toured in 2002, ranked by income. The figures, which are taken from *Rolling Stone* magazine, should be viewed as rough estimates. Another *caveat* to bear in mind is that some sources of income – such as revenue from merchandise sales, movies, commercials and (don't laugh) cell phone jingles – are not itemized in the table, but included in the total. These other sources of revenues can be substantial. The Osbournes, for example, had a huge success with their reality TV show that aired on MTV. Nevertheless, the table provides an indication of the relative importance of live concerts, record sales, and publication royalties in performers' income. Although the concert figures are somewhat inflated because artists do not tour every year (and our sample conditions on having toured), it is clear that concerts provide a larger source of income for performers than record sales or publishing royalties. Only four of the top 35 income-earners made more money from recordings than from live concerts, and much of the record revenue for these artists probably represented an advance on a new album, not on-going royalties from CD sales. For the top 35 artists as a whole, income from touring exceeded income from record sales by a ratio of 7.5 to 1 in 2002. Royalties from publishing music was slightly less than income from recordings. Consequently, we will devote much attention to live concerts in this chapter.

The remainder of the chapter is organized as follows. The next section describes the organization of the music industry, devoting particular attention to live performances. Section 3 discusses theoretical issues in the pricing of concerts. Section 4 considers major developments in the popular music concert industry, with particular emphasis on prices, ticket sales, revenue, and concentration among promoters. Section 5 considers the important role played by scalpers. Section 6 provides a method for ranking performers based on economic data. Section 7 considers the role of the superstar model in the rock and roll industry. Section 8 discusses the role of radio and royalties, and Section 9 considers related issues involving file sharing. Section 10 concludes by highlighting important questions for further research.

## 2. The players

The market for popular music has many players and complex contracts. [Figure 1](#) provides a schematic diagram of the organization of key elements of the popular music industry. First and foremost, of course, are the musicians, who form a band. The band may write its own music and lyrics, or it may purchase music from an outside composer. In [Figure 1](#), we have illustrated a situation for a band that writes its own music. The bands have managers who represent them and take a share of their earnings in exchange for their managerial services. On behalf of the bands, managers make contracts with promoters to promote live concerts. The promoter secures a venue, advertises the

Table 1  
 Estimated pre-tax gross income by source for 35 top artists who toured in 2002 (millions of US dollars)

Rank	Artist	Live concerts	Recordings	Publishing	Total income

Notes: Figures are estimates of pre-tax gross income in 2002. The total income may exceed the sum of the first three columns because of TV, movie, merchandise and other potential sources of income.  
 Source: LaFranco (2003).

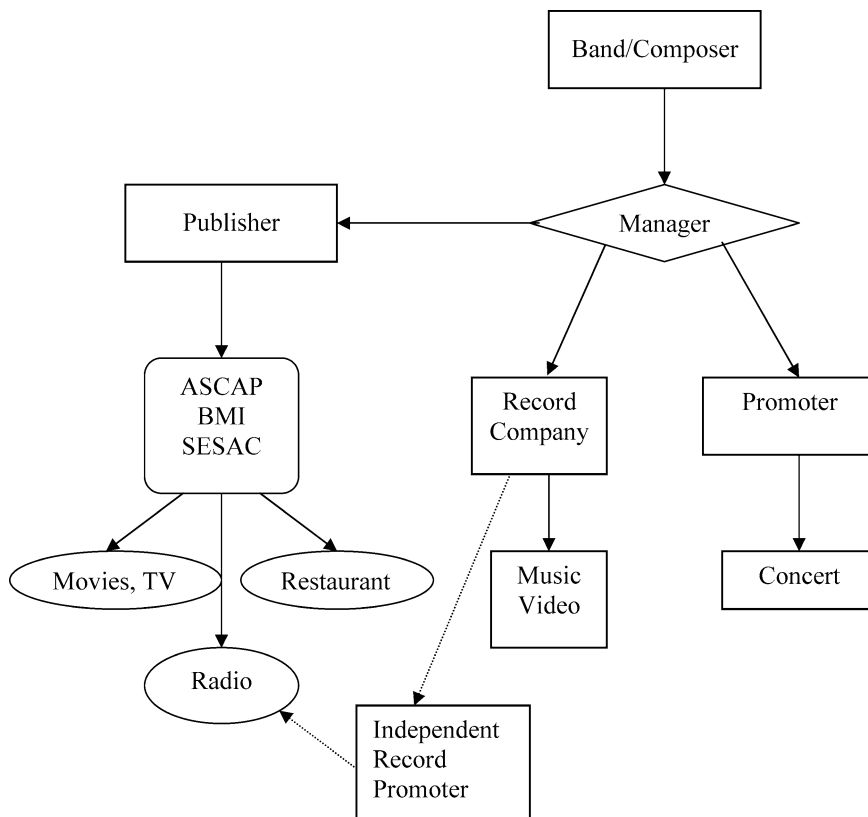

Figure 1. Organization of the popular music industry.

event, and takes care of other arrangements. Successful bands also have contracts with recording companies to produce and market CDs. Record companies are occasionally involved in promoting concert tours, but they typically play only a peripheral role in concerts, when they are involved at all.

If a band composed its own music, it will also contract with a publisher to copyright the music. The publisher will contract with a performing rights organization, which licenses the music for radio stations, television and other users, monitors the use of the music, and collects royalties. The publisher usually takes half the royalties, and the composer receives the other half (some of which goes to the manager). The performing rights organizations also coordinate with performing rights organizations in other countries to collect and distribute fees for music played abroad (see Section 8). Costs are not deducted from the publishing royalties the band receives.

As is clear from Table 1, bands receive relatively little of their income from recording companies. Indeed, only the very top bands are likely to receive any income other than

the advance they receive from the company, because expenses – and there are many – are charged against the band’s advance before royalties are paid out. In 2003 the total value of recording sales (including CDs, singles, LPs, etc.) in the US was \$11.8 billion according to IFPI (2004), while the total value of concert ticket sales was \$2.1 billion according to our tabulations. Thus, from the consumers’ perspective, recordings are a much larger market, but from the artists’ perspective, concerts represent a much more important income source. This point was made by Scott Welch, manager of Alanis Morissette and LeAnn Rimes: “The top 10 percent of artists make money selling records, the rest go on tour.”<sup>1</sup>

### 2.1. *Contracts*

Contractual arrangements between bands, promoters and record labels are heterogeneous, but the typical contract resembles a book contract, with an initial advance and then royalties if sales exceed a certain level. The typical contract between a band and a concert promoter is most easily illustrated with a hypothetical example. Consider an agreement covering a single concert.<sup>2</sup> The band receives a “guaranteed advance” – e.g., equal to the first \$100,000 of ticket sales, and then, before additional revenue is distributed, the promoter recovers his expenses and a “guaranteed profit” – say \$50,000 for expenses and \$22,500 for profit. The expenses could include advertising, rent for the venue, costs of unloading the equipment, etc. The band also has expenses (e.g., travel), which it pays for out of its income. The promoter and the band split any ticket revenue above the guarantee plus expenses and minimum profit (above \$172,500 in this case), usually with the band receiving 85 percent and the promoter receiving 15 percent of these revenues.<sup>3</sup> The band’s guaranteed advance and percent of revenue after expenses is higher for bands with greater bargaining power.

In its negotiation with the promoter, the band (or its manager on the band’s behalf) agrees to the concert price, which naturally affects the amount of revenue collected. In addition, the band usually receives 100 percent of merchandise sales (e.g., T-shirts) that take place at the concert.<sup>4</sup> The venue usually receives the beer and parking revenue. An interesting economic question is why the contracts for concerts take this form. Because the parties receive revenue from the sources for which they are most responsible – the band and promoter from ticket sales, the band from merchandise sales, and the venue for parking and food – it is possible that this division of revenue streams provides optimal incentives for efficient provision.

<sup>1</sup> Quoted in Kafka and Powers (2003).

<sup>2</sup> It is interesting to note that as promoters have become more consolidated, more bands have signed nationwide tours with a single promoter.

<sup>3</sup> These hypothetical figures were used by the head of a major management firm to illustrate a “typical” contract.

<sup>4</sup> In some cases, the band will be required to give a proportion (e.g., 30 percent) of the merchandise sales to the venue for the right to sell there, however.

Promoters contract with a ticket distributor to distribute tickets. Tickets may also be distributed directly by the venue box office and by the band to its fan club. By far the largest ticket distributor is Ticketmaster. Ticketmaster also has exclusive arrangements to distribute tickets for some venues. Ticketmaster fees are usually around 10 percent of the list price. Unknown to the consumer, in some cases the venue, promoter or performers receive a portion of this fee, depending on their contract.

Record companies tend to sign long-term agreements with bands that specify an advance on royalties and a royalty rate. The typical new band has very little negotiating power with record labels, and the advance rarely covers the recording and promotion costs, which are usually charged to the band. Because fixed recording costs vary little with band quality, only the most popular artists earn substantial revenue from record sales.

In the following passage from his book, *So You Wanna Be a Rock & Roll Star*, Jacob Slichter (2004), the drummer for *Semisonic* (and grandson of former AEA President Sumner Slichter), describes a typical recording contract:

Thus, armed with an attorney and a manager, we began our negotiations with Elektra. Dan [the lead singer] would relay the developments of those negotiations after our evening rehearsals, when we went out for drinks. I leaned back in my chair, sipped merlot, and listened as Dan and John tutored me in the basics of record contracts.

Elektra would lend us money, called an *advance*, so we could pay for the recording costs of making an album. As I already knew, those costs would be high – studio rental could run \$2000 per day and recording could take months. Producers' and engineers' fees might add another \$100,000, not to mention mastering, flights, hotels, rental cars – we could easily spend \$250,000. If there were anything left over, we'd get to keep it, but it wouldn't amount to much.

In return, we would grant Elektra the exclusive rights to our recordings. As money from the sales of records came in, we would be allotted a percentage of the proceeds, known as *points*. In a typical deal, the band gets thirteen or fourteen percentage points. We'd have to give a few of our own points (four perhaps) to the producer of our record (producers typically get a fee *and* points). Then we'd be down to ten points. Before calculating the value of those ten points, however, Elektra would subtract a large percentage of the gross sales to account for *free goods*, records given away for promotional and other purposes. Thus, the amount on which our 10 percent was calculated would be reduced by 20 to 25 percent. So we'd be down even further, perhaps 10 percent on 75 percent of the wholesale album revenue. If our CD was sold in stores for fifteen dollars, the band's share of the revenue might be something between fifty cents and a dollar per CD. Would we get to keep it? No! Elektra would add up all of the expenses of recording and promoting our album – rock videos, radio promotion, touring costs, and so on. The total of those costs, which could run into the millions, would be our *recoupable debt* to the record company. Our share of each CD sold would be swallowed up by that debt

... When it came time to record and release future albums, any unpaid debt from our past albums would carry forward. In fact, even if we sold millions of records (in which case the size of our share would increase), we might never recoup. As one friend of mine joked, we'd be rock-and-roll sharecroppers. (pp. 34–36)

Caves (2000) analyzes the contractual arrangements in the music industry in terms of the efficient division of risk, incentives and rewards. He emphasizes that reputation and the prospect of repeated contracts are essential for contract enforcement. Eliot (1993) provides many colorful examples of malfeasance in music contracts. For example, the Beatles accused Capitol Records of failing to pay royalties on 19 million albums and singles. An audit revealed more than 20 separate areas where Capitol/EMI had “wrongfully accounted” for costs or revenue concerning promotion, manufacture and sales, resulting in \$19 million of unpaid royalties due the Beatles from 1969–1979. Caves prosaically notes that, “From the artist’s viewpoint, a problem of moral hazard arises because the label keeps the books that determine the earnings remitted to the artist” (p. 65).

An analogous problem arises with live concerts. The following remark by Sharon Osbourne (2002, p. 56) underscores the difficulty of contract enforcement in the concert industry: “My husband’s whole career, people stole from him. They walk off with thousands of dollars that’s yours. So the only way, unfortunately, for me is to get nasty and to get violent.” She described the following disagreement with John Scher, a legendary New York promoter, who claimed advertising expenses for ads placed long after a concert had sold out: “[H]e would not give in, and he was threatening that ‘Ozzy will never work in the New York area again.’ All this crap. So I got up and nuted him with my head, and then I kicked him in the . . .” Caves notes that contract enforcement in this industry relies heavily on repeated transactions among parties who value their reputations. The Osbourne method is apparently another contract enforcement mechanism.

### 3. Some theoretical issues regarding concert pricing

Here we consider some of the main theoretical issues in concert ticket pricing, the main source of performers’ incomes. As an economic good, concerts are distinguished by five important characteristics:

- (1) although not as extreme as movies or records, from a production standpoint concerts have high fixed costs and low marginal costs;
- (2) concerts are an *experience good*, whose quality is only known after it is consumed;
- (3) the value of a concert ticket is zero after the concert is performed;
- (4) concert seats vary in quality;
- (5) bands sell complementary products, such as merchandise and records.

Rosen and Rosenfield (1997) provide a thorough treatment of ticket pricing, devoting particular attention to price discrimination, the practice of charging different prices to

different customers.<sup>5</sup> Price discrimination tends to occur when marginal costs are below average costs. Because fixed costs for a concert are high relative to variable costs, and because high- and low-elasticity demanders can be sorted by seat location, price discrimination is possible. Furthermore, bands are likely to have monopoly power, deriving from the fact that they produce differentiated products and have loyal fans.

Rosen and Rosenfield consider a case where there are two types of seats, high quality and low quality. Buyers prefer high quality to low quality. The seller chooses the total number of seats and the quantity of each class of seat, and a pricing policy for complementary goods, such as merchandise. Buyers have reserve prices for high- and low-quality seats, conditional on the seat quality and prices of complementary goods. The seller knows the distribution of reserve prices, but cannot identify customers with high and low reservation prices; ticket quality is used to sort buyers. Rosen and Rosenfield show that the seller would solve the pricing problem in two steps: "First, given the quantities and quality of the two classes of seats and the price of complements, the seller chooses ticket prices to maximize revenue . . . Second, given the optimum pricing policy, the seller decides on the quantity and quality of seats and on the price of complements" (pp. 353–354).

The price of a concert ticket is set lower than it would be in the absence of complementary goods, because a larger audience increases sales of complements and raises revenue.

One puzzle in actual pricing is that price discrimination is surprisingly rare, as we will see in the next section. Another puzzle is that pricing results in excess demand for many concert performances, which leads to scalping; scalping is addressed in Section 5.

#### 4. Concert industry trends

This section, which draws heavily from Krueger (2005), makes extensive use of *Pollstar's* Box Office Report database to describe developments in the concert industry from 1981 to 2003. *Pollstar* is the trade magazine of the concert industry, and a widely recognized authority on concerts. Since 1981, the magazine has collected and published data on concert revenue, venue capacity, ticket sales and prices. The data are provided by venue managers, who have an incentive to report their data because *Pollstar* disseminates it to potential clients. Managers report data on a wide range of musical concerts, and occasionally on other entertainment events, such as comedians, professional wrestling matches and traveling Broadway shows. The data are most complete for concerts, and we tried to exclude the non-concerts from the sample. Before restrictions, the database contains 260,081 box office reports. After eliminating non-concerts, benefit concerts (which we think of as charity events), and events that occurred outside the United States, the sample contains 232,911 reports, representing 270,679 separate performances.

<sup>5</sup> Also see Courty (2000) for a thoughtful summary of theoretical issues in ticket pricing.

Reporting of concerts to *Pollstar* increased substantially in the 1980s, so one potential problem is that the dataset may not be representative of the entire concert industry in all years. Major acts are more likely to be included in the dataset throughout. As a partial adjustment for changes in sample composition, in some of the analysis we restrict the sample to artists listed in *The Rolling Stone Encyclopedia of Rock & Roll*, hereafter called *Encyclopedia* bands.<sup>6</sup> This *Encyclopedia* contains information on 1786 artists, and 1275 of these artists performed at least one concert represented in the *Pollstar* database. The edition of the *Encyclopedia* we use was published in October 2001; two earlier editions were published in 1984 and 1995. Thus, the *Encyclopedia* contains something of a moving average of the leading bands in the period under study, which produces more of a consistent sample. Bands listed in the *Encyclopedia* are responsible for 75 percent of the dollar value of ticket sales in the *Pollstar* data from 1981 to 2003.

Two other limitations of the data should be noted. First, the ticket price and revenue pertain to the list price. Any service fees charged by the ticket distributor are excluded. Because service fees have been growing rapidly in recent years, this omission probably serves to understate the acceleration in ticket prices in recent years. Second, we do not have information on the secondary market, and it might be common for tickets to be resold in a scalper market. Nevertheless, the list price, not the resale price, is relevant from the standpoint of artists and promoters, as their ticket revenue is derived from tickets sold at the list price. Moreover, fragmentary evidence summarized in Section 5 suggests that scalping is a less common phenomenon than widely believed.

#### 4.1. Trends in prices

Figure 2 displays the average price of a concert ticket (total revenue divided by total tickets sold each year) for all concerts from 1981 to 2003, and the (ticket-weighted) average high and low price of a concert ticket. The figure also shows what the average price would have been had it grown in lockstep with the CPI-U. From 1981 to 1996, concert prices grew slightly faster than inflation: concert prices grew a compound 4.6 percent per year while overall consumer prices grew 3.7 percent per year. From 1996 to 2003, concert prices grew much faster than inflation: 8.9 percent a year versus 2.3 percent a year. And if the sample of concerts is limited to those performed by bands listed in the *Encyclopedia of Rock & Roll* in an attempt to hold constant changes in composition and quality, the acceleration in concert prices after 1996 is slightly greater: 11.1 percent a year growth from 1996 to 2003 versus 4.9 percent a year in the 1981–1996 period.

The cost of the highest priced ticket in the house has grown even faster than the average ticket (see the top dashed line in Figure 2). Weighted by total ticket sales, the average high price ticket grew by 10.7 percent per annum from 1996 to 2003, while the average of the lowest price ticket grew by 6.7 percent a year. Thus, price dispersion increased across seats for the same concert. (The rise in income dispersion among

<sup>6</sup> George-Warren, Romanowski and Pareles (2001).

Figure 2. Average price per ticket, high and low price tickets, and overall inflation rate, 1981–2003. Source: Krueger (2005).

consumers may partially account for the rise in price differentiation; unfortunately, data on consumers is unavailable.) Nonetheless, in 43 percent of concerts in 2003, *all* seats in the house were priced the same, suggesting less price discrimination than might be expected from Rosen and Rosenfield (1997).<sup>7</sup> Even in venues with more than 25,000 seats, 26 percent of shows charged just one price for all seats in 2003. The amount of price differentiation has grown over time, however: in the 1980s, 73 percent of concerts with more than 25,000 seats charged just one price for all seats.

Instead of overall consumer price inflation rate, probably a more appropriate comparison for concerts is the price of other live entertainment events. Figure 3 reproduces Krueger's (2005) comparison of concert prices to the CPI-U sub-index for movies, sporting events and theater.<sup>8</sup> To make the data as comparable to the CPI as possible, a Laspeyres price index for concerts using the *venue* as the unit of observation was

<sup>7</sup> Larger concerts are more likely to vary prices. A quarter of all tickets in 2003 were for shows that had just one price, as compared to 43 percent of concerts.

<sup>8</sup> To be precise, the BLS produces a CPI for movies, sporting events, theater *and* concerts. A separate sub-index covering just movies, sporting events and theater is not available from BLS, so Krueger adjusted the index as follows. In November and December 2001, concerts accounted for 8.4 percent of price quotes for this sub-index (e-mail correspondence from Patrick Jackman, February 7, 2002). Consequently, Krueger netted out the concert component using his Laspeyres estimate of the concert CPI.

Figure 3. Concert prices tracked prices of movies, theater and sports tickets well until 1997. Laspeyres price index for concerts versus CPI-U for movies, theater and sports events. Source: Krueger (2005).

computed. It is clear that price growth for entertainment events exceeded overall price inflation throughout the period. Concert price growth tracked price growth for movies, theatre and sporting events remarkably well from 1981 to 1996, but beginning in 1997 the two series diverged. From 1997 to 2003, the concert Laspeyres index rose 64 percent, whereas the CPI for other entertainment events increased 32 percent.

4.1.1. More on price indices

Recall that the Laspeyres price index is defined as

$$L = \frac{\sum p_1 Q_0}{\sum p_0 Q_0}$$

and the Paasche index is defined as

$$P = \frac{\sum p_1 Q_1}{\sum p_0 Q_1}$$

where  $p$  is the price and  $Q$  is the quantity, and the subscript refers to either the base period (0) or the follow-up period (1). Intuitively, the Laspeyres index gives the proportionate increase in money needed to buy the exact same bundle of goods in the follow-up period as was purchased in the base period, and the Paasche index gives the proportionate difference in money if the bundle purchased in the follow-up period had been purchased in the base period at the base period prices. If tastes are constant – a strong

assumption for musical entertainment – and other assumptions are met, the Laspeyres Index is expected to overstate the cost of living, and the Paasche Index is expected to understate it. The Fisher Ideal index, which approximates a true cost of living index, is the geometric mean of these two indices:  $F = (LP)^{1/2}$ .

Left unstated in these formulas is the unit of observation. When the CPI is computed, the sum is taken over products within stores. For entertainment events, the venue is the unit of observation in the CPI. In essence, the BLS interviewers go to a venue and ask for the price this month, and compare it to last month's price, *regardless of what the performance is*. This could obviously create a good deal of noise in the price data, as the product being compared is not exactly the same. For example, in April 2004, Beyoncé, Alicia Keys, Missy Elliott and Tamia performed a concert at Madison Square Garden for an average price of \$81, and in May 2004, Yes performed there for an average price of \$61. The within-venue price index would record this as a decline in price, while it might more appropriately be viewed as a decline in quality. (As further support for this view, we note that Beyoncé et al. sold out, while Yes only sold 79 percent of the seats.)

An alternative to using the venue as the unit of observation is to use the performer as the unit of observation; that is, to follow the same movie or concert over time in different venues. Krueger (2005) computed a Fisher Ideal price index using the headline *band* as the unit of observation in an effort to hold composition constant. The artist was selected to more directly control for composition effects, although there are clearly problems with this approach as well: the venue could be larger or smaller, or in a more remote location, so the experience is different from concert to concert.

Thus, concerts by different performers in the same venue over time, or concerts by the same band in different venues over time are not the same products. It is therefore worthwhile to consider the impact of measurement error in prices on the various price indices. Suppose the baseline price is measured correctly, and the second period price is a noisy measure of the price of the same performance in the baseline. The simplest case is classical measurement error. Let  $p'_1 = p_1 + e$ , where  $p'_1$  is the observed price,  $p_1$  is the correct price (i.e., price for the same quality of performance), and  $e$  is a white noise, mean-zero measurement error. In this scenario, the Laspeyres and Paasche indices are still unbiased estimators, but the Fisher Ideal index will overstate the true rate of price inflation in the limit. The probability limit of the square of the Fisher Ideal index with the noisy price data in the second period ( $F'$ ) is:

$$p \lim[F'^2] = p \lim \left[ \frac{\sum P'_1 Q_0}{\sum P_0 Q_0} \cdot \frac{\sum P'_1 Q_1}{\sum P_0 Q_1} \right] = F^2 + \frac{\sigma^2 \sum Q_0 Q_1}{\sum P_0 Q_0 \sum P_0 Q_1}, \quad (1)$$

where  $\sigma^2$  is the (assumed constant) variance of  $e$ . Because the last term is positive, in expectation the Fisher index will overstate the value of the index if prices were measured without error. Intuitively, the reason the index is biased upward is because the error in follow-up period prices appears in the numerator of both the Laspeyres and Paasche indices.

If the error in prices were in the first period, the asymptotic bias would be in the opposite direction, because the variance of the errors would appear in the denominator.

Table 2

Various price indices for concert tickets and other entertainment events, using either the headline artist or venue as the unit of observation

Year	Artist			Venue			
	Laspeyres (1)	Paasche (2)	Fisher (3)	Laspeyres (4)	Paasche (5)	Fisher (6)	Movies, sports and theater (CPI) (7)
1981	100.0	100.0	100.0	100.0	100.0	100.0	100.0
1982	112.8	108.9	110.8	106.0	106.3	106.2	106.1
1983	129.6	118.0	123.6	115.2	115.7	115.5	113.4
1984	143.8	126.0	134.6	124.7	127.0	125.8	120.8
1985	157.2	136.5	146.5	130.8	132.8	131.8	127.8
1986	166.5	144.9	155.4	142.7	142.1	142.4	133.0
1987	179.1	155.0	166.6	150.7	148.4	149.5	140.3
1988	199.6	171.6	185.0	167.4	165.2	166.3	147.1
1989	215.3	187.6	201.0	168.1	169.3	168.7	159.6
1990	236.0	200.3	217.5	181.2	185.1	183.1	170.5
1991	254.0	207.7	229.7	182.3	188.6	185.4	180.3
1992	273.9	214.3	242.3	190.8	198.8	194.7	186.0
1993	286.6	225.8	254.4	198.3	207.0	202.6	188.7
1994	310.0	209.5	254.9	229.3	235.1	232.2	195.7
1995	340.5	219.5	273.4	216.4	227.7	222.0	205.4
1996	398.5	234.6	305.8	220.1	225.2	222.6	217.1
1997	426.2	238.6	318.9	238.6	230.9	234.7	223.7
1998	518.0	273.9	376.7	258.2	251.5	254.8	230.1
1999	606.0	273.0	406.7	298.0	288.5	293.2	240.4
2000	671.7	300.9	449.6	312.2	304.7	308.4	256.1
2001	750.1	324.7	493.5	340.3	326.9	333.5	264.3
2002	802.1	334.9	518.3	348.5	336.1	342.2	272.9
2003	877.1	365.1	565.9	360.7	347.3	353.9	287.5
	Per annum percentage growth rate						
1981–1989	10.1	8.2	9.1	6.7	6.8	6.8	6.0
1989–1996	9.2	3.2	6.2	3.9	4.2	4.0	4.5
1996–2003	11.9	6.5	9.2	7.3	6.4	6.8	4.1

Notes: Authors' calculations based on Pollstar data and data from BLS. Index sets 1981 to 100. Weights are updated each year for columns 1–6.

It seems more natural, however, to think of the first period concerts as defining the quality standard.

Table 2 explores the effect of the unit of observation on the various price indices for the *Pollstar* concert data. The first three columns report the Laspeyres, Paasche and Fisher ideal indices, respectively, using the headline artist as the unit of observation. The next set of three columns report the same indices using the venue as the unit of observation. The seventh column reports the CPI for movies, sporting events and theater, based on BLS data, which also uses the venue as the unit of observation. The weights

used to compute the price indices for the concert data are updated each year, which is more frequent than the CPI.

Looking at [Table 2](#), it is immediately clear that the price growth is much greater if the artist is used as the unit of observation instead of the venue, especially for the Laspeyres index. This is probably a result of sample selection: only artists who perform in adjacent years can be used in the analysis if the artist is the unit of observation. These artists may not be representative of all artists, and their prices appear to be growing very rapidly, especially when base period quantities are used as weights. It is also interesting to note that when the venue is used as the unit of observation, the growth in the Paasche index exceeds that of the Laspeyres index in two of the three subperiods.

A final issue about price indices worth mentioning involves rationing. The price indices, which already have well known deficiencies as measures of the cost of living [see [Moulton \(1996\)](#)], are even more problematic if there is rationing. If a concert is sold out, there is likely some degree of rationing. In 2003, a third of tickets sold were to concerts that were sold out, down from 55 percent in the 1980s. These figures may overstate the amount of rationing, however, if artists perform multiple shows in the same city, and tickets are available for some shows.

#### 4.2. Shows, sales and revenues

[Figures 4\(a\), 4\(b\) and 4\(c\)](#), taken from [Krueger \(2005\)](#), summarize trends in the number of shows performed, tickets sold, and revenue collected from 1981 to 2003. The figures restrict the sample to artists in the *Rolling Stone Encyclopedia* because coverage in the *Pollstar* database should be more consistent for these artists.<sup>9</sup>

Several trends are noteworthy. First, the number of shows performed rose in the 1980s, plateaued in the first half of the 1990s, and has declined by 16 percent from 1996 to 2003.

Second, the number of concert tickets sold by these bands fluctuated around 30 million per year from the late 1980s until 2000, and has dropped since 2000. In 2003, 22 million tickets were sold to concerts performed by these bands. The drop in ticket sales is also consistent with a Gallup poll, which found that the percentage of teenagers who said they attended a rock concert fell from 40 percent in 1976 to 31 percent in 2000. (By contrast, the percent of teens who said they attended a pro sports event rose from 43 percent to 63 percent over this period.)

Third, despite flat or declining tickets sales, total revenues (in 2003 dollars) trended upwards until 2000 because of price increases. Other things equal, these trends suggest the elasticity of demand was less than 1 before 2000. Since 2000, however, there has been a 10 percent drop in ticket revenue for these artists, suggesting that prices increases have been offset by a larger than proportional demand response.

<sup>9</sup> The trend in capacity utilization for the full universe is similar to that for the *Encyclopedia* bands, but the number of shows and tickets sold has trended upwards if the larger sample is used.

(a)

(b)

(c)

Figure 4. *Rolling Stone Encyclopedia* Artists: (a) number of shows each year; (b) number of tickets sold each year; (c) total ticket revenue in 2003 dollars. Source: Krueger (2005).

Another trend worth noting is that the capacity utilization rate, or the fraction of available seats that are sold, has fallen over the last two decades. The fraction of tickets sold fell from around 90 percent in the late 1980s to just over 75 percent in 2003. Interestingly, the drop in the capacity utilization rate was much steeper for concerts held in larger venues.

One possible interpretation of these trends is that these artists are becoming less popular. But this view is hard to reconcile with the sharp increase in ticket prices for *Encyclopedia* bands. Instead, it seems that price growth is causing a movement up the demand curve for tickets.

#### 4.3. Distribution of revenues

As was documented, concert revenues increased in the 1980s and 1990s. Figure 5 displays the share of ticket revenue going to the top 1 percent and top 5 percent of all performers, ranked by their total annual concert revenue. Bear in mind that these are ticket revenues, and not income, but they still indicate how the fan dollars are allocated across the distribution of acts.

The figure indicates that concert revenues became markedly more skewed in the 1980s and 1990s. In 1982, the top 1 percent of artists took in 26 percent of concert revenue; in 2003 that figure was 56 percent. By contrast, the top 1 percent of income tax filers in the US garnered “just” 14.6 percent of adjusted gross income in 1998 [see Piketty and Saez (2003)]. The top 5 percent of revenue generators took in 62 percent of concert revenue in 1982 and 84 percent in 2003. Surely, this is a market where superstars receive the lion’s share of the income. We return to the issue of superstar effects in Section 7.

To further investigate the distribution of concert revenues, we followed De Vany’s (2006) Chapter 19 on movies in this *Handbook* and De Vany and Walls (2004), and

Figure 5. Share of total ticket revenue accruing to top performers, 1982–2003. Source: Krueger (2005).

fit a Pareto distribution to the revenue data. As is well known, a Pareto distribution is characterized by thick tails (on one or both sides), and thus provides a good fit for income distributions. The Pareto distribution is part of a more general class of stable distributions,  $S(\alpha, \beta, \gamma, \delta)$ , of which the Gaussian is also a special case. The parameter of interest here is  $\alpha$ , the tail weight, with  $0 < \alpha \leq 2$ . A tail weight of 2 implies a normal distribution. As  $\alpha$  approaches 0, greater weight is placed in the tail of the distribution. To estimate  $\alpha$ , we used a simple regression method.<sup>10</sup> We first assigned ranks to each artist's 2003 revenues, with rank 1 indicating the highest revenue, rank 2 the second highest, and so on. Then we regressed log revenue on the log of the ranks as follows:

$$\text{Log(Revenue)} = a - b \text{Log(Rank)}, \quad (2)$$

where the inverse of  $b$  is an estimate of  $\alpha$ . Note that in the class of stable distributions, the variance is infinite when  $\alpha$  is less than 2, and when  $\alpha$  is less than 1 the mean does not necessarily exist either.

We used this method to estimate  $\alpha$  for the distribution of artists' concert revenues, as well as for promoters' revenues, in 2003. We find a coefficient  $\alpha$  of 0.45 for artists' revenues, and 0.55 for promoters' revenues. In comparison, [De Vany \(2006\)](#) and [De Vany and Walls \(2004\)](#) estimate  $\alpha$  to be in the range 1.3 to 1.7 for motion picture box office revenues. This suggests that the concert performers' revenues are not only very far from being Gaussian, but they are also more skewed than movie revenues. Probably a more appropriate point of comparison for artists' revenues is actors' lifetime cumulative movie grosses, however, for which De Vany estimates an  $\alpha$  of 0.4 – very close to what we find for artists' revenues in 2003. Thus, the movie stars' lifetime revenues are positively skewed to about the same degree as concert performers' annual revenues.

Despite the infinite expected variance of revenues in the parametric distribution, in the finite sample of data we have the distribution of artists' revenues is fairly stable from year to year, with a correlation of 0.75 between revenues in 2002 and 2003. Promoters' revenues are even more stable, with a correlation of 0.98 between 2002 and 2003.

#### 4.4. *Explanations: Baumol and Bowen's disease; cartelization; Bowie theory*

[Krueger \(2005\)](#) examines several explanations for the coincidence of declining ticket sales and rising prices, which he notes is consistent with the market becoming more monopolized over time, and inconsistent with a downward shift in demand. We consider these in turn.

In some respects, popular music concerts are a slow productivity growth sector: it takes just as long and about as many people to perform a concert today as it did 20 years ago. As [Baumol and Bowen \(1966\)](#) point out, prices should rise faster than overall inflation in low-productivity growth sectors because of cost increases. Baumol and

<sup>10</sup> See [De Vany \(2006\)](#).

Figure 6. Percent of total revenue handled by biggest four promoters, nationwide and by Clear Channel Communications. Source: Krueger (2005) based on Pollstar data. Only concerts performed in the US are included in the analysis. Sample consists of artists listed in *Rolling Stone Encyclopedia*.

Bowen's disease may well account for the mildly faster price growth in live entertainment events than overall price inflation in the pre-1996 period. Yet it is unlikely that there was a discrete jump in costs in the concert industry compared to other industries – let alone other entertainment industries – after 1996. Indeed, reductions in the costs of audiovisual electronics equipment probably reduced the cost of concerts. Nevertheless, some concert promoters do point to an increase in production costs (e.g., pyrotechnics) and insurance costs as a rationale for the acceleration in prices.

Another popular explanation for the acceleration in concert prices is that the concert industry has become monopolized by Clear Channel Communications, the giant multimedia conglomerate. On the surface, there is an air of plausibility to this story. After the Telecommunications Act of 1996 relaxed constraints on radio station ownership, Clear Channel acquired nearly 1200 stations. It also owns amphitheaters, billboards and TV stations. Clear Channel entered the concert promotion business in a major way by acquiring SFX Entertainment in 2000. As shown in Figure 6, the share of concert revenue that Clear Channel promotes rose dramatically from 1999 to 2001 and then fell sharply in 2002 and 2003. Despite the recent dip, concentration in the industry is still high at the national level.

Many critics have accused Clear Channel of using its vertical and horizontal concentration to monopolize the concert industry. Although anecdotal evidence abounds, and some court cases have charged Clear Channel with anticompetitive practices, Krueger finds little evidence linking Clear Channel to the sharp growth in concert prices.

First, he finds that Clear Channel's share of listeners in the radio market in a city was unrelated to the share of ticket revenue for concerts promoted by Clear Channel in those markets in 2000 and 2001. Additionally, at either the city or state level, Clear Channel's share of concert promotion dollars was insignificantly or negatively related to

the growth in prices. It is possible that Clear Channel uses its muscle to sign up concerts for national or international tours, obscuring the city- and state-level correlations, but it is surprising that the company does not exercise its monopoly position at a regional level as well.

Another fact that casts doubt on Clear Channel's role is that ticket prices have also risen sharply in Canada and Europe since the mid-1990's. Although, to some extent, prices are arbitrated between countries because bands play across national borders, it is unlikely that deregulation of radio in the United States and the rise of Clear Channel can account for concert price growth worldwide.

Perhaps the most important strand of evidence against the concentration argument is that concert promotion has always been a highly concentrated business on a regional level. In the 24 largest cities, the four-firm concentration ratio within cities has hovered around 90 percent, on average, for the last two decades. The average within-city Herfindahl–Hirschman Index (HHI) for promoters actually fell from a lofty 4200 in 1986 to a still high but less lofty value of 2800 in 2001. (An industry with an HHI above 1800 is considered highly concentrated according to the Justice Department Merger Guidelines.) Thus, the concert industry has gone from having regional monopolies to having a large national firm, but within cities competition could quite possibly have increased.

Krueger's final hypothesis is that concert prices have accelerated because recording artists have seen a large decline in their income from record sales, a complementary product to concerts. Record sales slumped from 1999 to 2002, and were flat for 5 years before then, putting downward pressure on artists' royalties [see [Weinraub \(2002\)](#)]. As discussed in Section 9, it is quite possible that record sales are down because many potential customers frequently download music free from the Web or copy CD's, either legally or illegally.

Formally, the problem is one of a firm with two complementary outputs, concert seats and record albums, denoted good 1 and good 2, and monopoly power in both markets [see [Tirole \(1988\)](#) or [Rosen and Rosenfield \(1997\)](#)]. The demand curves for the band's products are denoted  $D_1(p_1, p_2)$  and  $D_2(p_1, p_2)$ , each of which depends on both prices. Costs are independent of each other and depend only on the quantity of the specific good produced,  $C_1(D_1)$  and  $C_2(D_2)$ . A profit maximizing band will set the proportionate markup of concert tickets over marginal cost so that:

$$\frac{p_1 - C'_1}{p_1} = \frac{1}{\varepsilon_{11}} + \frac{(p_2 - C'_2)D_2\varepsilon_{12}}{p_1 D_1 \varepsilon_{11}}, \quad (3)$$

where the  $\varepsilon_{ij}$ 's represent the value of the own- or cross-price elasticities of demand. Bands will keep the price of concerts below the single-market monopoly price if greater attendance raises record royalties, but if this is no longer the case because of file sharing or CD copying, the price of concerts will rise.

To some extent, this model was anticipated by the rock and roll singer David Bowie, who predicted that, "Music itself is going to become like running water or electricity"

and he advised performers, “You’d better be prepared for doing a lot of touring because that’s really the only unique situation that’s going to be left” [quoted from Pareles (2002)]. Hence the name *Bowie Theory*.

As support, Krueger (2005) notes that relative to album sales, jazz fans are much less likely to download music from the Web than are fans of rock and pop, and that from 1996 to 2003 concert prices increased by only 20 percent for jazz musicians, but by 99 percent for rock and pop performers.<sup>11</sup> The declining complementarities argument can also account for the price growth in Canada and Europe. Section 9 provides a detailed review of the direct evidence on the effect of file sharing on record sales, and concludes that the evidence is mixed. Thus, the reason for the sharp acceleration in concert prices remains something of an open question.

## 5. Ticket distribution and scalping

As was mentioned, promoters and venues utilize a variety of options for ticket distribution, including the box office, Ticketmaster, and direct sales to fan clubs. Tickets are almost always initially distributed at a fixed price, as opposed to a floating price determined by an auction or other mechanism. Ticketmaster and other distributors have recently begun experimenting with using auctions to sell tickets, however. We suspect that ticket auctions will be more prevalent in the future, and a worthy topic for research.

About a third of popular music concerts currently sell out. Tickets for the hottest concerts are often sold on a secondary market, through unregistered scalpers, over the web (e.g., eBay), or through ticket brokers (who can also be online). These distribution channels are often lumped together and viewed as a *scalper or secondary market*. Persistent pricing of tickets at a level that permits scalping is a puzzle for neoclassical economic models of concerts. Why don’t performers or promoters raise the price of tickets and capture some of the revenue from the secondary market for themselves?<sup>12</sup> Below we consider theoretical issues and available evidence on scalping.

### 5.1. Scalping: Theoretical issues

Various theories have been proposed for why a firm – restaurant, ski lift, or rock band – may price their services below the market level. None of them is entirely satisfactory. Becker (1991) presents a model in which eating at a popular restaurant (or going to a concert) is a social event, so customers’ demands are positively related. The bigger the

<sup>11</sup> Oberholzer and Strumpf (2004) note that jazz is the genre least downloaded on the Internet, but do not provide a reason. Perhaps it is that MP3 files are of lower quality than CDs, and that jazz enthusiasts value quality more than others.

<sup>12</sup> As an aside, we note that Warren Buffett recently came to this realization. Tickets for the annual meeting of Berkshire Hathaway were given to shareholders, and then often resold. Apparently, Mr. Buffett was distressed by this practice, and began selling tickets for \$5 a pair on eBay in 2004 to capture the secondary market.

audience, the more enjoyable the experience. Concert promoters and fans often do treat concerts like social events, lending some credence to this view. As Courty (2000) points out, however, although Becker's model "explains why a firm may not raise prices in the short run when capacity is fixed, it does not shed much light on the long run outcome that firms typically do not raise capacity to meet excess demand". Kahneman, Knetsch and Thaler (1986) argue that customers value being treated fairly, and the market clearing price may be considered unfair. Fairness is likely to be a more important consideration if attendance at a concert is viewed as a social event rather than an economic transaction.

Courty (2003) makes the insightful point that customers for live entertainment events have time-dependent demands. He presents a model in which there are two types of consumers: die-hard fans who want to see a concert and secure a ticket in advance, and others who are not sure if they will be free during the concert. As time elapses, the uncertainty is resolved for the latter group. The late-demanders have higher valuations of the event than the die-hard fans in his model. He further assumes that promoters cannot compete with ticket brokers or scalpers, and that die-hard fans outnumber the late deciders. With these assumptions, in equilibrium ticket brokers will buy tickets early at face value and resell them for a profit. Although the model requires many ancillary assumptions to prevent promoters from taking over the secondary market, the observation that some customers learn about their demand over time is undoubtedly an important feature of the ticket market.

## 5.2. Evidence on scalping

Because scalping is primarily an underground activity, little systematic empirical analysis has been done on secondary ticket markets. In an effort to make a small step toward closing that void, one of us (Krueger) conducted a survey of 858 fans at Bruce Springsteen and the E Street Band's concert at the First Union Center in Philadelphia on October 6, 2002, with the help of 12 Princeton students.<sup>13</sup> As was common in the past, every ticket in the house was originally sold for a single price, \$75 (plus service charge if distributed by Ticketmaster). The concert was part of the group's "The Rising" tour, and it quickly sold out when tickets were put on sale. Thus, the concert would be expected to have a high scalping rate.

Several results of the survey are worth noting. First, only 20 to 25 percent of the tickets were bought through a scalper or ticket broker or over the Web. Many industry analysts had expected a higher reselling rate prior to the survey. Scalping at the stadium was quite rare; it was much more common for the secondary market to clear through purchases from licensed ticket brokers or the web. Second, the average ticket that was resold went for around \$280, yet most fans paid the list price. Third, tickets for the

<sup>13</sup> The survey of fans was conducted shortly before the concert began. A stratified random sample of rows and sections was drawn. Weights were computed to make the sample representative of the entire venue. The response rate for the survey was very high. Ticketmaster and the First Union Center arranged for us to have access to the venue before the start of the show.

best seats were *less* likely to be resold than were seats in the upper deck, even though the consumer surplus was greater for the better seats. One interpretation of this finding is that serious fans queued for tickets (or applied to Ticketmaster early), and if they obtained a good seat they attended the concert and if they obtained a bad one they sold it. This finding, which was not anticipated, is consistent with how one would expect tickets to be allocated in a market: those who valued the best seats the most were the ones who sat in them. But one could argue that the distribution mechanism is inefficient (e.g., because of time wasted queuing and uncertainty), even if it mimics the market in terms of allocative efficiency.

Fourth, fans were asked when they purchased their tickets, in an effort to test Courty's model of scalping. The results yielded mixed support. On the one hand, tickets on the secondary market were purchased later than tickets sold by Ticketmaster or the box office, as expected. (Ninety percent of those who purchased their tickets from the box office or Ticketmaster bought their tickets more than a month before the concert, compared with 47 percent of those who bought from ticket brokers.) On the other hand, the price did *not* rise as the date of the concert approached, as Courty's model would seem to predict. Instead, prices on the secondary market fell as the day of the concert approached, consistent with the literature on the declining price anomaly in auctions [see Ashenfelter (1989)].

Fifth, the concert would have earned substantially more revenue if tickets were priced high enough to eliminate the secondary market. If the market price equaled \$280, the average price of a ticket in the secondary market, then \$4 million [=  $(\$280 - \$75) \times 19,738$  tickets] of additional revenue could have been collected by Springsteen and his band. Given that the actual revenues collected were \$1.5 million, this figure is staggering even if one allows for some error. The revenue foregone by the band in the secondary market alone was sizable, between \$1.1 and \$1.4 million, according to our estimates. These calculations suggest that, at least in the short run, performers sacrifice considerable income if they price their shows below the market rate.

An important cautionary note, however, is that these results pertain to just one concert, and it is unclear whether they generalize to concerts for other performers. The nature of the First Union Center, which is isolated alongside Interstate 95, may also have led to less on-the-street scalping than in other, more centrally located venues. But we would argue that replicating this type of survey in other concerts will yield valuable insights into secondary markets.

### 5.3. *Scalping and price trends*

An important question concerns the effect of the secondary market on the trends documented in Section 4. We have seen that the secondary market can be substantial, at least for some concerts. It is possible that the list price does not represent the price to consumers, because of widespread scalping. Perhaps the rise in ticket list prices has only cut out scalpers, and not affected the price to consumers.

Although we have no doubt that the secondary market is important in the popular music industry, the following three reasons lead us to doubt that a disconnect between the list price and price to consumers is responsible for the major trends documented in Section 4. First, the total number of tickets sold has declined. If concerts are no more expensive to consumers than before, then one would not expect to see attendance fall. Second, the decline in the capacity utilization rate also suggests that customers are finding concerts more costly. Moreover, even in the early 1990s, most concerts did not sell out, so it would have been possible to avoid the higher priced secondary market. Third, [Krueger \(2005\)](#) found that prices surged in the late 1990s even when he limited the sample to concerts that sold fewer than 90 percent of their tickets, events where scalping would have been unnecessary.

## 6. Rankings

It is common in the arts for various parties to devise schemes for ranking artists. Music is no exception. For example, Billboard provides numerous “music charts” based on record album sales and radio airplay. Being ranked high on the charts is important to artists because future sales and recording contracts are related to their placement on the charts. Evidently, many consumers turn to rankings to decide which music to purchase or listen to, and radio stations rely on the charts to determine which music to play on the air. When information is costly to obtain, rankings can be very valuable to consumers, especially for goods that have social externalities (e.g., when you play music at a party, you would like your guests to enjoy the music).

*Pollstar* produces three sets of rankings of bands: one based on gross concert revenue; one based on the number of tickets sold; and one based on the number of hits seeking information about each band’s schedule on its web page. Although useful, these methods have their limitations. An important limitation can be seen from [Figure 7](#). Hypothetical demand schedules for two bands, denoted A and B, are reported. As drawn, the demand curves all have the same slope but different intercepts. Band B is the most popular: at any given price, it has the greatest ticket demand.

We can write the demand curves in [Figure 7](#) as:

$$\text{Log } Q_i = a_i - \varepsilon \log P_i, \quad (4)$$

where  $Q$  is quantity of tickets sold,  $P$  is price,  $a_i$  is an indicator of band popularity, and  $\varepsilon$  is the elasticity of demand. The subscript  $i$  indicates the band. This constant elasticity demand curve is, of course, a simplification, but it illustrates a serious problem with current rankings, and provides an easily implemented solution. A more realistic model would also allow for the elasticity ( $\varepsilon_i$ ) to vary across bands, but greatly increase the parameters needed for implementation.<sup>14</sup>

<sup>14</sup> Another addition to the model would be to allow for rival bands’ prices to affect the demand for band  $i$ ’s concerts, and then take into account the effect of all other band’s price on the choice of band  $i$ ’s price. We will leave this extension for IO economists.

Figure 7. Hypothetical demand and supply curves for 2 bands.

Now if the market clears, the band's concert supply curve also affects revenues and ticket sales. (We will discuss disequilibrium shortly.) Bands have different concert supply functions. Suppose band B hardly tours (e.g., Barbra Streisand) and band A tours a great deal (e.g., Dave Matthews). Band A could sell more tickets than band B and collect more revenue if it wanted. This framework highlights problems with *Pollstar's* methods for ranking bands. First, it is clear from Equation (4) that as long as the band is on the demand curve, the quantity of tickets sold is not a good indicator of popularity because price varies. Second, total revenue would only be an appropriate measure of popularity in the unlikely event that the elasticity of demand equaled 1. Third, bands that tour frequently (or set prices lower) are likely to receive more hits from potential consumers on the web, but that reflects concert supply as well as popularity.

A simple solution is to rank the bands according to

$$a_i = \text{Log } Q_i + \varepsilon \log P_i.$$

To implement this solution, one needs an estimate of  $\varepsilon$ . The first two columns of Table 3 provide rankings of the top 50 bands using  $\varepsilon = 1$  and  $\varepsilon = 2$ .<sup>15</sup> The former corresponds to the *Pollstar* Top 100 Tour ranking, which is based on gross revenue.

If the market is in disequilibrium, the price and quantity may not be determined on the demand curve. In particular, if the band sets the ticket price below the market clearing level, the quantity of tickets demanded at the list price will exceed the quantity of

<sup>15</sup> For simplicity, we have ignored price discrimination, and just used the average concert price as a measure of  $p_i$ .

Table 3  
Alternative rankings of artists who toured in 2003

Artist	Rank1	Rank2	Rank3	Rank4	Rank5	Rank6

Notes: *Rank1* assumes elasticity of demand is 1 (gross revenue); *Rank2* assumes elasticity of demand is 2; *Rank3* assumes elasticity of demand is 1 and that latent demand is 25% greater than ticket sales for sellouts; *Rank4* assumes elasticity of demand is 2 and that latent demand is 25% greater than ticket sales for sellouts; *Rank5* is based on revenue per performance; *Rank6* is based on number of tickets sold. Rankings are computed for all artists, but only the first 50 according to *Rank1* are shown.

tickets sold, and our method would not provide an accurate measure of  $a_i$ . We can still conceptualize notional demand curves in this situation, however. The challenge is to determine how much excess demand exists. As we saw in the previous section, at the Bruce Springsteen concert about 25 percent of tickets were purchased above the list price, suggesting that excess demand was at least 25 percent as large as the number of tickets sold. (An alternative method for estimating excess demand would be to use information on the number of willing – or at least interested – buyers who sought tickets from on-line sales venues after tickets were sold out.) A simple solution is to apply the 25 percent figure to all concerts that sell out. Accordingly, in columns 3 and 4 of Table 3, we inflated the quantity of tickets sold by 25 percent in all sold out concerts, and recomputed the rankings for  $\varepsilon = 1$  and  $\varepsilon = 2$ .

For comparison, in column 5 we present the ranking based on revenue per show, which can be thought of as a crude indicator of the performers' wage rate. If demand for artists' performances were infinitely elastic, as in a competitive market, this would provide a ranking of artists' potential income. And lastly in column 6 we report the ranking based on total tickets sold, which is one of *Pollstar's* criteria.

The results are sensitive to the type of ranking. Bruce Springsteen and the E Street Band, for instance, move from the top ranked artists by revenue in 2003 to second place when an elasticity of demand of 2 is used (or 3rd place if rationing is taken into account), to fifth place when revenue per show is used, and back to first place when the number of tickets is the basis of the ordering. Celine Dion is ranked second based on revenue and 14th based on tickets sold. The Rolling Stones move from 13th to 5th place when the elasticity is increased from 1 to 2. Overall, however, the rankings are fairly similar if popularity ( $a_i$ ) is the criteria (the correlation between the ranks in column 3 and 4 is 0.91), and quite different if revenue per show or total tickets sold is the criterion (the correlation between columns 4 and 5 is 0.56).

We should emphasize that our framework misses many important features of the concert industry. Most importantly, we have made an *ad hoc* assumption about the elasticity

of demand, and imposed the same elasticity for all bands. In addition, we have ignored advertising and promotion efforts, which are endogenous and undoubtedly influence ticket sales. A more complete approach would adjust for promotion efforts. Nevertheless, considering rankings in the framework of a simple supply and demand model highlights an often overlooked feature of existing rankings: popularity depends on both price and quantity. This simple insight applies to record sales as well as to concerts.

## 7. Superstar effects

As we saw in Section 4.3, the distribution of concert revenues is highly skewed, suggesting that the music industry is a superstar industry, where a small fraction of the performers earn a substantial share of the revenues. [Sherwin Rosen \(1981\)](#) was the first to provide a formal theoretical model to explain why “relatively small numbers of people earn enormous amounts of money and seem to dominate the fields in which they engage”. Building on the intuition of [Marshall \(1947\)](#), Rosen models a market where demand is characterized by imperfect substitution among the sellers (here, the performers), and where “the costs of production (writing, performing, etc.) do not rise in proportion to the size of a seller’s market”. At the heart of the imperfect substitution of performers is the notion of quality, or talent, of a performer. As [Rosen \(1981\)](#) puts it, “Lesser talent often is a poor substitute for greater talent. The worse it is the larger the sustainable rent accruing to higher quality sellers because demand for the better sellers increases more than proportionately: hearing a succession of mediocre singers does not add up to a single outstanding performance.” When combining the demand and supply as depicted above, Rosen ends up with a market equilibrium in which small differences in talent at the top of the distribution can account for large differences in revenue.

[Borghans and Groot \(1998\)](#) also address the issue of superstardom, arguing that a certain degree of monopolistic power of the artist generates higher revenues for superstars, on top of a difference in talent. They note that a stylized fact concerning superstars is that those whose talent is “suitable for media replication” earn much more than others. They argue that the availability of a mass media market gives the most talented artists an endogenous property right, derived from the fact that the public prefers to watch the best performances – consistent with the imperfect substitution assumption of Rosen’s model. Borghans and Groot conclude that, “Due to media production, only one person is needed to serve the whole market, where without this technology many producers are needed. Efficient allocation requires the most talented producer to be assigned to this task, but in practice the situation provides this person with an opportunity to exploit the number-one position.”

[Adler \(2006\)](#), in his [Chapter 25](#) in this volume, takes exception with Rosen’s view of talent, and maintains that superstars do not exist because of differences in talent, but because of “the need of consumers to have a common culture.” Because Adler’s chapter thoroughly addresses this and related issues, we tread lightly on theoretical aspects of superstar models.

Empirical evidence and tests of the superstar model are not straightforward, because of the lack of reliable income data and, more importantly, because of the inherent difficulty of objectively measuring talent or quality in a meaningful metric apart from economic success. What is a small difference in talent? On what objective, cardinal metric is Celine Dion only slightly more talented than Rod Stewart? As Krueger (2005) notes, “An objective measure of star quality for popular musicians is hard to define and even harder to quantify.” Measuring talent on a meaningful scale independently of economic success is an obstacle to testing the superstar model.

Hamlen (1991, 1994) looks at singers of popular music, and uses a measure of voice quality to assess the artist’s quality. The measure, which is external and objective, is the harmonic content of a singer’s voice sample. Hamlen then regresses the value of total record sales on harmonic content and a few observables for 107 singers, and finds an elasticity of 0.14. Since the Marshall–Rosen model would predict an elasticity above unity, Hamlen concludes that his empirical findings do not support the superstar model. Krueger (2005) points out, however, that “it is unclear whether the scaling of units of quality is appropriate (a different scaling could produce an elasticity above 1) and consideration of other dimensions of star quality could possibly rescue the theory”.

Krueger (2005) considers escalating superstar effects – perhaps due to the revolution in consumer electronics equipment which reduce the cost of copying and listening to music – as a possible explanation for the rising cost of concert tickets and increased concentration in concert revenue, which were documented in Section 4. Specifically, he tests whether the increase in prices (or revenue per artist) could be linked to a stronger superstar effect over in the 1990s. He uses a novel measure of star quality: namely, the number of millimeters of print that are devoted to each artist in *The Rolling Stone Encyclopedia of Rock & Roll*.<sup>16</sup> This information is then merged with the *Pollstar* data on concert revenue and prices, and the following regression is estimated:

$$\ln Y_{it} = \alpha + \beta_t S_i + \mathbf{x}'_{it} \boldsymbol{\gamma} + \delta_t + \varepsilon_{it}, \quad (5)$$

where  $\ln Y_{it}$  is the log average price (or log annual revenue or log revenue per show),  $S_i$  is the measure of Star Quality,  $\mathbf{x}'_{it}$  is a vector of covariates (number of supporting acts, years of experience of the band, and dummies for genre, gender and foreign status),  $\delta_t$  is a set of 22 unrestricted year fixed effects, and  $\varepsilon_{it}$  is an error term.

Notice that the coefficient on star quality,  $\beta$ , has a  $t$  subscript, indicating time period (1981–1986, 1987–1991, or 1997–2003). This allows the effect of star quality to vary across time periods. In the regressions, this is accomplished by interacting the amount of print with dummies indicating the four periods. The test of the rising-return-to-superstardom hypothesis amounts to a test of whether there is a discrete jump in  $\beta_t$  after 1996.

Krueger finds that the return to superstardom has indeed increased over time, but that the timing does not coincide with the increase in ticket prices. He concludes that we must look at other factors to explain the rising prices.

<sup>16</sup> See Krueger (2005) for a more detailed explanation of the data and procedures.

Empirical testing of superstar models lags behind the development of new theoretical versions of the model. At least when it comes to music, and probably for many other branches of the arts, a major limitation of tests of superstar models is the absence of natural units with which to measure talent. Rosen postulates that “small differences in talent become magnified in larger earnings differences”. But what is a “small” difference in quality of popular music performers? Surely there is an intrinsically subjective component to quality; some music appeals to a subset of listeners but not to others. Also, one might argue that talent should be measured within genres: otherwise, how is it possible to compare a jazz band to a heavy metal band? More empirical work could certainly be done on the superstar model, and perhaps the popular music industry could help shed light on some distributional and marginal return to labor issues in broader fields, but we are skeptical that current methods of measuring talent will shed much light on the superstar model.

## 8. The world of radio broadcasting

Ever since radio broadcasts started in the United States, England, and other countries in the early 1920s, the business of radio has been intertwined with that of music. As we will see, even if at first record companies and music publishers’ profits were threatened by the supply of “free” music on the radio, they quickly learned to promote their records and collect royalties from performing rights sold to radio broadcasters. Now, bands and composers also benefit from radio exposure. From a publicity standpoint, radio is an important part of record promotion. And from a royalties standpoint, composers can garner substantial returns if they have a hit song on the radio. [Table 1](#) documents that artists receive substantial revenue from performing rights royalties.

### 8.1. *Royalties from performing rights*

Under Section 106 of the US Copyright Act, a copyright on a musical work grants an exclusive right to reproduce, distribute copies, publicly perform, and create a derivative of the work in question. Thus, anyone who wants to legally play a copyrighted song on the radio, or press it on a compilation CD, must acquire a license to do so from the copyright owner. Artists generally transact with music publishing firms, which are often but not always affiliated with their record company, to collect their publishing income. Music publishers acquire administrative rights from the copyright owner, which entitle them to find users, issue licenses, collect money and pay the songwriter. The traditional split of publishing income is 50/50 between the publisher and the songwriter [see [Passman \(2000\)](#) and [Krasilovsky et al. \(2003\)](#)].

Various uses of a musical work are covered by different rights that must be purchased separately. [Table 4](#) summarizes these rights.

The *reproduction right* is the exclusive right of a music copyright owner to authorize the mechanical reproduction of the work in a record, cassette or CD. The license

Table 4  
Rights attached to musical compositions

Right	What it covers	Standard rate
Public performance right	The right to publicly perform a composition, for example, on the radio, in a club, in a concert, or on a jukebox	Blanket license via a performing rights organization (ASCAP, BMI, SESAC), rate based on factors such as advertising revenues and size of audience reached
Compulsory mechanical right (called compulsory because the composer cannot refuse to grant it once he gets paid)	The right to record and distribute recordings of a composition, only once it has been made public	8.5 cents per composition, or 1.65 cents per minute, whichever is greater
Synchronization right	The right to use a sound recording in a movie, commercial, or TV program (must be coupled with a performance right)	It depends on the length used and the use itself (background, integral part)

Source: Krasilovsky, Shemel and Gross (2003) and Passman (2000).

granting such a right is called a *mechanical license*, and the fees charged for it are the mechanical royalties, calculated at a certain rate per song and per unit manufactured and sold.<sup>17</sup> In the case of audiovisual productions, the license of reproduction rights is often referred to as a *synchronization license* because the music is to be synchronized with the images.

The public performance right gives the copyright owner the exclusive right to authorize the use of the musical work in public. Radio and television broadcasts, as well as jukeboxes and music played in bars, restaurants and any type of public establishment, all fall under the public performance right. As such, broadcasters and establishment owners must acquire public performance licenses anytime they want to use copyrighted music. Because searching and bargaining with every single copyright owner and publisher would prove costly and infeasible, and because an individual owner of copyrighted music could not possibly survey all the radio stations to enforce his public performance right, all licenses are handled by performance rights organizations (PROs). PROs issue public performing licenses to broadcasters and establishment owners, monitor and survey radio and television broadcasts to determine the amount of airplay for each composition, and then remunerate the copyright owners.

Performing rights also cover cellular phone *ringtones*, which cell phone owners increasingly download from the Internet. In 2003, ringtones were a \$2.5 billion industry

<sup>17</sup> Once a work has been made available to the public (after its first-use), a copyright owner is obligated to grant a mechanical license to anyone paying the statutory rate. For this reason, it is called a compulsory mechanical license.

worldwide [Flynn (2004)]! PROs have struck deals with the ringtone providers, and now compensate composers for each ringtone downloaded. On their website, BMI, one of the American performing rights organizations, boasts of having deals with 175 ringtone providers reaching more than 90 percent of US cell phone subscribers. BMI's payments are of 5¢ per ringtone, 2.5¢ each for the publisher and the composer.<sup>18</sup>

In the United States there are three performing rights organizations, typically known by the acronyms: ASCAP, BMI and SESAC. All offer blanket licenses, which grant the right to use all the songs in their respective catalogs.<sup>19</sup> Artists and composers can sign on with only one PRO. Radio stations can contract with multiple PROs. A radio station that wanted to play both Springsteen and Madonna, for example, would need to contract with both ASCAP and BMI.

Founded in 1914, the American Society of Composers, Authors, and Publishers (ASCAP) is the oldest of the performing rights organizations. It was the first organized effort to collect fees for public performances of music, which had been protected since the inception of the Copyright Act of 1897. In its first few years, ASCAP struggled to establish itself and persuade publishers to become members. Only in 1921 did it write its first royalty checks to publishers and composers. That is also the time when radio broadcasting began, suddenly creating a whole new market for ASCAP compositions. Broadcasters, however, were reticent to pay for the performing rights, arguing that once they had a copy of the record they were allowed to do whatever they pleased with it, including playing it on the radio. By 1932, the radio lobby had convinced seven states to outlaw ASCAP, on the basis of illegal racketeering practices and attempted extortion. Eliot (1993) relates: "In 1940, as many of the contracts ASCAP held were about to expire, the organization threatened to withdraw all member recordings if radio stations didn't agree to a broad-based, cohesive form of royalty payment . . . In retaliation, even as the FCC was threatening to outlaw the paying of records on the air, which ASCAP felt was largely the result of the broadcast lobby, station owners decided to start their own organization, to break what they claimed was ASCAP's monopolistic tactics."

Kleit (2000) notes that ASCAP's blanket license rate rose from 2 percent to 7.5 percent in the 1930s, parallel with the popularization of radio. Needless to say, the radio broadcasters were unhappy with the rising cost of the copyrighted music. To increase competition and to provide an alternative to writers and publishers not represented by ASCAP, the National Association of Broadcasters, together with NBC and CBS, created Broadcast Music Incorporated (BMI) in 1939.

ASCAP is now a not-for-profit entity owned by its members. The membership totals more than 180,000, including composers, songwriters, lyricists, and music publishers of every kind of music. Approximately 100,000 new songs are added to the catalog every year. The fees charged by ASCAP for its blanket license are not based on the amount of

<sup>18</sup> See BMI's website at [www.bmi.com/news/200406/20040616b.asp](http://www.bmi.com/news/200406/20040616b.asp).

<sup>19</sup> See Passman (2000), Krasilovsky, Shemel and Gross (2003), and Besen, Kirby and Salop (1992), as well as [www.ascap.com](http://www.ascap.com), [www.bmi.com](http://www.bmi.com), and [www.sesac.com](http://www.sesac.com) for more on the different American PROs.

airplay its music gets, but on the station's or venue's gross revenues less certain adjustments. The current basic rate is just under 2 percent of the adjusted gross advertising revenue for radio stations. BMI is a non-profit company owned by broadcasters. It now represents approximately 300,000 songwriters, composers, and music publishers in all musical genres, and its website mentions a repertoire of about 4.5 million compositions. BMI's blanket license rate for radio stations is about 1.6 percent of adjusted gross advertising receipts.

The Society of European Stage Authors and Composers, or SESAC, is the smallest of the three American performing rights organizations, with a market share estimated at 3 percent. Market shares are not easily computable, but [Krasilovsky, Shemel and Gross \(2003\)](#) report that a 1990 court proceeding concerning pay cable determined the current market shares at 54 percent for ASCAP, 43 percent for BMI and the remaining 3 percent for SESAC. SESAC is a for-profit private licensing company founded in 1930. It currently represents over 8000 publishers and writers and has a repertoire of more than 200,000 compositions. SESAC specializes in country and Latin music, and operates differently from ASCAP and BMI. It has a somewhat more selective procedure to accept new writers in their catalog, but also it charges fees for blanket licenses based on fixed determinants, such as market population served by the radio station and the station's standard advertisement rates.

While law papers on the topic abound, few articles have been written about performing rights in the economic literature. Notable exceptions include [Besen, Kirby and Salop's \(1992\)](#) article on copyright collectives and [Kleit's \(2000\)](#) study of competition among PROs. Besen, Kirby and Salop present an economic model that attempts to explain why copyright collectives are formed, how they operate and how they may compete. They start with a model of an unregulated monopoly copyright collective, where the cost for each individual copyright owner to collect fees from the broadcasters is prohibitively high, justifying the formation of the copyright collective as a means of saving costs. A collective also gives the copyright owners the possibility of cooperative price setting, and thus of more market power vis-à-vis big broadcasters. Besen et al. look at both models where the collective has the ability to limit the membership, and where it lacks such ability. They analyze the competition between the collectives as well as the effect of different types of government regulation. No formal statistical tests of their models are presented, although their predictions accord with certain stylized facts. As [Johnson \(1992\)](#) notes in a commentary, Besen et al. address the puzzle of the coexistence of ASCAP and BMI, but cannot test their suggested answer.

Interestingly, in most countries there is only one copyright collective. Besen et al. suggest three explanations for this fact: "First, government regulation may authorize only a single collective to administer a particular right. This is especially likely in countries like Austria, Germany, and Switzerland, where collectives must be licensed by the government. Second, government policies that mandate open entry and equal treatment of members may lead to a single collective . . . Third, efficient negotiation between the monopoly collective and user groups may eliminate any incentive for competitive entry." Why exactly did three organizations come to coexist in the US is still something

of a mystery. Besen et al. suggest that perhaps ASCAP miscalculated its hold on the market, and by requesting too high fees, it led excluded songwriters and broadcasters to form a collective of their own.

Kleit (2000) takes the blanket licenses offered by the PROs as a form of bundling, or block booking. He proposes a model of competition between PROs using blanket licenses, and shows that such licenses lead to higher profits for the PROs and higher costs for the users of the copyrighted music when there are a small number of competing licensing organizations.

### 8.2. *Music publishing in the US*

The United States is by far the largest market for music publishing. Table 5 gives a breakdown of revenues by source of income. In 2001, the performance-based revenues alone almost reached \$1 billion, for a total publishing income of nearly \$2 billion. That represents 29.3 percent of the world publishing income. By comparison, Germany, the second biggest market, shows a total income of just over \$800 million, for 12.2 percent of world income (see Table 7 below).

### 8.3. *Foreign markets*

In the US, both ASCAP and BMI earn just above 20 percent of their revenue from foreign sources. Performing rights organizations have agreements with their affiliates

Table 5

Unites States of America	American Society of Composers, Authors, and Publishers; Broadcast Music Incorporated; Society of European Stage Authors and Composers	ASCAP; BMI; SESAC
Germany	Gesellschaft für musikalische Aufführungs- und mechanische Vervielfältigungsrechte	GEMA
Japan	Japanese Society for Rights of Authors, Composers and Publishers	JASRAC
United Kingdom	Performing Rights Society	PRS
France	Société des Auteurs, Compositeurs et Éditeurs de Musique	SACEM
Italy	Società Italiana degli Autori ed Editori	SIAE
Spain	Sociedad General de Autores y Editores	SGAE
The Netherlands	BUMA-STEMRA	BUMA-STEMRA- CEDAR
Canada	The Society of Composers, Authors, and Music Publishers of Canada	SOCAN
Switzerland	Société Suisse des Auteurs, Suisse Auteurs	SSA, SUISA

in other countries to share revenues. They both collect revenues from abroad for their national members, as well as collect from users in the United States on behalf of foreign PROs. Table 6 lists the PROs in the US and the other top ten markets in the world.

While figures on the flows of revenues from copyright licenses from country to country are hard to obtain, we can observe total revenues for each country. Table 7 shows the top ten countries and the breakdown of the publishing revenues.

Table 8 shows ASCAP's flows of revenues from foreign publishing companies. Overall, we can see that the balance is positive, meaning that the United States (or at least ASCAP) is a net exporter of musical talent to the rest of the world.

#### 8.4. Payola

Payola is the practice of record companies giving cash or gifts to radio stations in exchange for airplay. Payola is interesting both for its history and from an economics standpoint because payola is an illegal economic transaction. Payola has been a federal criminal offense since 1960.<sup>20</sup> One may ask, What is wrong with payola? It could be argued that payola only creates a market for radio hits, a market in which the amount paid by the record company to the radio station becomes the price of a hit. It is akin to advertisement and promotion of a song by a record company. Indeed, if record companies

<sup>20</sup> It is legal for a record company to directly pay a radio station to broadcast a song as long as an announcement is made to the public. Undercover and undisclosed payments are illegal.

Table 7  
Publishing income in the top ten countries in 2001 (millions of US dollars)

are willing to pay to promote their songs on the radio, it must be that radio promotion translates into higher record sales.<sup>21</sup>

So why has payola become illegal? Perhaps an analogy is instructive. Payola is analogous to a professor paying bribes to the editor of the *American Economic Review* to publish his paper. The professor would be willing to pay since a publication is good for career advancement, and eventually translates into higher future earnings. But AER readers expect the published articles to be the best and most relevant to the field, not the ones written by those with the deepest pockets or the most eager to get tenure. An essential function of a scientific journal is to screen papers. One could argue that an essential feature of a radio station is to screen records, especially since the right to broadcast on the radio waves is licensed by the government.

Payola has a colorful history. Payola is a contraction of the words “pay” and “Victrola”, an early type of LP record player.<sup>22</sup> The first laws and court cases involving payola were in 1960, but payola had been around for much longer, and still persists today, albeit under a different name. Coase (1979) traces the history of payola, going as far back as 1867 in England. Of course, back then the payments were not made to radio stations, but to public performers, with a request to play a song from the publisher's catalog. The agents that involved in this business were referred to as song-pluggers, and it became commonplace for vaudeville singers to be compensated for adding certain songs to their repertoire. When radio came about, song-pluggers turned to big bands performing live on radio stations to plug their songs. And then, when records made their appearance on the air, radio stations and their employees were approached by record companies to play their songs.

Coase (1979) explains, “Payola took the form of cash payments (which might be on a regular weekly or monthly basis), royalties on the sales of records, a share in a record company, advertisements in the disk jockeys' hit sheets, the reimbursement of recording stars' fees for appearances on the disk jockeys' programs or at record hops which

<sup>21</sup> Liebowitz (2004) points out that even though radio spins seem to increase sales of the particular record being spun, it does not mean that the recording industry as a whole benefits from radio broadcasting. Indeed, record sales fell in the first half of the 1920s after the popularization of the radio.

<sup>22</sup> See <http://www.history-of-rock.com/payola.htm>.

they organized, expensive gifts, and mortgage loans on disk jockeys' homes." Early on, payola was viewed as an impediment to competition. Many attempts were made to outlaw the practice, but these attempts only succeeded in pushing payola underground. The situation changed in 1959, when the president of the American Guild of Authors and Composers wrote a letter to the FCC (Federal Communications Commission) and the FTC (Federal Trade Commission) about payola and other deceptive practices, urging a congressional inquiry.<sup>23</sup> After a year of widely publicized hearings, the FCC amended the Communications Act of 1934 to make unannounced payments to deejays a criminal offense. Over twenty-five deejays and program directors were exposed in the scandal, but the top two deejays in the country, Dick Clark and Alan Freed, were the hardest hit.

Most of the pressure to outlaw payola came from ASCAP, which lost ground to BMI-licensed rock and roll records from small independent record labels during the 1950s. Coase (1979) points out that "during the period 1948 through 1955, 68 percent of the tunes which were number 1 on *Billboard's* top hits were controlled by ASCAP, and ASCAP's share was never less than 50 percent (in 1951). In 1956, its share was 23 percent, in 1957 and 1958, 25 percent and in 1959, 31 percent. In the circumstances, it is hardly surprising to find that the suppliers of 'good music' [ASCAP-licensed music] came to the conclusion that something was wrong with the economic organization of the popular music industry."

After 1960, program directors took over the playlist and left the disk jockeys out of the loop, shielding them away from payola charges. However, the pay-for-play business did not stop there. Soon, what became known in the industry as "independent record promoters" started acting as middlemen between the record companies and the radio stations, blurring the transactions and making this sort of payment not quite payola, but with a similar result and intent. Coase (1979) sees this as inevitable: "When a pricing system is not used and something of value is provided for nothing, people are willing to incur costs up to its worth in order to secure the benefits of that service." He goes on to argue that a payment system "is both natural and desirable", and that a ban on payola leads to a lower real income of the community. True enough, independent record promoters, or *indies*, could also be compared to food and beverage distributors who pay for placement in grocery stores, facilitating the connection between wholesaler and retailer. But Boehlert (2001) warns that "radio isn't really retail – that's what the record stores are. Radio is an entity unique to the music industry. It's an independent force that, much to the industry's chagrin, represents the one tried-and-true way record companies know to sell their product."

How big is the independent promoter business? Boehlert (2001) explains: "There are 10,000 commercial radio stations in the United States; record companies rely on approximately 1000 of the largest to create hits and sell records. Each of those 1000 stations adds roughly three new songs to its playlist each week. The *indies* get paid for

<sup>23</sup> This came at the end of a Congressional hearing on a television quiz show scandal, in which shows were exposed to be rigged and fixed in advance.

every one: \$1000 on average for an “add” at a Top 40 or rock station but as high as \$6000 or \$8000 under certain circumstances. That’s a minimum \$3 million worth of indie invoices sent out *each week*.” While it is easy to think that big record companies have a financial advantage in playing this game, Surowiecki (2004) argues that the big players already have the biggest names in show business, the biggest sales staff and the connections that go with it. Independent record promoters could thus enable small labels to get their artists on the radio, much the same way payola helped propel rock and roll in the 1950s. “Paying to play, then, creates a rough marketplace democracy: if you can come up with the cash, you get a shot. But that’s all. Labels can buy themselves exposure; they can’t buy themselves a hit. If people don’t want to hear a record, radio stations won’t keep playing it of their own accord”.<sup>24</sup>

So payola, even if disguised a bit, is still present.<sup>25</sup> Whether or not the current laws are optimal for the society is a good question for economists. Surowiecki (2004) says that pay for play is simply a signaling mechanism enabling record companies to signal which songs they think will be hits, thus reducing the radio station’s scouting efforts. Interesting developments are sure to come, with the growing consolidation of the radio business and power houses like Clear Channel Communications, which owns well over 1000 radio stations in the US, and with the advent of Internet radio stations and file sharing. Some stations, such as KROQ in Los Angeles and Clear Channel, also refuse to accept payment from independent record promoters. Perhaps the record companies will find new ways to promote their records, or perhaps big radio conglomerates will need to exert caution and stay away from the independent promoters business, to avoid payola charges or to enhance their reputation for independent judgment. It is also possible that large media conglomerates will use their position in multiple markets to extract even larger payments from record companies.

### 8.5. *Digital recordings in the Internet era*

With the advent of new technologies, such as streaming and downloading on the Internet, the Copyright Act no longer provided adequate protection for copyrighted works. In 1995, the Digital Performance Right in Sound Recordings Act was passed in an effort to strengthen copyright protection. The Act recognizes that digital transmissions of sound recordings are required to have an appropriate license. Interestingly, the license is administered by SoundExchange, a non-profit entity created by the RIAA (Recording Industry Association of America), and not by the performing rights organizations. Krasilovsky, Shemel and Gross (2003) note that between 1996 and March 2000, 80 million performances were licensed by SoundExchange. The revenues are split: 50 percent goes to the record company (NOT the publisher), 45 percent to the featured musicians

<sup>24</sup> Surowiecki (2004).

<sup>25</sup> Interestingly, these promotion payments are among the many costs that are deducted from record sales before bands receive royalties.

and vocalists, and 5 percent to an escrow fund for distribution to the non-featured musicians and vocalists. In addition, the Act establishes a statutory digital mechanical license rate, separate from the one for physical records.

Another Act was passed in 1998, the Digital Millennium Copyright Act. This Act was designed to implement two 1996 World Intellectual Property Organization Treaties dealing with copyrights in a digital environment. It provides restrictions on the use of technologies to copy and transmit copyrighted works, by making it illegal to circumvent measures put in place to guarantee the copyrights. The next section explicitly addresses new technologies and copyright issues.

## 9. File sharing and other new technologies

Throughout the 20th century, the rise and fall of various technologies have affected and shaped the way the world listens to music. Broadcasting, first via radio, jukeboxes, and movies, and then through television, cable television, and satellite television – including music channels like MTV and VH1 – and, very recently, via Internet webcasts, has allowed music to reach more and more listeners. Sound recordings also have evolved, with new formats – and along with them new playback machines – being introduced, and most often completely replacing the earlier generations. Recordings began with Edison's cylinders and Berliner's gramophone, then vinyl 33 1/3 rpm records, then 45 rpm singles, eventually followed by 8-track tapes, and then cassette tapes and Sony's Walkman. Records, as we know them today, in the form of laser compact disks (CDs), were introduced in the mid 1980s. By 1992, CD sales eclipsed cassette sales in the US.<sup>26</sup> Since 2000, CDs account for more than 90 percent of the market, whether one looks at total value of records sold or number of units shipped. In 2003, the CD market share was 95 percent.<sup>27</sup>

The supremacy of the compact disk is now threatened by a new format: the MP3, which stands for MPEG-1 Layer 3, a standardized digital file format that compresses audio to enable many songs to fit in a small amount of disk space.<sup>28</sup> Along with the spread of broadband Internet connections, file sharing and peer-to-peer (P2P) software, MP3 players have dramatically grown in popularity in the early 2000s. The actual number of song downloads seems to be impossible to pin down, but estimates suggest that more than one billion songs are downloaded *each week!* [See Oberholzer and Strumpf (2004) and Zentner (2006).] While many music lovers rejoice and engage in massive downloading and illegal file sharing, record companies and many music copyright holders deplore the practice, alleging that file sharing is responsible for declining album sales and lower profits. Industry executives were quick to put the blame on MP3 sharing. The

<sup>26</sup> In units per capita. See Liebowitz (2003a, Table 5).

<sup>27</sup> Source: RIAA, [www.riaa.com](http://www.riaa.com). Note that the figures do not include digital download sales.

<sup>28</sup> MPEG is the acronym for Moving Picture Experts Group.

Recording Industry Association of America (RIAA) successfully sued to shut down Napster in 2001, and as P2P networks provided an alternative platform for users, the RIAA is now suing thousands of individual users.<sup>29</sup>

### 9.1. Intellectual property issues

Economists have begun to look into the question of file sharing and CD sales. The situation can be considered from a normative perspective, questioning the legitimacy of the existence of copyright protection, especially since it can be seen as hindering the development of new technologies. Indeed, as Liebowitz (2004) notes: “It is common in the literature, particularly in the more popular press, to encounter the claim that copyright owners always cry wolf when a new technology appears to threaten the old, only later to discover that the new technology was nothing short of a bonanza. This claim implies that foolish copyright owners misunderstood the new technology and were fortunate enough to have been thwarted in their attempts to restrict the new technology.”<sup>30</sup>

How far does intellectual protection go? Are rights strong enough to encourage the optimal amount of innovation? The problem stems from the fact that musical compositions are non-rival goods, whose property rights, as laid out by Nordhaus (1969), generate a trade-off between under-provision of the non-rival good (with weak rights) on the one hand and monopoly distortions (when the property rights are strong) on the other.<sup>31</sup> The RIAA is clearly pushing for stronger rights, and is lobbying for greater governmental control over technology. Romer (2002) points out that “The relevant economic question is whether the net harm (if any) created by a shift along the Nordhaus trade-off justifies this kind of intervention.” He also warns that “giving an industry veto power over new technologies that threaten its current business model would set a very dangerous public-policy precedent”.

Boldrin and Levine (2002) argue against intellectual property protection. They present a model of competition where downstream licensing, in this case copyright protection, leads to the Pareto *worst* outcome, whereas a case without copyrights results in first-best. “‘Intellectual property’ has come to mean not only the right to own and sell ideas, but also the right to regulate their use. This creates a socially inefficient monopoly, and what is commonly called intellectual property might be better called ‘intellectual monopoly’.” Klein, Lerner and Murphy (2002) reject Boldrin and Levine’s model and reach the opposite conclusion: file sharing technologies reduce the value

<sup>29</sup> Napster was up and running in its original incarnation between June 1, 1999, and July 11, 2001.

<sup>30</sup> Liebowitz (2004) goes on to argue that, for example, when the VCRs were introduced, television broadcasters had a legitimate concern because of the possibility that users would be able to time-shift television viewing and thus kill the possibility for broadcasters to sell advertisement, their principal source of revenue.

<sup>31</sup> Musical compositions are non-rival goods, since once their reproduction cost is paid, they can be simultaneously enjoyed by many. Efficiency would dictate a price (above reproduction costs) of zero, but then composers would be underpaid, and the production of music recordings would be too low. See Liebowitz (2003b).

of the copyright to its holder.<sup>32</sup> These models remain theoretical, without any support from empirical evidence.<sup>33</sup> The first question to ask here is whether or not there exists a causal relationship between file sharing and the slump in CD sales.

9.2. Does file sharing lower CD sales? Preliminary considerations

There is no unambiguous theoretical prediction regarding the effect of MP3 file sharing, or other illegal forms of music piracy, on CD sales. Various effects have been suggested that point in opposing directions. Furthermore, available evidence is, at best, mixed. Liebowitz (2005) and Peitz and Waelbroeck (2004b) present the most thorough reviews of the existing theoretical and empirical literatures. Before we review the results, it is informative to take a look at trends in record sales. Figure 8 shows the evolution of

Source: IFPI World Sales History  
 Notes: All values in millions of 2003 constant US dollars.  
 Turkey and China are excluded as they do not comply with IFPI standards and definitions.  
 Other audio formats (MiniDisc, DVD-A, SACD) included in totals from 1997 onwards.  
 Music video figures included in totals from 2001 onwards. Digital download sales excluded.

Figure 8. Total value of record sales, 1969–2003.

<sup>32</sup> Klein, Lerner and Murphy (2002) reject Boldrin and Levine’s model on the basis that it is based on “the innocuous assumption that the copyright holder’s demand is elastic”.

<sup>33</sup> Hui and Png (2002) provide empirical evidence on the movie industry by estimating the impact of economic incentives on the supply of motion pictures.

recording sales (of all formats) worldwide and in the United States from 1969 to 2003, in constant dollars. It is apparent that the value of sales has declined in recent years, after peaking in 1999 in the US and in 1995 worldwide.<sup>34</sup> Sales have dropped an average of 7 percent per year since 2000 in the US. The picture is similar for the global music industry. At least for the US, the downturn coincides with the launch of Napster and new portable MP3 players, such as Diamond's Rio in 1999. One should also note that CD copying became widely feasible on home computers in the late 1990s. Could these technologies be responsible for the drop in record sales?

The timing for the US is certainly suggestive, but it should be noted that there have been periods of sharp declines in sales before. In the late 1970s and early 1980s, sales plummeted, though not as sharply as in the last few years. Furthermore, the fact that the decline in sales began outside the US before it did in the US is suspicious, because Internet technology was more widespread in the US than elsewhere in the 1990s.

Before jumping to conclusions from the coincidence of these trends, one needs to also consider other factors that affect record sales. Liebowitz (2003a, 2005) lists the price of records, income, population, changes in taste, and prices of substitutes and complements as relevant factors. Liebowitz (2005) looks at these standard demand determinants and concludes, "They do not appear capable of explaining the decline in sound recordings that had occurred."

On a theoretical level, file sharing, or more broadly piracy, can have many potential effects on CD sales.<sup>35</sup> The main argument set forth by Napster and other "pro-file-sharers" is commonly called the *sampling* argument.<sup>36</sup> Sampling is thought to have a positive effect on CD sales by allowing potential customers to hear songs before they purchase them. Because of file sharing, customers would be better informed, making CDs a less risky purchase. Like advertising, sample could have the effect of increasing sales. However, Liebowitz (2005) questions the force of the sampling argument, pointing out that once someone has in his or her possession a song obtained for free, he or she might not go the extra step of actually paying to legally purchase the CD. He concludes that "the effect of sampling (more music-listening services at a constant CD price) is to lower the price of music-listening services. The net effect should be to lower the revenues generated by music-listening services. With a price per CD that is independent of the sampling effect, this implies that the quantity of CDs will fall due to sampling." Thus, sampling could be viewed as a supply shift as well as an information source, with opposing effects on sales.

Another effect, known as the *substitution* or *replacement* effect, clearly is expected to have a negative impact on sales: here, music downloaded simply replaces purchased CDs. Even if MP3s and CDs are not perfect substitutes since CDs come in a package

<sup>34</sup> One limitation of these data is that the dollar value is based on the suggested retail list price, not on the actual sales generated by the albums.

<sup>35</sup> This section focuses on file sharing. For more on piracy and the effect on CD sales, see Hui and Png (2003). Using international data from 1994 to 1998, they find that piracy reduces CD sales by 6.6 percent.

<sup>36</sup> See Gopal, Bhattacharjee and Sanders (2006) for a formal model of sampling.

with the CD jacket and perhaps lyrics and liner notes, and since the sound quality of MP3s can be inferior to CDs, we would nevertheless expect that if people can download a song for free, it will to a certain extent replace their purchases of music.

A third effect that [Liebowitz \(2005\)](#) cites is the *network* effect, but again, there is no clear prediction as to whether this would have a positive or a negative impact on CD sales. A network effect occurs when the value of a commodity varies with the number of people that are using it.

Another point to consider is that perhaps what has occurred is not just substitution of CDs for MP3 files, but a shift in leisure activities brought about by the new technologies. Internet and computers could have created a change in how people spend their time, possibly reducing the demand for pre-recorded music. [Peitz and Waelbroeck \(2004b\)](#) look at different surveys of time use and daily Internet activities, and conclude that “there is evidence that the increasing availability of broadband is changing the spare time activities of consumers in favor of online activities”.

### 9.3. *Empirical studies*

Perhaps the first empirical study of the effect of illegal file sharing on CD sales was produced by the RIAA during the Napster trial. SoundScan’s CEO, [Michael Fine \(2000\)](#) had been engaged by the plaintiffs to produce evidence on the question. His report is not very compelling. His main claim is that because sales declined more at stores near colleges and universities, and because college students are heavier downloaders than the rest of the population, then it must be that file sharing reduces CD sales. However, this analysis does not take into account the fact that the students might use the Internet to legally buy CDs online, thus also reducing the sales at local music stores.

[Liebowitz \(2005\)](#) surveys the existing empirical literature, classifying papers in terms of their unit of analysis. He distinguishes between countries, records, cities, households, and genres as possible units of analysis. [Liebowitz \(2005\)](#) notes that a methodology relying on genres would be interesting, but dismisses such studies because of lack of consistent and reliable data. He reviews the household methodology quickly, citing [Michel \(2004\)](#) as an example. Michel builds a model in which the consumer has the choice between buying a CD and copying music illegally. He then derives the market demand for CDs, and finds that the introduction of new file sharing technologies actually brings to the market people who were not previously buying any music. This would imply that CD sales should not decrease because of P2P networks. Michel uses household level data from the Consumer Expenditure Survey, taking computer ownership as a proxy for file sharing. This has obvious problems, since it measures neither Internet access nor file sharing behavior. Michel uses a difference-in-differences estimator to assess the impact of MP3 downloads on CD sales between 1998 (pre-treatment) and 2001 (post-treatment). He finds an insignificant effect, and is therefore unable to reject the hypothesis that “some file sharing (prior to 2002) was undertaken by consumers formerly not in the market for music”. One caveat that we need to mention here is that this result would hold if nothing else had changed between the two years studied. We can

however suspect that computer ownership and Internet use has greatly expanded in that time period, so we would not necessarily be capturing the behavior of the same type of households.

Liebowitz (2005) also criticizes Boorstin's (2004) study, which used cities as the unit of analysis, with Census data from 1998, 2000, and 2001. Boorstin regressed CD sales by city on the number of people with Internet access. Liebowitz argues that the regression is flawed because it includes dummy variables for the years 2000 and 2001, which are likely to pick up the effect of file sharing. He redoes Boorstin's analysis without the year dummies, and regressing on *per capita* CD sales (not total sales), and ends up finding that file sharing could explain a decline in CD sales of 12 percent in the US, when the actual total decline was of 15 percent. Liebowitz concludes that "These two values are so close that we can say that this evidence is consistent with a view that all of the decline is due to file sharing. This is a charming story, but it isn't clear how reliable these results are".

A study by Zentner (2006) uses data from a European consumer mail survey from October 2001. In an OLS regression of a dummy for buying CDs on a dummy indicating regular downloading, he finds an insignificant effect. However, as he points out, "simultaneity between tastes for music and peer-to-peer usage makes it difficult to isolate the causal effect of music downloads on music purchases". Consequently, Zentner instruments for regular downloading, using variables such as the speed of the individual's Internet connection and measures of Internet sophistication.<sup>37</sup> He then finds a negative and significant effect, indicating that music downloads reduce the probability of CD purchases by around 30 percent, which would explain a drop of 7.8 percent in the sales of music in the countries covered by the survey.

Peitz and Waelbroeck (2004a) use countries as a basis of analysis, with data from 16 countries representing 90 percent of world sales and from an IPSOS-REID survey, for 2000 and 2001. Taking first-differences, they run a regression of CD sales (expressed in units of CDs sold) on GDP, downloads (defined as the percentage of adults who downloaded MP3s at least once during the period) the percentage of households with broadband connection, and two variables indicating the sales of musical cassettes and the number of CD players per household. They find a significant and negative effect of downloads on music sales, reducing the sales by about 11 percent between 2000 and 2001. They then use survey data from the US for the period 2000–2002 to try to assess the partial effect of Internet piracy on CD sales. After making necessary assumptions, they conclude that "Internet piracy alone can only explain 22.5 percent of the CD decline in 2002 and is most likely not to be a significant factor in 2003 as the percentage of Internet users who download music is reported to have declined further after the series of legal actions undertaken by the RIAA in the summer of 2003". They note

<sup>37</sup> Zentner's (2006) measures of Internet sophistication include whether or not the individual publishes his own webpage, participates in online auctions, asks for technical support online, reads computer magazines, and how long he or she has used email and the Internet.

that this implies that a coefficient more than 4 times bigger would be needed to fully explain the drop of 8.9 percent in CD sales in the US in 2002. Peitz and Waelbroeck note, however, that their “results should be taken with caution since we consider a small number of countries in the econometric analysis. Also, the use of aggregated data and the particular choice of explanatory variable can be questioned.”

One study that stands out from the others in terms of sophistication and data is Oberholzer and Strumpf (2004), which reaches the controversial conclusion that file sharing does not have a significant impact on CD sales. They have access to unique data on actual downloads and sales, whereas the rest of the literature mostly relies on small-scale survey data or national and international aggregates.<sup>38</sup> Their data set contains 1.75 million file downloads, which represent about 0.01 percent of the world downloads for the seventeen-week period spanning from September 8, 2002, to December 31, 2002. They link this data set to album sales from Nielsen SoundScan from the second half of 2002, and also merge on information on the artists and track time taken from the website [www.allmusic.com](http://www.allmusic.com). They use the data set to regress observed record sales on album characteristics and the number of downloads for that album, using a fixed effects model to control for album-specific, time-invariant characteristics. To avoid endogeneity problems they instrument for the number of downloads, using shifters related to download costs, which they argue influence downloads but should have no effect on sales. The shifters they use as instruments are: album average and minimum track length, time length of albums in the same music category, and also the percentage of German students on vacation due to German school holidays. They maintain that the last variable is a valid shifter of the supply of files available for downloads because in their sample, one out of six US download is from Germany. When German children are on vacation, they would spend more time at their computer at home sharing files, thus shifting up the supply of MP3s. This choice of instruments has been criticized on various grounds. One criticism is that if, as the authors argue, file sharing leads to more CD sales through an advertising or (sampling effect), then cost shifters should enter the demand equation for CDs directly, rendering the identification strategy invalid. In any case, throughout their various specifications, they find that downloads have an insignificant effect on album sales. When comparing their estimates with the sharp drop in record sales, Oberholzer and Strumpf conclude that “At most, file sharing can explain a tiny fraction of this decline.”

Liebowitz (2005) criticizes this conclusion and the underlying methodology. He warns about a potential fallacy of composition that would arise because records are the unit of analysis. Just as the elasticity of demand at the industry level is expected to be lower than at the firm level, downloading could increase the sales of one particular album and reduce overall CD sales. This effect, as Liebowitz points out, can

<sup>38</sup> Their download data are logs from two OpenNap servers (centralized P2P network), which tells them which files users searched for and which files they downloaded, for seventeen weeks from September 8 to December 31, 2002.

seriously change the interpretation of Oberholzer and Strumpf's results: "A regression using downloads to explain sales would return a positive coefficient, assuming that all other simultaneity problems were overcome. After all, increases in downloads, by assumption, lead to an increase in the sales of the downloaded recordings in this example. But that does not mean that downloads increase overall record sales. A positive coefficient could be entirely consistent with record sales being severely harmed by downloads and thus couldn't answer the question about the overall impact of downloading."

Needless to say, the effect of file sharing on record sales remains a hotly contested issue. This is one area where we expect a good deal of research in the near future.

#### 9.4. Searching for a new business model

The jury might still be out on the effect of file sharing on CD sales, but one thing is certain: the record industry is suffering. And it is likely that the business model for distributing music will change dramatically in the near future. Zhang (2002) claims that the current music distribution system is inefficient and that peer-to-peer file sharing networks might be a solution: "P2P networks help to provide a better information environment for music listeners to experience the music works." He further predicts, "While smaller labels and unknown artists welcome the new technology, the big labels and stars suffer from the transition. The overall effect on social welfare is positive, but it is harmful to the music industry if only a small proportion of P2P users buy albums." Gayer and Shy (2006) present a model of an artist and her publisher, and show that the artist's revenues are greater under file sharing since the more revenue comes from live concerts, which get better publicity from the distribution of songs on P2P networks. However, in that model, music publishers lose from file sharing. In an interesting twist on Rosen's superstar model, Gopal, Bhattacharjee and Sanders (2006) predict that sharing technologies erode the superstar phenomenon widely prevalent in the music business. This implies that top artists actually lose from file sharing, but that less popular artists may gain from the extra exposure and lower distribution costs that the Internet has to offer. Michel (2003, Chapter 3) similarly predicts, "It appears that the artists and the consumers will reap most of the benefits of the new technologies". It is not surprising then to see how strongly the record companies react to the technological changes.

Legal issues are also prominent. Millions of people are infringing copyright laws, and the RIAA, as well as the Motion Picture Association of America (MPAA), its equivalent in the movie industry, are actively suing users and P2P software companies alike. In the midst of all this, some are proposing new copyright systems. A compulsory license system, much like the performing rights system right now, where radio stations acquire a blanket license to have the right to broadcast songs, and artists and publishers get compensated via a performing rights organizations (ASCAP, BMI, SESAC in the US), has been proposed, for example, in a recent book by Fisher (2004).<sup>39</sup>

<sup>39</sup> See also Liebowitz (2003b, Footnote 2 on p. 2), for a list of references. Liebowitz (2003b) discusses the pros and cons of the compulsory license, insisting on the cons and concluding that "only as a very last resort should we replace the current system with a compulsory license".

Peitz and Waelbroeck (2004b) describe technology developments known as Digital Rights Management, or DRM. DRM refers to technologies aimed at monitoring and blocking the use of copyrighted files. Some companies have already included such features in their software. It is unclear whether blocking technology will succeed in the race against file sharing.

### 9.5. *New business practices*

Napster is now back – as a legitimate service selling songs over the Internet. Other competitors include Apple's iTunes and RealNetworks' Rhapsody. The terms they offer vary. Some offer a sort of rental service where, for a monthly subscription fee, the user can download an unlimited quantity of songs onto his PC or portable device, but cannot burn CDs; once the subscription expires, the files can no longer be read. Others sell songs for a fee – 49¢ or 99¢ per song, or \$9.99 per album – and the tracks belong to the buyers forever. These services originally received a lukewarm reception: why pay for songs that are available for free on P2P networks? But interest at universities and colleges, fertile grounds for illegal file sharing (and lawsuits) with their broadband connections and student population, is growing. Some schools are starting new partnerships with music providers, in order to save bandwidth and curtail piracy. Napster has signed deals with eight colleges, including Penn State University, the University of Rochester, Cornell and George Washington University, through which the students receive free subscription to the regular Napster service (which is usually \$9.99 per month).<sup>40</sup> Berkeley and the University of Minnesota have signed agreements with RealNetworks.<sup>41</sup> Others, including Yale, Duke, Wake Forest and the University of Colorado at Boulder, have a similar deal with Cdigix (formerly Cflix), to receive not only music but also movies.<sup>42</sup>

## 10. Conclusion

Rather than summarize our lengthy survey, we conclude by suggesting some worthwhile questions for further study, which might stimulate research on the popular music industry. Below is our list of 11 areas that seem particularly worthy of further research:

- Why do contracts in the popular music industry take the form that they take? Are they efficient?

<sup>40</sup> See Young (2004a).

<sup>41</sup> See Young (2004b).

<sup>42</sup> The movie industry is also confronted with illegal file sharing, albeit perhaps on a smaller scale. Like the RIAA, the MPAA has taken legal action. On August 19, 2004, the 9th US Circuit Court of Appeals in Los Angeles ruled that P2P software developers were not infringing the copyright law by making products that people use to illegal download copyrighted material. The case was against the Grokster and Morpheus softwares. This is probably only an early opening round in the battles to come.

- Why have prices for popular music concerts grown so much faster than prices of other entertainment events since the late 1990s? Can more appropriate price indices for concerts – that take into account price discrimination, rationing, shifts in demand, and other factors – be constructed?
- What determines the amount of price differentiation within concerts, and why has price discrimination grown since the 1980s? Is there less regional variation in prices for the same concerts than one would expect in an efficient market? If so, why?
- How has increased concentration in promoters and media affected the popular music industry? Will continued technological change cause the industry to become more or less concentrated?
- There is a paucity of evidence on demand elasticities for concerts. As always, identifying demand and supply parameters requires some assumptions or exclusion restrictions. One potential approach is to use supply shocks, caused by factors like bad health (especially for older performers), to identify the elasticity of demand for concerts. Once a set of parameters is available, more elaborate rankings could be computed.
- The Internet lowers the cost of band promotion. How will the continued development of the Internet change the music industry? If bands rarely receive much income from record sales, will they seek other means for distributing their music? Will start-up bands have greater bargaining power with record companies because they can directly promote their music themselves on the Internet?
- How will future technological developments, which are hard to predict at present, affect the concert industry and the distribution of recorded music? Will the variety in popular music increase because of new distribution technologies?
- We lack systematic data on concert production costs over time. What are the trends in concert production costs? Can these costs account for the trend in prices?
- Tickets are beginning to be distributed in auctions. How do ticket auctions affect the average price and the size of the secondary market? What strategies do fans use when they have the option of purchasing tickets in an auction.
- Why is there a secondary market for tickets? Why do tickets appear to be underpriced for many concerts?
- Does the practice of legal payola (i.e., payments to radio stations via independent record promoters) affect the popularity of bands? Will payola become a common practice in new domains, such as webcasts, as technological change continues to shape the popular music industry?

## Abstract

This chapter analyses the tensions between books and book markets as expressions of culture and books as products in profit-making businesses and includes insights from the theory of industrial organisation. Governments intervene in the market for books through laws concerning prices of books, grants for authors and publishers, a lower value-added tax, public libraries and education in order to stimulate the diversity of books on offer, increase the density of retail outlets and promote reading. An overview of the different ways by which countries differ in terms of market structures and government policies is given. Particular attention is paid to retail price maintenance. Due to differences between European countries it is not a good idea to harmonise European book policies. Our analysis suggests that the book market seems quite able to invent solutions to specific problems of the book trade and that, apart from promoting reading, there is little need for government intervention.

## 1. Introduction

The arts have a special character. This combined with market failures may provide grounds for government intervention. The nature of intervention depends on the characteristics of the art and culture involved and on the potential failures of the market to provide an adequate and diverse enough supply of goods and services. Books are sufficiently different to warrant special attention. According to a 1964 UNESCO definition, a book is a “non-periodical, printed publication consisting of at least 49 pages, excluding cover pages”. Usually, three categories of books are distinguished: educational, scientific and general books. Educational books are intended as a means of learning for the institutionalised educational system up to higher vocational training, often based on government rules and regulations. Scientific books aim at users starting from higher vocational training. General books are all those that are not educational or scientific. Each category has its own characteristics and warrants different treatment. In this chapter we focus primarily on a sub-category of general books: cultural books. There are many other general books, such as cookbooks, travel guides or commercial fiction, which do not deserve the interest of ministers of culture. With cultural books there is always a tension between books as instruments of culture and books as products in a profit-making business as recognised by the Director-General of UNESCO at the World Book and Copyright Day, 23 April 2002:

Being one of the oldest means of communication and distribution, books not only have spiritual, educational and cultural implications, but also involve the legitimate industrial and economic aspects of the publishing trade. The association of these two factors – cultural impact and economic interests – results in a complex system of parameters that may seem incompatible. Developing the publishing and reading universe requires understanding of the existing internal relations between the different elements comprising the book chain: literary intervention, the respective functions of the publisher, printer, distributor and bookseller, and the reader.

Governments influence book markets through subsidies for libraries, authors and publishers, tax concessions on the sale of books, and laws concerning the pricing of books. This chapter first provides an overview of differences between countries in terms of market structures and reading behaviour. Section 3 discusses the special features of the book market and stresses the importance of principles such as *nobody knows, time flies, A-list/B-list* and *infinite variety* put forward by Caves (2000, 2006). It also discusses the grounds for government intervention. The market is quite capable of inventing solutions to specific problems (think of contracts for authors, literary agents, gate keeping by publishers, joint distribution by wholesalers cooperating on distribution, agreements concerning stocks between retailers and publishers, joint publicity, best-seller lists, reviews, etc.). Apart from stimulating reading, it is not clear what role there is for government intervention. The *pièce de résistance* as seen by most people in the cultural sector and among ministers of culture primarily in Europe is rightly or wrongly the fixed book price agreement. It may be viewed as a solution of the book

industry to specific problems, as laws are typically inspired by the book trade. Section 4 therefore provides a critical appraisal of retail price maintenance and fixed book price agreements. Section 5 discusses a spectrum of different government policy instruments to stimulate reading and to promote the diversity of publishing and distribution. It also gives some empirical details. Section 6 concludes.

## 2. Cross-country statistics and trends

### 2.1. General overview

To illustrate general trends in the book market and highlight differences between countries, this section presents stylised facts for 20 OECD countries. International comparative information is scattered and it is difficult to get a full overview for all countries. Although the focus is on cultural books, statistical information is only available for all books or for a different classification (e.g., the Universal Decimal Classification – UDC). Furthermore, due to differences in definitions and measurement, it is difficult to compare countries at a particular moment in time or differences within a country across time periods. Nevertheless, on the basis of the general overview presented in Table 1, some clear cross-country differences are visible in book reading, book production, and book services provided by public libraries.

There are large differences in book reading. About half of Portuguese adults never read a book. This is in sharp contrast with the 20 percent of readers in Belgium, Denmark, Italy and Norway. Reading is popular in Finland, Sweden and Switzerland where about 90 percent of adults read. Nevertheless, even in Sweden almost 30 percent failed to read a book during the past year. Although in most countries a majority of the adults read, there are also large numbers of people who never read a book. Among those who read, a substantial part read a book only every now and then.

UNESCO provides statistical information on the number of titles. These are non-periodic publications (first editions and re-editions) published in a particular country and made available to the public.<sup>1</sup> Table 1 presents cross-country differences in title production for ‘arts and culture’ and for all titles. At the low end of the distribution one finds the US, with 24 titles per 100,000 inhabitants of which 6 concern arts and culture. At the high end, Denmark produces 275 titles per 100,000 inhabitants, of which 80 concern arts and culture. Most titles per inhabitant are produced in the Scandinavian countries, in Switzerland and in the UK. Relatively few titles are produced in Italy, Japan, Greece and Australia.

For most of the countries for which information is available, the average annual number of books sold per inhabitant is about 5 to 6. The exceptions at the lower end are

<sup>1</sup> The term ‘title’ is used to describe a printed publication which forms a separate whole, in one or several volumes. Different language versions of the same title published in a particular country are considered as individual titles.

Table 1  
Economics of books – international comparison

	Reading		Titles		Copies sold	Revenues	Value added	Public libraries

*Notes. Reading:* Percentage 'ever' reading books at home in population 16–65 years, 1994–1998; Belgium = Flanders, Norway = Bokmal. Source: International Adult Literacy and Life Skills Survey. Last year = for reasons other than work or study, percentage of population of 15 years and over, 2002. Source: Eurostat.

*Titles:* Annual book title production per 100,000 inhabitants, 1996–1999 (most recent year available), Belgium (1995) and Ireland (1999). Source: International Publisher's Association; all other countries = UNESCO Statistical Yearbooks.

*Copies sold:* Number of book copies sold per inhabitant, 2000–2002 (most recent year available). Sources: UNESCO, Statistical Yearbooks (Italy, 1996, Portugal, 1994, Spain, 1994), Stichting Spoorwerk betreffende het boek (Netherlands, 2000), Book Market Ltd. (UK, 2001), International Publishers' Association (all other countries).

*Revenues:* Publishers' revenues from book sales, Euro per inhabitant (US dollars for Australia, Denmark, Japan, Sweden, UK and USA), rounded numbers, 2000–2002 (most recent year available). Sources: International Publishers' Association (Australia, Italy, Japan), Association of American Publishers (US), European Commission (2004; all other countries).

*Value added:* Percentage of GDP contributed by the book publishing industry. Source: European Commission (2004). Spending on books in 1999 (percentage of GDP) was 0.30% in France, 0.42% in Germany, 0.36% in the UK, and 0.35% in the US. Source: Publishers Association.

*Public libraries:* Number of book volumes and number of loans to users, both per inhabitant, 1997–1999 (most recent year available). Source: UNESCO, Statistical Yearbooks.

Portugal and Sweden with an average of 2.6 and 3.6 books per inhabitant, while at the high end there is the France with 6.9. Publishers' revenues from sales also vary a lot from a low 20 Euro per inhabitant in Greece to a high 115 Euro in Finland. In most countries the revenue from book selling is about 40 to 60 Euro per inhabitant. In terms of GDP the book publishing industry is not very important. In absolute terms the largest industries are located in the US, Germany, the UK, France and Italy. In 2001, value added of the book publishing industry represented about 0.11 percent of GDP and employed some 140,000 in the EU-15. The industry is stable in terms of turnover and per capita sales. Books thus remain popular with readers and have not lost out to other media.<sup>2</sup>

Table 1 also provides information about cross-country differences in services provided by public libraries. The number of books available through public libraries is low in Greece, Italy, Portugal and Spain. It is much larger in Denmark, Finland and Sweden. The number of loans per inhabitant correlates highly with the number of books available. It ranges from less than one in Greece, Portugal, Spain and Switzerland to at least ten in Denmark, Finland and the Netherlands.

## 2.2. A closer look at book reading

People read books in a variety of ways. They read books at home, at work, while travelling, during holidays, etc. To find out how much time individuals read one has to clearly define time spent reading. This is especially important when different activities are performed simultaneously, say reading and travelling or reading and listening to music. Furthermore, reading may not be distributed evenly across the year. Some people may read on a regular basis while others read especially during holidays. Reading time measured as a regular activity in a typical week leads to a much lower estimate than reading time measured as the product of the number of books read and the average time spent reading a book. In time-use surveys it is therefore not easy to establish how much time individuals spend reading. While comparing results within the same time-use survey is easy, cross-comparisons between different surveys is difficult.

Table 2 presents information about the frequency of reading as measured in the International Adult Literacy and Life Skills Survey, which is based on similar surveys in a series of countries. Cross-country comparison is informative. As shown, differences in book-reading frequency are clear and large. Reading a book daily varies from about a quarter of all adult males in Australia, Canada, Ireland, Sweden, Switzerland, UK and US to a mere 5 percent for Portuguese male adults. In most countries 10 to 20 percent of adult males read daily. A common element is that females read substantially more often than males. The differences are smallest in Belgium (Flanders) and Portugal, and very large in Australia, Canada, Denmark and the Netherlands.

Cross-country differences in reading behaviour are present already at a young age. Table 2 also presents the reading behaviour of 15-year old children. Greece and Finland

<sup>2</sup> See European Commission (2004).

Table 2  
Frequency of reading books – adults and 15-year olds

	Adults aged 16–65 (daily reading)		15-year olds (read at least 1 hour per day)
	Males	Females

Switzerland	24	39	11
UK	25	37	12
US	25	39	12

*Notes.* Percentages of population. Sources: Adults – International Adult Literacy and Life Skills Survey, 1994–1998, 15-year olds – Programme for International Student Assessment, 2000.

are countries where many children like to read. Note that there are also differences in reading behaviour between adults and children.

The level of education is also an important determinant of reading habits but here no systematic cross-country information is available. We illustrate the situation for France and Italy.<sup>3</sup> In France 71 percent read at least one book during the past twelve months.<sup>4</sup> These percentages are 62, 78 and 92 percent for lower-, medium-, and higher-educated individuals, respectively. The same differences in reading behaviour are present for Italy, where on average 44 percent of the population read a book in the past year. The percentages are 32, 64 and 82 percent for lower-, medium- and higher-educated people, respectively.

There is not much cross-country information concerning trends in reading. We use information about the Netherlands as an illustrative example. As shown in Table 3, there is

<sup>3</sup> See [www.readingeurope.org](http://www.readingeurope.org).

<sup>4</sup> This number is slightly different from the number in Table 1, which refers to reading at home.

Table 3  
Reading books: males and females, Netherlands, 1975–2000

	1975	1980	1985	1990	1995	2000
<i>Males</i>						
Hours per week per capita	1.4	1.5	1.1	1.1	0.9	0.7
Reading books (%)	43	43	36	33	30	22
Hours per week per reader	3.3	3.5	3.1	3.3	3.0	3.2
<i>Females</i>						
Hours per week per capita	1.9	1.7	1.6	1.9	1.5	1.2
Reading books (%)	56	53	52	54	46	40
Hours per week per reader	3.4	3.2	3.1	3.5	3.3	3.0

Table 4  
Reading books: Finland, Germany, Norway, Sweden and UK, 1998–2002

	Finland	Germany	Norway	Sweden	UK
<i>Males</i>					
Hours per week per capita	1.1	0.7	0.8	1.1	0.6
Reading books (%)	13	9	12	13	8
Hours per week per reader	8.1	7.8	6.8	8.1	7.3
<i>Females</i>					
Hours per week per capita	1.6	0.9	1.3	1.5	0.8
Reading books (%)	20	13	20	23	13
Hours per week per reader	8.2	7.2	6.4	6.6	6.3

*Notes.* Reading connected with work and for an exam and reading as a joint activity, for instance with travelling, is not included. To some extent other reading (not reported here) may include reading books too, which may lead to underestimation of the time used for reading books. Source: Sociaal en Cultureel Planbureau for the Netherlands and also Time Use Surveys of Eurostat (2004).

a clear downward trend in book reading both for males and females. Furthermore, fewer people indicate that they read books, though the average time spent reading has hardly changed. Table 4 gives similar information for other countries. Females are more likely to read than males, but conditional on reading there is not much difference between males and females. The main differences in reading behaviour are related to the participation in reading and not to the time spent reading by readers. All readers irrespective of gender or country spend about 6.5–8 hours per week reading books.<sup>5</sup> In Europe, people spend most their time watching television. In the US trends suggest that Internet use is

<sup>5</sup> In the Netherlands reading participation is much higher but the number of hours read per week per reader is lower. This is likely to be a measurement issue, since the number of hours read per capita is similar to other countries.

increasing, mainly at the expense of watching television rather than reading [European Commission (2004)].

### 2.3. Producing books and selling them

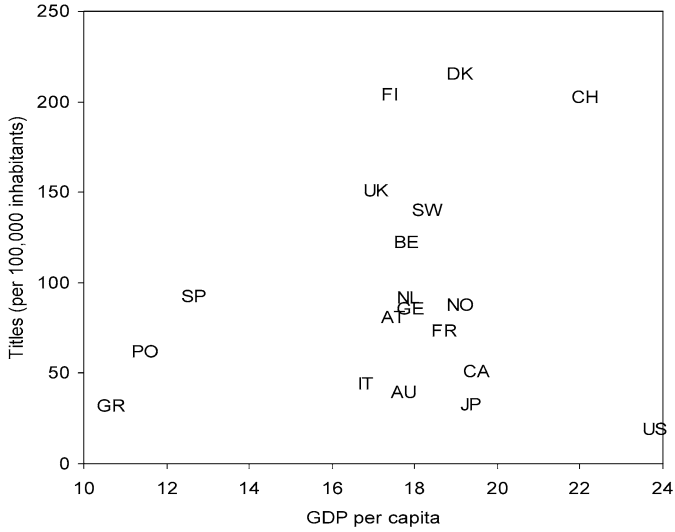

Table 5 shows that during the past decades production of book titles increased in all countries, but there are differences between countries. From the mid 1970s to the late 1990s there was virtually no increase in Norway and relatively mild increases in Austria, France, Greece and Sweden. In contrast, up to 1990 production more than doubled in Belgium, Finland, Spain and the UK. Although the number of titles produced increases each year in most countries, the number of publishers is stable. The average size of a publishing enterprise in the EU is small. Most publish only between 20 and 40 titles per year [European Commission (2004)].

Differences in the number of titles published may be related to economic prosperity, to the educational level of the population, or to population density. With rising incomes people may buy more books, thus increasing the supply of book titles. Figure 1(a) illus-

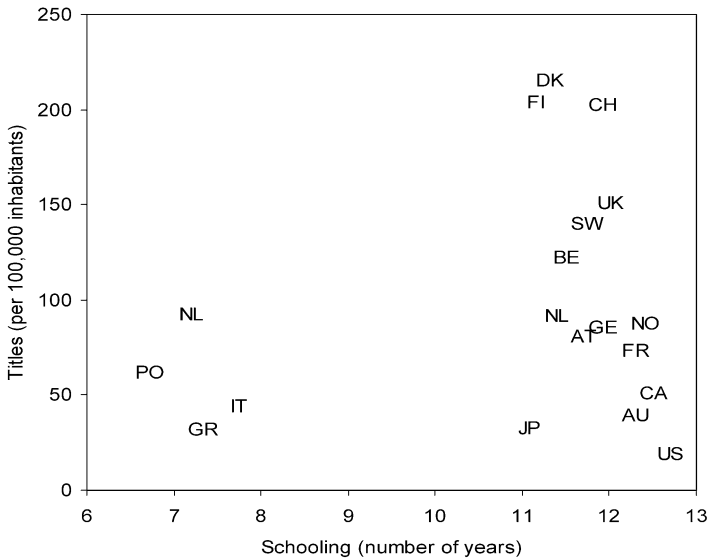

Table 5  
Annual book title production, 1975–1999 (per 100,000 inhabitants)

	1975	1980	1985	1990	1995	1999
Australia	40	66	67	39	38	37

US	39	33	21	19	23	24

Notes. The calendar year for which information is given is sometimes slightly different from the year indicated. The definition of ‘book title’ differs between countries and sometimes changes over time. Data for Belgium and Ireland (1995, 1999) are from the International Publishers’ Association, so they may not be fully comparable to the information for previous years. Source: UNESCO, Statistical Yearbooks.

(a) Book titles and GDP per capita, 1990

(b) Book titles and level of schooling, 1990

Figure 1. Book titles, GDP per capita, schooling and population density.

trates the relationship between titles per capita and GDP per capita. There seems to be a positive relationship, but it is not very strong. Countries with a low per-capita GDP, such as Greece, Portugal and Spain, have the lowest numbers of per-capita book titles, but

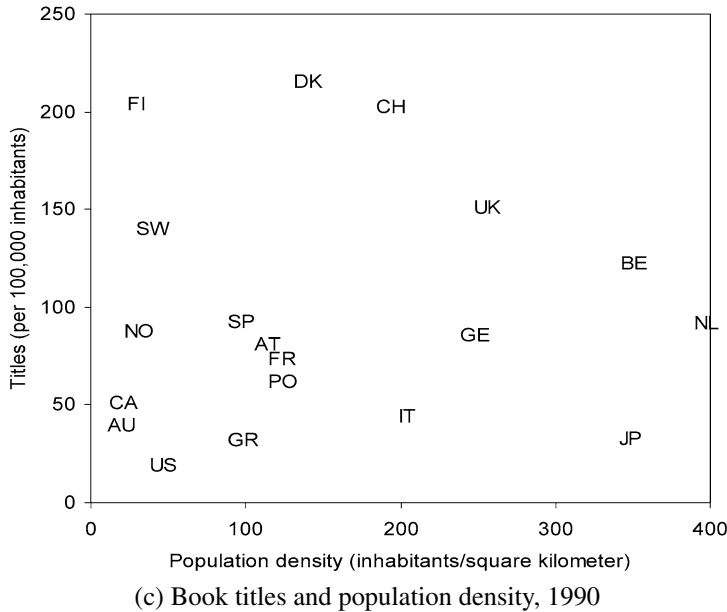

Figure 1. (continued)

among the countries with a higher per-capita income there is a lot of variation. The US, for example, has a lower per-capita book title production than some southern European countries with half the per-capita income of the US.

Figure 1(b) shows that there is also a positive relationship between the average educational level of a population and the number of titles produced. Again, the relationship is not very strong, and fuzzy for countries with a higher level of education. Figure 1(c) shows that there is no association between book titles and population density.

In terms of book title production distinguished by the Universal Decimal Classification the most important categories in each of the countries are social sciences, applied sciences and literature. Nevertheless, in terms of distribution of titles across UDC classes, there are big cross-country differences. In Austria, Canada, Portugal and Switzerland more than a quarter of all titles concern the social sciences. In France, Greece, Norway, Portugal and Spain more than 30 percent concerns literature. In other countries the distribution across the three main categories is more even. Table 6 shows that in the late 1990s in Canada, Finland and Germany only 20–25 percent of all titles concern arts and literature. For countries such as Greece, Norway and Portugal this percentage is 45–50. Table 6 also shows the evolution of the number of titles in arts and literature since 1975. The share of titles in arts and literature changes but no clear patterns emerge. For some countries, e.g., Belgium, France, Norway and Portugal, the share of literature increases, but in Sweden and the UK there is a decline.

US	–	26

Notes. See Table 5.

European Commission (2004) presents a recent overview of the European book market. Total sales amount to 27 billion Euro in 2000. The biggest market is Germany with some 9.5 billion Euro (2000/2001). Both Germany and UK are strong exporters of books to countries that share their languages. Other large book markets are found in France, Spain and Italy. During the first two years of this decade, the UK book publishing industry has grown to be the largest in Europe. In contrast, there has been a decline in Germany.

Table 7 provides some information about publishers' revenues distributed by type of books and by distribution channel. About half the revenues in most countries come from general books. Table 8 shows that most of the sales are made through retail channels (trade), except in the US. In some countries there are strong retailers, but in others there are many independent bookshops. In France, the multimedia retailer Fnac accounts for around 15 percent of sales. In Italy Feltrinelli commands 25 percent of the retail market [European Commission (2004)]. However, in Germany, the largest bookseller, Thalia, has only 3 percent of the market and there are many small independent bookshops. The largest retailers in the UK in 1998 were Waterstones and W.H. Smith with 20 percent and 18 percent of the market [Latcovich and Smith (2001)]. The US book industry has limited opportunities for growth in a mature market and competition is focused on growth through market shares.<sup>6</sup> The US has seen consolidation among retail chains.

Barnes and Noble commands 30 percent of the market and independent booksellers struggle to compete in the market [European Commission (2004)].

Table 8 shows that the share of book clubs is high in Australia (26 percent), about 15–20 percent in Denmark, Finland, France and Sweden, and low in Italy, UK and US. Although Internet sales have grown in importance, they are still rather small. In the UK around 17 percent of books go through Internet retailers, a percentage that is no longer thought to be growing very fast. For Germany estimates suggest between 4 and 5 percent of sales are made through Internet retailers, although recent growth has been much faster than in the UK. Some reports have estimated Internet sales in France and Italy at 1–1.5 percent. Spain has even lower Internet sales than France.

Internet is mainly used as a channel for books and so far not for digital products. For example, E-books are not sold much in the European market. In the US E-books are more important; over 7000 titles were published in 2003 while over 1.3 million E-books were sold. Concentration in the world wide online book market is high with 60 percent for Amazon.com [Latcovich and Smith (2001)].

### 3. The characteristics of the book market

Section 2 yields a colourful but opaque picture. The book market seems to flourish in one dimension (production) but not in the other (reading). The functioning of the market and its impact on both reading and production is not so clear. However, missing data frustrate an empirically sound judgement on the functioning of the market. There are also substantial differences between countries, both in descriptive data (number of books, beginning authors, Internet selling) as well as in government policies. This section follows up on Section 2 by zooming in on the nature of books and the book market.

#### 3.1. Perspective from industrial organisation

Many cultural goods share a number of properties; for example, in the words of Caves (2000) these properties can be listed as: *nobody knows* (uncertain demand), *time flies* (short period of profitability), *infinite variety* (horizontal differentiation) and *A-list/B-list* (vertical differentiation). To this Beck (2003) adds spontaneous purchases of about half books [Fishwick (1989)], non-convexities in production with large fixed costs and small marginal costs, and free entry for the book trade. Relevant questions are: in what mix do these properties come in the case of books; to which problems does that give rise; in what sense does the market solve the problems; and finally is there a role left for the government?

Economics can shed light on these questions. A book is a private good, since its consumption is rival and excludable. This implies that at first blush there is no fundamental market failure, so that government provision is not a serious option. Books can be borrowed by other people. However, in so far as that yields utility to the owners, there is no market failure. The market for books has a traditional supply chain: production,

wholesale, distribution and retail. In each part of the chain there is competition between private entrepreneurs. Government provision only occurs with libraries, but that does not exclude competition between private firms in the rest of the chain. There is substantial product differentiation in each part of the chain, which generates niche markets. Branding is important. Making a new product successful often requires substantial investment and innovation. This includes accepting that some products will never make it.

As a result of these features, most parts of the supply chain are characterised by a fairly large number of players. Consumers of books can easily switch from one product to the other. The book market knows relatively few consumer lock-ins, which helps the market to function properly. Transparency adds to that. Even though books are experience goods, author reputation, book reviews, book clubs and word-of-mouth create a fair amount of transparency. The book market is also dynamic: there is innovation, market shares fluctuate and there is entry and exit. An exception might be the European retail market, where government policy may have stifled innovation. From the perspective of industrial organisation, the characteristics of book markets are not that different from many other markets [Allen and Curwen (1991)]. This suggests that the book market should not be exempted from competition law. Still, in many countries retail price maintenance is tolerated. This is discussed further in Section 5.

### 3.2. *Differentiated products and uncertain prospects*

What are the consequences of the above features? The book market seems to be characterised by monopolistic competition. It has the following features:

- (a) the products sold are differentiated;
- (b) firms set the price of the goods;
- (c) the number of sellers is large and each firm disregards the effects of its price decisions on the actions of its competitors;
- (d) entry is unrestricted.

There then exists a trade-off between efficiency (exploiting scale economies by producing more of the same product type) and diversity.

This notion can be illustrated by looking, for example, at the market for cereals. Consumers have a love for variety, but variety can come at a cost. Each individual cereal variety becomes more expensive. In addition, the market becomes less transparent. Since firms do not take the potential downside of the variety decisions of other firms into account (the business stealing effect), there could be a market failure and optimal product diversity is not guaranteed. The book market is different in the sense that consumers do not engage in repeated purchases in the same way as they do for cereals. Book consumers rarely buy the same book twice. This changes the traditional trade-off in the sense that it greatly reduces possibilities for exploiting economies of scale. This is particularly true in the light of *nobody knows*. This does not mean that the book market can never have too much variety, but the argument then rests on lack of transparency and not on the more common economies of scale argument. Unlike in standard monopolistic

competition models, the book market is not characterised by repeated entry by publishers with each publisher filling a niche. It is books that occupy niches, not publishers. Publishers have a portfolio of authors and books that serve as a way of risk smoothing. Some books will make it while others will not, but publishers either have difficulties of forecasting the success or are happy to accept differences in success out of cultural motives. Additional complexities arise for two other reasons. First, the book market is characterised by the fact that a single product (a book) has a very short life cycle. This is not unlike products that depend on fashion. Bertarelli and Censolo (2000) formalise the idea that firms exercise monopoly power for a short period of time, but then have to cut prices under influence of entry and 'running-out-of-fashion'. Second, publishers may face a trade-off between risk smoothing and specialisation; that is, a publisher specialised in science fiction may have a competitive edge to non-specialised publishers, but may face the extra risk that science fiction lovers switch to video games.

A publisher thus has a quickly changing portfolio of books. Its strategy consists of deciding on the portfolio (trading off risks and specialisation) and on the prices of the portfolio. An 'industrial organisation' translation of portfolio may be economies of scope. In Ottaviano and Thisse (1999) multi-product firms in a monopolistic competitive market face the decision whether to engage in new product lines (exploiting economies of scope) or not (reducing cannibalisation). Depending on the parameters, in such a market there can be too much or too little variety [Dixit and Stiglitz (1997)]. This is akin to the decision by a publisher whether to employ a new author in the same field as his current portfolio. Here too there is a trade-off between economies of scope and cannibalisation. Similarly, the publisher has to face up to the decision whether to engage in a new field or not. It is not clear whether the accumulation of the complex decisions by publishers generates too much or too little variety. This trade-off combined with publishers' differences in 'love for culture', leads to a mix of publisher types. There are specialised publishers, small publishers and large publishers. This has been the case for many years in many countries.

### 3.3. Other characteristics of books

There exist several features that distinguish books from other products.<sup>7</sup> First, books are experience goods. One only learns the value after consumption. Second, books are characterised by high fixed and low marginal costs. Many other information goods markets share these two features. Third, some books are extremely successful, while most are unsuccessful. Success is hard to forecast (the *nobody knows* principle). In some circumstances this leads to 'winner takes all' economics as developed by Rosen (1981), but clearly not as extreme as in other information goods. Cowen (1998) reports that the number of copies sold in 1990 of the top-fifteen books accounts for less than one

<sup>7</sup> See also Appelman and van den Broek (2002), Throsby (2001), Cowen (1998), and Chapter 34 by van der Ploeg in this volume.

percent of total sales. It also means that booksellers and publishers – should they wish to do so – can cross-subsidise higher-risk books with profits on other books. Indeed Appelman and van den Broek (2002) present evidence that such cross-subsidies exist. These potentially welfare-enhancing cross-subsidies can be thwarted by non-branch shops (typically supermarkets) which might use books as a sales product (see Section 5). Fourth, the opportunity costs of consuming a book (i.e., time) typically outweigh the price of a book. This is one of the rare truly unique features of a book and contributes to a low price elasticity compared to other goods. In fact, the little evidence that is available suggests that the market for books other than best sellers is price-inelastic, probably because most purchasers have high incomes or buy them for study purposes.<sup>8</sup> Fifth, reading a book can be interpreted as a private investment in culture rather than consumption. Sixth, there is an (almost) free substitute for buying books, namely libraries. However, one can argue that the quality of the product is lower, which makes substitutability imperfect. Seventh, there is a public good nature associated with (the cultural value of) a book. Throsby (2001) mentions that a book (or, more generally, art) can be seen as possessing an option value ('I always have the option of buying a book'), an existence value ('I like the fact that there exist books') and a bequest value. Added to this are values associated with national identity, social cohesion, national prestige and the development of criticism and experiments [O'Hagan (1998)]. None of these values is (fully) reflected in the price, so that indeed the total value of books is higher than what has been paid. It turns out that these characteristics influence the way publishers, wholesalers, retailers and readers interact.

### 3.4. *Authors, publishers, retailers and readers*

The characteristics mentioned above create various problems. For most of these the market has found a solution. This subsection is organised around the solutions in various parts of the supply chain.

#### 3.4.1. *Author versus publisher*

The properties listed above make the book market relatively simple [compared to other cultural markets, see Caves (2000)]. A theatre production or movie is much more complex for a number of reasons. First there is the *motley crew* property. A play or movie involves a complex set of different professionals to interact. The success of the play or

<sup>8</sup> Van Ours (1990) and Appelman and van den Broek (2002) find a price elasticity of  $-0.8$  for the Netherlands, de Grauwe and Gielens (1993) find  $-0.6$  for Belgium, and Ecalle (1988) and Fishwick and Fitzsimons (1998) find  $-0.9$ . However, Hjorth-Andersen (2000) find  $-1.4$ , which suggests that demand for Danish books is highly elastic. Bittlingmayer (1992) finds an even higher price elasticity between  $-2$  and  $-3$  for the demand for individual books, which suggests more substitution possibilities between varieties of books than between books and other (cultural) goods. For example, the falling price of TV may have diverted demand away from books.

movie crucially depends on how these different professionals get along. Many parts of the chain have the possibility to break it and kill the project. This leads to a complex set of contracts and other institutions, largely unnecessary and therefore absent in the book industry. Second, the *nobody knows* and *time flies* principles are even more applicable to a play or movie than to a book. Third, the production costs of a play or movie are much higher than those of a book. As a consequence, movies and plays involve problematic financing, subsidies and complex contracts.<sup>9</sup>

Authors and publishers share the risk associated with the *nobody knows* and *time flies* principles. This implies that authors get a percentage of the sales (typically 10 percent) and a split of the gross profits (typically 58–42 percent) between author and publisher. Only with celebrity authors or authors with a strong reputation, there are advances (which can be substantial). While celebrity authors do reduce the risk of publishers somewhat, there are also serious large scale flops. Former US President Clinton's *Between Hope and History* had 70 percent of copies shipped to bookstores returned unsold [Caves (2000)].

Changing the terms of the contract either in favour of the author or the publisher can lead to misallocations. A higher fee for the publisher leads to a higher number of published books, since it becomes more lucrative to publish books and there still exists a reservoir of authors wanting to accept lower fees [Caves (2000, p. 57)]. However, there will be less commercial success per book on average and lower quality as good authors may spend their time on more profitable activities. This could be justified if the perception is that there is a lack of supply of books. There is no evidence of that however (the contrary is more likely). A higher percentage for the authors implies higher risk for the publisher, less books and less possibilities for beginning authors. Section 2.3 showed that there was substantial variation in production of books even corrected for underlying factors such as GDP per capita or education. It is thus not clear whether any given country is in the 'right' equilibrium.

In a simple world a contract, such as the one described above, would do and there is not much more to say on the matter. The world is not so simple though. One reason is that incentives differ between publishers and authors. Publishers want to make money. After a publisher has decided to accept a certain manuscript (even some potentially low-selling poetry) he still wants to make as much money as possible. Even the culture-loving publisher wants to use opportunities of money making to compensate for the failings; otherwise he simply does not survive. This can contrast with the interest of authors, who want to maximise sales and impact. The reason has to do with the payment schemes of the authors, who receive a certain percentage on books sold, but can supplement this with other sources of income. The potential of related side incomes (lectures, TV, film) has grown. With globalisation and the Internet the likelihood of superstar incomes for authors has become a real possibility. The increased importance of media

<sup>9</sup> See Chapter 19 by De Vany in this volume for an explanation of the functioning of the particularly complex market for movies.

makes it easier for them to leverage their reputation into sources of income. Indeed, Coser, Kadushin and Powell (1982) suggest that there is asymmetry of power with publishers having the right to refuse to publish even after accepting a manuscript, but there seem to be sufficient countervailing powers. Authors can change publishers, should they wish to do so. A large number of beginning authors find their way to the book market. In addition, sales of a novel increase the probability of future sales, a factor that influences an author more than his publisher. As a result of these differing incentives, authors may want to use agents. There is no marketplace for literary reputations of beginning authors. The chance that a publisher accepts a manuscript is extremely low; Caves (2000) mentions one in 15,000 for novels. Agents reduce the cost of publishers by filtering out good and bad manuscripts. The publisher can then use the reputation of a good agent as a proxy for quality. Agents can also perform useful commercial activities for authors.

The differences in incentives have created a love–hate relationship between authors and publishers. Coser, Kadushin and Powell (1982, pp. 224–225) report a number of funny incidents:

Thus, the nineteenth-century British prime minister and author Benjamin Disraeli, had received the unprecedented sum of ten thousand pounds from the house of Longman for his last work of fiction, *Endymion* (1880); when it did not sell as well as expected, he told an associate ‘My conscience will force me to disgorge’ and offered Longman a new contract that virtually amounted to returning three thousand pounds to the firm. Longman at once replied that it ‘could not think of availing [itself] of Beaconsfields [Disraeli] liberal and considerate suggestion’. But such instances of ‘*Après vous Gaston*’ are rare indeed.

And on the other side of the spectrum:

... a letter from the nineteenth-century writer of books on Japan, Lafcadio Hearn, to his New York publisher, Harper’s (which had resented something Hearn had done): ‘Please understand that your resentment has for me less than the value of a bottled fart, and your bank account less consequence than a wooden shithouse struck by lightning.’

The relationship between authors, publishers and readers can be better understood by considering the temporary monopolies created by intellectual property rights of authors [Plant (1934); Landes and Posner (1989)]. Copyright is a strong feature of book markets.

### 3.4.2. *Publisher versus retailer*

The properties of books also create problems in the relationship between retailers and publishers. Most notably, *nobody knows* and *time flies* create problems with stocks in retail outlets. If a book does not perform, the retailer wants to get rid of it as quickly as possible. Shelf space is scarce and new potentially successful books are looming. Market solutions to this problem include second hand sales shops, sales of remainders, pricing strategies and policies that aim at sharing risks between publishers and retailers.

In many countries book retailers have a right of returning books for full credit (variants of this principle exist). Again, and similar to the contracts between authors and publishers, history has determined a sort of equilibrium here. Too much leeway to retailers makes them 'lazy' and puts too much risks on publishers. Increasing the risk for retailers also creates problems, perhaps not all covered by market solutions. Retailers can further reduce risks by smart wholesaling agreements. There are distinct differences in market shares of wholesale firms in Europe. The largest wholesaler in the Netherlands has 70 percent of the market. In France, Finland and Denmark the wholesale market is also concentrated. In contrast, in Belgium the wholesale market is more scattered and efficiency of distribution is lacking [EIM (2001)]. In Anglo-Saxon countries, on the other hand, wholesale is less concentrated, but there are many integrated firms (publisher and wholesale). The fact that publishers are larger makes it worthwhile for them to vertically integrate into distribution. All in all, there is no reason to believe that the market will necessarily fail to solve the coordination problems needed to sort out the economies of scale.

It remains unclear in what sense the retailing sector is in the 'right' equilibrium in any individual country. The fact that there are such large differences between countries in retailing – and these differences are very unlikely to reflect just differences in preferences – suggests that the market solutions to the problems created by the properties of books are most vulnerable in the retail sector. Indeed, the number of independent book retailers reduces and they are replaced by chains [Epstein (2001)]. We come back to this later on.

There also exists a trade-off between exploiting economies of scale in retail and other policy goals. Examples are the reduction of transportation costs for consumers or equity 'universal service' type of arguments. The hermit on the Shetlands wants his bookshop. This trade-off is, at least in Europe, also apparent in banking, where efficiency requires shutting down local outlets, potentially frustrating elderly people who value the service, and supermarkets where there is a trade-off between environmental and planning issues and efficiency of large stores. Various trends tilt towards scale. First and most importantly is the possibility of the Internet. Even more than banking and supermarket products, books are easy to sell on the Internet. They are well-defined, easy to transport and personal contact with the seller is not (always) needed. In fact, interactive service and personal advice from Internet bookstores is often excellent. The storage, review and search possibilities are unlimited. The success of Amazon.com is no surprise.<sup>10</sup>

### 3.4.3. Readers

Since books are experience goods, consumers – when left to themselves – have a hard time deciding which book to buy. To facilitate the choices there are a number of institutions, mainly independent experts in various outlets. There are book reviews in

<sup>10</sup> See also Chapter 11 by Baumol in this volume on the role of the 'New Economy' in Arts and Culture, and Soon-Yong, Stahl and Whinston (1998), Creemers (1999), Yetkiner and Horvth (2000), Klein (2000) and Goolsbee and Chevalier (2002) for a discussion of book retailing on the Internet.

newspapers and the Internet, best-seller lists, and a fairly strong word-of-mouth culture. There is also some information transmitted through prizes and awards, and book clubs that pre-select titles. One of the best known clubs is the one associated with Oprah Winfrey's Book Club selections. The books chosen by Oprah often immediately hit the bestseller lists and are able to generate extra demand. For example, the first pick *Deep End of the Ocean* by Jacquelyn Mitchard was already on the market for some time and immediately became a top bestseller. All these institutions serve as intermediary between readers and booksellers. There is no reason to believe that the market for information is failing, with the possible exception for payola [Caves (2000)], a system in which the author (or his agent) 'bribes' a gatekeeper to influence his choices. The phenomenon is best known in Radio channels for Pop music.<sup>11</sup> Payola makes sense if airplay leverages future incomes. Since the government does not want the media to lose its independence, it has forbidden payola (although it still prevails). In the book market payola is less frequent and the argument runs through the best sellers list. An American consultant once bought so many copies of his own management book that he topped the best-sellers list for many weeks, leveraging his income in his regular consultant job. Another channel through which payola comes into play in the book market is through sticky prices. Chain bookstores can offer deals to book publishers to selectively display books in eye-catching positions. Caves (2000, p. 295) mentions the following example:

Barnes and Noble's 'Discover Great New Writers' program assures that a book appears face-out in every store for every two or three months and gets a review in a special brochure for \$1700 per title . . . These practices have entered into the controversy between publishers and the traditional independent booksellers over promotional allowances and other terms that disproportionately benefit chains and superstores.

Since payola runs against the vital role of objectivity (for culture) that gatekeepers perform, one is inclined to treat payola with scepticism.

### 3.5. *Books and culture*

The characteristics of Sections 3.1 and 3.2 and the market solutions of Section 3.3 lead to an assessment on how the book market performs in reaching cultural goals, which are:

- (i) a diversified portfolio of supply of books;
- (ii) books must be available for all, both in term of price and in terms of distance.

A diversified portfolio can imply several things: number of titles, number of genres, number of cultural titles or cultural genres. Similarly, availability (distance) can imply number of retailers, (cultural) stock of the retailers or variety in retailing. Finally, availability in price may refer to the prices of books or the possibility of reading [Appelman

<sup>11</sup> See Chapter 20 by Connolly and Krueger in this volume.

and van den Broek (2002)]. Obviously, difficulties in defining what cultural performance is, makes general assessments on performance somewhat heroic.

There are a number of observations that help assessing the cultural performance of the book market. First, books are rival and excludable. They share this with other cultural goods (CDs), but not with all of them (radio, TV, monuments are non-rival, buildings are non-excludable). The consequence of this (already mentioned earlier), is that the book market is more 'normal' than some other cultural markets, and hence requires less government interference. It is also important in the light of the discussion on technological trends, some of which transform non-excludable or non-rival goods into excludable or rival goods (think of pay-TV again). For books these discussions are unnecessary, but with the Internet one may expect a demand-driven growth in the sale of selected parts of handbooks and guidebooks. Second, books are reproductive cultural goods (unlike, say, the 'Nightwatch' by Rembrandt), implying that spreading books is easier than non-reproductive forms of art. Third, most fiction books are *not* luxury goods as are visits to the opera. One reason is that there is little social aspect to reading. Another reason lies in the presence of libraries, even though higher educated and richer people read more.

As a result, the market produces a large variety of books, with prices that are low enough (with libraries as a fallback as well) to make books available to everybody interested. O'Hagan (1998) and Cummings and Katz (1987) report that despite of this there are often additional policies towards arts directly aimed at equal access. We conclude that the market solutions, complemented with the presence of libraries, seem to be reasonably effective in reaching cultural goals, with the retailing sector as the most vulnerable part. This is a general assessment of the book market performance compared to other cultural markets. It does not say anything on the book market's cultural performance in any given country. From the empirical analysis in Sections 2.2 and 2.3 it follows that there are substantial differences in reading, production and retailing. These differences persist when correcting for factors such as GDP per capita and education, and are unlikely to be attributed only to differences in preferences. The assessment in this section points to existent market solutions to problems created by the characteristics of books. There are two possible explanations for these persistent differences. One is that some countries are in the wrong equilibrium. The fact that the market provides solutions does not imply that these are always used in a way that maximises social welfare. So it may well be that in some countries retailers are unsuccessful in dealing with the stock risks. This may lead to too few books, too few cultural books, too little reading or too many authors. Another explanation has to do with differences in public policy towards the book market.

### 3.6. *Grounds for government intervention*

The most important reason to intervene in the book market is to protect a dense network of well-stocked, high-quality bookshops and stimulate the publication of a large variety of books. Indeed, the number of high-quality bookshops is decreasing. This might be due to commercial motives if it does not pay to invest too much in variety in low-selling

books. Monopoly profits and cross-subsidies from profitable to less profitable books may allow bookshops to store a greater variety of books and publishers to take more risks. The current practice in many European countries of a fixed book price (FBP) in combination with a variety of subsidies handed out by literary funds is often motivated by these considerations. Critics argue that a FBP or subsidies for high-brow books may harm reading by the general public, since monopoly prices and cross-subsidies for less popular books are paid for by ordinary people reading popular books. Furthermore, subsidies for authors, translators, bookshops and publishers are paid for by ordinary people who may not be interested in more culturally valuable books or high-quality bookshops.

When considering policy instruments for reaching cultural objectives, there are at least two trade-offs. The first is between efficiency and density/distance. Increasing the scale of booksellers can enhance efficiency, but leads to longer travelling time for consumers. The second trade-off is between efficiency and cultural goals. Diversity of books in a bookstore may conflict with productive efficiency. The optimal choice of policy instruments is not the same for all countries.<sup>12</sup> It depends on culture-political preferences and on country-specific characteristics that determine the market outcome. Certain characteristics (e.g., a large 'language size') generate market outcomes where cultural objectives are more easily. In such countries the use of cultural policy instruments could be counterproductive. It is mainly for that reason that the United States, Australia and Canada do not have policies aimed at the book market, while they do have policies aimed at other cultural markets. This also implies that harmonising book policies in Europe is not a good idea.

Governments may wish to stimulate reading of worthwhile books, production of a diverse menu of titles and/or an extensive network of high-quality bookshops. None of the countries investigated by EIM (2001) specified the explicit targets for, say, the number of titles or bookshops. It thus is hard to evaluate the effectiveness and efficiency of the instruments used to attain cultural objectives.

#### **4. A critical appraisal of fixed book price agreements**

The fixed book price agreement (FBP) involves retail price maintenance, by which the publisher reserves the right to set the retail prices of books. Since the publisher also influences wholesale prices, he effectively sets gross margins for retail outlets. The cultural merits ascribed to such agreements have almost reached mythical proportions. No public debate in Europe on the cultural value of books is complete without a discussion of the FBP.<sup>13</sup>

<sup>12</sup> See Appelman and Canoy (2002).

<sup>13</sup> Tietzel (1995) and Rürup, Klopffleisch and Stumpp (1997) provide a thorough analysis with applications to Germany, Fishwick and Fitzsimons (1998) deal with the UK case. Hjorth-Andersen (2000) analyses the Danish situation, and Appelman and van den Broek (2002) discuss the Netherlands. See also Ornstein (1985), Uitermark (1986), Whyte (1994) and Ringstad (2004).

#### 4.1. Welfare analysis

We first compare a competitive equilibrium (CE) with a monopoly outcome for the book market. We assess the effects of a FBP which lasts forever, ignoring that in some countries the fixed price on a book expires after a few years and after which discounts are permitted and competition can play its role [van der Ploeg (2004)]. The full cost of reading a book  $Q$  includes the price of the book and the sales tax, but also the opportunity cost of the time needed to read a book ( $\phi W$  where  $W$  is the wage and  $\phi$  the hours spent reading books). Households use their time to work ( $1 - \phi B$ ) or read books ( $\phi B$ ), where  $B$  is the number of books bought. There is no utility of leisure, but utility of taking time to read books. Utility is quasi-linear in consumption of other goods  $C$ , say  $U(B) + C$  with  $U' > 0$ ,  $U'' < 0$ , and is maximised subject to the household budget constraint. Book demand follows from setting the marginal rate of substitution between books and other consumption goods equal to the ratio of the full cost of books to the price of other consumption goods. With quasi-linear preferences the marginal utility of private consumption equals one, so book demand follows from  $U'(B) = Q$  or:

$$b \cong -\varepsilon[(1 - \beta)(p + t) + \beta w] \\ \text{with } \varepsilon \equiv -Q/BU'' > 1/(1 - \beta) \text{ and } 0 < \beta \equiv \phi W/Q < 1, \quad (1)$$

where lower-case romans denote logarithmic deviations (e.g.,  $b \equiv dB/B$  except  $t \equiv dT/(1 + T)$ ),  $\varepsilon$  is the demand elasticity with respect to the full cost of reading a book, and  $\beta$  is the share of the opportunity cost of the time needed to read a book in the full cost. The demand elasticity,  $\varepsilon(1 - \beta)$ , is less than  $\varepsilon$ , since the price is only part of the full cost of reading a book. To have positive marginal revenue, assume  $\varepsilon(1 - \beta) > 1$ .

Publishers/booksellers maximise profits,  $PB - K(B) - F$  with  $K' > 0$  and  $K'' > 0$ , where  $K(B)$  denotes variable costs and  $F$  fixed costs. They set prices above marginal cost,  $P = K'\varepsilon(1 - \beta)/[\varepsilon(1 - \beta) - 1] \equiv P^{**} > K'$ . Prices are higher if the price elasticity is low, that is if few substitutes are available and the book price is only a small part of the full cost. Booksellers may find price discrimination, whereby high-income earners get charged a higher price for books, profitable. They may also use hardcovers and paperbacks as a tool of price discrimination, especially if the former are less price elastic than the latter. Equilibrium sales are given by

$$b = -\varepsilon[(1 - \beta)(t + m) + \beta w]/[1 + \varepsilon(1 - \beta)K''B/K'], \quad (2)$$

where  $m$  is the change in the mark-up. Book sales rise if the sales tax is cut or the opportunity cost of reading (the wage) falls. Figure 2 shows the effects of the FBP. In the competitive equilibrium,  $P^*$  and  $B^*$ , willingness to pay is the area under the demand curve  $x + y + z + v + w + a + b$ , which is more than consumers actually pay  $v + w + a + b$ . Subtracting total production costs  $v + w + F$ , we obtain total surplus, that is profits  $a + b - F$  plus consumer surplus  $x + y + z$ . Publisher/booksellers would have been prepared to deliver books below the equilibrium price. In the FBP equilibrium,  $P^{**}$  and  $B^{**}$ , willingness to pay equals  $x + y + a + v$ . Again subtracting production

Figure 2. Welfare costs of the fixed book price agreement.

costs  $v + F$ , we obtain total surplus, that is profits  $y + a - F$  plus consumer surplus  $x$ . The loss in welfare resulting from the fixed book price is thus equal to the area of the familiar “triangles”  $z$  (the consumer loss if profits  $y$  are distributed to households) and  $b$  (the producer loss).

Under the FBP firms only publish/sell a particular book title if sales revenues  $y + a + v$  exceed costs  $v + F$ , that is if profits are positive or  $y + a > F$ . In a competitive equilibrium an individual title is published/sold if profits are positive, that is if  $a + b > F$ . If fixed costs  $F$  are very high, fewer titles are published and sold because it is less likely that sales revenue minus variable costs will be high enough to cover fixed costs.

Since monopoly profits are higher than profits in competitive equilibrium ( $y + a - F > b + a - F$ ), more titles are profitable and are published/sold under the FBP than in competitive equilibrium. It is possible to print and sell extra books at low and almost non-increasing marginal cost, so the producer loss  $b$  is likely to be small. Also, the price elasticity of the demand for books  $\epsilon$  is likely to be small as a large part of the full cost of reading is the opportunity cost of time. Hence, the monopoly mark-up is likely to be large and monopoly profits  $y$  are large. It thus seems likely that more titles are published under the FBP than under perfect competition. Some monopoly profits are necessary for marginal titles to recoup fixed costs, which is not feasible under perfect competition. However, if a particular title is published, fewer copies will be

sold at a higher price than in the competitive equilibrium. Even though the FBP leads to more variety in book titles published, prices will be higher and sales of each title lower.

The FBP also has dynamic costs. Of course, price competition between retail outlets becomes impossible but it also is more difficult to vary prices in response to local conditions. A store on a remote island may want to charge more for the same book than a store in the capital, but under the FBP it cannot do so. Also, it is more difficult to vary prices for different types of customers or for different seasons. Some customers need no service and low prices, while others prefer service at a higher price. Most important is that the FBP discourages the development of innovative distribution channels, since realised cost savings cannot be passed on to customers. Competition triggers independent small bookshops to be more attractive for the customer than big chains, supermarkets and the Internet. This seems indeed to be the case for the UK and the US. With the FBP, unconventional distribution channels (bookclubs, supermarkets, petrol stations, the Internet, etc.) have less of a chance. Against these costs there is the benefit that independent small bookshops may be able to recommend interesting books and order books from the publisher or distributor.

Tullock (1980) argues that publishers and booksellers lobby and spend time, energy and other resources to get and maintain the privileges of the FBP. Monopoly profits  $y + a - F$  are then not handed back to consumers. Publishers and booksellers go on with lobbying and rent seeking until a large part of these profits is dissipated, so monopoly profits  $y + a - F$  should be added to the sum of the consumer and producer surplus welfare loss “triangles” of the monopoly agreement. The total welfare loss is then  $y + a - F + z + b$ . If these profits are dissipated, the gain in the diversity of book titles will evaporate as well.

The FBP may thus lead to a bigger diversity of book titles (if rent seeking does not dissipate all profits) but to worse incentives to develop new distribution channels. It also leads to higher prices and less sales revenue for each title published. However, the experience of the UK after liberalisation has been that, while the number of bookstores has declined and new channels of distribution have opened up, book prices have gone up by more than the retail price index. Liberalisation of taxi fares often raises some taxi fares in order to reap the benefit from the uninformed tourist trade while others charge lower prices and enjoy a higher business volume targeted at the residents’ market.<sup>14</sup> Competition in the book market may fail for different reasons than in the taxicab business, since consumers can with the aid of the Internet, quickly be informed about prices. A different problem is that the public has difficulty in assessing the quality of particular books before they are read. This may lead to a “lemon” problem in which bad-quality books drive out good-quality books [Akerlof (1970)]. Book reviews and book clubs may prevent this.

<sup>14</sup> See Salop and Stiglitz (1977) and Sutton (2000).

#### 4.2. *Retail price maintenance may increase non-price competition*

Advocates of the FBP also argue that, even though price competition is eliminated, non-price competition may intensify. For example, a bigger sale margin stimulates booksellers to give better service to customers [Holahan (1979); Mathewson and Winter (1998); Deneckere, Marvel and Peck (1997)]. With a bigger profit margin, it pays to spend more effort on service in order to get extra customers. If the extra service (more attractive presentation in bookshops, better information to customers, more promotion, etc.) generates more sales than the fallback in sales due to higher monopoly prices, the FBP may be desirable. Otherwise, the market fails to deliver sufficient service, because bookshops have an incentive to operate as free-riders by offering discounts and expecting their customers to get their information and service elsewhere. Bookshops hardly refuse service or charge for information provided to people who in the end may not buy a book. Still, most customers rarely engage in such a strategy, as the costs of roaming around various bookshops seem high in relation to the possible discount one might obtain. Much of this service is already made available through publishers' advertisements or book reviews in newspapers and other media or on the Internet. In any case, it is questionable whether the demand for books really depends on service. Better service does not seem a good argument for supporting a FBP.

The book trade also argues that a bigger margin provides incentives for better-stocked bookshops. Booksellers may take over some of the inventory risks from publishers, so that more titles will be published. At the margin it is more profitable for retail outlets with relatively high costs to open up. This argument only works if customers want to purchase their books at particular high-cost bookshops. The gain in sales from these outlets may then offset the drop in sales resulting from higher monopoly prices. Although a dense network of bookshops may be desirable from a cultural point of view, this argument for the FBP is difficult to justify on grounds of market failure. Another popular argument is that higher margins encourage more retail outlets to put new book titles with uncertain sales prospects on their shelves. Given that there seems to be no problem for beginning authors to get their first book published, this is not a strong argument either. Marvel and McCafferty (1984) suggest that resale price maintenance may sustain a luxury image, but that seems more relevant for the markets for perfumes and jewellery than for books.

In sum, the above discussion suggests that there is not a clinching economic argument for the FBP. Even if there is a greater variety of book titles being published under the FBP, there may be more efficient instruments to achieve this. In any case, lowering of production costs due to technological progress will benefit the diversity of books being published.

#### 4.3. *Imperfect competition: Is the cross-subsidy argument valid?*

The novel *Endurance* by Ian McEwan is not a perfect substitute for *Il Nome della Rose* by Umberto Eco. They are different books, because the authors have different styles,

the themes of the two novels are different, and last but not least the original languages in which the books are written are different. Still, Umberto Eco's books are closer substitutes for the novels of Ian McEwan than, say, a cookbook or a travel book. On the other hand, Martin Amis may be a closer substitute than Umberto Eco for Ian McEwan. One must therefore leave the realms of homogeneous goods and adopt a framework of Chamberlinian monopolistic competition in which books are imperfect substitutes. Publishers/booksellers carve out a niche and make monopoly profits, which enable them to recoup fixed costs. It is thus profitable to publish books. In fact, an important argument of the lobby of booksellers/publishers rests on imperfect competition. They argue that the FBP allows for cross-subsidies from best-sellers to less popular books and leads to a more diverse supply of book titles and bookshops. In addition, the book lobby suggests that publishing and stocking a large selection of books enhances reputation, yields economies of scope and satisfies the idiosyncratic taste of individual publishers and booksellers even though these arguments do not seem very strong (also see Section 4.2).

The cross-subsidy argument seems at first blush irrelevant. In competitive markets with imperfect information about the success of a product, it is common to invest in many products and reap a success on only a few. Even without a fixed horse price agreement, horse owners purchase lots of yearlings, many of which subsequently are sold to the riding school or the butcher if they do not win races. Similarly, in a market without a FBP publishers invest in beginning authors, just like horse owners invest in yearlings. Indeed, the industry's rule of thumb formulated by Denis Diderot in 1767 suggests that one out of ten new editions is a profitable success, four cover costs, and five make losses [Beck (2003)]. There are few barriers to beginning authors in the book market even though publishing is a risky business with only a third of published books being profitable. The FBP then has all the welfare and political economy costs of a monopoly. This situation may arise if best-sellers are easily digestible, require little time to read and have high price elasticities of demand, while, say, poetry readings demand a lot of time and effort and have low price elasticities of demand. Indeed, anything worthwhile from a cultural point of view takes time and effort to appreciate and contributes to a low price elasticity of demand.

Non-fiction books (dictionaries, cookbooks, travel guides, textbooks, etc.) are likely to be close substitutes within each genre and will thus have high price elasticities. Fiction books (children books, mysteries, etc.) often have close substitutes (perhaps with the exception of *Harry Potter*), especially for the pocketbook versions of old titles, and thus high price elasticities. We do not expect large monopoly profits on such titles, and there is little room for cross subsidies to books with a special or unique character. Such books have low price elasticities and generate high monopoly profits. If this is the situation, the cross-subsidy argument is likely to be wrong. The problem with a FBP is that there is no guarantee that publishers/booksellers will use the monopoly profits to make sure that more esoteric titles will be published and stocked in the stores. Monopoly profits may well be directed towards unproductive managerial slack.

4.4. *Fixed book price policies*

In countries like Australia, Canada and the US a fixed book price is not an issue. However, in Europe books are subject to European competition law. Nevertheless, some countries allow for fixed book price policies for cultural reasons. Table 9 presents an overview. There are twelve countries with and eight countries without a fixed book price. The details of the book price regimes differ across countries [see [European Commission \(2004\)](#)]. Belgium, for example, has a self-regulation agreement restricting price competition for six months, after which pricing is unrestricted. In some countries the fixed book price policy may change, because they are tested by the competition authorities. These countries include Austria where the fixed book price is in force until 2005, Denmark where some changes to fixed pricing are under consideration by the Competition Authority, Greece where a recent court case has allowed newspaper stands to sell books at less than the fixed retail price, Italy where the law concerning the fixed book price was extended until 31 December 2004, and the Netherlands where the current law expired in January 2005 and a new law is currently presented to the Parliament. In the

Table 9  
Public policies on books

	VAT rates (2001)		Fixed book price policy
	Books	Standard	
Australia	10	–	No, not since 1972
Austria	10	20	Yes
Belgium	6	21	No
Canada	7	15	No
Denmark	25	25	Yes, adjusted since 2001
Finland	12	22	No, not since 1971
France	5.5	20.6	Yes
Germany	7	15	Yes
Greece	4	16	Yes, since 1997
Ireland	0	21	No, not since 1995
Italy	4	19	Yes
Japan	5	5	Yes
Netherlands	6	17.5	Yes
Norway	0	23	Yes
Portugal	5	17	Yes, since recent
Spain	4	16	Yes, since 1974
Sweden <sup>a</sup>	6	25	No, not since 1970
Switzerland	2.4	7.6	Yes
UK	0	17.5	No, not since 1995
USA <sup>b</sup>	1–7	1–7	No

<sup>a</sup>Before 2002, the VAT rate on books was 25%.

<sup>b</sup>Sales tax.

UK the fixed book price was abolished in the mid 1990s. Because of this smaller independent bookshops claim to have found it harder to remain in business despite offering high-quality service. Prices also went up in the UK, but this may have been due to a shift from pocket to hardcover books.

The UK, Sweden, Finland, Belgium and Ireland do not have a FBP, but the latter two countries are thinking of introducing it. France, Italy, Spain, Portugal, Greece, Austria, Luxembourg, Denmark and most recently Germany introduced FBP agreements in their laws. Most of these are based on the French law (the “*loi Lang*”). The Netherlands exempts collusive agreements within the book trade from the competition bill, but it has not anchored the FBP in the law as such. Some countries (e.g., Italy, Denmark, Spain and soon the Netherlands) exclude educational books from the FBP. Hence, the FBP is with the exception of the UK, Sweden and Finland popular throughout Europe [EIM (2001)]. Some European countries with FBP practise *collective* retail price maintenance, so that all associated publishers impose fixed retail prices on all associated retail outlets. Other countries (e.g., Germany) have *individual* retail price maintenance with prices of some titles free, which may have the advantage of some residual competition and less distortions.

The European Commission is not in favour of the FBP, which it sees as infringement of the ideal of a common market. However, it recently gave up its competition proceedings against the German book price fixing system (the ‘*Sammelrevers*’) because German publishers and booksellers gave sufficient evidence that their FBP did not hinder trade appreciably between member states and thus did not violate the European Union’s competition rules. Effectively, this guaranteed the freedom of direct cross-border selling of German books to final consumers in Germany, particularly, via the Internet. German publishers and booksellers thus will not hinder or put an embargo on direct cross-border Internet sales or on advertising of cheaper German books by foreign retailers. They have agreed not to violate the ‘*Sammelrevers*’, so that they will not cooperate with foreign retailers in order to circumvent the FBP. This prompted former European Commissioner Mario Monti to say:

On the basis of EU competition law the Commission has no problem with national book price fixing systems which do not appreciably affect trade between member states. By clearing the German price fixing system the Commission, in a perspective of subsidiarity, also takes account of the national interest in maintaining these systems which are aimed at preserving cultural and linguistic diversity in Europe.

Thus, there appear to be no European obstacles to national book price fixing agreements, provided that they do not hamper cross-border trade.

In sum, a FBP may induce higher prices and less sales of any book title that is published. It may also hinder innovation and distribution, but more titles will be published and there will be more bookshops with a diverse assortment of titles.<sup>15</sup> In any case,

<sup>15</sup> However, German data suggest that retail price maintenance does not facilitate above average focal pricing where prices are bunched around focal points [Beck (2004)].

many FBPs are of limited duration and characterised by sensible exceptions. The welfare costs are probably not very large, but may be reduced a little by reducing the term and coverage of the agreement. It may also be helpful to abolish certification and exclusive trade arrangements, scrap the fixed discount for recognised booksellers, and move to individual rather than vertical price agreements.<sup>16</sup> Since educational and scientific books typically have relatively low price elasticities and are more susceptible to monopoly abuse, it helps to exclude them from the FBP. As a dogma, the FBP diverts attention and energy away from making the book trade more innovative and customer-oriented. It may be more worthwhile to stimulate reading of a wide variety of books by investing in public libraries and education, subsidising authors to write books of high cultural value, translating the best books into other languages and promoting them abroad.

## 5. Other public policies

Apart from influencing competition in the market for books, governments actively interfere in the book market through prizes, grants, subsidies to bookshops, public libraries and special VAT-regimes for books. This way the government wishes to recognise that books are not products with just economic value, but also have cultural value.

### 5.1. *Stimulating demand: Lower value-added tax*

The general consumption of books can be increased by lowering the specific VAT-rate on books. This is a general instrument, which is not well suited to direct at special books of literary value. The lower VAT on books applies to cookbooks as well to poetry. This instrument is therefore mainly used to stimulate the purchasing and hopefully reading of books. Administrative costs are low, since no apparatus of literary experts has to be called upon. [Table 9](#) presents an overview of VAT policies on books. All countries of Europe, except Denmark, use this instrument. The UK and Ireland even abolished the VAT on books altogether. The European Commission misguidedly attempts to harmonise VAT-rates on books making it difficult for other member states to abolish VAT on books. The Commission fails to take account of the subsidiarity principle. Since book trade especially between the non-English speaking countries hardly distorts intra-European book trade, there is no danger of tax competition and no harm in countries pursuing their VAT-policies on books independently of each other.

### 5.2. *Stimulating supply: Prizes and grants for writers and subsidies for bookshops*

Governments and commercial sponsors do many things to encourage writers. There are many prestigious and less prestigious prizes for the best novelist, the best detective

<sup>16</sup> See also Appelman and van den Broek (2002).

writer, the best poet, the best translator, etc. All of these are meant to encourage quality. More important, they might guide the uninitiated reader to better books. Book clubs, best-seller lists and book programmes on television also help in this respect. They also probably increase sales. Literary funds help struggling authors to make a living if their project is deemed to be of literary interest. Since only best-seller authors can make a living on royalties and related incomes, others may need some help especially if their output has cultural value but is perhaps of less general interest. These policies are designed to stimulate quality rather than quantity. Sometimes subsidies for publishers of high-quality books may help as well (witness Sweden).

Many politicians attach cultural importance to a dense network of retail outlets. Section 2.3 already suggested that density seems to be falling in some countries, perhaps more in countries without a FBP; and concentration is increasing as well. From a cultural point of view this is bad news. Consumers have to travel longer and there is less variety of bookshops. If the main objective of cultural policies is to increase the density of high-quality outlets, subsidies for high-quality bookshops may be more effective than the FBP. If they act as cultural centres in less-populated areas, they may deserve public support.

Subsidising in order to maintain well-stocked bookshops would probably prove an administrative nightmare, which may explain why there is not much experience. Subsidising publishers to publish books of literary and cultural value would also seem to hinder the market mechanism and lead to adverse effects. In Sweden the government subsidises in this manner roughly a third of all fiction and a fifth of books for children. However, Swedish retailers do not stock all titles as the government, rather surprisingly, does not require subsidised books to be offered for sale.

### 5.3. *Make reading cheap: Public libraries*

Table 10 overviews the use of public libraries. Cross-country differences are substantial. With 0.4 service points per 10,000 inhabitants the density of public libraries is very low in France, Italy and Portugal. However, it is quite high with more than 3 service points in Switzerland and the UK. Figure 3(a) shows that in cross-country terms there is a clear positive correlation between public library service points and book titles. Of course, this correlation does not necessarily imply causality. More likely, the correlation has to do with preferences for books. In some countries preferences are low and therefore lead to few public library service points and titles, whereas in other countries the reverse is true. The highest number of library employees is found in Austria, in the Nordic countries and Switzerland. Less than 20 library employees per 10,000 inhabitants are present in Greece, Japan, Portugal and Spain. Two indicators of library use are available: the number of registered users, and the number of library visits. There is a large variation in the first (11 percent in Austria and 59 percent in the UK) but, with the exception of Greece, little variation in the second. Figure 3(b) shows that there is also a positive correlation between public library loans and book titles, though Switzerland is an outlier.

Table 10  
Public libraries, 1997/1999

	Year	Service points	Library employees	Number of books	Registered users	Number of visits	User loans
Austria	1998	2.4	116	1.2	0.11	–	2.0
Belgium	1997	1.5	38	3.0	0.23	–	6.7
Canada	1999	1.2	42	2.4	–	–	6.6
Denmark	1999	1.6	93	5.5	–	–	13.7
Finland	1999	2.2	82	7.2	0.47	–	19.2
France	1997	0.4	22	1.5	–	4.5	1.5
Germany	1998	1.5	29	1.4	0.14	–	4.0
Greece	1997	0.8	17	0.9	–	0.2	0.2
Ireland	1998	0.9	35	2.9	0.23	–	3.3
Italy	1997	0.4	41	0.7	–	4.8	4.5
Japan	1999	0.3	15	1.5	0.28	–	3.9
Netherlands	1997	0.7	53	2.6	–	4.4	10.0

*Notes.* Most recent year. Service points and library employees are per 10,000 inhabitants; book volumes, registered users, number of visits, loans to users are per inhabitant. Source: UNESCO, Statistical Yearbook 1999.

#### 5.4. Bringing the pieces of information together

From the stylised facts presented some conclusions may be drawn. People read fewer books and there are cross-country differences in reading. Some differences are already present at a young age. Females read more than males and higher educated people read substantially more than less educated individuals. Title production is increasing over time. Per-capita title production varies between countries, which suggests that some countries have more best-sellers than others. There are also cross-country differences in VAT and FBP policy. Furthermore, there are important differences in the use of public libraries. In Scandinavian countries, the Netherlands and the UK the use of public libraries is large. In Southern Europe the use is quite low.

To investigate the potential determinants of title production (see Table 5) we investigate to what extent per-capita GDP (taken from the Groningen Growth and Development Dataset), the average schooling level [taken from Barro and Lee (2000)] and fixed book price policies (Table 9) are relevant. We use information for 1975, 1980, 1985, 1990, 1995 and 1999, and allow for country-specific effects to account for possible cultural and taste differences and for time effects to account for changes in production

(a) Book titles and public library service paints, 1990

(b) Book titles and public library loans, 1990

Figure 3. Book titles and public libraries.

costs. We thus estimate the following equation:

$$\log(\text{TITLES}_{it}) = \alpha_i + \alpha_t + \beta_1 \log(\text{GDP}_{it}) + \beta_2 \log(\text{SCHOOLING}_{it}) + \beta_3 \text{FBP}_{it} + \varepsilon_{it}, \tag{3}$$

where TITLES is the number of titles per 100,000 inhabitants, GDP is real GDP per capita, SCHOOLING refers to average years of schooling of the population of age 25 and more, and FBP is a dummy equal to 1 if a country has a fixed book price regime and zero otherwise. Furthermore,  $i$  is a country index, and  $t$  a time index. The  $\alpha_i$  represent country-specific effects, the  $\alpha_t$  are time effects, and  $\varepsilon_{it}$  is an i.i.d. error term.

The first column of Table 11(a) shows the parameter estimates if the fixed effects are excluded. There is a significant positive effect of GDP per capita with an elasticity of 0.86, but neither the schooling level or the fixed book price regime have significant effects. If we introduce country-specific (random) effects, the parameter estimates hardly change. If we also introduce time effects, GDP per capita is no longer significant. Obviously, there is a high correlation between time and country-specific developments in GDP per capita (growth rates are correlated). Because of this, GDP per capita may have a positive effect on title production, but we cannot distinguish this effect from other correlated time effects representing production costs or taste changes. Table 11(a) also

Table 11  
Determinants of book titles and library loans

(a) Titles	(1)	(2)	(3)
GDP	0.86 (2.4)*	0.84 (2.9)*	-0.11 (0.3)
Schooling	-0.23 (0.6)	0.09 (0.2)	-0.02 (0.0)
FBP	0.02 (0.2)	-0.18 (0.9)	-0.20 (1.0)
Country effects	no	RE	RE
Time effects	no	no	FE
$R^2$	0.06	0.35	0.42
$\chi^2$	-	1.6	2.4
(b) Library loans	(1)	(2)	(3)
Schooling	3.55 (5.6)*	1.43 (5.8)*	0.92 (1.9)
Service points	0.41 (2.6)*	0.43 (4.1)*	0.41 (3.7)*
Country effects	no	RE	RE
Time effects	no	no	FE
$R^2$	0.45	0.39	0.38
$\chi^2$	-	4.0	1.5

Notes. Estimation period 1975–1999; titles: 20 countries, 109 observations; library loans: 18 countries, 90 observations;  $t$ -values in parentheses; all variables (except for FBP) are specified as natural logarithms; RE = random effects, FE = fixed effects;  $R^2$  = (within) correlation coefficient;  $\chi^2$  = test-statistic comparing random country effects and fixed country effects.

\*Indicates significance at the 5% level.

shows that the number of titles produced is unrelated to the average level of education and to fixed book price policy.

We also study the potential determinants of the use of public libraries, estimating the following equation for the same countries and years:

$$\log(\text{LOANS}_{it}) = \gamma_i + \gamma_t + \beta_4 \log(\text{SCHOOLING}_{it}) + \beta_5 \log(\text{SP}_{it}) + v_{it}, \quad (4)$$

where LOANS is the number of public library loans per inhabitant, SP is the number of service points per 100,000 inhabitants and  $v_{it}$  is an i.i.d. error term. Estimates are presented in Table 11(b). Average schooling in a country has a positive effect on the number of loans. The effect becomes smaller if country-specific (random) effects are introduced. This suggests that there could be correlation between schooling and library loans, caused by a joint preference for both. The effect becomes even smaller if time fixed effects are introduced, which suggest that over time there is a non-causal correlation between schooling and loans. Nevertheless, even after country-specific and time fixed effects are introduced, schooling has a positive effect on loans. This is not surprising, since (as discussed above) there is a positive correlation between education and reading. Table 11(b) also shows that there is a positive effect of library service points on loans.

Table 12 presents a similar analysis based on information for seven countries over the period 1990–1999 (production numbers are from the International Publishers Association). The estimated equation is similar to the previous one, where country-specific time trends  $\delta_i$  account for possible changes in schooling variable and tastes:

$$\log(\text{TITLES}_{it}) = \alpha_i + \alpha_t + \delta_i t + \beta_1 \log(\text{GDP}_{it}) + \beta_3 \text{FBP}_{it} + \varepsilon_{it}. \quad (5)$$

Now we find that GDP per capita has a positive effect, which is however reduced when time effects and country-specific time trends are introduced. The difference in results between Tables 11(a) and 12 may arise from GDP per capita being more correlated across countries over a long than over a short period. The first column of Table 12 shows that countries with a FBP price regime produce 25 percent more titles. However, this effect is estimated on cross-country differences. If we introduce country-specific fixed effects, the coefficient becomes significantly negative. This negative effect of the FBP on titles is driven completely by the abolishment of the FBP in 1995 and the subsequent increase in titles in the UK.

## 6. Concluding remarks

The book market ensures reasonable cultural performance with little government intervention, especially in large language areas. Yet there are differences between countries in reading, retail outlets, wholesale and production. Due to lack of data and research it is not easy to explain these differences. They may be due to differences in preferences, logistics, population density or public policies or due to being stuck in the wrong equilibrium. One important trend is that people seem to read fewer books over time. Perhaps

Table 12  
Determinant of book titles

Titles	(1)	(2)	(3)	(4)
GDP	0.87 (3.5)*	1.24 (7.6)*	0.50 (2.1)*	0.93 (1.7)
FBP	0.25 (2.9)*	-0.11 (2.2)*	-0.11 (2.6)*	-0.10 (2.3)*
Country effects	no	RE	RE	RE
Year effects	no	no	FE	no

they are reading on the Internet or spending time on other cultural leisure activities. Here are some important areas for further research: investigate the relationship between production of titles, books sold and prices; use survey data to study the effects of personal characteristics of readers on market outcomes; analyse empirically differences between the book market and other cultural markets; and use industrial organisation to understand pricing and stocking behaviour of publishers and retailers.

The book industry is characterised by relatively few market failures and these can be relatively easily corrected with market instruments. The book industry can fend well for itself, in contrast to opera, movie or theatre, characterised by high production costs, high risk and complex interactions between a large number of different professionals. Even though there are obvious returns to scale, production costs are low. Thresholds for beginning authors, publishers and retailers are small, contracts are relatively simple and fairly uniform. The market is quite capable of inventing solutions to specific problems and public policies are not always called for, except perhaps to stimulate reading.

Nevertheless, there is a strong lobby for government intervention. Prizes and grants for authors, translators, publishers, bookshops, special VAT-regimes for books, stimulating reading through public libraries, and the fixed book price (FBP) are possible policy instruments. The standard case against the FBP is that book prices are higher and sales lower than under perfect competition. This hurts the interests of buyers, particularly those with lower incomes since prices will be higher. One possible argument in favour is that the FBP may induce more and better-stocked bookshops and lead to publication of more marginal book titles. The cross-subsidy argument of the lobby in favour of the FBP is not convincing, however. First, even without the FBP, the market cross-subsidises beginning authors and other risky projects in the hope of a possible best-seller. Second, even if this policy “works”, there is no accounting for what is done with the cross subsidies and no democratic checks. Third, there is no guarantee that profits on best-sellers will be used to cross-subsidise less popular books. In fact, pub-

lishers and booksellers have an incentive not to do this. Fourth, if less popular books are less price elastic than popular books (perhaps as they take more time to read), monopoly profits on less popular books are higher and the cross-subsidy argument does not work. Fifth, even if cross-subsidisation does occur, one should evaluate whether its cultural gains outweigh the distortionary costs of the FBP. Arguments put forward to defend the FBP, stressing improved service, better distribution and retail networks, and other forms of increased non-price competition, do not stand up to scrutiny either. The book industry produces many titles and beginning authors do not experience severe problems. The FBP may slow down or even stop the declining number of well-stocked bookshops outside big cities, but hinders sales through the Internet and supermarkets.

A comparison of policies towards the book industry in different European countries teaches us that harmonisation is a bad idea. There is not much inter-European book trade, so that book policies hardly distort the single European market. Also, characteristics of book industry, cultural and social features and political preferences of the different countries of Europe differ substantially. It is therefore best to allow member states of the European Union to design their own book policies. For example, a FBP makes more sense for Greece than for the UK as it has a smaller 'language size' and fewer people have access to the Internet. Although there may be a problem of a 'race to the bottom' if VAT-rates are not harmonised, tax competition seems pretty irrelevant for the book market. European countries should be free to lower or abolish VAT on books in order to promote reading.

Many granted privileges in the book industry will eventually be undermined by technical changes. Digital cameras, recording and editing equipment have made low budget radio and television as well as narrow casting possible, thus undermining the monopoly power of public and other broadcasters. Similarly, the Internet has stimulated virtual book suppliers, printing and publishing on demand and E-books. Virtual dictionaries, encyclopaedia and other handbooks have already overtaken, to a large extent, their physical counterparts. A dense network of well-stocked bookshops remains important. While more retailing will take place through the Internet, for some the physical bookshop where one can feel the book and bump into surprise titles and people, will remain indispensable.

There are, however, trends that endanger books, the most important being that people read less and less. Some worry that the next generation will stop reading books altogether, but this may be too pessimistic. First, the population is ageing so that more leisure time becomes available and the opportunity costs of reading decrease. Second, books are doing great. Back in 1947 85,000 books were in print in the United States, against 1.3 million in 1996. This is, in part, due to sharp reductions in production and printing costs. Third, there is no reason to believe that a cultural carrier as old as the book suddenly disappears. Modern technology more than anything else complements books rather than substitutes for it [Cowen (1998)]. However, as (among others) the French historian of written culture Roger Chartier argues:

The image that has become so familiar, that of surfing the web, clearly indicates the characteristics of a new way of reading: segmented, fragmented, discontinu-

ous. If such reading is suited to encyclopaedic texts, whose fragmented structure corresponds to that type of reading, it is disturbed or disoriented by genres the appreciation of which implies a less choppy reading, a familiarity to be maintained with the work, and perception of the text as an original and coherent creation . . . One of the great questions of the future is whether or not digital textuality will be able to overcome the tendency toward fragmentation that characterizes both the structure of texts and the modes of reading that it proposes.<sup>17</sup>

Each new development in the craft has led to outbursts of cultural pessimism allegedly indicating the end of the book. Most of the developments only improved the book business [Cowen (1998)]. Also, prices fell considerably and steadily. The future of the book market may look very different. Chartier's analysis indicates that E-books will replace parts of the market where E-reading already outperforms traditional reading. As for novels, nobody knows. We do not see ourselves reading Shakespeare from screen, but perhaps our children will.

## Abstract

This chapter studies how and why artistic labor markets have expanded along a path of unbalanced growth. Long-term employment which nurtures the Baumolian cost disease persists only in large, heavily subsidized and sponsored organizations. The now dominant project-based system of production, with its functional needs for flexibility, relies on short-term assignments. Large parts of the business risk are transferred down onto the workforce in vertically disintegrated organizational settings. Artists and technical workers act mainly as contingent workers, freelancers and independent contractors; labor supply is patterned by repeated and discontinuous alternations between work and unemployment, and workers cycle between multiple jobs inside and outside the arts. Thus artistic labor markets display the main characteristics of a textbook model of imperfect monopolistic competition: excess supply of labor, unbounded differentiation of production, reputational rents, a population of small firms that has been growing as fast as the number of artists. On the supply side, the attractiveness of artistic occupations has to be balanced against the risk of failure that turns ideally non-routine jobs into ordinary or ephemeral undertakings. Learning by doing plays such a decisive role that in many artforms initial training is an imperfect filtering device. Individuals learn to manage the risks of their trade through multiple jobholding, occupational role versatility, portfolio diversification of employment ties, and income transfers from public support, social insurance and social security programs. Ironically, the study of the artists' risk management shows how rationally they behave, although artistic work may be highly idiosyncratic. Thus artists may be seen less like rational fools than like Bayesian actors.

How do vertically disintegrated systems of production shape individual careers and organizational behavior? Loose employment relationships do not preclude contractual stability. Employers use reputations as screening devices and signals of employability. Artists learn how to compose balanced sets of recurrent and non-recurrent hiring ties in order to secure a living as well as to increase their human capital. Considerable inequalities in amounts of work and earnings are observed, caused by the skewed distribution of talent and by joint consumption technologies that turn small differences in talent into huge earnings differentials. Inequalities may also trace back to the way a disintegrated labor market operates, since both the allocation of piecemeal work based on reputational rankings and team formation based on selective matchings magnify the power of differences in talent and work opportunity to increase inequality. These factors should not cause the kind of permanent excess supply of labor in the arts that has been noted for decades if the occupational commitment of artists were not combined with the management of business uncertainty through overproduction of infinitely differentiated goods and services.

## 1. Introduction

### 1.1. A steady growth in numbers of artists

Evidence of sustained growth in artistic employment over recent decades is amply documented by several surveys and Census sources, and trends are quite similar in most advanced countries. For instance, in France, over the period 1982–1999 the number of artists grew at a rate of 98 percent; in the USA, from 1980 to 2000, the rate of increase was 78 percent. In both cases, the growth in numbers of artists was much higher than for the civilian labor force. All artistic occupations with the exception of musicians have seen a steady shift towards a higher proportion of women; by contrast, ethnic composition of the artistic workforce remains unbalanced, the non-classical music sphere being one of the relatively few exceptions.

One may speculate as to why artistic employment growth has been so rapid. On the demand side, increases in real disposable per capita income have shifted demand curves for the arts and resulted in an increasing fraction of national income and employment being devoted to the arts. In Europe much of the employment gain, especially in the 1970s and the 1980s, has been attributable to the steady growth of federal and local government subsidies leading to a large expansion of the non-profit sector providing services for artistic training and for conservation and display of cultural heritage. Public spending under non-arts headings (e.g., local economic development, urban regeneration) as well as support for the cultural industries has also stimulated opportunities for cultural employment. Furthermore several industrial sectors which draw heavily on the skills of artists and other creative occupations underwent rapid expansion during the 1980s. The most striking change within the cultural industries was the rapid growth of the audiovisual and broadcasting sector, along with growth in the advertising industry, the new media industries (video, corporate video) and the computer game industry. No less striking is that employment in these growing sectors was mainly on a short-term contract or freelance basis, which magnifies the shift towards numerical flexibility observed elsewhere in the economy [Smith (1997)]. One should also mention the expansion of the crafts and of the design sector, which increasingly contribute to the rise in the numbers of artists in Census data [Feist (1998)].

The economics of artistic labor markets has long paid attention on one hand to the unbalanced growth of stable organizations employing workers on long-term contract and subject to the well-known Baumol disease, and on the other hand to how individuals acting as self-employed workers have to be compensated for highly uncertain prospects in artistic occupations. Artistic labor markets have now evolved to approximate the spot-market model of textbook economics; employment relationships on an unfixed-term basis have largely vanished, and short-term hirings and self-employment strongly dominate. In that respect, arts have often been mentioned as forerunners in experiencing the trend toward increasingly flexible high-skilled labor markets where workers may be hired for only two or three hours, without any costly dismissal proce-

dures. In fact, some parts of the skilled labor force have long been experiencing high flexibility in employment relationships. As stated by Okun (1981, pp. 82–83),

... these weak employer–worker attachments also seem to apply to certain types of blue collar craftsmen who have relatively high skills and earn high pay – construction and dock workers, workers in the printing industry, and so on. These characteristics seem to arise most prominently when 1) an industry has many firms within a locality; 2) a firm has extremely variable demands for labour; 3) the worker’s skill is “general” in Gary Becker’s sense, that is, readily transferable across firms within an industry; and 4) the individual worker’s degree of skill categorized by conventions that develop among employers or unions or through government-sponsored occupational licensing. Carpenters thus may be classed as apprentices, journeymen, or masters; and references from one employer to the next carry weight. In such cases, workers develop an attachment to a local industry rather than to an individual employer.

Okun might have mentioned artists and technical cultural workers as well. Thus the labor market in the arts is a rather paradoxical competitive one. On one side employment is more and more contingent, as in secondary labor markets; on the other side individuals are highly skilled and non-substitutability is a core value, as in the so-called primary labor market. Therefore, though the segmentation of the workforce is fairly strong, the distinction between primary and secondary markets could hardly apply to the arts.

How do short-term assignments translate into worker flows and careers? From a *labor supply* standpoint, one artist equals one long-term occupational prospect, especially when employment relationships are long-term and careers are well patterned. But the gap is widening between the vocational commitment and the way it transforms into a career: self-employment, freelancing and contingent work bring in discontinuity, repeated alternation between work, compensated and non-compensated unemployment, searching and networking activities, and cycling between multiple jobs inside or outside the arts. From a *labor demand* standpoint, the spot-market profile of the arts makes things simpler: the focus is on contracts, on hirings and on works sold on the market. Thus the labor market here can be investigated at its most disaggregated level, that of the series of hirings, of work opportunities and of bargaining relationships. These represent an individual artist’s working life in a given period; when considered longitudinally, they display a career trajectory.

What is the impact of the fact that labor demand is expressed mainly in terms of contingent work? Numerous studies have shown that an increase in the number of artists may be far from corresponding to a similar increase in the level of activity. If there is more work but an ever more rapidly growing number of individuals, a fiercer competition takes place that implies higher inequalities in access to employment, more variability in the level and schedule of activity and on the whole work rationing for those who share the labor pie and cycle more often from work to unemployment or from arts work to arts-related or non-arts work.

The resulting overall picture of artistic labor markets and of their growth is however quite a paradoxical one: employment, underemployment and unemployment have all been increasing steadily and simultaneously. The pattern of change may vary across the different artistic occupations, but the trend is almost everywhere the same. Obviously, fluctuations in supply and demand of artistic labor do not provide a satisfying explanation of what appears to be a highly unbalanced growth. Several historical studies on artistic professions have repeatedly insisted on an “oversupply of artists” phenomenon, which they have associated with changes in the organizational apparatus of the art worlds or with technological innovations or, more radically, with the emergence and expansion of a free market organization for the arts. But in each case, ad hoc arguments may overshadow structural disequilibria; the present development of labor markets for the arts, by highlighting an apparently irresistible trend towards flexibility, helps to understand the underlying processes of such a course of development, namely the pervasive uncertainty of artistic careers, and the ways for individuals and organizations to handle uncertain prospects and to manage individual and business risks.

From a large sample of studies on artistic labor markets, the following picture emerges. Artists as an occupational group are on average younger than the general work force, are better educated, tend to be more concentrated in a few metropolitan areas, show higher rates of self-employment, higher rates of unemployment and of several forms of constrained underemployment (non-voluntary part-time work, intermittent work, fewer hours of work), and are more often multiple jobholders. Not surprisingly, artists earn less than workers in their reference occupational category (professional, technical and kindred workers), whose members have comparable human capital characteristics (education, training and age). And they experience larger income variability, and greater wage dispersion.<sup>1</sup> Taken together, these features portray oversupply disequilibrium [Stigler (1962)]. Moreover, they have been documented for so long that excess supply of artistic labor appears to be permanent and may act as a true structural condition of the arts’ unbalanced growth.

A closer examination of descriptive statistics would provide us with considerable detail about each of these traits and would allow for the kind of fine-tuned differentiation between the several categories of artists that we find in the comprehensive NEA report on *Artists in the Work Force* [Alper et al. (1996)], in the Australian report by Throsby and Hollister (2003), in the British one by O’Brien and Feist (1995) or in French official annual reports based on Census and Labor Survey data [Observatoire de l’emploi culturel (2004a, 2004b)]. However, our main aim here is rather to review explanatory models of work organization and labor supply in the arts and to focus on four main issues: the status of employment and career patterns, the rationales of occupational choice, the oversupply of artists, and occupational risk diversification. Our approach will deliberately be a multidisciplinary one, bringing together a number of studies in sociology, economics and history.

<sup>1</sup> See also Chapter 23 by Alper and Wassall in this volume.

## 1.2. *Definitional issues and methodological caveats*

The definition of art and culture has obviously been broadened as cultural policies have developed. The anthropological definition of culture has become more and more legitimate as public support has taken into consideration the local community level and its whole apparatus (amateur activities, associations, so called socio-cultural activities) by setting up links between art, culture, leisure, schooling and social work. At the same time, one may note an opposing trend in cultural policies; the development of a discourse about culture as a real economic sector. A new form of “cultural accountancy” has in fact emerged that seeks to quantify the economic output of public spending on culture; of course, the wider the definition of culture, the more culture can claim to play an economic role, and the stronger the economic rationale of public support may appear to be, at least at first sight.

These changes also raise definitional issues concerning what the artistic occupations are and where the boundaries of the artistic sector lie. Research on British Census data [O’Brien and Feist (1995)] builds on an occupational as well as on a sectoral breakdown; the redefined categorizations cross both classifications. As a result, cultural work appears to spread across a number of professional occupations and industrial activities; among individuals involved in the cultural sector, 25 percent work in the cultural industries in cultural occupations, 40 percent have cultural occupations outside the cultural industries, and 35 percent work in the cultural industries in non-cultural occupations.

Almost every research report on artistic occupations opens with a list of the limitations and discrepancies of Census and non-Census data including: problems of defining who are professional artists and how their occupation is determined; the delimitation of artistic fields, and the inclusion or exclusion of peripheral specialties within a field; the variations in job classifications and the periodic addition of new occupations to the artists’ subset in the Census classification; and the lack of any serious treatment of multiple jobholding. Regarding the tricky issue of the comparative merits of survey versus Census data, one need only mention the primary source of most variations, as noted above: the definition of the artist. The Census uses a parsimonious classification rule, which narrowly interprets the “chief job activity or business last week”. Two serious problems confront researchers using the Census source [Wassall and Alper (1990)]. First, since many persons who identify themselves as artists are multiple jobholders, their labor market behavior (earnings, working time) cannot be attributed solely to their artistic involvement. Second, those who earn a living mainly in non-artistic jobs, and yet identify themselves as artists, are reported as members of non-artistic occupations.<sup>2</sup> Surveys, by contrast, generally use one or several criteria [Frey and Pommerehne (1989)] and may categorize various activities as art in accordance with the particular interests of

<sup>2</sup> One should add that measurement of the unemployment level in the arts is consequently disputable, since artists switch temporarily to work in different occupations when unable to make a living in their primary vocational field, without stopping producing art works; they would therefore not be classified as unemployed in their artistic occupation if they are primarily engaged in non-artistic work during the Census week.

the researcher. The most controversial of these criteria is, of course, that of subjective self-definition as an artist; this criterion encapsulates a temporal dimension of occupational commitment, since artists may cycle between several jobs and yet continue to think of themselves as artists.

As stated by Adler<sup>3</sup> “a study of artists in a society in which occupational membership is (fortunately) not defined or restricted by a guild, an academy or a state system of licensing can neither comfortably ignore problems of occupational definition nor resolve them”. Indeed, although some of the most remarkable studies by sociologists, economists or art historians on art labor markets and careers have been historical ones,<sup>4</sup> the definition of the artist as well as the orderly course of an artistic career appear today to be dependent variables in the operation and evolution of highly competitive and contestable labor and product markets, interacting or not with state intervention.

Such theoretical and methodological issues are by no means new in social science; labels, taxonomies and classification systems are core issues in interactionist and constructivist sociological theories. Sociologists deal with these matters more cautiously than do economists; while the former run the risk of questioning endlessly the significance of any quantitative measurement, the latter run that of taking for granted that Census data (almost the only source they use) will lead to strong results by virtue of sophisticated econometrics, once the obvious limitations from which the data suffer have been acknowledged.

Despite all these discrepancies, a review of a number of recent studies will allow us to highlight the key issues for a comprehensive approach to artistic labor markets.

## 2. Employment status and careers

The steady increase in the number of artists across all art sectors during the last three decades appears to be driven by the rapid increase of independent, self-managed work, with increasing numbers of artists now to be found in the sectors where self-employed practitioners work such as creative writing, the visual arts and the crafts, and by the rise of contingent work wherever salaried employment relationships prevail. Unfixed-term employment represents a rapidly declining share of the cultural work force today. Only long-lasting organizations such as symphony orchestras, opera houses, and visual art and music schools may hire a large part of their artistic personnel on long-term contracts [Towse (1993, 1996)].

Among the salaried artists who work on a long-term basis, musicians and their careers meet a rather well-patterned job system that has been carefully studied.<sup>5</sup> Bureaucratic careers can be found in permanent orchestras with positions ranging on a well-defined

<sup>3</sup> Quoted in Alper et al. (1996).

<sup>4</sup> For example, White and White (1965), Montias (1982), Ehrlich (1985), Warnke (1985).

<sup>5</sup> See, for example, Westby (1960), Faulkner (1973), Allmendinger, Hackman and Lehman (1994), Allmendinger and Hackman (1996).

scale of status; a majority of the orchestral players become anchored in their organization, experience little or no mobility and become committed to their role in a stable work setting. Advancement on the job ladder is limited since top ranks are filled mainly through external recruiting, so that the mechanics of vacancy chains operate rather poorly. Individual career opportunities develop through mobility within a stratified set of organizations ranked on a hierarchy of prestige, musical excellence, caliber of musicianship, working conditions and operating budgets, either towards similar or higher positions in higher ranking orchestras or towards higher status positions in lower ranked orchestras. Such moves are few in a professional lifetime; as described by Westby (1960), each musician behaves like his or her own employment agency, compiles an inventory of probable and possible jobs, gets information about the approximate ages, professional histories and abilities of the current holders of the most desirable jobs, so as to be prepared for an opportunity that may appear only once in a lifetime. The curvilinear profile of such career mobility means that the artist has to move early to reach the peak of this organizational set, and that chances of mobility diminish rather quickly after an age of 30 or 35, at least with respect to the top-level tier of prestigious organizations. Publishing houses [Powell (1985)] and architecture firms [Blau (1984); Champy (1998)] are additional examples of permanent organizations that combine constraining hierarchies of jobs and career development through lateral mobility. However an increasing proportion of salaried cultural workers now work on a short-term contractual basis. Proportions may vary with national contexts and occupations, but trends are similar and exhibit the search for increasing flexibility and the minimization of fixed costs in the arts.

The search for flexibility is a core feature of artistic work, due to the “high rate of change over time of the content of activities”, according to Stinchcombe’s (1968) phrasing. This occurs for at least three reasons:

- artistic products are often designed as prototypes and their market value depends on their originality and on a more or less pronounced differentiation;
- the combination of activities needed to produce a movie, play or opera involves a large number of different artistic occupations and crafts, and each participant shifts to a new project just hours, days or weeks after the initial one, with new requirements and challenges; and
- consumer versatility and taste for novelty give social and economic value to newness and originality to the extent that these are more or less radically unpredictable. Uncertainty is the true condition of the breakthrough innovation that opens up to its author a new (temporary) monopoly; it is also the threat contained in the destructive aspect of every true innovation. Tastes are subject to unpredictable shifts, especially in the most speculative art markets such as popular music, hyped contemporary painting, blockbuster novels, mass audience designed movies and serials.

Flexibility can be attained through several avenues: a system of performance contracts, a system for transmitting information about the performance capacities of people, and a minimization of overhead costs [Stinchcombe (1968)]. For each project – film,

opera or theater performance, musical show, gallery exhibition – new teams are formed and then dispersed, or parts of the production process are subcontracted afresh. Networks help to build stable relationships that are needed to lower transaction costs; hiring procedures very often operate through patronage and trustworthy ties among peers that rapidly convey reliable information about skills and talents; increasingly hiring also operates through the development of a brokerage system that enhances the role of talent agencies in mediating the labor market for contingent employment [Bielby and Bielby (1999)]. As a result, vertical disintegration in the production and distribution of performances and products has increased. Firms minimize their risks by using contractual relationships which transmit the market uncertainty down the hierarchy of control to subcontractors and ultimately to individual workers.

Consequently, expansion of artistic worlds leads to a rapid increase of the population of employers and small organizations. In the record and motion picture industries, for instance, although oligopolistic market control by major companies remains a striking feature mainly through the control of distribution and finance [Aksoy and Robins (1992) and Storper's reply (1993)], a vertical disintegration scheme at the production level has occurred resulting in an increasing number of independent film producers [Christopherson and Storper (1989); Storper (1989)], record companies [Burke (1997)], and publishing houses [Boin and Bouvaist (1989)]. In the performing arts, the expansion of the non-profit sector and the increase in public support have favored the multiplication of dance companies [Sussmann (1984)], theater groups [Menger (1997)] and music ensembles. Even if demographic trends concerning the rise and fall of organizations differ across the various arts scenes,<sup>6</sup> on the whole the expansion of the “craft-administered” and “flexibly specialized” production sector, with its growing product differentiation, has brought temporary organizations or small organizations to hire performing artists and craft workers almost only on a short-term basis.

Thus performing artists act like independent contractors and cycle between employers and between work and unemployment spells. Although asymmetrical, the relationship between the employer and the freelancer is that of a matching process where both sides build a career interdependently, as carefully demonstrated by Faulkner in his study of the Hollywood job system.<sup>7</sup> Artists as well as entrepreneurs accumulate a history of results and their performance ratings translate into reputations and into distinct industry identities. Careers are two-sided affairs, with entrepreneurs making distinctions among qualified artists, and artists (directors, screenwriters, composers, etc.) making distinctions among film productions. Careers advance incrementally through recurrent and non-recurrent matches; artists learn how to spread their occupational risks by forming career portfolios, i.e. by mixing one-shot ties which are the normal feature of a loosely coupled hiring system and recurrent “bread and butter” accounts with a few producers. Faulkner shows that such a spreading of accounts allows the artist to hedge his or her

<sup>6</sup> For an extreme example, see the case of dance music [Hesmondhalgh (1998)].

<sup>7</sup> See Faulkner (1983) and Faulkner and Anderson (1987).

bets, to get information about a wider environment and to accumulate credits in a human capital investment program through a variety of work, stylistic diversification and adaptation to changing teams. As cumulative productivity profiles greatly differ, distinct matching proclivities segment the labor market; team matchings are neatly stratified in equivalent classes of market agents. Yet given the high variance in activities and the volatility of the cultural industries, career advancement and attainment are never secured.

In the creative arts, self-employment has been for long the prevailing work status. Self-employed artists' careers display most of the attributes of the entrepreneurial career form: the capacity to create valued output through the production of works for sale; the motivation for deep commitment and high productivity associated with their occupational independence (deriving from the capacity to control their own work, a strong sense of personal achievement through the production of tangible outputs and the ability to set their own pace); and a high degree of risk-taking, as shown by the highly skewed distribution and high variability of earnings [Alper et al. (1996)]. Thus, as stressed by Freidson (1986a), self-employment may bring with it only an illusory independence and autonomy; the freelancers who fail to move into the inner circles of successful colleagues get locked in a precarious situation. Being neither a stage process nor a simple bargaining process [Abbott (1990)], career trajectories under a self-employed or a contingent work status combine traits from professional as well as from entrepreneurial careers as defined by Kanter (1989). Artists rely on skills as well as opportunities to take on evermore challenging assignments that bring them greater knowledge and more rewards; they have an external market value based on reputation; they exhibit less loyalty to particular organizations than to the professional community; and they may manage their working life much as property owners do when spreading their risks. Indeed flexibility requirements and career concerns lead individuals and organizations to combine different contractual forms and use many opportunities within a whole range of contractual arrangements; for example, musicians in orchestras can also be hired as freelancers for some studio recording jobs and hold a teaching position in a conservatory, so that the employment-status distinction is somewhat blurred at the individual level.

Thus artists, even if operating as single input firms, may behave like entrepreneurs managing small businesses and work portfolios, and their labor market may be compared to a network of small ad hoc firms trading along matching processes from one project to the other. The analogy with small firms may be taken one step further when multiple jobholding behavior and role versatility are brought into the picture, as shown below. The large number of small artistic organizations and their high rate of turnover may be explained that way, since composers [Burke (1997)], choreographers [Sussmann (1984)] and stage directors [Menger (1997)] can easily set up companies or fringe firms by relying on a portfolio of resources and multiple roles. Although brokerage has emerged as a major device for mediating labor allocation and matching processes in a highly fragmented labor market [DiMaggio (1977); Bielby and Bielby (1999)], artists may be induced to exercise supervisory or managerial skills and in so doing to blur the line between management and labor [Christopherson (1996)]. In that respect, the

artist's earnings, like those of any self-employed worker, depend not only on her skill, talent and effort, but also on how well she performs the managerial and entrepreneurial functions [Aronson (1991)].

According to Weick's notion of self-designing organizations [Weick (1979); Weick and Berlinger (1989)], careers in such a labor system are subjectively patterned since they are committed to impermanence, to cumulative learning and exploration rather than tied to external career markers. Regarding the dynamics of personal growth and achievement, one striking feature of careers in the arts is their temporal aspect: to take only each end of a working life in the arts, precocity often plays a significant role, not only as a mythical feature of the "self-generating genius" topic described by Kris and Kurz (1987), but also a symptom of the ambiguity of the transition from training to work, since many creative artists and performers produce serious work and get credits before their formal training is complete [Menger (1997)]. Conversely, late starters are particularly prevalent among writers [Throsby and Hollister (2003)] and the increasing occupational flexibility of careers also leads to late entry for a second career, whether this be corresponding to a deferred vocational choice or to reconversion following redundancy, as is the case in the crafts sector surveyed by Knott (1994). Of course, self-employment status typically allows for such switches.

The span of a career varies greatly with the type of art (e.g., dance vs. creative writing), with the subsector of each art world (classical dance vs. contemporary dance), with the occupation in it (performing vs. creative work), and with the organizational and market features of each world.<sup>8</sup> Only sharply contrasting examples may be cited here: a conductor's career may extend until near the end of his life with almost no time for retirement, but classical dancers have career schedules constrained by severe physical requirements [Baumol, Jeffri and Throsby (2004); Rannou and Roharik (2006)]. In the high arts sphere, reputation may be a factor explaining exceptional longevity, enhancing the sense of achievement well beyond the average working-life terms [Anzieu (1981)]; furthermore the reputation capital may be converted into an artistic and economic rent, since the famous artist faces an inelastic demand for his praised work [Moulin (1987)]. By contrast, skyrocketing success in the mass-market arts and entertainment industries is subject to sudden shifts in market demand towards new competitors, and is characterized by highly volatile reputations.

### 3. The rationales of occupational choice and risky careers

In most advanced countries, census data provide quite similar pictures about artists' earnings: mean annual earnings appear to be less than those in occupational groups which require similar levels of professional training and qualification. Filer (1986), in a

<sup>8</sup> For empirical research results on careers, persistence in occupations, quit determinants, and transition profiles, see Chapter 23 by Alper and Wassall in this volume.

provocative paper, claimed to have refuted the “myth of the starving artist”, estimating the income penalty in artistic occupations to be less than 10 percent. But his study did not distinguish between arts and non-arts sources of income nor between income from creative activity and that from arts-related work. Moreover, the income gap estimated by Filer varied greatly among the different artistic groups (–69 percent for dancers, +58 percent for actors and directors).

In short, as summarized by [Throsby \(1994b\)](#) and by [Alper and Wassall \(2006, Chapter 23 in this volume\)](#) in their review of numerous studies, artists actually appear to suffer from significant income penalties, to have more variable income both across time for an individual artist and across artists at a given point in time, and to get lower returns from their educational investments than is the case in other comparable occupations. Although data based on similar sources and similar methodological design may be difficult to obtain for a careful comparison of each category of artists’ incomes over time, the distributional evidence remains the same: the skewed distribution of artists’ income is strongly biased towards the lower end of the range and artists as a group experience huge income inequalities. Nevertheless artists are not deterred from entering such an occupation in growing numbers, nor is there as much withdrawal from artistic careers as would be expected.

Are artists irresistibly committed to a labor of love, or are they true risk-lovers, or perhaps “rational fools”, to use Sen’s phrase [[Sen \(1976\)](#)]? The “labor of love” argument [[Freidson \(1990\)](#)] insists that occupational commitment and achievement in the arts cannot be matched to the monetary considerations of a market economy of exchange; they should better be conceived as skilled and sustained activities that entail a transfer value and that artists carry out by making a living in host occupations such as teaching. Artists’ notion of their “calling”, analyzed by [Kris and Kurz \(1987\)](#) as an historically recurring feature of artistic biographical narrative, calls to mind the “inner drive” reported by [Jeffri \(1991\)](#) and by [Throsby \(1994a\)](#) as the foremost criterion of professionalism according to US visual artists. The ideology inherited from the “art for art’s sake” era may even reverse the meaning of success and failure, so that only recognition by the peer group matters, at least in high art worlds [[Bourdieu \(1992\)](#)]. One way to deal with this ideological dimension is to turn it into an inherent cultural trait – a kind of occupational characteristic that goes along with artistic life or, to be more precise, that blurs the boundaries between occupation and private life. However, once this trait is regarded as belonging to the initial socialization process of the artist via a very early manifestation of ability and taste for the arts, such an explanation turns out to be highly deterministic and ultimately tautological; artists are committed to their art and linked to their community of fellow artists whatever degree of success in the market they may meet. Inescapable commitment results in a highly inelastic labor supply function.

The second argument is that of occupational choice under uncertainty: artists may be risk-lovers (whatever origin one may assign to this preference), or they may be induced to take risks by a probabilistic miscalculation. Occupations where enormous rewards are concentrated in the hands of a small number of practitioners while the majority of entrants may do poorly entail a high degree of uncertainty; entry into these fields

is like a lottery where players overestimate their chances, as has been emphasized by Alfred Marshall (1947). The analogy with a lottery is not entirely appropriate; while it is helpful to think of the skewed distribution of incomes as a matrix of payoffs, it would be misleading to suggest that success is purely random and has nothing to do with individual abilities.

A third, less deterministic view may be offered that substantiates an occupational choice dimension without overshadowing the characteristics either of work or of workers. Rewards in artistic jobs are of two sorts: monetary and non-monetary, the latter being “psychic income” flows which have in fact been regarded for a long time as an essential dimension of work. Analytically speaking, every job can be regarded as a bundle of characteristics; wage differentials compensate for more or less attractive work and equalize among workers the total monetary and non-monetary advantages or disadvantages. This theory of equalizing differences [Rosen (1986)], which goes back to Adam Smith, seeks to explain the diversity of characteristics of work and workers by giving central consideration to individual preferences and choice, provided that there is perfect information on both sides of the market. Artistic work can be considered as highly attractive along a set of measurable dimensions of job satisfaction that include the variety of the work, a high level of personal autonomy in using one’s own initiative, the opportunities to use a wide range of abilities and to feel self-actualized at work, an idiosyncratic way of life, a strong sense of community, a low level of routine, and a high degree of social recognition for successful artists. All these benefits have a shadow price, which may be compensated for by a lower income than would be expected from less amenable jobs.<sup>9</sup>

The benefits derived from non-monetary income are, however, not of a uniform magnitude; an analysis in terms of equalizing differences requires that we adjust the total amount of these benefits according to the job, the level of professional achievement, and the conditions which prevail for those in the profession who, still waiting for success, are forced to take on secondary jobs. Comparisons between artists salaried and independent artists [Fohrbeck and Wiesand (1975); Taylor (1987)] reveal, for example, that the latter obtain higher levels of non-monetary satisfaction, but have lower average incomes, higher levels of job insecurity, higher rates of unemployment and greater variance in individual incomes around the mean. On the other hand some studies reject to a great extent the presence of any compensating “psychic income”: the emblematic case of orchestral musicians illustrates the counter-mythology of the artist subjected to the constraints of an organization, resigned to a humdrum and narrowly-specialized job that is very distant from what long years of apprenticeship oriented towards individual accomplishment in a soloist career had led him to expect [Arian (1971)].

Conversely, in contingent work the risk of unemployment is pervasive and insurance devices through long-term contractual relationships are by definition missing. The typical worker will view the risk of unemployment as something that must be compensated

<sup>9</sup> It should be noted that in strong contrast to the ideological argument, especially to its deterministic aspect, people discover what a non-routine job really is only by experiencing it.

for by a higher hourly wage. Such compensation for uncertain labor prospects is in fact observed in the performing arts since intermittent artists and workers earn higher hourly wages than those employed on a long-term basis [Debeauvais et al. (1997)]. The wage premium is paid by employers in order to draw on a reserve army of underemployed individuals whose availability has to be secured; a loss of flexibility in employment decisions would be more costly for firms. Yet this compensating differential scheme operates only imperfectly, since hourly wages are no higher for seriously underemployed workers than for their more successful colleagues.

Compensating wage differentials therefore play their role mainly at the industry level. Individual differences in hiring probabilities are, by contrast, not subject to compensation, leading to another kind of risk. The mechanics of freelance and contingent employment are such that accumulation of hiring acts as a reputation signal in a self-reinforcing process: hiring calls for more hiring. Thus as the intermittent working system expands, at any given time the number of job candidates increasingly exceeds the supply of full-time jobs. In their extensive study on the vertical disintegration and flexible specialization trend in the Hollywood film industry and on its effects on the labor market, Christopherson and Storper (1989) showed that through subcontracting, financing and distribution of independent producers, utilization of less costly production methods and expansion of auxiliary markets, the demand for short-term contract workers increased. They went on to demonstrate that the aggregate quantity of work available increases far less rapidly than the pool of individuals employed intermittently, generating a growing competition and resulting in a decreasing average participation in production. Thus, when production undergoes a process of increasing vertical disintegration, employment instability and labor market segmentation develop; since job allocation takes place on an individual basis and involves on-the-job accumulation of skills and reputation, experienced and network-building artists and workers are frequently hired and face less discontinuous employment than beginners and individuals only loosely connected with the most active entrepreneurs. Thus differences in annual earnings of workers may reflect differences in hours worked more than in wage rates.

Research on the French performing arts labor market highlights these mechanics of work contingency [Menger (2003)]. The French labor market for the performing arts has constantly expanded over the period 1986–2002. However, the supply of work (the number of artists working) has evolved at rates of increase much higher than the demand-side trend (the number of hirings, the number of worked days declared and the total amount of earnings). As a result, the median amount of working time and earnings per artist decreased over the period, although the number of hirings increased; individual intermittent work was increasingly fragmented in shorter hirings, and competition turned out to become fiercer among the growing numbers of artists sharing the less rapidly growing “work pie”. People have been partly compensated for the increasing risk that goes along with the shortening of individual hirings, since hourly wages have been increasing faster than in other sectors. On the whole, however, the decrease of median earnings over the period indicates that employers do not insure the artists they choose to hire under such a working scheme against the consequences of the unbalanced

growth of that labor market. Employers and consumers may benefit from the increasing variety of talents supplying their work, but at the expense of increasing variability in individual working arrangements, both across the workforce and during the career of each artist.

It should be also stressed that the non-monetary dimensions of work contingency might vary with a freelancer's age [Spilerman (1977)]. Artists offer many examples of a "career-line vulnerability to aging"; as they get older, freelancers such as actors appear to be increasingly sensitive to job insecurity and to the steady strain of searching for jobs, of gathering information about new projects and of maneuvering repeatedly to remain visible in a highly competitive labor market [Laplante (1990); Menger (1997)]. Orchestral musicians and dancers also experience well-patterned sequences of job change over their life cycle; the upward mobility chances of the former decrease quite abruptly after about age 35, inducing them to adjust their occupational commitment [Faulkner (1973); Allmendinger, Hackman and Lehman (1994)], while the latter have to plan their transition to a new career at about the same age [Federico (1983); Baumol, Jeffri and Throsby (2004)].

#### **4. Talent, tournaments and the manufacturing of inequalities**

The "equalizing differences" argument is attractive for its elegant parsimony. Artists who remain in artistic occupations despite low and uncertain earnings gain something else that has to be taken into account in order to preserve the rational occupational choice frame; the additional income flow that one would expect to draw from another occupation has been exchanged for psychic goods. However such an argument formulates its notion of the compensating wage premium with respect only to the differences in average income levels across occupations standardized for a number of individual income-related characteristics (mainly education, experience, age, sex and ethnicity, location of residence and of work). From a distributional perspective, artistic occupations show a strikingly high variance in income. Factors behind this skewedness include talent, the formation of teams and the existence of tournaments in the arts.

##### *4.1. Talent*

Stinchcombe (1963) distinguishes between talent as a complementary factor of production and talent as a nearly additive factor. The former is found in firms, activities and positions (e.g., scientific research, soloist performances in classical music concerts and lyric productions) where output value may benefit more than proportionately from inter-individual differences in levels of ability; accordingly, earnings inequalities are high. By contrast, the distribution of rewards is less skewed and seniority a more important factor where individual performance has a less dramatic impact on the value of the total pro-

duction, as in a symphony orchestra.<sup>10</sup> Moreover, in the first case small differences in talent can become magnified into wide earnings differences, as shown by Rosen (1981) in his superstar model;<sup>11</sup> on the demand side lesser quality is a poor substitute for greater quality, so that preferences are strongly biased towards the latter, while on the supply side, due to joint consumption technology (that of mass production and the distribution of art and entertainment through records, books, TV, radio, etc.), the marginal costs of production do not rise in proportion to the size of a seller's market, but profits do. This is all the more so as media technologies and the internationalization of markets expand the scope of talent valorization. Such a model is consistent with the distribution of incomes observed in the industries relying on scale economies of joint consumption.<sup>12</sup> However, it has been objected that the basic assumption that small differences in talent may lead to huge return differentials requires a measurement of talent and quality other than income [Hamlen (1991, 1994)]. As that measurement is impossible to standardize in those artistic fields in which creativity runs against widely accepted canons (as opposed to the calibration of performances of a standard repertoire of works by unequally skilled performers), the explanatory power of the Rosen model underscores why the process of valuation of art and artists is indeed subject to considerable inflexibilities, asymmetries and imperfections.

Creative artists and their works are usually ranked according to notions of talent rather than skill. Artistic creation is built on a distinctive property, that of fine-grained differentiation of its products due to highly individualized strivings for originality and novelty. But how can talent be measured if its embodiments come to life under the rule of infinite differentiation? And should we accept in the name of creative talent all aesthetic infringements, especially those that break repeatedly with conventions, traditions and norms? The multidimensional nature of differentiation encourages recognizing many different embodiments of originality as true manifestations of creative talent. Yet critics, experts and consumers never cease making comparisons by ranking filmmakers, visual artists, writers, composers or actors. Both the market sellers, experts, critics, and eventually the end consumers sort and organize in a hierarchy those products of individual creativity which the criterion of originality by itself would tend at first sight merely to juxtapose. This occurs through multiple comparisons, disputes, controversies, strategic maneuvers, affiliated evaluations and marketing policies that turn horizontal differentiation into a vertical and inegalitarian one, based on more or less overtly publicized market scores and reputation ratings.

<sup>10</sup> On the additively separable vs. multiplicative production function, see also Caves' (2000) and Seaman's (2003) comparative study of cultural and sport economics.

<sup>11</sup> See further in Chapter 25 by Adler in this volume.

<sup>12</sup> See, for example, Menger (1997) for differences in actors' earnings distribution in theater vs. audiovisual and cinema industry.

#### 4.2. Teams

Another main dimension of this manufacturing of spectacular inequalities is the matching of individual skills and abilities within a world seeking to mine increasing productivity benefits from new designs of teamwork. The flexible organizational architectures most prevalent in this world (networks, project-based organization and vertically-disintegrated systems of production) favor structuring teams by co-opting professionals of similar reputation or quality – in other words by selective matching. A successful career means upward mobility within a stratified world of network collaborations by optimally mixing recurrent and unique ones [Faulkner (1983); Baker and Faulkner (1991)]. Theoretically speaking, the selective matching process between similarly high-skilled agents or talented creative professionals within team projects combines Rosen's analysis of multiplicative quality effects with Gary Becker's analysis of matching in marriage markets, as proposed by Kremer (1993) in his O-Ring theory of economic development. To the Stinchcombe distinction between the complementary vs. additive dimension of talent as a production factor, this model adds the notion of increasing returns to skill according to a non-standard production function, once the workforce of a firm or of a team project is considered as a whole.

#### 4.3. Tournaments

In the art world, as in the sport world, highly unequal distributions of both monetary and non-monetary rewards are not only tolerated but demanded and even celebrated through all sorts of devices: celebrity tournaments, prizes, Oscars, awards, competitions of all sorts, publicity for highly priced artworks, lists of best selling novels and records, media coverage of super incomes, etc. Even though individual dedication to creative work is supposed to belong to the realm of intrinsic motivation, the business of fame turns inequality and hierarchy into subjects for fascination and admiration. These labor markets are built on the most astounding defense of inter-individual competition. Indeed artists' talents and their outputs' quality may be hardly judged by standardized, cardinal measurement devices; as stated by Lazear and Rosen (1981), competitive lotteries are here superior to more familiar compensation schemes.

Yet critical expertise is fallible, a matter that is less harmful for the critic than for the misranked artist [Ginsburgh (2003)]; moreover there are countless cases of collusive maneuvers, critical herd behavior, or even illegal practices such as payola [Coase (1979); Caves (2000)]. Actually the valuation process that produces quality ratings and translates them into rank positions is a noisy process, and the sorting procedure of the best has its long-lived pathologies. Artistic markets also generate a causally reversed rating process due to a cumulative signaling advantage, fairly similar to the Mathew effect observed by Merton in science. Since the market for artistic products and performances is an imperfectly competitive one, problems arise as to how consumers can know and appraise many characteristics of so many widely differentiated goods. Employers have search and information costs, as do consumers. Both may minimize their search costs by

using price or the artist's reputation as an index of quality. An artist's established reputation is less elastic to perceived and appraised quality than the competitive structure with its tournaments and sorting rankings would suggest. The vocabulary of reputation also brings to light the fact that the appraisal of art and artists varies with the organizational traits of each art world, since it reflects the cooperative and competitive activities of the various members of each world. Several dimensions of appraisal exist, of which the spot market value of the outcome is only one. Deferred financial success occurs especially in art markets where the appraisal is initially undertaken by a narrow community of experts and learned consumers, and where a capital of recognition may be accumulated that is eventually converted into an increasing share of demand, which may provide the most famous artists with a slowly increasing flow of earnings [Bourdieu (1992)].

## 5. The excess supply of artists

### 5.1. Causes of excess supply

Sociologists, economists or historians dealing with artistic labor markets have almost always referred to the oversupply of artists. For example, in their analysis of the economics of musical composition in Mozart's Vienna, Baumol and Baumol (1994) explain the "profusion of composers" by the merging of two forces, that of the still powerful imperial patronage and that of the rise of the free market, a process entailing an additive effect on employment opportunities and on the attraction into the musical profession of many "who would otherwise have sought to earn a living elsewhere" (p. 73). In the first half of the nineteenth century the glut of novelists and poets in Paris led to Parisian bohemianism and accounted for the success of the "art for art's sake" ideology, which acted as a compensating device for the subordination of the artist to impersonal market forces [Graña (1964)]. In several other European countries, literary proletariats were similarly spawned by the mid-century publishing boom.

The Impressionists' revolution took place in a Parisian art world whose institutional apparatus – the Academic system – was collapsing under pressure from the greatly expanded number of professional painters. White and White (1965) show how control was lost over the flow of recruits through art schools, the flow of paintings produced, and the careers of the painters; a free market took over to launch innovative artists and movements on a more flexible and also much riskier basis of open competition involving dealers, critics, painters and buyers. Supply was no more to be regulated, hence oversupply became a permanent feature of that market. Furthermore, in Berlin and Munich at the turn of the century the art market was similarly overcrowded with painters competing for recognition and success; periodic panics about the glut and the high rate of unemployment didn't deter students from entering art schools in growing numbers [Lenman (1989)]. A further example comes from the minute study of the music profession in Britain carried out by Cyril Ehrlich (1985) who reported substantial evidence of a glut at the turn of the nineteenth century, at the end of a 60-year period during which

musicians had become one of the fastest growing professional groups; he showed how musicians, aside from lamenting over the damnable flood, tried to react to the pressures of relentless competition and its consequences (very low fees and depressed incomes, underdealing practices, etc.) by establishing professional associations and trade unions, despite increasing segmentation among the workforce.

Summarizing the evidence at hand, [Lenman \(1989\)](#) states that

... the problem of surplus artists was part of a much broader, international cultural phenomenon. Between the 1860s and 1914, for example, steeply rising enrollment in German higher education led to periodic panics about overcrowding and unemployment. In several European countries, literary proletariats were spawned by the mid-century publishing boom. Music and theatre were overflowing with excess labour; in Britain in 1891 there were nearly twice as many musicians as bank clerks, and extreme variations in status and pay. Though the market free-for-all enhanced the importance of dealers, agents, professional organizations and other stabilizing elements, it also created a reserve army of starving music-teachers, hack authors and painters forced into all kinds of low-grade and shady occupations (p. 131).

In each of the cases mentioned above, a similar array of factors is invoked: a rising level of demand (enhanced by factors such as urbanization, increasing educational level, growing incomes, more leisure time, public support), changes in the commercialization of art that bring market principles of organization and bargaining into harmony with the stream of artistic innovations, and technological innovations affecting the transmission and distribution of art. Unlike short-term fluctuations that may be provoked by fads and fashions, long-run shifts causing an increase in private and/or public demand trigger an expansion in training facilities, and more artists appear. But, as Ehrlich shows in the case of musicians, inflexibilities may dramatically hinder the equilibration process if demand turns down, as in the case of the briefly flourishing demand for musicians in cinemas which collapsed with the coming of talkies. Existing practitioners are trapped in a disintegrating market while new aspirants continue to flood in; the training system may play an unintended role in the self-congesting spiral of oversupply, since teaching positions and kindred activities in non-profit art organizations shelter artists from occupational risks.

Innovations in artistic production resulting from the interaction between new techniques, aesthetic shifts and market transformations have often been studied in respect to their impact on labor supply. Some of these innovations tend to lower or to modify the usual skill requirements, and/or the quantity of input factors in the production process, resulting in an increase in artistic productivity, a growing competition among artists and a declining control over entry and professional practice through the traditional devices of the professionalization system.<sup>13</sup> Also technical innovations such as

<sup>13</sup> Among numerous possible examples we may cite the new methods of production of paintings in seventeenth-century Holland [[Montias \(1996\)](#)]; the deskilling process at stake in many avant-garde innova-

motion pictures, radio, television, records and other recent changes increase the extent of scale economies in artistic and entertainment activities [Rosen (1981)]; as the market supply of works and services grows, the scope of each performer's audience gets larger, and more numerous artists are induced to enter the labor market, though some occupational trades and niches of specialization may disappear. Even if this results in a greater concentration of rewards among the most talented who can operate on an international scale, the lure of enormous rewards and the associated social recognition may favor gambling behavior, as success seems like a lottery game in a more speculative market of talents.

Organizational flexibility in the arts plays a major causal role in nurturing steady over-supply. For record companies or book publishers,<sup>14</sup> overproduction of new items, along with the allocation of numerous personnel to boundary-spanning roles and co-option of mass-media gatekeepers, is a rational organizational response to an environment of low capital investments and demand uncertainty, especially in the most speculative and entrepreneurial segments of the market; because of a strategy of differential promotion of the numerous items released, the firm's attention eventually focuses itself on a small proportion of them. Since "nobody knows", too many contestants are induced to enter the success race [Caves (2000)]. The same holds true for employment relationships in the performing arts. Employers in project-based performing arts organizations seek to draw from a large pool of artists and personnel in order to reduce overheads and build efficient and well-matched teams, gaining from the variety of talents and skills at hand.

## 5.2. Agglomeration and congestion

Excess supply of artists is still more than ever evident today. Its spectacular manifestations occur exclusively in the main cities where artists and cultural producers and employers agglomerate [Menger (1993); Scott (2000)]. An effective way to overcome the complexities of a vertically disintegrated and highly flexible production process is indeed to rely on spatial concentration. Especially dense transactional relationships between production units have geographically-sensitive cost structures. The greater the costs per transaction, the greater the probability that firms will agglomerate in order to benefit from external economies of scale [Hall (1970); Storper and Walker (1989); Glaeser (1998); Quingley (1998)]. This leads to an original scheme of competition between the firms. The distinction between short contractual arrangements (at firm level) and employment processes (at industry level) is blurred by the multi-sided activities of each worker as well as by the dense formal or informal relations between employers. Indeed, artistic production is based on three components:

tions in visual arts [Moulin (1992)]; the pop music revolution [Peacock and Weir (1975)]; and the success of dance music [Hesmondhalgh (1996)], which can be partly explained as the result of the widespread availability of production technology, the transformation of the record industry, shifts in authorship and the segmentation of market demand.

<sup>14</sup> As highlighted in Hirsch's pioneering paper [Hirsch (1972)] and by Coser, Kadushin and Powell (1982).

- a nexus of ties between firms involved in the different parts of the production process and between the many employers who draw from the artistic labor pool;
- an original way of processing information through this network in order to minimize the costs and length of sorting and hiring operations; and
- conventional industry-wide negotiations and arrangements regarding wage and reward schemes as well as the mitigation of risky employment prospects.

Employers compete for contracting with the most profitable talents, but they all need to have access to a reserve army of artists; they are of course better off if the major part of the costs of securing pools of employable artists fall on these mechanisms.

For these reasons artistic activities show a very high level of spatial concentration in a few locations or even in one dominant city in each country. A threshold or critical-mass effect exists both on the supply and the demand side, as suggested by Blau's study of the cultural organizations in the largest US cities [Blau (1989)]. The relation between increase in the city population and increase in cultural supply (artists, organizations) is linear in the case of popular culture, but multiplicative for elite arts institutions. In other words, popular culture depends directly on market forces and consumer sovereignty, when the less popular high culture needs a larger pool of potential consumers to develop. It is also remarkable that even in the presence of an actively decentralizing cultural policy, as in France over the last two decades, the concentration of artists and art professionals did not significantly decline. The Parisian case is striking: during the 1980s, the population of artists and professionals involved in cultural production expanded rather rapidly in France (+55 percent between 1982 and 1991) but the share of artists living and working in Paris and the Parisian region also increased (from 45.8 to 54.1 percent).<sup>15</sup>

Artistic supply also has its seasonal congestion peaks. The dramatic example of the 19th Century annual Salon exhibition in Paris has been for a long time a prime symbol of a congestion phenomenon in the arts, with exhibition halls full of paintings from the bottom to the ceiling.<sup>16</sup> Today we see bookstores overwhelmed by crowds of debutant writers' novels, especially at the start of the literary calendar – how often do critics lament over the crazy publishing policy that releases hundreds of such novels over a very short span of time during the literary prizes peak period in Paris. Or take the example of the simultaneous release of many big-budget movies on the same weekends, discussed by Camerer and Lovallo (1999) in their study on overconfidence and excess entry. One may also mention the ever more numerous classical musical contests with queues of contestants trying to win a prize and to attract critical and public attention, although in this case filtering procedures<sup>17</sup> are quite strict, unlike the situations mentioned by Camerer and Lovallo where the criterion for success is more vague and ambiguity permits excess optimism, letting people or firms overcompete.

<sup>15</sup> See further in Menger (1993).

<sup>16</sup> As satirically drawn and painted by Daumier.

<sup>17</sup> Note, however, that these procedures are subject to significant evaluations biases such as the order of appearance at the competition, as studied by Ginsburgh and van Ours (2003).

Excess supply of artists, insofar as it is causally related to the lottery-like structure of occupational prospects in the arts, has been subject to interpretative controversies among economists. Frank and Cook (1995) call into question the way the winner-take-all markets operate, with their damaging features; the payoff structure generates a spiral of individual and social occupational waste, since it leads both to increasing inequalities in monetary and non-monetary rewards, overcrowding in markets, and occupations prone to an overestimation of one's chance of success. As a result when excess numbers of contestants are induced to invest in performance enhancement in order to raise their individual odds of winning, these investments will be mutually offsetting and socially inefficient; end consumers may get more valuable products but the social costs are excessive. By contrast, Cowen (2000) argues that the superstar effect is welfare-improving (consumers get better performances) even if it leads to increased income inequality, but that it should not be overstressed. Indeed, fame is a positive-sum game, not a negative nor a zero-sum one. Instead of an unambiguously increasing concentration of rewards, Cowen states that countervailing forces operate such as a convergence of quality that limits the ability of the very best stars to dominate the market for long, or more radically the elastic supply of fame, so that when demand for fame increases, the number of prizes, rewards etc. rises too.

### 5.3. *Monopolistic competition*

Common traits of monopolistic competition include high product differentiation (works and performances), a large variation in consumer preferences and excess capacity of production [Lancaster (1979)]. The application of a monopolistic competition model to the market for art works is well known. In regard to artists, a temporary monopolistic position in the market may be provided by an artist's reputation, as long as her skills and talents are in demand. As cultural industries develop, several markets get related and monopolistic return to reputation may be increased according to different pricing schemes. A striking example is provided by Krueger's (2005) study of the market for rock concerts. Uniqueness of sound and style of a rock band, when successfully meeting the consumer demand, provides it with a monopoly power. Until the late 1990s, famous rock bands were able to exploit the two complementary markets of concerts and records. Krueger assumes that when greater concert attendance correlates with greater artists' record sales, artists may be induced to price their tickets below the profit-maximizing price for concerts alone. When new technology allowed many potential customers to download music, the link between the two markets weakened. Krueger's data and statistical study show a sharp increase in the average concert ticket prices and in price dispersion from 1996 to 2003; star bands were able to compensate for their income loss from declining record sales by maximizing their monopoly profit from concert attendance.

In theory, the supply of artistic talent is infinitely differentiated; every artist claims to be endowed with unique skills and to supply original achievements. One may therefore speculate about generalizing the monopolistic competition model to the entire work-

force of creative and performing artists. The level of reputation, the amount of work, and the degree of occupational success vary considerably among artists; shall we consider as monopolistic suppliers of their own work not only those artists who face a rather inelastic demand curve due to their temporary or established fame, but also those in the lower segments of each artistic occupation who are induced to act as monopolistic suppliers (i.e. to trade their human capital and work as freelancers) although their market value and market power are very poor? In the latter case, young aspiring artists, or moderately or poorly successful ones, may claim to be endowed with a unique set of skills, talents and abilities, yet do not benefit from the rent attached to its seemingly monopolistic supply.

Consider also creative artists whose compositions, paintings, manuscripts and screenplays are put up for sale by gallerists, publishers, talent agencies and so on. Because most of them are self-employed, it would seem meaningless simply to equate fewer working hours with unemployment spells or underemployment levels. Their income does not derive from a quantity of working time at a given wage rate [Frey and Pommerehne (1989)]. Creative artists decide whether or not to continue to work in their chosen field according to their income and to the stream of their expected earnings. If their income is low, because of low demand for their work, a simple increase in production through more work may have no effect and an increasing supply of the works for sale at lower prices may not trigger an equilibration process, since the price acts as a signal of quality and a decrease in the pricing of a contemporary artist will promptly be interpreted negatively. Since these artists can make their own work opportunities, oversupply of the works they produce cannot be defined at any given price; this explains why so many creative artists, though working hard and being fully committed, may suffer from low or very low income levels, and develop a sense of null or even negative correlation between effort and earnings in their vocational trade.<sup>18</sup>

Caves (2000) views creative products as a mixture of vertical and horizontal differentiation. This may help solving the intriguing issue of the competitive nature of artistic labor markets. Horizontal differentiation stems from the fact that artists and their work differ from one another in many ways; vertical differentiation refers to the rankings of artists according to their skills and level of talent, and to the quality and originality of their products and performances. The mixture of both types of differentiation may blur the ranking process and generate evaluations that are disputable and volatile. Would excess supply be less pathological in the arts if artists worked more uniformly like scientists? In the sciences, the winner-take-all structure of competition takes an extreme form wherever the priority race in discovery prevails. There is only one winner in each race, and inequality with regard to scientific productivity and to the awarding of priority is considerable and increases over the careers of a cohort of scientists, due

<sup>18</sup> As reported by Moulin (1992) in her extensive study on visual artists.

at least to some state dependency and cumulative advantage process.<sup>19</sup> The priority system obviously creates an excessive attraction to scientists in certain extremely well-rewarded contests. Note however that this portrayal of scientific competition mirrors the vertical differentiation process of creative destruction of knowledge when innovation proceeds along predictable paths of accumulation. Yet the creative game in science also has a serendipity dimension and benefits from hybridization of different specialized knowledge. Since every scientific field grows by splitting itself into increasingly fine-grained subspecialties where the intensity of competition varies according to the prominence and reward-generating power of each field, room is left for more horizontal differentiation and its subsequent monopolistic competition aspects as well as for cross-disciplinary innovations.

Vertical differentiation in the arts goes closer to that found in the sciences whenever a dialectic process of discovery, obsolescence, destructive creation of styles and languages takes place, especially in the fine arts and within periods of time strongly committed to the *avant-garde*. Under such conditions, priority becomes a key value and generates a strong opposition between an elite group of innovators, groups of followers, and crowds of more or less instantly displaced artists producing old-fashioned art whose market shrinks and eventually vanishes. However it is well known that such a priority-driven competition scheme fits only parts of the artistic production landscape. Caves' analysis very aptly captures the complexities of the valuation process within a context of mixed production:

The process of distinguishing significant innovation from everyday creativity varies among creative activities due to the filtering porosity of their filters. In a creative activity with tight and clearly articulated standards of performance, critical presumption is loaded against the acceptance of novelty as a valid and desirable innovation. An innovation must either carry the credential of manifest face value, or eke out slow victory in localized skirmishes between novel and traditionally accepted creative goods. On the other hand, an art realm that welcomes any novelty as a noteworthy innovation necessarily lacks consensus on any critical paradigm. Critical rankings lose their value for consumers to calibrate and rationally order their selections among creative wares. A list/B list rankings are impaired for contributing to the efficient organization of complex creative activities. It is the old issue of liberty versus license. A creative activity that yields the most value for its participants as a group will need a suitable compromise between tight critical standards that resist those innovations that will ultimately overrun the "establishment", and loose standards that yield no stable valuations or points of reference to guide either artists' training or consumers' investments in cultural consumption capital [Caves (2000, pp. 202–203)].

<sup>19</sup> See Stephan (1996) for a review of the literature.

## 6. Remedies to excess supply? Creative prospects and chances of self-actualization

Things would be simple if artists could form correct expectations about their chances of success or at least about their odds of decent living within the occupational sphere they choose to enter. Competition would seem to be less wasteful, failures and occupation switching less frequent if not marginal, misallocation of talents due to excessive lure of stardom or of self-achievement promises wouldn't hamper the development of other occupational worlds that might be short of such diverted abilities, training systems wouldn't favor wasted investments, risky occupational prospects with their possible generous unemployment insurance wouldn't claim increasing public support at the expense of other economic sectors, and competition might gain in fairness, since artists would have enough time to prove themselves.

Such an argument has a strong and a weak version. The *strong* version is that of an optimal allocation of talents according to an "optimal division of labor" scheme. Such a world can be found in functionalist models of society originating in early Durkheimian sociology, and also in some economic models of welfare analysis of work such as Lancaster's model of optimal division of labor which matches people to the occupation where their abilities and skills are optimally employed. Required are: a set of well-defined standards of performance and creative content on which critical evaluation and competition may be based; the optimization of the educational and training system that detects abilities and provides individuals with the best-fitting skills; and the use of optimal reward schemes that deter people from choosing what happens to their first-best occupational fate.<sup>20</sup> This view could hardly apply to art. In its sheer essence, art has been celebrated and valued as the symbol of creative, innovative and non-routine work. Creative and non-routine work provides psychic and social gratification proportional to the degree of uncertainty of success. The more the work is non-routine, the less one can be certain about the immediate or long-term chances of individual achievement. To be sure, artistic work also entails routine aspects both in relative and absolute terms.<sup>21</sup> Yet as the non-routine dimension points to the challenging and intrinsically rewarding side of work, it gives artistic creative work its differential value. Performance in non-routine activities does not depend on skills that could be easily objectified, transmitted and certified in the training system. Indeed, the impact of schooling on earnings is typically

<sup>20</sup> The two Lancastrian propositions in his welfare economics of work are, first, the optimal match proposition: "Among all the allocations of persons to jobs which satisfy the requirement that every person holding a job has the skills needed to perform it, there is an optimal allocation", and second, the optimal division of labor proposition: "If the number and specification of jobs can be varied, there is an output-maximizing division of labor which gives the greatest output from the skills available in the population and an optimal division of labor which gives the greatest overall welfare from work and consumption. The output-maximizing and optimal divisions of labor need not be the same" [Lancaster (1979, pp. 326–327)].

<sup>21</sup> Various artistic occupations and individual achievements may be ranked according to how routine or non-routine the work is, and no artist could every time reconstruct afresh his own frame of activity and no collective work could be achieved if conventions didn't exist as stabilizing forces [Becker (1982)].

smaller for artists than it is either for all workers or for managers, professionals and technical workers [Filer (1986, 1990)]. Insofar as non-routine activity refers to a wide range of changing and challenging work situations, it therefore implies that abilities may be revealed and skills acquired only progressively through a process of learning-by-doing which is highly informative and which cannot be perfectly anticipated *ab initio*. Even if one were to assume that innate abilities command success much more than formal training, talent could express itself only by coping with work situations that reveal the multiple characteristics of what artistic achievement really is.

A *weak* form of the optimal division of labor argument is the optimal trial-and-error process. If talent can be detected more rapidly, then quit rates in artistic professions will be much higher and turnover rates will help to form more realistic expectations about one's chances. And if artists behave rationally, expected risky occupational outcomes should be experienced in a way quite similar to that predicted by the theory of option pricing in finance. An optimal sequential decision scheme orders occupational alternatives with respect to risk; it is rational to choose the job with the greater risk first and to switch to a less risky alternative if the outcome turns out to be unfavorable. In the spirit of Johnson (1978) and Jovanovic (1979), MacDonald (1988) applies his theory of job assignment and sequential accumulation of information [MacDonald (1982)] to artistic careers; he conceives of the stochastic dynamic superstars model as a model of occupational choice where performers accumulate information on the likely outcome of a subsequent performance and learn to rate their job match.

Indeed, in a realistic dynamic occupational choice model, informational considerations are brought in, as in the job-matching approach of occupational choice [Miller (1984)] that seems to fit rather well with the results of surveys on the careers of freelancers. Job applicants learn only gradually how well they are suited for a particular artistic occupation and to what extent they can expect to meet success in it. It is a costly and rewarding "trial and error" process; one becomes more and more informed about the various facets of the occupation and about one's own abilities through doing the job. Workers accumulate skills through experience and learning-by-doing. As non-routine work implies a steady human capital investment, it takes place in a matching process where jobs are "tied packages of work and learning" [Rosen (1986)] and are ranked along their varying learning potentials, as shown in Faulkner's (1983) research on freelance composers in Hollywood. The attractiveness of artistic jobs can therefore partly derive from their high learning potential, at least as long as the work is non-routine enough. In fact, many artistic occupations provide this kind of information only through a learning-by-doing process, either because formal training is not strictly required to enter the professional community and to succeed (in some artistic occupations like that of writer, formal training seldom exists), or because formal training doesn't act as an efficient means for selecting talents and for screening abilities. This is probably why so many artists think of themselves as self-taught, even in occupations where formal training plays a genuine role. For example, most actors, while satisfied with the technical aspects of their training, are nonetheless critical of the lack of preparation; information about one's abilities and chances of successful professionalization is mainly

acquired in the course of practicing [Jackson et al. (1994); Menger (1997)]. Yet the learning and information acquisition process is costly; jobs where one can benefit more from learning-by-doing are on average less well-paid initially than jobs where applicants can be selected on the basis of university degrees or through other immediate skill certifications.

However, application of this job-matching model to artistic occupations raises two issues. First, it may be asked how much information one needs before being able to assess the quality of one's job match, considering that occupational practice acquires so many different forms, and takes place in so many environments and in relation with many diverse employers and patrons. In addition, this high variability in practice probably influences the artist's behavior regarding risk-taking. In some respects, each work experience in the performing arts such as theater or movie production is unique, and each team of artists and technicians is different; there seems to be no end to the learning process and to the assessment of one's talent and no situation seems really crucial when one has to decide how far to go in such a career. This could explain why many artists maintain for so long the hope that they will eventually become famous, even after death. Romantic writers and poets invented a psychological and ideological device for fighting against short-term disenchantment: the "loser is eventually the winner" game [Sartre (1971); Bénichou (1985)], which designs the consolatory counterpart – the "loser-take-all" society – of the world depicted by Frank and Cook (1995). More generally, under a highly flexible working scheme the explanation of oversupply by the "risking-and-learning" model is especially appealing. Where information about the quality of the individual occupational match is delivered only through on-the-job experiences which are subject to contingency and discontinuity, aspirants are not screened at entry; experiencing the more or less unbounded autonomy of creative work may raise the non-monetary valuation of work and lower the opportunity costs of the choice to stay in the trade, even if facing low success. This helps explaining why barriers at the exit may rise although dropping at the entry.

Second, once multiple jobholding is taken into account, risk diversification considerations may suggest an enlarged definition of occupational choice, where several related jobs provide switching opportunities that may result in a cycling pattern between various kindred activities instead of building irreversible sequences of choices. In this case, an interesting way to test the assumption that, against the standard economic view, workers may derive satisfaction from the process of work itself and not just from the income it earns, is to study whether artists turn down better-paid jobs in order to pursue their vocational work. In estimating labor supply functions for Australian artists with arts and non-arts wage rates as explanatory variables, Throsby (1992) showed that artists supply the non-arts labor market only up to the point where an adequate return is received to support their primary artistic work. Similar results have been obtained by Alper and Galligan (1999). It follows that the notion of oversupply due to labor rationing turns out to be questionable [Killingsworth (1983)] when the standard model of conventional income and substitution effects on leisure has little relevance and when the causal link between oversupply and rationing refers to a disequilibrium in only one of the labor mar-

kets the artists supply, that of their principal vocational work. When multiple jobholders cycle between rationed and less- or unconstrained job markets, underemployment or oversupply may be hard to specify, provided that under such a steady “management of risk” scheme, work remains more attractive than occupational alternatives outside the arts sphere.

Another view of the “excess supply” disease, quite the opposite of the functionalist one, assumes that competitive markets not only magnify and exploit unequal individual endowments of artistic ability and talent, but that the market organization of the arts neglects to recognize the sheer potential of creativity of everyone. In that respect it fails to implement the optimal level of innovation and creativity, both from an individual and from a social standpoint. This is the Marxian view of the self-achievement ideal which could be implemented in a society that overcame the alienating division of labor organization of work. Such a conception has its roots in a powerful tradition, the expressivity model of praxis that can be traced back at least to Hegelian philosophy [Habermas (1988)], if not to the Aristotelian conception of action. In this model, self-actualization through creative work entails a basic distinction between labor as a routine and alienating activity, and work as a non-routine pursuit. This distinction plays a major role in Arendt’s (1959) theory of work as a non-utilitarian kind of lasting human achievement, as well as in Freidson’s (1986a, 1986b, 1990) view that artistic professions present a challenge to conventional conceptions about vocation and labor. Hirschman’s (1986) classification of different kinds of work in terms of the varying predictability of their intended outcome brings to light the non-instrumental nature of the artist’s effort; in the uncertain course of creative action, the strenuous overcoming of obstacles takes place through alternations of tension and the anticipated savoring of the future result. Therefore self-actualization through work, which makes artistic activity so attractive, occurs only if the outcome is unpredictable enough; the possibilities of personal invention are wide open, and at the same time the artist is never sure that she will express herself in her work as she expected to.

Clearly the expressivity model catches the link between creativity and unpredictability of work, but it suffers from an internal contradiction when it precludes the possibility of failure, as in the Marxian conception of self-actualization. In Marx’s view, everyone is endowed with the same abilities; the considerable variation in artists’ reputations and incomes is mainly ascribed to strongly biased consumer preferences shaped by market forces rather than to talent differences. In fact, artists quite commonly conceive of softer market competition as a means of favoring self-actualization of everyone’s creative endowments. A non-rationed labor market would require either sufficient homogeneity on the supply side or a quality inelasticity of demand high enough so that the substitutability of artists and of works would allow for market equilibrium. Yet both supply and demand of creativity are based on inter-individual comparison and competition.

The risk of failure is a built-in characteristic of artistic undertakings. Moreover, failure or success does not merely depend on the creators’ own appraisal of their work, unless their art world forms a community of producers who have no interest in others’ production or in anyone’s consumption [Elster (1985)]. Individuation through creative

work, which greatly accounts for the admiration of artists, requires that others have an interest in one's work [Cohen (2000)] and consequently that some competitive comparison occurs. True, artistic individualism has been recognized as a sign of a trend towards autonomization of the artistic sphere and towards professionalization of its members, according to Max Weber's theory. However, artistic individualism could hardly be equated with an intrinsic, competition-free striving towards self-expression and self-actualization. Thus individualism, apart from characterizing a lifestyle and referring to a loosely structured occupational community, may signal the tension between a strong sense of personal achievement experienced in absolute terms, and the way one's creative work unavoidably involves relative comparison with others. As experimentally shown by Camerer and Lovallo, overconfidence and optimistic excess entry in a business may be due to the fact that people neglect the reference group of competitors, each one estimating they are skilled enough to succeed; "neglecting the increased level of competition is like the neglect of adverse selection which leads to the 'winner's curse' in bidding" [Camerer and Lovallo (1999, p. 307)]. Relative skill perception may entail miscalculation of one's chances especially when the skill requirements are underspecified, when the performance feedback needed to adjust one's level of aspiration is fairly noisy, and when the employment system magnifies heterogeneity among the workforce.

This highlights the complexities of uncertainty as a double-sided incentive. One side is the non-routine and non-instrumental aspect of work that makes it attractive; since work experiences have to be constantly renewed in order to be attractive, a strong sense of challenge, and of competition against oneself, nurtures the artist's quest for individual achievement. On the other side, given that the production of creative work has been increasingly market-driven since the nineteenth century, the quest for systematic originality and innovation brings to light the strategic dimension of uncertainty, that of inter-individual competition. Ironically enough, the non-monetary value of expressive self-actualization through creative work is the genuine fuel of market competition.

Uncertainty management techniques and learning processes related to the core of artistic invention on one hand, and to the market structure of competition among widely differentiated talents and products on the other, provide economic research with insights into the behavioral type of the artist. The artist may be portrayed neither as a conventional rational actor well-equipped to survive in an ever more competitive market, nor as a myopic one induced to take occupational risks only because she forms probabilistic miscalculations of her chances of success or because she was programmed by her initial socialization to enter an artistic occupation. Rather, she may be portrayed as an imperfect Bayesian actor gathering information; learning by doing; revising her skills, expectations and conception of herself; building networks in order to widen her range of experiences; and acting without knowing her initial endowment of ability and talent or what she may be able to express over the course of her loosely patterned career. Insofar as she acts as a monopolistic supplier, the artist tries to expand the control over her own work and over the market of the goods or services she provides. However this outward-oriented goal, driven by the competitive pressure in the market for the arts and entertainment services, would be meaningless were it not matching the inward-oriented

goal of self-discovery and self-actualization, a goal that may be pursued only as long as the variety of work experiences and challenges is optimal and if the balance between invention, security at work and temporary routine exploitation of innovation is secured.

## 7. Managing the risks of the trade

Studies of artistic occupations show how artists can be induced to face the constraints of a rationed labor market and how they learn to manage risky careers. Pioneering empirical research by [Baumol and Bowen \(1966\)](#) found that artists may improve their economic situation in three main ways which are not incompatible and may be combined: artists can be supported by private sources (working spouse, family or friends) or by public sources (subsidies, grants and commissions from the state, sponsorship from foundations or corporations, and other transfer income from social and unemployment insurance); they can work in cooperative-like associations by pooling and sharing their income and by designing a sort of mutual insurance scheme; and finally they can hold multiple jobs. Most studies, both in sociology and in economics, have focused on this last means, since apart from being widespread and becoming more so, it brings into light a puzzling feature of the artistic labor market: that of the diversification of risk through one's own human capital and labor, which seems a much more unusual phenomenon than risk management in the financial sphere. In fact, it makes artists resemble entrepreneurs since, just as property owners spread their risk by putting bits of their property into a large number of concerns, multiple jobholders put bits of their efforts into different jobs [[Drèze \(1979\)](#)].

Multiple jobholding shows a general upward trend, and artistic workers in many countries rank among the highest in the percentage of all workers who have secondary jobs; in addition, artistic occupations rank at the top in the percentage of all jobs held as secondary jobs. In the US, for example, almost every artistic occupation appears among the 25 occupations employing the largest proportions of their workers through a secondary job [[Amirault \(1997\)](#)]. In their survey of 3000 New England artists, [Wassall, Alper and Davison \(1983\)](#) found that only 24 percent of artists did not hold a non-artistic job. In their 2000 study on moonlighting in the arts, [Alper and Wassall \(2000\)](#) provide an extensive review of the multiple-jobholding behavior of American artists from 1970 to 1998 based on the monthly Current Population Survey date files. As their calculations show, rates of moonlighting by artists have increased over the years much faster than in the overall labor force or than in the category of professional workers whose personal characteristics are closer to those of artists; performing artists experience the highest rates of moonlighting; educational level is the only personal factor strongly positively related to multiple-jobholding behavior.

As shown by [Throsby \(1992, 1994a, 1996\)](#) in his studies on artists' income and labor supply, not only must economic studies recognize the arts/non-arts earnings distinction as providing a more complete picture of artists' income sources, but that simple

dichotomy in itself does not go far enough. In order to capture the full range of relationships between labor supply and earnings experienced by artists, a three-way division of working time and earnings is essential<sup>22</sup> between:

- the creative activity itself, which corresponds to the primary creative labor and the tasks associated to the preparation of the artistic product (thinking, dreaming, searching for materials, rehearsing, practicing);
- arts-related work, which includes the various activities within the particular art-world that do not contribute directly to producing the artistic product, but still rely on the skills and qualifications possessed by the professional artist – common examples of such work are teaching activities and management tasks in artistic organizations; and
- non-arts work, which may differ considerably among individuals, among artforms and over the individual life-cycle in an artistic career; for example, recent US Census and survey data report that while a majority of authors (as primary occupation) hold secondary jobs in other professional occupations and especially in educational fields, actors' and singers' secondary jobs are mainly in sales, clerical or service jobs, i.e. jobs with a history of low pay and poor benefits [Alper et al. (1996)].

The range of various jobs may be compared to a portfolio of financial assets.<sup>23</sup> This way of handling uncertainty has already been evoked above in the case of freelancers, who may insure themselves against downswings on the employer side as well as strengthen their position by building a career portfolio that is mixed with tightly and loosely coupled work associations. With sectoral diversification of hirings, artists may also be financially better off and have greater career continuity in a disintegrated labor market. Holding other jobs outside one's vocational field of activity corresponds to a better known scheme of occupational risk diversification. Instead of thinking statically in the terms of the old dilemma – freedom or alienation – the portfolio model of occupational risk management offers insights for the dynamic study of how artists cope with uncertainty throughout their careers and allows us to maintain the centrality of choice of career path.

Sources of income are much more dispersed at the beginning of an artist's professional life, coming under greater control when the artist's reputation grows and when his ability to select among different opportunities allows him to reach a more careful balance between constraints and fulfilling commitments. However, in focusing on the combination of insecure and secure sources of income, the "diversification of risk" approach fails to deal with the characteristics of different kinds of work, assuming that a secondary job doesn't provide the artist with anything else except income. As a result another complementary dimension of multiple job-holding is overshadowed, concerning the relationship between creative work and related artistic work, as described in

<sup>22</sup> See Throsby (1996), Menger (1997), Paradeise (1998).

<sup>23</sup> Faulkner (1983) and Menger (1989); for a more committed, prophesying view on the rise and desirable future of portfolio work in our society, see Handy (1989).

the “role versatility” scheme [Nash (1955)]. In certain art worlds such as that of “serious” music, high technical skill requirements act as a selective barrier to entry as well as an integrating device among the professionals employed in the various occupational roles (composer, performer, conductor, publisher and so forth) whose differentiation has increased with the professionalization process. Through role versatility, the composer may reduce the financial risk in his creative activity but also extend his control over the distribution process of his music, facilitate his interaction and communication with the other roles, and increase his prestige among his peers. Roles simultaneously or successively played are thought of in terms of positions in various spheres, as in Abbott and Hrycak’s (1990) study on eighteenth century German composers, or as in Baker and Faulkner’s (1991) study which examines the shifting combinatorial patterns in Hollywood filmmaking and sees roles (e.g., producer/director/screenwriter) as resources to enact positions in evolving organizational settings. More generally, organizational or aesthetic innovations induce role combinations and hybridizations and transform both the content of cooperative activities and the extent of control over new market resources.<sup>24</sup>

Wherever practice needs a specific training, the center of the artistic role constellation is traditionally the teaching role, the most frequent “pool” profession [Abbott (1988)] or “host occupation” [Freidson (1986b)] for creative artists. This teaching position in the arts has been compared by Baumol and by Freidson to the role of teaching in academic life, which hosts and supports research activities; this might explain why creative artists so often consider themselves researchers. The paradox of artists whose educational profile as a group is close to that of managerial and professional occupational categories but has far less impact on their earnings can also be solved. Throsby (1996) shows that relationships between arts income and art training may be strong for arts-related activities such as teaching whereas income from primary creative practice is more influenced by on-the-job experience. Human capital and role versatility considerations militate for arts-related rather than non-arts jobs, and portfolio choice considerations tend to favor supplementary jobs that are stable and salaried, such as teaching. White (1993) suggests that the artist as teacher combines two opposing forms of career, one (teacher) that represents the image of the traditional career since it entails seniority and some order and sense of cumulation from training, and another (the artist as genius) that is built on originality and conveys a sense of destructive creation. That paradoxical role combination is especially striking in avant-garde music [Menger (1983)] and in the visual arts [Moulin (1992)].

<sup>24</sup> See Moulin (1992) on the case of the entrepreneurial artists who work as performers and producers of services in the contemporary visual art market; Christopherson (1996) on the emergence of entrepreneurial filmmakers whose managerial skills blur the lines between management and labor; Kealy (1979) on the emergence of the hybrid ‘artist mixer’ in rock music; and Hesmondhalgh (1996) on the entrepreneurial strategies of sound mixers and DJs in the dance music record sector.

## 8. Collective action and public support in occupational risk management

Risky employment prospects in the arts may also be mitigated via co-operative and collective action [Peacock and Weir (1975)]. Artists may share the occupational risk by pooling their resources, as in the case of groups of visual artists [Simpson (1981)] who provide each of their members with mutual support, or the main symphony orchestras in London which operate on a self-managed organizational basis, with musicians being shareholders of their own company and augmenting that position with freelance hirings elsewhere [Peacock (1970)]. Most small organizations in the live performing arts (dance companies, chamber orchestras, baroque and contemporary music ensemble, etc.) work on this co-operative basis.

Studies on the collective action of unions in the arts are far fewer than those devoted to state and public support for the arts.<sup>25</sup> One common feature of unions' action concerns income transfers and redistributions that may allow workers to adapt to more flexible and more unbalanced artistic labor markets. Apart from traditional direct and indirect forms of public support to artists that are prevalent in European countries [Mitchell (1992)] and mainly intended for self-employed creative artists, collective action regarding artistic labor markets relates to the funding of non-profit organizations such as performing companies employing artists, as well as dealing with the impact of increasing flexibility. Paul and Kleingartner (1994) show that in the US Film and TV industries, the actors', writers' and directors' unions, unlike craft unions, have expanded in spite of the introduction of highly flexible production. A three-tier compensation allows artists both to be covered on an egalitarian basis (through minimum pay rates), to allow those whose market value exceeds union scale to negotiate additional compensation, and to get additional payments (residuals) for the re-use of the films and TV programs to which they have contributed. This last device can hardly be underestimated, although the importance of residuals to total compensation varies greatly among labor market segments. In 1988, according to the American Screen Actors Guild statistics (quoted in Paul and Kleingartner), the total residual compensation from all markets was almost equal to total initial compensation. Not only a compensation mechanism, the residual's role is also that of softening the impact of work contingency and frequent periods of unemployment by generating a passive income stream. As film and audiovisual markets expand and flexibility increases, residuals have become the focus of individual contract negotiations and collective labor relation bargainings in that sector.

In many countries access to unemployment insurance compensation is beyond the reach of freelancers who are numerous in artistic professions. In some countries however, freelancing can be equated with a wage-earning position and is eligible to unemployment compensation. Where benefits are paid by the state, they may be used as a deliberate means of public policy in support of the arts. When unemployment insurance expenses come under a self-administered fund aimed at compensating every worker in

<sup>25</sup> See Gray and Seeber (1996).

the economy for her unemployment spells, a cross-subsidization between sectors may play the supporting role. For those freelancing artists and cultural workers who are eligible for unemployment benefits, the resulting combination of security and of autonomy at work may perform two different functions:

- that of providing earnings replacements which reduce the compensating pay differential associated with the risk of unemployment and the uncertainty about lifetime earnings – in fact the position on the contingent labor market may be optimized so that each individual permanently combines fees and unemployment benefits; and
- that of subsidizing non-working time which can be used as leisure time, or as training time for a future demanding job, or as a searching spell for new jobs.

In the former function, unemployment is seen as a constraint on individual behavior via a labor-demand explanation, whereas in a labor-supply explanation unemployment can be interpreted as the outcome of a worker's choice with regard to job search. Ambiguity also arises from the way uncertainty itself is interpreted; as observed by Drèze (1979, p. 349) "in the case of the self-employed, the distinction between endogenous and exogenous economic uncertainties is not always clear-cut". Consequently, insurance against career failures does raise questions.

The French unemployment insurance system put in place for artists and craft workers in the performing arts provides a striking illustration of these interwoven functions [Menger and Gurgand (1996)]. A generous compensation scheme had been designed to fit the requirements of contractual flexibility but it ran into financial problems because compensated unemployment grew more rapidly than paid work. Work has indeed been allocated quite exclusively in the form of contingent jobs and short-term hirings which typically spread the available work among a growing number of agents. Employers have been able to hire personnel at lower cost, to sort out the most talented, to build well-matched teams and to draw at will from a considerable reserve army of underemployed workers. Thus the performing arts sector did expand by having an increasing part of the income required to attract workers paid through unemployment insurance allowances. In aggregate, the amount of unemployment insurance benefits paid to those workers today in France represents more than two-thirds of their total amount of wages and fees [Menger (2005)].

Actually substantial moral hazard is pervasive, induced by the insurer's inability to distinguish unpredictable exogenous constraints on the hours intermittent workers are able to sell in the market from the worker's choice with regard to job search or allocation of non-market time. In their survey on unemployment insurance issues, Topel and Welch (1980) noted that "to the extent that workers take future unemployment benefits into account when evaluating a job offer, this effect must be ambiguous. While workers will certainly be more selective with respect to job offers if benefits are increased, the value of any particular job must be comprised of both income from working and benefit income from contingent unemployment. The increase in benefits will allow firms to offer the same value of an employment contract with a lower wage" (p. 354).<sup>26</sup> Much

<sup>26</sup> See also Atkinson and Micklewright (1991).

less ambiguous are the effects on employers, who are able to exploit asymmetrical information about their work and job allocation agenda in order to include entitlement to unemployment insurance benefits in their wage bargaining with their contingent employees. Firms may also collude with their employees by hiring them repeatedly for short periods in order to secure a kind of internal labor market without bearing the full cost of long-term relationships. It seems quite obvious that the implementation of an experience rating formula under which an employer's unemployment insurance tax rate depends upon the stability of employment he provides is the only way to make employers responsible for the impact of their hiring decisions on the fund's finances.<sup>27</sup> Yet, in so doing, the state and the local authorities would be asked to provide the non-profit performing arts sector with an extra amount of subsidies heretofore passed on to the insurance fund, and to acknowledge the actual supporting role that it plays [Menger (2005)].

Public support for the arts has increasingly supplied additional means of income diversification and career enhancement opportunities to artists by funding artistic and art-related jobs, by financing or securing compensation systems like those described above, by enforcing property rights and by adapting them to new technological and market conditions. However, cultural policies are at odds with the way firms and entrepreneurs take advantage of the attractiveness of artistic occupations and of mistaken expectations. Increasing flexibility can be associated with higher rates of artistic innovation or at least with increasing differentiation in production. Yet it transfers more and more of the business risk down onto the artists. Cultural policies cannot disentangle the individual risks (those of discontinuous employment prospects and uncertain course of a freelance career) and the social risks (those of having innovations underrated or overlooked and of experiencing a suboptimal cultural development). Moreover, cultural policies and non-profit organizations have mostly developed while the contemporary artistic scene has become more contestable. The valuation process is subject to more volatility, leaving more room for speculative bets and for joint action by several categories of actors (curators, critics, dealers, experts and boundary spanners of different sorts) to promote artistic movements, innovations and fashions. Therefore public support needs to be driven by the same uncertainty principle that underlies the market competition for successful innovation.

Let us consider the ever-increasing number of pieces of art and culture that are consecrated and offered for public admiration in museums, concert programs, books, and audiovisual or computerized archives. These pieces act as permanent reminders; they have emerged from a large stock of works whose significance needed time to be correctly appraised and sorted out, after several rounds of celebrity tournaments and valuation proofs. This process legitimates a transfer of the title and merit of celebrated

<sup>27</sup> As it is well known, without an experience rating scheme, the structure of the unemployment insurance financing subsidizes the benefit payments of some industries at the expense of others, provided that the aggregate unemployment insurance system does balance.

artists of the past onto their contemporary heirs, whether the latter are known or unknown at this time. The definition of art as a public “merit-good” [Musgrave (1959); Netzer (1978)] may catch that mix of elitism and democratization of genius, i.e. the contrast between the dramatic super selection of a few hundreds of world famous masters in each art world and the crowds of candidates to fame which feel entitled to ask for accountable decisions of public support [Menger (2003)].

Uncertainty again plays a double-sided role here. According to DiMaggio (1986), the uncertainty principle which is at the core of the evaluation of any work bears on public and collective choices, both from an intra- and intergenerational point of view. In the long term, uncertainty regarding an artist’s or an artwork’s value, as it vanishes over time, turns into an extremely skewed distribution of fame and success. Yet in the short term, any public support to the arts has to balance efficiency against equity considerations, both by giving the best-rated artists the largest opportunities to develop their talent according to a market competition structure, and by mitigating the market proclivities by sheltering potential but uncertain talents from the “winner-take-all” market structure effects. Thus the uncertainty principle provides a true rationale for the public support of a large number and variety of artists. It can be claimed that it is in the interests of society at large to nurture an oversupply of artists so as to have the best possible choice of talented artists. Indeed, as pointed out by Nisbett and Ross (1980), people sometimes may require overly optimistic subjective probabilities to goad them into effective action. The social benefits of probabilistic mistakes are supposed to be great enough even when the individual cost for an unsuccessful career is high. However, the claim for such positive externalities, though belonging to the rationales of public support to the arts, may trigger an endogenously unbalanced growth.

What kind of uncertainty is it that in the short term has to be managed through insurance devices? Is it exogenous or endogenous? Should a lack of jobs and an unsuccessful career be attributed to insufficient ability? Or are they due to insufficient demand for the kind of ability with which the artist is endowed? The answer lies in the fact that ability and talent themselves should be considered not only as an exogenous factor of market success but also as an endogenous factor shaped by competition through innovation. The more competition raises the rate of innovation or at least of differentiation between prototype-like works by exploiting and stimulating consumer demand for novelty, the more the sorting mechanism will be based on shifting specifications of marketable talent.

## **9. Art as a model for creativity-enhanced work in advanced societies?**

Both capitalism and anti-capitalism celebrate innovation, knowledge, learning and intrinsic motivation as the most powerful leverage to ensure growth and to overcome the alienating dimensions of labor division and routine careers. Marx saw the artist as possibly the highest embodiment of his disalienated worker. Today creativity is one of the key managerial requests to raise productivity levels through changes in work organization.

The economic theory of endogenous growth assigns a central role to idea generation, creativity and knowledge [Romer (1990); Aghion and Howitt (1998); Baumol (2002)]; firms and markets have to know how to draw from what is supposed to be the ultimate inexhaustible source of growth, human creativity, both in its specialized form (that of professional work in the creative activities of workers such as scientists, researchers, engineers, artists) and in its more mundane manifestations, that of everybody's intelligent behavior at work. The creative knowledge principle applies to work organization and management as well; according to these premises, art as a most celebrated realm of creative work should provide managers and workers with some insights as to what creative behavior and intrinsically motivated commitment to one's work can be, once the rhetoric of radical idiosyncrasy, irreducible originality and the undecipherable secret of creation in art has been set aside. Indeed, artists voluntarily supply the golden legend of creation, that of a subversive, anti-conformist, inspired behavior, rebelling against social conventions and commercial utilitarianism; in fact, however, they evolve daily within the economic settings most compliant to the demands of modern capitalism – extreme flexibility, autonomy, tolerance of inequality, innovative forms of teamwork. So the artist and the post-taylorist worker may be able to merge into the same figure, that of a creative professional. How far does that assertion fit the actual transformations of work organization?

The usual picture of organizational design and human resource management (HRM) fits the labor market segmentation theory by distinguishing between:

- secondary labor markets where flexibility, worker substitutability, skill transferability and fixed cost minimization through low-wage policy for low-skilled jobs are at their highest;
- internal labor markets developed by firms that emphasize low turnover and high productivity, bear costs of screening, trying out and training, and use optimal reward schemes based on long-term contracts and tenured jobs; and
- professional labor markets for highly skilled workers who enjoy weak attachment to a firm, even if incorporated, and considerable bargaining power due to high market value of their expertise and high transferability of their competencies [Baron and Kreps (1999)].

Artistic labor markets mix elements from the secondary spot market and from the professional market model. On one side, employment is more and more contingent, as for secondary labor markets, but on the other side individuals are skilled or highly skilled, and non-substitutability is a core value, as in the so-called professional market. This is especially true of the performing arts which appear to have been quite avant-garde in designing and experiencing the process of increasingly flexible labor markets.<sup>28</sup> Contractual work arrangements and organizational forms in the whole economy have been

<sup>28</sup> On Hollywood, see Storper (1989); on the diffusion of the Hollywoodian flexibility model, see Kanter (1995); and on the trend towards flexibility and its strongly contrasted effects see Smith (1997), Cappelli (1999), Kalleberg (2000).

repeatedly portrayed as evolving along a similar path. Contingency is increasing, although at first glance it may have completely different meanings at both ends of the labor market, low-quality and low-skilled work being contingent at the bottom and highly-skilled work being more often independent contracting and free-lancing at the higher end. At the same time, firms increasingly try to build internal professional markets or to secure networks of recurrent collaborations with independent highly-skilled contractors and service firms once having outsourced part of their previous operations. So contingency, networking and individualization of working ties take on contrasting meanings depending on one's labor market value.

How significant are these changes and how far could a comparison with the arts be drawn? Prophecy on the changes in employment, management and society has grown over the last decade, mainly under the headlines of flexible specialization, flatter hierarchies, networks of organizations, the learning firm, self-designing teamwork, creativity enhancement and the knowledge society [DiMaggio (2001)]. Taken together, are these changes cumulative and do they result in a coherent new architecture of work and organization? Or do they belong to the toolkit of management textbooks and gurus? Has unfixed long-term employment inside big companies been dramatically eroded? Or, as some scholars in Europe claim, is it still and well alive? And should the alternative between traditional employment and all sorts of contingent employment not be better conceived as a matter of cyclical management, depending on the condition of business?

Dimensions of change are of course far too numerous at individual, organizational and societal levels to be caught in a unique new formula designing a new working age with its new rising class. Yet repeatedly the future of work organization is prophesied with reference to the core values that artistic professions share with other "knowledge workers" – autonomy, responsibility, self-control in teamwork, extended range of competencies enhancing the sense of initiative, creativity-driven commitment to work, individualized reputation based on track records and team project organization of work. In order to get a better understanding of what is at stake, the following distinction may be useful.

First, creativity- and knowledge-oriented change in work can be discussed with reference to economic sectors where it occurs most extensively. For example, network forms of organization have been for long studied as a special trait of craft industries and cultural industries (publishing, film and record industries), and research now concentrates more and more on organizational models supplied by all sorts of knowledge-intensive activities such as scientific research, cultural production in general, design work, computer programming, software development and professional services. A sectoral distinction leads to a specification of the kind of worker concerned; as stated by Powell (1995), these are highly-skilled and talented people possessing fungible knowledge that is not limited to a specific task but applicable to a wide range of activities, relying also on know-how and tacit knowledge that is difficult to codify, and being less creative and less productive under hierarchical governance. In this perspective, work systems of artists and "knowledge workers" share enough common characteristics to allow for illuminating comparisons. They also allow for meaningful contrasts; after all, R&D in

science and technology are intended to be cumulative, while art is contradictorily oriented towards the preservation of masterpieces and past achievements as well towards frenetic search for originality and novelty, be these a source for long-lasting innovation or for ephemeral fads and fashions.

A second way to make a strong claim to creativity is to envision a new architecture of society involving the emergence and rise of a new class, as authors like Florida (2002) have proposed. In this case, the various changes mentioned earlier are said to have converged up to a critical point where a significant part of the labor force shares values, life style, work ethos and leisure habits. A creative class is made up of people sharing a number of similar characteristics (high skills, knowledge intensive activities, learning potential and several other traits of the creative worker), but above all sharing paradoxically the feature of idiosyncratic individualism. In so saying, Florida reverses the usual social map; the bohemian fringe becomes the social core. This view leads to expansion of the boundaries of creative people by including many occupations and professions without any sense of sorting them out according to the hierarchical structure of each occupation. And not surprisingly, the new social map is mainly a locational one; the places where bundles of creative workers live are made out of dense, relaxed, flexible, inter-individual relationships.

It is worth remembering how the founding fathers of social science at the turn of the nineteenth century contrasted two types of society and social organization: the *Gemeinschaft* versus *Gesellschaft à la* Tönnies, or the mechanic structure versus organic structure of society *à la* Durkheim, a distinction on which Burns and Stalker (1961) have built later to characterize innovation-friendly organizational designs. Durkheim's organic structure of society refers to a society where people, being more and more differentiated due to more sophisticated division of labor and increasingly specialized skill requirements, are at the same time induced to get in closer contact and in more dense relationships with each other, since they need to exchange more and more knowledge and information. Yet Durkheim saw the risk of conflicting interests, of growing individualistic hedonism that would undermine social order and economic efficiency – in a word, of growing anomy (social disorder) necessitating regulation and social governance. Quite the opposite view is taken when the celebration of everyone's creativity causes the highly unequal chances of self-actualization to disappear; the homogenization of infinitely differentiated creative workers or of individualistic loosely-tied workers operates horizontally only. The specific characteristics of each trade's organization, its internal and external competition structure and its vertical differentiations vanish inside the large pot of a communitarian creative life style.

Lastly, emphasis on creativity at work may be more general and may concern organizational changes with no exclusive reference to particular sectors or to specific occupational groups. In that case, a bundle of closely related factors increases the need for organizational change toward more efficient, more rewarding and more stimulating work settings; such factors include computerized systems of production and information, just-in-time practices and computerized inventory control systems, increasing variety of products, shortening of product life cycle, new standards of competition in

industries, etc. These factors have all a strong impact on the challenges workers have to face, challenges that include increasing variability, quality problem solving, flexible coordination, management of formal and informal communication networks, rising information needs and evolving skills. These new challenges are core elements of the high-performance work systems implemented by managers in the post-taylorist era of HRM innovations [Baron and Kreps (1999); Appelbaum et al. (2000)]. Of course, such systems claim to be in line with a long tradition of work design improvement intended to overcome the disincentive dimensions of alienating work fragmentation and mechanistic specialization, and intended to promote motivation and self-actualization at work. Central aspects of such work systems are autonomy, participation in decision, coordination and communication among employees, selective staffing and extensive on-the-job and formal training opportunities, self-directed work teams, more sophisticated compensation policies taking into account the bundle of the financial incentives, intrinsic motivation incentives and long-term relationships that secure mutual trust and promote stakeholder behavior. Furthermore a sense of ownership, so decisive in creative activity, should be also acknowledged, insofar as each skilled worker's personal contribution to the output can be tracked and brought to his or her personal credit.

Each of the three approaches to creativity in labor markets and organizations reviewed above – sectoral-occupational, class-remodelling, and organizational – is built on a similar ground; that of one common good, be it that of knowledge and creative learning-by-doing produced and shared through networks of firms, or that of positive identification with work inside the firm, or that of creativity as a shared ethos of work and life. In a sense, the performance of artistic work systems, as reviewed previously, falls into each of these rubrics. Yet, one crucial issue is missing in the broadened picture of creativity at work: that of the several dimensions of inequality magnified by the work system in the arts, which builds on networks, reputation, short term contracts, and highly individualized performance ratings. Ironically enough, although most of the artists and professionals in the cultural sector are ideologically left-oriented and prone to advocate egalitarianism in society, art worlds have developed an insuperable engine to rank artists by quality level and market value, to select and signal the best works out of an ocean of products through winner-take-all tournaments and endless competitive comparisons, to let the whirl of fads and fashions promote or eliminate aspiring superstars, to celebrate skyrocketing and ephemeral celebrity as well as to provide civilization with Pantheons of eternal values. This corresponds mainly to the distributive justice principle of equity, which prevails especially where performance varies significantly across individuals, and “according to which individuals ought to be rewarded commensurate with the outcomes they generate, factoring in the inputs – efforts, ability, and so on – they brought to bear in performing the task” [Baron and Kreps (1999, p. 107)].

Thus inequalities in earnings may be occupationally legitimate if several requirements are met. A first condition is that each individual contribution to the team work or to the end result be identified specifically, which presumes there is an economic and legal value associated with the “traceability” of each individual work performance. Credits, signatures and individualized reputations mean each worker can be distinctively

identified with the complete history of his jobs, assignments and realizations. This has to do with the sense of identification with the end product of one's work as distinct from an anonymous contribution to an output whose production is heavily fragmented and standardized. A further condition of legitimization is that a professional's performance can be judged in comparison to and in direct competition with other works and professionals, and that inter-individual comparisons must occur frequently enough to submit rankings and valuations to periodic re-assessment, so that a long-lasting monopolistic rent of talent remains the rarest exception. Lastly, unforeseeable streams of successes and failures should signal to new candidates that creative innovation remains a highly uncertain game; in that respect, uncertainty in its several dimensions acts as a veil of ignorance thrown over the ultimate causes of achievement and success, as these stem from an undecipherable mix of chance, talent and work.

## 10. Summary and conclusion

Artists supply the innovation engine in the arts with work mainly under contingent arrangements. Long-term artistic employment has been vanishing except in heavily subsidized and sponsored organizations like orchestras and opera houses. The population of small artistic and cultural organizations has been growing as fast as the number of artists. Firms compete increasingly under flexible production schemes that bring them close to the nexus of spot transactions. Do vertically disintegrated systems of production favor only loose employment relationships? Studies show how filtering mechanisms and selective matching processes generate transactional stability as well as labor force segmentation. Employers use reputations as screening devices and signals of employability; artists learn how to compose well-balanced sets of recurrent and non-recurrent hiring ties, in order to secure a living as well as to increase their human capital. Talent agencies mediate the contingent labor market and do increasingly broker artistic projects.

Considerable inequalities in amounts of work and earnings among artists are observed, caused by the skewed distribution of talent and by joint consumption technologies that turn small differences in talent into huge earnings differentials. It has been shown that they may also trace back to the way a disintegrated labor market operates, since both the allocation of piecemeal work based on reputational rankings and team formation based on selective matchings magnify the power of differences in talent and work opportunity to increase inequality. Allocation of work under a contingent employment scheme should not cause the kind of permanent excess supply of labor in the arts that has been noted for decades if the occupational commitment of artists were not combined with the management of business uncertainty through overproduction of infinitely differentiated goods and services. On the whole, artistic labor markets provide a textbook model of imperfect monopolistic competition.

Large parts of the business risk are transferred down onto the artistic and technical workforce in a highly flexible and disintegrated organizational setting. The study of

artistic careers illuminates how individuals learn to manage the risks of their trade: through multiple jobholding, occupational role versatility, portfolio diversification of employment ties, and transfer incomes from public support, social insurance and social security programs. Institutional arrangements regarding the legal status and financial support of artists may differ greatly between the countries and states, yet occupational risk management is a common and basic condition of economic survival and personal success; ironically enough, this shows how rationally artists behave, although artistic work may be highly idiosyncratic. Thus artists may be seen less like rational fools than like Bayesian actors.

## Abstract

This chapter is a continuation of ongoing work by economists and others on artists' labor markets and careers. It highlights the use of quasi-panel data obtained from census data to examine the employment and earnings of artists while comparing them to all the other professional and technical workers. It also provides a glimpse into what can be learned about artists' careers from true panel data.

Quasi-panels from the seven most recent US censuses (1940–2000) provide a reasonably consistent set of findings in each census year. Artists are found to work fewer hours, suffer higher unemployment and earn less than members of the reference group. Over the sixty year period, disparities in unemployment and annual hours worked are found to shrink somewhat, but disparities in earnings do not. Artists earned less across all years even when only members working full-time year-round of each group are compared. The earnings of artists are found to display greater variability than those of other professional and technical workers.

The National Longitudinal Survey of Youth 1979 is used to examine almost twenty years in the artists' lives and provides some insights into their careers. It suggests that many people participate in the artistic labor market, but that few succeed to the point that enables them to develop a career in the arts. In part due to their relatively high educational levels, artists are found to be able to transition from forays into arts occupations to jobs in professional and managerial occupations, not into service occupations as artist 'mythology' might suggest. We find that when the artists are young and struggling to make it they do work in various service occupations that tend to provide greater work schedule flexibility.

## 1. Introduction

Economists' research into the economics of art and culture has a relatively short history. Baumol and Bowen's (1966) book, written forty years ago, is seen by many as the starting point of the economists' foray into this sub-discipline. Research on the artists' labor markets and their careers has even a shorter history. Its empirical roots lie in studies of single artistic occupations that are, for the most part, barely 30 years old.

As might be expected, these early studies were cross-sectional and provided important, but limited information on careers and labor market behavior. Economists learned a great deal from these studies, but they also raised a number of unanswered questions. Table 1 provides a list of some of the landmarks among the empirical studies of artists many of which are discussed in more detail below. The passage of time has allowed economists to enhance their knowledge through the use of increasingly available panel data of various types.

This chapter starts with a description of a framework for categorizing and reviewing existing studies (Section 2). This is followed by a review of some of the major studies in these categories (Section 3) and concludes with two studies of our own. One will provide an overview of many major themes learned from the cross-sectional analysis by examining a quasi-panel for the US (Section 4) based on the US Census Bureau's Public Use Microdata Samples (PUMS) drawn from the US decennial censuses for 1940 through 2000. The other (Section 5) addresses some themes regarding the artists' careers and labor market experiences that cannot be answered by cross-sectional data through the use of the 1979 National Longitudinal Survey of Youth (NLSY79). The last part (Section 6) provides a summary, conclusions and suggestions for further research.

## 2. A classification scheme for studies of artists' careers

For the most part current research examining the careers' of artists can be placed into four categories. The one to receive the least attention in this chapter develops theoretical models of artistic career processes. MacDonald (1988), for example, developed a two-period model of performers' behavior that predicts young performers will earn incomes that are less than what they could earn outside the arts. The three additional categories of current research relate to empirical research.

The second category utilizes existing information on a group of artists obtained from a variety of sources to develop an understanding of an aspect of artists' careers. Sometimes the data for this research is anecdotal, as in Richardson's (1980) study of opera

Table 1  
Some landmarks in empirical research into artist labor markets

Empirical Finding	Authors	Artist Group/Database
Artists as risk-takers	Santos (1976)	US Census
Determinants of artists' earnings using statistical earnings function	Filer (1986)	US Census
Artists' dependence on non-arts jobs for income	Throsby (1986) Jeffri (1988) Wassall, Alper and Davison (1983)	Australian artists Artists in several US cities New England artist survey
Issues in identifying and defining artists	Filer (1986) Wassall and Alper (1985) Karttunen (1993, 1998a)	US Census New England artist survey Finnish artists
Artist moonlighting patterns	Alper and Wassall (2000)	Current Population Survey
Longitudinal analyses of artists' careers	Rengers (2002)	Dutch artists
Career transitions of artists	Alper and Wassall (1998) Smith (2000) Montgomery and Robinson (2003)	Nat'l. Survey of College Graduates US Census College graduates
Examination of artists' entire careers	Galenson (2000a, 2000b)	Painters

singers. Other times it is much more quantitative as in Galenson's (2000a, 2000b, 2001, 2002) studies of painters' careers. Galenson uses auction transactions in order to identify at what point over their lifetimes artists produce their best work.

The third category is based on surveying artists and asking them to recreate their careers by responding to written questionnaires or personal interviews. There are two types of retrospective studies, one utilizing special surveys of artists and the other using surveys of a broader group, including the general population. Examples of the former include Montgomery and Robinson's (2003) study of dance majors and Stohs' (1989, 1990, 1991a, 1991b, 1992a, 1992b) study of graduates of the School of the Art Institute of Chicago. The research by Smith (2000) using the 1970 census for the US and Alper and Wassall (1998) are examples of the latter.

The last category is based on panel data. There are very few examples of research on artists' careers based on true panel data. There are a number of studies that are what might be called "quasi-panels". They follow groups of artists, many of whom are likely to be the same from survey to survey over time rather than following the same group of people/artists from the start to the end of a multiyear period. Two examples of quasi-panel research are the studies of Bielby and Bielby (1987, 1989, 1993b, 1998) based on the administrative records of the Writers Guild of America, west, the union for writers

in the US television and film industries, and the work of Throsby and his colleagues (1986, 1989, 1994, 1995, 2003) utilizing the four surveys of Australian artists for 1983, 1988, 1993 and 2002. The research on US artists from 1940 to 2000 to be discussed later in this paper would also fit into this category.<sup>1</sup>

There appear to be only a few true panel studies. One, by Rengers (1998a, 2002), specifically targeted artists by following a group of 540 artists who graduated from several art schools in the Netherlands. The artists were surveyed twice over a six-year post-graduation period. The first interview was approximately one and one-half years post-graduation and the other was six years post-graduation. The other by Alper and Wassall (2002), which will be presented in detail below, is a study of artists who were part of a panel survey of the US population. It has followed essentially the same group of people for more than twenty years. The former study is limited by the small number of years of information making it difficult to observe and examine the artists' career paths. The latter, while covering a significantly longer time period and thus potentially providing greater insights into artists' careers, was not specifically designed to examine issues that are unique to artists. It also suffers from being a survey designed to represent the general population and therefore includes relatively few artists.

There are a number of advantages to using panel data rather than cross-sectional data [Federal Committee (1985)] when studying artists. Perhaps most important is the reduced variability in the estimates of change when compared to the results from unrelated or pooled cross-sections taken over time. There is no need to control for as many factors related to the change that might impact the reasons for the observed patterns, because in each time period it is the same people being examined. For example there is generally no change in the composition of the sample related to gender, race or ethnicity, all of which can influence the phenomena being measured.

The reliability and accuracy of the information obtained is also another advantage of a panel survey. A panel survey is repeated on a regular basis, so the reference period is generally shorter resulting in less recall bias than a single retrospective survey. Trying to remember what one did over the last twelve months when asked about work activities is much easier than trying to recreate an entire working career that may extend 10, 15 or 20 or more years. Information on income, expenses, and the like, can be recalled for the last year or so, but certainly most people would find it difficult to recall much beyond that. In retrospective surveys, participants tend to selectively telescope, suppress or embellish events that happened to them in the more distant past.

A panel enables data to be collected in a clearly identified time sequence so the direction and causation of change can be more easily and reliably identified. For example, when examining the determinants of who becomes a successful artist it might be interesting to study how a young person's goals and attitudes towards work and his/her

<sup>1</sup> Except for the works discussed in this paper or listed among the references, the authors were able to find little evidence of empirical research on artists in other countries. Most of the research not directly discussed in the paper is either simply cross-sectional or quasi-panel.

chosen profession influences his/her future success. Retrospective information on these issues may be influenced by events that have occurred while information collected at the time these goals and attitudes are being developed is unaffected by subsequent outcomes. Also, it might be useful to examine how attitudes toward the profession are developed over time and the relationship individual experiences have in this process.

The repeated nature of a panel, with a short time period between surveys, tends to lessen the burden on the respondents and therefore is likely to increase their willingness to participate and to provide accurate information. The amount of information that needs to be collected at each interview is less than for a single retrospective survey so the time commitment for each interviewee is reduced. Many questions would not need to be repeated and may simply be updated when necessary, so that new information can be obtained without increasing the respondents' burden. The total amount of information collected through a panel is generally greater than what could be collected in a single retrospective survey.

This is not to say that panel studies do not have disadvantages and problems as well. Perhaps the most problematic is that the full set of benefits to be gained from panel surveys generally cannot be obtained for a number of years. While information from each cross-section can be very useful, the benefits from being able to measure change and long-term outcomes will take time. Participant attrition can lead to serious biases above the typical refusals of any cross-section survey. The cost of a panel survey is generally higher than a retrospective cross-section. For there to be significant value from a panel survey the original budget commitment must be for more than one survey.

Using a panel to study artists has an additional problem if it is not designed specifically for a sample of artists. In the US artists comprise less than two percent of the US labor force so that unless it is a large survey, the number of artists who are likely to be part of the sample is small making it difficult, if not impossible, to obtain reliable estimates. This is an especially difficult problem if there is an interest in exploring the differences among the various genres of artists.

### **3. Empirical studies of artists' careers**

#### *3.1. Careers but not panel*

First is an examination of research on artists' careers based on data that are neither panel in nature nor based on surveys of artists. Examples that fit into this category are studies done by Galenson (2000a, 2000b, 2001, 2002), Galenson and Weinberg (2001) and Richardson (1980).

Galenson is interested in determining at what point in the artist's career he/she is most productive. In particular he attempts to identify when artists, i.e., painters, produce their most valuable work and their best work. He is also interested in seeing whether this point in an artist's career has remained constant over time. He uses two sources of information. To determine value he uses data from art auctions. To determine quality he

uses surveys of art history, texts and published monographs, and the paintings that are selected for retrospective exhibitions of the artists' works. He characterizes the authors of the surveys and the curators of the exhibitions as art experts who can provide quality assessments of the artists' works.

Galenson examined the careers of French artists born between 1796 and 1900 and American artists born 1870 to 1940. He found that both the artists' most valued works and their best works tended to occur at particular points in their careers and that these changed over time. For both the French and American artists he determined that the artists born at the beginning of each period produced their most valued and their best work at significantly later points in their careers than those born at the end of each period. His explanation for this result is that the two artist groups introduced innovations into their art in very different ways. The younger artists were "conceptual innovators" who were quick to introduce new ideas into their paintings. As in many other fields requiring considerable amounts of intellect, e.g., physics and mathematics, the best years for what Galenson calls "radical conceptual innovation" tend to be early in a person's career and it is this innovation that makes the artist's product the most valued and his/her best work. The older artists, those born earlier in the periods, were "experimental innovators" who spent many years working to solve a single problem and thus produced a body of work that illustrated the evolution of the problem's solution they wanted to solve rather than a single, revolutionary work. Thus their most valued and best paintings tended to occur much later in their careers.

Richardson's (1980) work was primarily case studies of various American opera singers' careers. He noted that unlike other performers, opera singers cannot really start to train their voices until their late teens or early twenties and that it takes at least five years to develop the voice; the stamina needed to sing an entire opera; to learn to sing the repertoire and how to act it on stage. Opera singers continue to train throughout their careers. Even with constant training few opera singers continue to perform past their early fifties. For many years American opera singers, especially black Americans, had to go to Europe for experience and to develop a reputation and then they would be able to return to a successful career in the US.

### 3.2. *Surveys via retrospection*

Montgomery and Robinson (2003) studied the graduates of the Five College Dance Program.<sup>2</sup> The graduates were asked to recreate, through a retrospective survey, their post-graduation behavior. Those surveyed completed their undergraduate degrees over the 1970 to 1998 period. The vast majority (84 percent) worked in dance at some time during the post-graduation period but that proportion decreases quite rapidly over time. Of those who graduated post-1990, 78 percent were still involved in dance in 1998

<sup>2</sup> The five colleges involved are: University of Massachusetts Amherst, Amherst College, Mt. Holyoke College, Hampshire College and Smith College.

with 41 percent dancing and an equal number teaching dance. Of those who graduated pre-1990, only 40 percent were still in dance with fewer than 20 percent indicating that they were dancers and about one-third identified themselves as dance teachers. The average number of years spent dancing, teaching dance or as a choreographer ranged from three to six years. One ramification of the career transition out of dance into other occupations Montgomery and Robinson found was that the program's graduates became more geographically mobile as they moved out of the dance occupations.

Stohs' (1989, 1990, 1991a, 1991b, 1992a, 1992b) studies of graduates of the School of the Art Institute of Chicago were more sociological and psychological than economic, but did identify some aspects of their careers that are of interest to economists. In 1981 she surveyed a group of students who had graduated in 1963. She categorized these artists as either fine artists, those who produce art products, or applied artists, those who produce art for commercial purposes. Stohs found that most of the fine arts majors left the fine arts for advertising, teaching or a non-arts occupation. Only six percent of the fine arts majors were still supporting themselves in the fine arts 18 years after graduation, what she identifies as 'midlife', while almost half were doing so as young adults shortly after graduation.

Stohs characterized artistic careers based on the number of related job changes the artists made over their careers. Her characterization of a continuous career was one with three or fewer related job changes. An interrupted career was one with four or more job changes. Perhaps not surprisingly, she found that men were much more likely to experience careers that were steady with steady promotions than women. Two-thirds of the men and only one-quarter of the women had steady careers with promotions from young adulthood to midlife. Reflective of this difference, Stohs found that for almost three-quarters of the men and just over half the women their artistic work was proving to be their primary source of support. At midlife the female continuous career artists were found to have greater personal income, a higher occupational prestige and significantly fewer children than those with interrupted careers. In a study of a subset of male artists, Stohs found that fine artists were more likely to identify intrinsic motives to explain why they were artists than were the applied artists.

Smith (2000) used the question in the 1970 US Census on the occupation held five years earlier and the respondent's occupation in 1970 to examine the movement of people into and out of artistic occupations. He found that slightly more than 70 percent of the artists in 1965 persisted as artists in 1970. Approximately one-third of those who were no longer artists were working in other professional occupations<sup>3</sup> in 1970 with the others distributed among the non-professional occupations. There were also new entrants into the arts over the five year period. They made up approximately 0.3 percent of those in non-arts occupations in 1965. Almost 55 percent of those who were artists in 1970 had also been artists five years earlier. Almost one-quarter of the artists in 1970 had not been working at any job five years earlier.

<sup>3</sup> The US Census Bureau classifies the artist occupations among the professional occupation category. This category includes other professional workers such as doctors, lawyers and professors of economics.

Smith's primary focus was the determinants of artists' earnings over their careers. He found that having been an artist in 1965 leads to significantly lower earnings (approximately 15 percent less) for people who were no longer artists in 1970. Overall work experience has the inverted 'U' shape effect on earnings for those former artists working in non-arts jobs suggesting that the skills learned while working as an artist may not be readily transferable to non-arts jobs. He found that experience in the arts and the apparent development of arts specific human capital had a positive and significant effect on arts earnings.

In a similar study, Alper and Wassall (1998) utilized the first round of the National Science Foundation's National Survey of College Graduates (NSCG) to examine the determinants of persistence in arts occupations. Like the census data used by Smith, the information in the NSCG was collected in the first interview round as part of a retrospective survey. Information was obtained for 1988 and 1993. Data from the 1990 Census was also part of the NSCG data so that there were three observations on these individuals over this five year period. Those who had worked as artists in any of the three years were included in Alper and Wassall's study.

Over the five year period artists' careers were found to be not that much less stable, at least in terms of occupational changes, than many other occupations. Approximately three-quarters of the artists in 1988 were still artists five years later. This is slightly larger than what Smith found and may reflect that these were artists with at least bachelor's degrees. In the majority of the non-arts occupations examined by Alper and Wassall, between 70 and 85 percent persisted in their occupations over the five year period.

When these artists did change occupations more than one-quarter entered managerial and executive occupations and fewer than two percent were working in food service occupations. An equal amount, approximately ten percent, worked in sales and clerical occupations. They also found a larger percentage of artists left for better pay/promotion or for a career change than did other professionals who left their jobs over the same time period.

There was a considerable inflow of people into the arts occupations over the five year period as well. Fully one-third of the artists in 1993 were not artists in 1988. Approximately one-third of the new entrants came from the stereotypical artists' non-arts occupations, e.g., sales, clerical and food service. People were considerably more likely to indicate that they entered an arts occupation to change their career than were those who entered other professional occupations. There was a smaller, but still considerable, difference in the proportion of people entering arts occupations who indicated they did so to change their working conditions than among those who entered other professional occupations.

Alper and Wassall, using a probit model, examined the determinants of occupational persistence for artists over the 1988 to 1993 period. Several demographic characteristics, the artist's age and gender, were found to significantly impact persistence as an artist over the five year period. Male artists were more likely to persist than female artists. The likelihood of persisting tends to increase with age, but at a decreasing rate with artists older than 50 having an increasing likelihood of leaving the profession, perhaps into re-

tirement. Neither the artist's race, ethnicity nor change in marital status had any impact on persisting as an artist. The only measure of human capital investments that significantly impacted persistence was experience. Whether the experience was full-time or part-time did not matter, the more experience the greater the likelihood of persisting as an artist. There was no significant impact due to differences in the highest degree received or in being an art major. Even with only a limited number of identifiable artistic occupations in the NSCG data available for analysis, Alper and Wassall did find that being a post-secondary school teacher of art significantly decreased the likelihood of remaining an artist over this five year period. Other factors that had significant effects were having a spouse who works part-time, which has a positive impact on persistence, and having a disability, which has a negative impact.

### 3.3. *Quasi-panels*

Bielby and Bielby's (1987, 1989, 1993b, 1998) analysis of the Writers Guild of America, west (WGA) membership initially focused on issues related to gender, age and minority status. They started with data from 1982<sup>4</sup> and continue to study these authors today. Over time their focus shifted from analyzing earnings and employment conditions at a point in time to changes over time and the writers' careers.

The membership of the WGA, west, is inclusive of most authors who write for television and film.<sup>5</sup> The WGA's data on these writers is limited to a few basic demographic characteristics (age, gender and ethnicity) and to the earnings received in activities covered by the union's agreements with television and film producers. This limits the conclusions. Without a broader set of information, especially on their other income generating activities, the Bielbys only have a partial picture of what these writers are doing at any point in time and, therefore, over time as well. Since less than half the union's membership works in the industry in any given year, the absence of information on what they are doing when not employed in television or film is difficult to overcome. Therefore, the Bielbys pool the information on the annual panels of WGA members rather than follow the behavior of individual members over time.

In their earliest reports the Bielbys found that women and minorities were disadvantaged relative to the white male members of the WGA. This was true from both the perspective of earnings and employment. While this has changed over time, differences still exist. Throughout the 1980s they estimated that the earnings gap between all female and white male writers ranged between 25 and 40 percent. In the 1990s, through 1997, the gap narrowed to between 10 and 15 percent. The gaps were larger in film than in television. Minority earnings in the 1980s were approximately one-half the earnings of white males, but in the 1990s they were approximately the same. In recent work they

<sup>4</sup> The first year the WGA, west computerized its data.

<sup>5</sup> Television writers do not include those who write for news, sports, other non-fiction shows, game shows and daytime dramas. Film writers do not include those who own the copyrights to their material.

found a much smaller gender gap in earnings between white male and female writers who are recent entrants into the occupation. The employment situation for female writers, as a percentage of total employment, has not changed much over the time period, especially in film and in television since the early 1990s. Minority employment in the industry increased by 66 percent during the 1990s, bringing it to seven percent of total employment.

Recently the Bielbys identified significant changes in the relationship between the writer's age and his/her likelihood of being employed as well as in the writers' age-earnings profiles. The biggest changes in the likelihood of employment occurred from the late 1980s through 1997. The biggest change was the decreased likelihood of older writers finding employment. Between 1987 and 1997, the proportion of writers 51 to 60 years old employed decreased by one-third. For writers in the two older cohorts (61 to 70 and 71 to 80 years old) the proportion employed decreased by 50 percent. The writers in the 30 years old and under cohort were the only ones to see the likelihood of being employed increase.

The change in age-earnings profiles over the 1982 to 1997 period was most profound among writers employed in television and much more modest for those employed in film. For the television writers the transition was from the traditional inverted 'U' shape in 1982 with a peak for writers 51 to 60 years old, to an 'M' shape in 1987 with dual peaks for writers 31 to 40 and 51 to 60 years old, to a relatively flat inverted 'U' in 1991 with little difference in median earnings for writers in the three cohorts between 31 and 60 years old, and ended in 1997 with another highly peaked inverted 'U' shape, as in 1982, but with the peak earnings for writers who were 31 to 40. For writers in film the pattern of change was similar but did not reflect as much change in the age of the peak earners. In 1982 the inverted 'U' shape identified the film writers 41 to 50 years old as having the peak earnings while in 1997 it was those 31 to 40, with the writers in the 41 to 60 cohorts earning only slightly less.

The Bielbys examined various career related issues through the estimation of pooled earnings functions that followed the basic form:

$$\ln Y_{ict} = \alpha + \beta_1 X_i + \beta_2 W_{it} + \gamma_c + \delta_t + \varepsilon_{ict},$$

where  $Y_{ict}$  is the WGA earnings for the  $i$ th artist who in the  $c$ th cohort<sup>6</sup> in year  $t$ ,  $X_i$  are time invariant characteristics of the artist (e.g., gender),  $W_{it}$  are traits that vary for the  $i$ th artist over time (e.g., experience),  $\gamma_c$  captures the effects that are unique to a specific cohort,  $\delta_t$  captures year specific effects (i.e., a vector of dummy variables for the year) and  $\varepsilon_{ict}$  is a vector of random errors [Bielby and Bielby (1993a, p. 14)]. They found that, regardless of the writer's age, experience in the industry has a positive impact on earnings, but that having been recently employed in the industry (i.e., within the past three years) overwhelms the importance of overall experience in determining writers' earnings.

<sup>6</sup> Was admitted as a member of the WGA in year  $c$ .

Third parties represent many writers, and other artists.<sup>7</sup> The Bielbys found that representation had a significant impact on both earnings and employment (through the estimation of a logit model for the probability of employment) and that the type of representation was also important. They separated “core” agencies<sup>8</sup> from all other agencies that represent writers and found that writers with “core” agency representation had an increased likelihood of being employed and significantly higher earnings than all other writers. When examining earnings data from 1982 to 1990 they also determined that the disadvantage faced by female writers was continuous over their careers at a constant differential and not cumulative.

Throsby and his colleagues (1986, 1989, 1994, 1995, 2003) have been studying Australia’s artists through direct surveys since the early 1980s. The first survey was undertaken in 1983, was repeated in 1987, 1993 and 2002, but does not represent a true panel as each survey involved a different group of artists. Its advantage over the Bielbys’ research is that Throsby et al. utilized a data collection instrument designed for artists. A considerably wider range of information tailored to the artists’ activities, their earnings and work experiences was therefore obtained.

The findings from the surveys suggest some significant changes in Australia’s artists and the career paths they have apparently taken. First and foremost there has been a considerable change in gender composition. In 1983 a bit more than one-third were female while in 2002 they were evenly split. Over the same twenty year period, the artists were getting older (mean age of about 46 years compared to 41.5) while the Australian labor force was staying about the same (37.5 years old in 2002 compared to 38.2 in 1983). They were also more likely to be native born Australians in 2002 than in 1983 (74 percent compared to 67 percent). In examining artists’ training, an important aspect of the development of artists’ careers, they found that the average time spent training went from about five years to slightly more than four (4.3) in 2002. While the time spent training showed a slight decline, the average age at which the artists start working as professional artists increased from 23 in 1983 and 27 in 1993 to 30 years old in 2002.

It appears that Australia’s artists spent considerably more time working at their art in 1993 than they did in 1983. This includes working in their primary artistic occupation, in another arts field and in arts related work, a circumstance that is not unusual for many artists. The increase in hours was approximately 25 percent over the ten year period. This increase in hours working in the arts led to a change in the proportion of time working in the arts, as well, from just over 71 percent to slightly more than 82 percent in 1993. Over the 1993 to 2002 period the time spent in the arts declined by almost eight percent and the proportion of their total time spent working in the arts decreased slightly to 81 percent.

<sup>7</sup> In the US unionization is relatively common among the performing artists, such as actors and musicians, and very uncommon among most other artists.

<sup>8</sup> “They negotiate unique arrangements with the talent guilds and cultivate long-term relationships with those who finance, produce, and distribute new projects.”

The artists' increased time and effort working apparently did not pay off in terms of earnings. Throsby (1986) reported that in 1983 artists' earnings from their art was approximately 60 percent of the earnings for all workers in Australia (full-time employees in their main jobs). In both 1993 and 2002<sup>9</sup> the artists' artistic earnings were only 40 percent of the earnings of all workers. If arts related earnings are included the difference was not quite as large, 70 percent in 1983, 60 percent in 1993 and 57 percent of the average earnings for all workers in 2002, but it still shows a decline in the relative earnings of Australia's artists. A comparison of total earnings from all sources shows that in 1983 artists earned approximately six percent more than the average Australian worker; in 1993 they earned only 80 percent of the average Australian's mean earnings. The period from 1993 through 2002 saw a slight improvement in overall earnings to the point where artists' mean earnings were 87 percent of the average full-time Australian employees' earnings.

In Australia, as in much of the rest of the world, artists tend to hold more than one job during the year in order to earn the income needed to survive. The proportion of artists who were multiple jobholders, decreased from almost three-quarters (72 percent) of the artists in 1988 to under two-thirds (63 percent) in 2002.

As far as career development, Throsby et al. find that artists are starting their professional careers increasingly later in life. In 1983 the mean age for the start of their professional careers was 23. A decade later it was 27. In 2002 it is 30. The increase was not uniform across all arts occupations. The 'community artists/community cultural development workers' had the largest relative increase in the average age at which they started their careers. The 'crafts practitioners' had the smallest increase. Perhaps this reflects differences in the relative importance of the formal schooling and training needed to enter these professions. Throughout this 20 year period it was the dancers who started their professional careers at the youngest age (19 in 1983 and 24 in 2002) and the writers who started at the oldest age (28 in 1983 and 37 in 2002).

### 3.4. True panel data

Rengers (2002) was interested in determining the best model to explain artistic careers. He compared the traditional human capital model, in which the artists' careers are affected by their intrinsic and learned qualities, to the winner-take-all model, in which the relative differences among artists are the most significant factor in explaining the differences in careers. He utilized data from several panels. One panel was comprised of 540 art college graduates in the Netherlands who entered the labor market between 1993 and 1995. Rengers had two observations on their activities. The first observation was approximately one and a half years after graduation and the second was six years

<sup>9</sup> In general, financial information from surveys and censuses are for the year prior to the survey year. For Throsby's 2002 survey the financial year extended from July 1, 2000 to June 30, 2001. In general the survey or census year will be used to identify all the data collected at that time.

later. Another panel represented all the visual artists in the Netherlands who had been surveyed annually starting in 1993. He used the results from four surveys of approximately 500 visual artists for the years 1993 through 1996. A third panel was comprised of 575 visual artists and covered the period 1980 to 1991. While Rengers' analysis was based on a panel, his ability to generalize and fully explore artists' careers was limited because some panels only covered a short period of time while others were limited to one group of artists.

The models estimated were for labor supply, as measured by hours of work, wages and gross earnings as well as for two non-monetary measures of artistic achievement. Rengers' results provided mixed support for both models. He found that inequality in hours, wages and earnings diminished over time, which would be consistent with the human capital model not the winner-take-all model. He did not find any evidence that the art school graduates who left the arts for non-artistic occupations were penalized in terms of their earnings, as one might have suspected in the winner-take-all model. He did find that differences in school location and field of study, measures of signals apparently used by the market, were important in explaining the variation in wages and he believes this provides support for the winner-take-all model. Additionally, Rengers finds that the winner-take-all model better explains the variation in the non-monetary measures he explores, one being the artist's assessment of his/her own reputation and the other a measure of whether the artist received the attention of the media.

Rengers also provides evidence from the Dutch artist samples for some overarching themes found in the literature on artists' careers. Dutch artists started their education and training at young ages, often outside formal schooling, and the vast majority received arts degrees (90 percent), but begin their arts careers relatively late in life because of the amount of education they receive. Their earnings early in their careers tend to be less than that of non-artists with the same amount of education because artists work fewer hours, not because they receive a lower wage. Characteristics of the artist's education were found to have little or no impact on the artist's career. Self-educated artists have the same earnings and the same supply behavior as those with formal arts education and the prestige of the arts college attended does not have long-lasting effects. Female artists' earnings are about one-third less than their male colleagues, a difference that is comparable to the non-arts labor market in the Netherlands. Six years after graduation approximately two-thirds of the artists work exclusively as artists and about an equal proportion work both in and outside the arts (approximately 13 percent). Both age and experience have positive impacts on a variety of measures of success including participation, wages, sales of art works, prices of art works and the frequency of exhibiting in art galleries. Receiving government grants has a positive impact on artists' earnings late in their careers.

Perhaps unique to the Dutch experience, Rengers identifies two distinct career paths for artists. One is the government market and the other is the private market. He finds that the majority of visual artists (approximately 60 percent) participate in both markets with the smallest proportion (approximately 15 percent) with earnings only from the public market and that getting established in a career in the private market takes longer

than getting established in one in the public market but that in both markets success breeds greater success.

#### 4. An empirical investigation of artists in the US: 1940–2000

This section analyzes the employment and earnings of American artists using decennial US Census data from 1940 to 2000. Since it is based on seven unique cross-sections of US artists it is most comparable to Throsby's work and can be categorized among those studies that are quasi-panels via separate cross-sections.

The information from the Census public use samples<sup>10</sup> will be used to examine various aspects of artists' employment patterns, earnings and earnings variability including the estimation of earnings functions for artists for census years between 1950 and 2000. The use of Census data over a 60 year time span provides a clearer perspective of three related issues that have been debated in the economics literature on artists: (1) As working professionals, to what extent have artists fared less well than comparably educated persons in other disciplines? (2) Has the oft-reported disparity in earnings between artists and comparably educated groups grown or shrunk over time? (3) Is this apparent "earnings penalty" due to the characteristics inherent in the nature of the artistic labor market? For example, are artists unusual risk-takers? Or are they unable to properly assess their likely outcomes in a job market increasingly dominated by "winner-take-all" characteristics? This section will not address a fourth important issue: the decision processes of those artists who routinely moonlight, both inside and outside the artistic profession.<sup>11</sup>

This section starts with (A) a discussion of the use of US census data to study artists. It is followed by (B) an analysis of growth in the artist profession between 1940 and 2000, and (C) a summary of the labor market for artists over the same period. The last two sections examine (D) the level variability in artists' earnings, compared to other professionals, and (E) the determinants of their earnings, and the existence of an artistic earnings penalty.

<sup>10</sup> The US Census Bureau as part of its decennial census collects detailed socioeconomic information from a sample of the population using the 'long-form questionnaire'. This information is made available to researchers through data sets that represent either 1 percent or 5 percent of the US population. They are known as the Public Use Microdata Sample or PUMS. The Census Bureau first created PUMS data from the 1960 Census, a single one percent sample was generated. In 1970, six independent one percent samples were generated; three were based on a long-form that went to five percent of the population, and three were based on a long-form that went to fifteen percent. This study uses data from four of these one percent samples to calculate descriptive statistics. In the regression analysis, all three one percent samples from the five percent survey are used. In 1980, three samples were generated: a five percent sample, used in this study, and two one percent samples. In 1990 and 2000, two samples were generated: a five percent sample, used in this study, and a one percent sample. Researchers at the Center for Demography and Ecology at the University of Wisconsin, in collaboration with the Census Bureau, reconstructed the one percent PUMS for 1940 and 1950.

<sup>11</sup> A detailed discussion of the multiple jobholding, moonlighting behavior of artists can be found in [Alper and Wassall \(2000\)](#).

#### 4.1. Using census data

A major constraint facing social scientists who study artists is the paucity of labor market data bases containing sufficiently large numbers of them. The artist labor force in the US is small having grown from 0.7 percent of the entire civilian labor force in 1940 to over 1.4 percent in 2000 (Table 2). Of the cross-sectional and quasi-panel data bases available to researchers in the United States, only the decennial Census Public Use Microdata Samples (PUMS) are large enough to permit meaningful statistical analyses. As a consequence, the information on artists presented herein utilizes public use samples from the 1940 through 2000 censuses. The actual number of artists contained in these data ranges from 3863 in 1940 to 109,469 in 2000, but they represent the entire population of artists in each census year.

Extensive information on housing and personal characteristics of household members is contained in the samples. The information collected in each decade has changed somewhat; a few questions have been dropped or added, and the definitions of terms used in some continuing questions have been altered. Nevertheless, there remains a substantial core information base across all six decades that can be utilized for comparative analyses.

Defining who is an artist can be problematic. Until recently, the National Endowment for the Arts (NEA) used the following eleven Census occupations: (1) actors and directors, (2) announcers, (3) architects, (4) post-secondary art, drama and music teachers, (5) authors, (6) dancers, (7) designers, (8) musicians and composers, (9) painters, sculptors, craft artists and printmakers, (10) photographers, and (11) artists not elsewhere classified (*nec*). They were originally located within the category called “professional and technical workers”. Since the 2000 Census this category has been narrowed to “professional workers”. Also, after the 2000 Census the NEA changed its artist definition.<sup>12</sup> The eleven occupations now defined as artistic are: (1) actors, (2) announcers, (3) architects, (4) artists and related workers, (5) authors, (6) dancers and choreographers, (7) designers, (8) entertainers and performers, sports and related workers, (9) musicians, singers and related workers, (10) photographers and (11) producers and directors [US Census Bureau (2003)]. Table A.1 in Appendix A provides a brief evolution of these categories, and reports on the sizes of the samples that were extracted for each artist category.<sup>13</sup>

<sup>12</sup> The Census no longer separately identified post-secondary art, drama and music teachers, and the actors and directors occupation was separated into two groups, one for the actors and the other for the producers and directors. The painters, sculptors, crafts artists and printmakers occupation was subsumed into the new artists and related workers occupation which also includes some artists who were previously in the artists not elsewhere classified occupation. The artists *nec* has been replaced by the narrower entertainers and performers, sports and related workers *nec* occupation.

<sup>13</sup> The definitions of many of the artist occupational categories used by the Census underwent changes. The major changes were as follows. The category “showmen” appeared in the 1940 Census only. Directors were not lumped with actors until 1980 (and were mainly classified as managers, and not artists, prior to 1980) and

The availability of Census public use samples to study the labor market behavior of artists is, however, a mixed blessing. Three principal issues arise from the Census data gathering methodology that affect the information published and its interpretation.<sup>14</sup>

One is that the Census artistic occupational categories used by the NEA and most researchers appear to be very inclusive. The Census dancer category incorporates ballet dancers, Las Vegas showgirls and barroom strippers, and the author category includes magazine feature writers as well as poets. The NEA definition of artists includes entire occupational categories that some would argue lie outside the fine arts, such as architects, designers, and radio and television announcers. However, in one respect, it might not be as inclusive as perhaps it should be. Prior to 2000, college and university teachers of artistic subjects were included among the artists, but not their counterparts at the elementary and secondary school levels; currently both groups are excluded from the definition. The eleven Census categories used by the National Endowment for the Arts define the artist profession in what follows.

The second and more critical issue is that the Census Bureau's methodology obscures important aspects of artists' occupational choices. The artistic occupation is unusual in that many of those in it also hold non-artistic jobs, i.e., they are multiple job holders. It has been frequently documented, using direct economic surveys of artists, that most artists report working in non-artistic jobs in a given year [e.g., Alper and Wassall (2000); Kingston et al. (1981, 1986); Throsby and Hollister (2003); Wassall and Alper (1984, 1985, 1990, 1992); Wassall, Alper and Davison (1983)]. Those who report working in non-artistic jobs also report that a significant percentage of their time is devoted to working in these other occupations, and that a significant percentage of their total earnings, typically well over half, derives from this non-artistic work.<sup>15</sup> However, the Census requires that a person filling out its long form choose a single occupation. This choice

in 2000 they were removed and placed in a separate category with producers, but the combined category was retained among the artist categories. Announcers was not a separate category until 1970; prior to that, they were not enumerated as artists at all. The category of art, drama and music teachers did not exist prior to 1970; before 1970, these artist/teachers were classified with their artist counterparts (e.g., "musicians and music teachers"). In 2000 the post-secondary school teachers of art category was no longer separately identified and therefore could not be included in the artist definition. Prior to 1980 window dressers were a category separate from designers; in 1980 both were lumped into the designer category. Other artist occupations experienced small changes over this period. The sole exception is authors, whose definition remained unchanged over the period. Citro and Gaquin (1987) have estimated the total artist population for the census years of 1950 through 1980 using reconstructed artist occupational categories based on the 1980 definitions cited above. Their estimates of total artists in these years are slightly different from ours, which are directly projected from Census Public Use Microdata Samples.

<sup>14</sup> For a more exhaustive discussion of the strengths and weaknesses of census data on artists see McNertney and Waits (1989) and Wassall and Alper (1992).

<sup>15</sup> Kingston, Cole and Merton (1981), in their survey of 2241 American authors, report that while the median 1979 income from the writings of these authors was \$4800, their median personal income from all sources was \$27,000. In a survey of 494 American composers, Felton (1978) reports a median family income of \$20,000 in 1974, but a median income of only \$168 from composing. Wassall, Alper and Davison (1983) asked 3027 New England artists to classify their 1981 work time and earnings into artistic, arts-related, and non-arts-related. With a definition of artistic occupations that was more narrowly defined than in the Census it was found that

is based on time spent at work during a single reference week. Once this occupational choice is made, all time spent working and all earnings in the year prior to the Census become attributed to that occupation.<sup>16</sup>

Nevertheless, the Census method of defining an occupation based on one's principal activity in a reference week is appealing to economists. As Filer (1988) notes, "a worker who spent 20 hours every week producing paintings and 30 hours a week teaching would be classified as a teacher. Conversely, a worker who spent 20 hours every week in the classroom and 30 at her easel would always be a painter . . . Census definitions result in a bias towards including only those who achieve the most success in their art form as artists."

The use of a market test to define who is an artist troubles some observers. Regardless of one's position on this issue, one must be aware that, when working with aggregated Census data on artists, unlike most other professions, an unknown but significant percentage of the reported work effort and earnings will be from other, non-artistic occupations. The dynamic choices members of this unique profession make in dividing their work time among diverse occupations cannot be observed using Census data.

The third issue is the Census policy of top-coding certain variables for reasons of confidentiality, including the individual's age and the individual's income and earnings. Most importantly, in the 2000 Census an individual's reported wage and salary earnings is capped (top-coded) at a maximum level of \$175,000.<sup>17</sup> All those individuals earning above this level are assigned the state's mean earnings for those earning above the top-code. For example, all Massachusetts residents who had wage and salary earnings in 1999<sup>18</sup> above \$175,000 would have their earnings reported as \$322,000. Thus the

only 24 percent of the survey respondents held artistic jobs alone during the year. Of the artists who held other types of jobs as well, 52 percent held artistic and arts related jobs, 29 percent held artistic and non-arts related jobs and 19 percent held all three types of jobs. Of the artists' average labor earnings of \$14,079 in 1981, 46 percent was derived from artistic work, 34 percent from arts-related work and 20 percent from work which was neither artistic nor arts-related in nature. In this study teaching and coaching were defined as arts-related work. Direct surveys of artists typically employ a more narrow definition of "artist" than the Census. While they contain a higher percentage of "traditional" artists, they incorporate some persons who spend little time and earn little money at their art, but who define themselves as artists. By defining artists' occupations more narrowly, these studies may also attribute a smaller percentage of their total earnings to their art work. Also, the low percentages of earnings from artistic work cited in the studies above are due in part to their not counting earnings from teaching in one's profession as part of artistic income.

<sup>16</sup> An intriguing question is: What choice do artists make when confronted with the reference week work question? In direct surveys of artists, it is common that they signify being an artist is their principal profession despite little evidence of work time or of financial success. Their artistic occupation often is more prestigious than any other stated occupation(s). Do artists behave similarly when filling out the Census form, or do they answer the reference week work question literally?

<sup>17</sup> Earnings in each category are top-coded in every year: at \$5000 for 1939, at \$10,000 for 1949, at \$25,000 for 1959, at \$50,000 for 1969, at \$75,000 for 1979, and at \$90,000 in 1989. In 1999 there were top-codes for each type of income with wage or salary income top-coded at \$175,000, self-employment income top-coded at \$126,000 and total earnings top-coded at \$310,000. Summing the categories to determine total earnings reduces the compression somewhat, but it is still true that actual means and standard deviations will be underestimated.

<sup>18</sup> US Census data on earnings and time spent working are for the calendar year prior to the census year.

earnings of the highest paid members of any occupation may be underestimated. These earnings caps have risen from decade to decade. To a small but unknown extent, the stated mean earnings and degree of earnings inequality in the artistic (and any other) profession will be underestimated using Census data.

#### 4.2. *Size and growth of the artist profession: 1940–2000*

The growth in the artist labor force during the period 1940–2000 has been dramatic. In 1940, there were 386,000 artists in the US labor force, or 0.7 percent of all its members. By 2000, the number of artists had increased fivefold to 1,931,000, or 1.4 percent of the labor force.<sup>19</sup>

During the post-World War II period, the growth of the civilian labor force was fueled by rapid growth of the service sector. Most professional workers, and most artists, work in service industries. A second trend abetting the post-war growth in the civilian labor force has been increasing labor force participation rates of women. The growth in both male and female professional and technical workers (and artists as well) substantially exceeded the growth in the labor force as a whole; part of this rapid growth reflects a higher proportion of women who work in these professions. Even though women have been disproportionately represented in the professions, professions other than artists have typically contained a higher proportion of women.

These trends are reflected in the relative growth rates of the three labor force categories in [Table 2](#). Between 1940 and 2000, the civilian labor force grew by 166 percent. The professional labor force, however, grew at a rate of 542 percent over this period. The artist labor force increased by 400 percent, somewhat less than the professionals overall but considerably greater than the labor force. In recent years, the growth in artists has been more pronounced. Between 1980 and 2000, for example, the professional labor force increased at 103 percent while the rate of increase of the artistic labor force was 77 percent.

The growth in artists is drawn from Census information published after each Census; thus they incorporate the differences in the definition of artists noted above and in [Table 2](#). In the sections which follow, the implications of changing occupational definitions of artists over time are minimized primarily by analyzing all artists as one broad occupation. There still exist less important definitional changes which over time have added to or subtracted from the artistic labor force. These, noted above, primarily affect the number of directors and announcers enumerated as artists from 1960 to 1980. The exclusion of the post-secondary school teachers of art from the 2000 Census is likely to have an impact, but the extent is not clear.

<sup>19</sup> Authors' calculations and Ellis and Beresford (1994, p. 6).

Table 2  
Growth in artists vs. growth in the civilian labor force and all professional workers: 1940–2000 (numbers in thousands)

Category	1940	1950	1960	1970	1980	1990	2000	Change (%) 1940–2000
Civilian labor force	51,742	58,999	67,378	79,802	104,058	122,473	137,669	166.1
Professionals	3879	5081	5543	8800	12,275	16,648	24,905	542.0
Artists	386	441	492	737	1086	1671	1931	400.3

#### 4.3. Labor supply and labor market characteristics

In examining the labor market outcomes of artists, some perspective can be gained by comparing them to an appropriate reference group of workers. Most Census-based studies have compared artists' labor market outcomes to a reference population. The choice of reference population has not been consistent, ranging from specific occupations with comparable educational attainment [Santos (1976)] to specific professional occupations [Waits and McNertney (1980)], to all workers [Filer (1986)], and to all managerial, professional, and technical workers [Filer (1988, 1989)].

This research lies in a similar vein. The conclusions drawn about artists are compared to those for all professional workers, excluding artists. All other professional workers were chosen as a reference group because (a) they possess similar demographic and socioeconomic characteristics, (b) they comprise the category in which artists were initially classified by the Census and (c) by choosing all other professional workers, one is unlikely to bias comparisons to artists as might occur by selecting specific occupations.

Some basic comparisons are shown in Table 3. In this table, labor force and socioeconomic characteristics of both artists and professional workers, excluding artists, are reported and compared.

In many respects artists closely resemble members of other professions. Some distinctions, however, are apparent. Perhaps most important is the additional years of schooling that other professional workers have achieved relative to artists. This difference has narrowed from 2.5 years in 1940 to less than one year in 2000.<sup>20</sup> Another less obvious (and perhaps less expected) difference is that the artist labor force has, for

<sup>20</sup> The comparison of educational levels for 1990 and 2000 to prior census years is weakened because since 1990 the Census has reported on highest degree or level of schooling completed and not years of schooling. Using data on both years of schooling completed and highest grade/degree completed for 1990 collected by the US Census Bureau [Kominiski and Siegel (1993)] the authors developed a method to convert highest grade/degree completed to years of schooling based on the average number of years it took to complete the grade/degree.

Table 3  
 Labor market characteristics of artists and other professionals in the experienced civilian labor force: 1940–2000 (median in parentheses)

\*In year prior to census year.

almost all the period, been composed of a higher percentage of men and whites than the other professions.

However, the most striking findings are related to the consistently poorer labor market outcomes of artists. Although the disparities between artists and other professional workers narrowed over the 1940–2000 period, they by no means disappeared. Across all seven census years, artists were more likely to be unemployed. Up to 1960, artist unemployment rates were at least three times that of other professional and technical workers; after 1960 artist unemployment rates were between two and three times greater. Artists also have consistently worked fewer weeks per year and fewer hours per week over this period. In each census year the proportion of artists working full-time, year-round (defined as working at least 50 weeks per year and 35 hours per week) was less than the proportion of professional workers. However, the gap between annual hours worked by artists and professional–technical workers fell over this period, with a difference of approximately 125 hours in 1999 down from 520 hours in 1939 and less than 200 hours in 1969. Similarly, the gap in percentage working full-time was lower between 1969 and 1999 than in earlier Census years.

Given that these labor market disparities persist across seven census years, any type of disequilibrium is unlikely to be the cause. Over a sixty year period, one would certainly expect any disequilibrium to have adjusted. This leads to a search for alternative explanations.

Several hypotheses have been advanced as to what characteristics make the artist labor market unique. First, it seems difficult to accept any explanation based on informational asymmetries; surely over sixty years artists and those training to become artists would recognize these disparities and alter their career choices.<sup>21</sup> It is possible that artists value leisure more highly than do members of other professional occupations. However, it seems unlikely that any single occupation would attract only those with a higher value for leisure. This “leisure theory” can be contrasted to Throsby’s “work preference” model of artist behavior [Throsby (1994a)], which postulates that the artist is driven to create, and will maximize time spent working as an artist subject to constraints of earning sufficient income, from either inside or outside the arts, to finance an acceptable level of consumption. On the one hand, this theory would imply that artists spend more time working than other workers who receive (greater) disutility from their work. This does not show up in the annual hours worked data. On the other hand, the theory also predicts that, for artists who supplement their arts earnings with jobs outside the arts, as wage rates for non-arts jobs rise, more time will be freed to create art. As the premium to a college or higher level education (which most artists possess) has risen over the last two to three decades, so has the gap in hours worked narrowed between artists and other professionals. This is consistent with artists being able to finance more creative time from higher non-artistic wage rates. Unfortunately,

<sup>21</sup> Compare this perspective to that of Towse (1992a), who argues that artists tend to enter the artistic labor market too frequently because they overestimate the likelihood of future success.

with all income attributed to the reported profession, it is impossible to test these relationships using Census data.

Another set of theories lies in the roles of risk-taking among artists and the rewards to those who rise to the top of their profession. Although these theories were mainly used to explain income distributions among artists, they also have implications for labor supply. This line of reasoning was initially raised by Santos (1976), who asserted that performing artists belong to a class of risk-taking workers who, unlike other workers, are willing to trade off a small chance at substantial financial rewards for a much larger chance of low earnings. Finding that artists' investments in training do not yield financial returns consistent with those in the labor market as a whole, he noted that "risk-preference and psychic income apparently prevail over financial considerations when considering the pursuit of a career in the performing arts" (p. 257). In a nutshell, too many persons pursue careers in the arts because of these two factors. Santos does not explain why artistic careers would disproportionately attract occupational risk-takers, however.

A related theory is found in the literature on the earnings of superstars [Rosen (1981); Adler (1985)]. The predicted effects of this theory on labor supply are more prominent in Frank and Cook (1995); they refer to superstar labor markets as "winner-take-all markets". They note that "market incentives lure too many contestants into winner-take-all markets, and too few into other careers" (p. 103). They attribute this outcome in part to contestants' overestimates of their talent. However, they add that as long as market entrants base their decision on expected earnings rather than marginal earnings, the number of entrants will be greater than that what is socially optimal.

In somewhat different ways, both approaches imply that the nature of artistic labor markets will induce too many entrants. These arguments are consistent with the observed data on employment found in the Census.

Benhamou (2000) has an additional set of hypotheses that do not focus on the artist. One focuses on the behavior of the arts institutions and organizations that employ artists rather than the artists' choices. The other focuses on the public policies that support artists, especially those who choose to be self-employed.

Finally, it is worth noting that ease of entry into artistic occupations combined with greater loss of work time due to more frequent transitions from one job to another (both inside and outside their occupation) have also contributed to the consistently lower labor market participation experiences of artists. Thus artists would likely experience greater friction in moving among jobs and, even in a world of perfect information, would spend more time unemployed than members of other occupations. Given the unique extent of multiple job-holding among artists, these phenomena can be viewed as occupational hazards of working in the arts, which must be tolerated even if known in advance. As noted, this conclusion could not be drawn from an examination of Census data alone.<sup>22</sup>

<sup>22</sup> Corroborating evidence may be found in Wassall, Alper and Davison (1983), who report that New England artists were unemployed more times in a year but for shorter durations than members of the labor force in gen-

#### 4.4. Earnings, calculated wage rates, and earnings variability

As noted above, two principal issues have been raised in the literature on artists' earnings. One is the existence and extent of an earnings penalty facing artists, compared to other workers of comparable education and skills. The other is the existence of unusual earnings patterns in the artistic labor market, such as greater earnings uncertainty and variability, relative to other occupations. The availability of Census earnings data over a 60-year period enables an extended comparison of earnings, and thus of these two issues. In this section, we examine earnings variability. In the following section, the existence of an earnings penalty is investigated.

In [Table 4](#) the current and real earnings (in 2004 dollars) and estimated hourly wages of artists and other professional workers are contrasted. Means as well as medians are reported since several categories have medians of zero.<sup>23</sup> We report wage and salary, self-employment, and total earnings separately.<sup>24</sup> The definition of labor earnings has remained consistent since the 1950 Census. In 1940, only wage and salary earnings were reported.

The information in [Table 4](#) shows that artists have earned less than other professional workers throughout this period. Both mean and median annual earnings of other professional workers have been higher in every Census year. Unlike disparities in time worked, differences in earnings have not narrowed over time. The difference in median earnings was 33 percent in 1949, and 30 percent in 1999. It has ranged from a low of 14 percent in 1969 to a high of 45 percent in 1979. Although there is no clear cut trend, the largest percentage earnings differences occurred in 1979 and 1989. The differences in mean earnings over the same period are similar, though slightly less. They range from 12 percent in 1969 to 30 percent in both 1979 and 1989.

A major part of the earnings differentials is attributable to artists working fewer hours per year. This is reflected in the generally smaller differentials in median wages between the two groups, and in the virtually equivalent mean wages. These figures suggest that a comparison of only full-time workers in the two groups would reduce earnings differences; in fact, it does.<sup>25</sup> This approach of limiting comparisons only to full-time workers

eral. It can also be found in [Menger and Gurgand's \(1996\)](#) study of performing arts in France. They document the role played by the French unemployment insurance system in the pattern of performers' employment over their careers.

<sup>23</sup> A median of zero exists for self-employment earnings because the majority of artists and professional and technical workers are employees and not self-employed.

<sup>24</sup> In the Public Use Microdata Samples, labor earnings are composed of (1) wage or salary income, (2) non-farm self-employment income, and (3) farm self-employment income. From 1970 to 1990 earnings are reported separately in each of the above categories. From 1950 to 1960 and again in 2000 earnings from (2) and (3) were collapsed into one category. In 1940 only wage and salary earnings were reported.

<sup>25</sup> For example, the median earnings of full-time year-round professional and technical workers were the same as those of artists in 1969, but exceeded artists' earnings by 15.2 percent in 1979, by 16.5 percent in 1989 and by 15.4 percent in 1999. The pattern of differences in mean earnings between the two groups was similar over the same time period.

\*Year of data is for calendar year prior to census year.

is not pursued here, since a defining characteristic of artists' careers is that they work fewer hours per year than members of virtually all other professions.

Real earnings of artists and other professional workers increased from 1939 through 1969. The decade of the 1970s was a period of high inflation so by 1979 the real earnings of the artists and other professionals had decreased considerably. Unlike the other professions whose real 1999 wage and salary earnings were thirteen percent higher and whose real total earnings were five percent higher, the real earnings of artists, regardless of source, had still not reached their 1969 levels thirty years later. In fact their 1999 wage and salary earnings were two percent lower than in 1969 and their total earnings were three percent lower.

The other issue raised above addresses the question of a possible relationship between the poorer labor market outcomes that artists experience and greater earnings variability among artists than other professions. In the previous section, we reviewed two explanations of such a relationship. Santos' (1976) theory of artists as risk-takers suggests that artistic careers should be characterized by earnings with lower means and greater variability than those in comparable occupations inhabited by risk-averse workers. In fact, he presents evidence from the 1960 Census that the earnings of dancers and singers had higher coefficients of variation than other workers with the same amount of education.

Rosen's (1981) superstar theory also implies greater variability in earnings. However, it further implies that the distribution of income will become more skewed as (1) improvements in technology make it increasingly possible for the top superstars in each field to reap relatively greater rewards, due to the joint consumption characteristics of their product (book publishing and recordings, e.g.), and (2) the number of consumers or the intensity of their demands increases. Both these conditions appear to hold across artistic professions.<sup>26</sup> The superstar model does not predict that mean earnings will necessarily be lower than in comparable occupations without superstar characteristics, however.

Surprisingly few attempts have been made to test these hypotheses. Filer (1989) tested extensively for the presence of greater earnings inequality among artists in the 1980 Census. Using several measures of inequality, he found that "there is greater dispersion of incomes among artists than among the entire work force, or among managers, professionals, and technicians", but that "this difference does not appear to be large" [Filer (1989, p. 72)]. This difference in inequality seems attributable to two factors. One is the greater variability in annual hours worked by artists compared to the above reference groups. Differences in inequality were less when only full-time, year-round workers were compared. They were also less when artists were compared to selected, narrowly-defined occupations. Looking at three-digit occupations, he found that measures of earnings inequality "for occupations where individual talent and performance are important determinants of earnings tend to be similar to those for artists" (p. 74).

<sup>26</sup> Frank and Cook put it like this (p. 121): "The growing importance of winner-take-all markets thus implies a change in the pattern of incomes observed in the economy. More specifically, it implies that even if we control for age, education, experience, ability, and other individual characteristics thought to influence productivity and hence income, we should see greater income variability now than in the past."

To address this issue more comprehensively, in [Table 5](#) we compare various measures of earnings variability by comparing artists to other professionals from 1940 to 2000. In [Table 6](#), we make similar comparisons among selected occupations at the three-digit

*Notes:* Reporting of self-employment earnings, total earnings and total income allows for negative amounts. Prior to the 1970 Census, self-employment earnings included earnings from farm sources; from 1970 on, they are from non-farm sources only. Total earnings include all wage and salary and self-employment earnings. All income sources were capped at a maximum amount by the Census. The maximum reportable amounts in each income category for each Census year were: in 1940, \$5000; in 1950, \$10,000; in 1960, \$25,000; in 1970, \$50,000; in 1980, \$75,000; and in 1990, \$90,000. In 2000 maximum reportable earnings/income varied by type of income and were: \$175,000 for wage and salary earnings; \$126,000 for self-employment earnings; and \$310,000 for total earnings. Total earnings were not directly reported in the 1950–1980 Censuses but were calculated by the authors. Income from all sources was also calculated by the authors. For 1940, earnings variability measures refer to wage and salary earnings only. See the text for more detail.

<sup>1</sup>Year of data is for calendar year prior to Census year.

level using 2000 Census data. Any comparisons using Census data are subject to some degree of bias because of the Census practice of top-coding all income categories. In both tables, earnings at the high and low ends of the distribution are examined, and two measures of earnings inequality are provided, the coefficient of variation and the ratio of median to mean. The initial comparison is limited to all artists and all professional workers.

The data in Table 5 show that earnings inequality among artists was greater than among other professional workers in all seven census years. Excluding 1939, the year in which self-employment earnings were not reported, both the coefficient of variation and mean/median measures show increases in inequality over time for both artists (as predicted by Rosen) and other professional workers. Earnings inequality among artists has grown at a faster rate than for other professional workers. In terms of the size of the tails of the earnings distribution, artists were more likely in every year to have total earnings (net of expenses) of zero or less than the other professional workers. The

likelihood of having total earnings at the maximum or top-coded level in each year was roughly equal for the artists and the other professionals.

To account for the possibility that non-earnings sources, such as royalty income, further contributed to inequality, the pattern of income from all sources was examined. This made little difference in the results. The same tests were further performed on full-time year round workers (not shown). Not surprisingly, the difference in inequality between artists and professional and technical workers narrows but does not disappear when only full-time, year-round workers are compared.

A detailed examination of the fifteen professional occupations with the greatest earnings inequality in 1999 is shown in [Table 6](#). The occupations were ranked using the mean/median and the coefficient of variation.

Although there are 123 professional occupations, nine of the eleven artist occupations show up in the top fifteen when ranked by coefficient of variation, and seven show up when ranked by mean/median. Regardless of the measure, actors have the greatest variation in total earnings. The three artist occupations with lowest earnings inequality, regardless of measure, are dancers, designers and architects. It is also true that within this group of high variance occupations the arts occupations generally have the largest percentage of members with earnings of \$0 or less in 1999 and the largest percentage with earnings above the Census established top-code (\$310,000).

It is also interesting to note the nature of the non-artistic occupations found in [Table 6](#). They do not generally correspond to ones expected to be listed among those in superstar or winner-take-all markets. Perhaps the sole exception is athletes, which ranked second using either variability measure.

#### 4.5. Earnings functions

To gain a deeper understanding of whether, how and why artists are different from other workers, and to more accurately determine any earnings penalty from being an artist, earnings functions for artists and for other professional and technical workers are estimated.

This is by no means the first use of earnings functions to explore possible differences in the rewards to education, training and other labor market attributes between artists and a reference group. Using 1980 US Census data [Filer \(1986\)](#) compared the earnings of artists to those of the general work force. [Filer \(1990\)](#), using the same data source, focused on the return to years of education among artists. Also, [Withers \(1985\)](#) compared the earnings of artists (collected from a special survey of artists) to the earnings of the general work force (using Australian Census data). In addition, this approach has been used to examine artists' earnings recorded in special surveys, as in [Snooks \(1983\)](#), [Wasall and Alper \(1984\)](#), [Montgomery and Robinson \(1993\)](#) and [Throsby \(1992, 1996\)](#).

In the earnings studies comparing artists to a reference group, some consistent findings emerge. Artists do not seem to fit the standard earnings model as well as other workers, and earnings functions for them have poorer goodness-of-fit [[Filer \(1986\)](#)].

The return to education for artists is lower [Filer (1986); Withers (1985)], or even negative [Withers (1985); Throsby (1992)].

As discussed in previous sections, what makes this research unique is the estimation of earnings functions from a consistent data source over a period of sixty years. Earnings functions for artists and other professional workers are compared using samples from the 1950 through 2000 Census years.<sup>27</sup> Selected results from these sets of earnings functions are presented in Table 7 and the definitions for the variables in the model are presented in Table 8. In each census year, identical functions for artists and for professional and technical workers are constructed. Across census years, the variables in these functions are essentially the same; however, some variables were not available in all six census years.<sup>28</sup>

In general, the earnings function coefficients are consistent both across census years and between the two occupational groups. Conventional wisdom and prior research suggests that the determinants of success for artists should be harder to quantify, and this is confirmed here. In four of the six census years the goodness-of-fit for the estimated equation (as measured by adjusted  $R^2$ ) of the professional and technical workers earnings function is greater than that of the artist earnings function, but not that different.

Consistent with results from other studies, the return to an extra year of education is found to be greater for professional and technical workers in all years except for 1949. The interpretation of this result, based on Wassall and Alper (1984), Towse (1992a) and Rengers and Madden (2000), is that since Census data mixes artistic and non-artistic earnings in reported total earnings of artists, the resulting coefficient of years of education in the earnings function reflects no or negative correlation of education with artistic earnings and a positive correlation with non-artistic earnings.<sup>29</sup> This was also observed by Montgomery and Robinson (1993) using data from a different survey. The relative difference in 1999 is among the largest it has been.<sup>30</sup>

<sup>27</sup> Earnings functions for 1940 are not presented. The failure of the Census to collect information on self-employment income in 1940 biases results for those professions with substantial income from this source; prominent among such professions are most artistic disciplines.

<sup>28</sup> Other independent variables not reported in Tables 7 and 8 include whether the artist was: a member of another ethnic group (not for 2000); in school at the time of the census; a veteran; a federal, state or local government employee. It also included regional and occupational dummy variables.

<sup>29</sup> Using the New England artist data, it was found that years of schooling was significantly and negatively correlated with artistic earnings, but significantly and positively correlated with arts-related earnings and with non-arts related earnings [Wassall and Alper (1984)]. The finding of a significant negative relationship between years of schooling and artistic earnings may overstate the adversity of this relationship. Presumably artists are maximizing earnings at the margin among all jobs; those who are better educated receive a higher return per extra hour worked in non-artistic jobs, so they reduce their artistic labor supply and thus their artistic incomes. Little or no correlation between education and artistic earnings is consistent with the notion that artistic talent is innate and cannot be enhanced by general education.

<sup>30</sup> US Census data does not provide information that allows the researcher to control for an individual's mental abilities, though there are controls for physical abilities in the data and model. This is likely lead to an upward bias in the estimated coefficients and therefore on the estimated returns to formal schooling [Angrist and Krueger (2001); Griliches and Mason (1972)]. It also is not possible to control for artistic ability, but the impact of this is unknown.

Table 8  
Variables in the estimated earnings functions

Variable	Values	Explanation
Education	Years of schooling	Assigned from Census variable measuring highest level of education attained. See footnote 12.
Experience, Experience <sup>2</sup> , Experience <sup>3</sup> and Experience <sup>4</sup>	Years of experience and years of experience up to the 4th power	Calculated as: age – education – 5
Head of household	1–household head, 0–not household head	
Female	1–female, 0–male	
Black	1–race black, 0–not black	
Asian	1–race Asian, 0–not Asian	
White and other	Racial category excluded	
Hispanic	1–ethnicity is Hispanic, 0–ethnicity not Hispanic	
Married	1–married, 0–not married	Not married includes: separated, divorced, widowed and never married
Children under 6	1–children under six years old present in household, 0–otherwise	
Disability	1–employment related disability, 0–otherwise	
Immigrant	1–born outside the US, 0–born in the US	
Non-citizen	1–citizen of the US, 0–not a citizen of the US	
English spoken	1–speaks English (well or very well), 0–otherwise	
Self-employed	1–self-employed, 0–employee	
Self-incorporated	1–self-employed in an incorporated business, 0–otherwise	
Self-unincorporated	1–self-employed in an unincorporated business, 0–otherwise	

Until 1999 both estimated earnings functions for the artists and the reference group of professionals showed the usual adverse effects on earnings of being a woman or a member of most minority groups. In 1999 the difference in earnings associated with the artists' race and ethnicity seems to have disappeared, not so for their professional peers. The difference between male and female artists' earnings is still significant, as it

Table 9  
Statistical rewards and penalties of being an artist

Reward/penalty	Year*					
	1950	1960	1970	1980	1990	2000
Percent return to extra year of education: artists	7.9	3.0	6.0	5.1	10.4	8.0
Percent return to extra year of education: professional & technical workers	6.0	5.3	8.1	8.0	11.6	11.6
Percent earnings difference between artists and other professional & technical occupations: actual	58.2	56.3	43.6	90.3	12.1	21.9
Percent earnings penalty to artists for not working in other professional & technical occupations: calculated using regression coefficients	19.3	25.3	33.2	50.7	5.9	8.4

*Notes:* Returns to education and earnings penalties calculated from regression equations with selected coefficients shown in Tables 6 and 7. In calculating penalty to artists for not entering other professional and technical occupations, it was assumed that they would distribute among these occupation in the same percentages as the then existing occupational distributions.

\*Year of data is the calendar year prior to the census year.

is for the other professionals. This difference has shown little change since 1989 and is still considerable. In 1989 black professionals' earnings were not significantly different from their white peers' earnings, and in 1999 they were actually earning significantly more than white professionals.

Being a head of household affects artists' earnings with a larger positive affect than it does for professional and technical workers in general. Being married has a larger positive affect on professional and technical workers' earnings than on the artists' earnings for the entire period.

Using these earnings functions, the return to an extra year of education can be observed (at mean values) for both groups. This is shown in Table 9. As noted, in all years but 1949, the return to an extra year of education is greater for professional and technical workers.<sup>31</sup>

<sup>31</sup> Though not reported because of possible bias due to missing self-employment income, the calculated return to an extra year of education for artists in 1939 was also (2.3 percent versus 4.2 percent) less than that for other professional and technical workers.

The earnings functions can also be used to estimate a more sophisticated version of the earnings penalty associated with being an artist, referred to earlier. This is accomplished by comparing the predicted earnings of an artist possessing average levels of all characteristics used as explanatory variables in the earnings function to what that artist would earn, with the same average levels of all characteristics, as a professional or technical worker (i.e., using the estimated coefficients from the professional and technical worker earnings function).

Using this technique, the earnings penalty to artists is estimated to be less than that revealed by the direct comparisons of earnings in the previous section. In 1959, an artist with average characteristics is estimated to have earned 25 percent more as a professional or technical worker. In 1969, an artist with average characteristics would have earned 33 percent more as a professional or technical worker. In 1979, an artist with average characteristics would have earned 51 percent more as a professional or technical worker. In 1989 the calculated difference was only six percent. Most recently, in 1999, the calculated difference in the predicted earnings of the average artist in a professional or technical job is eight percent more than they would have earned as a professional or technical worker.

In comparison, Filer (1986, p. 72) calculated, using the same method, the earnings penalty to artists relative to members of the general work force. He finds that an artist with average characteristics would have earned 10.3 percent more as a member of the general work force. He was subsequently criticized by several authors for comparing artists to the general work force. Clearly one would expect a larger earnings penalty to be calculated if artists were simulated as members of occupations where more education is required and returns to additional education are greater. This is consistent with these findings.

Filer (1986) dismisses the notion that artists have a lifetime earnings penalty because the penalty, calculated at the mean, is offset over one's work years by the steeper age-earnings profile of artists than those for the general work force.<sup>32</sup> In this paper a larger earnings penalty is found to exist in each census year when artists are compared to professional and technical workers. Further, since artists' returns from extra years of experience are comparable to that for the overall professional and technical work force, this argument becomes moot when a more appropriate reference group is used.

## 5. US artists' careers: 1979–1998

In the United States several nationally representative panel surveys have been in existence for some time. Perhaps the best known is the US Department of Labor's National Longitudinal Survey of Youth. Initiated in 1979, it was designed to follow a sample of young people from high school throughout their working careers. Alper and Wassall

<sup>32</sup> Filer (1988) does not calculate an earnings penalty in his paper.

(2002) utilized these surveys to examine issues of longevity and career change among artists in the US.

The survey participants were 14 to 22 years of age when first interviewed in 1979. Two additional panels were added over the years to make the sample more representative of the population. One panel was a military sample that was later dropped. The other was a group of economically disadvantaged youth, some of whom were later dropped as well. In total 12,686 individuals were part of the survey at some point during the more than 20 years it has been in existence. The participants were interviewed annually from 1979 through 1994 and every other year thereafter. The number of artists in the survey is not large enough to provide detailed information by type of artist. Therefore, the artists are grouped into four artistic occupations: performers, architects and designers, visual artists and 'other' artists.

What follows presents a sampling of what can be learned about artists' careers through the use of panel data. It starts by examining the stock and flow of people into and through arts occupations (Section 5.1). Then there is a brief discussion of who they are at the start of their artistic careers (Section 5.2). The next section examines the transitions that occur during artistic careers with respect to the artistic and non-artistic jobs they held (Section 5.3). The last two sections describe who permanently leaves the arts (Section 5.4) and what they do afterwards (Section 5.5).

### *5.1. Flow and tenure*

Clearly evident from this panel survey is the fact that many people explore the arts as an occupation but very few remain as artists for significant periods of time. When comparing the number of people who indicated that they were artists in any given year, i.e., the stock of artists, to the total number of people who moved into and out of artistic occupations over the survey's 19 years, i.e., the flow of artists, a significant difference in these numbers is found. Throughout the period 766 of the 12,686 people indicated that they had worked as artists at some point in time. This is more than five times the number of people who were artists in any given year (Table 10).

Of those who were part of the artist population at some point over this period, almost fifty-seven percent were male. This is slightly greater than the overall male representation in the survey of just under fifty-one percent, suggesting that over their careers men are more likely to explore the arts as a means of earning income than women.

The average time spent working as an artist was only 2.2 of the survey years. In comparison, people who had been artists at some time during the survey period also worked at non-arts jobs in approximately 10.2 of the 16 survey years. The number of survey years working as an artist was slightly, but not significantly, higher for men than women (2.3 years versus 2.1 years). Almost 60 percent of those who worked as artists worked as artists in only one of the survey years. In comparison, more than 98 percent of those who were artists at some point during the period also spent time in more than one year employed in non-arts jobs. Just slightly more than two percent of those who were artists at some point were artists in 10 or more years while more than 60 percent

Table 10  
Number of artists by year: NLSY79

	Architect or designer	Performer	Visual artist	Other artist	Total
1979	2	15	10	8	35
1980	3	25	10	14	52
1981	8	23	16	17	64
1982	11	35	13	21	80
1983	13	38	20	23	94
1984	21	41	22	29	113
1985	25	32	19	25	101
1986	33	53	21	24	131
1987	36	39	24	43	142
1988	33	40	29	26	128
1989	20	39	45	5	109
1990	32	43	29	28	132
1991	24	38	28	25	115
1992	32	45	28	26	131
1993	22	42	33	30	127
1998	56	37	29	22	144

worked in 10 or more years at non-arts jobs. The female artists' behavior was not that different from the male artists. Only 1.5 percent of the female artists worked as artists in 10 or more survey years, while 2.5 percent of the male artists did the same.

## 5.2. The start

Artists started working as artists, on average, at just about 25 years of age (Table 11). The difference between starting ages for men and women (approximately a half year) was not statistically significant.<sup>33</sup> Only for the visual artists was the difference in starting age significant (marginally), with women starting to work as painters and sculptors two years later than men.

Overall there is a significant difference in the ages at which the artists started working in their arts occupations when comparing across their first arts occupations. The average age for the architects and designers was significantly greater than any other artist group. This probably reflects the additional years of formal schooling required to become an architect.

<sup>33</sup> It is likely that the true average age at which these artists started working as artists is somewhat lower. Some of the artists were 14 years of age at the first interview and were not likely to have worked at all prior to their participation in the survey, while others were as old as 22 at the first interview. Those who were older may well have already been working as artists by the time they were first interviewed.

Table 11  
Average age started being an artist by gender and first arts occupation (years)

	Total	Male	Female
Architect or Designer	27.2	27.4	26.8
Performer	24.2	24.1	24.3
Visual artist	25.4	24.4	26.4
Other	24.9	24.6	25.1

Source: Authors' tabulations and calculations from NLSY79, 1979–1998, Release 10.0.

### 5.3. The transition

An examination of those employed in the arts at some time during any given year reveals that the proportion that had an arts occupation as their primary occupation tended to diminish over time. This was determined by looking at the employed artists' current occupations at the time of the interview.<sup>34</sup> While the decline in the proportion with their primary occupations being arts occupations is not constant as artists mature, the trend is clearly in the downward direction. It was at the time of the fourth round of interviews (1982), when the artists were 18 to 26 years old, that the largest proportion of people employed as artists reported having an arts occupation as their primary occupation. Almost 85 percent were working as artists (Table 12). By 1998, the proportion had decreased to approximately 70 percent.

A transition that occurred over the period is the change in variety of artists' non-arts primary work activities.<sup>35</sup> In 1979, the year in which the artists were the youngest, approximately 17 percent of those artists whose primary occupations were not in the arts were working in some other professional or managerial occupation and about one-half were working in sales and clerical occupations. By 1998 more than two-thirds of the artists with primary occupations not in the arts were working in other professional and managerial jobs while fewer than ten percent were working in sales and clerical jobs. Additionally, 17 percent were working in service occupations at the beginning of the survey period, all in food service, but by 1998 only five percent were doing so, none in food service.

There were transitions among the arts activities the artists participated in as their current or primary occupation. They may reflect factors including changes in the artists'

<sup>34</sup> When the artist indicated that s/he was working at more than one occupation, then the one in which s/he worked the most hours was determined to be his/her primary occupation.

<sup>35</sup> This was determined by looking at the primary work activities at the time of the interview for those who indicated that they had worked as artists within the last 12 months but did not indicate that they were working as artists at the time of the interview.

Table 12  
Occupation in the years working as an artist (percent)

	Prof. & mang. <sup>1</sup>	Sales & clerical	Craft, operative, laborer or farmer	Service	Total non-art	Arch. or design <sup>2</sup>	Perf. <sup>3</sup>	Visual artist	Other	Total art

labor markets, changes in the markets for their art, the end result of a search process for the “right” arts occupation or the completion of the requisite education and training. For example, in 1979 approximately 22 percent of the employed artists had occupations among the “not elsewhere classified” group. By 1998 the proportion had dropped to fewer than 15 percent. The performer occupations were the most popular for most of the early part of the period. They were replaced by people transitioning into the architect and designer occupations during the latter part of the period probably reflecting the time required to become trained as an architect.

An examination of the non-arts occupations held by the artists in the years they did not work as artists provides some insights into what the artists were doing to survive and what they do as they stop exploring the possibility of an artistic career. In part reflective of the ages and educational backgrounds of those surveyed in 1979, almost 30 percent of those people who did not work as artists were working at sales or clerical jobs with another 30 percent working in service jobs (Table 13). The proportion working at sales or clerical jobs peaked in 1982, when they were between 18 and 26 years old, and declined throughout the remainder of the period. There was an even greater decline

Table 13  
Occupation in the years not working as an artist (percent)

	Professional & managerial	Sales & clerical	Craft, operative, laborer or farmer	Service
1979	12.5	27.6	29.5	30.4

in the proportion working in the service occupations. By 1998 only seven percent held service jobs. The greatest growth in employment was found in the other professional and the managerial occupations with the proportion increasing fourfold over the period. This change is reflective not only of the artists aging, but in the investments they made in education and training.

#### 5.4. *The leavers*

Push and pull factors are both important in the decision to leave the arts as it is for any occupation. By 1998 only 42 percent of those who indicated that they had worked as artists at some time during the period were still working, to some degree, as artists.<sup>36</sup> This means that either the person's current job was among the arts occupations or one of the five other jobs they could have possibly held during the time since the previous

<sup>36</sup> Those who had been artists but who were no longer working as artists were anyone who did not report that s/he worked as an artist for at least three consecutive years. This definition was used to examine the former artists' post-artist careers and to assist in developing a better understanding of the factors that may have enticed them to leave the arts.

Table 14  
Artists' current status by first arts occupation (percent)

	Still artist	No longer artist	Status unknown
Architect or designer	53.1	39.6	7.3
Performer	39.8	50.3	9.9
Visual artist	38.7	51.4	9.9
Other	36.3	53.9	9.8
All	41.6	48.1	9.3

interview was in the arts. Almost half were no longer working at all as artists. The status of the remaining 10 percent was not known.<sup>37</sup>

Based on their first-arts occupation, the architects and designers were the most likely to still be working as artists in 1998. Approximately 53 percent were still working in the arts (Table 14). Fewer than forty percent of those in the performing arts occupations (actor, dancer, musician, composer and announcer) were still artists. The proportion is basically the same for visual artists. The artists who started out in the 'other' arts occupations were somewhat less likely to still be artists than performers and visual artists.

For the most part artists who stopped working as artists did so from the same arts occupation that they had started in. By comparing the first-arts occupation to the last-arts occupation for those who were no longer working as artists, it was found that the vast majority were participating in the same occupation at both points in time (Table 15).

<sup>37</sup> After the 1990 survey a portion of the people who had been in the supplemental samples was dropped. Included among them were the economically disadvantaged non-black, non-Hispanic males and females who were part of the supplemental sample. They also included those who were lost due to natural attrition.

Architects and designers were the most likely to have persisted in the same occupation. Visual artists were second while the performers and 'other' artists were the least likely to persist in their starting occupations indicating that these artists have experimented the most in the arts.

### 5.5. *The post-artist period*

On average, the age at which artists stopped working in the arts was 24 (Table 16). This estimate, like the age at which artists started working, is not likely to be representative of all artists. In fact it is likely to be an underestimate of the actual age since the oldest members of the sample were only 41 years old at the time of the last survey, and the youngest were 33. Without observing the artists over their entire lifetimes, the estimate is smaller than the true value. The variation in the age at which artists stopped working as artists related to gender was not significant.

For the most part, those people who had been working as artists but who stopped working in the arts continued to work (Table 17). Almost three-quarters were still employed. Another ten percent were still part of the civilian labor force but were un-

Table 16  
Average age stopped being an artist by gender and last arts occupation (years)

	Male	Female	Total
Architect or designer	24.7	25.3	24.9
Performer	23.9	23.3	23.7
Visual artist	23.5	23.5	23.5
Other	23.4	23.2	23.3
All	23.8	23.7	23.8

Table 17  
Post-arts employment status (percent)

	Male	Female	Total
Employed	74.6	70.8	73.1
Unemployed	8.0	12.6	9.9
Keeping house	0.9	7.3	3.6
In school	7.5	5.3	6.6
Other	5.6	4.0	4.9
Armed forces	3.3	0.0	1.9

*Source:* Authors' tabulations and calculations from NLSY79, 1979–1998, Release 10.0.

employed in the year immediately following the year in which they last worked as an artist. The remainder dropped out of the civilian labor force with almost seven percent attending school, nearly four percent “keeping house” and almost two percent joining the armed forces. The remaining five percent were doing something else or were unable to work for some unspecified reason. Some differences were found in what the male and female former artists were doing after leaving the arts.

Post-artist employment status did vary with the last-arts occupation. Architects and designers were the most likely to still be employed in the year after they stopped working as artists. The artists who comprised the ‘other’ category were the least likely to continue working in the year after they stopped working as artists. Those former artists in the ‘other’ group of arts occupations were the most likely to be unemployed. Unemployment rates for the former performers and visual artists were essentially the same. The visual former artists were the most likely to be “keeping house” in the year post-art work. Those who were most likely to stop working as artists to attend school were the artists in the ‘other’ arts group.

There were also differences in the post-arts jobs associated with the former artists' gender (Table 18). There was little difference between the proportion male and female former artists whose post-arts employment was in a non-arts professional or managerial occupation. A major difference in post-arts employment was the proportion of female artists working in sales or clerical occupations. The female former artists were almost twice as likely as their male peers to be working in these occupations. Females were also 50 percent more likely to be working in service occupations than males. Males were considerably more likely to have post-arts jobs in the craft, operative and laborer occupations than their female colleagues.

Reflective of many factors, including their education, training, and prior work experience, the former artists' post-arts occupations varied by their last-arts occupation. Those who had been architects and designers were by far the most likely to be working in non-arts professional and managerial occupations. Those who had been visual artists were the least likely to be working in professional and managerial occupations. The “other” artists, who include college art-teachers and authors, and performers were between the other two groups in the proportion working in professional and manager-

Table 18  
Post-arts occupation (percent)

Occupation	Male	Female	Total
Professional + managerial	38.3	34.5	36.9
Sales + clerical	19.5	35.4	25.9
Craft, operative, laborer + farmer	30.1	11.2	22.5
Service	12.0	18.6	14.7

Source: Authors' tabulations and calculations from NLSY79, 1979–1998, Release 10.0.

ial occupations. Overall, almost 25 percent of the former artists were working in either sales or clerical occupations with the former visual artists most likely to be doing so. Overall, almost 15 percent were working in service occupations with the visual former artists most likely to be doing so. Relatively few former artists worked in the crafts, operatives (including transportation) and laborer occupations.

## 6. Summary, conclusions and future research

The survey and research presented here is a continuation of the ongoing work of economists, and others, on artists' labor markets and their careers. It highlights the use of a quasi-panel obtained from census data to examine the employment and earnings of artists and compares them to those of all other professional and technical workers. It also provides a glimpse of what can be learned about artists' careers from a study of artists based on true panel data that follows the same individuals over a period of time.

The quasi-panel of data from the seven US censuses, along with research from other countries such as Throsby's work in Australia, provides a reasonably consistent set of findings in each census year. Artists work fewer hours, suffer higher unemployment and earn less than members of the reference group. Over the sixty year period, disparities in unemployment and annual hours worked shrink somewhat, but disparities in earnings do not. Artists earn less across all years even when only members working full-time year-round of each group are compared. The earnings of artists display greater variability than those of other professional and technical workers. The greater earnings inequality of artists is reduced when only full-time year-round workers from each group are compared.

Evidence on earnings and earnings distributions give credence to theories of artists as risk-takers and as participants in winner-take-all markets. Earnings inequality measures for artists (as well as for the general work force) increased over the 1949–1999 period. However, the consistently lower mean and median earnings of artists compared to their reference group over the 1939–1999 period is more in line with a risk-taking theory of artist behavior than one of superstardom, which does not predict that mean earnings should suffer.

Earnings functions for artists and for professional and technical workers are estimated for six of the seven census years. It is shown that the return to years of schooling is lower for artists in all but one year. This is consistent with findings by several authors that education does not significantly increase artistic earnings but does increase their non-artistic earnings.

Earnings penalties that artists face because of their career choices are found to be quite large, varying from 6 to 51 percent of annual artistic earnings across the six census years. In all but one year, the estimated earnings penalty is as great as or greater than the actual observed earnings difference.

The panel data that cover almost twenty years in the artists' lives provides a limited set of insights into their behavior. It does suggest that many people participate in the

artistic labor market, but that few succeed to the point that enables them to develop a career in the arts. In part due to their relatively high educational levels, artists are able to transition from their forays into arts occupations to jobs in other professional and managerial occupations, not into service occupations as the 'mythology' of the arts might suggest. It is true that when they are young and struggling to make it as artists they do work in various service occupations that tend to provide greater work schedule flexibility.

There are a number of questions which are not addressed in this paper. Does the greater amount of multiple job-holding by artists, both inside and outside their artistic occupation, explain some or all the observed differences in annual hours worked and unemployment rates? To what extent does holding jobs outside the artistic profession reduce risk and thus earnings inequality as well as supplement earnings? What triggers the artists' decision to leave the arts for good? How does the allocation of an artist's time to various income generating activities change over his/her career?

These and other questions raised in this paper can best be answered using more detailed data on the careers of artists. There is clearly a need for additional survey-based panel data on artists. The existing national panel surveys in the US, like the NLSY79, are too small. The sample of artists from these data sources are not large enough to provide reliable empirical models of their behavior without aggregating to a level where disparate types of artists are grouped together. Additionally, the information collected, while quite extensive in most cases, is not tailored to unearth information about the unique labor market activities of many artists, especially their multiple jobholding behavior, sources of earnings, allocation of time and costs of producing their art. While a great deal has been learned, there is a great deal more to learn.

**Abstract**

It is argued that human capital theory applies only weakly to artists' decisions about investment in schooling and training and about occupational choice. However, the same can be said about the sorting model. What is lacking in cultural economics is an understanding of talent and creativity, what economic factors motivate artists and how creativity can be encouraged as part of government cultural policy. Bringing social and cultural capital into the equation do not seem to add much in the way of understanding artists' labour markets. A novel argument is made that the reproducibility of works of art in combination with copyright law alters the established view that human capital cannot be separated from labour, in this case that of the artist.

*Lady Bracknell.* (to her daughter's suitor) . . . Do you smoke?

*Jack.* Well, yes, I must admit I smoke.

*Lady Bracknell.* I am glad to hear it. A man should always have an occupation of some kind. There are far too many idle men in London as it is. How old are you?

*Jack.* Twenty-nine.

*Lady Bracknell.* A very good age to be married at. I have always been of the opinion that a man who desires to get married should know either everything or nothing. Which do you know?

*Jack.* I know nothing, Lady Bracknell.

*Lady Bracknell.* I am pleased to hear it. I do not approve of anything that tampers with natural ignorance. Ignorance is like a delicate exotic fruit; touch it and the bloom is gone. The whole theory of modern education is radically unsound. Fortunately in England, at any rate, education produces no effect whatsoever. If it did, it would prove a serious danger to the upper classes, and probably lead to acts of violence in Grosvenor Square. What is your income?

*Jack.* Between seven and eight thousand a year.

Oscar Wilde, *The Importance of Being Earnest* (Act I). First published in 1899.

## 1. Introduction

The role of human capital in labour economics has a long history, going back to Adam Smith. Smith recognised the effect of both training and talent in determining wages, the latter in his famous comment on the 'exorbitant' rewards of opera singers and dancers.<sup>1</sup> The influence of innate ability and knowledge acquisition on earnings has been much discussed in human capital theory and this discussion is particularly relevant to artists. The study of artists' labour markets is important in cultural economics because we need to understand what factors affect the supply of work by creative artists and performers since cultural policy, whatever its explicit aims, is ultimately designed to encourage creativity.

In this chapter, two basic questions are addressed: what contribution does human capital theory make to understanding creativity in the arts and culture and what contribution does cultural economics make to our understanding of human capital? Much of the analysis of human capital over the last 30 years has been about the econometric problems of identifying the specific contribution to earnings of innate ability rather than of ability acquired through 'schooling'. Because the role of innate ability or talent is far greater in the arts than it is in non-arts occupations, its influence is an area in which cultural economics can make a contribution to human capital theory. It also seems likely that on-the-job training and experience are more important in the arts than in other

<sup>1</sup> See Smith (1976, p. 124).

occupations. Another distinguishing feature of artists' supply behaviour is their concern with utility and reputation, which considerably modifies their desire for financial reward. Furthermore, the arts and cultural industries are areas in which there is dependence on copyright law for protecting artists' earnings, enabling them to obtain future as well as present income. There is, therefore, reason to believe that artists' labour markets differ from those of other workers and this raises the question whether human capital theory applies in them. However, while there has been a great deal of empirical work on the role of human capital in 'ordinary' labour markets, there have been relatively few econometric studies of artists' labour markets.

This chapter is organised as follows: an introduction to human capital theory precedes a brief summary of issues in the measurement of human capital using earnings functions, including those relating to artists. Then the role of talent and creativity in artists' labour markets is discussed, with particular reference to the superstar phenomenon. That is followed by a section on artists' training and occupational choice, after which we consider the analogy between human capital, social capital and cultural capital. We then turn to the relation in artists' labour markets between human capital, the ability to reproduce artists' work and copyright law, showing how that alters the 'in-alienability' problem in human capital.

## 2. The theory of human capital

### 2.1. *The basic theory*

Sherwin Rosen has defined human capital as "... the stock of skills and productive knowledge embodied in people. The yield or return on human capital investment lies in enhancing a person's skills and earning power, and in increasing the efficiency of economic decision-making both within and without the market economy" [Rosen (1987, p. 682)]. This definition captures two essential features of the theory: that human capital cannot be separated from the person, and that human capital embodied in an individual may be increased by investment. What it does not recognise, however, is the ambiguity of the concept of human capital as a combination of inherited characteristics, tacit knowledge, innate ability and acquired skills; each plays some role in the individual's productivity and earning power but how much influence is exerted by one or the other has proved difficult to pin down.

A thumbnail sketch of the theory is as follows: though the concept of human capital had been recognised by Adam Smith and Alfred Marshall, it was only in the 1960s that Theodore Schultz (1961) set the stage for the present day interest in human capital theory. The fundamental conceptual framework of analysis for virtually all subsequent work in this area was developed by Gary Becker (1964) in his path-breaking book *Human Capital*. In it, he introduced the distinction between specific and general labour training, arguing that schooling (formal education) was in fact a leading example of human capital formation by general training. Jacob Mincer (1958) then specified the now

standard human capital earnings function that has given rise to a huge literature on the measurement of lifetime income and wealth [Willis (1986)].

Adam Smith had understood the essence of the notion of human capital investment: the formation of human capital through costly education, the necessity for higher earnings to compensate those who had made the investment in human capital, and the accrual of these earnings over a lifetime.

A man educated at the expense of much labour and time to any of those employments which require extraordinary dexterity and skill, may be compared to [an expensive machine]. The work which he learns to perform, it must be expected, over and above the usual wages of common labour, will replace to him the whole expense of his education, with at least the ordinary profits of an equally valuable capital. It must do this too in a reasonable time, regard being had to the very uncertain duration of human life, in the same manner as to the more certain duration of the machine.

The difference between the wages of skilled labour and those of common labour, is founded upon this principle [Smith (1976, pp. 118–119)].

Marshall also pursued the analogy between physical and human capital and between the wage rate and the rental rate of capital. He emphasised the difference between physical and human capital on the grounds that there is no market in human capital but rather a market in the hire of labour embodying the investment. This is what Rosen (1987, p. 682) refers to as “differences in the nature of property rights between them”. Furthermore, Marshall made the case for subsidies to education based on the implications of social inequality of access to the capital market for the finance of education [Blaug (1970, pp. 3–6)].

Blaug (1970) raised the question whether the concept of human capital is perhaps no more than a metaphor, and moreover whether all education indeed has an investment motive or whether it is not to some extent a consumption good. Education and learning may yield utility directly to the individual rather than a deferred utility of potential higher earnings. Furthermore, occupational choice may not be determined solely by financial reward because people may choose an occupation for non-pecuniary motives such as a preferred lifestyle. Occupations that require a higher level of human capital investment and so pay more are also ones, contrary to Adam Smith, that may be more attractive on non-monetary grounds. The identification of consumption elements, utility and the pursuit of non-monetary rewards might therefore be difficult to disentangle. These observations are particularly relevant to artists' training and occupational choices. We return to a discussion of the usefulness of the capital metaphor in Section 6 below.

For Becker, however, the analogy between physical and human capital is central. According to Becker, individuals invest in human capital formation up to the point at which the discounted costs of formal education and on-the-job training equal the discounted future earnings over the individual's lifetime. The rate of return that equates these two streams must in equilibrium equal the rate of interest, that is, the cost of borrowing the outlay on the investment. The private rate of return, which accrues to the individual,

is calculated from the out-of-pocket (direct) costs of schooling and the indirect costs of earnings forgone during the investment period. The social rate of return takes into account the return to society via income taxes and the total cost of providing schooling. Empirical estimates of the two rates of return produce the result that the private rate typically exceeds the social rate, if only because the social cost of schooling exceeds its private cost.

Like Marshall, Becker recognised that all families do not have equal access to financial resources and that affects the human capital investment decision. Family background may exert other influences on the costs and returns to human capital investment; inherited characteristics and early advantages such as health, greater investment during childhood, above average ability and innate talent all mean that some individuals learn more easily than others and therefore achieve higher productivity from a given period of study or, *pari passu*, need to spend less to achieve the same learning outcome. These family background and interpersonal differences give rise to the so-called ‘ability bias’ in measuring the rate of return to investment in human capital. We shall see later that this is an important topic in artists’ labour markets.

Becker also considered the question of who pays for post-compulsory education and training, the individual or the employer. The employer has no incentive to pay for general training that can be transferred between firms but does have the incentive to pay for firm-specific training.<sup>2</sup> Firms may well offer general training to employees but then ‘charge’ them for it by paying them lower wages (as in an apprenticeship training).

## 2.2. *Sorting models*

Human capital theory in its Chicago School version (Schultz, Becker, Mincer and Rosen) is not accepted by everyone in the economics of education or labour economics. The most fundamental criticism comes from those who support an alternative explanation of the observed positive relationship between investment in schooling and higher earnings – the screening hypothesis. Screening, which is always linked to signalling (the education system screens and students signal), is a form of sorting; indeed Weiss (1995) recommends using the generic term ‘sorting’ to include both aspects. According to sorting models, employers use educational choice to draw inferences about unobserved attributes that are correlated with schooling. Employers use formal qualifications (a university degree, for example) as an information signal about worker quality, but information is asymmetric – workers know their own productivity but employers cannot tell which workers are the most productive. Workers signal their superior productivity to employers by acquiring paper qualifications which high ability students acquire more easily. This ‘self-selection bias’ is exacerbated by the finding that many highly educated students come from higher socio-economic family backgrounds. The extreme version

<sup>2</sup> It has, however, proved difficult to find convincing examples of specific training other than the necessary learning period that marks the first few days or weeks of employment for any worker.

of the sorting model combines screening and signalling to conclude that higher earnings do not reflect higher marginal productivity at all, but only society's institutional commitment to 'credentialism'. Ability bias and signalling are difficult to separate and in general it has proved impossible to identify them empirically, at least so as to persuade the sceptic. All agree that more time spent in schooling yields higher earnings but sorting models dispute precisely what it is that leads to greater productivity.

Becker has argued that a refutation of sorting models lies in the fact that the education system is an inordinately expensive screening device; such inefficiency is unlikely to develop spontaneously in a competitive economy and is even more unlikely to be sustainable over long periods of time. This argument carries greater force in the USA where students pay for further and higher education, but in many European countries both are either free or available at very low fees. So the direct cost of post-compulsory education in Europe is small, leaving only the cost of forgone earnings to be borne by students and their parents. Indeed, many European countries even offer students grants and rewards for completing a course. In the arts, we see courses being oversubscribed as hopeful students who do not have to pay the full cost of training crowd into art, music and acting colleges [Towse (1996)]. We also observe that employers in the arts place little reliance on certification based on formal schooling and often use their own screening devices, a refutation of Becker [Towse (1993)]; we return below to these and other differences between artists' and other labour markets.

Before leaving the general theory of human capital, it is worthwhile anticipating a later discussion of the way copyright law (in combination with 'reproducibility' by means of copying technologies) alters property rights in human capital in the cultural sector. Many writers [for example, Blaug (1970)] have dwelt on the absence of a market for human capital separated from the labour of the individual and have claimed that only a slave economy would permit direct purchase of human capital analogous to the purchase of physical capital. However, human capital embodied in works protected by intellectual property rights can be 'alienated' by the assignment or transfer of the right to use them. For example, take the case of a sound recording: copyright law provides a number of rights for composers and performers, who use their skill and labour to create works that are recorded in a CD; but once these rights have been transferred to the record company, they become its assets, which it can exploit or sell as it sees fit. Copyright is therefore intimately tied up with the appropriation of artists' human capital. Nor is this only a feature of artists' labour markets; the growth of the 'Information Society' or the 'Knowledge Economy' and the spread of intellectual property law into ever more sectors of the economy have created similar conditions in other labour markets.

### 3. Earnings functions

#### 3.1. Estimation

Earnings data are the single most important source of information about human capital as they represent both the returns to investment and the cost of the time taken to make the

investment. Lifetime earnings are typically represented in age-earnings profiles. Earning starts when compulsory education ceases – if the legal school leaving age is, say, 16 years of age, any schooling beyond 16 incurs the opportunity cost of the earnings of 16+ year olds. Thus the age-earnings profile begins at age 16 and continues to retirement age. Normal age-earnings profiles display a common pattern: from the age of entry into the labour force they rise, then flatten out at around mid-career and fall towards retirement age.

Investment in human capital does not cease with the start of work, however, since on-the-job training now begins. On-the-job training is a loose concept that includes experience or learning-by-doing, which increases with age. Mincer (1958) recognised that workers could also choose at each point to invest in formal on-the-job training as a substitute for years of schooling and that that would eventually be compensated by higher earnings. Workers may rationally choose different jobs that enable them to gain experience, accepting lower earnings while they are trained on the job. Mincer analysed these different choices by individuals as yielding a series of age-earnings profiles whose shape is determined by the different combination of direct and indirect costs of education and on-the-job training. Because they represent different combinations of earnings forgone and lifetime earnings, the age-earnings profiles must cross. Mincer called this the ‘overtaking point’, which he argued would depend on the reciprocal of the internal rate of return, the discount rate that equates the stream of lifetime earnings with the cost of the investment. This approach enables the researcher to take into account the effect of family background effects such as financial constraints, but it does not solve the problems of ability bias or self-selection bias.

The Mincer earnings function has become the standard model for statistical measurement of the supply of educated labour and for estimating the internal rate of return to education:

$$\log Y = \log Y_0 + rS + b_1X + b_2X^2 + u, \quad (1)$$

where  $Y$  is income,  $S$  is length of schooling,  $X$  is length of time in the workforce as a proxy for years of work experience and  $u$  is the error term; the constant term is the log of the equivalent annuitised income of initial human capital value (innate and family background effects),  $r$  is the rate of return to schooling,  $b_1$  and  $b_2$  capture the effects of experience [Rosen (1992, p. 162)]. Several econometric specifications of the earnings function have been tried out and innumerable empirical studies have been made; a survey of the early literature is to be found in Willis (1986).

The ideal data for measuring the effect of investment in human capital would consist of longitudinal information on individuals’ lifetime earnings combined with individual tuition expenses. Such data are rarely available and in practice aggregate cross section or panel data are used; however, they abstract from individual decision-making and give rise to bias in estimation. Simplifying assumptions are therefore needed to enable researchers to use the data available. Briefly these are: that the only cost of education is earnings forgone; that individuals enter the labour force immediately on complet-

ing their studies; and that the individual's working life is independent of her years of education.

The problem of estimating the ability bias is aggravated by the use of aggregate cross-section data; individual data would avoid much of this problem by providing information on family background and possibly even on early IQ and other measures of innate ability. In the attempt to separate out the influence of innate ability and human capital investment on earnings differentials, studies of identical and non-identical twins have been used. Rosen (1987) reports that such studies have found that around one-third of the difference in earnings was due to differences in human capital investment, one-third was due to 'person effects' (unmeasured ability, health and other such factors) and one-third was due to random events, luck and suchlike. These findings are particularly relevant to artists, for whom variations in talent and luck may well be higher than for other professionals. This is discussed in more detail below.

### 3.2. Artists' earnings functions

We now turn to empirical studies that have been done of earnings functions in arts occupations. These studies have tested the human capital model outlined above, treating artists as workers like any others making rational choices about investment in education and on-the-job-training and occupation. There are considerable difficulties concerning the definition of the artist population and of obtaining data.<sup>3</sup> Suffice it to say here that in most countries in which these studies have been attempted, there are severe problems in obtaining artists' earnings data. Census data either cannot be disaggregated to appropriate artistic occupational levels or are subject to severe bias due to multiple job-holding. In the USA, Filer (1986) used Census data to estimate earnings functions for a range of artistic occupations but the validity of his results have been widely disputed by cultural economists because he used aggregate income data [Towse (2001a, Chapter 3)]. Consequently, cross-section survey data have been used in preference to Census data but response rates may be low and sample sizes may be relatively small and possibly unrepresentative. Interestingly, however, Filer found only a very weak effect of human capital variables on artists' earnings. In a later study in which he analysed earnings functions separately for different arts occupations, still using Census data, he found that longer schooling even had a negative effect in the case of performing artists [Filer (1990)]. Wassall and Alper (1985) did one of the first earnings-function studies of artists using data from their survey of 3000 artists in New England that allowed them to separate arts from non-arts income. They found that education was not positively correlated with income from arts work though it was from non-arts work, a finding that has been since replicated in other studies.

Large-scale national surveys of artists' earnings have been carried out in Australia and enabled two authors Withers (1985) and Throsby (1992, 1994, 1996) to estimate

<sup>3</sup> See Chapter 23 by Alper and Wassall in this volume; also McNertney and Waits (1997).

earnings functions.<sup>4</sup> Withers varied the standard Mincer specification by making a distinction between formal education and other qualifications (trade and technical certificates), using the imputed hourly wage rate and reported hours of work to measure earnings. He noted that the standard assumption of continuous employment from entry into the labour market to retirement age overstates work experience for females, a higher proportion of whom are in the arts compared to the non-arts workforce. This, however, would apply to all artists since many artists work irregularly and have frequent periods of unemployment during job searches. Withers' results showed that, compared to all Australian workers, artists earned 40 percent less, which he interpreted as the 'subsidy of artists to the arts'. The 40 percent penalty can also be viewed as a compensating differential, the 'psychic income' for the net advantages of a preferred occupation – the interpretation depends on whether or not you assume that changing occupations is frictionless. On the latter point, Filer (1987) found that the penalty for the choice of artistic occupation in the USA was not high and that 'failed' artists were able to move into other occupations without a high earnings penalty – a striking testimony to the power of general training. Withers also found that human capital variables had only a very weak effect on earnings and concluded that innate characteristics (talent and motivation) and luck, though not identified, must play a considerable role in determining earnings in the arts.

Using the same data set, Throsby (1994) estimated an important variation on the standard form of the earnings function. The Australian survey (which he had directed) collected data on earnings and hours of work in arts and non-arts work. This was done because it was known from qualitative research that artists typically divide their work time between their chosen artistic occupation (arts work) and jobs outside the arts (non-arts work), mainly because they are unable to earn a living wage from the former. This approach was a means of overcoming the bias introduced in census data, which defines artists on the basis of their occupation in census week and attributes earnings from all sources to their arts work, even if a substantial part is due to non-arts work; this was a criticism that had been made of Filer's 1986 study (which he had defended as a 'market test' of who is and who is not an artist). Throsby therefore was able to estimate earnings functions for arts and non-arts work and he was able to separate out the private rate of return to education, training and experience in both arts work and in non-arts work. That had the advantage that he was able to compare rates of return for the same sample, unlike Withers (and others) who had made comparisons between aggregations of different sets of individuals. Throsby found that human capital investment *was* an explanatory factor of income differentials in both sectors, though the human capital model performed less well for arts work than for non-arts work, again due to the unspecified effect of talent and other innate ability factors. It should be noted, however, that the studies by both Withers

<sup>4</sup> Withers' estimation was done in 1984 and Throsby's in 1992; the references cited are reprinted in Towse (1997). The McNertney and Waits survey was done in 1988 and is also reprinted in Towse (1997), the earlier version now being difficult to obtain.

and Throsby had low  $R^2$  values, indicating that much about earnings differentials was left unexplained.

Subsequently, Throsby (1996) estimated another earnings function for Australian artists using data from a later survey and testing two different specifications, one a linear model using two-stage least squares and a second using the Mincerian earnings function (Equation (1) above), again breaking down earnings and hours worked, this time identifying arts, arts-related (such as art teaching) and non-arts work. His hypothesis was that income from arts and arts-related work are influenced by the level of professional arts training, whereas non-arts income is more likely to be influenced by the level of general education, and that time spent on-the-job as an artist is the appropriate explanatory variable for arts and arts related work, with age (as a proxy for experience) being more relevant to non-arts earnings. Dummy variables for level of training, education and gender were used. The models were tested with a further division between creative artists (writers, composers, choreographers and so on) and performers (actors, musicians, dancers and the rest). Interestingly, this elaboration of his earlier study did not yield very different results. The linear model performed better than the standard Mincer model and the hypotheses of the standard model were confirmed. Even so,  $R$ -squares for arts income were low, indicating that factors other than human capital were at work. The experience of testing human capital models in the arts has led Throsby to develop a work-preference model of artist behaviour [Throsby (1994)] as an alternative to the human capital investment model. Cowen and Tabarrok (2000) also develop a utility-based model. It remains to be seen how these models stand up to empirical testing.

### 3.3. Methodological aspects

By way of conclusion to this section on estimating earnings functions, it is worth considering the methodological aspects of human capital theory (methodology being the logic of different methods, not merely a comparison of methods of econometric estimation). Blaug (1976) subjected the theory of human capital to methodological analysis based on Lakatos' concept of a scientific research programme and asked what empirical tests would refute it? Is it 'a theory' or a set of theories – in Lakatosian terms, is there a 'hard core' of theory or just a 'protective belt' of ad hoc empirical generalisations? Though sorting models appear to provide a rival theory, Blaug believed they would eventually become a complement to the human capital hypothesis; moreover, as noted earlier, no discriminating test has been found that could refute one hypothesis and confirm the other, despite a huge battery of empirical work.<sup>5</sup> In the absence of a rival theory, Blaug concluded that the human capital research programme had to be evaluated on its own terms: the predictions of the theory cannot unambiguously be tested because of the unsolved question of the separate influence of innate ability and the assumption

<sup>5</sup> Thirty years later Blaug's insights have been confirmed by Weiss (1995), who states that sorting models are a refinement and an extension of human capital theory rather than an alternative.

of individual rational behaviour regarding the schooling decision. The question therefore is not so much whether schooling explains earnings, a fact commonly accepted, but why it does so.

Despite these objections, Blaug acknowledged that there has been empirical progress in human capital theory in the sense of better data, more sophisticated modelling and econometric analysis. That could also be said of empirical testing of earnings functions in the arts, though there are far, far fewer examples. The absence of reliable data sets still inhibits research in artists' labour markets but what studies there are point to fundamental difficulties. Apart from the obvious question of what is talent – to be discussed below – other problems are present in relation to artists' earnings that are more pronounced than in 'ordinary' labour markets. The distribution of artists' earnings is far more skewed than is found in other occupations and therefore estimates of mean earnings lack conviction.<sup>6</sup> The associated greater variance of artists' earnings points to a far greater risk for artists but whether that suggests that artists are risk-averse and have to put up with greater risk, or are in fact risk-takers is open to debate; however, that is also a question of the validity of the assumptions rather than the accuracy of predictions. Artists' labour markets are dominated by self-employment, with frequent job search and other information problems. Artistic output almost by definition is heterogeneous and demand for it is radically uncertain; *Caves (2000)* has shown that these circumstances lead to contracting problems in the creative industries. Persistent excess supply of artists is widely inferred from the prevalence of unemployment among them [*Towse (2001a)*]. Moreover, there has been little empirical research on the demand for artists, though such studies have increasingly been done for other occupations [*Acemoglu (2002)*].<sup>7</sup> These observations suggest that artists' labour markets may be fundamentally different from other labour markets and that the human capital model is therefore less likely to apply to them.

#### 4. Superstars, talent and creativity

In this section we discuss specific features of artists' labour markets that reinforce the view that they differ fundamentally from other labour markets. Chief among these features is the absence of a clear specification of talent and creativity and their role in artists' labour markets.

*Sherwin Rosen (1981)* in his seminal article 'The Economics of Superstars' focussed on talent as the cause of the skewed distribution of earnings in certain professions and the vastly higher earnings of the few superstars in them.<sup>8</sup> His explanation revolves

<sup>6</sup> See *Seaman (2003)* for recent analysis of variances in artists' earnings and for a comparison with sports-people's earnings.

<sup>7</sup> *Towse (1993)* collected information on the demand for classically trained singers.

<sup>8</sup> See further *Chapter 25* by *Adler* in this volume.

around two causes: on the supply side the development of media technologies, for example sound recording, which have considerably increased economies of scale, enabling artists to serve a far greater market; and on the demand side, consumer preferences for greater rather than for lesser talent when there is imperfect substitutability between suppliers such as artists and entertainers. Superstars, according to Rosen's definition, are people who 'earn enormous amounts of money and dominate the activities in which they engage'; they are highly talented and highly rewarded for their talents because, as Rosen shows, the net revenue earned from talent is a convex function, causing small differences in talent to be magnified into larger differences in earnings [Rosen (1981, p. 845)]. Rosen does not attempt to analyse talent other than by giving some examples – gifted surgeons, sportspeople, singers – but he does state that talent can be ranked; indeed, he specifically avoids the problem of measuring talent by saying 'a cardinal measure of quality or talent must rely on measurement of actual outcomes' [Rosen (1981, p. 848)].<sup>9</sup> Very Chicago!

We might try to analyse talent and creativity in the arts by analogy with the role of innate ability in human capital theory. In relation to education, innate ability reduces the cost of investment in schooling needed to achieve a given outcome, such as a university degree, as it is an argument in the educational production function; the greater the innate ability, the higher the productivity achieved by a given level of investment, or *mutatis mutandis* less investment is needed to achieve a given level of attainment. Innate ability therefore has similar effects to the fertility of land on cultivation. The analogy with the Ricardian theory of rent is a strong one. In that theory differential rents are explained in terms of differential natural fertility of land and the demand for corn; as the demand for corn shifts out (say, due to population growth), land of ever less fertility is brought into cultivation with lower yields of corn. But which is cause and which is effect in determining rents?

Talent can be thought of as akin to the fertility of land, assumed to be a free gift of Nature; it is an inborn asset, which often manifests itself early in life and it enables the 'owner' not only to acquire skills more easily but also to achieve a high level of 'artistic productivity' – great performances – that few competitors can supply. In the human capital model, rents to innate ability accrue on the supply side. By contrast, Rosen's model puts the explanation on the demand side in which the perception of small differences in talent between individual artists causes multiplicative effects to incomes. One might paraphrase the Ricardian argument as follows: 'is the price of opera high because singers' fees are high, or are singers' fees high because the price of opera is high?'

But there still remains the problem noted earlier of the inalienability of human capital. When the output is a personal service such as a surgical operation or a live performance, it can only be supplied in conjunction with labour. The performer must be present to supply her talent live to the audience and therefore limitations on the supply of her time

<sup>9</sup> See Towse (2001a, Chapter 3) for a more detailed discussion of this point.

lead to rewards like rent being determined by demand. Towse (1992) argued that this is the case for the fees of singers. The story changes, however, when the constraints of the performer's time are lifted by making her services available in a reproducible form like a sound recording; this is what Rosen analysed in his model. Recording technology has enabled performers and other artists to reach vastly greater markets, exacerbating the effect of small differences in talent and reducing the possibility of substitution between artists of lesser or greater talent.

It is time to consider what is meant by talent and creativity: 'You've either got it or you haven't' is something frequently said in conservatories of music and colleges of art. As with the inalienability problem in human capital theory, talent does not have a price because there is no direct market for it – you cannot buy yourself some genius to get through university or become a singer (except, perhaps, with a Faustian contract!).<sup>10</sup>

Talent and creativity are widely viewed as the *sine qua non* of art, so what has cultural economics to say about it? A quick answer is that it has been little discussed. Throsby (2001) has a short chapter on creativity, which he links to his concept of cultural value and to a utility model of artistic supply; Frey (2000) discusses the motivation and incentives to create and the role of public support for artists; Castañer and Campos (2002) deal with innovation by arts organisations, adopting a Schumpeterian approach; Caves (2000) deals with what could be called the industrial organisation of creativity, without however explicitly discussing the concept; Towse (2001a) analyses the reward of creativity, again with only a token discussion of creativity, and like Throsby, associates it with artistic supply. All these authors skate around the central issue, which is the contribution of creativity and talent to artists' productivity and earnings.

Creativity is often regarded as an individual activity, though there are many joint creative activities such as theatrical rehearsals and teams of scriptwriters for soap operas.<sup>11</sup> When we speak of creative artists such as composers, authors or painters, they are essentially envisaged as working alone, experimenting with ideas. Another feature of creativity is originality, a spark of novelty that comes to the artist 'out of nowhere' or from reworking existing ideas in new ways. Creativity in these terms clearly parallels innovation and invention in science and technology. Following Schumpeter (1942), the reception of creativity must also be considered [Wijnberg (1995)]. Is it recognised? Can it be marketed? Can it be motivated by financial reward? These are questions that are relevant to the exploitation of talent and creativity by arts organisations and the cultural industries, as well as to cultural policies aimed at fostering the production of art. The economic value of creativity and talent is that they are necessary inputs to satisfy consumer demand for novelty and new experiences and to create lasting works of art.

Enough has been said to indicate that artistic creativity and talent are perceived differently in cultural economics than in human capital theory. Bearing this in mind, we

<sup>10</sup> Whether or not it can be produced through investment in schooling is discussed in the next section on the economics of training.

<sup>11</sup> Seaman (2003) contrasts research in the economics of sport on sportspeople working in teams with the far more limited work in cultural economics on teamwork in the arts.

now turn to the question of artistic training and consider the role of investment in human capital as a preparation for artistic occupations.

## 5. Artists' training and occupational choice

### 5.1. Expected income

According to human capital theory, occupational choice is made on the basis of expected lifetime income. As ability bias reduces the cost of acquiring skills and qualifications, students sort themselves into occupations in which they have a comparative advantage. Taken over a whole society, individual rational behaviour is thought to lead to an optimal allocation of human capital. Equilibrium is achieved in the usual way: excess supply in one occupation reduces earnings and thus the private rate of return, causing workers – at least to some extent – to switch jobs to other occupations. Skill shortages encourage on-the-job training; jobs/professions requiring a greater investment in higher education and professional training offer higher lifetime earnings to compensate for higher costs of study. Experience adds to human capital over the workers' career and is rewarded by higher earnings.

The question is: could this theory apply to artists' labour markets or are they really different from other labour markets? Artists may not be rational wealth maximisers, something that is widely believed and frequently stated by artists themselves [Abbing (2002)], but that is a behavioural assumption that cannot be tested directly. The key question is whether the choice of an arts occupation is based on the private rate of return to investment in human capital that is determined by the costs of schooling and artists' earnings. As reported earlier, Throsby (1992) found some limited support for human capital theory in the arts, so it is worthwhile taking it at face value and seeing what resonance the theory has for artistic training and occupational choice.

Surveys have shown that median earnings in the arts are always lower than those of other equally qualified workers, even though the artist population has a higher than average level of educational attainment. The lower expected lifetime earnings in the arts, combined with the higher indirect costs, ensure that discounted costs exceed discounted benefits in arts occupations [Towse (1996)]. What may modify these results in the arts is the longer working life of some artists; cross-section studies assume a normal age of retirement and that is misleading because retirement may be very late in some artistic professions. Some artists continue to work until they die, and with royalties from copyrights they can continue earning even beyond the grave. Even in the performing arts, where there is a premium on strength and (sometimes) youth, many performers teach and adjudicate long after they retire from performing. On the other hand, the direct cost of training (schooling<sup>12</sup>) performing artists in specialised institutions is higher than the

<sup>12</sup> At the risk of confusing formal training in the sense of schooling with on-the-job-training, I have switched to the common way of speaking of the lessons and other forms of teaching that are provided in specialist

average cost of higher education in general [Towse (1993)]. However, as noted earlier, in many European countries higher education is provided free or at very low fees and even in the USA some students obtain scholarships that cover the cost of training; public finance therefore reduces the direct costs of training and, other things being equal, should increase the private rate of return to training.<sup>13</sup> But even if, following Mincer, we ignore the direct costs of training, the fact that courses in performing arts are longer than those for most other subjects raises the indirect cost of study and would therefore reduce the private rate of return.

Despite the unfavourable prospect of financial reward in arts occupations, higher education courses for artists are typically oversubscribed and that contributes to the oversupply of artists. The question of how many places should be offered in specialist colleges has been a hotly debated one for many years: should the number be restricted so as to ensure that only the most highly talented students receive artistic training, or should more be admitted in the hope that good quality training will enable them to reach a satisfactory standard of competence? It is widely accepted that all students who complete formal training in the creative and performing arts will not be able to make a living from their art. However, when it comes to the public finance of higher education, considerations of equity often override those of efficiency. Moreover it is not easy to define what efficiency would mean in the circumstances of artists' labour markets, given the uncertainty surrounding the chances of success.

### 5.2. *The role of training*

The question still remains whether it is possible to increase an artist's human capital by investment in formal schooling and whether training can add value in the case of less talented students. 'You can't make a silk purse out of a sow's ear' is a saying that resonates through specialist art, music and drama colleges. Even if they have strict entrance requirements, colleges cannot assess the quality of entrants with any certainty – heterogeneity and the absence of objective information about quality pervades all aspects of artists' labour markets. It is also difficult to assess colleges' success in preparing students for work in the arts; the demand for artists' services in the labour market is uncertain and difficult to define since there are few 'regular jobs', with most artists working in self employment on short term contracts [Gurgand and Menger (1996)]. These problems raise a number of points about artists' training that can be analysed

colleges as artists' 'training'. Not all arts training in that sense is confined to specialist art, music or drama colleges, even for performers: writers and composers often do academic courses in universities. There are different institutional arrangements in different countries. The point is that students receive formal education apparently dedicated to artistic occupations.

<sup>13</sup> The social rate of return in specific occupations is used to evaluate public policy decisions about the allocation of educational funding; Towse (1996) suggests the social rate of return to training artists is very low, even negative.

separately (though they may well interact in practice): the content of training; certification in artists' labour markets; and students' expectations about lifetime earnings, the nature of work opportunities and the duration of employment and career possibilities.

### 5.2.1. *The content of training*

Given the importance of talent and creativity in the arts, one might be tempted to conclude that the content of higher education courses in art and music colleges adds nothing to students' innate ability, the more so if only the most gifted students are able to gain entrance. In dance and music most students have already had years of specialist teaching, and in other art forms students are expected to show a portfolio or other such evidence of attainment as an entrance requirement. What therefore can colleges offer such students? Here it is useful to draw a distinction between the 'art' element and the 'craft' element of artistic training. Even very talented students need to learn how to present their work, study repertoire or the craft of drawing and writing, and so on. Colleges also provide facilities that are difficult or expensive for individuals to provide for themselves, such as studios, artists' models, participation in theatrical productions, orchestras and suchlike. Colleges also provide students with a forum for displaying their talents to the outside world in exhibitions, performances, etc., and enable them to develop networks, learn professional conduct and assess their own abilities. This last point is particularly important because information about one's own quality is needed in order to make career choices – whether to choose another occupation, whether to aim high or low, etc. MacDonald (1988) explains drop-out rates after the first few years of work in artistic occupations as the outcome of this search for information. Colleges may perform a preliminary sorting function by providing that information before entrance into the labour market takes place.

As a coda to this brief discussion of a complex subject, it is worth pointing out that surveys of artists' labour markets have revealed that a significant proportion of working artists did not receive specialist arts training.<sup>14</sup> There are two possible explanations: that they made the decision to be artists after having done another higher education course; and/or that they regarded the content of arts training courses as irrelevant, something that is frequently reported in surveys of working artists. Either way, the finding is hostile to the human capital model, as well as to the sorting model, as these artists were able to make their way without either formal training or a certificate and apparently with no earnings penalty [Towse (2001a)].

### 5.2.2. *Certification in artists' labour markets*

Although colleges training artists award degrees and diplomas, studies of artists' labour markets have found that certification apparently plays a less important role in the arts

<sup>14</sup> 30 percent is a not untypical figure; see Towse (2001a).

than in it does other labour markets. Certification is of course highly correlated with formal schooling, which tests students for their achievement in following the curriculum. However, that may not provide the kind of information wanted by employers or others hiring artistic labour for several reasons. Artists typically are self-employed and so need not signal to an employer. A reputation for professionalism and high quality talent/creativity are very important in artists' labour markets and certification by art colleges apparently does not provide adequate information about these characteristics. Employers may not trust colleges' certification because they produce too many graduates, not all of whom are sufficiently talented. Colleges have their own objective functions and they maximise their income from student numbers, and they may also be pressed by funding authorities to offer a mix of services to a mix of students; these factors combine to give higher education institutions training artists the incentive to 'oversupply' graduates. Indeed as stated earlier, many 'employers' who hire artists show no interest in their paper qualifications and set up expensive screening arrangements of potential employees for themselves [Towse (1993, 1996)].

### 5.2.3. *Students' expectations*

Students face problems in forming expectations about the probability of making an artistic career pay because there is little objective information available. Their subjective assessment of their own talent and creativity is likely to be overestimated due to 'the overweening conceit of the young', as Adam Smith put it in the *Wealth of Nations*, and objective information about future earnings and the ease of obtaining work is difficult to obtain in a labour market in which there is a wide dispersion of earnings and frequent job change. Following criticism that young people are let out into the real world without adequate preparation, colleges have made considerable efforts to offer courses on business methods and how to manage a career in the arts but often to little avail; students apparently fail to attend such courses, though they later complain that they 'should have been warned' about the difficulty of making and managing a career [Towse (2001a)]. These problems might seem to support the view that young artists are irrational. However, when 'nobody knows' about quality and demand for artistic output [Caves (2000)], irrationality may be confused with radical uncertainty. Rationality is inevitably bounded in artists' labour markets.

Students also form expectations about non-pecuniary rewards such as the opinion of peers, the desire to work on one's own account and other 'psychic rewards'. These are particularly important to artists: and they accept earnings lower than those available in alternative occupations as a price worth paying for the chance to work in the arts and, as long as they can earn enough to live on from other work (arts-related or non-arts jobs), they do not change occupations. Throsby's evidence shows that once a 'satisficing' level of income has been reached from earnings from all sources, artists devote more time to arts work, eschewing the opportunity to earn more from doing more hours of non-arts work [Throsby (1992)]. Abbing (2002) has reinforced this view with ample anecdotal

evidence from the visual arts world.<sup>15</sup> Artists often report choosing work that offers new challenges rather than repeating a former piece of work even if that would raise their earnings [Jeffri and Throsby (1994)]. This behaviour could be superficially interpreted as opting for utility rather than money but it may also be efficient in improving the artist's reputation, which is the best investment in her future, particularly for self-employed workers [Benhamou (2000)]. It is difficult to know when artists absorb these values – whether they do so as students or after they have entered the labour market. There have been few longitudinal studies of artists' careers by cultural economists that match students' expectations to their labour market experience.<sup>16</sup>

### 5.3. Does the human capital model explain artists' training decisions?

Finally, we come to the question of how well the human capital model performs in explaining artists' decisions on training and career development. If we were to take the extreme view that talent alone determines an artist's career and earnings, investment in schooling would not be worthwhile; by definition it could not raise productivity. However, casual evidence from the biographies of artists goes contrary to that view, as many highly talented artists have trained at art, drama or music college. Of course that could be for institutional reasons and we may question whether an alternative organisation of training such as private lessons could have yielded the same results. Apprenticeships in the performing and visual arts – the only source of training before the nineteenth century – are alternatives that are still sometimes available today, for example, for potters and for opera singers.<sup>17</sup>

However, as noted above, part of the experience of attending college is socialisation and professionalisation. Blaug (1985) has pointed out that the three Ss – skilling, screening and socialisation – are as important in the labour market as the three Rs. All artists need to learn the ropes; networking – forming working partnerships, meeting with other artists and with agents who may in future be in a position to offer work, getting recommendations from well-known teachers – may be more important than the schooling function. Tacit knowledge, trust and reputation, are also important in artists' labour markets. These are all features of social capital; are they also part of human capital formation? An important question is whether they are amenable to investment decisions. Tacit knowledge acquired in childhood for example cannot be regarded as an

<sup>15</sup> Abbing is writing mostly about the position of artists in the Netherlands, where a government support scheme for visual artists was tried in the 1970s, resulting in a vast oversupply of very large works of art. It also led to a considerable oversupply of artists with the result that art prices are low, creating a vicious circle of dependence on state basic income payments [Abbing (2002); see also Rengers and Velthuis (2002)].

<sup>16</sup> See Chapter 23 by Alper and Wassall in this volume for a discussion of longitudinal studies.

<sup>17</sup> Until the mid-twentieth century in Italy, the standard training of singers consisted of the pupil going to live with the Maestro and having daily lessons. Tito Gobbi trained that way and so did Cecilia Bartoli, whose singer parents taught her at home. Conductors often started as repetiteurs in opera houses teaching singers their parts or even, as in the case of Georg Solti, as pianists working for a singing teacher. Opera houses have fairly recently reintroduced apprenticeship schemes for trained young singers to acquire work experience.

investment as it is not deliberately fostered, though early childhood education within the family may be, and often is in the case of children's dance and music lessons [Seaman (2003)]. Acquisition of tacit knowledge and early training certainly seem to play some role in occupational choice in the arts; there are many instances of children following in a parent's footsteps (and not only in the days when there was only on-the-job training). Early acquisition of knowledge is probably easily confused with innate talent in the arts. However, there have been no systematic studies of the influence of family background on occupational choice in the arts and it is all too easy to generalise from the Placido Domingos and Vanessa Redgraves of this world. This topic would be a very interesting research project and could shed light on the role played by social as compared to human capital investment; I return to this matter below.

These qualitative arguments may explain the weak effect cultural economists have found for the influence of human capital on artists' earnings. Schooling helps the artist get her first work assignment and that may be a critical step on the career ladder. Schooling also provides general training that can be used outside the arts and it teaches good networking and other 'social capital' skills. But if investment in human capital only marginally explains the observed high demand for arts training, does that suggest that sorting models perform better? It seems from the earlier discussion that certification also plays an ambiguous role in artists' labour markets. Besides formal schooling, there are other screening devices available such as prizes and competitions, awards from Arts Councils and other forms of informal certification that offer information.<sup>18</sup> However, employers do take note of the fact that artists have attended college because the college screened them on entrance; they also treat attendance as a signal that arts students will have acquired some basic professional skills, even if these are marginal to the innate talent necessary for undertaking work in the arts. It seems that in a situation with oversupply of new entrants and the presence of a sea of amateurs, the position of the potential 'employer' in the arts (as compared to other labour markets) is especially difficult because of information problems; on the other hand, making the right choice matters less in a situation in which frequent job change and working on short term contracts is normal. And, as reported earlier, having a higher education qualification pays off in arts related and non-arts work even if not for artistic work and that is an important consideration for the majority of artists who inevitably hold multiple jobs. Thus, there is some supporting evidence for the sorting model.

In short, the jury is still out on what is an appropriate model to explain artists' training and occupational decisions.

## **6. Human capital, social capital, cultural capital and their implications for training artists**

We now return to the fundamental question of what purpose is served by the use of the term 'capital' in human capital theory. Originally raised by Blaug (1976), who asked

<sup>18</sup> See Wijnberg (2003) for a discussion of the role of awards in the arts.

whether human capital is in fact a useful metaphor, this question is being asked again in relation to social capital and it is also relevant to the notion of cultural capital that has appeared in the literature of cultural economics. Social capital is a concept that originated in social theory. It has provided an umbrella term under which a range of diverse topics has been investigated by economists. Bowles and Gintis (2002, p. F419) define it as follows: "Social capital generally refers to trust, concern for one's associates, a willingness to live by the norms of one's community and to punish those who do not". However, Putnam (2000, p. 19) defines it as "... connections among individuals – social networks and the norms of reciprocity and trustworthiness that arise from them ...". Both aspects have been related to labour markets in general and specifically to human capital. In a recent review article, Sobel (2002) states: "economists find the social capital *metaphor* useful in studies of economic development, transition economies, common-resource property use, and education" (p. 143, my italics). The concept of cultural capital was introduced by Throsby, who defines it as "an asset that embodies, stores or provides cultural value in addition to whatever economic value it may possess", where cultural value is defined as a combination of aesthetic, spiritual, social, historical, symbolic and authenticity values, typically produced by artists [Throsby (2001, p. 46)].<sup>19</sup> Thus we have three somewhat related concepts carrying the label 'capital'. What do these concepts contribute to an understanding of artists' labour markets and indeed how appropriate is the capital metaphor in all these cases?

Since the World Bank's adoption of the concept of social capital, a number of objections have been levelled against it by economists, notably by Kenneth Arrow (2000) and Robert Solow (2000), who judge it according to the standard notion of capital in economics due to Irving Fisher. Arrow's definition of (physical) capital identifies three features: capital is deferred consumption; it can be deliberately accumulated by investment; and it is alienable. Solow added two further criteria: capital has a rate of return that can be used as a measure of its value; and capital depreciates, whether from use or from technological obsolescence. Both Arrow and Solow conclude that social capital does not have these characteristics. As Solow has said "social capital is an attempt to gain conviction from a bad analogy" [quoted in Sobel (2002)]. Many other economists have criticised the concept from various points of view [Fine (2001); Durlauf (2002)].

Be that as it may, it seems that several features bundled together as social capital are relevant to artists' labour markets. How do these features help us understand artists' incentives to invest in acquiring skills and competences? If, as is the strong implication, social capital is a 'public good' (in the technical sense of that term, that is, non-rivalrous and non-excludable), the inference is that individuals would not have the incentive to invest in themselves and therefore artists' training would have to be collectively financed. However, if artists can appropriate the benefits for themselves, as they can with the human capital model, then they would have the incentive to invest

<sup>19</sup> For a full discussion, see Throsby (2001, Chapter 2).

in their own training. Though much of the research on social capital has been on its communal benefits, Glaeser, Laibson and Sacerdote (2002) make the case that standard microeconomic analysis can indeed be applied to social capital formation. Their model of individual investment in social capital, in which individuals choose optimal levels depending upon the opportunity cost of their time and time preference rate, is almost identical to the human capital investment model. Clearly they assume that social capital is not a public good, although it may have some degree of publicness. More important for our present purposes is their assertion that: "(T)he connection between social capital and human capital is one of the most robust empirical regularities in the social capital literature. Better understanding of this connection should be a key goal for future research" [Glaeser, Laibson and Sacerdote (2002, p. F455)]. The clear implication of this is that investment in social capital is analogous to that in human capital – indeed, the two are 'joint products'. But if that is so, there is an identification problem of distinguishing the private rate of return to one from that to the other. That muddies the debate about the relevance of human capital theory in artists' labour markets. It is clearly important for policy purposes to understand their separate contributions to lifetime earnings in view of the public/private dichotomy.

The public/private division also arises in respect of cultural capital. Throsby defines cultural capital as the stock of goods and services that constitute society's cultural assets, which have been created by artists (past and present). He distinguishes tangible from intangible cultural capital: tangible assets may be privately or publicly owned but intangible cultural capital (which overlaps significantly with social capital) is always a public good. Both yield a return of cultural value that Throsby regards as a communal rather than an individual variable. However, the motive for the artist in creating these assets, according to the human capital view (which Throsby has tested more than any other cultural economist), is the desire for private gain, whether pecuniary or non-pecuniary. Thus, artists' human capital creates cultural capital – Adam Smith would have liked the implied doctrine of the unintended consequences of private action, the coincidence of private incentive with public benefit. As with social capital, there are strong externalities present in cultural capital (if not true public goods characteristics) that call for communal rather than individual investment.

One way of identifying the differences between these three obviously related capital concepts is to focus on their implications for cultural policy. A central concern of cultural policy is how society can best invest in the supply of artistic creativity. According to human capital theory, we should encourage artists to raise their productivity through subsidies to formal training courses in colleges and possibly also by giving artists basic income support or price subsidies in order to raise their earnings. Social capital instead suggests that developing social skills, joining professional networks, acquiring a reputation and the rest are what is needed to pursue a career; acquiring the right experience for building a reputation for reliable professional behaviour takes precedence over schooling. Some social skills may be acquired in specialised colleges but investment in social capital on-the-job through work experience is likely to be more effective. The policy implications of the social capital model are therefore that there should be subsidies to

colleges providing hands-on experience with teachers who are professionally active, agreements with professional associations and trade unions to accept young entrants, and so on. It possibly also implies a policy of restricting the number of training places in college so as to raise the 'exclusiveness' and reputation of being accepted on a course. However, apprenticeship schemes and artist-in-residence placements would seem to be more effective in building social capital. As noted, social capital and human capital are likely to be formed side by side and for both there is a private return to the individual that is an incentive to investment.

The implications of the notion of cultural capital for cultural policy are complex and reach to the heart of artistic creativity and the difficulty of applying economic analysis when motivation and outcomes are not easily understood in terms of economic rationality. To say that artists are motivated by the desire to supply cultural value (as I interpret Throsby to do) is simply to 'pass the buck' by changing the language. It does not tell us how that translates into economic terms such as productivity or earnings. We may accept that cultural heritage (or accumulated cultural capital), whether tangible or intangible, is a public good formed by artists in pursuit of their own motives but that does not tell us how it influences successive generations of artists. It could be argued that the greater the stock of cultural heritage, the more difficult it is for artists to be creative, and training that makes students aware of that heritage runs the risk of frightening them off. Conversely, making your mark may best be achieved by shock tactics rejecting that heritage. Therefore, investment in cultural capital by preserving heritages could be either an incentive or a disincentive to individual creativity and furthermore may similarly influence consumers' taste or distaste for new works. It is certainly difficult in some art forms, notably music and opera, to get audiences to attend performances of contemporary creators. The public good nature of cultural capital also implies that it is difficult for individual artists to appropriate the full economic value of their work [Wijnberg (1995)]. This is one of the rationales for copyright law (see below).

The above points raise the question how artistic motivation may be stimulated by government policy. Frey (1997) has developed a general theory of economic motivation based on human psychology that includes the response to pecuniary incentives – extrinsic reward – but extends the maximand to the satisfaction of an inner intrinsic motivation. While other cultural economists have recognised this distinction, Frey's insight is what he calls the 'Crowding Effect', the proposition that inappropriate rewards can displace incentives; for example, monetary payment, an extrinsic reward, may crowd out intrinsic motivation and become a disincentive rather than an incentive for acts which are intrinsically motivated. A better response may be achieved by offering intrinsic rewards to inner-motivated output; an optimal system combines appropriate incentives and rewards. In applying this analysis to the arts, Frey (2000) asks how government support for the arts affects creativity. He distinguishes what he calls 'institutional creativity' from 'personal creativity': institutional creativity is motivated by extrinsic rewards and personal creativity is motivated by intrinsic rewards. Extrinsic rewards are what the market and the state can offer – the market via prices for artists' work and the state through direct financial measures such as subsidy, and indirect measures such as copyright law

[Towse (2001b)]. Personal creativity is clearly more closely related to intrinsic motivation, which in its extreme form is the Romantic concept of the driven genius pursuing art for art's sake at all costs. Its reward is intrinsic, for example, via recognition by one's peers; this is not something the state can offer. But even personal creativity is subjected by Frey to an economic interpretation by applying the all-powerful doctrine of opportunity cost: younger artists can 'afford' to be more creative than older established artists because they have less to lose artistically and financially.

Frey's theory seems to get us somewhat closer to the crucial question about creativity and cultural policy: can we 'create' creativity by investment, private or public? That obviously has important implications for the present-day policy in many countries that emphasise the role of the creative industries. However, whether we espouse the concepts of human, social or cultural capital as our guide to cultural policy towards artists, it is difficult to get away from the role of innate talent. In fact, none of these theories comes to terms with this issue. Even distinguishing intrinsic and extrinsic motivation does not solve the matter. All told, we must accept the fact that the probability of backing the right horse and choosing only highly talented artists to nurture and support is very low. 'Many are called but few chosen' has to be the motto for art colleges and artists' labour markets. At best, they filter out the least able and create conditions in which the best can make their way. Throwing money at arts training by way of investing either in human, social or cultural capital does not really solve the problem of how to create or improve creativity. So how should we attempt to create and improve creativity? The answer is quite simply that we do not know.

## 7. Human capital theory, copyright law and reproducibility

I now turn to an old problem in human capital theory – its inalienability – and argue that the combination of the ability to reproduce works of art ('reproducibility') and copyright law overcome previous objections to the capital analogy, namely that human capital cannot be separated from labour. There is a close relationship between human capital and copyright since both spring from the human mind. Copyright law protects authors and performers by establishing statutory property rights that enable them to control the exploitation of their works, granting them the exclusive right to authorise their use.<sup>20</sup> The economic purpose of copyright is to encourage creativity and the dissemination *inter alia* of works of art.<sup>21</sup>

The evolution of copyright law is inextricably connected to the ability to make mechanical copies that began with the invention of the printing press. The development of

<sup>20</sup> Copyright law in the Anglo Saxon tradition applies both to authors, performers and 'publishers' – companies in the cultural industries, such as producers of sound recordings and film. In the European civil law tradition, authors' rights pertain to human creators and neighbouring rights to the other groups. Here I use the term copyright loosely to refer to both types of rights.

<sup>21</sup> See Landes (2003) and Chapter 7 in this volume.

recording technologies – sound recording, motion picture making, photocopiers, home recording equipment (VCRs, CD burners) and now the Internet – that duplicate a work from a master copy (a performance, a book, a photograph) has vastly extended reproducibility. These inventions have created markets for copyrighted works embedded in CDs, videos, computer games etc., that have been alienated from the person of the artist or creator. Creators mostly have their work marketed by ‘publishers’ (record, film, TV, publishing companies, art galleries and so on – firms in the creative or cultural industries) who act on the assignment or licence of the copyright by the creator. The typical contract is a royalty contract, which may or may not include an advance payment, sharing the sales revenue of the publisher for a fixed percentage, often 10 or 15 percent.<sup>22</sup> Once economic rights have been assigned, however, the artist has little residual control over exploitation (though moral rights may not be alienated). When firms decide to delete works from the catalogue, artists can rarely do anything to stop them. Copyright enables artists to earn from their investment human capital but it does not ensure they do so and how much they earn depends on market forces. It was noted earlier that superstar earnings are disproportionately higher than ‘middle income’ artists. That is also the case with copyright royalty income. Because superstars have greater bargaining power with firms in the cultural industries, they are able to strike a better bargain than ‘ordinary’ artists [Caves (2000)]. ‘Average’ artists’ royalty earnings, by contrast, are typically low [Towse (2001a)].

One other feature of copyright that can be mentioned in this context is ‘works-for-hire’, according to which copyright is conferred on the employer in cases where the employee was directed to do the work; that is typically the situation for Hollywood script-writers and animators, for example. Therefore the control of copyright assets depends on the way the labour market for artists is organised – the less full-time employment there is, the more important copyright is for freelancers.

The exploitation of the author’s work embodied in reproducible form has a double-sided effect: it ‘alienates’ the author’s human capital input from her labour as the work can now reach the market without the necessity of her presence; and through copyright law the publisher acquires a durable asset, the master copy, which he can exploit independently of the author (who may even be dead since the copyright term is life plus 70 years).<sup>23</sup> Thus the joint effect of reproducibility and copyright law has been the creation of capital assets in the hands of the firms in the cultural industries that may be traded and transferred in mergers. The AOL/Time Warner merger, for example, involved the transfer of 1.5 m song titles. This effect is believed by writers on the cultural industries to be responsible for increased merger activity [Bettig (1996)].

Another effect of the combination of copyright law and reproducibility on artists’ labour markets is that an artist can decide to allocate her time to earn a spot price or a

<sup>22</sup> Watt (2000) analyses royalty contracts in detail from the economic point of view.

<sup>23</sup> It is often forgotten that an author’s work is protected for a longer period than the copyright term. If, for example, an author creates a work at the age of 25 and she lives to the age of 75, that work is protected for 120 years.

future return – for example, doing a sound recording in preference to a concert (since the concert pays a fee and the sound recording a royalty). Copyright therefore alters the duration of human capital and artists' supply decisions. In addition to dividing their time between arts and non-arts work [Throsby (1996)] or 'high art' and 'low art' [Cowen and Tabarrok (2000)], artists can optimise a portfolio of copyrights that form part of an inter-temporal decision about present and future earnings. Taking this into account, an artist's earnings at any point in time depend upon wages and fees for the hours of work done in that period *plus* copyright royalty payments (the royalty rate times the number of copyrights the artist holds). It is to be expected that the higher the royalty income, the fewer hours of work artists would do in any given period. A model along these lines could be tested using data from artists' surveys that asked for separate information on fees and wages and on royalties.<sup>24</sup>

The combination of copyright law and reproducibility therefore fundamentally alters two issues in human capital theory, the inalienability of human capital from labour and the period over which the worker can recoup the investment in human capital. As a result of these two features, human capital thus becomes conceptually far closer to physical capital. It is likely that these features are also present in other labour markets, especially those in the 'information' industries. Casualisation of labour, preferences for self-employment, the increased value of information and knowledge, and the increased value of protection through copyright and other intellectual property law are growing in the economy at large. Artists' labour markets may indeed be the forerunner of a more general trend in the evolution of labour markets.

It remains to consider whether a policy of 'strengthening' copyright law or 'increased copyright protection', both much touted by the cultural industries and their pressure groups as assisting artists (as well as themselves). That is a complex question that has been little researched. Strengthening copyright for artists, for example by lengthening its duration, is a two-edged sword: while increasing protection it also takes more work out of the public domain, thus also increasing the cost of creation [Landes and Posner (1989)]. It also benefits companies in the cultural industries more than individual artists since companies have better access to capital markets and a higher time preference rate, though it must be admitted that this is an assertion that remains unproven [Towse (1999)]. In Towse (2001b), however, I argued that copyright may well meet Frey's call for intrinsic motivation for artists by providing symbolic recognition of their status. This is something that could be investigated further.

## 8. Conclusion

In this chapter, I have argued that human capital theory applies only weakly to artists' decisions about investment in schooling and training and about occupational choice.

<sup>24</sup> For a preliminary attempt at such a model, see Towse and Watt (2005).

The same, however, can be said about the sorting model, though the case for it is possibly somewhat stronger. What is lacking in cultural economics is an understanding of talent and creativity, what economic factors motivate artists and how creativity can be encouraged as part of government cultural policy. Bringing social and cultural capital into the equation do not seem to add much in the way of understanding artists' labour markets. The case has been made in this chapter that reproducibility of works of art in combination with copyright law alters the view that human capital cannot be separated from the labour of the artist but that separation, while intellectually interesting, does not help artists to greater rewards in and of itself; indeed, it may well be a cause of increasing skewness of artists' earnings. The effect of copyright earnings on artists' supply decisions is something that must be tested empirically and I have sketched a model that could be used as a basis for further investigation. It could be linked to longitudinal studies of artists' careers, another piece of research that is badly needed.

By concentrating on the role of human capital in artists' labour markets, the focus has been on the supply side. So far there have been no systematic studies of the demand for artists or attempts to analyse skill-bias in the arts. This type of study has increasingly been done in labour economics in order to understand changes in rates of return to human capital over the last 30 years [Acemoglu (2002)]. Cultural economists who have studied artists' labour markets are certainly aware of the increasing demands that are made on artists' skills and competencies and also of the ever growing skills of certain kinds of artists – for example, singers and instrumentalists now routinely perform music that was considered unplayable 75 years ago and do so with little rehearsal. That is surely a sign of increased productivity.<sup>25</sup> This is another important topic for future research in artists' labour markets.

It is essential that cultural economics in general and the study of artists' labour markets in particular continue to apply standard economic ideas to the arts and to test them. The arts form part of the economy; they use resources and produce consumer goods. Artists are workers – they may be more like ministers of religion, inventors or creative engineers than accountants or travel agents but as a starting point it is right to look for similarities between artists and other workers using labour economics and human capital theory. That has been the approach of those who initiated research on artists' labour markets; however, experience so far suggests that the human capital model is not the way forward. The overall conclusion, then, is that there has been empirical progress in the analysis of artists' labour markets but there is much more to be done.

In closing, it is interesting to note that there are some strong parallels between aspects of artists' labour markets and those of sportspeople. In both fields the role of talent, innate ability and ability acquired early in life exert a strong influence on earnings and career success, and superstardom is probably even more marked in sport than in the

<sup>25</sup> One of the long run effects of the espousal of Baumol's Cost Disease in the performing arts has been the assumption that no technical progress is possible in the arts or on the part of artists. That is, however, a misunderstanding. See Cowen (1998) for a counter view; see also Chapter 11 by Baumol and Chapter 15 by Brooks in this volume.

arts. Seaman (2003) concludes that there is much to be gained by cultural economists from joint research between the two fields. Maybe artists are after all not so completely different!

**Abstract**

The Economics of Superstars sets out to explain the relationship between talent and success in the arts, but there is no agreement about what this relationship is. But whatever its other features may be, superstardom means that market output is concentrated on just a few artists. Concentration always raises the question of efficiency. Superstardom may be inefficient not only because it raises prices for consumers but also because it deprives other artists of the opportunity to practice art. Artists who do not practice art lose psychic income. Because psychic income cannot be transferred from one person to another, the loss of this income may be inefficient. This chapter reviews theories of superstardom and theories about the emergence of stars. The efficiency of superstardom is discussed in terms of effects on consumers and the use of publicity rights by the star. The chapter goes on to deal with the loss of opportunities to practice art that are caused by superstardom and suggests ways to alleviate the problem. Finally the empirical literature that tests the different theories of superstardom is reviewed.

## 1. Theories of superstardom

### 1.1. *Why does superstardom occur?*

Superstars in the arts, sport etc. are individuals who attain considerable prominence and success in their field and whose earnings as a result are significantly greater than the earnings of their competitors. According to Rosen (1981), superstardom in the arts is due to two factors: a hierarchy of talent, and the perfect or nearly perfect reproducibility of art. A good illustration of Rosen's argument comes from the music or theater markets. In the past a singer or an actor, no matter how good she or he was, could serve only a limited number of people. Hence singers and actors of all levels of talent could find audiences. But now that music can be perfectly reproduced on recordings, and theater has been supplemented or displaced by movies and videos, every consumer can inexpensively consume the performances of the best artist.

But if the best artist is significantly better than her competitors, then in fact "each consumer consuming the best" is a special case. Consider singers producing and selling CDs. The best artist in these circumstances is a monopolist, and whether profit maximization calls for a low price and selling to all consumers, or a high price and selling only to a few, depends on the elasticity of the demand for her product. Only if demand is highly elastic will it be profit-maximizing to serve the whole market. Particularly interesting in Rosen's model is the case in which there are several artists with the same top-level talent. Because the average cost of producing CDs is decreasing (the cost of producing the music recorded on a CD is a fixed cost), there will still be only one star even in this case. But since competition among these top-level artists to be the star would be fierce, the star would be able to charge only the average cost of production in selling her CDs. The star would, therefore, be poor.<sup>1</sup>

Hence in Rosen's model there are two extreme possibilities. If there is an artist who is significantly more talented than the rest, this artist, unless the demand is nearly perfectly elastic, sets a high price for her art and sells it to only a fraction of consumers. If there are several artists of equal talent, one of them serves the whole market, but she is poor. Thus according to Rosen's model, if a star is extremely popular and extremely rich, her talent must be greater than the rest by just the right amount.

Adler (1985) argues that the existence of superstars is not due to differences in talent. He suggests that there are in fact many artists who possess stardom-quality talent; what produces superstars is the need on the part of consumers to consume the same art that others do. This need arises from the fact that the consumption of a piece of art is not a momentary experience but a dynamic process in which "the more you know, the more you enjoy". Consumers build "consumption capital" in art, and the larger the capital

<sup>1</sup> Rosen (1981, p. 852).

the greater is the enjoyment from each encounter with the art and the artist [Stigler and Becker (1977)].<sup>2</sup>

The acquisition of this knowledge occurs in three ways. It can result from exposure to the art itself, from discussions about the art with friends or acquaintances, or from reading about the art in newspapers and magazines. When the artist is popular, it is easier to find discussants who are familiar with her or to find media coverage about her. This is why consumers prefer to consume what others also consume.

Because the number of artists who can be popular at any one time is limited, not all talented artists can be successful. However, the frustration of an unsuccessful artist does not end with not having an audience. She must also suffer consumers' judgment that she deserves her fate. It is easy to conclude that an artist who is not as popular "is not as good". Thus, the hierarchy of success manufactures a hierarchy of pseudo-talent in its own image, tending to reinforce the spurious perception of a talent differential.

### *1.2. The emergence of superstars*

Rosen's model relies on known differences in talent and it therefore includes a straightforward process by which superstars emerge. MacDonald (1988), considering only the performing arts, defines talent differently, and describes a dynamic process through which stars emerge. He argues that every performing artist is capable of producing either a good or a bad performance. The difference in talent between artists is seen not in the quality of their good or bad performances, but in the probability that a particular performance will be good. This probability is the same throughout the artist's career. But from the vantage point of audiences, the probability of a good performance is lower for a new performer than for a known performer. This is because many artists try their luck at performing and those who perform poorly drop out. Those who perform well, on the other hand, stay, and their probability of performing well in the future is higher. Therefore artists with a good track record can command higher ticket prices and entertain larger audiences. In these circumstances, artists of equal talent do equally well.

Adler (1985) also describes a dynamic process for the emergence of a star, but in this process the star emerges from among several artists who are all equally talented. In this model the emergence of the star arises from a chance event: consumers select an artist at random when they add a new artist to their consumption basket, and it is simply by pure chance that one of these artists ends up with more patrons than the rest. This initial advantage makes the lucky artist the most popular, and since consumers prefer popular artists, other consumers will switch to her as well. An initial advantage can thus snowball into superstardom.

Pure luck is just one possible mechanism by which consumers initially choose a particular artist. Indeed artists themselves do not usually entrust this choice to chance.

<sup>2</sup> Harvey Leibenstein (1950) described a "bandwagon effect" that causes consumers to consume the same goods that other consumers do. Leibenstein attributed the effect to the need of consumers to conform or to be stylish.

An author, for instance, may purchase copies of her own book in order to try to push it onto the bestseller list. A musician may pay “payola” (even though it is illegal) to convince a disk jockey to play her music on the radio. And, most importantly, artists use publicity such as appearances on talk shows and coverage in tabloids and magazines to signal their popularity. None of this detracts from the possibility, however, that the allocation of publicity resources to artists is independent of differences in artistic talent.<sup>3</sup> We return to this issue in a following section.

### 1.3. *The efficiency of stardom*

#### 1.3.1. *The effect on consumers*

Are the prices that stars charge too high? Economists do not have a yardstick for determining whether prices are too high or too low. But they distinguish between prices that are determined in markets with free entry and markets with barriers to entry. We can analyze the issue of market power via the example of the market for music CDs.

Entry into a market is said to be free if an artist who is as talented as the star can offer her CDs for a slightly lower price and capture the market. According to Rosen, this is indeed the case, and the art market is therefore efficient. However in Adler’s model, consumers prefer the most popular artist and therefore even an artist who is as talented as the star cannot entice audiences away from the star, not even by offering a lower price. Hence in this model entry is not free, and there are theoretical grounds for government control of prices.

Borghans and Groot (1998) explain why the prices that the stars charge are too high. They first reject Adler’s theory because it is based on the assumption that the stars may not be more talented than other artists. They argue that if there are several artists who have the potential of being a superstar, each would invest resources in enhancing her chances to be the one, and as a result the total income of the superstar would decrease. While this is of course true, Borghans and Groot acknowledge that the maximum that an artist would be willing to invest in promotion is the expected value of becoming a superstar. If there are many artists with the same superstar-potential, the probability that any particular one will become the winner will be low, and the expected value of becoming a superstar will therefore be low as well. Thus each artist’s investment in promotion will be small and the lucky superstar’s income, even after accounting for the promotion expenses, will be large.<sup>4</sup>

Borghans and Groot begin their analysis of Rosen’s theory by proving that talent differences and the reproducibility of art are not sufficient on their own to produce superstar earnings. Their proof is via an example of  $n$  consumers and  $n$  artists, but the case of two consumers and two artists is just as illustrative.

<sup>3</sup> This raises the possibility that the star could be an artist of a lesser talent; see Adler (1985), Bonus and Ronte (1997).

<sup>4</sup> Borghans and Groot (1998, p. 557).

Assume that art cannot be replicated, and that the cost of producing art is zero. Assume also that artist *A* is less talented than artist *B*, that the consumers *a* and *b* are identical, and that the consumers' reservation prices for the art of *A* and *B* are \$1 and \$2, respectively. Each consumer consumes just one unit of art. Finally assume that artist *A* charges \$1 for his art, which he sells to consumer *a*, and artist *B* charges \$2 for her art, which she sells to consumer *b*; with these prices, each consumer is equally satisfied. In other words, the lower price that artist *A* charges constitutes full compensation for his lower talent. Now suppose that all of a sudden art can be replicated costlessly. Intuition may lead one to believe that artist *B* would be able to increase her income by selling to both consumers, but Borghans and Groot show that this is actually not the case. If *B* were to charge more than \$1.00 for her art say \$1.50, then artist *A* will charge a price that is at least \$1.00 lower than *B*'s price, say \$0.25, and capture the whole market. Hence, competition would force the superstar to charge only \$1.00 and as a result the superstar would earn exactly the same income that she would have earned had replication not been possible.

Borghans and Groot conclude that something else must explain the high incomes of superstars. It must be that consumers stay with the superstar even when there is another artist who charges a price that is so low that it is sufficient to compensate them for his smaller talent. According to Borghans and Groot the reason for this loyalty is that consumers prefer to "watch the performance of someone known to be 'the best'".<sup>5</sup> The problem with this argument is that it is contradictory. If the lower price already constitutes full compensation for the smaller talent, why would the consumer still prefer to watch "the best"?<sup>6</sup> Substitute "most popular" for "the best" in their statement, however, and the argument, now identical to Adler's, is consistent. When replication is not possible a price difference compensates consumers for the talent difference, and each artist is equally popular (or equally unpopular). When replication becomes possible the same price difference continues to compensate consumers for the talent difference, but it does not compensate them for the difference in popularity, which exists when all consumers patronize the same artist. Of course, if consumers value popularity no difference in talent is required to produce it.

### 1.3.2. *Publicity rights*

The most novel challenge to the efficiency of the stardom system comes from the literature about publicity rights. The seminal article in this literature is by Madow (1993) who argues that the existence of these rights is inefficient because they restrict the public's use of symbols. Madow cites as an example a greeting card that carries a photograph of John Wayne wearing lipstick. The card's message is probably that masculinity and

<sup>5</sup> Borghans and Groot (1998, p. 561).

<sup>6</sup> There must be a price differential that constitutes full compensation for the talent differential, because otherwise there would be no equilibrium in a world in which replication is not possible.

homosexuality are not contradictory. But whatever the exact message is, it is clear that John Wayne was not its creator. Had the greeting card company had to pay for the use of the photograph it would have paid for a symbol that was in large part its own creation. Furthermore, Wayne might well have refused to sell his image for this use. In fact, during hearings on a bill to create publicity rights in New York State in 1989, Wayne's children cited this "abuse" of their father's image as a justification for the bill. Thus publicity rights amount to censorship.

While the distance between a star's intentions and the actual symbol that she becomes may be larger in this particular case than it is in most other cases, Madow argues that a large distance is nevertheless typical. Even the U.S. military does not treat Wayne as a positive hero, according to Madow, because when it warns soldiers against taking foolish risks, it admonishes them not to "John Wayne it". Nevertheless, do stars deserve to have publicity rights in those cases in which they are indeed the creators of the symbols that they become? If the stars had not created these symbols, consumers would have created them themselves, Madow argues, perhaps through the snowballing process discussed above.

As an example for this process Madow cites the emergence of Albert Einstein as the symbol of genius. According to Missner (1985, p. 268), Niels Bohr and Werner Heisenberg made equally great contributions to science. It was serendipity that favored Einstein. In 1921 he came to New York as a member of a Zionist delegation that was headed by Chaim Weizman, the head of the Zionist movement at the time. Thousands of New York Jews went to the port to greet the Zionist delegation, but the newspapers reported that the enthusiasm was not for Weizman and Zionism but for Einstein and his theory of relativity. This made Einstein a subject of newspaper interviews, and propelled his ascendance as the symbol of genius.

The moral justification for the existence of publicity rights notwithstanding, the question is whether stars can charge prices that are inefficiently high for these rights. Can a star who is not a symbol offer to serve as a symbol at a lower price, and enter the market? Even if a star could turn herself into a symbol at will, she could not do so overnight, since she would need the active participation of the public. Hence there are barriers to entry into the market for symbols, and the prices charged for the use of publicity rights are probably inefficiently high.

## 2. Superstars and other artists

### 2.1. *Are there too many artists?*

According to Frank and Cook (1995), the large incomes that superstars earn cause too many artists to attempt to be the winners. While seeking stardom these "surplus" artists forgo income from non-artistic jobs and some may even neglect the normal education that would have permitted them to earn high incomes doing regular jobs. Hence false

dreams of success may cause poverty. Frank and Cook call on the government to limit the remuneration of artists in order to make superstardom less attractive.

In his review of Frank and Cook's book, Rosen (1996) was skeptical about the empirical relevance of their argument, arguing that artists who seek success learn what their personal odds are quickly; when these odds are low they quit the field rapidly. Rosen also suggested that the effect of false dreams on the rate of poverty is negligible; in other words, the poor are not poor because they dream of being rich.

### *2.2. Superstardom and the psychic income of artists*

It appears that artists derive psychic income from practicing art, because their monetary incomes from producing art are consistently lower than in equivalent alternative occupations [Jeffri (1991); Throsby (1992); Wassall and Alper (1992); Menger and Gurgand (1996)]. When artists do not practice art this psychic income is lost. In regular markets when a business fails, its loss is another business's gain. But when an artist cannot practice art because consumers flock to superstars, her loss of psychic income is not transferred either to the superstar or to her audiences.<sup>7</sup> It is simply lost. This loss would only be efficient if there were other gains from superstardom that exceeded this loss. Whether there are depends in part on what gives rise to superstardom in the first place. If artists are displaced because they are less talented than the superstar, as in Rosen's model, then their displacement would be efficient. Why encourage anyone to produce an inferior product? But if the displaced artists are just as talented as the stars, and the only reason they are displaced is that consumers prefer popular artists, then the loss of benefits to the artists no longer practicing art must be weighed against the benefits to consumers from increasing the concentration in the art market.

There is no doubt that a certain degree of concentration in the arts is desirable. If every consumer patronized a different artist there would be no common culture. But is more concentration always better than less concentration? As we have noted, increased concentration results in an uncompensated loss of psychic income as unsuccessful artists stop practicing their art. But a government policy measure to increase the number of artists as a means of reducing concentration is likely to be costly. These costs need to be balanced, suggesting that there will be an optimal level of concentration, i.e. an optimal number of artists.

### *2.3. Government policy and the optimal number of artists*

If concentration is regarded as excessive, it could be reduced by means of a tax. What sort of tax might this be? The loss of psychic income amongst artists when superstars emerge arises because of an externality; a consumer who flocks to a star instead of

<sup>7</sup> This assumes that artistic psychic income, while perhaps requiring a minimum audience in order to exist, does not increase with audience size.

patronizing a lesser-known artist disregards the loss of psychic income that she inflicts on that artist. This externality can be internalized by a Pigouvian tax, but implementing the tax poses a unique problem. While a consumer should pay the tax if she flocks to a star who is already overly popular, she should not pay the tax if she were one of the star's first patrons. How could the "first" patrons be distinguished from the "rest"?

A way to implement a discriminatory tax is as follows. Let the total number of consumers be  $C$  and let the optimal number of artists be  $N$ . Assume that each consumer buys one CD, on which they would have to pay a tax. At the same time, however, the government would issue each person who claims to be an artist a book containing  $C/N$  tax-rebate certificates that bear her name. The artist would distribute these certificates free of charge to consumers who would then present their certificates to the government for payment. The number of artists who receive the rebate books may be large, far exceeding  $N$ , but the number of artists who end up having patrons would nevertheless be the optimal number, because consumers will prefer the most popular artist who is not yet "full". Thus a successful artist would sell  $C/N$  CDs. The level of the tax will be set sufficiently high to discourage consumers from paying the tax and flocking.

It should be emphasized that under this system it is consumers, not the government, who determine who the successful artists are, and that no consumer actually pays the tax, because each gets a rebate. Nevertheless, the artists are still being subsidized, because consumers end up spending more on collecting information about "their" artists than they would under the unencumbered superstardom system. Of course, like with any other tax policy the cost of implementing this policy would have to be taken into account in any assessment of its desirability.

### 3. Empirical testing of superstardom theories

Is stardom the reward for superior talent or does stardom arise because of consumers' need for a common culture? This section reviews the studies and makes a suggestion for an additional test.

#### 3.1. Testing superstardom in the arts

Whereas talent in general is not measurable, the harmonic quality of a singer's voice is. Hamlen (1991, 1994) measured the relationship between it and record sales and discovered that record sales do increase with the quality of the voice, but that the differences in talent far exceed the differences in sales. Hamlen interprets this result as being inconsistent with Rosen's "reward for talent" explanation, but Schulze (2003) argues that "it is by no means clear that the harmonic content of voice is the relevant measure for artistic quality for singers of non-classical music (rock, folk and so on)". There is no

doubt that the quality of the songs, not just the quality of the voice, must be measured as well, but this may not be possible.<sup>8</sup>

Chung and Cox (1994) take another approach to testing the two theories. They show that the distribution of success among artists follows a snowballing process (a Yule distribution). In that process the probability that a consumer would buy a particular CD increases with the number of previous sales of that CD. There always remains a small probability that a consumer will choose a new CD that no other consumer has yet bought. When this happens, other consumers may follow suit and an initial small advantage may snowball into success. Chung and Cox believe that this lends support to Adler's theory over Rosen's, but Schulze (2003) argues that the process is also consistent with consumers' choices that are based on talent.

Regardless of whether or not one agrees with Chung and Cox, their study shows clearly how important it is for artists to have an initial advantage. But how do artists acquire this advantage? Do they employ techniques that emphasize their talent, or do they choose entirely unrelated means? The proverbial "casting couch" comes to mind, but the singer Britney Spears showed that it is also possible to capture headlines by claiming to be chaste. Madonna captured headlines at the beginning of her career when her husband "protected" her by routinely beating up photographers. What is required is a systematic study of a sizeable sample of stars' (unauthorized) biographies in order to determine how important non-talent factors were in the early stages of their careers. Ideally these biographies would be compared to the biographies of artists who have not been successful. However, because there are few biographies of unsuccessful artists, the ideal may be impossible to achieve.

One example of how an initial advantage is generated is provided by Ginsburgh and van Ours (2003) in an article about the Queen Elizabeth Piano Competition. Pianists who achieve high success in the competition are rewarded by subsequent success. While this may appear to be as it should be, Ginsburgh and van Ours show that the order in which the pianists perform in the competition – which is assigned randomly – affects the results of the competition. Since success in the competition is random, why does it influence subsequent success in the market place? The answer may be that success in the competition serves not as an indicator of the artist with the most talent (consumers may even believe that all those who make it into the finals are equally talented) but as a focal point for consumers who wish to listen to artists that others listen to.

### 3.2. *Testing superstardom in sports*

Theories of superstardom have also been tested empirically in sports. Talent differences are easier to measure in sport than in art, and Seaman (2003) has asked whether it is possible to learn from the relationship between talent and income in the two areas. He found

<sup>8</sup> Hamlen also finds that success in the singles market leads to success in the regular album market, but this finding is consistent with both theories of stardom and is therefore not informative. A consumer may buy the full album either because she liked the single or because the success of the single is a signal that the artist is popular.

only two studies about talent and income in sports. [Lucifora and Simmons \(2003\)](#), in a study of Italian soccer, showed that the distribution of soccer players' incomes is more skewed than the distribution of talent, attributing this finding to audiences' preference for watching star players over watching equally talented but less well-known players. This may be a confirmation of Adler's theory that consumers prefer to watch players or artists with whom they and other spectators are already familiar. The preference for familiar athletes may also explain the finding of [Blass \(1992\)](#) that the income of baseball batters increases with experience rather than with productivity.

It is important, however, to note some differences between art and sports that diminish the value of sports economics for the understanding of art economics. Sports are competitive and in a competition every participant must accomplish the same task. For example, in a country where sumo wrestling does not exist an athlete who is a great sumo wrestler and only a mediocre football player will have to play football. In art, however, there are no such limitations and therefore an artist has more opportunities to display his or her idiosyncratic talent. This is why in art, unlike in sports, there are no measurable standards.

#### 4. Conclusion

As the debate about the international enforcement of copyrights makes clear, globalization intensifies the phenomenon of superstardom. A global culture, with a global set of superstars, is replacing local cultures with local stars, and it is therefore important to know what this means for consumers, artists and art. Economists have started to examine these questions only very recently. As this chapter has shown, there are those who believe that the global superstars will simply be the best artists on the planet. From their vantage point, there is no reason for concern. However, this chapter has also shown that a single global culture could possibly destroy local cultures not because it is better but simply because it is global. If the emergence of a global culture cannot be stopped, and if this culture does not have to be superior to be triumphant, the question becomes how to democratize the process that builds this culture. "The Economics of Superstars" is thus rife with open questions.

**Abstract**

This paper contains a new review of the research of the last decade that has been designed to shed light on how the art auction system works, what it indicates about price formation, and how well it performs. We begin with a short description of the mechanics of the auction system and then organize the remainder of our discussion around two major topics. The first topic concerns how researchers have used auction prices. We begin by discussing the returns to holding art and whether certain classes of art make a better investment. We then discuss studies that have used auction prices to determine the importance of individual works of art and individual artists. We conclude this topic by discussing whether different auction houses achieve systematically different prices. The second topic focuses on studies that examine the influence of the auction mechanism on prices. We begin with a discussion of the Christie's and Sotheby's price fixing case and the role of the competitive behavior of auction houses in the determination of prices. We move on to discuss the role of experts and price estimates in auctions. We then look at whether items that fail at auction subsequently return less than items that have not failed and furthermore discuss sale rates and reserve prices. We conclude this topic by reviewing the extensive literature that has documented and tried to explain why the prices of identical objects are more likely to decline than to increase when multiple units are sold. Subsequent empirical research has tended to document declining prices even when the objects are imperfect substitutes.

## 1. Introduction

The value of most important works of art is established by public auction, either directly, by an actual sale, or indirectly, by reference to other sales. How the auction system works is thus a critical determinant of how the public's preferences are translated into the evaluation of high-quality artistic work. The auction system is an important factor in the determination of the incentives for artistic work, and the efficiency of the auction system is a determinant of the cost of creating and distributing works of art. This paper contains a review of the burgeoning research of the last decade that has been designed to shed light on how the art auction system actually works, what it indicates about price formation, and how well it performs. We begin the paper with a description of the mechanics of the auction system. We organize the remainder of our discussion in sections around two major topics.

In section two, we discuss how researchers have used auction prices. We begin by discussing the returns to holding art and whether certain classes of art make a better investment. We find that in recent years returns on art assets appear to be little different from returns on other assets. Some researchers have recently found that, because of the weak correlation between art asset returns with other returns, there may be a case for the inclusion of art assets in a diversified portfolio, though investing in art is inherently risky. Furthermore, the evidence clearly suggests that, contrary to the view of the art trade, "masterpieces" under perform the market, although the precise interpretation of this finding is still open for study.

We move on in section two to discuss other studies that have made use of auction prices to determine the importance of individual works of art and individual artists. Several recent studies have used auction prices to test alternative models of the innovative process in artistic work, thus bringing some of the ideas of classical aesthetics into the area of testable hypotheses. One primary finding indicates that artists in different periods have produced their greatest works at very different ages. This has led some authors to theorize that conceptualists produce their greatest works when young and experimentalists produce their greatest works when older. We conclude this section by discussing whether different auction houses achieve systematically different prices. The evidence suggests that there are fairly long periods in which art prices may diverge across geographic areas and even auction houses.

There is now considerable theoretical research on strategic behavior in auctions, much of it in response to empirical findings. Section three focuses on studies that determine the influence of the auction mechanism on prices. We begin with a discussion of the Christie's and Sotheby's price fixing case and the role of the competitive behavior of the auction houses in the determination of prices. We review the public record of the criminal trial of Sotheby's former Chairman, who was accused of price fixing, to show how the collusion with Christie's, the other great public auction house, was actually engineered. Contrary to the way the proceeds from the settlement of the civil suit in this case were distributed, we show that actual buyers were almost certainly not injured by

the collusion, but that sellers were. In addition, based on the public record of settlement, it appears that the plaintiffs in the civil suit were very handsomely repaid for their injury by the auction houses.

We continue in section three to discuss the role of experts and price estimates in auctions. Some evidence suggests that art experts provide extremely accurate predictions of market prices, but that these predictions do not optimally process the publicly available information. Next, we look at whether items that fail at auction subsequently return less than items that have not failed. We then discuss sale rates and reserve prices. High reserve prices, and the resulting high unsold (“buy-in”) rates are best explained as optimal search in the face of stochastic demand. We also discuss why reserve prices are secret. Finally, extensive research has documented that the prices of identical objects are more likely to decline than to increase when multiple units are sold, and this has led to a large body of theoretical research. Subsequent empirical research has tended to document declining demand prices even when the objects are imperfect substitutes, although the empirical analysis required in this case must be much more sophisticated.

In section four, we conclude our review of studies on art auctions. Because of the unique nature of many art objects and the effect of the auction mechanism on price, the interpretation of market prices requires great care. However, art auctions provide key information for the evaluation of artistic work, and they also provide a key laboratory for testing and refining economic models of strategic behavior.

### *1.1. The mechanics of art auctions*

Historically, the major auctioneers of art have been the English houses of Sotheby’s and Christie’s. These firms, along with other smaller or regional houses such as Phillips in England or Butterfields in California, have developed and refined the rules of what have now come to be called “English” or “ascending price” auctions. Almost all art is auctioned in this ascending price format. Bidding starts low, and the auctioneer subsequently calls out higher and higher prices.<sup>1</sup> When the bidding stops, the item is said to be “knocked down” or “hammered down”, and the final price is the “hammer price”.<sup>2</sup> Not all items that have been put up for sale and “knocked down” have been sold. Sellers of individual items will set a secret reserve price, and if the bidding does not reach this level, the items will go unsold. Auctioneers say that an unsold item has been “bought-in”. Furthermore, the art trade refers to “bought-in” items as having been “burned”. That is, their value has been hurt because they failed to sell at auction. As we show below, sale rates vary tremendously across time and across different types of auctions.

<sup>1</sup> What is called an English auction is, in fact, Roman. The word auction comes from the Latin “auctio”, which means to ascend.

<sup>2</sup> For an interesting history of the development of auction rules in late seventeenth century London, see de Marchi (2004).

An item that has not been sold is rarely, if ever, actually bought by the auction house. It may be put up for sale at a later auction, sold elsewhere, or taken off the market. It is a part of the auctioneer's art to "get the bidding started", and this may involve accepting fictitious bids ("off the chandelier" or "from the order book") so long as the bidding has not exceeded the reserve price. Legally, the auctioneer is bidding on behalf of the seller when this occurs, but must refrain from accepting further bids on behalf of the seller once the bidding exceeds the reserve price.

Auction houses differ with respect to whether they announce during the sale whether an item has been "sold" or is merely "knocked down" and is unsold. In New York, all the auction houses have been compelled by law since the early 1980s to announce whether the bidding has resulted in a sale. The practice elsewhere varies by location and auction house, but there has clearly been a slow movement toward adopting the practice originally enacted by law in New York. While difficult, it is sometimes possible during an auction, if one listens carefully, to determine whether an item has been sold or "bought in".

Prior to an auction, it is common for a pre-sale catalogue to be published with information on the individual items coming up for sale. Common information included in the pre-sale catalogue is the title of the painting, the artist, the size of the painting, the medium, whether the painting is signed, monogrammed or stamped, the provenance, number of exhibitions, and a bibliography of published critiques of the painting. The auction houses also publish a low- and a high-price estimate for the work. The auction house does not publish, and indeed is very secretive about, the seller's reserve price for the work of art. The auction houses do commonly observe an unwritten rule of setting the secret reserve price at or below the low estimate, but the auctioneer is very careful about revealing anything about the reserve price during the bidding process.

Auction houses earn income primarily from commissions charged to buyers and sellers. The commission charged to buyers is called the "buyer's premium". The total sale price to the buyer is thus the sum of the "hammer price" and the buyer's premium. In recent years published buyers' premiums have typically hovered around 10 to 20 percent of the hammer price of an object, with large purchasers paying the lower amount. Although buyers may attempt to negotiate special arrangements regarding buyers' premiums, it is our impression that the typical buyer purchases such a small fraction of the objects on sale at a particular auction house that special terms for buyers are unusual.

Sellers also pay a commission to the auction house called the "seller's commission". Although the seller's commission is often stated as a percentage of the hammer price (typically 10 percent), it is our impression that actual sellers' commissions are often negotiated arrangements that differ by seller. In some cases, sellers pay no commission and may even be guaranteed a minimum sale price. Some key issues related to the negotiation of sellers' commissions, and the extent of competition and collusion in the setting of commission rates have recently surfaced in the trial of Alfred Taubman, former Chairman of Sotheby's, who was convicted of price fixing. We discuss issues related to competition among auction houses in more detail below.

## 2. The price of art

Art objects are generally unique, so that determining time-series movements in their prices requires careful measurement and extensive data. We begin the discussion below in Section 2.1 with a review of the methodology used in constructing price indices. A primary goal of the measurement of time-series movements in art prices is to evaluate the benefits of including art assets in a balanced investment portfolio, and we review the key findings on this topic in Sections 2.1.1 and 2.1.2. Since the key parameters for making this decision are difficult to estimate, this issue deserves far more research. In Section 2.2 we review some of the work by Galenson that looks at when, in an artist's career, his most important works were produced. By first identifying regularities regarding age of artist in different genres of art, Galenson develops a theory as to why these regularities exist. Finally, in Section 2.3, we focus on studies that have shown persistent differences in prices at different auction houses and in different locations.

### 2.1. Art price indices

A key feature of art auctions is that the items on sale are typically unique, or nearly so. The result is that there will be some ambiguity in the construction of a single index of the movement of prices over time. One concern about simply using average prices is that price rises may be exacerbated during booms as "better" paintings may come up for sale. For example, Wynne Kramarsky, whose family formerly owned Van Gogh's *Portrait of Dr. Gachet*, said of the London market prior to the unsuccessful sale of May 15, 1990: "I did not think that London was poor in terms of performance; I thought that the pictures were not up to it" [Watson (1992, p. 10)]. In general average prices will indicate variability over time in art prices that is better described as movements in the heterogeneity of the quality of the objects offered, rather than movements in prices for the same objects.

The extent of heterogeneity, and thus the ambiguity in the construction of auction price indices, differs across the items typically offered for sale by auction. Identical prints may be offered for sale monthly, while identical Impressionist paintings, such as the *Portrait of Dr. Gachet* may not be offered at all in a single decade.

Most art auction indices are based on a model where the price of the  $i$ th object sold in time period  $t$  is

$$p_{it} = p_i + p_t + \varepsilon_{it}, \quad (1)$$

where  $p_i$  is the fixed component of the price that reflects the unique and fixed character (or "quality") of the object,  $p_t$  reflects the index of aggregate movements in prices, and the remainder is an idiosyncratic error term. The key distinction in the construction of price indices is whether the fixed component is treated as determined by a small number of hedonic characteristics,  $x$ , that may be controlled by regression, or whether it is treated as a parameter that must be controlled explicitly.

“Hedonic models” control for the fixed effect  $p_i$  with the assumption that  $p_i = \beta x_i + \varepsilon_i$ , where  $\varepsilon_i$  is an error term independent of the  $p_i$ 's, and estimate

$$p_{it} = \beta x_i + p_t + \varepsilon_i + \varepsilon_{it}. \quad (2)$$

Alternatively, “repeat sale” models include a dummy variable for each painting.

The great attraction of hedonic models is that all the data may be used in the estimation, including data on objects that are only offered for sale once in the sample period. The disadvantage of these models is the strong assumption that a (typically small) set of  $x$  variables captures much of the variability in the fixed components of price (important if the estimates of the time effects are to be precise) and that the characteristics of the objects offered do not vary systematically over time (important for unbiased estimates of the time effects). An example of a painting where this may be a problem is Van Gogh's *Two Rats*. By hedonic characteristics such as artist and medium, this should be one of the most expensive paintings, equivalent to *Portrait of Dr. Gachet*. However, *Two Rats* is widely perceived to be a painting in much less demand than *Dr. Gachet*. A hedonic model would rarely be able to pick this up. If less important paintings such as *Two Rats* tend to come up when the art market is struggling and more important paintings such as *Dr. Gachet* tend to come up for sale during boom times, then an index constructed from a hedonic model will be biased. Thus, repeat sales indices rigorously control for differences in quality of paintings, whereas hedonic models can only control for effects that are observable to the econometrician.

Although the repeat sale method overcomes the primary disadvantages of the hedonic model, it does so at the cost of discarding much data. There must be at least two observations on a painting's price or it provides no information to help identify the time index. Indeed, depending on the frequency at which repeat sales occur, it may not be possible to identify all the time effects in the model.

The problem of sparse data when using repeat sales models has been extensively explored with regard to real estate sales.<sup>3</sup> One well-known problem is that if only a small percentage of paintings change hands in a given period, this will result in near-collinearity of the dummy variables for the time effects. Near collinearity results in imprecise coefficient estimates and an extremely variable series. Furthermore, sparse data can result in spurious negative autocorrelation in the estimated returns. This effect diminishes as the number of observations increases, but this effect is often present in the beginning of the period in which the returns are being estimated. As a result of the problems described above, Goetzmann and Spiegel (2003) recommend constructing indices for most major styles of art on at most a semi-annual frequency and for some styles, at most at an annual frequency.

For use in computing sub-indices in areas where the data is sparse but where there is ample data elsewhere, Goetzmann and Spiegel (1997) have developed a “Distance-Weighted Repeat-Sale” procedure where the distance is defined as the distance in characteristic space. They apply this method to calculating housing indices for a particular

<sup>3</sup> See Goetzmann (1992) and Goetzmann and Spiegel (1997).

neighborhood, but the method could be easily modified for use on particular sub-indices of art.

One other issue to be aware of in repeat sales data is identifying that the paintings are actually the same. Many paintings can have the same title, size, author, painting date, and medium, but yet are different paintings. Depending on the way in which the dataset was constructed, this may or may not be a problem. For example, [Mei and Moses \(2002\)](#) construct their dataset by looking at the provenance (that is, ownership history) of a particular painting, and then determining whether a prior sale is listed in the provenance. This method avoids false matches. However, when [Goetzmann and Spiegel \(2003\)](#) requested all existing repeated-sales from Gabrius, a company that tracks art auction sales, they found a number of unusual observations and found them to be mismatches. One sure way to avoid mismatches is to go back to the art catalogues and compare photographs of paintings.

Comparisons of the results from repeat sale and hedonic models have been reported by [Chanel, Gérard-Varet and Ginsburgh \(1996\)](#). The overall results indicate that both hedonic and repeat sales regressions yield estimates of real rates of return in art assets over long intervals that are the same magnitude. Hence, in some cases the hedonic model may also provide adequate estimates of time-series movements in aggregate prices. However, the danger remains that systematic movements in the unobserved characteristics of the objects being offered for sale may bias the results.

The nature of possible systematic movements is made clear when we do a detailed comparison using our data on Impressionist and Modern Art, as we did in [Ashenfelter and Graddy \(2003\)](#). When yearly price indices are constructed, the two types of indices at first appearance are very similar. [Figure 1](#) presents a graph of the hedonic and repeat sales price indices for Impressionist and Modern Art from 1980 to 1991. The correlation between the two estimates is 0.9559, the standard deviation of the hedonic price index is 1.024, and the standard deviation of the repeat sales index is 1.166. However, because of movements in the very last year, the two indices give very different internal rates of return. The hedonic index gives a real return of about 4 percent, while the repeat sales price index results in a real return of about 9 percent! Which is correct? For 1991, our data ends in May. The “major” impressionist sales are generally held in October. One explanation is that the hedonic index has underestimated the returns for this short period of time, because it was unable to correct for quality differences that occur during sales in the early part of the year. An alternative explanation is that because the repeat-sales index is based on such a small number of paintings during that period, these paintings were unrepresentative (i.e. their price held up better in poor market conditions) of the market as a whole. Our hedonic model incorporates as many as 8792 observations, while the repeat-sale estimates are based on only 474 observations.

It is not necessary to discard a great number of observations for all types of art. For example, the number of observations that are discarded when using repeat sales is smaller when studying the market for prints, as many prints are virtually identical. [Pesando \(1993\)](#) excludes less than one percent of the realized prices on modern prints

Figure 1. Repeat-sales and hedonic indices for Impressionist Art.

when using the repeat-sale methodology to construct the print price index. In this case, repeat-sales models would dominate hedonic models.

One can also measure the extent to which one type of index deviates from the other. Suppose, for example, that the repeat sales index,  $x$ , is the true index, and  $x^*$  is a measured hedonic index, and  $v^*$  is independent of  $x$ , so that

$$x^* = x + v^*.$$

If  $x$  were measured exactly, then a regression of  $x^*$  on  $x$  would give a slope of unity. If  $x$  is measured with error, the difference from unity provides an estimate of the measurement error as a fraction of the total variance in the repeat-sales index. (A more complex model would have  $x$  measured with error, but uncorrelated with  $v^*$ , say as a result of sampling error.) Computing the above regression, we find that  $x$  has a coefficient of 0.8400, and a standard error of 0.086, thus indicating statistically significant measurement error. The implication is that about 16 percent of the variance in the repeat sales measure of prices is measurement error.

Many of the recent papers that study art as an investment use regressions on repeat sales to construct an index of returns with the purpose of determining the suitability of art for investment. Rather than using a dummy variable for each painting as discussed above, these papers in effect difference prices for two identical paintings. Thus, taking Equation (1) above, and letting  $s$  refer to date of sale,  $b$  refer to date of purchase, the

individual painting characteristics ( $p_i$ ) drop out and we are left with

$$p_{is} - p_{ib} = (p_s - p_b) + \varepsilon_{is} + \varepsilon_{ib}. \quad (3)$$

Price is expressed in logs, and these studies interpret the above equation as follows.  $p_{is} - p_{ib}$  is the continuously compounded return for a particular art asset  $i$  between the purchase and the sale (often expressed as  $r_i = \sum_{t=b_i+1}^{s_i} r_{i,t}$ , where  $r_{i,t}$  represents the returns in each of the individual periods between the purchase and sale)  $p_s - p_b$  is the sum of the average return (that is average return for all paintings in the portfolio) in each period  $t$  between the purchase and sale of painting  $i$  (often expressed as  $p_s - p_b = \sum_{t=b_i+1}^{s_i} \mu_t$ ) and  $\varepsilon_{is} - \varepsilon_{ib}$  is the sum of the error terms in each period.<sup>4</sup> Our derivation suggests that the dummy variables for each pair should equal 1 at the time of sale,  $-1$  at the time of purchase, and 0 in all other periods. Goetzmann (1992, 1993) shows it is more efficient to allow the dummy variables to equal 1 during the periods between purchase and sale, zero otherwise, and then do a generalized least squares regression using the weights suggested by Case and Shiller (1987), which are based on the time the painting is held. The intuition behind the weighted regression is that the longer a painting is held, the larger the error term.

In the first stage of Case and Shiller's (1987) method, the log of the ratio of the sale price to purchase price is regressed on time dummy variables. In the second stage, a regression of the squared residuals from the first stage is run on a constant term and the time between sales. In the third stage, a generalized least squares (weighted) regression is run that repeats the stage-one regression after dividing each observation by the square root of the fitted value in the second stage.

A recent study by Biey and Zanola (2004) has combined the hedonic and repeat sales approaches. They use a method developed by Carter Hill, Knight and Sirmans (1997) for the real estate market, in which a hedonic and a repeat sales equation is jointly estimated. Case and Quigley (1991) pioneered this methodology for real estate. The coefficients on the time dummy variables are then restricted to be the same in the two regressions. They show that the standard errors on the regression estimates are decreased by using the combined method but, of course, only under special assumptions does this procedure avoid bias.

In this volume, Ginsburgh, Mei and Moses (2006) provide a thorough analysis of the different methods of constructing art indices. Other authors that have calculated price indices for art include Anderson (1974), Stein (1977), Baumol (1986), Frey and Pommerhne (1989), Buelens and Ginsburgh (1993), Pesando (1993), Goetzmann (1993, 1996), de la Barre, Docclo and Ginsburgh (1996), Chanel, Gérard-Varet and Ginsburgh (1996), Pesando and Shum (1996), Czujack (1997) and Mei and Moses (2002). The

<sup>4</sup> This methodology was developed by Bailey, Muth and Nourse (1963) and used by Case and Shiller (1987) and Hosios and Pesando (1991) for the real estate market, and subsequently used by Goetzmann (1993), Pesando (1993) and Mei and Moses (2002) for the art market. In these papers  $\varepsilon_{i,t}$  is assumed to be uncorrelated over time and across paintings.

details of these studies and the estimated rates of return on art assets they contain are presented in Table 1. In addition to art, economists have calculated price indices for other items that are sold at auction. Graeser (1993) has estimated a price index for American antique furniture, and Ross and Zondervan (1989) have estimated an index for Stradivari violins.

The estimated returns to holding art are quite dependent upon the time frame actually studied, which is not unexpected. For example, Goetzmann (1996) estimates real returns from 1907–1977 on auction data to be 13.3 percent, and even after correcting for survivorship problems, the returns remain at 5 percent. In Goetzmann (1993) he finds nominal returns for the period 1766–1986 to be only 3.2 percent. Even among authors looking at similar time frames, the returns can vary. The variation reflects differences in data, along with differences in method. It is difficult to come to any broad conclusions about the differences in estimates when using repeat-sales or hedonic indices. Anderson (1974) finds a real return of 2.6 percent using hedonic indices and 3.0 percent using repeat sales on art data from 1780–1960, and Chanel, Gérard-Varet and Ginsburgh (1996) find real returns of 4.9 percent and 5.0 percent for hedonic and repeat sales indices, respectively, for the period 1855–1969.

Commissions are another issue that various studies treat differently and can clearly affect the levels of returns. Ideally, to properly measure financial returns one would like to account for trading costs and thus to increase the purchase price by the level of the buyer's premium but then decrease the sale price by the level of the seller's commission. However, sellers' commissions are negotiable and not easily available. Therefore, one is left with information on buyers' premiums which different authors treat differently. For example, Goetzmann and Spiegel (2003) do not include premiums. However, Mei and Moses (2002) include buyers' premiums in the data they use to compute returns by increasing the recorded price of all items by the amount of the buyer's premium. This is problematic in that before 1979, auction houses did not charge buyers' premiums. After 1979, buyers' premiums were stable at approximately 10 percent from the mid-1970s to 1992, but then started to rise thereafter, mostly for the less expensive works of art. As premiums have increased over time, including buyers' premiums in repeat sales data in this manner may slightly increase returns.

Almost all studies of repeat sales data only use information on actual sales rather than information on all items, including those that were bought in. Goetzmann and Spiegel (2003) assume the "price" for bought-in items is 80 percent of the low estimate. They then use this "price" to compare indices in which all items were used to calculate the index with indices in which only sold items are used. They find that the indices calculated with and without bought-in data were fairly close to each other. However, they found that including bought-in data increased the explanatory power of the repeat sales regressions by about 20 percent. They conclude that bought-in data should be used in estimation of the repeat-sales indices.

Finally, survivorship bias or sample selection issues are a caveat that should be acknowledged after calculation of an index. As noted by Goetzmann (1996), "the use of repeat-sale data implicitly conditions upon artworks being in demand, and thus un-

Table 1  
Estimated returns to art from various studies

Author	Sample	Period	Method	Nominal return	Real return
Anderson (1974)	Paintings in General	1780–1960	hedonic	3.3%	2.6%*
	Paintings in General	1780–1970	repeat sales	3.7%	3.0%*
Stein (1977)	Paintings in General	1946–1968	assumes random sampling	10.5%	
Baumol (1986)	Paintings in General	1652–1961	repeat sales		0.6%
Frey and Pommerehne (1989)	Paintings in General	1635–1949	repeat sales		1.4%
		1950–1987	repeat sales		1.7%

\*As many of the surveys only report nominal returns, the authors calculated the real return rates as follows. For the Anderson and Baumol studies, an inflation rate of 0.7 percent a year was used. This number is based on Baumol's estimate of inflation during the 300 year period of his study using the Phelps-Brown and Hopkins price index. Goetzmann's estimate of inflation during the period of his study (also based on Phelps-Brown and Hopkins) is 1.2%. French price inflation between 1962 and 1992 according to OECD statistics was 7%.

\*\*Assumes random sampling within a portfolio of fixed furniture types.

derstates the risk of obsolescence” (p. 71). Goetzmann (1996) attempts to estimate the degree of this bias. He creates eight hypothetical portfolios of paintings, one for each decade, from 1907 through 1977. He then appraises the pieces as of 1987 using sales data for comparable art works. He then assigns a small residual value to artworks by those painters who did not show up at least once between 1977–1987. He deems these painters to be obsolete. Using this methodology, he finds his estimates to be 8.3 percent below his estimates of the real annualized rate of return for a similar period when the survivorship bias is not taken into account.

However, it is not clear that sample selection bias only serves to decrease returns to art. Many dealers insist that the very best paintings are purchased by museums, and therefore also never show up at auction in repeat sales data. We do not know of any work that has attempted to estimate this possible downward bias. Both survivorship bias and “museum” bias can also apply to hedonic price indices.

The research reviewed above has focused on the accurate construction of indices that measure aggregate price movements of unique objects. As discussed below, these indices are crucial for answering the question of whether art is a good investment.

### 2.1.1. Art as an investment

A primary concern of many of these papers is whether art outperforms or underperforms stocks and bonds and the correlation of art investment returns with other investment portfolios. Once a rate of return on art assets is calculated, it is possible to use this return to decide whether it may be sensible to include art investments in a diversified portfolio. Generally, art investments are more attractive as investments (using the standard capital asset pricing model – CAPM) the greater is their return relative to the return on a risk free asset and the weaker the correlation (or beta) between art investment returns and the return on other assets. Pesando (1993) has used the standard market model to assess these two characteristics of art investments in the case of modern prints. Pesando estimates the model:

$$R_t^P - r_{f,t} = \alpha + \beta(R_{m,t} - r_{f,t}) + u_t, \quad (4)$$

where  $R_t^P$  denotes the return on the print portfolio,  $R_{m,t}$  denotes the return on the market portfolio (Pesando uses the S&P 500 stock index), and  $r_{f,t}$  denotes the risk free rate (Pesando uses 180-day Treasury Bills). Pesando estimates a  $\beta$  for the entire print portfolio of 0.315 and estimates negative, but insignificant, risk adjusted returns. This implies that print investments tend to reduce the riskiness of a portfolio comprised of stocks only.

Determining whether art outperforms or underperforms a market portfolio is not an easy question to address. First of all, as pointed out above, there are many problems with the calculation of the returns to art, beginning with selection bias in the data. As all of the sales prices are drawn from auction records, with repeat sales regressions only paintings that have been re-auctioned are included. This excludes both the high end and the low end of the return distribution. Paintings that fall drastically in value or are not generally

in demand are usually not resold at auction; in addition, paintings that are donated to or bought by museums do not reappear. Furthermore, whether or not an owner decides to sell a painting at auction may be determined by whether or not the painting has increased in value. Other problems with estimating returns are that transaction costs are excluded and in contrast to stocks and bonds, these can be quite high (as much as 25 percent of the value of the object considering both buyers' premiums and sellers' commissions). Finally, there is significant theft and fire risk (and hence insurance costs) and cleaning costs involved in investing in art.

On the other hand, unlike stocks and bonds, art also pays some dividends in the form of pleasure the viewer (and owner) receives. In principle, the value of these dividends could be measured by the rental cost of similar art assets, but we are unaware of any study that has attempted to do this. Moreover, it seems unlikely that these returns would be significant for a large, diversified art portfolio that is not displayed.

Baumol (1986) and Goetzmann (1993) tend to concur that art is dominated as an investment vehicle. Goetzmann (1993, p. 1370) writes "While returns to art investment have exceeded inflation for long periods, and returns in the second half of the 20th century have rivaled the stock market, they are no higher than would be justified by the extraordinary risks they represent". Goetzmann does not formally estimate a CAPM, but simply reports correlations of art returns with inflation, the Bank of England Rate, consol bond returns, and the London Stock Exchange.

Although their estimates of the return to art are not significantly different from previous estimates, Mei and Moses (2002) take a different view. They argue that "a diversified portfolio of artworks may play a somewhat more important role in portfolio diversification than discovered in earlier research". They base their conclusions on the finding that their art price index has lower volatility and a much lower correlation with other asset classes than reported in previous research. They report that these differences are partly due to sample selection and partly due to a different time frame studied. Although Mei and Moses (2002) estimate a more sophisticated form of CAPM than has previously been estimated for art, they primarily base their conclusions on their estimates of the art index and simple correlations with bond and stock portfolios.<sup>5</sup>

Some authors have looked at the financial returns to holding other collectible items. For example, Ross and Zondervan (1989) estimate the real returns to holding Stradivari Violins between 1803 and 1987 to be 2.2 percent, and Graeser (1993) estimates

<sup>5</sup> For the CAPM, Mei and Moses follow Campbell (1987) and estimator

$$r_{i,t+1} = E_t[r_{i,t+1}] + \sum_{k=1}^K \beta_{ik} f_{k,t+1} + \varepsilon_{i,t+1},$$

where  $r_{i,t+1}$  is the excess return on asset  $i$  held from time  $t$  to time  $t + 1$ .  $E_t[r_{i,t+1}]$  is the conditional expected return on asset, conditional on information known to market participants at the end of time period  $t$ . It is allowed to vary over time [see Mei and Moses (2002) for details].  $f_{k,t+1}$  are excess returns on  $k$  different asset classes.

returns to holding antique furniture between 1967 and 1986 to be 7 percent. For a very good survey of papers calculating the rate of returns in various markets, see Frey and Eichenberger (1995).

It is clear that some collectors have benefited enormously from holding art. As documented in Landes (2000), Victor and Sally Ganz are a nice example. The Ganz's operated a family costume-jewelry business, but collected art on the side. Through clever purchases, they managed to build a collection worth over \$250 million over a fifty year period. For example, one of their successes was a Picasso that they acquired in 1941 for \$7000 which they subsequently sold at auction for \$48.4 million. Overall, Landes estimates that they achieved between about a 12 percent and 21 percent per year annual real return, depending upon the auction in which they sold their collection. Landes argues that their high return occurred because of their skill in investing, not because of pure luck. His claim is that the return is not based on a few big winners, but they made consistently good purchases. This argument is still open to debate as their high returns may statistically have resulted from them being on the upper tail of a random distribution in returns to art. Nonetheless, as in stock-picking, it may be possible that some individuals have skills that allow them to consistently outperform the market.

McAndrew and Thompson (2004b) study the loan quality of fine art. As with other investments, they find that the value of fine art in case of bankruptcy is quantifiable, and thus art can be used as quantifiable collateral on loans.

What can we conclude from these studies on the returns to art? On the positive side, the studies reviewed in Table 1 mostly report positive returns and many of the studies show that the returns to art may outperform bonds. Furthermore, the correlation to other investment portfolios may be low. On the negative side, returns to art generally appear to be less than the real rate of return on common stock. In addition, as is clear from Figure 1, investing in art over a short period of time can be risky.

From current research, it is difficult to conclude whether art should be included in a diversified portfolio. It appears that different views about the financial benefits of investments in art assets are primarily based on empirical issues that revolve, in part, around the temporal instability and sensitivity of the estimates of key parameters related to the market performance of art investments. This suggests that an important area for additional research is the development of a more general empirical model that will provide an explanation for temporal instability and thus lead to better-informed decisions.

### 2.1.2. *The masterpiece effect*

Pesando (1993) describes the “Masterpiece Effect” by quoting art dealer Edward Merin: “...it’s always better to buy one \$10,000 object than ten \$1000 objects, or one \$100,000 object – if that is what you can afford – than ten \$10,000 ones”.<sup>6</sup> There have now been several authors who have tested for the masterpiece effect. Pesando tests for

<sup>6</sup> Quote originally taken from “Antiques”, *Art and Auction*, September 1988, p. 131.

the effect by constructing a portfolio of the top 10 or 20 percent of prints by price, where price is determined during the first few years of his sample. If the “art trade” view is correct, the estimated price indices for these “Masterpieces” should uniformly outperform the general portfolio. He finds no support for this view and in fact finds that in part of his sample, masterpieces provide the lowest cumulative return. [Mei and Moses \(2002\)](#) measure a similar negative effect for masterpieces, and in fact estimate this effect to be uniform across American, Impressionist and Old Master samples. Other authors have found no masterpiece effect [[Goetzmann \(1996\)](#); [Ginsburgh and Jeanfils \(1995\)](#)].

As pointed out by [Pesando \(1993\)](#), there should not be a positive masterpiece effect. An efficient art market should capitalize favorable properties into their prices, and their risk-adjusted rates of returns should not exceed that obtained on other art objects in the same class. However, the art market and its participants may not always be efficient. [Pommerehne and Feld \(1997\)](#) conclude that museums outside the US pay above average prices in auction markets. If museums generally purchase masterpieces and do not resell them, this could contribute to a positive masterpiece effect.

Various plausible reasons exist as to why there should be a negative masterpiece effect. [Mei and Moses \(2002\)](#) speculate that it may be due to overbidding and then mean reversion. This explanation appears quite reasonable given the way that various studies above have defined “Masterpieces” as the highest price paintings that were sold. If a “Masterpiece” is defined purely by price, there may be some paintings in the “Masterpiece” sample that randomly commanded a higher price, perhaps because two or more bidders had high private valuations for the paintings. At a later auction, the prices on these paintings revert to the mean, thus resulting in a negative “Masterpiece” effect.

A different explanation for the negative “Masterpiece Effect” may be what [Goetzmann \(1996\)](#) terms “survivorship bias”. It is likely that the more expensive paintings remained in the sample throughout, even if they decreased in value, whereas less expensive paintings have dropped out of the sample. Hence it may appear that “Masterpieces” have underperformed in the sampled data, but in actuality less expensive paintings that have underperformed are no longer in the sample. A summary of papers estimating a “Masterpiece Effect” is presented in [Table 2](#).

A very nice addition to the literature on Masterpieces would be a classification of Masterpieces based on something other than price. For example, [Galenson](#), in a number of studies, uses a tabulation of illustrations in published surveys of art history [see, for example, [Galenson \(2002, 2004\)](#)]. He uses these tabulations for two primary purposes. First, to determine in which point of an artist’s career his most important work was created (see below), and secondly, to simply rank different artists. Using these tabulations, he ranks painters and paintings and compares rankings using tabulations from different textbooks. A very interesting use of these rankings would be to determine whether or not a “Masterpiece Effect” exists for the highest ranked artists.

[Schoenfeld \(2004\)](#) uses the *Konstkompass* rankings to determine whether or not certain artists can be classified as “Masters”. The *Konstkompass* is a publication that ranks artists based on where and how often an artist’s work is shown and written about. For example, an artist would receive 650 *Konstkompass* points for an exhibition in the Tate

Table 2  
The “Masterpiece Effect”

Author	Sample	Period	Result
Pesando (1993)	Modern Prints	1980–1992	Return of 11% less for “masterpieces”
Ginsburgh and Jeanfils (1995)	Impressionist, Modern and Contemporary European Masters, Other minor European painters, Contemporary US painters	1962–1991	No effect
Goetzmann (1996)	Paintings in General	1897–1987	No effect
De la Barre, Docclo and Ginsburgh (1996)	Impressionist	1962–1991	Great impressionists return 4% more than other impressionists
Mei and Moses (2002)	American, Impressionist, and Old Masters	1875–2000	A 10% increase in price reduces returns by 1%
Schoenfeld (2004)	Contemporary Art	1982–1985	No effect

Modern, London, or 800 points at the Guggenheim Museum, New York. Schoenfeld defines a “Master” by using the top twenty artists as ranked in 1983 and then follows the prices they receive at auction. She also defines “Master” by price by following the top twenty artists when ranked by gallery price. She does not find a Masterpiece effect in her study, whether using rankings or gallery prices.

We have summarized the findings of papers estimating a masterpiece effect in Table 2. Out of the six studies reported, only one study, [de la Barre, Docclo and Ginsburgh \(1996\)](#), finds a positive masterpiece effect. Interestingly, they have constructed their subsamples by choosing masterpieces by reputation of painter, rather than by price. More studies where price is not the primary determinant of a masterpiece are clearly needed in order to separate out any masterpiece effects from mean reversion in price.

## 2.2. *The life cycle of an artist*

Galenson and Weinberg have used art auction prices to determine at what point during his career an artist produces his most important work. For example, [Galenson \(2000\)](#) shows that in a sample of 42 of the most important Contemporary artists (broadly defined by auction houses as those who have become known since World War II), more than 90 percent of the artists born before 1920 did their most important work after the age of 40, whereas more than three-quarters of those born after 1920 did their most

valuable work before the age of 40. Galenson reconciles this fact by saying that the nature of modern art changed during the 20th century.

In Galenson and Weinberg (2000), the authors find that within two successive cohorts of American modern painters, the second cohort produced their most valuable works at a younger age than the first cohort, and in Galenson and Weinberg (2001), the authors document that painters born at the very end of the 19th century tend to produce their most valuable paintings at a younger age than other 19th century painters. Using this information, Galenson has gone on to develop a controversial hypothesis as to why some artists have produced their best works early in their career, and others have produced their best work later in their careers.<sup>7</sup>

Galenson and Weinberg's evidence is interesting. In this research auction prices have been used to discover the empirical regularities in which different artists produce their more important works at different ages. This empirical regularity has thus spawned a debate as to why this is so.

While in many of his papers Galenson uses prices to test for age and importance of work, as discussed above, in several of his papers he uses number of illustrations in art history texts. There are possible advantages to using measures other than price. For example, in Galenson (2002) he constructs a variable (a Gini ratio) that measures how unequally a given artist's paintings are illustrated. He then uses this measure to determine the extent to which an artist has one or two great works, or a large number of important paintings.

As in some of his work Galenson uses critical evaluation and in other works he uses auction prices, a natural question to ask is how well do results using auction prices match up with critical evaluation. In Galenson (2000, 2004) he demonstrates that critics' judgment of when in an artist's career his most important works were executed coincides very closely with market valuation.

### 2.3. *The law of one price*

The "law of one price" dictates that in the absence of different transactions costs, no systematic price differences should exist between distinct markets. Several authors have tested for price differences in different auction houses and in different geographical locations and have found that the law of one price does not hold.

Pesando (1993) focused on the sale of identical prints in different markets which occur within 30 days of each other for the period 1977–1992. For the entire period, he found that prices were 7 percent higher in New York than in London, and 10 percent higher in New York than in Europe. However, these differences were not statistically significant for the period 1977–1989. For the remaining period of the sample, 1989–1992, he found that prices were 11 percent higher in New York than in London and 17 percent higher in New York than in Europe. Pesando (1993) describes the trade explanation as being the presence of Japanese buyers in the New York market during that

<sup>7</sup> See Galenson (2004) for a review.

period, though one would expect any systematic price differences to disappear when buyers respond to incentives. Pesando also measures significant differences among auction houses. For the entire period, Pesando found that prices average 14 percent higher at Sotheby's New York than at Christie's New York, but there was no difference in the prices of prints at Sotheby's and Christie's in London.

Mei and Moses (2002) find mixed evidence on the law of one price. When they do find price differences, these differences tend to be small.

Pesando and Shum (1996) look specifically at the law of one price using prints only by Picasso. As this is a narrow and homogeneous segment of the market, this can provide a good test. They further restrict their sample to the 100 prints that comprise Picasso's Volland Suite, and test for price differences on this sample. They compare the prices of identical prints that were sold in two different international markets or auction houses within 30 days of each other. Using the entire sample of Picasso prints, they find no significant difference between New York and London, but they find that prices are significantly higher in Europe (excluding London) than in the US. Furthermore, they find higher prices at Sotheby's than at Christie's in New York, and at Kornfeld's than at the rest of the world. Using only the Volland suite, the price differences between New York and Europe disappear, as do the price differences between Kornfeld's and the rest of the world (though the Kornfeld price difference is again significant if the window is increased to 90 days). For the Volland suite only, prices remain significantly higher at Sotheby's than at Christie's New York.

De la Barre, Docclo and Ginsburgh (1996) compare prices of Great Masters at Drouot in Paris with Christie's and Sotheby's prices in New York and London. They use the coefficient on the auction house in a hedonic regression to test for price differences. They find that prices fetched in Paris are significantly lower than prices fetched for similar items in New York or London. They give two reasons for the differences. First, they argue that it may simply be unobserved quality differences that are driving the price differences, as Christie's and Sotheby's, being more well-known, may attract better paintings. Secondly, they point out that the French government has the right to prevent "important" works from leaving France, if they are sold by collectors living in France. This may discourage foreign collectors from purchasing and thus have a downward effect on price.

Ashenfelter (1989) studied differences in prices for wine between auction houses that were attributed to changes in buyers' premiums. In the spring of 1986, buyers' premiums were 10 percent at Sotheby's London (and at other locations), but Christie's in London had no buyer's premium. In the spring of 1986, prices at Sotheby's in London were 12 percent less than prices at Christie's in London, perhaps reflecting the difference in buyers' premiums. In the fall of 1986, Christie's had instituted a 10 percent buyer's premium in the London auctions. In auctions held in the fall of 1986, there was no difference in prices, while in an auction held in the spring of 1987, prices at Sotheby's in London were 5 percent higher than at Christie's, and in the fall of 1987, prices at Sotheby's in London were 4 percent lower than at Christie's. These price movements may provide empirical support for the observation that the incidence of the buyer's

Table 3  
The law of one price

Author	Sample	Period	Result
Ashenfelter (1989)	Wine	1986	Differences in prices reflect differences in commission rates
Pesando (1993)	Modern Prints	1977–1992	Prices average 14% higher at Sotheby's NY than at Christie's NY; prices were 7% higher in New York than in London; prices were 10% higher in New York than in Europe
Pesando and Shum (1996)	Picasso Prints	1977–1993	Prices average 7% higher at Sotheby's NY than at Christie's NY; no significant differences in price between NY and London; prices were 2% higher in New York than in London
De la Barre, Docclo and Ginsburgh (1996)	Old Masters	1962–1991	Prices were significantly lower at Drouot's in Paris than at Sotheby's or Christie's in New York or London
Mei and Moses (2002)	American, Impressionist, and Old Masters	1875–2000	Mixed evidence on differences between Sotheby's and Christie's; differences when they do exist are small

premium should fall on the sellers. As described below, significant changes to sellers' commissions and buyers' premiums occurred during the 1990s. These changes may provide an interesting subject for study by economists.

A summary of papers testing for the law of one price is presented in [Table 3](#).

### 3. The auction mechanism and the price of art

We begin our discussion in Section 3.1 with a review of the Sotheby's–Christie's price fixing case. This case shows just how important it is to understand the influence of the auction mechanism on price, and how this influence can easily be misunderstood.

In the remainder of Section 3, we discuss various aspects of auctions and the influence of each of these aspects on the price achieved. We begin by discussing whether auctioneer's pre-sale estimates are biased, and whether or not they take account of all information available. Most work suggests that these estimates are unbiased, but other work suggests that there may be systematic under and over predictions. We also discuss implications of the width of the spread between the low estimate and the high estimate. In the following three sections we examine the role of reserve prices in art auctions. We

begin by reviewing work that tests whether paintings that fail at auction are “burned” (lose value), as is claimed by many individuals in the art trade. We then move on to discuss sale rates across different types of auctions and why they may differ, and we end our examination of reserve prices by discussing why they are secret. In the last section we review the large body of work on declining prices.<sup>8</sup>

### *3.1. Competition (or collusion) between auction houses*

Prior to 1995, Sotheby’s and Christie’s were in fierce competition for consignments. At times, they would drastically cut commission rates paid by sellers, in many cases to nothing, make donations to their favorite charities, and even extend financial guarantees. In March of 1995, this competition abruptly ended. Christie’s announced that it would charge sellers a fixed nonnegotiable sliding-scale commission on the sales price, and a month later Sotheby’s announced the same policies. Detailed documents kept by Christopher Davidge, Christie’s former chief executive, show that the abrupt change was due to a price-fixing conspiracy. By admission, the conspiracy involved at least Christopher Davidge and Diana Brooks, Sotheby’s chief executive, and it was alleged to have involved Sir Anthony Tennant and A. Alfred Taubman, the chairmen of Christie’s and Sotheby’s, respectively. In fact, after a lengthy criminal trial, Taubman, a US citizen, was convicted of price fixing, which is a felony in the US. Although Tennant, a UK citizen, was also indicted in the US, price fixing is a civil offence in the United Kingdom and thus he was not extradited or tried. Christopher Davidge (and in some cases Sir Anthony Tennant) had kept detailed records describing the conspiracy. A civil suit, which has been settled, also alleged that Christie’s and Sotheby’s conspired since 1993 to fix buyers’ premiums. Because it ended in a public trial, this lawsuit provides an extraordinary window for viewing the operation of successful price conspirators.

The case progressed as follows [see especially [Stewart \(2001\)](#) for a detailed description]. The Justice Department agreed in January of 2000 not to prosecute Christie’s in return for its cooperation in the case. Diana Brooks, former president and chief executive of Sotheby’s, pleaded guilty to one felony count of price-fixing on October 5, 2000, and promised to cooperate fully in the government’s investigation. In September of 2001, Sotheby’s pleaded guilty to conspiring with Christie’s to fix sellers’ commissions, and agreed to pay a fine of forty-five million dollars over five years. Sotheby’s maintains their innocence with respect to fixing buyers’ premiums. Also in September of 2001, a civil suit was settled where Sotheby’s and Christie’s consented to a payment of two hundred and fifty-six million dollars each to the plaintiffs. This class-action suit comprises anyone who had bought or sold items through the auction houses since 1993.

<sup>8</sup> Our discussion is primarily motivated by empirical regularities (or irregularities!) that researchers have uncovered in their study of art auction prices. For an excellent review of auction theory and the effect of the auction mechanism on prices for telecommunication licenses, please see [Klemperer \(2004\)](#).

From an economist's point of view, the settlement of the civil suit is interesting, but appears to be misguided. Although Sotheby's did not admit to fixing buyers' premiums in the criminal settlement of the case, both Christie's and Sotheby's agreed to each pay \$256 M to both buyers and sellers. This amount was calculated taking the price-fixing of buyers' premiums into account. According to *In Re Auction Houses Antitrust Litigation* (2001), "The proposed plan of allocation estimated the overcharges to sellers as 1 percent of the hammer price, and those for buyers to be 5 percent of the hammer price up to and including hammer prices of \$50,000, and \$2500 for buyers at hammer prices exceeding \$50,000. The net settlement fund would be distributed to class members pro rata based upon each class member's overcharges during the relevant period."

Even if Sotheby's and Christie's admitted to colluding on buyers' premiums, the usual theory of private value auctions implies that, to first order, buyers deserve no compensation! The following is the reason why. When a buyer decides to bid in an ascending price auction, his strategy should be to bid up to his reservation price, if necessary. The price that the winning bidder has to pay is essentially (epsilon above) the reservation price of the second highest bidder. When buyers' commissions are raised, each buyer should reduce his reservation price by an equivalent amount, resulting in a reduction in revenue to the seller by the amount of the buyer's commission. Hence, the entire increase in buyers' commissions should fall on the seller. Thus, the standard model of private value auctions implies that the entire settlement arrangement in the civil suit was misguided!

There are several caveats to this argument. If sellers' supplies are elastic, some sellers may not offer their objects for sell due to the increased commissions. This could result in more buyers competing for the same item, and the increase in the number of bidders for each item may push up the price paid by the winning bidder. Furthermore, in art auctions, the private value assumption doesn't strictly apply. If some bidders are factoring into their value estimate the likely future market value of the piece of art, bidders' values are correlated. Bidders may increase their reservation prices if they believe market values will increase in the future. However, it is unlikely that either of these effects justify buyers receiving 2/3 of the 512 million. In addition, it can be argued that the real losers in this case were the buyers and sellers who did not manage to transact because of the price-fixing. Welfare was clearly reduced, as these transactions were lost.

Ashenfelter et al. (2003) provide a more detailed explanation of the incidence of the settlement and Ginsburgh, Legros and Sahuguet (2004) provide a general theoretical exploration of the incidence of commissions in auction markets with reserves. In this paper, they show that under sufficient assumptions, while commissions indeed make sellers worse off, some buyers may actually gain. Their intuition is that buyers who actually purchase can be better off since the impact of commissions is compensated by less participation and a lower degree of competition.

The criminal trial of Alfred Taubman, previously Chairman of Sotheby's Board, in the fall of 2001 provided some dramatic revelations about the details surrounding the price fixing. Many of these details were provided in the testimony of Diana Brooks, previously President of Sotheby's. First, although remarkably candid about her role in

the fixing of sellers' commissions, Ms. Brooks did not provide any evidence of collusion with respect to buyers' premiums. Second, Ms. Brooks estimated that the collusion on sellers' commissions resulted in higher profits to Sotheby's of some \$10 to \$15 million per year. Assuming that Christie's received the same increased profits implies that a total per year increase in profits would be on the order of \$20 to \$30. Assuming the conspiracy lasted 5 years (approximately the time period involved) suggests a total increase of \$100 to \$150 million. While profits may not be equivalent to the damages suffered by a group for a variety of reasons, it appears that the plaintiffs were more than amply compensated for the harm they incurred, especially in view of the fact that they did not have to proceed to the uncertainty of a trial.<sup>9</sup>

Finally, the details of the arrangement for price fixing revealed by Ms. Brooks suggest that great care was ensured to keep virtually all other employees of the auction houses from learning of the conspiracy. Taubman met solely with Tennant, and Brooks solely with Davidge in arranging the details of the conspiracy. For a full discussion of the price-fixing conspiracy including other economic and legal implications, please see [Ashenfelter and Graddy \(2005\)](#).

### 3.2. Role of estimates and experts

Before an auction takes place, in their pre-auction catalogues, auction house experts provide a low and a high price estimate for each item. Determining the accuracy of these estimates raises some important questions for the study of the role of expert opinion in economic decisions.<sup>10</sup> Of especial interest is the motivation of the auctioneer in choosing the high and low estimates. The theoretical literature stresses that auctioneers should provide truthful information about the items being sold.

[Ashenfelter's \(1989\)](#) results generally show that auction houses are truthful; the average of the auctioneer's high and low estimate is very highly correlated with the price actually received. Furthermore, [Abowd and Ashenfelter \(1988\)](#) find that auctioneer's price estimates are far better predictors of prices fetched than hedonic price functions.

The details of the arrangements for price fixing revealed by Diana Brooks during the Christie's–Sotheby's price-fixing trial provide further insight into the role of experts at auction houses. Brooks reported that at one point her boss, Alfred Taubman, proposed that the auction houses collude in providing clients with similar estimates of the value of their art. Brooks reported that this was impossible because she could not simply tell Christie's departmental experts, who produce the estimates, to do a dishonest job.

While the regressions in [Beggs and Graddy \(1997\)](#) generally uphold these results, they do find systematic under and over predictions. For example, they find that for Contemporary Art, more recently executed artworks are overvalued and longer and wider

<sup>9</sup> Price fixing damages are, by statute, tripled.

<sup>10</sup> [Ashenfelter \(2000\)](#) defines expert opinion as efficient if it incorporates all of the publicly available information that is useful in making predictions. He also provides one example of inefficient expert opinion.

paintings are undervalued. For Impressionist and Modern Art, they find that wider, signed, and monogrammed paintings may be underestimated relative to their value. One explanation for these findings may simply be that auction houses are unwittingly overestimating consumer demand (and hence willingness to pay) for recent Contemporary Art, and underestimating consumer demand for size! Many people in the trade express surprise at the strong correlations that many economists have found between size and price.<sup>11</sup>

Other authors have also found that ex-ante valuations cannot be considered unbiased predictors of market prices, although it is our impression that biases are not quantitatively large when they are precisely estimated. [Bauwens and Ginsburgh \(2000\)](#) study 1600 lots of English silver sold between 1976 and 1991 by Christie's and Sotheby's. They find that Christie's has a tendency to underestimate systematically, while Sotheby's overvalues inexpensive pieces and undervalues expensive ones. [Bauwens and Ginsburgh \(2000\)](#) also show that experts do not take into account all available information. They do this by running a regression of the difference between the actual price and the estimated price on observable characteristics. They strongly reject the hypothesis that the coefficients on the characteristics are jointly equal to zero.

[Chanel, Gérard-Varet and Vincent \(1996\)](#) studied jewelry auctions, and found that experts have an ex-ante valuation that is lower than the hammer price for all types of jewels, except for some watches. They speculate that some strategic undervaluation is occurring. These results are interesting, in part because, as [Milgrom and Weber \(1982a\)](#) show, in general, for auctioneers, "honesty is the best policy".

If price estimates are biased, this raises some interesting questions about the reason for the bias. One possibility is simply that the "experts" make systematic errors because they are not as "efficient" as the linear predictors they are being tested against. Evidence in favor of this hypothesis would be the finding that observed biases are not stable and vary from one sample to another or from one time period to another. Judging from the results reported above, there is certainly some evidence to support this view. [Mei and Moses \(2005\)](#) have recently taken up this issue. They conclude that estimates for expensive paintings are biased upwards. However, [McAndrew and Thompson \(2004a\)](#) find evidence for unbiased estimates.

A related question is, "what motivates the auctioneers when they determine the spread between the high and the low estimates that are published in the pre-sale catalogues?" One explanation of how the spread is determined is by the auctioneer's estimate of the uncertainty or possible variance in the price of the painting. In this case, the high estimate might reasonably be interpreted as the estimate of the mean price plus a multiple of the estimated standard deviation ( $H = \mu + r\sigma$ ). Likewise, under this interpretation, the low estimate would be the mean minus a multiple of the standard deviation ( $L = \mu - r\sigma$ ). With this interpretation the high estimate minus the low estimate divided by 2 is proportional to the estimated standard deviation ( $(H - L)/2 = r\sigma$ ) and

<sup>11</sup> For example, see [Anderson \(1974\)](#) and [Beggs and Graddy \(1997\)](#).

the average of the high estimate and the low estimate would be the estimated mean  $((H + L)/2 = \mu)$ . A large difference in the high estimate and the low estimate would therefore signal a high estimate of price variance or a lot of uncertainty. However, as the seller's secret reserve price, by convention, lies below the low estimate, it is very likely that the spread between the high and low estimate is not simply a reflection of the auctioneer's uncertainty surrounding the possible price. If the seller wishes to set a high reserve price, the auctioneer may increase the low estimate. [Ashenfelter, Graddy and Stevens \(2002\)](#) study the plausibility of these two explanations with regard to sales rates in Contemporary and Impressionist Art Auctions. A summary of papers addressing the role of estimates is presented in [Table 4](#).

A recent work by [Beggs and Graddy \(2004\)](#) suggests that auctioneers may not behave fully rationally when setting the pre-sale estimate, but instead may engage in partial information processing. Building on a methodology developed by [Genesove and Mayer \(2001\)](#) for loss aversion in the housing market, they show that experts may engage in "anchoring".<sup>12</sup> Auctioneers may anchor the pre-sale estimates using the price the painting fetched at auction in its previous appearance. This is somewhat surprising given that it may have been years (and in very different market conditions) since a particular painting appeared at auction. Of particular interest, their estimates show similar effects for paintings in which there are prospective (i.e. estimated) gains and losses and no diminishing effects with the size of the loss or gain.

In summary, there is evidence that pre-sale auction estimates are highly correlated with price outcomes, but there is also evidence that these estimates might well be improved by the use of appropriate statistical methods.

### 3.3. *Is there evidence that paintings are "burned?"*

As [Ashenfelter \(1989\)](#) noted, it is often claimed that when an advertised item goes unsold at auction, its future value will be affected. Such items are said to have been "burned". A perceived loss in value after a failed auction has acted as part of the basis for legal proceedings such as "Cristallina, S.A. vs. Christie, Manson and Woods, International, Inc." Cristallina S.A. was a Panamanian corporation engaged in the sale and purchase of art. In 1981, Cristallina consigned eight impressionist paintings to Christie's. During the auction that took place in May of 1982, seven out of the eight paintings failed to meet their reserve price. The prosecution alleged that Christie's did not use sufficient care in marketing and auctioning the paintings, and this lack of care resulted in a loss of value. The suit was eventually settled out of court.

[Beggs and Graddy \(2006\)](#) test whether failed paintings return less than other paintings by constructing a new dataset of repeat sales. In this dataset, some of the items that were

<sup>12</sup> [Kahneman and Tversky \(1979\)](#) proposed a theory of decision making under uncertainty. One of the components of "prospect theory" is that individuals exhibit riskier behavior when holding losses than when holding gains.

Table 4  
Role of estimates

Author	Sample	Period	Result
Milgrom and Weber (1982a)			Honesty is the best policy
Abowd and Ashenfelter (1988)	Impressionist Art	1980–1982	Auctioneer's price estimates are far better predictors of prices than hedonic models
Ashenfelter (1989)	Impressionist Art	1980–1982	Auction houses are truthful
Chanel, Gérard-Varet and Vincent (1996)	Jewelry	1993–1994	Pre-sale estimates undervalue most types of jewelry, with the exception of some watches
Beggs and Graddy (1997)	Impressionist Art Contemporary Art	1980–1991 1980–1994	Systematic over and under valuations (recently executed works of art tend to be overvalued, longer and wider paintings are undervalued)
Bauwens and Ginsburgh (2000)	English Silver	1976–1990	English silver: Christie's systematically underestimates Sotheby's overvalues inexpensive pieces and undervalues expensive pieces
Ashenfelter, Graddy and Stevens (2002)	Impressionist Art Contemporary Art	1980–1991 1982–1994	Examines whether spread between high and low estimate is indication of auctioneer's uncertainty or reflects seller's wish to set a high reserve price
Mei and Moses (2002)	American, Impressionist and Old Masters	1973–2002	Higher priced paintings are systematically overvalued
Beggs and Graddy (2004)	Impressionist Art Contemporary Art	1980–1994	Anchoring plays a significant role in estimate formation

sold twice appeared at auction between repeat sales and failed to sell, whereas others did not appear at auction (and thus could not fail) between the two repeat sales. They then estimate a variation of Equation (3) above,

$$r_i = \ln\left(\frac{P_{i,s}}{P_{i,b}}\right) = \sum_{t=b_i+1}^{s_i} \mu_t + \beta \text{fail} + \sum_{t=b_i+1}^{s_i} v_t. \quad (5)$$

$r_i$  is the return for painting  $i$  between the date of purchase ( $b$ ) and the date of sale ( $s$ ).  $\mu_t$  is the average return for all paintings in period  $t$ , fail is a dummy variable equal to 1 if a paintings fails and 0 if not, and  $v_t$  is an error term.

The return is thus conditioned on whether or not a painting appeared at auction and failed. Their regressions indicate items that fail to sell at auction end up returning about 30 percent less than other paintings.

A natural question to ask is what actually drives the burning effect. Or more specifically, is the burning effect causal, in that a painting failing to sell causes the price to fall, or is failing simply correlated with a fall in price? [Beggs and Graddy \(2006\)](#) show within a general auctions model of affiliated values that there can be a variety of reasons why “burning” occurs including trend effects, reserve price effects and of course common values. Trend effects occur when a lower price is observed after the painting fails at auction simply because that failure is correlated with a downward trend in common tastes for a specific painting. Reserve price effects could occur if a seller lowers the reserve price after a failure because, for example, of an urgent need to sell. Common value effects occur if failing causes a drop in price, because bidders take into account other bidder’s valuations of the painting.

[Beggs and Graddy \(2006\)](#) also find that failing has a significantly negative effect on the pre-sale estimates, indicating that auctioneers anticipate the effect of failing on price. This is not surprising, given the widespread belief that failed items are “burned”.

### 3.4. Sales rates and reserve prices

As we noted above, items that are put up for sale at auction often go unsold because the bidding in the auction does not meet the reserve price. Sale rates vary tremendously over time and they also vary systematically across different types of auctions. [Table 5](#) shows sale rates in different departments at Christie’s in London in 1995 and 1996 along with average value of a lot sold. As can be seen from the table, 96 percent of items put up for sale in auctions of arms and armor were sold, 89 percent of wine at auction was sold, and 71 percent of impressionist and modern art items were sold.

[Ashenfelter, Graddy and Stevens \(2002\)](#) provide a study of sale rates through time and across different types of auctions. Based on the observation that an item is bought-in if and only if it does not meet or exceed its reserve price, they develop a model of optimal reserve prices. The seller of a painting faces the following problem: if he participates in an auction the highest bid for the painting can be regarded as a random draw from some price distribution. When a seller sets a reserve price, he must decide at what price he would be indifferent between selling now and waiting for the next auction. The optimal policy is to set a reserve price that is a constant proportion of the current expected price. Sale rates can then be modeled as being explained by price shocks and a constant, or “natural sale rate”. This natural sale rate (which may vary across different types of auctions) depends only on the variance of log prices and the seller’s discount rate. They estimate that the reserve price is generally set to be about 70 to 80 percent of the auctioneer’s low estimate. Although reserve prices are generally secret, the available evidence suggests that this prediction is reasonably accurate.

Table 5  
Average sale rates by department

Department	Average sold lot value		No. of auctions in sample	Sale rate (% of lots sold)		% Sold by value	
	1996	1995		Mean	Std. dev.	Mean	Std. dev.
Impressionist	£122,820	£135,430	8	71%	(0.11)	80%	(0.10)
Old Masters Drawings	£50,670	£29,210	4	77%	(0.09)	89%	(0.08)
Contemporary	£36,820	£36,840	7	79%	(0.04)	87%	(0.06)
British Pictures	£29,710	£23,560	7	78%	(0.14)	83%	(0.17)
Old Master Pictures	£29,180	£6560	11	73%	(0.15)	82%	(0.15)
Continental Pictures	£21,810	£10,450	7	72%	(0.11)	79%	(0.10)
Clocks	£14,340	£5130	4	88%	(0.03)	89%	(0.07)
Jewellery	£12,190	£6750	8	86%	(0.05)	89%	(0.04)
Furniture	£11,670	£8220	25	85%	(0.09)	92%	(0.06)
Silver	£11,080	£5910	10	87%	(0.11)	92%	(0.07)
Sculpture	£11,070	£6340	5	78%	(0.21)	81%	(0.20)
Modern British Pictures	£10,340	£7190	9	70%	(0.05)	81%	(0.05)
Victorian Pictures	£9460	£8400	6	66%	(0.13)	75%	(0.11)
British Drawings & Watercolours	£9160	£3400	14	72%	(0.14)	87%	(0.10)
Rugs & Carpets	£9160	£3700	8	80%	(0.17)	85%	(0.14)
Topographical Pictures	£8640	£8010	2	68%	(0.13)	81%	(0.00)
Islamic	£6670	£6950	5	68%	(0.22)	82%	(0.12)
Cars	£5750	£7610	6	71%	(0.16)	65%	(0.22)
Chinese Works of Art	£5640	£6400	8	70%	(0.19)	79%	(0.16)
Books & Manuscripts	£5220	£4270	15	81%	(0.12)	86%	(0.09)
Russian Works of Art	£4490	£5480	4	64%	(0.14)	69%	(0.15)
Japanese	£4410	£2840	5	72%	(0.04)	76%	(0.05)
Musical Instruments	£3960	£4110	5	77%	(0.05)	76%	(0.16)
Watches	£3870	£2190	6	71%	(0.09)	81%	(0.11)
Prints-Old Modern and Contemporary	£3850	£4230	8	81%	(0.12)	92%	(0.09)
Miniatures	£3350	£3260	2	82%	(0.05)	92%	(0.07)
Antiquities	£3260	£3640	3	57%	(0.08)	66%	(0.13)
Porcelain and Glass	£2700	£2600	14	76%	(0.12)	85%	(0.10)
Tribal Art	£2650	£2090	3	67%	(0.08)	75%	(0.19)
Photographica	£2580	£1660	3	61%	(0.27)	79%	(0.08)
Modern Guns	£2510	£3620	5	93%	(0.06)	94%	(0.04)
Garden Statuary	£2120	£1540	4	91%	(0.10)	91%	(0.11)
Arms & Armour	£1890	£2400	4	96%	(0.03)	99%	(0.01)
Frames	£1800	£2260	4	81%	(0.15)	85%	(0.14)
Stamps	£830	£650	22	78%	(0.13)	82%	(0.12)
Wine	£690	£580	37	89%	(0.09)	91%	(0.08)

Genesove (1995) tests a related theory in the context of wholesale automobile auctions. He finds that on average sale rates in used auto auctions are actually quite low; between about 58 percent and 68 percent of automobiles go unsold. In his paper, he

finds that an increase in the variance of price is associated with a lower probability of sale, and hence the “natural sale rate” is again dependent on the variance of prices.

A related question is whether the reserve prices that are set in art auctions are optimal. This question has not been looked at in the context of art auctions, but McAfee, Quan and Vincent (2000) derive a lower bound on the optimal reserve price for a general auction model with affiliated signals, common components to valuations, and endogenous entry (all characteristics which can be applied to art auctions or other auctions of cultural objects). They apply their computations to FDIC real estate auctions and find that the lower bound on the optimal reserve price for real estate to be about 75 percent of the appraised value.

Overall, there has been little research into why sales rates differ between items and whether reserve prices are optimal. Given the persistent differences in sale rates between items (which suggests differing reserve prices), more research in these areas would be useful.

### 3.5. *Why secret reserve prices?*

In almost all auctions of cultural items, not only are there reserve prices, but these reserve prices are secret. Auctioneers generally do not reveal the reserve price and they make it as difficult as they can for bidders to infer it. A reserve price clearly contains information about the seller’s valuation of an item; intuitively, revealing information matters if the items contain a common value component among buyers.

While people buy art for enjoyment, there is an investment component to many buyers’ motives; that investment component leads one to classify art as having common-value components. Thus, the fact that auctioneers tend to keep reserve prices secret has remained a puzzle since the publication of Milgrom and Weber’s (1982a) paper, where it was shown that it is optimal for a seller of a good at a common-value auction to reveal their valuation.

One reason that has been suggested for secret reserve prices is that these may be used to deter collusion. As Ashenfelter (1989) suggests, when the turnout is low, some sellers may prefer that their goods be bought in and offered for sale at a later date rather than risk a collusive ring bidding to depress the item’s price. If there is a ring operating, a secret reserve price might encourage bidders to bid higher than they would have otherwise.

Vincent (1995) has cleverly built upon (and overturned) the intuition from Milgrom and Weber’s (1982a) original result. His explanation is based upon the inhibiting effect that the announcement of a reserve price may have on the participation of bidders in a given auction. This announcement could discourage some bidders from participating. As revelation of information is very important for increasing revenues in a common value auction, the fact that these bidders are not participating prevents their information from playing a part in the auction and may lower overall bids. Hence, there is a trade-off between the reserve price revealing the seller’s information, and a reserve price discouraging participating which lowers total aggregation of information.

Table 6  
Secret reserve prices

Author	Result
Milgrom and Weber (1982a, 1982b)	Optimal for a seller of a good at a common-value auction to reveal valuation
Ashenfelter (1989)	Secret reserve prices deter collusion
Vincent (1995)	Announced reserve prices deter participants This deterrence could lower overall bids in a common-value auction
Horstmann and LaCasse (1997)	A secret reserve price could delay sale, allowing truthful information to be revealed over time

Horstmann and LaCasse (1997) provide yet another reason for secret reserve prices. If the seller in a common-value auction possesses information that cannot be directly transmitted to the buyers, then a seller can either attempt to signal his information via a reserve price announcement, or choose a secret reserve price. A secret reserve price could result in delay in sale. If the true information about an item is revealed over time, the delay in sale could be profitable for high value items, but costly for low value items, and hence sellers of high-value items will not be tempted to mimic sellers of low-value items. While this explanation may appear reasonable for oil leases, it appears less applicable to art auctions, though sellers of art are given access to professional valuation services provided by the auction house, which may provide an asymmetry of information. A summary of papers relating to secret reserve prices is presented in Table 6.

### 3.6. *The declining price anomaly*

Since Ashenfelter (1989) showed that prices are twice as likely to decrease as to increase for identical bottles of wine sold in same lot sizes at auction, there has been a tremendous amount of study of the declining price anomaly in many types of auctions. The literature on the declining price anomaly is extensive. Pesando and Shum (1996) and Beggs and Graddy (1997) address declining prices in art auctions, and much of the other literature is applicable to art. We review this literature below. We begin with a brief review of the theoretical literature on why declining prices may occur, and then review the types of auctions where declining prices have been found.

Soon after publication of Ashenfelter's (1989) article, there were many theoretical papers written to explain declining prices. Black and de Meza (1992) claimed it was no anomaly; declining prices in wine auctions exist primarily because the winner of the first auction in a sequence has the option to buy the remaining objects at the winning price. However, this theory is unable to explain why the anomaly continues to exist even where this option is not permitted. McAfee and Vincent (1993) showed that risk

aversion could create declining prices. One unappealing feature of their explanation is that a pure-strategy equilibrium exists only when there is nondecreasing absolute risk aversion, which is usually thought implausible. Mixed strategy equilibria are ex-post inefficient, which is sometimes also thought to be weakness of this theory, but which may nevertheless be a correct characterization of the actual market. [Beggs and Graddy \(1997\)](#) attribute a declining price to pre-sale estimate ratio throughout an auction to the fact that the value of art auctioned (as measured by the pre-sale estimate), on average, declines throughout the auction.

Other theoretical papers are as follows. [Von der Fehr \(1994\)](#) shows that participation costs could create declining prices through strategic bidding. [Engelbrecht-Wiggans \(1994\)](#), [Bernhardt and Scoones \(1994\)](#), [Gale and Hausch \(1994\)](#), and [Pezanis-Christou \(2001\)](#) relate the price decline to heterogeneity among buyers, and [Ginsburgh \(1998\)](#) shows that the presence of absentee bidders can generate declining prices.

The declining price anomaly has been documented in a number of different types of auctions with different auction structures. [Buccola \(1982\)](#) found it occurring in livestock auctions, [Milgrom and Weber \(1982b\)](#) for transponder leases, [McAfee and Vincent \(1993\)](#) and [di Vittorio and Ginsburgh \(1994\)](#) confirmed [Ashenfelter's \(1989\)](#) wine findings, [Thiel and Petry \(1995\)](#) in stamp auctions, [Ashenfelter and Genesove \(1992\)](#) and [Vanderporten \(1992a, 1992b\)](#) for condominiums, [Engelbrecht-Wiggans and Kahn \(1992\)](#) for dairy cattle, [Lusht \(1994\)](#) for commercial real estate, [Chanel, Gérard-Varet and Vincent \(1996\)](#) for gold jewellery; [Pesando and Shum \(1996\)](#) for Picasso prints; [Thurston \(1997\)](#) for mink pelts, [Pezanis-Christou \(2001\)](#) for fish auctions, [van den Berg, van Ours and Pradhan \(2001\)](#) for Dutch flower auctions, and [Ginsburgh and van Ours \(2007\)](#) for Chinese porcelain recovered from shipwrecks. [Burns \(1985\)](#) and [Keser and Olson \(1996\)](#) have set up experiments that have reached the same conclusions.

Several authors have also found increasing prices. Among them are [Gandal \(1997\)](#) for Israeli cable television licenses, and [Donald, Paarsch and Robert \(1997\)](#) for Siberian timber-export permits. [Jones, Menezes and Vella \(1996\)](#) found that prices could increase or decrease in sequential auctions of wool, as did [Chanel, Gérard-Varet and Vincent \(1996\)](#) for watches; [Milgrom and Weber \(1982b\)](#) show theoretically that if bidders' valuations are affiliated, then prices will tend to rise over time. [Deltas and Kosmopoulou \(2001\)](#) find in a sale of library books that expected prices increase over the auction, but that probability of sale decreases. They attribute their findings to "catalogue" effects: it is important how and where and item appears in the pre-sale catalogue. [Natzkoff \(2001\)](#) provides an excellent survey of papers on the declining price anomaly.

It is an interesting result that in a variety of different types of auctions, price direction throughout an auction can be predicted. As reported in [Table 7](#), declining prices (on average) have been documented in more types of auctions than have rising prices. A variety of economic theories have been developed to explain price direction, and in all likelihood, the price direction results from a combination of these effects. Declining prices do not occur in every auction or every art auction, but they appear to be an important effect that the auction mechanism has on price.

Table 7  
Declining price anomaly

Beggs and Graddy (1997)	Ordering by value can generate price/estimate declines
Ginsburgh (1998)	Absentee bidders can generate declining prices

---

An important corollary to the declining price debate is the extent to which auction houses, given the choice, should organize their sales differently. [Ginsburgh and van Ours \(2007\)](#) look at the results of three auctions of shipwreck findings where different setups were used. They find that parcels containing lots with the same number of items (rather than increasing or decreasing the number of items) achieve greater prices relative to the pre-sale estimate than parcels that were organized differently. They conjecture that organizing an auction with the same number of items in a parcel is revenue maximizing.

#### 4. Conclusion

The empirical study of art auctions really has two purposes. On the one hand, the auction mechanism provides a very public report on the prices of art objects. As we have shown, because of the unique nature of many art objects, the interpretation of market prices requires great care. Nevertheless, this information is the primary way that high-quality art objects are valued and it provides us with our primary objective information on preferences regarding art. Although the market is surely not all that is important in the judgment of art and artists, it is certainly one of the key components of our understanding of what is good and bad.

The empirical study of art auctions also has another purpose. Art auctions provide data that may be used to test and refine strategic models of behavior. Here the object of study is the economic mechanism and it makes very little difference what object is for sale. It appears that a great deal of what we know about the operation of auction mechanisms may also lead to the rather happy study of objects of considerable interest in their own right.

The empirical study of art auctions and the price of art assets has been a growth field in the last decade and has resulted in an increasing sophistication in the questions being asked and in the empirical methods being used. It seems likely that this trend will continue into the future.

#### Appendix A

The dataset on Impressionist and Modern Art auctions was constructed by Orley Ashenfelter and Andrew Richardson. This dataset is restricted to 58 selected Impressionist and Modern Artists and includes only paintings, not sculptures. These artists were chosen primarily because their work is well represented at auction. The period covered is 1980 to 1990, and the dataset includes over 16,000 items in 150 auctions that were held in London and New York at both Christie's and Sotheby's. The auction prices were collected from public price lists, and the estimated prices and observable painting characteristics were collected from the pre-sale catalogues. This dataset does not include all items sold in each auction, only a sample of the 58 selected artists. Furthermore, we only have prices for items that were sold at auction.

To construct a repeat-sales price index, we identified 230 paintings that sold at least twice during the period 1980–1990 (for a total of 474 observations). To make a positive identification, we required that paintings have an identical title, medium, artist and painting date. As many paintings have identical titles, title and artist are not sufficient identifiers. We regress the log of the sale price of the painting on a dummy variable for each painting, and the time period in which the painting was sold. We include a dummy variable for each year. Using the antilogs of the coefficients on the time dummies, we construct our repeat sales price index for Impressionist Art as reported in [Figure 1](#).

For the hedonic price index in Figure 1, the log of the sale price is regressed on the hedonic painting characteristics in addition to time dummies for each period. The hedonic characteristics used for Impressionist and Modern Art are painting date, length, width, signed, monogrammed, stamped, medium in which it was painted, and artist. We also include dummy variables indicating whether the painting was sold at Sotheby's or Christie's and New York or London.

## Abstract

While there are no significant investment characteristics that inhibit art from being considered as an asset, a major hurdle has long been the lack of a systematic measure of its financial performance. Due to its heterogeneity (each piece is different) and its infrequency of trading (the exact same piece does not come to the market very often), the determination of changes in market value is difficult to ascertain. Two estimation methods are commonly used to construct indices. Repeat-sales regression (RSR) uses prices of individual objects traded at two distinct moments in time. If the characteristics of an object do not change (which is usually so for collectibles), the heterogeneity issue is bypassed. The basic idea of the hedonic regression (HR) method is to regress prices on various attributes of objects (dimensions, artist, subject matter, etc.) and to use the residuals of the regression which can be considered as “characteristic-free prices” to compute the price index. The chapter deals with the basics of hedonic and repeat-sales estimators, and tries to interpret in economic terms what both are trying to achieve. It also goes into some more technical details which may be useful for researchers who want to construct such indices, and gives some guidelines on how to go about collecting data, and the choice between RSR and HR that this induces. Both methods are compared using simulated returns, pointing to which method should be used given the data at hand.

## 1. Introduction

While there are no significant investment characteristics that inhibit art from being considered as an asset, a major hurdle has long been the lack of a systematic measure of its financial performance. Due to its heterogeneity (each piece is different) and its infrequency of trading (the exact same piece does not come to the market very often), the determination of changes in market value is difficult to ascertain.

Anderson (1974) and Stein (1977) were among the very first to study returns in art markets. But it is undoubtedly Baumol's (1986) surprising result about the very small long-term return of art (0.55 percent between 1600 and 1950), coupled with the price boom in the late 1980s, shortly after his paper was published, that triggered most of the literature. It became so large, that it is hard to find, quote and do justice to all studies.

Many different art or antique markets have been looked at: African art, books, vintage cars, ancient coins, Old Master drawings, furniture, crafted ivory objects, jewelry, photographs, prints, sculpture, silverware, stamps, and probably others.<sup>1</sup> Of course, the largest effort was devoted to portfolios of paintings, often Impressionists and their followers, but also American, Belgian, Canadian, Italian, Latin-American, Pre-Raphaelite, and other groups of painters. Some papers look at individual painters, some study individual collections.<sup>2</sup>

There are several important uses for a well-constructed art market index:

- (a) Outline general market trends, much like the Dow Jones Industrial Average describing the general direction of the US stock market. This would help us measure art market returns and compare it to other asset classes so that we can ascertain whether art is a viable investment asset class.
- (b) Provide a concise measure of art market volatility as well as its correlation with other financial instruments, such as stocks and bonds, making it possible to address the question whether investing in art would diversify risk in a long-term investment portfolio.
- (c) Allow to examine what are the major social and economic factors affecting art market price movements. It would be easy to examine, for example, how inflation affects art market prices.
- (d) Provide a simple way of appraising the value of artworks. By assuming artworks appreciate at the art market rate, just as assuming a US stock price moves at the rate of the S&P 500, one can mark-to-market and derive a simple valuation for artworks. Recent studies, such as Mei and Moses (2002b) have discovered that this simple valuation estimate can provide some anchor to art prices, much like book-value is a useful valuation tool for stocks.

There are several important properties that art indices must have in order to serve as investment benchmarks:

<sup>1</sup> As well as wines, which can also in some sense be considered as art.

<sup>2</sup> See Appendix A for details and references.

- (a) They must be based on reliable and publicly available price information (catalogues or computer databases) so that they can be independently replicated.
- (b) Methods used to construct indices must address the heterogeneity issue raised above and should be based on well-established economic models and estimation procedures that make the results transparent and easy to verify.
- (c) The data should avoid sample selection biases.
- (d) Indices should distinguish many different collecting categories, since returns may vary dramatically.
- (e) The data must be regularly updated to provide a real time investment guide; it may also allow an art portfolio to be “marked to market” on a timely basis.

We now briefly turn to each of these aspects. Most papers use auction prices, since these are easily available; very few are able to get hold of other data. Gallery prices are analyzed by [Candela and Scorcu \(2001\)](#), while the analysis of returns for stamps [[Feuillolay \(1996\)](#)] or coins [[Verbert \(1991\)](#)] is sometimes carried out on catalogues.

Two estimation methods are commonly used to construct indices. Repeat-sales regression (RSR) uses prices of individual objects traded at two distinct moments in time. If the characteristics of an object do not change (which is usually so for collectibles), the heterogeneity issue is bypassed. This approach, extensively used in real estate studies, is applied to art markets by [Anderson \(1974\)](#), [Baumol \(1986\)](#),<sup>3</sup> [Goetzmann \(1990, 1993, 1996\)](#), [Goetzmann and Spiegel \(2003\)](#), [Locatelli Biey and Zanola \(1999\)](#), [Mei and Moses \(2002a, 2002b\)](#), [Pesando \(1993\)](#), and [Pesando and Shum \(1996, 1999\)](#). The basic idea of the hedonic regression (HR) method is to regress prices on various attributes of objects (dimensions, artist, subject matter, etc.) and to use the residuals of the regression which can be considered as “characteristic-free prices” to compute the price index. The method was used by [Frey and Pommerehne \(1989a, 1989b\)](#), [Buelens and Ginsburgh \(1993\)](#), [Chanel et al. \(1993\)](#) and became very popular in the mid-1990s. The benefit of HR is that the index is constructed from all sales, not from an (often small) subset of the available transactions. One of its drawbacks is that it depends on the characteristics used to describe the objects, and on the functional form of the equation.

Auction prices may give a biased view, since auctions seem to represent 33 to 50 percent of the art market. Other biases are problematic with auction prices. The first is especially relevant for studies that use repeat-sales sales, since some transactions do not go through salesrooms. This point was raised by [Guerzoni \(1994\)](#), who shows that [Reitlinger's \(1961, 1971\)](#) data,<sup>4</sup> on which [Baumol \(1986\)](#), [Frey and Pommerehne \(1989a, 1989b\)](#), [Buelens and Ginsburgh \(1993\)](#), and others base their calculations miss some important transactions, and this may seriously alter rates of return. The other problem is that works that are bought-in at auction are generally not included, since there is no hammer price. [Ashenfelter, Graddy and Stevens \(2001\)](#), [Ekelund, Ressler and Watson \(1998\)](#), [Goetzmann and Peng \(2003\)](#), [Goetzmann and Spiegel \(2003\)](#), and [McAndrew](#)

<sup>3</sup> Note that Baumol does not construct an index. See below.

<sup>4</sup> This may of course affect all resale data, not only those collected by Reitlinger.

and Thompson (2003, 2004) analyze the consequences, and suggest some solutions, such as estimating the secret reserve prices, or using some percentage of the lower bound of the pre-sale estimate published nowadays by most salesrooms.<sup>5</sup>

As mentioned above, many categories of collectibles have been studied: African art, books, vintage cars, coins, Old Master drawings, furniture, ivory objects, jewelry, photographs, prints, sculpture, musical instruments, silver, stamps, etc. Some are reasonably easy to describe (drawings) some are less so (furniture, sculpture). Some are sold frequently, since there are many “copies” available (prints), some are seen very rarely at auction (paintings by Vermeer). This points to which type of method (RSR vs. HR) can be used with some success, given the shortcomings of each one, and in particular, their dependence on the number of observations, and the possibility to describe objects by characteristics.

Timeliness is another important issue. There are fortunately more and more databases that are updated on a regularly, if not daily, basis, such as Artprice.com (<http://www.artprice.com>), Hislop’s Art Sales Index (<http://www.art-sales-index.com/system/index.html>), Gabrius (<http://gabrius.com/>), Gordon’s On Line Art Mall (<http://www.onlineartmall.com/limited/lgordon/>) and probably some other. Still, for many types of collectibles (furniture, violins) this is not so. In some cases, prices are made available in annual catalogues (such as Mayer for paintings and drawings, Gordon’s for prints), but often it is necessary to go to individual sales catalogues of auctioneers to get hold of the data. This again has an influence on the estimation method used to construct price indices.

The paper is organized as follows. Section 2 deals with the basics of hedonic and repeat-sales estimators, and tries to interpret in economic terms what both are trying to achieve. Section 3 goes into some more technical details which may be useful for researchers who want to construct such indices. Section 4 briefly discusses on how to go about collecting data, and the choice between RSR and HR that this induces. Section 5 compares both methods using simulated returns, and tries to point to which method should be used given the data at hand.

## 2. Hedonic and repeat-sales estimators: A first approach

In this section, we describe possible estimators of price indices, obtained from observing a set of  $2N$  transactions related to  $i = 1, 2, \dots, N$  different objects, that are also described in terms of some attributes or characteristics. To simplify exposition, we assume that each object is transacted twice. The set of dates (say, years) is  $t = 0, 1, \dots, T$  and defines possible periods (period  $t$  goes from date  $t - 1$  to date  $t$ ) or market runs. There exist data on prices for each object during some (here, 2) periods, but not for all

<sup>5</sup> Mei and Moses (2005) show that the publication of pre-sale estimates since the mid-1970s has an influence on hammer prices.

objects in every period. A transaction of object  $i$  in period  $t$  is indexed by subscripts  $(i, t)$ .

The estimators considered are the hedonic and the repeat-sales estimators, and include some others, that can be obtained as special cases. In particular, we show that the repeat-sales estimator is a special case of the hedonic estimator.

We illustrate our discussion using an example in which there are  $2N = 12$  sales of  $N = 6$  objects at three possible dates ( $T = 2$ ). We denote by  $p_{it}$  log of the price  $P_{it}$  of object  $i$ , sold at date  $t$ , and assume objects 1 and 4 were sold in  $t = 0$  and 1, objects 3 and 5 were sold in  $t = 1$  and 2 and finally, objects 2 and 6 were sold in  $t = 0$  and 2. The logged price (column) vector is denoted by  $p = (p_{10}, p_{20}, p_{40}, p_{60}, p_{11}, p_{31}, p_{41}, p_{51}, p_{22}, p_{32}, p_{52}, p_{62})$ . For convenience, we rank the observations for  $t = 0$  first, then those for  $t = 1$ , etc., without taking into account that some of the prices concern resales of the same object. We also define a vector  $y = (p_{11} - p_{10}, p_{22} - p_{20}, p_{32} - p_{31}, p_{41} - p_{40}, p_{52} - p_{51}, p_{62} - p_{60})$  with elements  $y_i$  (the logged differences of prices obtained at two dates for object  $i$ ).

### 2.1. The hedonic estimator

Hedonic regression is typically used to control for the changing quality of goods transacted. It seems to have been introduced by Court (1939), and subsequently used by Griliches (1961), Triplett (1969), and Griliches (1971a, 1971b) to construct price indices for automobiles. It is widely used by statistical offices to estimate consumer price indices,<sup>6</sup> and in academic work to establish price indices for real estate, computers, automobiles, dishwashers, the arts, and more generally for cases in which quality varies over space and/or time.

We start, however, with the simple case that ignores characteristics. Let  $C$  be a matrix consisting of  $2N$  rows and  $T + 1$  columns, denoted  $c_0, c_1, \dots, c_T$ . Element  $c_{it}$  is equal to *one* if a transaction on commodity  $i$  occurs in year  $t$ , and is *zero* otherwise. For the example at hand in which the (column) vector of prices is  $(p_{10}, p_{20}, p_{40}, p_{60}, p_{11}, p_{31}, p_{41}, p_{51}, p_{22}, p_{32}, p_{52}, p_{62})$ , the first column of  $C$  contains four ones, followed by 8 zeros, the second contains four zeros, followed by four ones and four zeros, etc.

We estimate the parameters  $\delta_t$  of the linear model:

$$p_{it} = \sum_{\tau=0}^T \delta_{\tau} c_{i\tau} + \varepsilon_{it}, \quad (1)$$

where  $\varepsilon_{it}$  is a random disturbance. The OLS estimator is:

$$\hat{\delta} = (C' C)^{-1} C' p. \quad (2)$$

<sup>6</sup> See, for example, Abraham, Greenless and Moulton (1998), Boskin (1996), Boskin et al. (1998) and of course the recent book by Triplett (2004) that is entirely devoted to this issue.

It is straightforward to check that the estimator for the price in year  $\tau$  is simply the average of the (log of) prices of the  $n_\tau$  objects sold during that year, that is a geometric average of prices:<sup>7</sup>

$$\hat{\delta}_\tau = \frac{1}{n_\tau} \sum_i p_{i\tau}, \quad \tau = 0, 1, \dots, T. \quad (3)$$

The index, normalized to 1 in  $\tau = 0$ , is obtained as the sequence of  $\exp \hat{\delta}_\tau / \exp \hat{\delta}_0$ .<sup>8,9</sup> Obviously, this is a sound approach as long as the mix of objects sold in each year has the same characteristics, or is of the same quality. This is often not the case, and then the hedonic approach is useful since it homogenizes sales mixes over time.

Consider therefore the set of objects sold in a specific year  $t$  and assume that the price of an object  $i$  sold in  $t$  can be considered as a function of  $m$  time-invariant characteristics  $v_{ik}$ ,  $k = 1, 2, \dots, m$  (e.g., the dimensions of a painting) and of  $n$  time-varying characteristics  $w_{ij\tau}$ ,  $\tau = 0, 1, \dots, t$  (e.g., the changing owners of a painting),  $j = 1, 2, \dots, n$ . If this assumption holds, we can write that  $p_{it} = f(v_{i1}, \dots, v_{im}, w_{i10}, \dots, w_{i1t}, w_{i20}, \dots)$ . We specialize the functional form to:<sup>10</sup>

$$p_{it} = \sum_{k=1}^m \alpha_k v_{ik} + \sum_{\tau=0}^t \sum_{j=1}^n \theta_{j\tau} w_{ij\tau} + \varepsilon_{it}. \quad (4)$$

The parameters  $\alpha_k$  and  $\theta_{j\tau}$  appearing in (4) are, often abusively,<sup>11</sup> interpreted as implicit prices of the various characteristics describing the commodity, and  $\varepsilon_{it}$  is a random error term. These implicit prices are thus obtained by a regression of prices on observable characteristics (also often in logarithmic form); once they are known, it is possible to compute, like in (3), the average price  $\hat{\delta}_\tau$  of a characteristic-free, or quality-adjusted commodity in year  $\tau$  as:

$$\hat{\delta}_\tau = \frac{1}{n_\tau} \sum_i \left( p_{i\tau} - \sum_{k=1}^m \alpha_k v_{ik} - \sum_{t=0}^T \sum_{j=1}^n \theta_{jt} w_{ijt} \right). \quad (5)$$

The sequence of  $\hat{\delta}_\tau$ ,  $\tau = 0, \dots, T$ , would then describe the price of an (artificial) characteristic-free commodity over time, and can obviously be obtained by a hedonic

<sup>7</sup> It is obvious that one can also derive an estimator for arithmetic averages of prices, using  $P_{it}$  instead of  $p_{it}$ .

<sup>8</sup> Alternatively, one can set  $c_0$  as a vector of ones, and estimate Equation (1) with an intercept. Then the sequence of  $\exp \hat{\delta}_\tau$  gives directly the index.

<sup>9</sup> Note that the antilog of the OLS estimates of the  $\delta$  are not unbiased, and that a correction has to be made, by adding one half of the coefficient's squared standard error to the estimated coefficient. Since such standard errors are usually small, this makes little difference. See Triplett (2004, Chapter 3, footnote 12).

<sup>10</sup> See more on the choice of functional forms, e.g., in Halvorsen and Pollakowski (1981).

<sup>11</sup> See the discussion below.

regression pooling the sales over time, by combining (1) and (4):

$$p_{it} = \sum_{k=1}^m \alpha_k v_{ik} + \sum_{\tau=0}^T \sum_{j=1}^n \theta_{j\tau} w_{ij\tau} + \sum_{\tau=0}^T \delta_{\tau} c_{i\tau} + \varepsilon_{it}.^{12} \quad (6)$$

The method allows for interactions between time and characteristics, if one believes that the implicit prices of some characteristics vary over time. For this, one merely has to introduce new variables  $\omega_{kt} = v_k c_t$ , which pick regression coefficients that describe the time path of the implicit price of characteristic  $k$ . The two previous estimators can also provide such information, by computing the parameters on sub-samples (e.g., a specific painter). However, given that the number of observations will be small compared with the total number of sales, the estimated coefficients will be estimated with little precision.

Obviously, there are many other ways to specify how prices depend on time. The  $\sum_{\tau} \delta_{\tau} c_{\tau}$  formulation makes it possible to construct a price index, in a reasonably flexible way. Alternatively, one can use a variable  $\tau$  which takes the values  $0, 1, 2, \dots, T$  and specify (6) with a term  $\phi\tau$ , where  $\phi$  would be an estimate of the price trend. One can also estimate time trends for sub-periods.

## 2.2. The repeat-sales estimator

The repeat-sales estimator was developed to derive price indexes for real estate. The method was formalized by Bailey, Muth and Nourse (1963), though they refer to previous suggestions by Wenzlick (1952) and Wyngarden (1927). The Bailey, Muth and Nourse paper was followed by a large number of theoretical approaches as well as applications, in most of the field journals.<sup>13</sup> This estimator is now also used for other markets, including artworks.

The usual approach to derive the underpinnings of the estimator is as follows. Assume that  $r_{it}$ , the continuously compounded return for a certain art asset  $i$  in period  $t$  may be represented by  $\delta_t$ , the continuously compounded return of “art”, and an error term  $\eta_{it}$ :

$$r_{it} = \delta_t + \eta_{it},$$

where  $\delta_t$  may be thought of as the average return in period  $t$  of artworks in the portfolio. We will use sales data about individual works to estimate the index  $\delta$  (a  $T$ -dimensional vector whose individual elements are  $\delta_t$ ) over some interval  $t = 1, \dots, T$ . The observed data consist of purchase and sales (logged) price pairs  $(p_{ib}, p_{is})$  of individual objects  $i$ ,

<sup>12</sup> Note that, following the usual specification, one can introduce an intercept  $\alpha_0$ , and estimate only  $T - 1$  parameters  $\delta_{\tau}$ , and normalize  $\delta_0$  to be equal to 1.

<sup>13</sup> AREUEA Journal, FRBSF Review, Journal of Environmental Planning and Management, Journal of Housing Economics, Journal of Real Estate Finance and Economics, Journal of Urban Economics, Land Economics, as well as in the Review of Economics and Statistics.

as well as the dates of purchase and sale, designated by  $b_i$  and  $s_i$ . Then, the logged relative price for object  $i$ , held between its purchase date  $b_i$  and its sales date  $s_i$ , may be expressed as:

$$r_i = p_{is} - p_{ib} = \sum_{t=b_i+1}^{s_i} r_{it}.$$

There are many ways to derive the repeat-sales estimator to understand how the regression should be run.<sup>14</sup> An easy way, which also happens to provide a link between the RSR and the HR estimators is to start with the hedonic equation, in which characteristics are constant over time:

$$p_{it} = \sum_{k=1}^m \alpha_k v_{ik} + \sum_{\tau=0}^T \delta_\tau c_{i\tau} + \varepsilon_{it}. \quad (7)$$

For notational purposes, it is convenient to define, as above,  $p_{ib}$  as the first sale, and  $p_{is}$  as the second one, and to redefine accordingly the columns of the matrix  $C$  and the  $\delta_\tau$  parameters. Then,

$$p_{is} - p_{ib} = \delta_s c_{is} - \delta_b c_{ib} + \eta_i, \quad (8)$$

where the  $\sum_k \alpha_k v_{ik}$  terms vanish, since the characteristics are identical over time, and  $\eta_i = \varepsilon_{is} - \varepsilon_{ib}$ . It is easy to check that for our example with six repeat-sales, this leads to the following system of equations:

$$\begin{bmatrix} p_{11} - p_{10} \\ p_{22} - p_{20} \\ p_{32} - p_{31} \\ p_{41} - p_{40} \\ p_{52} - p_{51} \\ p_{62} - p_{60} \end{bmatrix} = \begin{bmatrix} -1 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & -1 & 1 \\ -1 & 1 & 0 \\ 0 & -1 & 1 \\ -1 & 0 & 1 \end{bmatrix} \begin{bmatrix} \delta_0 \\ \delta_1 \\ \delta_2 \end{bmatrix} + \eta,$$

where  $\eta$  is a vector of the six error terms  $\eta_i$ .

The three columns of the matrix that appears in the right-hand side are linearly dependent, so that one column, say the first, should be discarded. This will set the normalization  $\delta_0 = 0$ , and leave us with an  $N \times T$  ( $= 6 \times 2$ ) matrix  $Z$  that will be interpreted later on. The  $T$  (here 2) regression coefficients can be estimated by OLS:

$$\hat{\delta} = (Z'Z)^{-1} Z'y. \quad (9)$$

An alternative way to derive the estimator – which leads to an easy interpretation of the coefficients – is to construct an  $N \times T$  matrix  $X$ , the columns of which represent periods (not dates); observation  $i$  is in row  $i$ , which contains *ones* for periods during

<sup>14</sup> We derive the so-called geometric repeat-sales estimator. See Shiller (1991) and Goetzmann and Peng (2001) who discuss an arithmetic estimator.

which the object was held and *zeros* otherwise. For our example, this matrix is:

$$X = \begin{bmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \\ 1 & 0 \\ 0 & 1 \\ 1 & 1 \end{bmatrix}.$$

The OLS estimator of the two coefficients, say  $\beta_1$  and  $\beta_2$ , is given by

$$\hat{\beta} = (X'X)^{-1}X'y. \quad (10)$$

The two normal equations are

$$\begin{aligned} 4\hat{\beta}_1 + 2\hat{\beta}_2 &= (p_{11} - p_{10}) + (p_{22} - p_{20}) + (p_{41} - p_{40}) + (p_{62} - p_{60}), \\ 2\hat{\beta}_1 + 4\hat{\beta}_2 &= (p_{22} - p_{20}) + (p_{32} - p_{31}) + (p_{52} - p_{51}) + (p_{62} - p_{60}). \end{aligned}$$

They can also be written as

$$\begin{aligned} \hat{\beta}_1 &= \frac{1}{4}[(p_{11} - p_{10}) + ((p_{22} - \hat{\beta}_2) - p_{20}) + (p_{41} - p_{40}) \\ &\quad + ((p_{62} - \hat{\beta}_2) - p_{60})], \\ \hat{\beta}_2 &= \frac{1}{4}[(p_{22} - (p_{20} + \hat{\beta}_1)) + (p_{32} - p_{31}) + (p_{52} - p_{51}) \\ &\quad + (p_{62} - (p_{60} + \hat{\beta}_1))]. \end{aligned}$$

If we now interpret  $\hat{\beta}_1$  and  $\hat{\beta}_2$  as being estimates of the mean rates of return in periods 1 and 2, respectively,  $(p_{22} - \hat{\beta}_2)$  and  $(p_{62} - \hat{\beta}_2)$  are estimates of the prices of objects 2 and 6, had they been resold in year 1 instead of year 2, while  $(p_{20} + \hat{\beta}_1)$  and  $(p_{60} + \hat{\beta}_1)$  are estimates of the prices of the same objects, had they been sold for the first time in year 1 instead of year 0. Once this interpretation is accepted, one immediately sees that  $\hat{\beta}_1$  is the average return of the objects sold in  $t = 0$  and in  $t = 1$ , while  $\hat{\beta}_2$  is the average return of the objects sold in  $t = 1$  and in  $t = 2$ .

It is straightforward to link formulations (9) and (10). Let  $B$  be a  $T \times T$  matrix constructed as follows: row  $t$  starts with  $t$  ones, while the other elements of the row are zeros. For our example, this matrix is:

$$B = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}.$$

We then construct a matrix  $XB^{-1}$  of explanatory variables, which is exactly the matrix  $Z$  used in (9). Some straightforward matrix algebra shows that (9) can also be written

$$\hat{\delta} = B\hat{\beta}, \quad (11)$$

which relates estimators (9) and (10), implying that

$$\hat{\delta}_t = \sum_{\tau=1}^t \hat{\beta}_\tau, \quad t = 1, 2, \dots, T.$$

For our example, this means that  $\hat{\delta}_1 = \hat{\beta}_1$  and  $\hat{\delta}_2 = \hat{\beta}_1 + \hat{\beta}_2$ . Since we can set  $\hat{\delta}_0 = \hat{\beta}_0 = 0$ , the sequence  $\exp(\hat{\delta}_0)$ ,  $\exp(\hat{\delta}_1)$ ,  $\exp(\hat{\delta}_2)$  is the price index over the three years.

A special case of the geometric repeat-sales estimator is the geometric mean estimator. Start with the following linear model:

$$y_i/\tau_i = \gamma + \varepsilon_i,$$

where  $\gamma$  is a parameter to be estimated and  $\tau_i$  is a variable which takes as value the number of periods during which an object was held by an owner (i.e. not sold); in the example,  $\tau_i$  is thus equal to 1 for  $i = 1, 3, 4$  and 5 and equal to 2 for  $i = 2$  and 6;  $\varepsilon_i$  is a random disturbance with the usual properties. The variable  $y_i/\tau_i$  is the annualized rate of return on commodity  $i$ . The parameter  $\gamma$  can be estimated by running a regression of  $y/\tau$  on a variable which takes the value one for each observation. It is trivial to check that the OLS estimate for  $\gamma$  is the average of annualized returns:

$$\hat{\gamma} = \frac{1}{N} \sum_i y_i/\tau_i. \quad (12)$$

For our example, (12) leads to:

$$\hat{\beta} = \frac{1}{6} [(p_{11} - p_{10}) + (p_{22} - p_{20})/2 + (p_{32} - p_{31}) + (p_{41} - p_{40}) + (p_{52} - p_{51}) + (p_{62} - p_{60})/2].$$

This is the estimator used by Baumol (1986) and Frey and Pommerehne (1989b).<sup>15</sup> It is obviously very easy to compute, but does not provide an index over time. Moreover, it puts equal weights on all annualized rates, irrespective of the length of time during which the object was held.

### 3. Hedonic, repeat-sales and other estimators: Further issues

#### 3.1. Rosen's interpretation of hedonic models

Lancaster (1966) was at the root of giving to the purely econometric technique used in hedonic regression, its theoretical foundations, based on the idea that commodities

<sup>15</sup> Actually, Baumol and Frey and Pommerehne use the exact formula  $(P_{it}/P_{it'})^{1/(t-t')}$  to compute the annual return of a work sold in  $t'$  and subsequently in  $t$ . We use the approximation instead. The two lead to comparable results if  $P_{it}$  is close to  $P_{it'}$ .

were not consumed per se, but for their combination of characteristics say, in the case of automobiles, speed, mileage, length, engine capacity, number of doors, etc., each of which carrying an implicit price. Rosen (1974) suggested that the simple estimation of such implicit prices by regressing observed prices on characteristics, was flawed, in the sense that, in general, the function does not allow “to recover the underlying utility and cost functions from such data alone” [Griliches (1990, p. 189)]. Implicit prices emerge from the equilibrium between demand and supply on markets for characteristics. Rosen outlines a two step procedure in which the first step is to estimate a hedonic function  $p = f(v)$ , to evaluate its derivatives at points corresponding to the observed values of  $v$ , and use these derivatives as prices in a system containing supply and demand functions for characteristics, paying attention to the usual identification problems in estimating simultaneous equations. Brown and Rosen (1982), Epple (1987), Bartik (1987) showed that the problem was even more complicated than what Rosen had thought, and suggest alternatives to Rosen’s estimation procedure. Empirical estimation was carried out by Wittke, Sumka and Ereksion (1979), Brown and Rosen (1982), Palmquist (1984), and Bartik (1987) for houses, Nerlove (1995) for wines, Pakes (2003) for personal computers.

Rosen’s (1974) approach deals with perfect competition. The analysis was carried to imperfect competition (or at least to cases in which the number of producers is small) by Goldberg (1995), Berry, Levinsohn and Pakes (1995), and Pakes (2003).

In many cases, and art markets are one of these, the purpose of hedonics is merely to determine a price index over time, and not, as in the case of hedonics in consumer price analysis, to derive consumer welfare, which is possible only if utility parameters can be inferred from the estimated model.<sup>16</sup> Therefore, in some sense, it is superfluous to appeal to Rosen’s theory in the case of art price indices.

### 3.2. *Issues with hedonic indexing*<sup>17</sup>

Still, reliable and unbiased estimates have to be obtained, and the problems that are present in single-equation model estimation, such as heteroskedasticity, multicollinearity,<sup>18</sup> choice of functional form, choice of characteristics (independent variables), etc. have also to be dealt with.

In order for the index to be as little contaminated as possible by the heterogeneity of the sales mix over time, and account correctly for quality adjusted price changes, the choice of hedonic characteristics is important. This is dealt with in some detail below.

A further issue is whether one can assume that the coefficients of the hedonic variables (other than time dummies) are constant over time. Though it is doubtful that the

<sup>16</sup> On this issue, see also Palmquist (1992), Feenstra (1995) and Diewert (2001).

<sup>17</sup> One feels somewhat uncomfortable to discuss in one double-spaced page, a topic for which Triplett (2004) needs over 250 single-spaced pages.

<sup>18</sup> Pakes (2003) observes that characteristics are often highly correlated for industrial products (in his case, computers). This is unlikely to be the case for artworks.

hedonic equation really captures changes in consumers' tastes, these can vary over time. Characteristics whose implicit prices are assumed to vary can be made variable, by introducing interaction terms between characteristics and time, or by running adjacent-period regressions, and testing whether the null hypothesis of constancy has to be rejected. Triplett (2004, Chapter 3, Section 2c) argues that constraining the hedonic coefficients to be equal over time does make a difference on the time index, and that, as long as the number of observations is sufficient, running a sequence of adjacent-period regressions produces better results.

A problem that is not encountered in art indexes, but in many other cases, such as computers, cars, and most other consumer durables, is that the ordinary least squares estimator does not take into account the size of the market for each brand or make. The same weight is given to every observation. The issue is dealt with in Silver and Heravi (2004) and Triplett (2004, Chapter 6, Section D).

A related problem is that brands often disappear from the market, and new brands with other characteristics are introduced. This is what makes for most of the difficulty in the construction of consumer price indices. See Boskin (1996) and Boskin et al. (1998), as well as Triplett (2004, Chapter 2).

Finally, we mention a problem analyzed by Melser (2004), who shows that the time-dummy method suggested above may fail to satisfy the monotonicity axiom, which requires the following properties to hold: a price index which compares two periods must increase (decline) if the second (first) period's prices rise, holding other factors fixed. Melser implements a suggestion made by Diewert (2001) which satisfies the axiom. Diewert (2003) also discusses many other unresolved issues in hedonic price indexing.

### 3.3. *Functional form of the hedonic function*

The most widely used functional form is the double-log function in which both prices and characteristics (as long as these are captured by continuous variables<sup>19</sup>) are transformed into natural logarithms, though, Rosen (1974) shows that, in general, theory has nothing to say on the functional form.<sup>20</sup> Therefore, as mentioned by Triplett (2004, Chapter 6, p. 10), "the form of the hedonic function is entirely an empirical matter . . . accordingly, one should choose the functional form that best fits the data, empirically". The empirical question is analyzed (for houses) by Cropper, Deck and McConnell (1988) who run some Monte-Carlo experiments to determine which form should be used to determine implicit prices as correctly as possible. They show that the linear

<sup>19</sup> Note that the space of characteristics is usually not dense. One can hardly find a car whose engine capacity is 1527.3 cc, or a computer whose memory cannot be expressed by an exponential of 2. Therefore, there is no need for the functional form to be smooth.

<sup>20</sup> See however Bartik (1987) who shows that some forms cannot be used in the two-step estimation procedure suggested by Rosen (1974).

Box–Cox functional form may be a reasonable compromise.<sup>21</sup> Wallace (1996) suggests non-parametric estimation which avoids the problem of choosing or imposing a functional form.

### 3.4. Hedonic characteristics for artworks

A good starting point is de Piles *balance des peintres*, added as an appendix to his *Cours de peinture par principes* [de Piles (1708)]. The balance is a table in which de Piles decomposes painting into four fundamental characteristics: composition, drawing, color, expression,<sup>22</sup> and rates each of these on a scale between zero and twenty for 56 painters from his and previous times. Rembrandt, for example, is very low on drawing and obtains 15, 6, 17 and 12 on the characteristics just mentioned, while Michelangelo is very high on drawing, with scores of 8, 17, 4 and 8, respectively. De Piles himself looked at this as a game, but his contemporaries considered it as a “clever way to characterize genius” [Thuillier (1989, p. xxvii)]. Later on, this view changed, and many art historians hate this idea, describing it as a “notorious aberration” [Gombrich (1966, p. 76)] or thinking that de Piles was “at his worst when he tried to be most systematic” [Puttfarcken (1985, p. 42)]. The originality of the *balance* is that it introduces a view of aesthetics that breaks up beauty into its parts. This is of course the very same idea as the one expressed by Lancaster (1966), and used in the early econometric work on hedonics.

Short of having been pursued by many other art critics,<sup>23</sup> such characterizations do hardly exist, and we must rely on alternative descriptions, that are surrogates for aesthetic characteristics. Mandeville, a physician, “attracted attention mainly as the author of provocative essays on economic and social subjects” [de Marchi and van Miegroet (1994)]. In one of his essays [Mandeville (1728)], he lists four factors which explain value: the name of the master, his age (in Mandeville’s words “the time of his age”), the scarcity of his work, and the rank of those owning them.<sup>24</sup>

Characteristics clearly depend on the type of collectible that is studied.<sup>25</sup> For paintings, which have been studied most, Sagot-Duvaurox (2003) singles out as characteristics signature (therefore, name of the artist), provenance (former owners, including exhibitions and literature describing the work), technique (oil, mixed media, etc.), subject matter (landscape, portrait, etc.), support (canvas, paper, etc.), size, place of sale. Nothing very new with respect to Mandeville. Note that, in the past, prices also depended on colors used, subject, number of figures represented.

Since most empirical studies are based on auction data, they use the characteristics made available in sales catalogues, which include name of the artist, size, technique,

<sup>21</sup> See also Halvorsen and Pollakowski (1981) and the discussion in Triplett (2004, Chapter 6, Section C).

<sup>22</sup> Note that the decomposition itself goes back to Plinius.

<sup>23</sup> See Ginsburgh and Weyers (2006) who used de Piles’ characteristics to price out their values in terms of today’s prices and aesthetic values.

<sup>24</sup> See de Marchi and van Miegroet (1994, p. 454).

<sup>25</sup> For details, see the papers cited in Appendix A.

elements of provenance (though names of previous owners rarely appear). Photographs of the paintings are also often included, so that subject matter, colors, etc. can be coded as characteristics as well.<sup>26</sup> Art prices may also be influenced by rarity, as suggested by Mandeville. It is however not clear whether rarity (for example, based on the number of works of an artist that are still in private hands) can be introduced as a hedonic characteristic since it is not a characteristic of the work (or of the artist), but of the market.

Table 1 shows the results for some of the studies that included characteristics in a reasonably uniform manner. Height and width always carry a positive sign, but the negative sign of the coefficient picked by the area variable shows that dimensions cannot become too large: price is a concave function of dimensions. Oil paintings and canvasses are generally more expensive than other media or supports. There is a positive influence of signature and date, when these appear on a painting.

The most controversial characteristic is probably the name of the master (dummy variables that are introduced when portfolios of art are studied), since this is no explanation for why his works are valued. Sociologists, art philosophers and economists seem however to agree that names do change values. Becker (1982), Moulin (1992) and Bonus and Ronte (1997) document in great detail how artists' reputations are constructed, and are responsible for the sometimes high prices that some works command. Art philosophers also hold the opinion that names make for aesthetic value. It is interesting to bring in what Danto, one of the great American analytic art philosophers, writes in one of his essays on contemporary art [Danto (1986, pp. 13–14 and 45)]: “Duchamp’s *Fountain* is, as everyone knows, to all outward appearances a urinal – it *was* a urinal until it became a work of art and acquired such further properties as works of art possess in excess of those possessed by mere real things like urinals . . .” or “The interpretation is not something outside the work: work and interpretation arise together in aesthetic consciousness. As interpretation is inseparable from work, it is inseparable from the artist if it is the artist’s work.” As economist, Grampp (1989, p. 131) purports that the name of the artist belongs to his work: the aesthetic object consists of the painting, the artist and the title. “Imagine”, he writes, “how a dealer would fare if he alone in the market and none of his competitors did not provide information about the painting he offered for sale: no name, no title, no provenance . . . nothing but the price.” Attribution matters. There are hundreds of such examples, one of the latest being Raphael’s *Madonna of the Pinks*, worth some £8000 until its attribution to Raphael in 1991, and paid £22 million by the National Gallery in 2004. All these are good reasons for not being afraid of introducing artist dummies as hedonic characteristics.

The main purpose of the work is to estimate a price index – though this may be biased if the choice of characteristics is poor, or if some important characteristics are omitted. Other hedonic coefficients should be interpreted with some care, given Rosen’s (1974)

<sup>26</sup> Czujack (1997) and Lazzaro (2003) who study respectively paintings by Picasso paintings and prints by Rembrandt are probably the two papers that make use of the largest set of hedonic characteristics.

*Sources.* Impressionists and Modern, and Other Europeans: de la Barre, Docclo and Ginsburgh (1994); American painters: Demortier (1992); Belgian painters: Ginsburgh and Mertens (1994); Mei and Moses database. All the regressions contain dummies for painters, years and auction houses, but the detailed results are not reported in the table.

warnings. In concluding this section, however, it is hard resisting to quote Triplett (2004, Chapter 5, p. 3) who suggests that “the first principle for conducting a hedonic study is [to] know your product”.

### 3.5. *Other repeat-sales estimators*

The OLS approach in (9) and (10) simply sets the weighting matrix as the identity matrix. While it is the easiest to use, it nonetheless makes the frequently unrealistic assumption that the error term in (8) is homoskedastic. Generalized least squares (GLS) set the weighting matrix as a diagonal matrix where the elements are the ex post squares estimation errors of a first step OLS estimation.

Palmquist (1982) shows that the use of OLS is problematic once there are more than two sales for a specific object and that GLS are needed to derive minimum variance estimates. Goetzmann (1992) shows that GLS provide maximum likelihood estimates of the parameters.

Case and Shiller (1987, 1989) propose an alternative weighting matrix. They assume that the variance of the error term in (8) is a simple linear function of the holding period plus a constant, and suggest a three-stage least square approach. In the first stage, OLS are used. Then one computes the error terms for (8). In the second stage, one regresses the squared error terms against a constant and the holding period. Then, based on the regression, one computes an estimated variance for each object using the holding period. Finally, one sets the diagonal term using the estimated variance and then runs a third stage regression using GLS.

The repeat-sales regressions discussed above are known to introduce certain biases. One of the most serious is spurious negative autocorrelation. This bias is potentially severe at the beginning of the estimated series. Goetzmann (1992) proposes a two-stage Bayesian regression to mitigate the problem over the early periods. The Bayesian formulation imposes an additional restriction that the errors are normally, independently and identically-distributed. The effect on the estimate is dramatic for the early period when data are scarce, and minimal for the period during which data are plentiful. Goetzmann (1992) also suggests a couple of other Bayes estimators.

The repeat-sales estimator is usually presented under its geometric form, since this gives returns in a straightforward way. Shiller (1991), and Goetzmann and Peng (2001) also propose arithmetic repeat-sales estimators that are unbiased and based on arithmetic averages of returns.

### 3.6. *Combining repeat-sales and hedonic estimators*

Case and Quigley (1991) try to use all the information and combine sales and resales (of houses) in a system of equations.<sup>27</sup> They use a hedonic equation for sales and a repeat-sales equation for resales. They also distinguish resales for which characteris-

<sup>27</sup> See also Shiller (1991) for more references and a discussion of combining both estimators.

tics have changed from other resales. Quigley (1995) complements Case and Quigley (1991) by introducing a procedure that is based on an explicit structure of the error term.

Though the results are extremely interesting – in particular, they provide estimates with smaller standard deviations –, the suggestion is hard to apply to paintings, since characteristics are mainly described by qualitative variables, while Case and Quigley deal with (a small number of) continuous variables only. Since in most cases, time is represented by annual dummies, one would need to introduce a very large number of variables.

### 3.7. Other estimators

Many alternative estimators have been suggested and used. A very simple one is discussed in the beginning of the section concerning hedonic regression, the geometric mean in each period. Clearly, one can also think of simple estimators such as arithmetic means or median prices in each period,<sup>28</sup> trimmed or not for outliers. During the 1980s, Sotheby's was carrying an index based on representative objects, the prices of which were reassessed by experts at regular time intervals.<sup>29</sup>

Mark and Goldberg (1984) add a long list of alternative methods, often based on hedonics:<sup>30</sup>

- the “transactions weighted by base period weights” index, in which base period implicit prices (obtained from a hedonic regression run on sales in the first year) are used to compute predicted prices for all units sold in each other year, and the unweighted arithmetic mean of the predicted values is used as the basic price series. This reflects changes in the distribution of the characteristics of units actually sold through time;
- the “transactions weighted by final period weights” index; the idea is the same as in the previous method, except that final period implicit prices are used;
- the “changing annual weights in every period” index; in this method, the weights change every year; predicted prices are calculated and serve as basis for the index;
- a “Laspeyre's index analog”; the Laspeyre index uses base period quantities as weights; the analog suggested uses as weights the average bundle of characteristics from the base year sample, while the changing prices are the hedonic coefficients obtained for each year;

<sup>28</sup> Median prices are used by the US National Association of Realtors. An index based on average prices is computed by Art Market Research in the UK and is regularly published by the *Daily Telegraph*.

<sup>29</sup> See also Clapp and Giacotto (1992) who use price assessments by tax assessors for residential properties, and show that these are strongly correlated with observed prices, so that assessments can play the role of hedonic characteristics. This is very close to using pre-sale estimates by salesrooms as describing artworks, and thus avoiding hedonic characteristics. See, e.g., Beggs and Graddy (1997).

<sup>30</sup> See also Triplett (2004, Chapter 3) for such methods, that he calls “characteristic price index methods”, in which implicit prices are used to compute an index, without any need for time dummies.

- a “Paasche’s index analog”; the Paasche index uses final period quantities as weights; otherwise, calculations are identical to the Laspeyre’s index analog.

Engle, Lilien and Watson (1985) estimate housing returns using a dynamic multiple-indicator multiple-cause system of equations, estimated by maximum likelihood. Candela, Figini and Scorcu (2002), and Candela and Scorcu (2001) discuss other possibilities.

#### 4. Developing hedonic and repeat-sales models: Data acquisition

We will develop this section assuming a researcher is starting at a moment in time and deciding on how to go about collecting data so that he can develop an index that portrays the movement of art prices or returns over some historical period ending with the current period. We assume that the only valid data to use for this type of analysis is auction data either from the direct source catalogs and/or an online computer database.

The RSR-researcher is only interested in the information contained in the provenance of the piece. This gives all the prior owners and any prior auction transaction, to the best of the auction houses ability. Prior auction prices are normally not provided and to find these requires finding the prior auction catalog and price lists. The prior transaction price can sometimes be found on computer databases such as the Hislop Art Sales Index or Art Net but care must be taken to insure that one has found the correct pairing (*Still Life* by Cezanne hardly gives a clue). Moreover titles can change and sizes can be miss-recorded. The shortcoming of the RSR technique is that the number of objects with prior sale results is usually much smaller than the total number of lots offered.

The HR-researcher can use the information given in sales catalogs to serve as a set of independent variables in a hedonic regression. This would allow him to forgo the search for the prior price data. With the help of on line databases, which provide a subset of the data available in catalogs, the task can be made even simpler. The major shortcoming of this technique is that two works can have very similar characteristics for the same year but widely different prices leaving the year dummy alone to try to explain the difference. But since the data collection is easier all the works that sell in each period can be used.

The following variables are usually available: artist, title, size, lot number, date, auction house, medium and support, whether the object is signed or dated and the date, and since 1973 the high and low price estimates. For important works, catalogs also include illustrations, ownership and exhibition history as well as the number of literature citations, and their dates. The ownership history is essential for those hoping to use repeat-sales techniques since it will mention any prior auction sale but rarely the hammer price. This is found by using a good library with an extensive auction catalog collection.

## 5. Comparing hedonic and repeat-sales estimation

### 5.1. The pros and the cons of both types of indices

*Number of observations.* The number of cases in which one can retrieve repeat-sales is usually small, and certainly much smaller than the total number of sales. Ashenfelter and Graddy (2006) compare a hedonic index using 8792 observations with a repeat-sales index with 474 observations. Mei and Moses (2002a, 2002b) have 4900 pairs (9800 observations) for the period 1875–2000 (of which 2300 are for Old Masters). By comparison, the database used by de la Barre, Docclo and Ginsburgh (1994) on Impressionists and followers for paintings sold between 1962 and 1991 contains 24,500 observations. In the Mei–Moses All Art Index that will be used in Section 5.3, the proportion of repeat-sales with respect to all sales is roughly 7% within a ten year time span (1971–1980), 13% within a 20 year span (1971–1990) and 15% within a 30 year span (1971–2000).

In some cases, such as prints which exist in several copies, the number of repeat-sales is much larger. Pesando (1993) collected almost 28,000 repeat-sales, though prints with the same title are not necessarily interchangeable: some may be in better condition than others, some have a good provenance, etc.

Repeat-sales estimation also needs much longer periods on which the index is estimated, since the one before the last sale may have happened long before the last one. The method hardly allows fine disaggregation into submarkets, not to mention constructing indices for individual artists, because the number of observations is usually too small. Goetzmann (1992) explores the issue of sparse data, and suggests some solutions. Sparse data are prone to generate spurious negative autocorrelation and too much volatility. Finally, there is the problem that most data (those for which no resales can be retrieved) are not used, and information is wasted.<sup>31</sup>

*Sample biases in repeat-sales estimators.* Gatzlaff and Haurin (1997) show that because only a small percentage of objects (in their case, houses) sell each year, the sample of those that sell may have non-random statistical properties, due for example to changing economic conditions which influence reserve prices of sellers. They suggest using Heckman's (1979) sample selection correction model. More generally, repeat-sales estimation may suffer from several other sample biases, such as transactions which did not go through auction and whose prices are missing, and outliers, which have more importance than for hedonic indexes, given that data are more sparse.

*Specification biases.* Choosing the functional form and the variables that represent quality are pervasive in hedonic indexing, and can lead to all the problems linked to mis-specification. This is of course avoided in repeat-sales estimation. However, the repeat-sales estimator will not capture the effects of changes in the characteristics of an object between two sales. This happens very often in the case of houses, less so in the

<sup>31</sup> See however the discussion on hybrid methods.

case of art objects, though these may get damaged, restored or even reattributed over time, and this may change their hedonic characteristics.

*Revision volatility.* Wang and Zorn (1997) among others note that “revision volatility” affects both types of indices. As new data become available, previous estimates of the index change, though this may be thought of as good since they result from increased efficiency in the estimators.

*Price inflation and exchange rates.* Inflation can be corrected easily, either by deflating prices themselves, or by deflating the index obtained using either method, since deflating is a log-linear operation. Exchange rates are hardly more problematic, except that here individual prices have to be corrected before going to the estimation work. Think however of a Japanese collector who buys in London in pounds, pays in yens, and sells a few years later in New York in dollars that he changes into yens. Obviously, the only thing that can be done is to compute the rate of return based on the first sale in pounds, translate the pounds into dollars at the going exchange rate, and compute the return in dollars with respect to the second sale. This computed return may be positive, though it may be negative for the collector. At least part of this will not happen with stocks, since most of these are bought and sold in the same place.

## 5.2. *The literature on comparing indices*

Many papers deal with the comparison of indices, but there is very little done in a systematic way. In most cases, real data are used, different indices are constructed, but since the “true” underlying return is not known, the indices are simply compared with each other. Most comparisons deal with real estate prices.

Mark and Goldberg (1984) find that among the indices that are enumerated under “Other estimators” in Section 3 (to which they add a hedonic index constructed on the basis of time dummies for every year, a hedonic index run on adjacent years, a repeat-sales index, an arithmetic (unweighted) mean of sale prices in each period index, a median sale price in each period index), the arithmetic mean, surprisingly, performs well as do several of the hedonic price indices. Case (1986) and Case and Shiller (1987) compare RSR with median prices, and find that the latter are not a good measure of appreciation.

Goetzmann (1992) runs simulations on seven different repeat-sales estimators, including those that are discussed above, using NYSE data from which he draws random samples. He shows that all estimators perform well when the number of repeat-sales is large relative to the number of time intervals. Otherwise, Bayesian-type estimators, such as those discussed in Goetzmann (1990, 1992) are the only ones to perform well.

Chanel, Gérard-Varet and Ginsburgh (1996) run simulations by bootstrapping from the real set of Reitlinger’s (1961, 1971) art data, but compute only a mean return and not an index. They compare the hedonic, the repeat-sales and the geometric mean estimators and find that none of them is biased, but the hedonic method provides much smaller standard errors for the return coefficient (which is obviously the consequence of a larger number of observations).

Meese and Wallace (1997) compare hedonic, repeat-sales and hybrid methods. They find that hedonic techniques are better suited. Repeat-sales techniques are subject to sample selection bias, they violate the assumption of constant implicit prices over time, they are too sensitive to small samples and to influential observations, and the usual method to correct for heteroskedasticity is inappropriate.

The results are thus far from clearcut, since most studies [with exception of Goetzmann (1992) and Chanel, Gérard-Varet and Ginsburgh (1996)] cannot really tell which method is better, since they do not control for the underlying “true” returns. Goetzmann (1992) only compares various repeat-sales estimators (and does not compare these with hedonic estimators), and the experiments run by Chanel, Gérard-Varet and Ginsburgh (1996) are not comprehensive enough to draw solid conclusions.<sup>32</sup>

This is the reason for which we decided to run some Monte-Carlo experiments, which are described and discussed now.

### 5.3. *Comparing hedonic and repeat-sales estimation: Some Monte-Carlo experimentation*

The major concern that faces researchers on finding index values for art have to do with the amount of information available and the time frame of reference. If we knew with certainty and transparency the purchase and the sale price of every object sold for a long period of time there would be no question that RSR would give the best measure of the financial return to holding the set of objects included. When the time frame is short or the ratio of repeat-sales data to total sales data is small, questions arise as to whether a hedonic regression with large amounts of data would give a better reading of market returns.

To study this question we utilized the data collected on the Impressionist and Modern market from 1950 to 2002 and used in the Mei–Moses All Art Index. For any sale that originated in New York during that period we used the existing catalogue description of ownership to search out any prior auction sale anywhere in the world in any time period, as well as for the prior hammer price.<sup>33</sup> If prices were available for both sales they were included in the database. This research produced over 2000 repeat-sale pairs, of which 1671 were usable (at least three observations per artist). In addition to collecting the prior prices we also collected hedonic variables for these pairs. These include dummies for artist, salesroom, shape, medium, aspect (height/width), as well as height, width, and area. Other characteristics (signature, date, number of previous owners, number of times auctioned, number of exhibitions, number of citations and whether pictured in the sales catalogue, shape, and subject) were also collected but not used in the Monte-Carlo experiments.

<sup>32</sup> See also Case, Pollakowski and Wachter (1991), and Crone and Voith (1992) for more comparisons.

<sup>33</sup> Using the resources of the Watson Library at the Metropolitan Museum of Art and the New York Public library, 42nd Street branch.

The steps taken next are as follows, and ensure that both the repeat-sales and the hedonic regressions should generate returns that can be compared with some “true” reference returns.

*Step 1.* Generate a “reference series” of returns, that will be used to compare the results obtained by repeat-sales and hedonic regression over varying time frames. This reference series is obtained from a repeat-sales regression using the 1671 pairs (3342 observations) over the 31 year period. Store the estimated returns, as well as the residual variance of the regression.

*Step 2.* Construct artificial repeat-sales prices using the estimated returns in Step 1.

*Step 3.* For each time frame consisting in years  $t = 1, 2, \dots, T$ , to be discussed later, construct 100 samples  $i = 1, 2, \dots, 100$  of prices obtained by adding to the artificial repeat-sales prices generated in Step 2, a normal random disturbance with the usual properties and whose variance is equal to the residual variance of the regression in Step 1. Run a repeat-sales regression on each of the 100 samples, compute the mean return, and the mean tracking error  $TE_R$  obtained as the square root of the sum of squares of the differences between the “true” and the mean returns over the whole period, that is,

$$TE_R = \left[ \frac{1}{T} \sum_t (\gamma_{R,t} - \hat{\gamma}_t)^2 \right]^{1/2},$$

where  $\gamma_{R,t}$  is the mean over the 100 samples of the RSR return in year  $t$ ,  $\hat{\gamma}_t$  is the “true” return in year  $t$ . Compute also the mean standard error of the estimated returns, obtained as

$$SD_R = \frac{1}{T} \sum_t \left[ \frac{1}{100} \sum_i (\gamma_{R,i,t} - \hat{\gamma}_t)^2 \right]^{1/2},$$

where  $\gamma_{R,i,t}$  is the RSR return in sample  $i$ , for year  $t$ .

*Step 4.* Compute a hedonic regression including the characteristics described above, as well as time dummies, using the 3342 observations. Store the estimated implicit prices for characteristics, as well as the residual variance of the regression.

*Step 5.* Construct artificial hedonic prices using the estimated implicit prices obtained in Step 2, and the “true” returns obtained in Step 1.

*Step 6.* For different time frames to be discussed later, pick 14, 8 and 6 times each observation<sup>34</sup> and construct 100 samples of prices obtained by adding to the artificial hedonic prices generated in Step 5, a normal random disturbance with the usual properties and whose variance is equal to the residual variance of the regression in Step 4.

*Step 7.* Run a hedonic regression on each of the 100 samples, compute the mean return, and the mean tracking error  $TE_H$ , obtained as the square root of the sum of squares

<sup>34</sup> Each sale (or resale) is taken 14, 8 and 6 times in order to “simulate” the fact that there are 14, 8 and 6 times more sales than resales in the 10, 20 and 30 year database.

of the differences between the “true” and the mean returns over the whole period, that is,

$$TE_H = \left[ \frac{1}{T} \sum_t (\gamma_{H,t} - \hat{\gamma}_t)^2 \right]^{1/2},$$

where  $\gamma_{H,t}$  is the mean over the 100 samples of the HR return in year  $t$ ,  $\hat{\gamma}_t$  is the “true” return in year  $t$ . Compute also the mean standard error of the estimated returns, obtained as

$$SD_H = \frac{1}{T} \sum_t \left[ \frac{1}{100} \sum_i (\gamma_{H,i,t} - \hat{\gamma}_t)^2 \right]^{1/2},$$

where  $\gamma_{H,i,t}$  is the HR return in sample  $i$ , for year  $t$ .

Observations cover the period 1950–2001. The time frames chosen are 10 years (1972–1981), 20 years (1972–1991) and 30 years (1972–2001), so that one can compare the performance of both estimators over ten, twenty and thirty year periods. There is one problem due to repeat-sales. In order to estimate a repeat-sales regression over the period 1972–1981 say, one may need observations for earlier years during which the first sale occurred. For this reason, all the regressions (repeat-sales and hedonic) are started in 1950, but the tracking errors and the mean standard errors are computed with 1972 as starting year.

Three estimators are compared: the OLS repeat-sales estimators,<sup>35</sup> the OLS hedonic estimator using all of the characteristics described above, and OLS hedonics that use only a subset of characteristics, to check how much ignoring some of the characteristics (in this case, dimensions: height, width, area and shape, that is width/height) matters. The three estimators are compared in Table 2 in terms of tracking errors and mean square errors.

The tracking errors  $TE_R$  and  $TE_H$  are much lower for hedonics than for repeat-sales for small samples (156 and 612 pairs), but, as expected, both methods tend to produce comparable results once the sample gets larger (1671 pairs). Ignoring characteristics does not seem to matter: both tracking errors and mean standard errors are of the same order of magnitude than before.<sup>36</sup> Figures 1–3 compare both the RSR and the HR returns and indices with the “true” ones. Simulation results also show that the mean standard errors are lower for hedonics than for repeat-sales.

As expected, HR performs much better than RSR, even if some of the characteristics are ignored, when the sample size is small. It seems clear that RSR methods should not be used for time frames that include less than 20 years, unless the number of pairs is large.

<sup>35</sup> Since in our artificial samples, errors are normal IID, a GLS estimator would lead to the same results as an OLS estimator. Therefore, the OLS estimator has all the required properties.

<sup>36</sup> For some reason that we do not understand, they are even smaller in some cases.

Table 2  
Comparing OLS hedonic and repeat-sales estimators (tracking errors and standard deviations over various time frames)

	1972–1981	1972–1991	1972–2001
No. of RSR observations	312	1224	3342
No. of HR observations	4368	9792	20,052
Tracking errors			
RSR	0.2723	0.1566	0.0306
HR full	0.0333	0.0110	0.0070
HR without dimensions	0.0307	0.0012	0.0026
Standard errors			
RSR	0.6580	0.4903	0.3775
HR full	0.3485	0.2983	0.2925
HR without dimensions	0.3914	0.3201	0.2665

HR without dimensions contains the same regressors as HR full, except Height, Width and Area of the work.

Figure 2. Repeat-sales and hedonic returns and indices 1972–1991.

Figure 3. Repeat-sales and hedonic returns and indices 1972–2000.

Table 3  
Comparison of OLS and GLS repeat-sales estimators

	OLS	GLS	Case–Shiller	Bayes
Mean return	0.118	0.119	0.118	0.119
Standard deviation of return	0.223	0.203	0.194	0.202
Correlations between annual returns				
OLS	1.00	–	–	–
GLS	0.74	1.00	–	–
Case and Shiller	0.87	0.96	1.00	–
Bayes	0.74	0.99	0.96	1.00

#### 5.4. Comparing three GLS estimators for repeat-sales estimation

Using the same dataset (1950–2001), we now compare the OLS estimator and three generalized least-squares estimators to compute repeat-sales regressions: the standard generalized least-squares estimator, with a diagonal weighting matrix in which the weights are equal to the squared estimation errors of a first step OLS estimation, the [Case and Shiller \(1987\)](#) three-stage least squares estimator and [Goetzmann’s \(1992\)](#) two-stage Bayesian estimator. [Table 3](#) reproduces the main results in terms of correlation between indices. Results show that though the mean return resulting from all four methods are almost identical, the correlation of the returns between the OLS and GLS estimators is not as high as the correlation of one GLS estimator with another. It also shows that all three GLS estimators give almost identical results.

### Appendix A: Studies on returns

A very large number of different art or antique markets have been looked at: African art [[Degand \(1994\)](#)], books [[Blogie \(1965–1967\)](#); [Ginsburgh and Orban de Xivry \(1994\)](#)], vintage cars [[Van Haverbeke \(1991\)](#)], ancient coins [[Verbert \(1991\)](#)], Old Master drawings [[Ginsburgh and Schwed \(1992\)](#)], furniture [[Graeser \(1993\)](#)], crafted ivory objects [[Lebrun \(1993\)](#)], jewellery [[Chanel, Gérard-Varet and Vincent \(1996\)](#)], photographs [[Pflieger and Sagot-Duvaurox \(1994\)](#)], prints [[Candela and Scorcu \(2001\)](#); [Czujack, Flores and Ginsburgh \(1996\)](#); [Lavand’homme \(1992\)](#); [Pesando \(1993\)](#); [Pesando and Schum \(1996, 1999\)](#)], sculpture [[Locatelli Biey and Zanola \(2002\)](#)], violins [[Heinen \(1993\)](#); [Ross and Zonderman \(1989\)](#)], silverware [[Dorchy and Ginsburgh \(1993\)](#); [Bauwens and Ginsburgh \(2000\)](#)], stamps [[Cardell, Kling and Petry \(1995\)](#); [Feuillolay \(1996\)](#)].

Paintings, often Impressionists and their followers, but also American, Belgian, Canadian, Italian, Latin-American, Pre-Raphaelite, and other painters, raised most of the effort. See [Agnello and Pierce \(1996\)](#), [Anderson \(1974\)](#), [Ashenfelter \(1989\)](#), [Ashenfelter, Graddy and Stevens \(2001\)](#), [Baumol \(1986\)](#), [Beggs and Graddy \(1997\)](#), [Buelens and](#)

Ginsburgh (1993), Candela and Scorcu (1997), Candela, Figini and Scorcu (2003), Chanel (1995), Chanel, Gérard-Varet and Ginsburgh (1994, 1996), de la Barre, Docclo and Ginsburgh (1994), de Limburg-Stirum and Ginsburgh (1995), Demortier (1992), Ekelund, Ressler and Watson (1998), Flores, Ginsburgh and Jeanfils (1999), Frey and Pommerehne (1989a, 1989b), Ginsburgh and Jeanfils (1995), Ginsburgh and Mertens (1994), Ginsburgh and Penders (1997), Goetzmann (1990, 1993, 1996), Goetzmann and Spiegel (2003), Locatelli Biey and Zanola (1999), Mei and Moses (2001, 2002a, 2002b, 2005), Pommerehne and Feld (1997), Schneider and Pommerehne (1983), Stein (1977), Valsan (2002). Some papers look at individuals painters: a couple of Impressionists and Post-Impressionists painters [de la Barre, Docclo and Ginsburgh (1994)] and Picasso [Czujack (1997); Pesando and Schum (1999)]. Landes (2000) looks at the Ganz collection, and some studies have dealt with the return on the collection built up in the 1980s by the British railway pension fund.<sup>37</sup>

Many more studies are compiled and surveyed in Ashenfelter and Graddy (2003, 2006), Burton and Jacobsen (1999), and Frey and Eichenberger (1995a, 1995b), who provide convenient tables with comparative results.

\* With the usual caveat, we express our gratitude to Françoise Benhamou and Victor Ginsburgh for constructive comments on an earlier version of this chapter.

**Abstract**

This chapter shows how economic theory and public policy analysis can illuminate decision-making relating to cultural heritage. We argue that from an economic viewpoint the appropriate conceptualisation of heritage is as a capital asset. Regarding heritage as cultural capital invites consideration of sustainability aspects, in parallel with the treatment of natural capital in economic theory, allowing us to derive a sustainability rule for cultural capital accumulation. The application of cost–benefit analysis to heritage investment appraisal is discussed, with particular reference to the assessment of non-market benefits. Turning to policy issues, we examine ways in which governments intervene in heritage markets, with particular attention to listing and other forms of regulation. Questions of institutional design, financing and policy delivery in a multi-jurisdictional framework are discussed, and finally the role of the private sector is considered, with emphasis on the possibility of crowding out and the incentive effects of public policy on private behaviour in the heritage field.

## 1. Introduction

There are a number of definitions of cultural heritage, though there is no agreement on a precise specification of how restricted or extensive the concept should be. Indeed, [Benhamou \(2003, p. 255\)](#) suggests that “heritage is a social construction where boundaries are unstable and blurred”. Nevertheless, common to most accounts is the fact that, as its name indicates, heritage is something that is received from the past; although we are accustomed to thinking of heritage as being old, bequeathed to us from generations long since dead, there is no reason why it may not have been inherited from the recent past, indeed from within the present generation. Attaching the term “cultural” to “heritage” signifies that the items of concern have some cultural meaning or significance that is regarded as important. So, for example, [Guerzoni \(1997, p. 107\)](#) defines cultural heritage as “a heterogenous set of goods that, in the course of time and in a process of historicization, comes to be recognised as the conveyor of specific cultural traditions”. Examples of cultural heritage that spring readily to mind include tangible items such as buildings, monuments, sites, artworks, artefacts, etc. and also intangible phenomena such as traditions, customs, memories, ideas, languages, beliefs, etc. The present chapter deals in principle with all of these, though most of our discussion focuses on heritage in its tangible form.<sup>1</sup>

Decisions about cultural heritage – what it is, how it should be conserved – are traditionally the province of art historians, conservators, archaeologists, museum directors and similar professionals. When economists raise questions about the criteria on which these decisions are based, their intrusion is often resented.<sup>2</sup> Yet at its simplest, the maintenance or restoration of heritage requires resources, and resources have opportunity costs. Since resources are limited in supply, choices are necessary: What can be preserved and what cannot? How much renovation or restoration is warranted? Whose preferences should guide conservation decisions? Economics may not be capable of providing a complete answer to these sorts of questions, but it can certainly illustrate the issues and point out some of the consequences of alternative courses of action.

In this chapter we examine first the theoretical underpinnings of an economic analysis of cultural heritage, building on the concept of cultural capital as a distinct form of capital in economics (Section 2). In this analysis heritage is interpreted as a set of assets with particular characteristics that affect the ways in which consumption and investment decisions are made. In particular, regarding heritage as cultural capital naturally invites consideration of sustainability aspects, in parallel with the treatment of natural capital

<sup>1</sup> For a comprehensive account of the evolution of ideas of heritage over time and space, see [Chastel \(1986\)](#), who notes that the term is also applied to natural and genetic heritage as well as to cultural heritage. He discusses how items of built heritage and their interpretation change as a result of human interventions and with the passage of time.

<sup>2</sup> Recent forays by economists into the heritage field include [Peacock \(1995\)](#), and the collections of essays edited by [Peacock and Rizzo \(1994\)](#), [Schuster, de Monchaux and Riley \(1997\)](#), [Hutter and Rizzo \(1997\)](#) and [Peacock \(1998\)](#); for an oppositional view from a cultural professional, see [Cannon-Brookes \(1996\)](#).

in economic theory (Section 3). Carrying further the idea of heritage as asset enables us in Section 4 to examine the application of investment appraisal methods to heritage projects. Not surprisingly, the assessment of benefits becomes a critical component of such an exercise. In Sections 5 and 6 we turn to public policy issues, looking at the ways in which governments intervene in heritage markets, and then in Section 7 at the particular financing issues raised in a multiple-jurisdiction framework. Finally, in Section 8, the role of the private sector is considered, with emphasis on the possibility of crowding-out and the incentive effects of public policy on private behaviour in the heritage field.

## 2. Heritage as capital asset

Heritage items such as a painting by Monet or a historic building can be seen as capital assets: both required investment of physical and human resources in their original manufacture and construction; both will deteriorate over time unless resources are devoted to their maintenance and upkeep; and both give rise to a flow of services over time which may enter the final consumption of individuals directly (e.g. when people view the painting in a museum or visit the historic building), or which may contribute to the production of further goods and services (e.g. when the painting inspires the creation of new artworks or when the historic building is used as a commercial office space). In other words, heritage items can be interpreted as capital assets with the standard characteristics of ordinary physical capital in economics. Recently suggestions have been made that heritage items are members of a class of capital which is distinct from other forms of capital; this class has been called *cultural capital*<sup>3</sup> [Throsby (1999); Ulibarri (2000); Shockley (2004)]. The distinction lies in the type of value that is embodied in these assets and is yielded by the goods and services they produce. A historic building such as Notre Dame Cathedral or the Taj Mahal is not just any building; certainly it has the characteristics of an “ordinary” building as an item of physical capital, but in addition it has historical and other attributes which an “ordinary” building does not have. These attributes can be described as the building’s “cultural value”, and the same type of cultural value can be attributed to the flow of services it provides.

This notion of the cultural value of certain goods and services such as heritage can be set alongside the more familiar concept of their economic value as measured by variables such as price or as assessed by the tools of economic analysis. Let us assume that cultural value can be measured according to a unit of account that plays a role comparable to that of a monetary scale in measuring economic value. Placing these two indicators of value, economic and cultural, side by side for a range of heritage items we

<sup>3</sup> The use of this term in economics differs from the concept widely used in sociology following Bourdieu (1986), where “cultural capital” refers to an individual’s competence in high-status culture within a holistic conception of society. Insofar as Bourdieu’s usage relates to characteristics of human beings, it is very close to the economic concept of human capital [Becker (1964)].

would expect some relationship between them – assets of greater cultural significance would generally be expected to be more highly valued in monetary terms than less significant ones. However, the relationship would not be perfect since contrary cases can be imagined – a remote religious building of little market value but with strong cultural or historical associations, for example. We return to the distinction between economic and cultural value below. For now we can proceed on the basis of these interpretations to define cultural capital formally as an asset that embodies a store of cultural value, separable from whatever economic value it might possess; in combination with other inputs the asset gives rise to a flow of goods and services over time which may also have cultural value (i.e. which are themselves cultural goods and services).

As noted above, heritage items can be *tangible* or *intangible*. Whilst the definition of tangible heritage in the above terms might be simple enough, the identification of intangible cultural heritage is more elusive. The recently formulated UN *Convention for Safeguarding of the Intangible Cultural Heritage* (2003) defines it as

“the practices, representations, expressions, knowledge, skills – as well as the instruments, objects, artefacts and cultural spaces associated therewith – that communities, groups and, in some cases, individuals recognise as part of their cultural heritage. This intangible cultural heritage, transmitted from generation to generation is constantly recreated by communities and groups in response to their environment, their interaction with nature and their history . . .” [UNESCO (2003, p. 2)].

Like any capital item, cultural capital (whether tangible or intangible) can be represented both as a *stock* of assets and as a *flow* of capital services over time. The value of the capital may be assessed in terms of its asset value at a given point in time or as the value of the flow of services to which it gives rise. Either way, the particular characteristic of cultural capital is that it embodies or gives rise to two types of value, economic and cultural.

Despite the apparent precision of these definitions of cultural heritage, two problems arise in applying them to the real world. First, if cultural heritage as a capital asset is distinguished from other forms of asset by its possession of a specific type of value, whose assessment of that value is to count and how is it to be measured? Formal statements of what should be regarded as heritage that are contained in conventions such as the UNESCO *Convention for the Protection of the World Cultural and Natural Heritage* [UNESCO (1972)], the Burra Charter [Australia ICOMOS (1999)], and the Intangible Heritage Convention referred to above do indeed rely on an appeal to notions of cultural significance, and go so far as to suggest criteria against which significance might be judged; nevertheless they remain imprecise as to the metrics that could be used and how they could be applied. As a result, the definitional problem is generally resolved in practice by looking for consensus judgements amongst a relevant group of experts, stakeholders or policy-makers, whose assessment of cultural value, however imprecisely expressed, is taken as decisive. Whether it is representative or not of society’s cultural perceptions is an open question, as will be examined further in a later section.

The second problem is that in some situations what is regarded as cultural heritage is not so much a well-defined item but rather an assorted collection of goods that were never thought of as having any particular importance at the time they were produced [Peacock (1995)]. This relates to the notion of “material culture” or “material heritage” as identified, for example, by anthropologists. What constitutes heritage in this context is no longer an objective fact but rather a social and cultural construct that is likely to change over time.

### 3. Cultural capital, natural capital and sustainability

#### 3.1. *Natural and cultural capital: Some similarities*

The concept of cultural capital bears some similarities to that of natural capital as it has developed within ecological economics over the last decade or so [El Sarafy (1991); Costanza and Daly (1992); Jansson et al. (1994)]. That is, cultural capital which has been inherited from the past can be seen to have something in common with natural resources, which have also been provided to us as an endowment; natural resources have come from the beneficence of nature, cultural capital has arisen from the creative activities of human kind. Both can be interpreted as imposing a duty of care on the present generation, the essence of the sustainability problem to be discussed further below. Further, a similarity can be seen between the function of natural ecosystems in supporting and maintaining the “natural balance” and the function of what might be referred to as “cultural ecosystems” in supporting and maintaining the cultural life and vitality of human civilisation. Finally, the notion of diversity, so important in the natural world, has an equally significant role to play within cultural systems. It is a characteristic of most cultural goods that they are unique, and this applies particularly to cultural heritage, both tangible and intangible. It can be suggested that cultural diversity is at least as far-reaching as is diversity in nature, and perhaps more so. Hence much of the analysis of biodiversity might be applicable to a consideration of cultural heritage.<sup>4</sup>

A parallel between natural and cultural capital of particular significance in the heritage context is the way in which the long-term management of both types of capital can be cast in terms of the principles of sustainable development. When applied to natural capital, sustainable development implies management of natural resources in a way that provides for the needs of the present generation without compromising the capacity of future generations to meet their own needs,<sup>5</sup> i.e. the principle of intergenerational equity. Another key element of sustainability in natural capital management

<sup>4</sup> On cultural diversity and cultural pluralism, see the report of the World Commission on Environment and Development (1995), contributions to the *World Culture Reports* of 1998 and 2000 published by UNESCO, and the *Universal Declaration on Cultural Diversity* adopted by UNESCO in 2001; see also Acheson and Maule (2004), Throsby (2004).

<sup>5</sup> This “definition” of sustainable development is a paraphrase of that proposed in the Brundtland Report [WCED (1987 p. 43)].

is the precautionary principle which argues for a risk-averse stance in decision-making when irreversible consequences such as species loss are in prospect. Both of these principles are relevant to cultural sustainability. Because the stock of cultural capital, both tangible and intangible, embodies the culture we have inherited from our forebears and which we hand on to future generations, it is inevitable that questions of intergenerational equity are raised; heritage decision-making is constantly faced with the long-term implications of strategies for conservation, preservation, restoration and re-use of buildings and sites. Similarly the precautionary principle can be invoked when demolition of a historic building is threatened; once gone, such unique cultural heritage cannot be replaced.<sup>6</sup>

### 3.2. Sustainability paradigms<sup>7</sup>

A key aspect of sustainability is the maintenance of capital stocks. In terms of physical capital, if a country's aggregate consumption is less than or equal to its net domestic product, it must be at least maintaining its total capital stock, and can therefore be defined as following a sustainable development path. If the capital stock referred to is extended to include natural, human and cultural capital as well as physical capital, the question arises as to whether different types of capital can simply be aggregated, such that a decline in the level of one type of capital can be compensated for by an increase in another. In other words, this raises the issue of substitutability between forms of capital. The contrasting positions in regard to the substitutability between natural and other forms of capital can be seen in two standard texts, Dasgupta and Heal (1979) representing a strictly neoclassical (substitutable) approach, and Pearce and Turner (1990) who put the non-substitutability case.

In the long-running debate about the issue of capital substitutability, two essential paradigms for sustainable development have emerged [Neumayer (2003)]. The first, which can be called "weak sustainability", derives from the original work of Robert Solow and John Hartwick. In a series of papers [Solow (1974a, 1974b); Hartwick (1977, 1978)] they investigated the question of investing the rents from exhaustible resources in the presence of concern for intergenerational equity.<sup>8</sup> In its simplest form this model portrays an economy in which the competitive rents from current use of the exhaustible resource are reinvested in human-made capital goods, enabling society to maintain a constant consumption stream; the accumulation of physical capital exactly offsets the decline in natural capital. As is apparent, this model assumes that natural and human-made capital are perfect substitutes in the production of consumption goods and in the direct provision of utility for both present and future generations. Hence it is the aggregate capital stock that matters and not how it is comprised; in other words, it doesn't

<sup>6</sup> Similar concerns may be expressed about intangible heritage such as languages or customs that may disappear if not maintained.

<sup>7</sup> The following discussion draws on material treated more fully in Throsby (2005).

<sup>8</sup> See also Solow (1986; 1994) and Hartwick (1995).

matter if the present generation uses up exhaustible resources as long as sufficient new physical capital can be provided to future generations by way of compensation.

The other paradigm is that of “strong sustainability” which regards natural capital as being strictly non-substitutable for human-made capital, a view deriving in part from the unique life-supporting properties of global air, land and water systems. Proponents of strong sustainability argue that no other form of capital is capable of providing the basic functions that make human, animal and plant life possible [Barbier et al. (1994)]. Moreover, some forms of natural capital cannot be reconstructed once they are destroyed; for example, the destruction of biodiversity is a loss of natural capital that cannot be reversed, and even climate change could result in ecosystem damage that is irreversible. In other words, the strong sustainability paradigm assumes that the functions of natural capital cannot be replicated no matter how spectacular future technological advances might be.

Particular interest has been focussed on the specification of optimal development paths for an economy under the different paradigms. This requires some means of measuring whether or not a given path is sustainable according to the assumed criteria [Victor (1991)]. An effort in this direction is provided by Pearce and Atkinson (1993), who propose a sustainability indicator  $Z$  for a weakly sustainable development path where the economy is defined as sustainable if it saves more than the combined depreciation on man-made and natural capital, i.e.  $Z > 0$  if and only if

$$S > (\delta_M + \delta_N), \quad (1)$$

where  $S$  is savings,  $\delta$  is depreciation, with the subscripts  $M$  and  $N$  indicating man-made and natural capital, respectively. Pearce and Atkinson proceed to estimate the indicator empirically for a range of countries, concluding that “even on a weak sustainability rule many countries are not likely to pass a sustainability test” (p. 105).<sup>9</sup>

How do these sustainability paradigms apply to cultural capital? Here it has to be recognised that cultural capital gives rise by definition to two sorts of value: economic and cultural. It is clear that provision of many of the *economic* functions of cultural capital is readily imaginable through substitution by physical capital; for example the services of shelter, amenity etc. provided by a historic building could as well be provided by another structure without cultural content. However, since by definition cultural capital is distinguished from physical capital by its embodiment and production of *cultural* value, there would be expected to be zero substitutability between cultural and physical capital in respect of its cultural output, since no other form of capital is capable of providing this sort of value; the new building cannot replicate the historical content of the old.<sup>10</sup>

<sup>9</sup> For further discussion of this model and of valuation problems more generally, see Pearce (1993), especially pp. 44–53.

<sup>10</sup> This is not to say that new buildings cannot themselves be regarded as cultural capital; see further the discussion below on investment in capital creation.

### 3.3. Sustainability of cultural capital

We turn now to the possibility of specifying sustainable development paths for cultural capital, taking account of its particular characteristics. For simplicity we assume a quasi-strong form of sustainability by defining it in terms of the cultural capital stock only, thus ruling out questions of substitutability with other types of capital. A possible model is summarised as follows.

Assume a closed economy which possess a stock of cultural capital  $K$  with an aggregate value to society of  $V = V(K^e, K^c)$  where  $K^e$  is the economic valuation of the capital stock at a given point in time, measured in financial terms, and  $K^c$  is the cultural valuation of the stock measured according to some agreed system of units reflecting the significance or worth to society of the cultural asset. During any time period,<sup>11</sup>  $K$  produces a flow of income  $y$  measured in both monetary-value and cultural-value terms. So, for example, if the capital assets in question are artworks in a museum, or historic buildings or sites, these income flows might be generated by displaying the artworks for people to look at, or by opening the buildings and sites to tourists. In each case a stream of monetary income is generated which accrues to the immediate owners of the asset in question; at the same time a stream of “cultural income” is also generated, some of which accrues to society at large as public-good benefits arising from the existence of these items of the cultural capital stock.

Assume that production takes place according to the following one-period production functions:

$$y^e = F^e(X, K^e), \quad (2a)$$

$$y^c = F^c(X, K^c), \quad (2b)$$

where  $X$  is a vector of other inputs (labour, operating capital, etc.) whose level is determined by the policy-maker, and where the functions  $F$ , for convenience, have the usual properties of constant returns to scale and diminishing marginal product.

We assume  $y^c$  is completely consumed in the period in which it is produced, whereas  $y^e$  can be allocated to current consumption ( $C$ ) or to investment ( $I$ ) in the maintenance of  $K$ , the existing capital stock.<sup>12</sup> Then

$$y^e = C + I. \quad (3)$$

For given  $X$  we can write

$$y^e = rK^e, \quad (4)$$

where  $r$  is interpreted as the economic rate of return on the capital stock. For simplicity, let us assume that all the income is re-invested, hence

$$I = rK^e. \quad (5)$$

<sup>11</sup> For simplicity, we omit time subscripts throughout.

<sup>12</sup> For the present we ignore the possibility of investment in new capital stock (see further below).

Similarly, for given  $X$  we can write

$$y^c = \alpha K^c, \quad (6)$$

where  $\alpha$  is defined as a “cultural appreciation parameter” measuring the extent to which members of society, in a given time period, understand and appreciate the significance or importance of  $K$ . (Thus for a society that cared nothing for its cultural assets,  $\alpha = 0$  and no cultural income would accrue.)

From the viewpoint of sustainability, we are interested in the rate of change in the capital stock from one period to the next, measured in both economic and cultural value terms. Changes over time in the level of  $K^e$  are caused by several different factors:

- exogenous influences affecting the price of the stock (e.g. for an art museum’s collection, these influences arise as a result of movements in the art market);
- depreciation caused by wear and tear (e.g. from damage to a cultural site caused by tourists) or by catastrophic events (e.g. war);
- conservation or restoration investment undertaken with the aim of maintaining the asset in good condition.

Let the first of these factors be measured by  $m$ , the rate of price appreciation (which could be negative) and let the second be measured by  $d$ , the rate of depreciation (always negative). The third factor is simply  $I$  as defined above. Without further ado we can write

$$\dot{K}^e = m - d + r \quad (7)$$

and note that economic sustainability of the capital stock, defined as  $\dot{K}^e \geq 0$ , will require

$$(m + r) \geq d. \quad (8)$$

Before turning to sustainability in the *cultural* value of the capital stock, we note the following assumption. We assume that the rate of change of the appreciation parameter  $\alpha$  is a function of the level of “cultural income” forthcoming in any period. In other words, the greater are the cultural benefits flowing from a given stock of cultural capital, the faster will the community’s cultural appreciation grow. In simpler words, the more people attend art museums, visit heritage sites, perform traditional cultural ceremonies, etc., the more “switched on” will the community become to their own cultural inheritance.<sup>13</sup> Correspondingly, the less these benefits are realised, the smaller will  $\alpha$  become. In fact it is quite possible for  $\alpha$  to be negative, that is, for cultural appreciation to decay if cultural participation falls below a given level. Specifically, let us assume there is a critical level of the flow of cultural value in a given time period,  $\hat{y}^c$  below which  $\alpha$  falls below zero, i.e. we assume

$$\dot{\alpha} > 0 \quad \text{if } y^c > \hat{y}^c, \quad \dot{\alpha} = 0 \quad \text{if } y^c = \hat{y}^c \quad \text{and} \quad \dot{\alpha} < 0 \quad \text{if } y^c < \hat{y}^c.$$

<sup>13</sup> Recall that we are assuming a closed economy, so the imposition of foreign cultural influences does not arise.

Now we can define the factors affecting the level of  $K^c$  in a given time period. We assume two factors are relevant:

- the rate of change of  $\alpha$  as discussed above; and
- the amount of maintenance investment  $I$ .

The reason for including the second of these factors should be readily apparent – at least some components of the cultural value of historic buildings, artworks, etc. will decline if they are neglected and allowed to fall into disrepair (i.e. if  $I = 0$ ).

Accordingly we can write

$$\dot{K}^c = f(\dot{\alpha}, I), \quad (9)$$

where  $f'(\dot{\alpha}) > 0$  and  $f'(I) > 0$ . We can now specify that cultural sustainability will require  $\dot{K}^c \geq 0$ . We note that implementation of this sustainability rule would require knowledge of the function  $f$  in (9) and in turn the critical value of  $\hat{y}^c$ .

It can be argued from a cultural viewpoint that it is *cultural* sustainability that matters in this economy. If this is so, the problem can be framed as follows. For a given initial stock of  $K$  with economic and cultural value of  $K^e$  and  $K^c$ , respectively, the decision problem is to choose  $X$  and  $I$  such that the cultural sustainability condition holds. In other words, in any given period society would need to allocate a sufficient level of resources to utilising its cultural capital stock rather than to other (non-cultural) purposes, and would need to re-invest a sufficient level of the financial income stream so generated in the conservation and maintenance of the stock, in order to ensure no deterioration in the cultural value of the stock in the next period.

Finally we turn to the matter of new investment in cultural capital. This refers to such actions as the creation of artworks, the construction of new buildings that may someday be regarded as “historic” and having particular cultural value, the cultivation of emerging cultural traditions that in due course will be handed on to the next generation, etc. Here it might be noted that the parallel with natural capital begins to break down. These forms of new cultural capital are not like renewable resources which have an inherent capacity for self-regeneration. They have to be created by deliberate production processes.

The incorporation of this new cultural investment into the above sustainability model raises the question of substitutability *within* forms of cultural capital. For example, is new cultural capital substitutable for old? If so, the loss of heritage items via destruction or neglect could be compensated for by the creation of new cultural assets. Alternatively, to what extent is new art capable of delivering the same level of cultural benefits as old art? And even if new art can produce the same level of benefits in some quantitative sense, there are likely to be qualitative differences in the types of value created. Furthermore cultures are not static, and some degree of decay and renewal may in any case occur, and indeed may be regarded as desirable as a means of maintaining cultural vitality over time.

Thus, whilst in principle there may be no formal difficulty in simply allowing for increments in the capital stock arising from new investment to be included in the above model, the specification of the cultural value yielded by the new capital goods presents

some problems. At one level these problems are no different from those of measuring cultural value elsewhere in the model; however, uncertainties surrounding evaluation criteria in contemporary culture may make measurement even more difficult than in the case of inherited cultural capital, when at least judgements have had time to mature and some consensus can be seen to have been reached. Moreover, there is a further problem with the introduction of new investment into the system – the difficulty of identifying how much of new artistic and cultural output will in fact add to the capital stock. In the case of built heritage, for example, a recognition of cultural significance may take some time to evolve – who is to know which modern building, large or small, will be regarded as culturally important in fifty or one-hundred years' time?<sup>14</sup> In regard to artworks, the transience of contemporary art presents a similar problem, since much currently produced art will sink without trace; only a very small proportion of works produced at any given time are likely to survive to become part of longer-term capital accumulation. In these circumstances, it is probably appropriate to regard a certain proportion – perhaps a majority – of contemporary art as consumption goods, or at least as investment goods that are fully amortised in the current period.

Overall, the approach adopted in specifying a sustainable development path in this model raises again the well-known debate about whether the intergenerational aspects of sustainable development are a matter of efficiency in intertemporal resource allocation, or whether they are matters of fairness or equity in the present generation's treatment of its successors. It might be observed that the admission of cultural value as an additional element in the picture does not change the basic propositions involved. The preservation of cultural capital for the benefit of future generations can be just as much a question of efficiency or equity in the allocation of resources producing *cultural* benefits as it is in the case of resources producing only economic return.

Finally, it can be noted that while the theoretical concept of a culturally sustainable development path defined according to explicit criteria may be an appealing one, it remains operationally constrained until robust value-assessment methods can be devised. A step in this direction might be to seek aggregate cultural indicators providing a first approximation to levels and changes in the cultural capital stock, along the same lines as Pearce and Atkinson (1993) did for natural capital. Of course this is more easily said than done; efforts to construct cultural indicators have some particular problems of their own [McKinley (1998), Pattanaik (1998)], and quantification is especially difficult because of the unavailability of suitable data on cultural resources for any country, let alone on an internationally comparable basis between countries. Nevertheless there are some hopeful signs that the documentation and measurement of cultural heritage stocks will benefit from current progress amongst official statistical agencies in improving the collection of cultural statistics more generally.

<sup>14</sup> Some contemporary architecture seems to acquire heritage status almost instantaneously, especially buildings devoted to some cultural purpose, such as the Bilbao Guggenheim Museum, the Getty Center in Los Angeles and the Sydney Opera House.

#### 4. Investment appraisal procedures applied to cultural heritage projects

We turn now to some consequences for economic analysis arising from the specification of heritage as cultural capital. In particular, we can ask how far we can go in applying conventional asset management techniques and investment theory to the assessment of cultural heritage, and how in particular the non-market benefits of heritage can be included in the analysis.

##### 4.1. Cost–benefit analysis applied to heritage decisions

As is well known, there are several methods for evaluating capital investment decisions, including the *payback method* (how long does it take for the asset's earnings to repay its initial capital cost?), the *benefit–cost ratio* and *net present value method* (do aggregate net benefits, suitably discounted, exceed the capital cost?), and the *internal rate of return method* (what discount rate just matches aggregate discounted net benefits with the initial capital cost?). There seems no reason why these methods could not in principle be applied to the appraisal of cultural capital. As we have already observed, heritage items have an existing asset value, require real resources in their maintenance, and yield flows of benefits into the future. Thus the evaluation of a heritage project involving, say, restoration of a site or of an artwork could aim to identify all the market and non-market benefits and costs involved, and then use one or other of these techniques to compare investment in this project with other competing heritage projects or with other (non-heritage) alternative investment opportunities. It is important to repeat, however, that since cultural capital is distinguished from ordinary physical capital by the cultural value it generates, evaluation methods applied to heritage projects, if they are to be comprehensive and account for the particularly cultural nature of the asset in question, should be focussed on *both* the economic *and* the cultural value of the projects under study.

How is this to be achieved? The economic calculus is straightforward: the future time stream of net benefits generated by the project, discounted to the present, can be readily compared with the project's initial investment cost, i.e. the project is economically viable if

$$\sum_t (b_{mt} + b_{nt} - c_t) / (1 + i)^t > I, \quad (10)$$

where

$b_{mt}$  are market (private-good) benefits yielded by the project in period  $t$  ( $t = 1, \dots, T$ );

$b_{nt}$  are non-market (public-good) benefits yielded by the project in period  $t$ ;

$c_t$  is operating cost of the project in period  $t$ ;

$I$  is project investment cost;

$i$  is rate of discount.

Both the market benefits and the operating costs, together with the initial investment cost, can be assessed as for any other investment project from known or assumed financial data.<sup>15</sup> The estimation of the non-market benefit component of Equation (10) is discussed in the following section.

#### 4.2. Estimation of the non-market benefits of heritage

Demand for those aspects of cultural heritage that are recognised as non-rival and non-excludable public goods can be ascribed to three sources. First, individuals may value the *existence* of a given item of cultural heritage, even though they may not consume the services of that item directly themselves. Second, they may have an *option* demand, i.e. a desire to keep open the possibility that they might consume the asset's services at some time in the future. Third, the asset may have *bequest* value, insofar as people wish to bequeath the asset to future generations. These values are sometimes described as *non-use* or *passive-use* values, in contrast to the *active-use* values enjoyed by those directly consuming the services of the asset themselves (reflected in  $b_{mt}$  in Equation (10)).

Measurement of the non-market demands for cultural heritage has made significant advances in recent years. Cultural economists have been able to take advantage of the extensive theoretical, methodological and empirical research that has gone into the evaluation of environmental amenities.<sup>16</sup> Methods used can be classified into revealed preference and stated preference approaches. Amongst the techniques relying on observation of market behaviour (revealed preference), *hedonic pricing* methods have some potential in the heritage field, but their use is limited to situations where a reasonably wide spread of market data can be found. So, for example, the influence of heritage values on property prices, including the effects of listing, might be able to be assessed by these means. An illustration is the study by Moorhouse and Smith (1994), who investigated the influence of architectural styles on the prices of nineteenth century terrace houses in Boston. Another application is that of Chanel, Gerard-Varet and Ginsburgh (1996) who used hedonic methods to analyse the auction prices of artworks. Despite the validity of such studies in terms of what they set out to do, they suffer from the fact that they essentially measure private individual benefit rather than wider public-good effects.

An alternative revealed preference approach is to use the *travel cost* method. Individuals are presumed to reveal how much they value the benefits provided by an environmental or cultural site by the amount they are prepared to pay in making the journey to visit it. Studies have been carried out on visitors to particular sites, asking

<sup>15</sup> Note that  $T$  might be unusually large in the case of heritage, since it may be expected to last indefinitely; however, of course, at any reasonable discount rate benefits in the remote future are effectively reduced to zero in present value terms.

<sup>16</sup> For an overview of environmental valuation see, for example, Braden and Kolstad (1991), Freeman (1993), Grafton et al. (2004, Chapters 8–10).

how much time they spent travelling to it, what financial outlays were involved, how many times they have visited, etc. From the results for many respondents, a demand function for the benefits of the site can be established from which, amongst other things, an estimate of consumers' surplus can be derived. However, there are a number of difficulties with this approach. Not all sites require a lot of travelling to visit them, and often multiple purposes are involved in the trip: for example, how does one allocate the cost of visiting Florence between the Duomo, the Uffizi, and Santa Croce? Furthermore, even if reasonable estimates can be made by these methods, they relate more to direct use value rather than to non-use values. Thus, the application of travel cost methods to the estimation of the non-market benefits of heritage would appear to be limited.

Because of the difficulties of finding appropriate market data, assessment of the non-market benefits of cultural heritage has concentrated overwhelmingly on *stated* preference methods using discrete choice modelling or contingent valuation methodology (CVM).<sup>17</sup> These approaches involve asking people their willingness to pay (WTP) for the benefits received, or their willingness to accept compensation for their loss (WTA). The asking may take place under quasi-experimental conditions, or more commonly may be administered through sample surveys of individuals drawn from the population of those experiencing the benefit in question. Thus, for instance, the non-use value of a local heritage site might be assessed using CVM by means of a survey of a sample of residents of the area. The survey might be conducted by telephone, mail or personal interview. The effects of various sources of bias such as the free-rider problem, the embedding effect, etc. can be reduced or eliminated by careful experimental design. Respondents might be asked hypothetically to indicate the maximum financial contribution they would make to a fund to support the site, or they might be asked whether or not they would contribute a fixed amount to such a fund. Either way an analyst could use the results to estimate a hypothetical demand function for the non-use benefits of the site in question.

The use of CVM was given some endorsement by the findings of an expert panel appointed by the US National Oceanic and Atmospheric Administration to review the applicability of the technique in determining liability claims following the *Exxon Valdez* oil spill in Alaska in 1989. The panel, co-chaired by Kenneth Arrow and Robert Solow, and including Edward Leamer, Roy Radner, Paul Portney and Howard Schuman, found that "CV studies can produce estimates reliable enough to be the starting point of a judicial process of damage assessment, including lost passive-use values" [Arrow et al. (1993)], provided that they are carefully carried out, with due attention paid to the biases and other problems affecting the technique.

Overall, it can be said that since the non-use values from cultural heritage are very similar in kind to those arising from environmental amenity, the fact that many successful applications of CVM in the environmental sphere have now been carried out augurs well for the further application of these same techniques in the heritage field.

<sup>17</sup> For overviews of the method and its application in the cultural heritage field, see Frey and Oberholzer-Gee (1998), Klammer and Zuidhof (1999), Navrud and Ready (2002) and Noonan (2003).

### 4.3. Cost–benefit analysis and cultural value

The above procedures can provide a comprehensive evaluation of the economic effects (including both market and non-market effects) of this investment project. But we noted above that a further step is required if a full account of the cultural benefits and costs of the project is to be provided, i.e. a form of cultural cost–benefit analysis in which the cultural value created by the project is the subject of appraisal. How is this to be done? In principle there is no reason why an approach similar to that shown in (10) above could not be applied also to the cultural value component of this investment. The project is expected to yield a flow of cultural benefits into the future; indeed it is the prospect of this flow, more than of the economic return, that is likely to have given rise to the project in the first place. Furthermore, cultural benefits can accrue both to individuals (as rival excludable benefits) and to society at large (as non-rival non-excludable benefits), suggesting that a division into private and public components is just as relevant to the assessment of cultural value as it is for economic effects. Moreover, it is reasonable to suggest that a unit of cultural benefit at some time in the future is worth less to the project's stakeholders than a unit now, making some form of discounting of future benefit streams appropriate.

But the problem remains of how these benefits are to be measured. Given the multi-dimensional character of cultural value, it can be suggested that the only sensible way to evaluate it will be via a disaggregation into its component elements. Throsby (2001) has suggested that, for cultural heritage, those elements might include

- *aesthetic value*: beauty, harmony;
- *spiritual value*: understanding, enlightenment, insight;
- *social value*: connection with others, a sense of identity;
- *historical value*: connection with the past;
- *symbolic value*: objects or sites as repositories or conveyors of meaning;
- *authenticity value*: integrity, uniqueness.

It may be possible to assign cardinal or ordinal scores to these components and aggregate them into a simple index according to given assumptions. If so, the flow of cultural benefits from alternative projects might be able to be compared. A limited step in this direction is provided by the example of Nijkamp (1995), who put together a composite index of different characteristics of historic urban districts evaluated according to a range of criteria. Alternatively, this set of characteristics can be placed in a broader context of public policy-making where the cultural value of the arts and culture is seen as a valid reason in its own right for government intervention [Holden (2004)].<sup>18</sup>

Nevertheless, it has to be recognised that comprehensive and replicable methods for assessing cultural value in these terms remain to be developed and applied. In the meantime, evaluation procedures derived from economic analysis have much to offer. Even if

<sup>18</sup> See also Ellis (2003) and the RAND Corporation report by McCarthy et al. (2004) which identifies the intrinsic benefits of the arts as a neglected area in contemporary policy-making with its stress on the instrumental (economic) benefits of culture; for a multi-disciplinary collection of essays on aspects of cultural value see contributions to Hutter and Throsby (2006).

they cannot capture those elements of cultural value that are not expressible in monetary terms, or that cannot be factored out to individual utilities [Throsby (2003)], they can at least provide important insights into the value of cultural heritage to individuals and to society, and make an important contribution to heritage policy-making, an area that we turn to in the following sections of this chapter.

## 5. Public intervention in heritage markets

Following the conventional normative approach of welfare economics, a long-sighted government adopting a public interest stance is assumed to provide efficient remedies for market failure through the use of the different tools of government intervention. In the case of heritage, market failure is presumed to arise through the existence of public goods, externalities, asymmetrical information, etc. and these arguments are usually put forward to justify public intervention aimed at avoiding under-provision of heritage services.

Government action to correct for market failure in the heritage area can follow different patterns involving direct or indirect intervention and using instruments with monetary or non-monetary content. Public spending, taxation and regulation are the tools usually adopted to promote heritage conservation, together with other wider instruments such as education, which can be used to spread information and improve citizens' awareness. These tools are summarised in the following table:

	Monetary	Non-monetary
Direct	Public expenditure	Hard regulation
Indirect	Tax expenditure	Soft regulation

*Public expenditure* involves both direct funding for the maintenance, operation and restoration of publicly-owned heritage and museums, and subsidies to private and not-for-profit entities. *Tax expenditure* refers to the provision of tax incentives to private individuals or firms who spend money on maintaining or restoring their own heritage properties or who donate funds to heritage causes.<sup>19</sup> There is a crucial difference between direct and indirect financial support; in the former case decisions regarding the size and the composition of heritage support (for instance, which monument should be restored or which form of art should be supported) are taken by the public decision-maker, while in the case of indirect financial support through the tax system, funding decisions are private and the policy outcome is likely to differ. Frey (2003), looking at the overall arts sector (including performing and visual arts) argues in this respect that private decisions might support a broader range of artistic activities than public

<sup>19</sup> See further Chapter 36 by Schuster in this volume.

ones, including those activities that are more controversial and experimental, since public decision-makers tend to shy away from scandalising public opinion.<sup>20</sup> However, this might not be the case when dealing with heritage; private decisions might be driven by the prestige of the monument or the institution gaining support, thus directing intervention toward well-known objects and institutions. Moreover, any comparison depends also on the functioning of the public decision-making process, whether it is supply-oriented or demand-oriented and how powerful is lobbying in influencing it, as will be discussed further below.

*Regulation* refers to restrictions or modifications imposed on the activities of economic agents in line with government policy objectives. In the heritage case, regulation is aimed at controlling the stock of heritage, its size and its quality. Following Throsby (1997, 2001) we can distinguish *hard* and *soft* regulation; the former involves enforceable acts, such as listing, permissions, authorisations, demolition orders, standards and penalties for non-compliance, while the latter consists of non-enforceable directives (charters, codes of practice, guidelines, etc.) implemented by agreement and not involving penalties. In the heritage field regulation has certain advantages compared to other government tools. Its adoption or removal takes less time than is required for other forms of public intervention such as subsidies or tax expenditures, and therefore it allows for a greater timeliness of public action. Flexibility, in fact, can be extremely useful in heritage to cope with the necessity for quick decisions and to avoid the infinite costs linked to irreversible decisions; such flexibility might be exercised, for example, in the rapid imposition of an order preventing the demolition of a listed building until such time as a full evaluation of the consequences has been undertaken.

However, some specific problems arise when regulation is applied to the heritage field. First, the identification of the scope and the range of intervention is a matter of discretion to a greater extent than in other fields of public policy because the definition of heritage is not straightforward. Moreover, such discretion varies according to the different types of heritage. For outstanding heritage with characteristics of uniqueness, such as items on the World Heritage List, no discretion problems arise and any decision about conservation comes of necessity under the scrutiny of public opinion. On the other hand, for minor heritage the extent of regulation as well as the type of intervention to be carried out might be by no means so clear-cut. In such a case, the identification of the scope of intervention is a matter for discussion based, for example, on evaluations made by hired experts who are well informed but may have contrasting views on orders of priority. As a consequence, the type of expert (archaeologist, art historian and so on) involved in this kind of decision, and the features of the decision-making process, are likely to be quite important in determining the size and the composition of the stock of cultural heritage, as well as the type of conservation that can take place.

Listing of heritage, whether based on local, national or international significance, is a regulatory instrument existing in most countries. Lists can be a useful source of

<sup>20</sup> On whether governments might prefer to avoid supporting arts which can give rise to controversies, see Zolberg (2000).

information concerning the social value of heritage and might offer the opportunity for voluntary collective action to preserve the listed items [Schuster (2004)]. However, whether the provision of information in this way is of itself an effective tool to stimulate individuals' and groups' concern for heritage is an open question. Indeed, there is little evidence in this respect, apart from observations of the stimulus exerted by the UNESCO World Heritage List in leading to improvements in visitor facilities and in cultivating regional and national pride. In practice listing, especially when coupled with other government actions, is not neutral. It affects prices as well as market decisions and may have relevant distributional implications because of the costs and benefits it generates.

The economic impact of regulation on the heritage market varies also according to the types of costs it imposes. In addition to the administrative and bureaucratic costs related to the drawing up of regulatory legislation and the monitoring of its effective implementation, regulation generates compliance costs imposed on all those private and public actors who have to comply with the prescriptions. Some of these costs can be foreseen in advance because they are closely connected to the conservation task (for instance, the requirement to use special materials and qualified operators to ensure quality of maintenance or restoration works); others are subject to a high degree of uncertainty as a consequence of the regulator's decisions. In the latter case, a modification to a building allowed by urban planning authorities might not be permitted by the heritage regulator [Rizzo (2003)]. Moreover, whenever heritage involves a combination of different styles and historical periods, as often happens in Italy, any discovery made while the work is in progress may reduce the scope for planned use. In such a situation the heritage authority may give priority to the preservation of the new discovery and as a consequence will interrupt the work and/or will impose changes compatible with the new discovery [Pignataro and Rizzo (1997)]. Finally, there are the indirect costs imposed on any activity that interferes with heritage; for instance, [Peacock (1995)] refers to the considerable hidden costs imposed by planning regulations, for example, those requiring the diversion of roads to protect archaeological sites. As will be pointed out below, these costs should not be disregarded and indeed some form of evaluation of the economic consequences of experts' decisions is highly desirable.

It is clear that no single policy tool is likely to be successful on its own in giving effect to heritage policy; rather what matters is how different instruments are combined and which level of government is entitled to use them. In many cases, a given tool can be used as a complement or a substitute for others. Complementarities arise between public subsidies and regulation when private cultural activities are publicly funded; for example, a private owner receiving public financial support for restoring a historic building might be compelled to carry out the project according to precise rules and may be obliged to allow for public visits. On the other hand, regulation and public funding can act as substitutes when a public activity related to heritage is privatised; for instance, if a publicly-owned building is sold to the private sector to be re-used, regulation can be applied to ensure that government objectives in regard to the building's heritage quality are fulfilled.

## 6. Public-choice approach to heritage decision-making<sup>21</sup>

In a principal-agent model of a representative democracy, politicians are construed as the agent of citizens and, in turn, the principal of the bureaucracy. Given that each actor pursues the maximisation of its own utility (politicians want to be re-elected and bureaucrats want to better their careers), the outcome of the public decision-making process in terms of society's well-being will depend on its institutional design, i.e. on the incentives imposed on the various agents. In the heritage case, uncertainty about the definition of cultural heritage and the lack of voters' information weaken the control on political representatives; also politicians may suffer information shortage because of the specificity of the knowledge and expertise required to understand heritage issues.

The institutional features of the decision-making process in the heritage field may vary. Delegation from politicians to bureaucrats can be *complete*, i.e. implemented with the institution of independent agencies, or *incomplete*, in the sense that politicians and bureaucrats interact, where the bureaucrat is assigned some goals by the politicians and chooses the tools to fulfil them [Alesina and Tabellini (2004)]. Moreover, different levels of government may be involved in various ways. Nevertheless, in most jurisdictions it seems realistic to describe the policy-making process as one in which politicians and bureaucrats interact, with the definition of goals and the decisions concerning the financing of cultural policies being determined at the political level, while the implementation of the policies is delegated to bureaucrats.

Typically decision-makers enjoy a high level of discretion, but face conflicting demands for conservation. In these circumstances there is room for bargaining and for rent-seeking activities. How the different interests will be represented and satisfied will depend on the institutional design, especially on the mechanisms used to prevent the opportunistic behaviour of agents, reducing their information advantage. It can be reasonably argued that heritage conservation is an avenue of government expenditure that enjoys general public support.<sup>22</sup> Moreover, an ageing society is likely to support an increase in heritage conservation, especially in a globalised context when cultural identities can be perceived to be at risk [Benhamou (2003)]. These various demands are likely to be stronger the less visible the opportunity cost of conservation. Public opinion can be considered as being subject to a form of "fiscal illusion" with respect to heritage conservation, especially when regulation such as listing is used. This proposition is based on the assumption that conservation generates mainly benefits for the community; costs, if any, are concentrated on the owners of listed buildings and/or those otherwise directly affected by the regulation.

Other issues are relevant in shaping the decision-making process. If heritage deteriorates or is misused, bureaucrats will suffer. Because monitoring of bureaucrats by the

<sup>21</sup> For an extensive analysis of the public choice approach see Mueller (2003); an overview of the implications of public choice literature for the heritage case is provided by Mazza (2003)

<sup>22</sup> This might be inferred, for example, from more general evidence for public approval of government support for the arts and culture; see Frey (2003).

politicians will be incomplete, they are subject to moral hazard and will therefore have an incentive to adopt a more cautious (i.e. conservationist) stance. Therefore they will seek to minimise the risk of irreversible losses, such as those caused by demolition or radical transformation of a building, and will oppose the use of historical or archaeological sites or buildings for mass events such as rock concerts, which can lead to the deterioration of heritage. The term “conservationist” refers also to a more general attitude leading to the unjustifiable enlargement of listing and to the implementation of very strict requirements for conservation, well beyond the correction of externalities; as a consequence the full enjoyment and utilisation of heritage can be endangered, for instance when restrictions prevent alterations needed to bring the interior of an old building up to modern standards of comfort. Bureaucrats will thus have an incentive to act in a very restrictive way. Such an incentive will be even stronger if the existing legal system makes them liable for any damage the heritage may suffer from the activities carried out on the site [Rizzo (2003)].

Thus in the heritage field the range and intensity of regulation appears to be not simply a policy instrument but rather an endogenous product of the public decision-making process [Rizzo (2003)]; from this perspective, it is not without significance that the large discretionary power enjoyed by regulators is coupled with the widening scope and extent of heritage observed in some countries.<sup>23</sup> It is worth noting also that a sustainability issue arises from the enlargement of the concept of heritage because “delisting” proves to be highly unlikely. These considerations may help to explain why economic advice tends to find a greater “barrier to entry” into the decision-making process in the heritage conservation field than in other areas of cultural policy [Peacock (2004)].

Similar arguments can be developed with respect to the international circulation of works of art [Giardina and Rizzo (1994)]. The alleged normative rationale for regulating the international movement of works of art is the preservation of the visual arts and the protection of national identity and prestige. However, doubts arise as to the effectiveness of such a policy tool, since excessive regulation might induce collectors and/or dealers to leave the official economy and to undertake their exchanges in the underground sector; the likelihood of such an event is greater the smaller the risk of punishment, which is in turn a function of the amount of resources government allocates to monitoring activities. A different argument can be made to question regulation preventing the sale of the works of art belonging to public museums. Many museums exhibit only part of their stock;<sup>24</sup> scarce resources are mainly used for conservation, and there is no room for an acquisition policy consistent with the specific artistic vocation of the museum. If museums (regardless of whether they are privately or publicly owned) were allowed

<sup>23</sup> Benhamou (2004) reports that the number of listed historic monuments in France more than doubled between 1962 and 1999 and that the same happened in the UK in the period 1990–2000.

<sup>24</sup> According to Grampp (1996, p. 225), many museums exhibit 10 percent or less of the objects they have in their collections, including the Art Institute of Chicago (3 percent), the Hermitage in St. Petersburg (7 percent), the Prado in Madrid (9 percent) and the Alte Pinakothek in Munich (10 percent). An exception is the Louvre in Paris which is reported to display well over 50 percent of its paintings.

to sell or to exchange works of art that are not strictly connected with the museum's artistic interests, they could use the proceeds to finance new acquisitions, thereby enriching the existing collections.<sup>25</sup> Mutatis mutandis a similar argument applies in the archaeological field; some museums which collect material from an archaeological site store thousands of identical items (small amphorae, pottery, etc.), none of which has peculiar features. Once an adequate number of them is kept, the others might conveniently be sold and the proceeds used to finance either the proper conservation of the museum exhibits or the acquisition of new items. A good example is provided by the Pompeii archaeological site, where thousands of identical amphorae have been found and are currently stored while new discoveries or the conservation of the existing ones are constrained because of budgetary stringency. In these circumstances protectionist arguments for regulation cannot be justified on efficiency grounds.

It is apparent from the above discussion that institutional design may have a perverse impact: if the decision-making process is mainly affected by bureaucrats/experts' interests, it is likely to bring about consequences that contrast with the claimed objectives of conservation policy. Even if the society's demands might *seem* to be satisfied, this depends on the low visibility of conservation costs and on the general issue of asymmetrical information which does not allow for a clear perception of sustainability effects. The extent of such an argument depends upon the degree of autonomy experts are granted and on the incentive schemes faced by the bureaucrats. Therefore, devices are needed to improve taxpayers' influence on public decisions, bearing in mind that these decisions will still need to rely on experts.<sup>26</sup> One way of achieving this would be to follow Peacock's (1994) suggestion that public participation could be enhanced if greater openness were to characterise the appointments of "lay" persons to decision-making bodies and if citizens who are active in heritage matters were allowed to vote for their own representatives within these bodies. Moreover, to fulfil the same purpose, compulsory consultation and review procedures might be introduced into the public decision-making process. However, the benefits of a greater political participation should be weighed against the likely increase in administrative and time costs which would derive from it.

From this perspective a relevant argument is that devolution, as Schuster (1997) defines it, increases the accountability of government and allows for a better control of the decision-making process. In the heritage case this implies that lower levels of government are entitled to use all the means – regulation, expenditure and taxation – available to pursue the objectives of heritage conservation and, as we shall show in the next section, this can have an impact on the policy outcome.

<sup>25</sup> See further Chapter 29 by Frey and Meier in this volume.

<sup>26</sup> The need for a governance structure to define a mechanism to restrain the discretionary scope of regulators is common to regulation in general [see Levy and Spiller (1996)].

## 7. Devolution in the formation and implementation of heritage policy

### 7.1. *Advantages and disadvantages of devolution*

The normative rationale for devolution is well known: the allocation of functions among the various layers of government should take account, among other things, of the geographical coincidence between taxpayers and beneficiaries of a given good or service. Such a conventional argument acquires specific relevance in the heritage field. The scope to be assigned to devolution in this field is likely to be larger than is usually claimed, because spillover effects are internalised [Rizzo (2004)]. Sub-central levels of government in fact will promote heritage conservation even when the geographical coincidence does not hold; the more important a particular item of heritage and the wider its reputation, the greater are the external benefits related to its existence and the beneficial impact it can exert on tourism and, as a consequence, on the local economy [Brau, Lanza and Pigliaru (2003), Cellini (2004)].

However, to rely mainly upon tourism motivation in defining heritage policies might create problems; apart from congestion, it might bias policy, leading to undervaluation of other long-term benefits related to cultural value but less visible in the political market. For instance, such undervaluation might affect policies directed at the education of younger generations in order to raise their appreciation for the arts; if these policies are successful, the need for public support to the art sector could eventually be reduced. At the same time, if the rationale of economic development promoted by tourism prevails, devolution might lead to a concentration of resources on heritage with higher economic return, penalising minor heritage that may be closely connected with local identity and history but of lesser economic value [Mazza and Rizzo (1998)], although such an effect might be mitigated by the presence of voluntary local associations devoted to preserving minor heritage because of its relevance to the local community. A further issue is that stressing the tourism motivation can give rise to other problems such as the imposition of values that conflict with local tradition and identity, a problem that can be significant in developing countries. Again, the relevance of decision-making process and of the motivations underlying it comes into the picture.

A positive aspect of devolution is that it may be helpful in overcoming or reducing the sorts of asymmetries in information discussed in the previous section. In general it can be argued that devolution improves citizens' information by allowing comparison among different alternatives, and also that the existence of many agents improves the principal's information.<sup>27</sup> The issue acquires specific relevance in the heritage case where public policy can offer a variety of solutions; hence comparison may turn out to

<sup>27</sup> The extreme consequence of this is described by the well-known phenomenon of people "voting with their feet" [Tiebout (1956)]; i.e. rational individuals exit communities which offer less attractive packages of taxes and local public goods to move to others offering more attractive packages.

be useful. Moreover, there is every reason to believe that sub-national tiers of government will be able to interpret the need for conservation better than the central government, given that the link between heritage and citizens is closest in the community in which the heritage is located.

This issue is relevant in multicultural societies where local governments can be considered more suitable for providing services for different ethnic groups and for promoting the participation of minorities [Fondazione Eni Enrico Mattei (2003)]. It would be interesting to investigate how such participation, coupled with the extension of the right to vote to immigrants and ethnic minorities, would affect the outcome of the political decision-making process as far as local heritage conservation is concerned. In multi-ethnic societies the heterogeneity of preferences weakens the assumptions behind fiscal federalism. Oates' theorem demonstrates that heterogeneity within a specific community does not necessarily ensure the superiority of a decentralised provision of public goods and services in terms of social welfare. Equally it has been demonstrated [Bridgman (2004), Alesina, Baquir and Easterly (1999)] that, when there is majority voting, ethnically heterogeneous jurisdictions tend to provide smaller amounts of public goods than homogeneous jurisdictions. These effects are more pronounced in the heritage case because in a multicultural society the concept of local identity is more controversial than in a homogeneous society; as a consequence, if resources are devoted to promote local heritage as a symbol of local identity, such a decision is costly for those who do not recognise themselves in such an identity and have other priorities in terms of local public goods. Moreover, stressing local identity through heritage might reduce rather than strengthen integration of multicultural minorities. Overall it is not clear whether the net effects of decentralisation in this case will be positive or negative.

A final advantage of devolution is that the monitoring of bureaucratic behaviour is likely to be simpler and easier at the local level (assuming the system favours political accountability), since the opportunity costs of bureaucratic decisions can be more readily observed. The fact that bureaucrats can be monitored might make it easier, for instance, to adopt at local level codes of practice or guidelines agreed between the regulator and those involved in conservation activities (architects, building firms, engineers, cultural associations, etc.); such procedures reduce the uncertainty related to investments in heritage conservation.

## *7.2. Practical issues*

We turn now to some practical issues relating to devolution. The implications of devolution for heritage policies can be quite different according to the kind of heritage existing in the region. Consider, for example, the case of outstanding ("superstar") heritage items. For such heritage the choice between devolution and centralisation is not crucial because, as noted above, the unique characteristics of the heritage affect the decision-making process in similar ways regardless of the level at which policy is made. In addition, financial constraints are likely to be less stringent in the case of outstand-

ing heritage even if it is located in a poor region, because private sponsorship will be more willing to provide financial support for the conservation of this heritage than for less well-known heritage. At the same time, in a devolved context the existence of outstanding heritage might lead to complementary policies for the conservation of minor heritage within the same area, using the attractiveness of the former to promote income-generating uses for the latter. Policies tend to be easier to promote if decisions are taken by one decision-maker, i.e. the sub-central level of government, while transaction costs will be higher if an agreement has to be reached between different layers of government, each with different responsibilities. An interesting example is the case of City Museums in Venice where network economies are generated: a visit to the Palazzo Ducale, which is an item of state heritage and whose management has been assigned to the city, is offered in a package with a visit to the lesser museums in Piazza San Marco, with the positive result that the local government “makes profits” out of them [Zan (2001)].

Devolution might also lead to enlargement of the range of what is perceived as “culture” in particular locations. For example, visitors to a city or region might be offered a package including visits to minor sites and museums, attendance at performances which take place in historic buildings or archaeological sites, visits to handicraft ateliers, and so on. Different types of itineraries can be designed around a leading theme. To illustrate, in Italy at the regional level “wine routes” are designed to present unfamiliar heritage associated with specific social and economic functions, illuminating local history and producing an impact on the related economic activities. Another example is the so-called “literary parks”, where an itinerary is created to illustrate the work of famous writers and to experience the places that gave birth to them and inspired their masterpieces. In these sorts of cases, horizontal cooperation among local governments is usually needed and the free-rider problem is likely to be overcome by the mutual interest in gaining the benefits deriving from a joint cultural supply. Devolution matters because it may contribute to the creation of a “virtuous circle”, developing a common strategy among different partners such as local governments, economic and cultural operators, crafts makers, associations and so on which can be helpful in supporting minor heritage, enhancing its capability of providing income-generating services.

A further argument in support of devolution relates to the potential conflict which may arise between different levels of government when a central or regional regulatory power impacts upon urban policy carried out at local level. For example, local government decisions on matters such as urban renovation may be constrained by regulation established and implemented at a regional level [Mazza and Rizzo (2000)]. If so, a conservation decision taken at the regional level will produce costs and benefits for a set of voters that are relevant for politicians at the local level but are not taken into account by the politicians at the higher level of government. As a likely consequence, self-interested regional policy-makers will find it convenient to adopt strict rules, since the social costs will be borne only by local owners within the local jurisdiction which is not relevant for them, and the benefits will be spread out over the whole population.

### 7.3. Summary

To sum up, we have argued that the issue of devolution acquires special relevance in the case of minor heritage. The argument rests on the assumption that at local level a better representation of citizens' preferences is likely to occur as well as better scrutiny of public decisions, which can be expected to induce decision-makers into taking account of the opportunity cost of their choices. Moreover, at a devolved level it is easier to identify those who gain and those who lose from regulation; members of the latter group may have more room to organise themselves, acting as watchdogs rather than being only passive adjusters to heritage authority decisions made higher up. This does not mean that devolution will necessarily provide optimal solutions, but only that the decision-making process will be less supply-oriented. On the other hand, the opposite argument, invoking central decisions to reduce the role of local pressure groups opposing conservationism, leaves unanswered the sustainability question and is less likely to satisfy the society's demand for conservation.

Nevertheless, the findings of recent research on heritage policies in Sicily [Rizzo and Towse (2002)] indicate that unless an adequate incentive system is introduced in the decision-making process, devolution as such is not enough to bring about improvements in the accountability and responsiveness of heritage authorities to public opinion or the introduction of better economic management of cultural institutions. Thus, despite devolution, museums in Sicily have not improved their performance, paying little attention to the needs of visitors, with limited use of multimedia information and a lack of strategic cooperation among different institutions at the local level. In addition, public opinion has not been mobilised, with few voluntary associations such as "museum friends" compared to other Italian regions. A possible explanation may be found in the institutional features of the Sicilian case; lack of real fiscal autonomy coupled with a proportional voting system have led to low levels of accountability of regional government in Sicily and high political instability, weakening the instruments of control over bureaucracy. Although political and administrative reforms have been recently introduced to improve political and bureaucratic accountability in this region, it is not clear whether they will bring about any change in the management of heritage and museums.

## 8. The role of the private sector

### 8.1. Effects of regulation

The role of the private sector in heritage conservation can be analysed from different perspectives: individuals and firms are private investors when they are owners of heritage and are directly involved in conservation; at the same time, other private agents contribute with donations and sponsorships to heritage projects of various sorts. The behaviour of these private participants in cultural heritage is based on a variety of motivations and is affected by whatever mix of policy instruments might be chosen.

Regulation affects private decisions to invest in heritage conservation and therefore shapes the public–private mix in the heritage market. If regulatory decisions are taken adopting a conservationist stance, private investors will face uncertainty and higher costs and are likely to be discouraged. The extent of such an effect, however, depends on the policy mix, i.e. whether direct or indirect public spending is coupled with regulation. If public financial support is indeed to be provided to the owners of listed buildings, the question arises as to how it should be designed. Direct spending leaves more room for discretion for the decision-maker to identify the eligible beneficiaries, while tax allowances are automatically enjoyed by all the owners of listed buildings. As far as effectiveness and equity are concerned, the effects will depend on how these tools are actually shaped. For instance, subsidies might be in the form of matching grants, tax allowances could be designed as tax exemptions or deductions, and so on. In regard to equity, tax allowances are generally likely to favour rich taxpayers compared with direct spending.

Empirical evidence allowing a comparison to be made between different countries is difficult to find. It is not so easy to isolate the impact of regulation from other policy measures. Feigenbaum and Jenkinson (1984) found that in the United States both the grants-in-aid and tax credit programs had a positive effect on per capita preservation expenditure and no major differences were found in the effectiveness of these tools. Benhamou (2004) points out that in France an extensive system of financial support does exist for private expenditure on conservation; overall, private owners of listed buildings benefit from listing, as shown by the difference in value between listed and non-listed buildings.<sup>28</sup> This differential is smaller in the United Kingdom because, whereas French regulation concerns only visible parts such as the façades, in the United Kingdom it refers to the entire building. No evidence exists for Italy as far as the impact of heritage policy on prices is concerned, but it can be presumed a priori that a disincentive effect is likely to exist.

## 8.2. *Sustainability in heritage financing*

Turning to the sustainability issue, we note that the likely unintended consequence of a conservationist stance might be the crowding out of private investment for conservation, if public spending is not directed toward compensating owners for the financial burden involved. To what extent this occurs is an empirical matter but the effect would be to reduce the overall amount of available resources for heritage conservation. On the other hand, if private investment is not crowded out by public spending, a conservationist stance will produce increasing pressure on public funds because, as noted above, listing is likely to expand; whether such pressure is sustainable depends among the other

<sup>28</sup> If, as appears to be generally the case, listing increases the market prices of buildings, owners benefit and might therefore be expected to bear a greater share of the cost of conservation; see discussion in Benhamou (2004) and Creigh-Tyte (2000).

things on the stock of heritage as well as on the strength of financial constraints. If the size of the stock is huge relative to GDP, a sustainability issue arises; heritage is likely to deteriorate, which is the opposite effect to that desired. This effect is likely to be self-perpetuating, producing increasing pressure on public funds and further decay. The same negative result is reached if private owners, because of the stringency of regulation, undertake their activities without complying with existing rules; the likelihood of this outcome is greater the lower the owners' risk of punishment. In all these situations, effective monitoring of the impacts of regulation is difficult because of the amount of resources required.

The above considerations suggest that no unique conclusion can be drawn as to the desirable path in the policy mix, since the solution will depend crucially on particular countries' features. [Netzer \(1998\)](#) offers an emblematic example comparing USA and Italy with respect to the ratio of annual heritage capital consumption to GDP, reaching the conclusion that in Italy the costs required to maintain the capital stock are unaffordable. He estimates that in Italy the capital consumption allowances would amount to nearly 35 percent of GDP while in the USA it would be only 0.05 percent of GDP. In fact, total public spending on culture in Italy comprises a low percentage of GDP (0.67 percent), which is around the average of OECD countries; almost half (45 percent) of such expenditure is devoted to heritage rather than to other cultural goods [[Pasquali \(2003\)](#)]. Thus Italy's public effort, though financially comparable with other countries, is inadequate to the heritage conservation task, calling at least for the introduction of an opportunity cost criterion into the decision-making process, whereby any decision in regard to heritage should take into account the costs and benefits stemming from different stances (conservationist vs. non-conservationist).<sup>29</sup> However, the public decision-making process in Italy has not been designed to take into account such a constraint; indeed, it offers an example of the "fiscal illusion" issue mentioned above. Listing applies only to private heritage while until recently any public item older than 50 years was considered by definition part of heritage, to be conserved regardless of its condition. Only recently has the possibility been introduced of selling these latter items provided that, after a complex bureaucratic procedure, heritage authorities agree that the item to be sold lacks any historical or artistic value and impose only weak constraints on the buyer in terms of allowed uses. Public opinion as well as experts have reacted strongly against such a possibility, claiming that Italian heritage was at risk but without suggesting alternative ways to find resources for the prevention of heritage decay. Interestingly enough, the relevant law was originally proposed by the Ministry of Treasury, with the clear objective of raising money from the sale of public property; a different and less conservationist mentality within the heritage authorities might have allowed for a more coherent policy based on clear cultural priorities and on more precise guarantees [[Rizzo \(2005\)](#)].

<sup>29</sup> However, as has been pointed out in Section 6 above, this is no easy matter.

How conservationist should public policy be? If a conservationist stance makes it difficult to pursue income-generating uses, it might have a negative impact on the conservation of historical districts etc. and therefore on the promotion of sustainable local economic development. The arguments put forward above would suggest that the larger the size of heritage stock, the less conservationist public policy should be. On the other hand, it might be argued that if attention is paid to other potential sources of support for heritage, such as forms of supra-national intervention or of international philanthropy, a conservationist stance might be perceived as a signal of quality, thereby creating the impression that the support is warranted. However, the extent of such an effect in reality does not seem significant enough to justify a reorientation of domestic heritage policy.

### 8.3. *Philanthropy and heritage*

We turn finally to the role of the private sector in the areas of philanthropy, sponsorship and voluntary action in support of heritage.<sup>30</sup> To encourage private giving in its various forms, governments mainly provide indirect support to individuals and business, via tax exemptions; however, direct support is also sometimes involved, as occurs when matching grants are given to arts institutions on condition that an equivalent amount of private support is raised. Public policies follow different patterns in different countries [Mussoni (2003)]. In some countries, such as the United States, the United Kingdom and recently Italy, equal tax treatment is accorded to patronage and sponsorship, while in other countries, such as France and Germany, tax treatment differs. Moreover, most countries, including the United States, the United Kingdom, France and Germany (but not Italy) provide tax incentives not only to monetary giving but also to in-kind giving. Of course, different tax devices have different effects. A tax system which is neutral with respect to the donor/sponsor choice is likely to strengthen private influence on cultural decisions; this may be perceived as a challenge to the development of culture as the autonomous outcome of the democratic collective decision making process, insofar as the control over the use of resources (of voters through their representatives) might be partially given up because private donors/sponsors would decide priorities. In the specific heritage field, as noted above, private decisions might be driven by the prestige of the monument or the institution concerned; for instance, in Italy empirical evidence shows that private contributions have privileged well-established institutions to pursue highly visible restoration activities.

The different policy measures in different countries give rise to varying patterns of private giving. As far as corporate support for the arts is concerned, Kirchberg (2003) notes that differences, though still consistent, have reduced in recent years. Mazza (1994) suggests that a possible explanation of differences in private giving among countries may lie in the fact that when the provision of cultural goods is primarily a government responsibility, social recognition for donations is low; therefore, sponsors

<sup>30</sup> See further Chapter 36 by Schuster and Chapter 37 by Katz in this volume.

will not have sufficient economic incentive to support the arts, and only patrons, who are not interested in social approval, will provide their support.<sup>31</sup> Such an argument is in line with empirical evidence in Italy, a country in which traditionally heritage conservation is considered a public duty; [Mussoni \(2003\)](#) reports that the overall amount of private giving in the first two years of the implementation of a new law encouraging private cultural support has been more modest than expected. Moreover, only 37.4 percent of private contributions have been directed to heritage while 62.6 percent have been devoted to support for the performing arts.

The United States case is widely taken as an example to stress how social norms or shared social recognition of the importance of the arts provide the fertile humus in which tax incentives act as effective tools to stimulate private contributions. This does not mean that the same tax scheme will exert similar effects everywhere because private support in whatever form is the result of a complex array of elements specific to each country.

## 9. Conclusions

In this chapter we have endeavoured to show how economic theory and public policy analysis can illuminate decision-making relating to cultural heritage. Several themes run through our discussion. First, we have argued that from an economic point of view the appropriate conceptualisation of heritage is as capital. In theoretical terms this opens up rich possibilities for analysing the productivity of heritage, and for formulating strategies for heritage investment; the distinctively cultural character of the capital assets under consideration adds a specific and challenging dimension to these analyses. In policy terms, regarding heritage as a capital asset places it alongside other items of the economy's capital stock for which governments have some responsibility, and conditions the application of the principles of public finance to this area.

Second, our concern throughout has been with sustainability. Our theoretical discussion has been particularly concerned to formulate conditions for defining sustainable development paths for cultural heritage. These considerations have informed our treatment of heritage policy, where maintenance of the cultural heritage stock has been seen as one of the critical issues facing policy-makers in many countries today.

Third, we have stressed that efficient institutional structures are an essential element in delivering sustainable policy outcomes. Questions of the appropriate mix of policy instruments, the allocation of functions between levels of government, and encouraging a positive role for private sector participation are all matters that are facilitated by good institutional design.

Finally, to come back to the beginning, we can reiterate the importance of information, especially via education in the arts and culture field. Public policy supporting

<sup>31</sup> For further discussion of sponsorship, see [O'Hagan and Harvey \(2000\)](#) and [Leclair and Gordon \(2000\)](#).

heritage can provide long term educational benefits, raising social appreciation for the arts and perhaps eventually reducing the need for increased public subventions in this area.

## **Abstract**

Museums fulfill many important functions in the art world and visits to museums are becoming an important leisure and holiday activity. This chapter surveys research about the functioning of museums from an economic point of view. Museum services are shaped by demand and supply factors and by the institutional setting constraining the decision makers in a museum. This chapter argues that the institutional factors, e.g., whether a museum is private or public, influence greatly how the museum is run with respect to the management of the collection, price setting, or the focus on commercial activities. Two current trends, the evolution of superstar museums and the growing importance of special exhibitions, are analysed from an economic point of view.

## **Keywords**

museums, collection management, pricing, commercial activities, superstar museums, special exhibitions

*JEL classification:* Z1

## 1. Introduction

Museums are becoming more important nowadays than ever before. They play a significant role in people's leisure activities and constitute important tourist attractions. Consumers spend substantial amounts of money visiting museums, both in terms of admission fees and expenditures in museum restaurants and shops. These expenditures have a strong effect on local economies, especially in popular tourist areas. There are many types of museums, classifiable according to four different criteria:

- *Content*: Museums may contain art, historical artifacts, scientific objects, and/or many other exhibits of general and sometimes very specific interest.
- *Size*: Some museums are huge and draw thousands of visitors a day from far and near; others are small, have few visitors, are run by amateur staff, have very restricted opening hours and are only of local interest.
- *Age*: Some museums lay claim to a long and distinguished history and are often situated in very old buildings, while others are newly founded and may impress visitors with their spectacular architecture.
- *Institutional form*: Traditionally European museums have been public, even forming part of the normal government administration. But there have always been private museums. Most museums are neither completely public nor private but lie somewhere in between. Almost all private museums receive some form of government subsidy, often in the form of contributions made by donors, who can claim tax exemption.

Despite these various differences, however, all museums share some particularities and similar functions.<sup>1</sup> This chapter analyses the various types of museums and points out where different aspects are crucial for understanding the behaviour of museums.

The term "Economics of Museums" may be understood in two different ways:<sup>2</sup> First, a museum may be looked at as an economic unit, or as a firm providing certain services. The analysis then focuses on the relationship between the input (exhibits, manpower, etc.) and output measured, for example, in terms of revenue. Moreover, the effect of museums on the economy may be analysed, e.g., how much employment is generated and

<sup>1</sup> A museum might have five different functions: to collect, conserve, study, interpret and exhibit [Noble (1970)]. These five functions could be condensed into three: preservation, research and communication [Weil (2002)]. Ginsburgh and Mairesse (1997) take an empirical look at the mission statement of Belgian museums and propose an alternative definition of a museum.

<sup>2</sup> The Economics of Museums has been the topic of a number of publications, including Montias (1973), Peacock and Godfrey (1974), Feldstein (1991), Bayart and Benghozi (1993), Frey (1994), Martin (1994), Robbins (1963), O'Hagan (1995, 1998b), Johnson and Thomas (1998), Schuster (1998a, 1998b), Benhamou (1998), Meier and Frey (2003), Maddison and Foster (2003) and Weil (1987). It has also been covered in more general surveys [Throsby (1994); Blaug (2001)], in monographs and textbooks [Frey and Pommerehne (1989); Frey (2000); Heilbrun and Gray (2001); Benhamou (2000)] and in readers in the field of cultural economics [Blaug (1976); Peacock and Rizzo (1994); Ginsburgh and Menger (1996); Towse (1997a)]. Early contributions in German are by Kindermann (1903), and in English by Robbins (1963, 1971), Baumol and Bowen (1966) and Peacock (1969).

how much added value is created in other sectors. Second, applying an economic way of thinking to museums involves assuming that individuals pursue their utility within the constraints imposed by institutions and the environment, especially where resources are scarce. This methodology has been applied to many different areas, such as politics, law, history, sports, or religion.<sup>3</sup> The economics of museums thus clearly distinguishes itself from other ways of studying museums, in particular the sociology of museums or the art historic points of view.<sup>4</sup>

The economic approach to museums may rely on standard or rational choice theory derived from neo-classical economics; individuals are then taken to be completely rational and selfish, and the analysis focuses on market relationships, which are assumed to function well. Political economy or public choice economics studies the behaviour of governments and public administrations as they affect museums, not only through subsidies and taxes but also through the web of regulations. Other types of economic theory may also be applied. In the context of museums, a particularly important variant is to take psychological aspects into account: individuals are not totally rational and are sometimes subject to anomalies, and they may to some extent be other-regarding and act in a pro-social way.

This chapter proceeds by looking first at the demand for museum services and then at the supply. Museum behaviour is analysed from a neoclassical and then from a more institutional perspective. The next section is devoted to public policy issues connected with museums, and the last section discusses current trends in the museum world from an economic point of view.

## 2. Demand for museum services

There are two types of demand for museums. The first is the private demand exerted by the visitors. These may be persons interested in the exhibits as a leisure activity or as part of their profession as art dealers or art historians. The visit may be undertaken by an individual or family, or may be part of an organised outing, e.g., by schools or firms. The second type of demand comes from persons and organisations benefiting from a museum. This social demand is based on external effects and/or effects on economic activity.

### 2.1. *Private demand*

By far the largest number of museum visits can be attributed to leisure time activity; since visits by the specialists mentioned above play a relatively minor role, they can be ignored here. The number of visits can be analysed by a traditional demand function,

<sup>3</sup> See, for example, Becker (1976), Hirshleifer (1985), Kirchgässner (1991) and Frey (1999).

<sup>4</sup> For example, Bourdieu (1979), Moulin (1986), Di Maggio (1986), Foster and Blau (1989) and Blau (1995).

capturing the major factors determining the number of visits in any given period of time. There are three major determinants relating to prices or costs:

(i) *Admission fee*. Econometric estimates for a large number of different museums in various countries suggest that the demand for museum services is price inelastic.<sup>5</sup> However, most studies are limited to case studies of one or two museums. For example, Goudriaan and Van't Eind (1985) found an average price elasticity of  $-0.1$  to  $-0.2$  for four Dutch museums. Darnell, Johnson and Thomas (1992) found a higher elasticity of  $-0.55$  for one particular museum in Great Britain. Luksetich and Partridge (1997), using US data from the 1989 *Museum Survey*, estimated demand functions for different types of museums. Their estimated price elasticity ranged from  $-0.12$  to  $-0.26$ , depending on the type of museum. The elasticity for art museums was found to be  $-0.17$ . Zoos, science museums and natural history museums showed the largest price sensitivity, probably due to greater competition from other leisure activities. Overall, the low price elasticities suggest that museums could generate significant increases in revenues through increasing admission fees.

(ii) *Opportunity cost of time*. For persons with high income or who are self-employed, the opportunity cost of time is higher than for people of low income or on fixed working hours who are therefore expected to visit museums more often, all other things being equal. The opportunity cost of a museum visit not only depends on the time actually spent in the museum, but also on how much time is required to get there. For tourists, the opportunity costs of time tend to be lower than for local inhabitants, because they often visit a city with the express purpose of visiting the respective museums. Econometric estimates have found no clear link between income and attendance [Luksetich and Partridge (1997)]; this is in line with Gapinski's (1986) findings for the lively arts. The increased opportunity costs of time for wealthy people attending art performances offset the positive income effect; the two effects have to be separated in order to find a positive income effect and a negative opportunity cost effect on demand.<sup>6</sup>

(iii) *Price of alternative activities*. These are, most importantly, alternative leisure activities such as going to other cultural events (theatre, cinema), taking part in sports, dining out in a restaurant, spending time with friends at home, etc. Even within the industry, one museum may be an alternative to another museum. But complementary costs also systematically influence the number of museum visits; for example, the costs incurred through travel, accommodation and meals may be important. These complementary costs constitute a high percentage of the total costs of a visit; Bailey et al. (1998) estimated them at more than 80 percent. Cross-elasticities have been found to be empirically significant for the arts,<sup>7</sup> but there have been no estimations of demand

<sup>5</sup> Apart from the question of how sensitive the demand is to price increases, there has been extensive discussion about the effect of charging an admission fee at all. For a general discussion about the question of what to charge, see O'Hagan (1995).

<sup>6</sup> See Withers (1980) for estimations for the performing arts.

<sup>7</sup> See Gapinski (1984, 1986) for estimations for the performing arts.

functions for museum services incorporating such variables. Income is another “classical” determinant affecting the demand for museum visits. Econometric estimates reveal an income elastic demand.<sup>8</sup> Estimates of income effects are often ambiguous, because the rising opportunity cost of time goes hand in hand with higher income. There is also a high correlation between income and education; better-educated people have the human capital necessary to benefit more fully from museums than people with lower education.<sup>9</sup> It can be suggested that this factor plays a larger role for museums of modern art and history than for museums of science and technology, especially transport museums (railways, cars, or space travel).

There are many other determinants to be included in a well-specified museum demand function.<sup>10</sup> One is the quality of the collection or the special exhibition mounted. Luksetich and Partridge (1997) estimated that the value of the collection increases attendance figures, especially for art museums. Or, as Oster and Goetzmann (2001, p. 9) state: “In fundamental terms, these results suggest that art matters.” Other determinants are how attractive the building is and the level of amenities provided by the museum, i.e. the general atmosphere, the extent of congestion in front of the exhibits, the cafés and restaurants, and the museum shop. The marketing efforts made by a museum also matter. A final determinant of the rate of museum visits is that of individual preferences, which are difficult to measure independently. Econometric studies of museum demand functions often indirectly capture individual preferences by introducing past visits as a determinant. In all empirical estimates, this factor has proved to be highly significant and important: persons who visited a museum in the past are more likely to do so in the present and future.

## 2.2. Social demand

Museums have effects on society which go beyond the experiences of the actual museum visitors themselves. These social effects include externalities and the effects on markets.

### 2.2.1. External effects

Museums create social value for which they are not compensated in monetary terms. As a consequence, museums tend not to produce these values, or in too low an amount. Five types of non-user benefits can be distinguished in the literature:

- *Option value*: People value the possibility of enjoying the objects exhibited in a museum sometime in the future.

<sup>8</sup> See, e.g., Withers (1980).

<sup>9</sup> For the influence of art lessons on museum visits, see Gray (1998).

<sup>10</sup> Many studies analyse surveys about museum visitors in order to see who actually visits the museums [see, e.g., Dickenson (1997)] and how much visitors benefit from their visits [Ashworth and Johnson (1996)].

- *Existence value*: People benefit from knowing that a museum exists, but do not themselves plan on visiting it now or in the future.
- *Bequest value*: People derive satisfaction from the knowledge that their descendants and other members of the community will be able to enjoy a museum in the future if they choose to do so.
- *Prestige value*: People derive utility from knowing that a museum is highly valued by persons living outside their community – they themselves need not actually like the museum, nor even visit it.
- *Education value*: People are aware that a museum contributes to their own or to other people's sense of culture and value it because of that.

Museums may also produce negative external effects, the costs of which are borne by other people. An example is the congestion and amount of noise museum visitors inflict on the local community.

The above non-user benefits and costs have been empirically measured by using three different techniques:

- An obvious possibility is to conduct representative surveys of both visitors and non-visitors to a museum. The questionnaires have to be carefully designed in order to elicit the true willingness to pay for the various social values produced by a museum. Contingent valuation studies, first developed to capture environmental values, have done a good job of capturing cultural values.<sup>11</sup>
- Other techniques rely on the revealed behaviour of individuals, for example, by estimating the extent to which property values increase in a city containing a museum, assuming that people are willing to pay more for a house or apartment situated in a location with a museum compared to an equivalent house or apartment in a location without such a museum. The same “compensating variation” can be computed by analysing wages, if persons are willing to work for lower compensation in a location housing a museum. The compensating variation method has been used, for example, by [Clark and Kahn \(1988\)](#).
- A third approach for capturing social values is to analyse the outcome of popular referenda on expenditures for museums. In Switzerland this approach has been successfully implemented in identifying options, such as the existence and bequest values of buying two Picasso paintings for a museum [[Frey and Pommerehne \(1989, Chapter 10\)](#)]. In the case of the performing arts, [Schulze and Ursprung \(2000\)](#) have analysed a referendum in Switzerland to gauge the amount of support for the opera house in Zurich. They were also able to identify external effects.

### 2.2.2. *Effects on markets*

Museums produce monetary values for other economic actors by creating additional jobs and commercial revenue, particularly in the tourist and restaurant industries. These

<sup>11</sup> See, for example, [Martin \(1994\)](#). The extensive empirical literature is surveyed in [Noonan \(2002\)](#); for a critical discussion from a behavioural point of view, see [Sunstein \(2002\)](#).

expenditures induce further expenditures and a multiplier effect results. Impact studies<sup>12</sup> measuring the additional market effects created are popular with politicians and administrators because they provide them with reasons for spending money on museums. However, these studies have to be interpreted very carefully:

- Impact studies tend to focus on the wrong issue. The *raison d'être* of museums is to produce the unique service of providing a certain type of cultural experience to its visitors, as well as providing non-user benefits.
- It is *not* the task of a museum to stimulate the economy; there are generally much better means of achieving that goal. A theme park, for example, may be better able to stimulate the economy.

### 3. Supply of museum services

#### 3.1. Cost structure

Museums have cost structures that differ from those of other firms in the service industry in at least four respects:

- *High fixed costs.* Museums in general operate with high fixed costs: buildings, exhibits, staff, insurance, technical outfits, etc. cannot be changed in the short run. Thus in the short run the operating costs of museums tend to be independent of output. In other words, variable costs constitute a relatively low percentage of total costs, and hence museums face rapidly decreasing unit costs when the number of visitors increases.
- *Marginal costs are close to zero.*<sup>13</sup> If a museum sets up an exhibition, the basic operating costs consist in opening the museum on a particular day, which to a large extent is independent of the number of visitors. In these circumstances the marginal costs of an extra visitor are close to zero. However, in some circumstances (for example, so-called “blockbuster” exhibitions), an additional visitor may impose congestion costs. Maddison and Foster (2003) analysed the congestion costs at the British Museum using contingent valuation techniques; they estimated that the cost imposed by the marginal visitor was £8.05, an estimate that seems to be exceptionally high.
- *Dynamic cost.* It might be claimed that museums face the same economic dilemma as most cultural organisations, namely the cost disease<sup>14</sup> whereby they are subject

<sup>12</sup> See, e.g., Seaman (1997, 2002) and, for two special exhibitions, Wall and Roberts (1984).

<sup>13</sup> Even if the output unit is the number of hours or days per year for which the museum is open, this statement probably holds. The British Museum tried to cut costs by closing some sections, but they did not achieve a big cut in costs – at least not in the short run [see Anon. (2002); Art Newspaper (2002)].

<sup>14</sup> For a detailed survey of Baumol's Cost Disease, see Towse (1997b). For a critique, see Cowen (1996) and Peacock (1993, pp. 66–70). See also Chapter 11 by Baumol and Chapter 15 by Brooks in this volume.

to a productivity lag that produces constant financial problems. However no empirical study exists analysing this claim for museums. Indeed, productivity advances in the museum industry seem to be possible: items can be shown on the Internet; surveillance can be undertaken by cameras; increased reliance may be placed on volunteers; activities may be outsourced; or institutional settings may be changed, like introducing New Public Management for public museums, or privatising them entirely. All these changes work against the potential effects of the cost disease.

- *High opportunity costs.* Museums own, through their collections, endowments which are often highly valuable. For most museums the value of their holdings is by far their greatest asset. The objects in a museum's collection generate not only storage and conservation costs but also opportunity costs. The opportunity cost of keeping a work of art is the return generated by its alternative use, i.e. by selling the work of art and investing the money in options. Other opportunity costs refer to the building and its alternative uses.<sup>15</sup> Most museums do not place a value on their collection in their accounts. In Great Britain, not placing a value is even a condition of registration with the Museums and Galleries Commission [Bailey and Falconer (1998, p. 173)]. Museums understate their true capital costs by not taking opportunity costs into account [Grampp (1989, p. 171)]. Neglecting opportunity costs can partly be explained by a rational reaction of the museum directorate to action undertaken by the political sector.<sup>16</sup>

### 3.2. *Cost functions*

It is important to know how museum costs vary with regard to output and input. One of the few museum cost functions to be estimated is that of Jackson (1988).<sup>17</sup> This study took various activities of the museum into account and analysed their influence on costs. The log-linear model is:

$$\ln TC = \ln a + b \ln Q + y \ln W + s \ln K + r_1 EX + r_2 ED + r_3 CN + r_4 MB + r_5 AC, \quad (1)$$

where  $TC$  is total operating cost,  $Q$  is the total attendance figure,  $W$  is the wage rate paid per worker, and  $K$  is the cost of capital measured as the ratio of promotional expenditures such as development, membership and advertising, to contributions from all public and private sectors. Because a museum can engage in various activities, the study looked at how priorities set by the museum influence costs. Therefore,  $EX$  are exhibition expenses as a fraction of total operating costs,  $ED$  are educational expenses,  $CN$  are

<sup>15</sup> In some cases, the opportunity cost of the land may be quite high, as museums are often situated in commercially attractive locations; see Rosett (1991) for more details.

<sup>16</sup> This question will be discussed in more depth in Section 4 below.

<sup>17</sup> For a cost function for performing arts, see, for example, Lange et al. (1985).

conservation and preservation expenses, and *MB* are expenses in connection with membership activities. Because quality strongly influences costs in the performing arts,<sup>18</sup> the study tried to capture quality by looking at which museum had been accredited with the American Association of Museums; *AC* is a dummy variable equal to 1 if accredited and 0 otherwise. This is only a rough proxy for quality.

The results, based on data from the Museum Program Survey 1979 for 326 US museums, yielded two interesting results: First, museum operation appeared to be characterised by economies of scale. Operational costs changed more slowly than attendance figures in small museums with up to 99,000 visitors a year. However, for bigger museums, diseconomies of scale were at work. Average cost curves for (art) museums were downward sloping with low attendance levels and rose only after the annual number of visitors exceeded 100,000. This result backs up the statement about museums being a decreasing cost industry. Second, an increase in expenses for membership activities as a fraction of total operating expenses decreased total costs. This may be due to the fact that a more active group of members stimulates voluntary work and that the cost of capital can be decreased as fundraising becomes easier.

Overall it can be said that more research is needed for us to fully understand the cost functions of museums.<sup>19</sup>

### 3.3. Firm structure

Museums can take different organisational forms. They are mostly either private for-profit organisations, private non-profit organisations, or public organisations run in a non-profit-making way. In Europe and the United States, the non-profit organisational form predominates for museums. Various hypotheses have been put forward to explain the dominance of non-profit firms in the museum world and the arts in general.<sup>20</sup> According to Weisbrod (1977), non-profit organisations were established due to an unsatisfied demand for public goods. Alternatively, the cost structure of museums may be responsible for establishing non-profit organisations.

Most museums face a demand curve lying below the average cost curve. This makes it impossible to set a price at which total admission receipts cover the total costs of the museum. If price discrimination is not applicable or only of limited use, Hansmann (1981) argued that arts organisations can still ask individuals for voluntary price discrimination. Visitors volunteer to pay more than the official admission price and thus become donors. The non-profit form is superior to the for-profit enterprise when it comes to getting donations, because consumers lack exact information about the quality of the

<sup>18</sup> See Throsby (1977) and Globerman and Book (1974).

<sup>19</sup> For a related branch of research on efficiency measurements in museums, see Mairesse and Vanden Eeckhout (2002) and the literature cited there.

<sup>20</sup> For a selection of articles dealing with non-profit firms in the arts, see Di Maggio (1986). For a general survey about non-profit firms and altruistic behaviour, see Rose-Ackerman (1996). See also Chapter 15 by Brooks in this volume.

good and service provided. It is impossible to draw up a contract which gives donors complete protection from being exploited. As a consequence, donors prefer non-profit firms, where the possibility of managers exploiting donors and consumers is limited.<sup>21</sup>

Smolensky (1986) argued that educational externalities, and not decreasing costs, led to the non-profit form of museums. In Europe, governments started to support museums because of these educational externalities while in the United States “public provision was rejected as a socialist solution” [Smolensky (1986, p. 768)]. The non-profit form that was subsequently established was a hybrid, applicable not only to museums but to performing arts organisations, universities, libraries and hospitals.

#### 4. Museum behaviour

Two theoretical approaches for analysing the behaviour of museums are presented here: the neoclassical approach, which assumes rational actors maximising the utility of a museum in a benevolent way, and the institutional approach, emphasising how various institutional settings (e.g., the dependence on public support) influence the behaviour of the museum management. These approaches are then used to analyse three major activities of museums: collection management, pricing policy and commercial activities.

##### 4.1. Neoclassical approach

###### 4.1.1. A representative model

Throsby (1994) presented a model of the behaviour of performing arts firms which can be applied to museums. The model assumes that there is no distinction between ownership and control of the firm. The directorate of the museum maximises the firm’s utility function. Assuming that a museum’s objective is non-profit making, the budget constraint requires zero net revenue. It has been proposed that the museum’s utility is related to the number of visitors to the museum ( $y$ ) and the quality of the exhibitions ( $q$ ). This assumes that the quality of the museum service can be measured. The museum management thus decides to maximise

$$U = U(y, q) \tag{2}$$

subject to

$$p(y)y + g(q) + h(y) - c(y, q) = 0. \tag{3}$$

The museum gains revenues from entrance fees ( $p$ ), which is a function of the number of visitors ( $y$ ); the level of donations and government grants ( $g$ ), which depend exclusively on the quality of the museum; and the revenue from ancillary goods from the shop

<sup>21</sup> For a similar argument, see Glaeser and Shleifer (2001).

and the restaurant or café ( $h$ ), which depends on the number of visitors. Costs depend on both output and quality.

The first-order conditions can be written as:

$$U_y/\lambda + p_y y + p(y) + h_y = c_y, \quad (4a)$$

$$U_q/\lambda + g_q = c_q, \quad (4b)$$

$$p(y)y + g(q) + h(y) = c(y, q). \quad (4c)$$

The subscripts indicate partial derivatives and  $\lambda$  is the multiplier on the constraint.

This formulation produces two insights: First, directors of a non-profit museum receive extra utility from a higher number of visitors. They therefore set the entrance fee in such a way that marginal revenue from entrance fees and ancillary goods is less than marginal costs. This result may explain why museums set too low a price compared to the revenue-maximising condition [e.g., Luksetich and Partridge (1997)]. Second, museums engage in quality beyond the point where marginal grant income is equal to the marginal cost of increasing the quality by one unit. This behaviour is due to the extra utility the museum gets from an increase in quality. According to the model, museums tend to provide too high quality at too low a price, compared to a revenue-maximising firm.

The objectives of the museum, the quality of the exhibition and the number of visitors are crucial elements in the above model. Hansmann (1981) analysed the extreme cases of a museum interested only in quality, a steady flow of visitors or budget. For example, the quality maximising firm sacrifices the number of visitors for the sake of quality. But different forms of public grants also affect the result. While lump-sum subsidies would lead to an increase in quality for the quality maximiser, the increase in the number of visitors has a less certain effect. It only happens if the increase in the flow of visitors does not increase the cost of quality, and if the marginal visitor attracted has an unusually marked taste for quality. Different behaviour results if the museum is supported in matching grants with the donations it receives. In this model, a subsidy does not only increase donations, but will induce the museum to adjust quality and price (and therefore visitor flows) to a level closer to maximising consumer welfare.<sup>22</sup>

#### 4.1.2. Critique

The model presented above assumes that managers of museums behave in a benevolent way and are driven only by a cultural aspiration favourable to the owner of the museum (e.g., the public, private donors and/or a foundation). But this assumption may be criticised in two respects: First, managers of museums and chief curators are likely to behave in a more selfish way than assumed by the model. Second, it may be that

<sup>22</sup> Many studies show that grants which match donations increase willingness to donate (see further Chapter 35 by Netzer and Chapter 36 by Schuster in this volume); see also List and Lucking-Reiley (2002) and Ribar and Wilhelm (2002).

museum managers are primarily interested in their reference group and try to maximise their respective reputations; in the absence of the right incentives, they will not produce the quality and quantity maximising the firm's or consumers' utility.

#### 4.2. *Institutional approach*

Museum managers (as well as all other actors in society) may be assumed to be primarily, or even exclusively, concerned with their own utility. They may therefore be taken to be interested in their own income and the prestige they get within their reference group, consisting mainly of art lovers and the international museum community. A second source of utility has to do with agreeable working conditions and job security. But the museum management is not free simply to pursue its own goals, because it faces certain constraints on its actions. Differences in these institutionally determined restrictions may explain the museum management's behaviour.

The financial resources available are the most important constraint on museum management. Other constraints such as limited space or legal and administrative burdens imposed by the public bureaucracy or labour unions can also weigh heavily. Income sources differ considerably between museums. Some depend mostly on public grants, while others rely more on private money (donations and sponsorship, or income generated from entrance fees, shops and restaurants).<sup>23</sup> From a politico-economic point of view, the institutional set up and the nature of funding museums has a dramatic influence on the behaviour of its management.<sup>24</sup>

Most museums lie somewhere between the extremes of purely public and purely private museums.<sup>25</sup> In the last couple of years, more public museums have moved in the direction of private museums because state support has decreased, especially in Europe [NEA (2000)]. Governments, as a consequence, have given the museum managers more independence. Both the discretionary room and the pressure to generate more income of their own has increased. Nevertheless, the institutional setting remains crucial for the behaviour of the museum management. The fact that public museums change their behaviour notably once they have more independence underlines the power of institutional factors.

In the following sections we distinguish between three types of museums: public museums, private museums, and museums dependent on donations. The three models of museums generate predictions for the behaviour of agents, e.g., managers, donors, and visitors.

<sup>23</sup> Rosett (1991) presents evidence on the financing of US museums, which support the notion of heterogeneous funding of museums.

<sup>24</sup> See Frey and Pommerehne (1989), Rosett (1991) and Meier and Frey (2003); see also the theory of non-profit organisation in Weisbrod (1998), James (1983), Schiff and Weisbrod (1991), and for a principal-agent model, Prieto Rodriguez and Fernandez Blanco (2002).

<sup>25</sup> See Schuster (1998a), van Hemel and van der Wielen (1997) and Meier and Frey (2003).

#### 4.2.1. *Public museums*

Directors of purely public museums rely exclusively on public grants. The government allocates them sufficient funds to cover the expenses considered necessary for fulfilling their tasks. While they are expected to keep within their budget, if a deficit does occur, it will be covered by the public purse. This institutional setting provides little incentive to generate additional income and to keep costs at a minimum. The management does not allocate energy and resources to generate additional income, because any additional revenue produced goes back into the national treasury. Moreover, with a surplus, the public grants would correspondingly decrease, which acts like an implicit tax of 100 percent on profits. Instead, the museum management emphasises non-commercial aspects, such as referring to intrinsic “artistic”, “scientific”, or “historical” values. This application of non-commercial standards helps the museum management to achieve their goal of prestige, top performance and pleasant working conditions. Even if museum revenue was not automatically to go back to the public purse, Maddison (2004, p. 89) shows that “(s)tatistically analyzing data drawn from a panel of UK museums, evidence is found that increases in non-grant incomes do indeed result in a statistically significant reduction in future government subsidies”. Based on this institutional point of view, one would therefore expect that:

- Public museums will not sell any paintings from their art collection because the management is prevented from using the income generated as it would wish, and selling part of the collection would leave management vulnerable to criticism from outside (be it by politicians or by public administrators) because “artistic” activities have now become monetised [Frey (1994); Montias (1973)].
- Directors of public museums will have little interest in the number of visitors, because they are not dependent on income from entrance fees or shops. Therefore, exhibitions will be designed to please an insider group of art “freaks”.
- Visitors’ amenities in public museums will be poorly developed, and little attention will be paid to the profitability of museum shops, restaurants and cafeterias.

#### 4.2.2. *Private museums*

Managers of purely private museums have a strong incentive to increase their income, because their survival depends on revenues produced by entrance fees, the restaurant, shop surpluses and additional money from sponsors and donors. If private museums manage to generate a surplus, the management can use it for future undertakings. Consequently, it is to be expected that private museums will behave in the following ways:

- They will rely on the market when managing their collection. Museums will actively sell paintings that no longer fit into the collection and use the money to buy new works of art.
- They will actively seek to gain additional revenue from museum shops, restaurants and cafeterias, and will be prepared to host non-artistic events such as corporate meetings in their facilities.

- Private museums will be concerned with attracting visitors. “Blockbuster” exhibitions will help the museum to earn revenue, because the preferences of a larger group of people will be catered to. The management will make a huge effort to have the exhibitions well arranged from a didactic point of view and appeal to a large crowd.
- Private museums will emphasise amenities to visitors, such as cafeterias and clean restrooms.

#### 4.2.3. *Museums dependent on donations*

In some countries, contributions to non-profit museums are deductible under the income tax rules for individuals and corporations.<sup>26</sup> A reduced marginal tax reduces the willingness to donate because the implicit price of doing so rises. The tax-deductible status, if chosen by the museum, affects behaviour fundamentally. There is an incentive to avoid profits by charging low or “social” prices (which strengthens the legitimacy of tax-deductible status). There is also an incentive to take out profits in the form of various kinds of payments, showing up as costs.

Museums depending on donations have an incentive to attract donors, and they devote a great deal of effort and resources to this end. Donors can exercise some measure of control over the activities of museums.<sup>27</sup> Museums dependent on financial and/or in-kind donations are expected to behave in the following way:

- Donors will directly influence museum policy by interfering in the programming, or they can set strictly binding constraints on the ways in which works they donate can be used. Most donors have clear ideas on how the works of art donated should be exhibited. Donors in general will also want to prevent paintings donated from ever being sold, which imposes considerable opportunity costs on museums. Donors can benefit from museums publicising their contribution, thus enhancing their prestige [Glazer and Konrad (1996); Harbaugh (1998)]. Museums have developed an elaborate system of honours, ranging from appropriate attributes (“benefactor”, “patron”, “contributor”, etc.), to naming rooms, wings and even whole buildings after the donor.
- Museums must make the impression that donations are well used, so that donors will have the feeling that they are contributing to a worthwhile cause. It is crucial that the art institution has a good reputation with the public and the media to encourage a regular flow of donations. This compels the museum management to act efficiently. Contracts cannot completely control the museum managers. Donors will therefore prefer to deal with non-profit firms acting under a “non-redistribution constraint” (i.e. prohibiting the personal appropriation of profits). Removing the profit goal avoids the problem that managers cheat on the donors to a certain extent [Hansmann (1981)].

<sup>26</sup> For an overview of the legal possibilities of deducting donations to the arts from taxes, see Schuster (1985, 1986), and Chapter 36 in this volume.

<sup>27</sup> As discussed in Glaeser (2001, p. 39) and Oster and Goetzmann (2001).

### 4.3. *Museum behaviour in three important areas*

#### 4.3.1. *Collection management*

In most art museums throughout the world, a considerable portion of the holdings of paintings is not exhibited and not accessible except perhaps to specialists. What constitutes a major part of a museum's wealth does not appear on any balance sheet; the bookkeeping procedures of art museums often do not even mention that the paintings collected are of any value, although at today's art market prices collections of even minor museums are likely to be worth millions of dollars and in the case of major museums many hundreds of millions of dollars.<sup>28</sup> The museum managers know, of course, that their holdings are very valuable. Three reasons can be put forward which may explain this behaviour:

(i) The government may impose a legal constraint on selling. Many, or even most, public museums in continental Europe are prohibited from selling works from their collection, a practice known as de-accessioning.<sup>29</sup> This practice is often allowed in the United States and to a lesser extent also in Britain [Grampp (1996)], but as O'Hagan (1998a, p. 171) notes: "The real opposition arises from the museum personnel and not from the law." Even in the United States where it is legal to sell paintings the curators argue that it is not ethically right to do so unless one improves the collections in the process. However, Temin (1991) for instance argues that museum directors should be allowed to be more flexible in using the money of de-accessioned paintings, e.g., for operation expenses.

(ii) Voluntary contracts between the museum management and the donors of paintings may act as a constraint. In these circumstances the management is faced with a trade-off between receiving additional paintings and having to accept certain restrictions [Thompson (1986); Weil (1987)]. Today, few museums are prepared to accept such restrictions being attached to a donation [Weil (1987)].

(iii) The most convincing explanation for the behaviour observed refers to institutional differences. For public museums, the museum directorate has no incentive to sell the holdings it has in storage<sup>30</sup> for two major reasons [Frey (1994)]. First, when a painting is sold, the revenue gained is not added to the museum's disposable income but, according to the rules of the public administration in most countries, goes into the general public treasury. Even if this were not the case, it is likely that the budget allocated to the museum would be correspondingly reduced. This institutional setting undermines the incentives to manage the collection on the market. Second, selling paintings means that the existing stock of art is at least partially monetised, which may encourage outside

<sup>28</sup> Most art museums hold a large part of their paintings in storage rooms – up to 80 percent of the collection; see, e.g., Lord, Dexter and Nicks (1989).

<sup>29</sup> For a discussion on the legal aspects of de-accessioning art, see White (1996).

<sup>30</sup> Pommerehne and Feld (1997) also found differences in buying paintings by public and private institutions; for example, public museums paid more in art auctions than private investors did, *ceteris paribus*.

interference by politicians and parliamentarians into the museum's business [O'Hare and Feld (1975)] since the museum directorate's "performance" becomes easier to evaluate. As long as the criteria for evaluation are exclusively of an art historic nature, the museum community is to a substantial extent able to define its performance itself. This is a useful and successful survival strategy that museum administrations do not voluntarily give up.

By way of contrast, private American art museums actively sell and buy art as they see fit; for example, in the period 1988–1989, 88 museums sold 1284 lots worth \$29.6 million, and 93 museums bought 142 lots worth \$37.5 million [Cantor (1991, p. 21)]. The director of the Getty Museum stated that "this practice . . . (is) the key to shaping the collections by the staffs of many major big city museums with large collections, and others too" [Feldstein (1991, p. 26)]. Note that if the name of the donor is attached to the painting, the donor's resistance to de-accessioning may be reduced.

Lending policy is a different but related phenomenon. There is a norm not to exchange works of art using the price mechanism [Caves (2000, pp. 345–347)].<sup>31</sup> Even private museums follow this rule.<sup>32</sup>

#### 4.3.2. Pricing

Museums differ in the way they set entrance fees. There is an extensive discussion on whether to charge or not to charge,<sup>33</sup> a discussion that probably goes back to Sir Hans Sloane, whose donation at his death in 1753 led to the founding of the British Museum, but with the explicit restriction not to charge an entrance fee. Even today, most British museums do not charge their visitors for admission. In the United States too, there are some museums, at least the national ones, which do not levy an explicit entrance fee. Two main arguments are put forward in favour of free admission. First, there are some positive externalities connected with a museum, as discussed above, and therefore the museum should be compensated for this service by tax money. Those who actually visit a museum probably benefit most from the museum; hence an entrance fee should be levied over and above the contribution from general taxation. There does not seem to be any evidence that this measure hits low-income groups disproportionately [O'Hagan (1998a, p. 178)]. Second, the low or zero marginal costs of a visitor suggest that a zero price is efficient. However, as mentioned above, the assumption of zero marginal costs can be criticised for various reasons.

There are a variety of pricing options besides free admission: donation boxes with and without price suggestions, seasonal tickets with zero marginal pricing or a free-day

<sup>31</sup> Russian museums are an exception. Western museums are prepared to waive their rule of not paying money for lending works of art, because they acknowledge that Russian museums are extremely short of cash.

<sup>32</sup> Note that there are many advantages to having instead a market relying on barter; for an overview, see Heilbrun and Gray (2001, pp. 202–209).

<sup>33</sup> For an overview, see, e.g., O'Hagan (1995), Heilbrun and Gray (2001) and Bailey and Falconer (1998).

policy.<sup>34</sup> In addition, price discrimination, often supported by economists [e.g., Frey (1994)], can be undertaken in times of high demand and/or with respect to the type of visitor. For example, many museums, even those who do not charge for their permanent collection, have higher entrance fees for special exhibitions. Additionally, the museum could charge more at weekends and less during summer holidays. Tourists could be charged more than local residents. Visitors who want to spend little time in a particular museum could be charged less. In periods of high demand when the art museum is stretched to capacity, a high and a low entrance fee could be set; the higher-priced entrance will have a shorter queue and will be used by visitors with high opportunity costs, often persons with above-average income, whereas the lower-priced entrance will be used by visitors not wanting to spend too much money, and having plenty of time at their disposal.<sup>35</sup> Such price differentiation is advantageous for both categories of visitors (the one gets in more quickly, while the other pays less) as well as for the museum, which can raise its revenue.

The question of how pricing influences the finances of museums depends not only on the price elasticity of demand. Charging can also influence the flow of public subsidies and donations. Moreover, pricing decisions also impact on the amount of income generated with ancillary goods, like revenue from the shop and restaurant. In some cases, the government enforces targets which the museum managers have to comply with, such as a given number of visitors or a given amount of revenue. Darnell (1998) analysed the effect of such targets on admission fees for the museum. In the case of inelastic demand curves, the museum may face the problem that there is no fee attracting enough visitors and bringing in enough revenue at the same time. The demand curve may be shifted (e.g., by advertising more or improving the quality of the visitors' experience) to make the two targets mutually compatible. However, this model does not incorporate the possibility of raising revenue from sponsors, donations or ancillary goods.

The complementarities between admission fees and sales in museum stores and cafeterias affect optimal pricing strategy.<sup>36</sup> The empirical result in Steiner (1997) did not suggest that an additional free day maximises revenue, since decreased admission revenue was not compensated for by larger sales in shops and restaurants.

#### 4.3.3. Commercial activities

In addition to the core activities of museums directly related to the works exhibited or stored, most museums also engage in ancillary activities. The revenues from these

<sup>34</sup> Museum passes have become quite common in Europe and America. A pass allows free entrance in every museum in a given city or region. Ginsburgh and Zang (2001, 2003) focused in their analysis on how the revenue of such a pass can be distributed to the participant museums. Based on theoretical arguments drawn from game theory, they proposed distribution using the Shapley value.

<sup>35</sup> Oberholzer-Gee (2002) presented evidence in a field experiment where money was offered in order to be able to jump the queue. While a majority would like to jump the queue, only a minority in the queue were prepared to accept the money.

<sup>36</sup> For a general theoretical discussion of the interdependence between entrance fees and ancillary goods, see Marburger (1997).

activities can make a large contribution towards the operational expenses.<sup>37</sup> Museums operate museum shops, restaurants and cafés, sell catalogues, make money from parking lots, organise cultural trips, etc.<sup>38</sup> When the first museum shop was established by the Metropolitan Museum of Art in New York in 1908 [Weisbrod (1988, p. 109)], it was rather the exception than the rule. Today, many American museums not only operate their own shops, but also run off-site stores even in a totally different city, as does the New York Metropolitan Museum of Art.

Why do museums engage in ancillary activities? Is the museum world increasingly commercialised? Directors of museums do not necessarily want to produce ancillary goods as such; often they only serve to generate revenue for the core activity. But institutional factors may force museum directors to engage in such activities.<sup>39</sup> Weisbrod (1998, p. 58) cites the example of the British Museum where, in 1996, the government announced it would reduce its subsidies; the museum then started to discuss new possibilities of raising revenues.<sup>40</sup> However, the empirical evidence on commercialisation is ambiguous. Heilbrun and Gray (2001, p. 210) state that “Earned income accounted for only 16.1 percent of the total in 1993 but rose to 25.9 percent in 1997.” In contrast, Anheier and Toepler (1998, p. 240) concluded from their more in-depth study: “Our data suggest that art museums have not become significantly more commercial in recent years.” Segal and Weisbrod (1998) found for the arts industry that a decrease in donations (or public grants) increases ancillary activities. Much more research is needed to gain more precise knowledge.

Does the commercialisation of museums lead to a new type of museum manager? Anecdotal evidence suggests that at least in Europe arts organisations increasingly demand that their managers have some business experience.<sup>41</sup> This trend is especially marked in the so-called superstar museums to be discussed in the next section.

## 5. Current trends in the museum world

Two developments relating to museums are worth special attention: superstar museums and special exhibitions.<sup>42</sup>

<sup>37</sup> See, for instance, Heilbrun and Gray (2001, p. 211) and Anheier and Toepler (1998).

<sup>38</sup> Many books offer advice on how to maximise profit from specific services such as the management of museum stores; see, for example, Theobald (2000).

<sup>39</sup> See the data in Frey and Pommerehne (1989).

<sup>40</sup> In the case of the British Museum, and general problems of extended management discourse within museums, see Zan (2000).

<sup>41</sup> See also Anon. (2001).

<sup>42</sup> This section follows Frey’s ideas closely [Frey (1998); Frey and Busenhart (1996)].

### 5.1. Superstar museums

There are a few really well-known and world-famous museums. They can be called “superstar museums” because they have a special status setting them far apart from other museums. They are distinguished by five characteristics:

- Superstar museums are a “*must*” for tourists. They are featured prominently in guidebooks, and have achieved a cult status almost everyone is aware of. European examples include the Hermitage (St. Petersburg), the Vatican Museums (Rome), the Uffizi (Florence), the Prado (Madrid), the National Gallery (London), the Kunsthistorische Museum (Vienna), the Rijksmuseum (Amsterdam), and the Louvre (Paris). In the United States there are certainly few tourists who would not visit the Metropolitan Museum of Art and/or the Museum of Modern Art when in New York, the National Gallery of Art when in Washington, or the Art Institute when in Chicago.
- Superstar museums have *large numbers of visitors*. Over the last decades, these museums have experienced a dramatic increase in the number of visitors. In contrast, many small museums have fewer and fewer visitors.
- Superstar museums feature *world-famous painters and world-famous paintings*. Rosen (1981) originally developed the superstar idea, emphasizing that differences in income often far exceed differences in talent and performance. This also applies to artists and painters. The great disparity among artists is a striking feature of all the studies on the distribution of income among artists.<sup>43</sup> The collections in large museums comprise works by thousands of artists; only a few of them are known to art lovers, let alone to the average visitor. Museums wanting to attract a large crowd have to concentrate on a few renowned artists. Some paintings are known to virtually everyone in the Western world (and far beyond), but the number of such paintings is rather small. Examples are the “Nightwatch” in Amsterdam’s Rijksmuseum, or “Las Meninas” in the Prado. The quintessential superstar painting is Leonardo’s “Mona Lisa”; the Louvre has responded by indicating the most direct way to get to the Mona Lisa from the entrance. Even the Vatican Museum now posts the (more or less) direct way to another world famous work of art, Michelangelo’s frescos in the Sistine Chapel. From the visitors’ point of view, even very large museums are closely associated with, or defined by, very few (often one or two) paintings – the superstar phenomenon. Museums are not only the proud owners of these masterpieces, but they are also their captives. They are forced to exhibit them, but this also means that in comparison their other paintings lose prominence. There may be a slight spillover of interest to less renowned pieces in the collection, but the main effect of the superstar works is to draw attention away from the rest of the collection.

<sup>43</sup> See, e.g., Filer (1986) or Frey and Pommerehne (1989, Chapter 9).

- Superstar museums often have an *architectural design* making the building itself a world-famous artistic feature. Examples are Frank Lloyd Wright's Guggenheim Museum in New York; the Centre Pompidou in Paris; Mario Botta's San Francisco Museum of Modern Art; Frank Gehry's Guggenheim Museum in Bilbao, and Richard Meier's Getty Center in Los Angeles.
- Superstar museums are *commercialised* in two ways: A significant part of their income derives from the revenue of the museum bookshops and museum restaurants and they have a major impact on the local economy.<sup>44</sup>

The importance of these five characteristics varies amongst the different superstar museums referred to above. Ideally, they would meet all of the criteria; the Musée du Louvre is an example of one that does (the architectural feature being Ming Pei's pyramid at the entrance). Other superstar museums are very strong with respect to some characteristics, while barely meeting others. Examples would be the Getty Museum in Los Angeles, which excels with respect to the architecture (including its location) but does not have as many world famous artists and paintings as other superstar museums. Another example is Amsterdam's Rijksmuseum, which is not particularly noted for its architecture, especially when compared to the Louvre.

Superstar museums are able to exploit economies of scale by reaching out to a large number of people. They are not only featured in newspapers, on the radio and TV, but can raise enough money to produce their own videos and virtual museums. These sorts of costs are essentially independent of the number of consumers and therefore favour the major museums, because the set-up costs are normally too high for smaller institutions. While the latter will certainly catch up (a homepage will soon be a matter of course for all museums), the major museums will have the funds to improve their scope and quality so as to maintain their lead. Superstar museums have started to branch out by establishing museum networks. Thus, for example, the London Tate Gallery has spawned satellite museums at Liverpool and St. Ives and, of course, the New Tate, and the Prado has started to lend out about one third of its holdings to museums in the provinces.

Superstar museums find themselves in a new competitive situation. Their reference point shifts from other museums in the city or region to *other* superstar museums. This competition between the superstars extends over a large area, including commercial activities and sponsors.

Superstar museums must make a huge effort to stay in that category. Frantic activities are therefore often undertaken: special exhibitions are organised in the hope that they turn out to be blockbusters, visitors' amenities are improved (e.g., a larger variety

<sup>44</sup> In the case of the Guggenheim Museum in Bilbao, a discussion emerged as to how much this superstar changed the economy. While Plaza (1999) showed that the number of visitors to the Basque region increased dramatically due to the Guggenheim Museum, Gómez (1998, 2001) emphasised that one should be more cautious in analysing the effect on urban regeneration, because it is still too early to assess the economic impact of the museum on the city. For a broader discussion of "museum cultural districts", see Santagata (2002) and Chapter 31 in this volume.

of fancy restaurants) and new buildings with stunning architectural designs are added (e.g., in the case of New York's Museum of Modern Art). The superstar status tends to transform museums into providers of "total experience". This new role stands in stark contrast to the traditional notion of museums as preservers of the past.

The "total experience" offered by superstar museums, and demanded by the huge crowds of visitors, must meet two conditions:

- Art must be placed in the context of history, technology and well-known events in politics and entertainment, such as motion pictures. Superstar museums are constantly under pressure to be "special", i.e. to also somehow embed the permanent collection in a context attractive to a large numbers of visitors.
- Superstar museums must be able to provide everything, not unlike entertainment parks; the activities offered extend beyond cafés, restaurants and museum shops. Many superstar museums have already gone far in this respect; the Louvre, for example, opened a commercial precinct called "Le Carrousel du Louvre", a large underground shopping mall. Activities of superstar museums supply all sorts of educational activities (not only for children but also adults), and most importantly, plain entertainment.

## 5.2. *Special exhibitions*

There is hardly an art museum not running, or at least preparing, a special exhibition of some sort. Such an exhibition may feature one particular artist (often in commemoration of his or her birth or death) or a group of artists, or it may focus on a period or a genre of paintings, or it may establish a connection to some historical event [Belcher (1991, p. 49)]. Some special exhibitions are composed solely of paintings from the holdings of the organising museum, but most of them bring together works of art from different museums and private collections. Once put together, large temporary exhibitions frequently travel to other museums coordinated with the organisers. Some exhibitions are shown in various countries. Often, important museums have several exhibitions simultaneously which they have either organised themselves or taken over from other organisers. The boom in special exhibitions poses a challenge to art economists, because of the glaring contrast to the financial depression in which many museums find themselves. Even in some of the world's leading museums, wings are temporarily closed, and opening hours are reduced in order to save money. Curators are concerned that they have less and less money available for the restoration and conservation of their collection.

### 5.2.1. *Demand aspects*

On the demand side, special exhibitions have some special features worth noting:

- *High income effect.* Consumers tend to spend an increasing amount of their income on visiting specially arranged art exhibitions. Scattered empirical evidence exists showing that econometrically estimated income elasticities of demand for

museum visits in general are larger than one (see above). Special exhibitions thus find themselves in the comfortable position of being in a growing market.

- *Attracting new visitor groups.* As has been well documented in cultural sociology [e.g., Klein (1990)], a large percentage of the population rarely if ever visits museums (except museums of technology and transport). This applies in particular to population groups with low education which are also short of cultural tradition.<sup>45</sup> The situation is clearly different for special cultural events, which are widely advertised and which are made attractive to new groups. As special exhibitions normally take place in museum premises, they still face the difficulty of attracting new groups. This is partly overcome by “dressing-up the museum”.<sup>46</sup> special exhibitions are marked by huge banners and other advertising strategies, and even the museum entrances (which to non-museum goers can otherwise look menacing) are made welcoming. Extensive promotion also plays a role.
- *Focusing attention.* A special exhibition seeks to attract consumers by presenting them with some extraordinary cultural experience. They specialise on some particular artist (e.g., Rembrandt or van Gogh), some period (e.g., Renaissance paintings), some topic (e.g., courtly paintings), some genre (e.g., mannerist paintings), or some type of presentation (e.g., portraits). As a result, the visitors interested in such forms of art come together, often from faraway locations. Special exhibitions, in particular the blockbusters, may even be compared with major sports events such as the Olympic games or world championships. Public attention is drawn away from regular activities towards a special and unique (or at least rare) event.
- *Newsworthiness.* Special exhibitions are *news*, and attract the attention of television, radio and the print media, which is otherwise impossible to get to the same degree, and especially free of charge, while the permanent collection is hardly newsworthy.<sup>47</sup> Large exhibitions devoted to iconic artists such as Rembrandt, Van Gogh or Picasso mobilise the press and thrust the museum organisers into the limelight.<sup>48</sup>
- *Low cost to visitors.* Special exhibitions are closely linked with tourism.<sup>49</sup> A considerable number of visitors come from out of town, from another region, and often from a foreign country. Being able to combine a cultural event with tourism lowers the individual’s cost of attending in various ways. In the case of the increasingly popular package tours, the consumers only have to take the initial decision and all the rest is taken care of by the travel agent. In the case of culture, where it is often burdensome to acquire the tickets from outside, the reduction of decision and transaction costs is substantial.

<sup>45</sup> See Blau (1989) and Di Maggio and Useem (1978).

<sup>46</sup> See also Elsen (1986).

<sup>47</sup> See, e.g., Bayart and Benghozi (1993, p. 210).

<sup>48</sup> See also Elsen (1986, p. 20).

<sup>49</sup> See, e.g., Getz (1989) and O’Hagan (1992, p. 65).

- *Low price elasticity of demand.* The strong attraction of special exhibitions to tourists also affects the price elasticity of demand. Tourists relate the entrance fee to their expenditures for the overall trip. A given price increase is then, in comparison, perceived to be relatively small and does not have much impact on demand.<sup>50</sup> This effect is supported by empirical evidence. Attendance figures at the Museum of the Palazzo Ducale in Venice, for example, have been fairly stable, although admission fees for the exhibitions presented in recent years have on average increased by more than 10 percent. In fact the number of people visiting the Palazzo Ducale seems to be in direct proportion to the number of people visiting the centre of Venice [ICARE (1994)].
- *High demand by business.* Special exhibitions offer museums ample opportunities to make money. Indeed, there is a large literature documenting the monetary profitability of such cultural events.<sup>51</sup> These opportunities not only extend to the tourist industry but also to firms catering for the production of festivals and exhibitions. In the case of special exhibitions, there is also a benefit to publishers of books and catalogues.

### 5.2.2. Supply aspects

There are also various special determinants on the supply side of special exhibitions which contribute to their boom.

- *Low production cost.* The absolute cost of many special exhibitions is certainly high, but it is low compared to the sum of money they would require if all the resource inputs used were attributed to them. Important resources are taken from the permanent venues and only additional costs are covered by the special artistic events. Museum employees are involved in organising and running special exhibitions, but the corresponding cost is not attributed to the special event [Montebello (1981)]. Some cost factors, though substantial, often only appear in disguised and long-term form. One such cost is the neglect of cataloguing and maintaining the permanent collection.<sup>52</sup> But also the museum rooms, where special exhibitions take place, do not enter into the costs accounted for, as the opportunities forgone are not part of the bookkeeping.
- *More scope for artistic creativity.* Museum directors are bound by artistic conventions; for example, the particular hanging of pictures at many museums has become part of the cultural heritage, and it is next to impossible to rearrange the permanent collection to any significant extent. Special exhibitions offer a chance to avoid such historical restrictions. One of the major tasks and potentials of an art exhibition is to arrange the art objects in such a way that they create new insights and effects. In

<sup>50</sup> For the general argument, see Thaler (1980); for museum admission fees, see Blattberg and Broderick (1991).

<sup>51</sup> For example, Feldstein (1991), Fronville (1985) and Di Maggio (1985).

<sup>52</sup> See Börsch-Supan (1993) for several pertinent examples.

addition, the actual assembly of art objects coming from many different permanent collections provides a much sought-after challenge to museum directors, curators, exhibition and graphic designers, conservators, editors and managing officers, to demonstrate their artistic creativity and sense of innovation, and possibly to raise controversy – aspects which are highly valued by museum people for their own sake, but also because it is beneficial for their careers.

- *Evading government and trade union regulations.* Cultural institutions' freedom to act is restricted by two major institutions, the government and trade unions. Government restrictions go far beyond budgetary affairs. They hinder the art institutions' way of acting and performing in a myriad of ways. Thus, pricing policy is greatly restricted, as well as opening times.<sup>53</sup> In view of the strong hand exercised by the government, and its persistence due to a long tradition, engaging in special events presents a major possibility for getting round these regulations. So, for example, special exhibitions provide an opportunity for directors of art museums to appropriate at least part of the extra revenue generated. Being an extraordinary event, the museum directors are in a good bargaining position vis-à-vis the public budgetary authorities to maintain some discretion over these funds, and not to be heavily "punished" by a reduction in future budget allocations. In addition, one of the most stringent public regulations imposed on public art institutions relates to government sector employment; the virtual impossibility of dismissing inefficient or downright destructive employees, of promoting and paying employees according to performance, and of adjusting working hours to actual needs are major factors in reducing creative endeavours and turning art institutions into mere bureaucracies. Special exhibitions make it possible to avoid at least some employment restrictions, especially as most of the respective employees are only part-time and temporary, are not union members, and are therefore not legally bound by trade union regulations.
- *More sponsoring.* Politicians and public officials have an interest in special exhibitions which enable them not only to respond to the demands of the art world and the local business community, but also to appear in the media as "patrons of the arts" (with tax payers' money). Business is also more prepared to sponsor special exhibitions than regular activities, where legal provisions often hinder sponsoring. The most important reasons for the attractiveness of these events to sponsors are the higher media attention they attract, and the fact that an individual firm has more control over the funds contributed and sees less of it wasted by an inefficient bureaucracy, as is frequently the case with opera houses or art museums. Sponsors "want a well-defined, high quality event aimed at specific audience" [Anon. (1989)]. For the reasons given above, the corporate sponsors also feel that their contributions add to cultural output, and do not simply induce the government to provide less subsidy.

<sup>53</sup> For many examples, see, e.g., Börsch-Supan (1993, pp. 11, 15).

### 5.2.3. *The future of special exhibitions*

As special exhibitions become the rule rather than the exception, there is pressure to have them carry their full costs, and to subject them to the same government and trade union regulations as other museum activities. Even if the rapid rise in special exhibitions cannot be expected to persist, they will continue to have a strong and lasting impact on the art world. On the demand side, they have opened up art to an increasing number of people. This “popularisation” may not be in the interests of some art suppliers and art lovers, but from the point of view of caring for individual preferences, it is a considerable achievement. On the supply side, the increased competition between producers of art has transformed career patterns at museums and has led to a new relationship between potential and actual art consumers. By subjecting art producers at least partly to the market, it has also favoured more efficient forms of organisation and production in the world of art. These trends are likely to continue.

## 6. Conclusion

This chapter has treated various aspects of the production of museum services. From an economic point of view, two different approaches have been distinguished: first, we have shown that museums may be looked at as an economic unit where inputs and outputs can be analysed; second, we have demonstrated how the economic way of thinking can be applied to museums and individuals (directors, curators, politicians, visitors, donors, etc.) connected with them. The chapter has discussed the demand and supply side of museums, the behaviour of museums, and the phenomena of superstar museums and special exhibitions as two recent trends in the museum world. We have emphasised that the behaviour of museum management is guided by the institutional setting. According to this theory, the main source of funds has a major impact on the behaviour of the museum. The management’s decisions to raise income through ancillary services, or to manage their collection on the market, or to set entrance fees depend to a large extent on the ownership of the museum. In looking at museum behaviour, we make a distinction between private and public museums and museums dependent on donations.

A worthwhile goal for future research is to understand more fully how the changing environments in which museums are acting influence the behaviour of the museums. How will museums adapt to the new situation? The rise of superstar museums and the reliance on special exhibitions are two such notable developments. But the future may well bring new environments. Museums will no doubt rise to the occasion.

## Abstract

This chapter critically assesses, from an economic viewpoint, the role of the arts and culture in urban and regional development and growth. This includes the analysis of short run spending impacts, and longer term effects on location quality and creativity. In addition, the specific possibilities for using arts and cultural activities as a focal point in strategies for urban revitalization are discussed including the role of tourism, the non-market demand for arts and culture as an element in local willingness to support urban and regional development policies, questions of sustainability, etc. The reverse influence of regional economic development on the demand for and supply of culture in the region is analyzed and the location of arts and cultural industries is discussed highlighting the role of agglomeration of cultural industries.

## 1. Introduction

### 1.1. On the relationship between economic and cultural development

What is the relationship between economic and cultural development at the urban or regional level? How does culture change in the course of economic development at these levels and conversely what contribution can culture make to overall development? These are important questions not only for urban, regional and cultural economics but also for cultural policy-makers and urban planners, given that culture has become an integral part of regional development strategies. Urban planning has increasingly become intertwined with cultural planning, and cultural programming is used as part of strategies to revitalize inner cities and old industrial areas.

This chapter contains a critical assessment, from an economic viewpoint, of recent research on the role of the arts and culture in urban development and redevelopment and in regional growth. It addresses the relationships between regional economic development and development of the cultural sector. This interdependence obviously has a dual causality – development of the cultural sector has an effect on overall economic development and at the same time general economic development affects the cultural sector in specific ways. These two directions of causality are explored in this chapter. First, we ask what is the contribution of cultural activities to economic growth and *how* do arts and culture generate urban and regional development? We thus focus on outcomes in terms of employment and income growth as well as on transmission channels through which these effects are realized. Examples of such transmission channels are cultural tourism which stimulates the tourism industries more generally, and improved location quality through better arts and cultural services that attract mobile firms or highly skilled labor. Of particular interest in this context is the question as to whether cultural industries tend to cluster, and if so why. If there are agglomeration advantages for cultural industries they will lead to an unbalanced growth of the cultural sector, resulting, for instance, in an urban–rural divide in the provision of cultural services; if this were to occur, the contribution of cultural industries to regional economic growth would be unevenly distributed.

Second, we investigate the reverse causality: How does regional economic growth influence the development of the cultural sector? Does the cultural sector benefit from the overall economic growth in a city, a metropolitan area or a region, and if so, what are the mechanisms through which this improvement is brought about? We can distinguish three lines of explanation: a demand-side effect, a supply-side effect, and altered support for the arts from the government and private sponsors. The demand-side effect is straightforward: in the course of economic development people become richer and typically also better educated; because demand for culture has been shown to depend positively on income and education this increased demand should result in a better provision of arts and culture as more cultural activities become commercially profitable. The supply-side effect is more intricate and works indirectly. On the one hand, economic development provides better infrastructure that makes remote areas more accessible for

traveling orchestras and the like and allows inhabitants to travel more easily to cultural centers, thereby effectively improving the cultural services provided for them. This also applies to broadcast cultural services such as radio and television sets become more widespread. On the other hand, technological progress is unevenly distributed across industries; many cultural sub-sectors such as orchestras, theaters, painters and fine art are much less subject to (labor saving) technical progress than, for instance, manufacturing. This leads to a rising *share* of the workforce employed in arts and culture and a rising relative price for cultural goods produced by these sub-sectors, other things being equal (the so-called “Baumol’s cost disease”). Finally, in many countries public subsidies to the arts account for the lion’s share of the revenues of performing arts institutions (theaters, orchestras, operas, ballets, etc.) and museums. Such subsidies could be expected to increase with regional economic development, thereby tending to improve the supply of arts and culture. The reasons are not only increased budgets of regional governments, but also increased demand for culture due to economic development (see above) which, depending on the political system, in turn may lead to higher subsidies for arts and culture through the political process.<sup>1</sup>

### 1.2. *The concepts of regional culture and regional development*

We distinguish three definitions of culture:

- *Culture as aspect*, i.e. the community of ideas, values, norms and habits that a society has.
- *Culture as sector*, i.e. if culture is defined by a series of genres like painting, sculpture, theater, dance, music, literature, poetry, film, video, architecture, etc., the cultural sector consists of those institutions, firms, organizations and individuals who work with these genres; in total the cultural sector so defined comprises a wide spectrum from commercial businesses on the one hand to subsidized cultural institutions and idealistic organizations on the other.
- *Culture as art*, where the word “art” includes an implicit quality valuation; for instance, not all paintings would be classified as art according to some quality criteria.

This chapter’s point of departure is the definition of culture as a sector. Thus, there are no underlying quality valuations regarding the definition, but only a specification of genre. For our purposes the cultural sector contains both the wide commercial culture and the narrower traditional culture, comprising artistic modes of expression like theater, music, visual art, architecture, design, arts and crafts, media, film/video, multimedia, literature and cultural heritage; it could also include fashion, advertising, computer software, games and toys, amusement parks, etc. Researchers in this field refer to arts and culture as an economic activity. That does not necessarily imply that these activities are

<sup>1</sup> On the other hand, however, the increase in relative prices for art tends to erode purchasing power of cultural budgets. The net effect on real subsidies for culture is thus an empirical issue.

predominantly motivated by economic considerations (income generation) nor does it require that the results of these activities are traded in the market place. In fact many cultural products, including items of regional or national heritage, are not sold and bought freely on the market. Yet in the creation of arts and culture significant flows of financial resources are involved.

We disregard leisure time cultural activities which are (almost) free such as unsponsored neighborhood or community cultural activities, music groups that play for fun only, and so on. This is clearly an omission as these activities are an integral part of regional culture. Presumably the extent and structure of these activities will change in the course of economic development and thus will change regional and local culture. However they have not been subject to extensive economic research and therefore will be disregarded in what follows.

How do we define economic *development*? First and foremost, economic development implies economic growth, i.e. an increase in goods and services produced by a (regional) economy in a given period of time. This typically goes in tandem with increased employment and enhanced standards of living.<sup>2</sup> Economic growth is thus the motor for economic development in a broader sense; it typically increases life expectancy at birth, quality of health care, reduces infant mortality and allows for shorter working hours including a reduction in child labor.<sup>3</sup> It frees more time and resources for cultural consumption and, through increased market demand, mobilizes more resources for its production. According to [Kindleberger and Herrick \(1977\)](#) economic development implies both more output and changes in the technical and institutional arrangements by which it is produced and distributed. Development implies changes in functional capacities – in physical coordination, for example, or learning capacity (or ability of the economy to adapt). Thus economic development might be viewed as a longer term increase in the capacity of a local economy to enhance the quality of life to its residents; this will require increases in human productivity and a balance among the economy's component sub-regions that increases its ability to coordinate economic activity and adapt to changing circumstances.

[Throsby \(2003, p. 183\)](#) has introduced a related concept of cultural sustainability which he defines as arising from the broader notion of sustainable development:

... a concept that marries the ideas of sustainable *economic* development, meaning development that will not slow down or wither away but will be in some sense self-perpetuating, and ecological sustainability, meaning the preservation and enhancement of a range of environmental values through the maintenance of ecosystems in the natural world. Furthermore, the term “sustainable development” embraces an interpretation of “economic development” that supersedes former notions of economic growth measured only in terms of increases in per capita GDP,

<sup>2</sup> The deficiencies of GDP as a measure of well-being are well understood by now and need not be detailed here. In particular GDP measurement disregards externalities (such as environmental degradation) and most non-monetized transactions.

<sup>3</sup> Cf. [Easterly \(2001\)](#) and references cited therein.

and replaces it with the wider concept of “human development”, focused on the individual as both the instrument and the object of development, and measured by a variety of indicators of quality of life and standards of living that go well beyond measuring simply material progress.<sup>4</sup>

As a definition of cultural sustainability seems impossible to him, Throsby (2001, 2003) argues that a list of criteria may be used instead by which to assess sustainable management of cultural capital: material and non-material well-being, intergenerational equity, intragenerational equity, maintenance of diversity, precautionary principle, maintenance of cultural systems and recognition of interdependence. The final criterion, in essence, draws together the entire concept of sustainability when applied to culture, providing an overall framework within which the other more specific principles can be seen to operate.

The concept of economic growth is of course simplest to apply in empirical studies, the concepts of economic development and cultural sustainability being more and more complex – and less operational. Most studies of arts and culture in urban and regional development thus apply the simple measures of economic growth such as income and employment. Broader concepts like cultural sustainability are interesting, as they evaluate the impact of culture in a broader perspective, including wider aspects of development. Therefore it would be interesting in principle to see more studies in the future applying concepts like cultural sustainability to measure the impact of arts and culture on urban and regional development. However, economic growth is a more clearly defined concept and thus much more operational,<sup>5</sup> and in any case it can be seen as the main driving force behind economic development and cultural sustainability.

This chapter proceeds as follows. First we will analyze how arts and culture promote urban and regional development in the short run by increasing overall demand for regional goods and services (Section 2.1), and in the longer run through increased attractiveness of a region for firms, people and economic activity in general (Section 2.2). Then we look at long run educational and creativity values of arts and culture for a region. We switch perspective in Section 3 to an analysis of how economic development will change arts and culture; we look in Section 3.2 at the changing demand for cultural goods in the course of development, and in Section 3.3 at changing supply that is affected by a productivity difference for the art sector (Baumol’s cost disease), technological change and globalization of culture. Remarks on changing patterns of public

<sup>4</sup> The most commonly quoted definition of sustainable development is that put forward by the UN World Commission on Environment and Development (“the Brundtland Commission”) in 1987, which specified sustainable development as “development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs”. A subsequent UN commission, the World Commission on Culture and Development, which reported in 1995, carried these ideas through to the arena of cultural development, where again the long-term needs of future generations for access to cultural resources can be seen to be important.

<sup>5</sup> In particular it is not clear how the various aspects of cultural sustainability shall be weighed in order to derive a measurement for cultural sustainability.

support for the arts and a final assessment round off this section. The location of arts and culture is discussed in Section 4 where we look at reasons for agglomeration of cultural industries and the relationship of urban versus suburban and hinterland development. Concluding remarks follow in Section 5.

## 2. How can arts and culture generate urban and regional development?

The role of arts and culture as a way of generating urban and regional development has been widely canvassed for some time. In this section we will look at the economic aspects of this, the methods applied and the magnitude of the effects involved. Arts and culture can generate urban and regional development through effects that can be divided into short-run spending impacts and long-run growth impacts. The short-run spending impacts are mainly due to the fact that the arts and culture can attract visitors – local and non-local consumers, who spend money in the local area (Section 2.1). The long-run growth impacts discussed in Section 2.2 can be divided into two different types: arts and culture as a localization factor for people, companies and investments (Section 2.2.1), and the impact of culture on creativity, etc. (Section 2.2.2). Arts and culture can also play an important role for both image and knowledge of a town or a region; this in itself is not important for economic development, but it could be a prerequisite for the creation of positive economic effects by attracting tourists, inhabitants and firms. In Section 2.3 we look into strategies for cultural and urban planning that take such a broader perspective on urban and regional development.

### 2.1. Short-run effects

The short-run spending impacts are due to the fact that the arts and culture can attract visitors – local and non-local consumers – who spent money on culture, but sometimes also on related goods and services like food, beverages, accommodation, shopping, etc. If there are visitors who have come to a city or a region because of the cultural activities on offer, their consumption constitutes an increase in aggregate demand that can be attributed to the arts. These kind of short-run spending impacts are mainly based on cultural tourism, but can also be due to the possibility that the region's own population spends less elsewhere.

#### 2.1.1. Measuring short-run spending impacts – economic impact studies

The most frequently applied method to study the short-run spending effects of the arts is economic impact analysis. This approach is a well-established and frequently-used methodology in economics, in which the impact of one activity on the rest of the economy is calculated using traditional multiplier models. In cultural economics many such studies have been carried out during the last 25 years,<sup>6</sup> with Cwi and Lyall (1977) being

<sup>6</sup> See Radich (1987, 1993) for an extensive overview.

one of the pioneering applications. In economic impact studies, the short-term spending impact of the arts on consumption, income and employment is measured, normally differentiating between direct, induced and indirect effects:

- *The direct effects* are the employment and income generated in a locality by the arts activities themselves.
- *The induced effects* (or linkage effects) – the customer effects – measure the spending of visitors to cultural events or institutions on transport, food and drink and perhaps accommodation.
- *The indirect effects* are multiplier effects, which are associated with both the direct and the induced effects.

The total impact can be calculated as:

$$\text{Total Impact} = \text{Direct Effects} + \text{Induced Effects} + \text{Indirect Effects},$$

$$\text{where Indirect Effects} = (\text{Direct Effects} + \text{Induced Effects}) \times \text{Multiplier}.$$

This approach typically assumes that there is sufficient free capacity in the local area in the form of unemployment.<sup>7</sup> Note that a short-run impact model has to be distinguished from a general equilibrium model, in which the required (cultural) production competes with other sectors in input and output markets. General equilibrium models can give very different results from impact analyses, particularly because they typically focus on the longer run.

Impact studies have been classified under the term “multiplier analysis”, although there are different types: export base, traditional Keynesian, input-output and proportion multiplier models [Cooper et al. (1993)]. The magnitude of the multiplier depends on interregional linkages; it will be lower in smaller, less self-sufficient geographical regions than in larger, more self-sufficient ones.

A sophisticated economic impact study should attempt to answer the question: “How much would short-run economic activity decline in a specific region if X were no longer to exist?” In other words the analysis should only deal with the net effects on consumption, income and employment, not with the gross effects, which means that care should be taken to distinguish between net injections into the region from tourists or other external sources and diversions of local spending. Extra expenditure attracted from outside the region is what matters most; thus in impact studies in the cultural sector it is spending by cultural tourists that is the main measured source of short-run impact on the regional economy. A cultural establishment or event which draws a considerable number of tourists will have a much higher impact than one which caters more to the interests of the locals. In other words, the more tourists that can be attracted by the arts and culture, the higher the economic impact.<sup>8</sup> This implies that there is a contrast between the local and the national level. Spending which happens to be additional at a

<sup>7</sup> Otherwise, multiplier effects would be lower and price effects for cultural products would have to be taken into account.

<sup>8</sup> See further Section 2.1.4 below.

local or a regional level (and therefore leading to economic growth) might not be additional at a national level, for example, if domestic tourist spending in one region is mostly at the expense of other regions; in the latter case the economic effects will be higher at the local/regional level than at the national level.

Besides, alternatives must be considered. If these kinds of studies are used as arguments for public support for the arts and culture<sup>9</sup> it must also be realized that it is not enough to show that the arts and culture can generate income and employment, because all economic activity does that. It is necessary (though difficult) to investigate whether the arts stimulate economic development more than if the subsidies had been used for alternative purposes such as developing infrastructure or subsidizing sports events.

Economic impact studies in the cultural sector have been conducted at different levels including the following:

- a single cultural event, e.g., a festival, or individual permanent cultural institutions;
- the entire cultural life of a town, municipality or a region; or
- the cultural life of an entire state or nation.

For our present purposes, analyses of the cultural life of an entire state or nation<sup>10</sup> are not very relevant, and so we concentrate in the following two sections on presenting several examples of studies in the other two categories.

### *2.1.2. Applications 1: The impact of a single event or institution*

Few comparisons or generalizations can be drawn from studies dealing with the economic impact of a single cultural event or individual permanent cultural institution, because the impact differs from event to event or institution to institution. Examples of these studies are the economic impacts of: eight cultural institutions in Baltimore [Cwi and Lyall (1977)], the Staatsoper, Volksoper, Burgtheater and Akademietheater in Vienna [Abele and Bauer (1984)], the Edinburgh Festival [Vaughan (1979)], the Stratford Festival in Ontario [Mitchell and Wall (1989)], three Canadian theater companies [Mitchell (1989)], the open Air Museum at Beamish [Johnson and Thomas (1992)], the Renoir and Barnes Art Exhibit [Stanley et al. (2000)] and the illustrative cases discussed in more detail in the following paragraphs.<sup>11</sup>

Christoffersen and Lyk-Jensen (1994) show the importance of cultural tourism in their impact study of a Danish art institution. They use an input-output model for the local area, and their study is one of the few that tries to compare the economic impact of an art institution with alternative ways of using the money. The cultural institution is Brandts Klaedefabrik, an old textile factory in Odense (a large provincial town in

<sup>9</sup> Economic impact studies often had that function; see, for example, van Puffelen (1996).

<sup>10</sup> For example, Myerscough (1988a) and Hummel and Berger (1988). Lately, creative industries mapping have been conducted in several countries based on national statistics [e.g., Department of Culture, Media and Sports (1998, 2001)]. See further Section 4.1 in this chapter.

<sup>11</sup> See also the guidelines for calculation of the economic impact of America's orchestras published by the American Symphony Orchestra League [Cooper (1997)].

Denmark) housing exhibition premises including Brandt's Textile Factory Art Gallery, the Museum of Photographic Art, Denmark's Museum of Graphic Art, and the Danish Press Museum. A two-phase analysis was carried out. First, demand with regard to the cultural establishment was determined by interviewing visitors. Second, the regional and national economic effects were calculated using economic models and a regional input-output table. The economic impact of the art institution was compared with alternative ways of using the money by way of two supplementary analyses: the effects of Brandts Klaedefabrik were compared first to the effects of another cultural establishment in Odense, the house of Hans Christian Andersen (the famous Danish writer of fairy tales), and second to the effects of a general expansion of public-funded activities.

The results indicate that the calculated effects of Brandts Klaedefabrik on economic conditions scarcely differ from the effects of a general expansion of the public sector distributed evenly among all public expenditure outlets. However, more significant economic consequences can be calculated for Hans Christian Andersen's House than Brandts Klaedefabrik using a demand-oriented approach as a starting point. The fact that the two institutions have such different economic effects from this perspective is mainly due to Hans Christian Andersen's House being a cultural establishment which attracts a very considerable number of tourists, while Brandts Klaedefabrik caters more to the interests of local inhabitants; in a demand orientated approach, a public activity will emerge with better results if there is actual production of goods or services for the export market (including tourism), as is very much the case for Hans Christian Andersen's House.

An economic impact study of the Wexford Festival in Ireland [O'Hagan (1989, 1992)] also shows the importance of attracting tourists for the analysis to come up with big multiplier effects. At the Wexford Festival (an opera festival in Ireland) attendees from outside the Wexford area accounted for 85 percent of all opera ticket sales during the study period. Attendees from outside the Republic of Ireland accounted for almost 33 percent of all ticket sales and 50 percent of total expenditures. The vast majority (96 percent) of those traveling to Wexford during the time of the Festival came primarily to attend the Festival. On this basis O'Hagan concludes that the Wexford Festival makes a significant contribution to Irish tourism by attracting a sizeable flow of foreign tourists to Wexford and Ireland, by attracting an equally large flow of domestic (Irish) tourists to the economically depressed Wexford area, and by generating these tourists flows in an off-peak period of the year.

A further illustration of the impact of a single event is provided by Gazel and Schwer (1997) who studied the economic impact of three "Grateful Dead" performances in Las Vegas in 1995. They estimated the economic impact for the local economy to range between US\$17 and 28 million and between 346 and 589 sustained jobs.

A hybrid phenomenon is that of the "cultural mega-event" such as the European Capitals of Culture program or the World Expositions. These are events of limited duration and consequently part of their economic impact is limited to the duration of the event, as for festivals; however, a substantial second part of the expenditure has longer-lasting effects as it increases the capital stock of the city or region where the event takes place.

The extent of these extra returns is difficult to measure. Consider, for example, the European Cultural Capital Cities program. Palmer (2004) estimates that out of the 2.133 billion euros spent on the 21 cities in this program during the period 1995–2004, 737 million were operating expenditures and 1.396 billion were capital expenditures that went into new provision and upgrading of cultural capital, urban revitalization, and also into infrastructure such as improving transportation facilities. In the latter case, it is difficult to measure to what extent these infrastructure projects were *additional* in the sense that they would not have been undertaken in the future if the cultural event had not taken place. Furthermore, it is difficult to assess what other investments these projects may have crowded out and what the effects of these alternative investments would have been.

In a very thorough analysis of the EXPO 2000 (the World Exposition) in Hanover, Brandt et al. (2001) included only those projects that had not been planned before and moved up due to the EXPO. They calculated a primary and total impact of the EXPO and showed how the geographical delineation influences the results. The primary impact of the EXPO amounted to 7.5 billion DM in Lower Saxony, and 11.2 billion DM in Germany, the total effect summed to 8.4 billion DM for Lower Saxony and 13.4 billion DM for Germany. The employment effect was 65,000 and 100,000 man-years, respectively. The long-term effects – a better transportation infrastructure, better infrastructure for the Hanover fair, the newly created industrial zone at the former EXPO area, image and learning effects, etc. – were very hard to quantify.

### 2.1.3. Applications 2: The impact of the arts on a town, a municipality or a region

We consider two studies dealing with the entire cultural life of a town, a municipality or a region: a study of the New York–New Jersey Metropolitan Area [Scanlon and Longley (1984)] and a study of the economic impact of the arts in Glasgow [Myerscough (1988b)]. Other such studies include van Puffelen (1987) on art and culture in Amsterdam.

Scanlon and Longley (1984) gathered data in the New York–New Jersey Metropolitan Area from 1580 non-profit cultural institutions including museums, orchestras, dance and opera companies and theaters, 54 commercial Broadway and Off-Broadway theaters, 335 galleries and auction houses and film and television producers. Furthermore, 5600 questionnaires were handed out to visitors to performing and visual art events. On the basis of these data the economic impact of culture on the metropolitan region was estimated using an input-output model. They found that the arts had an impact of \$5.6 billion on the regional economy and generated more than \$2 billion in personal income and over 117,000 jobs for the area in the study period. Of the \$5.6 billion regional impact, \$1.3 billion was created by the 1580 non-profit institutions; \$360 million by art galleries and auction houses; \$650 million by Broadway and Off-Broadway theaters, plus Broadway road companies; and \$2 billion by local film and television productions. Moreover, the arts constituted a major export industry for the region by generating \$1.6 billion in expenditure by visitors who came primarily or extended their stay for arts and

culture and from touring companies. The more than 1900 arts institutions in the region inspired and entertained an annual audience of 64 million, 13 million of whom were visitors from outside the region. The regional arts institutions and the proportion of their non-resident patrons who visited the area primarily for the arts generated a total of \$150 million in regional income taxes and sales taxes revenues. Industries that benefited most in order of importance were: real estate; business and professional services; wholesale and retail trade; eating and drinking establishments; hotels and personal services; utilities; transportation; medical and educational services; and finance and insurance. Lastly, the arts at that time were shown to be a larger industry than advertising, hotel and motel operations, management consulting, or computer and data processing services. These results seem to show that cultural life is of great importance to the New York economy. No doubt this is true, but it is also worth remembering that in many ways New York is the cultural center of the USA, and thus not representative. Ten years later a second study was carried out on the same region, which showed that the total impact was 75 percent greater than in 1982, but its structure was almost unchanged (The Port Authority of New York and New Jersey, 1993).<sup>12</sup>

The economic contribution of culture to the Glasgow region<sup>13</sup> was assessed by Myerscough (1988b) for the year 1985–1986. He found that cultural life in Glasgow had a gross turnover of £204 million in that year, a value-added of £79.5 million and employed 8000 persons or 1.2 percent of total employment in the Glasgow region. Of the 6.5 million visitors to cultural events, 2.1 million went to cinemas, pop, rock, folk music and jazz concerts, 3.2 million visited museums and galleries and 1.2 million went to theaters and classical concerts; of the 4.4 million who went to museums, galleries, theaters or concerts, 64 percent lived in the Glasgow region, 17 percent were one-day visitors and 19 percent were tourists. Among the one-day visitors to museums and galleries, 66 percent stated that culture was the most important reason for their visit to the region, while only 16 percent of the tourists stated that culture was the most important reason for their stay. The total employment effect of cultural life in Glasgow was 14,731 direct and indirect jobs, amounting to 2.25 percent of the total number of people employed in the Glasgow region. Note that care must be taken in interpreting the figures from Myerscough's study to distinguish between gross and net effects (see Section 2.1.5).

#### 2.1.4. *The role of tourism*

As the above studies show, cultural tourism is decisive for the economic impact that a cultural institution or cultural life of a region has on the local or regional economy. However it is very difficult to define what should be included in cultural tourism. How many tourists can really be regarded as arts tourists? The problem is to distinguish those

<sup>12</sup> See also Heilbrun and Gray (2001).

<sup>13</sup> The Glasgow region was subject of one of three regional analyses of the economic importance of culture, which formed the basis of Myerscough's national analysis of the importance of culture to the British economy [Myerscough (1988a)]; the two others were carried out in Merseyside and Ipswich.

visitors who are in the region because of the cultural activities offered there from those who would have gone there anyway; furthermore, for those who came for multiple reasons it is necessary to determine to what extent they have prolonged their stay in order to enjoy the cultural amenities. Even though people say that the main reason for their visit is art and culture, it cannot be concluded that they would not have visited the place anyway. Conversely, in the case of visitors whose main aim is not art and culture, it cannot be excluded that the cultural activities on offer have not had some influence on their decision. These difficulties suggest the exercise of caution in interpreting the results of tourism-related studies. For example, lack of an exact distinction between “solely-culturally-motivated” tourists and those who are “combined-motivated” may bias the results. Another possible source of exaggeration lies in the overestimate of the complementary expenses incurred by the consumption of the cultural goods themselves such as transport and lodging expenses [Bonet (2003)].

The European Association for Tourism and Leisure Education (ATLAS) conducted a survey in 1997 with a sample of 8000 visitors to 20 different cultural locations in Europe. More than 50 percent claimed to have toured a museum during their trip, 40 percent had visited a monument, 30 percent had seen an exhibition, and 23 percent had seen a live performance. Between 20 and 30 percent of those surveyed could be classified as cultural tourists in the sense that they chose a destination with the primary objective of enjoying a cultural activity or product, and they identified themselves as cultural tourists [Bonet (2003)]. This study shows clearly that tourists visiting a cultural attraction should not be confused with cultural tourists. The biggest impacts of cultural tourism are presumably at regional or local level, since a larger percentage of one-day visitors than of tourists typically mention the arts as the main reason for their visit.

Another important question from an urban and regional development perspective is: which cultural assets are most likely to attract tourists and generate development and under which circumstances? An isolated attraction within a largely unknown or remote region has perhaps little hope of standing out in a dense market of tourist products and services. On the other hand, large-scale internationally famous cultural artifacts such as the Eiffel Tower in Paris, the Sydney Opera House, and the Statue of Liberty in New York operate as central tourist attractions, becoming symbols of their respective cities. There is, however, no statistical estimate dealing with the impact of a single large-scale cultural artifact and its contribution to tourism [Landry and Bianchini (1995)]. Obviously it is difficult to disentangle the attractiveness of a single cultural institution if it is embedded in a rich environment of culture and other amenities.

Bilbao in Spain may serve as a test case for the impact of a single internationally famous facility because of the Guggenheim Museum located there. Bilbao was not previously known for its tourism potential, and did not otherwise lend itself to large flows of tourism [Gomez (1998)]. Plaza (1999, 2000) has studied the influence of the Guggenheim Museum on tourism in Bilbao; although these studies show that the Guggenheim

Museum Bilbao exerts an important effect on the attraction of tourism, they do not calculate the economic impacts.<sup>14</sup>

Finally, tourism also can have negative effects on the local community, such as crowding effects, pollution and wear and tear. The latter can especially be the case in connection with some special items or places of cultural heritage, which are not able to stand intensive use.<sup>15</sup>

### 2.1.5. *Assessment and critique*

What kind of generalizations can be drawn from the different results of economic impact studies on the arts? First, these impact analyses show that the arts, like any other economic activity, have economic effects on the rest of the economy. If the arts create growth in aggregate demand, income will rise by more than the initial rise in demand, because of multiplier effects. The size of the multiplier depends on factors such as tax rates, the marginal propensity to consume, the marginal propensity to import, the area's size, etc. The results do not, however, indicate that the multiplier effect is greater in the arts sector than in other sectors of the economy, although the economic effects on the regional economy could indeed be greater if art activities attract a lot of tourists.

Second, the economic effects are greater for some cultural activities than for others. In general, theaters and concerts have a larger turnover than museums and galleries, but museums and galleries attract more day visitors than theaters and concerts. If we take into account that tourists spend more money per visit than one-day visitors who in turn spend more than the local population, and the fact that visitors at museums and galleries spend more money on shopping and on food and beverage consumption during their visit, we arrive at the conclusion that the economic effects are in general bigger for museums and galleries than for theaters and orchestras.

Although economic impact studies are very well established by now, many authors have criticized them on the interpretation of their results.<sup>16</sup> Recently, Seaman (2003) has summarized the sources of errors linked to impact studies as follows:

- direct base error (errors of counting the direct effects);
- induced base error (errors of counting the ancillary spending, or the induced effects);
- multiplier error (errors of calculating the multiplier effects);
- supply constraint error (errors arising if the assumptions about the capacity of the local area are not correct);
- ex-post verification error (the failure to verify whether any observed changes such as closures of local arts organizations had economic effects consistent with prior economic impact claims); and

<sup>14</sup> Note that the Guggenheim Museum itself carries out economic impact studies of their activity, which are published as part of their annual accounts.

<sup>15</sup> For a consideration of heritage conservation and tourism in urban regeneration, see Stabler (1996).

<sup>16</sup> For example, Bille Hansen (1995), van Puffelen (1996), Graves (1987), Peacock (1991) and Seaman (1987, 2001, 2003).

- policy interpretation error (the drawing of wrong policy conclusions from results of impact studies, as discussed further below).

As a consequence of the heavy critique of economic impact studies some authors have even suggested that no more impact studies of the arts were needed [e.g., van Puffelen (1996)].<sup>17</sup> Especially it is not clear that a positive economic impact of cultural events or institutions can be used to justify public subsidies to the arts. Many economic impact studies have been carried out to provide extra arguments for government subsidies to the arts. These studies are, however, not very well suited for this purpose. Most importantly, they risk evaluating the arts on an incorrect basis, because the main purpose of the arts is not to attract tourists or to generate consumption, income and jobs. These economic impacts are extra gains, not the main goal. The most important impact of the arts – and the main argument for their public support – is in their cultural or social influence. If one only analyzes the impact of the arts in relation to the economic side effects, a wrong picture will emerge. In particular this could imply a risk of focusing on cultural events with the greatest short term economic impacts – for example, big concerts with star performers – with the aim of attracting a big (foreign) audience, instead of focusing on cultural activities that are to the benefit of the population and to its cultural development.<sup>18</sup>

The problem is that impact studies use traditional indicators of economic growth such as national income, consumption expenditures, employment, etc., thus reducing the definition of development to one of economic growth in the short term; as noted earlier, this is a narrow definition of development compared to one containing not only economic but also human and cultural (sustainable) development.<sup>19</sup> Moreover the period studied is of great importance; the demand effects calculated in economic impact studies occur at once and they can be estimated quite exactly, whereas the economic effects which are due to the substantial importance of cultural activities for society and human development only occur in the long term and are very difficult to estimate.

Nevertheless the present knowledge which the existing economic impact studies provide can probably be useful in a broader assessment of policies and strategies for development where other kinds of development (i.e. human and cultural development) are taken into account. Throsby (1997, 2001, 2003) has made some initial suggestions on how the concept of “culturally sustainable development” can be made operational. He proposes “the specification of the concept as a set of principles or criteria which

<sup>17</sup> Seaman (2002) has however argued, that what he calls “naïve” economic impact studies, may provide more accurate estimates of the “true” total economic impact (more broadly defined) than more defensible methodological approaches, like “sophisticated” impact studies or contingent valuation studies.

<sup>18</sup> Schuster (1995) analyzes the motivations for two large urban festivals, La Mercè in Barcelona and First Night in Boston, and identifies motives to develop urban infrastructure, to upgrade the image of the city, to attract tourism, and to address social problems by bringing different types of people together (p. 184). Obviously, creating enjoyment for the population is the dominant motivation. Only part of these motivations is captured by economic impact analyses, thus making them a very narrow concept.

<sup>19</sup> See Throsby (2001, 2003) and the discussion in Section 1.2 above.

provide a means of systematizing the assessment of policies and strategies for development and for evaluating the extent to which, in terms of each criterion, such policies or strategies may or may not be consistent with culturally sustainable development". The first step is simply listing a set of variables: economic, social and cultural indicators. Having determined the appropriate set of indicators, the next step is to identify the range of relationships that might be postulated between them. In this process the knowledge from the existing economic impact studies can be of great help in identifying and estimating the relationships between some of the cultural and economic indicators. In other words even though economic impact studies are very narrow – looking only at economic growth in the short term, not taking into account the long-term effects and the public-good characteristics of the arts – properly conducted economic impact studies can be important tools in identifying the linkages between the cultural sector and the wider economy and in estimating the magnitude of the relationships involved.

## 2.2. Long-run effects

### 2.2.1. Location choice

In addition to the short-run effects that can be measured in economic impact studies, cultural activities may have more indirect and longer-term effects. In particular a lively cultural atmosphere may attract people and firms to particular regions, for example, because people enjoy arts and culture (as they enjoy a beautiful environment) and are willing to forgo some of their income compared to other locations in exchange for better access to cultural institutions. Such a positive externality will make this location more attractive to firms which can save on their payroll costs.<sup>20</sup> Moreover they may find more creative people in these areas which enhances their possibilities to hire qualified workforce.

Thus culture can have an impact on urban and regional development by attracting people, companies and investments. For most individual cultural institutions these effects will be without importance, because they are too small to trigger such a process of development. But these effects can be important for some few very large institutions such as the Guggenheim Museum in Bilbao or, more importantly, for a vibrant cultural life created by many cultural institutions in cities like London, Berlin, and Paris. Moreover, other kinds of investments may be attracted by a high level of cultural activity, such as investments in better transportation infrastructure, etc., but these effects are in general difficult to verify.

In regard to the locational choices of *people*, we could observe the arts and culture leading to population growth in a geographical area if cultural institutions and events attracted new citizens to live there. The arts can be one factor among others affecting where a household decides to live. In fact studies based on interviews generally show

<sup>20</sup> That is the entry point for the hedonic approach, cf. Clark and Kahn (1988).

that the arts are not the first factor considered when employees are deciding where to live and work; rather, it is job opportunities, housing, family relations, schools, transport facilities, and sports and leisure facilities that are the deciding factors.<sup>21</sup>

In regard to the locational choices of *firms*, it is widely believed that there is a positive relationship between the arts environment and industrial development in a region. But what do we really know about this relationship? Arts may have some influence on the location of industrial firms because the cultural environment may be important for a company's possibilities for attracting key manpower, in addition to such factors as infrastructure, land prices, wage level, manpower, sales opportunities, etc.<sup>22</sup> The question is, however, how important the arts and culture are as a localizing factor? Some attempts have been made to determine this by means of interviews with company managers and key manpower.<sup>23</sup> The results of these studies show that the arts are not at all the first factor considered when companies are deciding where to locate; companies regard hard business factors – sales opportunities, infrastructure, manpower, wage level, land prices and tax level – as far more important than cultural factors. But other studies have found stronger relationships. For example, Kotkin (2000) identified the relationships between lifestyle amenities and the locational preferences of some high-technology industries for neighborhoods such as New York's Silicon Alley, San Francisco's SOMA and Mission Districts, and Seattle's Pioneer Square. Sommers and Carlson (2000) found that some 50 percent of high-technology firms and employment in Seattle is located in a high-amenity district surrounding the urban core.

Florida (2002a) has introduced a new perspective on economic growth. His theory is that companies move where the creative people are, because human creativity today and in the future is the most important resource for companies. Creative people shift jobs very fast, and it is important for companies to locate in a place which have a "critical mass" of creative people. Florida (2002a) has stressed, that the "creative class" now comprises more than 30 percent of the entire workforce.<sup>24</sup> He emphasizes the "three T's": tolerance, talent and technology, which in his view drive economic growth. Technology and talent (a concept closely related to human capital) are very well established determinants of economic growth. The new concept is tolerance. Tolerance is important because diversity and an open society attract all kinds of creative people who cannot be discriminated between on the basis of place of birth, race, sexual preference, dress, age, etc. As a measure of how open an urban area or a region is, Florida has constructed several indexes such as the gay index, the bohemian index and the melting-pot index, measuring the share of the region's population who are gays, bohemians or foreign-born people respectively [Florida (2002b)]. A second important ingredient is lifestyle

<sup>21</sup> See, for example, Rubernowits and Rubernowits (1990).

<sup>22</sup> For an extensive review of the empirical literature on the location of firms, see Bartik (1991).

<sup>23</sup> See, for example, Myerscough (1988a).

<sup>24</sup> This includes computer and mathematical occupations, architecture and engineering occupations, life, physical, and social science occupations, education, training, and library occupations, arts, design, entertainment, sports, and media occupations, management occupations, business and financial operations occupations, legal occupations, healthcare practitioners and technical occupations, high-end sales and sales management.

amenities that people care about such as sport facilities, parks and other environmental amenities and – notably – arts and culture!

The presence of such creative human capital in turn attracts and generates innovative, technology-based industries. To test this hypothesis Florida (2002b) uses different correlations, e.g., between geographic concentrations of bohemians (measured by an index) and concentrations of high human capital individuals, and between the bohemian index and high-technology industry. Florida concludes that the findings support the hypothesis: “The presence of a significant bohemian concentration in a region signals an environment that is open and attractive to high human capital individuals. This in turn stimulates the kind of creativity and innovation associated with high-technology industries.” There are, however, problems with causality in this conclusion. Even if the positive correlations are the result of some type of causality, neither the direction nor the magnitude of the effects can be determined. It could well be the case that some latent third factor attracts both bohemians *and* creative firms but that there is no causality between the latter two (endogeneity problem).<sup>25</sup>

Ottaviano and Peri (2005) study whether cultural diversity measured by the variety of native languages spoken enhances productivity. Using census data for 1970–1990 they find that wages and employment density of US-born workers are systematically higher in cities with richer linguistic diversity.

To conclude, the interaction between the arts and industrial development is complicated and our present knowledge in this field is relatively sparse. We need more knowledge about which kind of industries are particularly interested in the level of art and culture in a region, and about the magnitudes of the impact and the complex interaction with other factors of importance. Apart from this more general effect of culture on the location of investments, companies and people, a special effect can be mentioned, namely that a high level of cultural institutions in an area could especially attract small companies working within the cultural or creative area, because they can use the network and cluster advantages arising from highly developed cultural institutions in a local area. We deal with this issue in Section 4 below. Finally, it may be noted that while the issue of attracting businesses and people is interesting from the viewpoint of an individual city or region, from a general point of view it may be a zero-sum game if the growth in one place happens at the expense of another place. This raises the question of how many (public) resources should be used in the presence of interregional competition in order to attract tourists, inhabitants and businesses.

### 2.2.2. *Educational and creativity values*

Different kinds of learning effects can be connected to arts and culture. Most people would agree that the arts are important for the formation of identity, personality, attitudes, job motivation, creativity, etc. – factors that are also important for economic

<sup>25</sup> It could also be the case that bohemians and foreign-born people follow creative and fast growing firms rather than the opposite.

development. In other words, the arts can provide inspiration for creative processes and trigger actions directed towards change and innovation. Artistic and cultural activity in a region can thus indirectly lead to more innovative industrial development through the creativity in the arts sector spreading to other economic activities. Creativity – in the form of innovation and breaking through boundaries – is something universal, and impulses from the arts can be important for actors on the business stage – and thus for economic growth. In this way, the arts may act as a dynamo in the development of society. Educational and creativity effects can only occur in the long run and are obviously very difficult to verify or to measure, in part because we do not know the transmission channels through which such creativity and personality spill-overs could materialize. It is thus necessarily a somewhat vague concept.<sup>26</sup> Yet again it must be remembered that, as in the case of economic impact studies, such productivity spill-overs are not the prime reason for supporting local art and culture.

A further arts-related development concerns so-called creative alliances. During the last few years, new forms of co-operation between culture and business have been developed which are broader than traditional sponsorship agreements, and, for instance, include design and product development, marketing and organization development. In some countries organizations have been set up with government support that try to organize this link between the arts and industrial innovation and development. The idea is to build networks between artists and industrial companies and induce companies to use artists in their innovative processes. In England the organization Arts and Business has existed for several years with this purpose, and similar institutions have gradually been established in many other western countries. The outcome of establishing these creative alliances is, however, an area where not much research has been done.

### 2.3. Cultural and urban planning

Over the last 10–15 years – primarily in Europe, the USA and Australia – a new trend has arisen using concepts like “cultural planning”, “cultural programming” and “urban planning” with the aim of revitalizing cities (especially inner cities) as well as old industrial areas and waterfronts.<sup>27</sup> The goal is to foster the development of “creative cities” [Landry (2000; Bianchini and Landry (1995)], to bring about “cultural regeneration” and to attract “the creative class” [Florida (2002a)]. Different development strategies can be applied which often define culture very broadly and which combine the cultural dimension with the extension of transport infrastructure, modern housing and industrial buildings, shopping centers, etc. Prime examples of cities that used such concepts in Europe include Glasgow, Newcastle, Barcelona and Bilbao.

<sup>26</sup> Many of these long-run effects are by their very nature somewhat vague and hard to measure. That does not mean that they may not be important, but it implies that they will not easily serve as a justification for government support of arts and culture; however, growth promoting effects should not be the prime reason for public support of arts and culture.

<sup>27</sup> See, for example, Mercer (2002) and Evans (2001).

These development strategies are interesting because they focus on the interaction between culture and many other factors of importance for the development of cities and regions in a broader planning process, where the art and culture are integral parts of the revitalization and development of cities and regions.<sup>28</sup> However, the question is what we really know about the result of such efforts and strategies, including the importance of culture in this connection. In the special issue of the *International Journal of Cultural Policy* on the theme “Urban Space and the Uses of Culture”, Gibson and Stevenson (2004) write in the introduction: “What is of most concern is the lack of rigorous research done on the cultural, economic, political and social short- and long-term effects of cultural planning. What evidence is there that the massive public expenditure required for these redevelopment and re-imaging strategies actually produces outcomes that are in the public interest?”, and they finish by concluding: “As this issue makes clear, the complexities of the cultural, economic, social and political implications of such programs are as multiple as their applications. It is clearly not simply a matter of ‘add culture and stir’.”

Glasgow and Bilbao are two of the most ambitious and outstanding cities in Europe that have deliberately used arts and culture in urban development. Both cities have experienced processes of deindustrialization and a subsequent loss in employment. They share a common past and a very similar approach to improving their current position as declining industrial centers on the European periphery. In terms of economic performance, the reality of Glasgow does not look as promising as it has been portrayed. Glasgow’s image may have changed, but the economic recovery has failed to materialize. According to Gomez (1998) employment had actually fallen. But it is undeniable that the image of Glasgow, both within and outside the city, has been radically reconstructed. There is also agreement on the success of these policies in terms of the physical renaissance of Glasgow’s central area. Overall, as Throsby (2001, p. 125) points out, “there may also be long-run externalities with real economic potential if the enhancement of the cultural environment of a city leads to greater social cohesion, a stronger sense of civic pride, lower crime rates, increased economic dynamism and so on. These sorts of factors may be important in improving the profile or image of the city as a desirable location for in-migration of capital and establishment of new business.” Nevertheless as noted above, these effects are very difficult to verify and trace out.<sup>29</sup>

<sup>28</sup> Stern (1999) found that even after statistically controlling for other determinants, arts and cultural organizations had an important independent effect on neighbourhood revitalization: “Compared to neighbourhoods with the fewest arts organizations . . . neighbourhoods with many arts and cultural organizations . . . were more than twice as likely to revitalize.”

<sup>29</sup> See also Vidarte (2000).

### 3. How does regional economic growth influence the development of the cultural sector?

Much of the debate on culture and development has centered on the issue we have dealt with above, namely the contribution that the arts sector can make to overall development of a region. The opposite causality however is of equal importance: How does regional culture change in the course of regional economic development? Or to put it more pointedly: Do economically poorer regions also have poorer culture? While the answer to this question is extremely difficult as it inherently implies value judgments on various forms of art (for instance, is a performance in a simple theater at a local inn better or worse than a performance in a large multipurpose auditorium?), we may be able to identify major lines of development of local culture as economic development proceeds. This refers not only to changes in the level of cultural activity measured by overall expenditures, but also to its structure.<sup>30</sup>

#### 3.1. Market prices and non-market values

If we assume for a moment that prices for cultural activities are determined freely in the marketplace, we could simply ask how demand and supply conditions will change in the course of development; i.e. identify the determinants of the demand and supply curves and analyze how they are affected by overall development. That would give us a clear idea as to how cultural industries will change in the course of development. Free price determination may be a reasonable assumption for a number of goods such as movies, popular and folk music, although markets may not all be competitive.<sup>31</sup> We will thus look at demand and supply conditions and their likely change brought about by development. However, if we look at cultural services provided by museums, theaters, or cultural heritage sites, such an analysis, valuable as it may be, will disregard the strong role that the state has in these areas. The heavy state involvement in arts and culture arises partly for historical reasons,<sup>32</sup> but partly also because it is a response to the existence of non-market values generated by the arts and culture, i.e. these activities

<sup>30</sup> Different cultural activities can be made comparable through the price system in order to determine the total level of cultural activity. This implies value judgments as well because prices reflect marginal utility, although these value judgments are made by the consumers and not the researcher. Note however that these expenditures reflect only the utility of people actually *consuming* the cultural services and not the option or bequest value offered by cultural institutions (see below); moreover it presupposes that prices are determined freely on competitive markets, which for cultural institutions often is not the case, given the strong involvement of the state.

<sup>31</sup> Note that measures of industry concentration may not be good indicators for the degree of competitiveness in industries producing information goods, such as the movie industry, due to the extremely high risk they face; cf. de Vany (Chapter 19 in this volume).

<sup>32</sup> For instance, the reason that Germany has so many orchestras is that it had been a nation fragmented into many kingdoms and princedoms each of which had its own court orchestra for the pleasure of the king and his court, cf. Schulze and Rose (1998).

impart values other than *use values* that may make people treasure art and culture even if they do not use these services directly. These values are: option, existence, prestige, and bequest values:

- *Option value* describes the utility that individuals receive from preserving the possibility that they may be able to enjoy the particular art or cultural service (even if they do not actually do so or have never done so before);
- *Existence value* is the value individuals derive from knowing that a particular cultural service exists (for instance, a particular museum, monument, etc.) even if they never intend to visit the site;<sup>33</sup>
- *Prestige value* refers to the value that a populace derives from national or regional heritage sites or monuments which help to identify and maintain national or regional identity or pride;
- *Bequest value* refers to the value that individuals derive from the knowledge that their children will be able to enjoy that particular service.

To the extent that culture creates these values in addition to the use or consumption value, it has public-good characteristics – non-rivalry and non-excludability. Of course, some important cultural and heritage sites as well as art in public spaces have public-good characteristics deriving also from their use values, even if some of their usages may be restrictable. For instance, access to the Eiffel Tower itself is restricted, but it is seen throughout the city of Paris – in its function as a national symbol and a monument of art and technology in the city of Paris it is a pure public good. Similarly a monument or statue in a public place is a pure local public good (or sometimes bad). Furthermore, art and culture may arguably have educational values that are not reflected in the price system. In all these ways culture produces positive externalities, constituting an obvious case for government intervention; indeed governments have played a very substantial role by subsidizing cultural institutions directly, or indirectly through tax concessions, or through public ownership.<sup>34</sup>

The strong government involvement in arts and culture means in turn that prices do not reflect solely consumer preferences for actual consumption of the cultural services and industries' supply conditions, but that they are distorted by subsidies, tax concessions, state-ownership and administered prices, etc. Consequently the value of the services produced depends crucially on what the political process is that determines the form and intensity of state involvement.<sup>35</sup> It is therefore important to understand this process and how its results will change in the course of development. The political interventions in arts and culture do not replace market forces, but rather they alter them. To the extent that cultural policy is demand-determined, i.e. politicians actually

<sup>33</sup> Sub-aqueous archeology is a case in point as many people do not dive; cf. Whitehead and Finney (2003).

<sup>34</sup> See, inter alia, Baumol and Bowen (1966, Chapter 16), O'Hagan (1998), Frey (2003), and Chapter 32 by Peacock, Chapter 34 by van der Ploeg, Chapter 35 by Netzer and Chapter 36 by Schuster in this volume.

<sup>35</sup> Of course private sponsorship and philanthropy could address the problem of underprovision of arts and cultural goods through private markets that stem from the public-good characteristics of arts and culture (positive non-use values); see Chapter 37 by Katz in this volume.

do what their constituencies want them to do, the factors that determine demand for culture are actually reinforced. Demand-determined policies refer not only the factors that determine effective demand in the market place, but also to the non-use values that individuals attribute to art and culture. We take up these issues in the next section.

### 3.2. *The demand for cultural goods*

#### 3.2.1. *Observable demand behavior*<sup>36</sup>

The empirical literature on the demand for arts has become quite sizeable, including econometric studies and a number of visitor surveys.<sup>37</sup> Given Seaman's comprehensive survey in this volume,<sup>38</sup> we simply present here our reading of the empirical evidence which refers mostly to performing arts (theater, opera, ballet, classical music) and the cinema.

Highly educated people are strongly overrepresented in audiences of performing arts as are people with high income; however this effect is significantly more pronounced for education than for income.<sup>39</sup> Demand for arts depends negatively on prices, although the estimates for the own price elasticity vary from very inelastic to highly elastic. Studies vary greatly in degree of sophistication and aggregation. The studies that use aggregate data (for instance, total revenue divided by attendance as a measure for the relevant price) tend to have lower price elasticities. They are of lesser value because they are not able to portray adequately the behavior at the margin. There is no clear evidence however that price elasticities for disaggregated studies exceed unity in absolute terms. Nevertheless our reading is that the evidence overall tends to support price elastic behavior.<sup>40</sup> Demand for industrially produced cultural goods such as movies has been shown to be price elastic [Fernandez-Blanco and Banos-Pino (1997); Dewenter and Westermann (2005)].

While it is intuitive that art is a luxury good and visitor surveys confirm a higher representation of well-off people in performing arts attendance, the econometric literature has not been unambiguous. Felton (1992) finds evidence of the luxury character for ballet but not for the opera, whilst in a sophisticated study Pommerehne and Kirchgässner (1987) find income elasticities greater than 1 for both average and high income visitors of German theaters. Gapinski (1984) and Bille Hansen (1991) find likewise income

<sup>36</sup> We are grateful to Bruce Seaman for sharing his views with us on the determinants of demand for art; see further Chapter 14 in this volume.

<sup>37</sup> For instance, the US National Endowment for the Arts sponsored visitor surveys in 1982, 1985, 1992, 1997, and 2002; in Germany the "Kulturbarometer", a national visitors survey, is frequently carried out, with varying focus; in Denmark similar studies have been conducted [see Bille et al. (2005)].

<sup>38</sup> See also Levy-Garboua and Montmarquette (2003).

<sup>39</sup> See Baumol and Bowen (1966) for the US and UK; Ford Foundation (1974) for the US; and Wiesand (1995) for Germany, cf. also Gray (2003). Obviously, overrepresentation does not necessarily imply that highly educated or high income people constitute the majority of the audience.

<sup>40</sup> Only few studies report cross-price elasticities [e.g., Gapinski (1986); Krebs and Pommerehne (1995)].

elasticities larger than one for theaters. Even though the evidence is not unequivocal, we see the balance of the existing evidence to be in favor of the performing arts as a luxury good.

In terms of overall *exposure* to the arts, the young population is overrepresented but in terms of overall *attendance* for the performing arts the opposite applies, i.e. the old constitute a relative larger share of the overall audience in a given period and the young are underrepresented.<sup>41</sup> Furthermore, arts consumption decreases with distance from the arts venue [Gray (2003); Schulze and Ursprung (2000)], women attend the performing arts more often than men (except for Jazz and Dance) and in the US there is a racial pattern depending on the arts form [Gray (2003)]. Other important influences for the demand for arts are life-style variables such as political or sexual preferences, which are notoriously hard to capture.<sup>42</sup>

How do these results relate to the problem at hand, i.e. the effect of economic development on the demand for culture? Development will affect all the described parameters. Generally, economic development tends to make people become richer, and typically also better educated. Since education and income have been shown to increase the demand for culture we should expect richer regions and cities to have a richer culture, other thing being equal. Note however that it is not only per capita income that is indicative of the demand for culture, but also the industry structure of the regional economy and thus the socioeconomic structure of the population. An old industrial town may have a lower demand for culture compared with a town with equal per capita income that is home for service industries, universities, government administration, etc. Of course the distribution of income is important as well. If income is concentrated on a few people with high incomes, some elitist art institutions may exist but the overall level of cultural activities may be lower than for a region with more equal income distribution. Geography and infrastructure matter as well – a largely dispersed population will have a higher average travel time and travel costs, which will tend to reduce the demand for cultural activities. Lastly a city or a region tolerant vis-à-vis homosexuality (and possibly other ‘alternative’ life-styles) might attract those people who *ceteris paribus* tend to have a

<sup>41</sup> One reason for age, but particularly education is that preference for arts and culture is an acquired taste, where consumption capital is built up over time [Stigler and Becker (1977)], which is easier for more educated people. Consumption capital tends to be higher for older people as they acquisition period is larger, cf. Lévy-Garboua and Montmarquette (2003). Very significant impact on arts attendance has exposure to arts education such as music lessons, etc., see Smith (1998). Art exposure is measured as relative frequencies, i.e. the percentage of people who go to the arts at least once in a given time interval. The exposure is larger for the young than for the overall or the older population, attendance is not.

<sup>42</sup> German voters of conservative parties have been shown to prefer more traditional art forms (opera, ballet, symphony) whereas voters of the social democratic and the green party have a higher probability to be in favor of experimental art forms [Wiesand (1995); Schulze and Rose (1998)]. Homosexuals are *much* more likely to attend the arts than demographically similar heterosexuals [Lewis and Seaman (2004)].

higher demand for cultural services. Those areas will probably also tend to attract more artists, but this becomes a supply side factor.<sup>43</sup>

Note however that existing demand studies mostly refer to performing arts and to institutions such as ballet companies, theaters, opera houses and orchestras that are well established, have a permanent legal form, and sell their tickets on the market. As regions become richer, they might not only enjoy a 'richer' culture in terms of reported per capita spending on culture, they might also experience a substitution from 'subsistence' and non-market art and culture towards more established art forms that our statistics would not capture.<sup>44</sup> Inasmuch as such a substitution takes place, the increase in cultural services in the course of development as reported by demand studies would be overestimated.

### 3.2.2. Non-market demand

As noted earlier, individuals' valuation of cultural goods and services is only partially reflected in the market demand for culture, since cultural goods produce non-use values as well. If government support for the arts reflects these non-use values, we have to study how they are systematically related to factors that change in the course of development. An increase in national or regional income over time will typically give rise to increasing public expenditures on culture, such that regions with a larger income per inhabitant will have relatively larger cultural expenditure per inhabitant than regions with a smaller national income. In Bille, Hjorth-Andersen and Gregersen (2003) the public cultural expenses of the Nordic countries have been compared for a number of years. This analysis shows that:

... we can conclude that cultural expenses have an income elasticity of 1 or perhaps a little more. Or in other, less technical, terms: when the national economy is doing well, there is a spill-over effect on culture. Every time Danish society becomes DKK 10 billion richer, this will affect culture with a 0.5 to 0.6 percent increase or DKK 50 to 60 million. Thus, economic growth seems to be the right thing for a rich cultural life! Seen in this perspective, the Nordic countries seem remarkably similar. [Bille, Hjorth-Andersen and Gregersen (2003, p. 343)]

In general four approaches have been used to study the magnitude of the demand for non-market goods and the determinants of non-market values [Frey (1997)]: the hedonic approach, the travel cost approach, contingent valuation studies, and the analysis of referenda.<sup>45</sup> We consider each one in turn.

<sup>43</sup> "The experience economy" [Pine and Gilmore (1999)] actually seems to be a concept that builds on this growing demand for culture, events and experiences. This relatively new and highly canvassed concept includes the demand for culture, events and experiences in a broad sense.

<sup>44</sup> This point has been made convincingly by Goldstone (2003) for the international context referring to the statistics of the UN World Culture Report.

<sup>45</sup> Of course, a very promising fifth method is discrete choice experiments (DCE) that have been used extensively in environmental economics [Adamowicz et al. (1998); Adamowicz and Boxall (2001)] and also in

(i) *Hedonic approach*. The hedonic approach can be used to analyze how land and housing prices are influenced through proximity to cultural sites (or the beauty of the landscape) after controlling for other factors.<sup>46</sup> Alternatively, hedonic studies might analyze the wage discount that people are willing to accept in exchange for a workplace in an area with high supply of cultural services. These studies need to rely, however, on competitive housing or labor markets and must be able to control for all other variables in the wage or land price regression. All other unobservable factors must not be correlated with culture, which is hardly met in reality as locations with a vibrant culture mostly tend to have other attractive attributes as well, so that a classical identification problem arises. Within cultural economics very few hedonic studies have been undertaken.<sup>47</sup>

(ii) *Travel cost*. The travel cost approach recognizes that willingness to pay for cultural services is not measured only by market prices for tickets but also by costs for travel in terms of money and opportunity cost of travel time. The sum of these latter costs and the entrance fee constitute a lower bound for the willingness to pay for the cultural service under consideration. However, this approach needs to assume that the visit to the cultural site is the only purpose of the travel and that there is no pleasure derived from the travel itself. There is no reason to believe that these assumptions typically hold in reality.<sup>48</sup> Thus this approach, like hedonic pricing, has significant drawbacks; most importantly both are capable of measuring only use-values (not the non-use values). We thus focus our attention on the remaining two approaches.

(iii) *Contingent valuation*.<sup>49</sup> Contingent valuation studies are a survey-based methodology where a sample of a population is asked about their maximum willingness-to-pay

health economics [Ryan and Gerard (2003)]. Boxall et al. (1996) show that WTP is much higher in CVM than in DCE, Carlsson and Martinsson (2001) show that the WTP for a public good is almost the same for hypothetical and real payments. DCE seem a very promising avenue of approach also for non-market evaluation in cultural economics, but it has hardly been used so far. An exception is Boxall, Englin and Adamowicz (2002) for cultural heritage (aboriginal rock paintings).

<sup>46</sup> The hedonic approach regards a good as a bundle of underlying characteristics which are valued by consumers and therefore the price can be decomposed into valuations of these components. In our context proximity and access to cultural institutions is such a characteristic for housing prices or wage regressions. The hedonic approach was developed 40 years ago by Lancaster (1966); Rosen (1974) was the first to include elements of the quality of the environment in this "hedonic" decomposition, which ultimately leads to an indirect value for changes in the levels of such characteristics.

<sup>47</sup> See, for example, Clark and Kahn (1988).

<sup>48</sup> For instance, a day trip to La Scala in Milan with friends or family will be enjoyable in itself and might involve other attractions such as shopping, enjoying the urban flair, etc., with the opera visit being but a special highlight of such a trip; for a recent contribution on travel cost, including a review of the literature, see Poor and Smith (2004).

<sup>49</sup> Contingent valuation studies measure the benefits to the individual consumers, not the importance of arts and culture for urban and regional development. Since in this section we are concerned with how arts and culture will change in the course of development we need to study the determinants of demand for them including non-use demand. The contingent valuation method is a way to do that. We need to formulate hypotheses about how the determinants of demand are changing in the course of development and whether local governments will accommodate these demand changes in their support for arts and culture.

(WTP) for a specified hypothetical change in a (public) good or service. Values for the good are then inferred from the respondents' valuations. The method is called the contingent valuation method (CVM) because the responses depend on a hypothetical market which the interviewer describes to the consumer. Different elicitation formats are available, including the open-ended (respondents are asked directly for their maximum WTP or WTA),<sup>50</sup> dichotomous choice (where respondents are asked to answer yes or no to a specific amount stated by the interviewer) and choice experiments (where respondents are asked to choose between different choice sets, where attributes, including price, are varied). All elicitation formats have their pros and cons.<sup>51</sup>

CVM has been developed in environmental economics, but recently has to an increasing degree been used for valuation of cultural goods; most of the studies have been concerned with cultural heritage and historic sites.<sup>52</sup> Most studies show a quite high willingness-to-pay among both users and non-users of the cultural good, with the non-use value constituting the biggest part of the total value and with a higher average WTP among users than non-users. There is also an increasing WTP with income and education, a result consistent with theoretical expectations, and average WTP is decreasing with distance to the cultural good [e.g., Bille Hansen (1997, 2002)]. An example of a CVM study conducted at the urban or regional level is Alberini, Riganti and Longo (2003) who conducted a survey of Belfast residents to elicit people's preferences for regeneration projects that change the aesthetic and use character of specific urban sites. They found that individual choices could be explained by these attributes of the regeneration projects. Another example is a study eliciting the value of protecting and restoring the Nidaros Cathedral in Trondheim, Norway, which is the oldest medieval building in Scandinavia [Navrud and Strand (2002)]. In this study a contingent valuation survey of visitors to the cathedral was carried out in the summer of 1991. Santagata and Signorello (2000, 2002) conducted a CV study aimed at measuring holistically the total benefits accruing to the local residents from maintaining the Napoli Musei Aperi, a cultural public good provided in Naples. When dealing with cultural heritage or cultural goods of national importance, the study has to be conducted at the national level, to get an estimate of the total value of the good.<sup>53</sup>

<sup>50</sup> Willingness to pay (WTP) refers to a situation in which the respondent is asked how much she would be willing to pay for a certain good whereas willingness to accept (WTA) refers to a situation where the respondent is asked how much she must be given in compensation for the loss of a certain good. Typically WTA exceeds WTP.

<sup>51</sup> For an in-depth discussion of the theoretical and empirical issues involved, see Mitchell and Carson (1989), Branden and Kolstad (1991), Freeman (1993) and Bateman et al. (2002).

<sup>52</sup> See Navrud and Ready (2002) and Bille Hansen (1998). Some of the pioneering studies are Throsby and Withers (1983), Morrison and West (1986), Martin (1994) and Bille Hansen (1997, 2002). Noonan (2003) presents a meta-analysis of existing CVM studies of cultural goods, and states that 139 studies exist within cultural economic, among which 61 have been published since 2000. The *Journal of Cultural Economics* devoted a special issue to the critical appraisal of the use of CVM in cultural economics, including a number of interesting applications (vol. 27, issues 2–3).

<sup>53</sup> See, for example, Bille Hansen (1997) on the Royal Theatre in Copenhagen.

CVM studies are subject to many kinds of biases including hypothetical bias (leading to an overstatement of WTP because the scenario is only hypothetical), strategic bias (where respondents are acting strategically), “warm glow” bias<sup>54</sup> (where respondents are willing to pay for doing something good – not for the particular change specified in the scenario) and so on. CVM has been widely criticized,<sup>55</sup> and has created a vehement debate among economists, who traditionally prefer estimates that are derived from observed behavior rather than from stated preferences [Carson, Flores and Meade (2001)]. Nevertheless, in many cases CVM is the only method capable of estimating the total value (use and non-use value) of a good.

(iv) *Referenda*. Referenda have the distinct advantage that they tie individual evaluation to a concrete decision that voters know will be implemented, in contrast to CVM studies where subjects’ stated willingness to pay need not reflect their *actual* demand behavior. Furthermore, anonymous referenda are not subject to the same sorts of biases as affect CVM, in particular anonymous referenda do not suffer from a systematic answering bias which may occur in CVM if individuals respond strategically or attempt to present themselves in a favorable light vis-à-vis the interviewer.<sup>56</sup> The obvious disadvantage of referenda is that only few countries hold referenda about cultural issues.

Pommerehne (1982) analyzes two consecutive referenda in the semi-canton of Basle-City in 1973 and 1974 on possible increases in theater subsidies provided by the canton; the first proposal (involving a larger subsidy) was voted down, the second approved. Frey and Pommerehne (1989, Chapter 10) study a referendum held also in Basle-City in 1967 to purchase two Picasso paintings for the Basle Art Gallery; the bill was approved by 54 percent. Schulze and Ursprung (2000) analyze a 1994 referendum that transferred financial responsibility for the Zurich opera house from the municipality to the canton; it was approved by 73 percent.

The results of the three analyses are consistent in showing that income and education exert a significant positive influence on the percentage of yes votes in a district.<sup>57</sup> Taxable income and travel time or monetary travel costs significantly reduce the share of approving votes. The bequest motive, approximated by the number of children aged 0–15 or the birthrate, are significantly positive and so is the share of people generally

<sup>54</sup> See Diamond and Hausmann (1994).

<sup>55</sup> See, for example, Diamond and Hausmann (1994), Hanemann (1994) and Portney (1994).

<sup>56</sup> A further advantage of referenda is that they contain data for more individuals. There is an extensive literature on the pros and cons of referenda and contingent valuation studies: see, for example, Frey (1997), Schulze and Ursprung (2000, p. 134), Bishop and Heberlein (1986), Mitchell and Carson (1989), the special issue of the *Journal of Economic Perspectives* in Fall 1994, and the special issue on contingent valuation in the *Journal of Cultural Economics* 2003 (vol. 27, issues 3–4). We note that both approaches have their relative advantages; inasmuch as they result in a consistent picture of the determinants of demand for cultural goods they are complementary approaches.

<sup>57</sup> Note that referenda analyses take the voting districts as the unit of observation since individual voting is anonymous. Thus the endogenous variable is the log odds ratio of the share of yes votes over 1 minus this share; the exogenous variables used are educational profile (e.g., share of population with secondary education), average income in the district, etc.

interested in cultural or public affairs (as measured by the share of subscribers to non-tabloid newspapers).<sup>58</sup> Results on age and self-employed versus employed as proxies for opportunity costs of time do not produce consistently significant results of the same sign. Although variables associated with use and option values account for a large share of the variation in approval rates, these analyses show that non-use values play a significant role in explaining support for art.<sup>59</sup>

### 3.3. The supply of cultural goods

#### 3.3.1. Production process in the arts

How will supply conditions for arts and cultural goods change in the course of regional or urban development? Obviously, a unique answer is impossible because supply conditions differ fundamentally between art forms. Consider the following classification:<sup>60</sup>

- *Live performing arts* (music concerts of all styles, plays, operas, ballet and dance);
- *Visual arts* (paintings, drawings, sculptures);
- *Reproducible art* (literature, recordings, movies, digital art) with an industrial reproduction process.

This classification is primarily based on production process and not on the sensual experience or content. Visual arts such as sculptures, paintings, sketches, etc. are produced with no scale economies – there is no reduction in unit labor input as production increases.<sup>61</sup> Moreover, production technology prevents easy and perfect copying, which makes this art unique. Replications are distinguishable from (and thus not interchangeable with) the original.<sup>62</sup> There are hardly scale economies in the *live* performing arts either as a given play, concert, or opera has a fixed duration. Only time for rehearsal and preparation of the backdrop per performance can be decreased by increasing output. This art form is unique to the extent that a particular performance of a particular (group of) artist(s) is not interchangeable with a performance of the same opera, concert, etc. by different interpreter(s). Uniqueness is thus a matter of degree. The common element that characterizes the production of these art forms is “the handicraft attribute of their supply processes” [Baumol (1996)]. Production processes differ fundamentally for reproducible art. Whereas the creative process of writing a book, composing a concert and

<sup>58</sup> The latter variable may indicate a stronger existence or prestige value. There is no clear proxy for the option value alone because those people who use the cultural institutions more will presumably also attribute a higher option value to this institution. In other words variables such as income, education and distance will proxy use and option values simultaneously.

<sup>59</sup> Further contributions are Frey and Pommerehne (1995) for Switzerland, Getzner (2004) for Austria, and Rushton (2005) for the US.

<sup>60</sup> See further in Schulze (1999, Section 2).

<sup>61</sup> The absence of scale economies does not preclude learning curve effects or economies of scope.

<sup>62</sup> Of course that does not preclude fakes that may be very hard to distinguish for the non-expert; but if detected they would command a significantly smaller price than the original [Frank (2004)]; see further Chapter 8 by Benhamou and Ginsburgh in this volume.

performing it once, etc. does not exhibit scale economies, the reproduction of the final output – a book, a CD or DVD, a film roll, etc. – exhibits very strong scale economies, the marginal costs being almost negligible. That gives rise to serious copyright issues; the cultural industries, which produce these goods industrially with advanced technology, are typically copyright-protected [Towse (2003)].<sup>63</sup>

Obviously, economic development, brought about by technical progress and accumulation of capital, affects these fundamentally different types of production processes – individual production versus industrial production – very differently. We discuss these effects in turn, starting with the effects of technological development on live performing and visual arts.

### 3.3.2. *Baumol's cost disease*

Baumol's cost disease is an intuitive general equilibrium story of relative price effects caused by differences in productivity growth between sectors that are linked through an integrated labor market [Baumol and Bowen (1966)]. Consider one sector (e.g., the live performing arts) that experiences no change in labor productivity and another sector (manufacturing) that experiences large productivity gains. The productivity growth in the manufacturing sector leads wage rates in this sector to rise in terms of the manufacturing good, the numeraire, as labor unit costs have fallen due to the productivity gain.<sup>64</sup> If manufacturing goods constitute a significant share of overall consumption, real wages in that sector will have gone up as well. If (real) wages in the other – stagnant – sector are linked to (real) wages in the manufacturing sector, they need to follow suit.<sup>65</sup> This leads to an increase in unit costs in this sector because the wage increase cannot be offset by productivity gains. The rise in unit costs must be recouped by increases either in prices or in subsidies. The relative price of the stagnant sector's product has increased, either as market price or as shadow price. The logic of the argument, of course, still holds if there is productivity growth also in the arts sector; for the relative price effect to materialize only a (significant) productivity *differential* needs to exist.<sup>66</sup>

This is a general story that can be applied to the arts as well as to education, health care, etc. [Baumol (1996)]. For live performing and visual arts the potential of labor

<sup>63</sup> Note that artists can be part of both production processes: the author performing a reading is a live performing artist but at the same time his or her books are produced industrially; another example is a symphony orchestra, which gives live concerts and records compact disks.

<sup>64</sup> Obviously, this argument presumes wage flexibility.

<sup>65</sup> Wage rates need not be identical (as they would be if labor were perfectly mobile and homogeneous across sectors). It suffices that the relative wage differential remains constant, maybe out of a sense of 'appropriateness' or 'fairness', or because unions use wage trends in other sectors as a yardstick for their own demands. Even if the wage gap widened but the wages in the arts sector responded to the general wage increases, art would become relatively more expensive.

<sup>66</sup> See further Chapter 11 by Baumol and Chapter 15 by Brooks in this volume.

saving technical progress is relatively limited;<sup>67</sup> rehearsal times cannot be cut substantially without compromising quality, a Beethoven symphony requires a full symphony orchestra, and a Mozart string quartet lasts a fixed amount of time. Even though there have been modest productivity gains in the performing arts, they have never come close to those in many other sectors<sup>68</sup> such as the manufacturing and IT sectors. This has led to price increases in the arts that have continuously exceeded inflation rates.<sup>69</sup> Economic development thus brings about relative price effects, which tend to make those art forms more expensive that have the “handicraft attribute” [Baumol (1996)]. These relative price effects trigger a substitution away from these art forms according to the price elasticity of demand. At the same time development has made people richer and thus an income effect running counter to the substitution effect is simultaneously at work. The net effect for the art forms subject to the ‘cost disease’ depends on the relative strength of these two effects and could go either way, although for other art forms and cultural industries it is unambiguously positive.

The cost disease refers to the increase in relative prices of cultural goods brought about by the increase in *relative* production costs. This price increase however need not reflect the movement in *effective* prices of cultural goods for the consumer thanks to countervailing secondary supply side effects. If in the course of development transportation and information infrastructure improves, the opportunity costs of visiting cultural institutions will decline, i.e. it will be easier to get information about cultural events, book tickets and get to the site. Conversely, previously remote areas will become more accessible to touring theaters and orchestras, etc. thereby improving the supply of arts and culture in these areas. Lastly, regional development tends to increase the urban population and thereby puts a larger share of the population within reach of the cultural centers. We thus have two supply side effects that run in opposite directions.

### 3.3.3. Innovation, globalization and cultural change

Technical progress in cultural industries has led to a reduction in prices or an improvement in quality of industrially-produced cultural products. Music CDs, movies on video cassettes and DVD have declined in price as has the necessary equipment (CD and DVD players, etc.). At the same time TV stations have switched from terrestrial mode

<sup>67</sup> Note that this argument applies strictly not to the performing arts, but only to the *live* performing arts. Technical progress may apply to the reproduction process of this art form (CD pressing, etc.), even if the contribution of royalties to orchestras’ revenues has been limited [Heilbrun (2003)].

<sup>68</sup> The fact that performing arts have experienced productivity gains as well has been levelled as criticism against the ‘disease’. Indeed there are productivity gains in the performing arts, for instance, the number of actors has been declining [cf. Baumol and Baumol (1985); Heilbrun (2001)] and festivals have emerged as low cost alternative to more established art forms [Frey (1996)]. Such a critique against Baumol’s theory [e.g., Cowen (1996)], however, misunderstands the general equilibrium logic of Baumol’s argument – *relative* productivity growth matters for the relative price effect, not the absolute. For a discussion of the cost disease see also Towse (1997).

<sup>69</sup> See Baumol and Bowen (1966), Baumol (1996) and Heilbrun (2003) for ample empirical evidence.

to cable and satellite and are beginning to switch from analogue to digital transmission.<sup>70</sup> These technical improvements disseminate to consumers unequally as they are costly; more well-off people tend to have them earlier and they only become affordable to more people as scale economies lead to price decline. For those cultural products that are network-based such as cable TV and digital terrestrial TV, the regional base is important as a threshold needs to be surpassed before investments in these networks are economically viable. In the course of regional economic development local purchasing power for these products increases and with the rise in user base, the average costs decline. Therefore the introduction of new network-based technologies depends on local development. For instance, digital terrestrial TV has been introduced in Germany only in selected areas such as Berlin and the Ruhr area [Perino and Schulze (2005)]. That implies a larger availability not only of movies, but also of cultural programs as these programs are seen by a minority only and are thus offered only if enough channels are available; however with satellite transmission this effect is of lesser concern.

Technical change brings about substitution that affects the local cultural industries. With the spread of television local movie theaters have suffered from declining audiences.<sup>71</sup> Due to decreasing costs of broadcasting equipment and deregulation, local radio and television stations have mushroomed. The number of local stations is affected not only by available bandwidth but also by the user base as these stations must finance themselves through advertisement, the rates for which depend on the average number of contacts, i.e. the local user base. With regional development this user base increases and so does the supply of local radio and television programs.

In a related vein, technological developments have led to the spread of the Internet and made data transmission more efficient; fast Internet connections in turn have made (illegal) music downloads possible on a large scale and the advent of CD burners and MP3 players has made copying easy. Not only does this crowd out regular sales [Rob and Waldvogel (2004); Zentner (2003)], but also makes this music effectively cheaper. It tends to make artists more global than they have already been.<sup>72</sup> This relative price movement (and the greater accessibility) may shift consumption from local live performing arts towards recorded international music. Obviously the spread of computers with fast Internet connections rises with the level of development.

### 3.3.4. Trade

Globalization has brought an increased exchange in cultural goods. While the trade in works of art follows normal trading patterns in the sense that closer and larger economies trade more with each other, it deviates significantly from normal in that the

<sup>70</sup> For Germany see Perino and Schulze (2005).

<sup>71</sup> In Germany, for instance, cinema turnover declined sharply in the mid 1960s with the spread of TV sets (see *Filmstatistisches Jahrbuch*, 2003).

<sup>72</sup> In addition, it reduces the complementarities between live concerts and record sales, which has led to a surge in concert prices [Krueger (2005)].

positive effects of common language, geographical closeness and GDP per capita are significantly stronger for trade in works of art than for overall trade [Schulze (1999)]. This demonstrates that cultural proximity proxied by geographical proximity and common language exerts an important influence. Stated differently, foreign cultural products are valued with a discount leading to a preference for local or national art and culture; cultures that are 'closer' to one's own have a lower cultural discount than others. In the course of increased trade this cultural discount may become less and less as culture-specific consumption capital is built up, with the consequence that *local* culture may play a diminished role in local cultural life.<sup>73</sup> A clear demonstration of this effect is the changing composition of trade in movies in European countries. The market share of German movies in German theaters declined from around 47 percent in the late 1950s to 16 percent in 2001, while the American movies increased their share from 30 percent to 70–80 percent [Dewenter and Westermann (2005)]. The same may be true also for other forms of local, traditional culture such as local dances, literature, and music.

As noted above, attracting tourists is an important way in which the arts and culture can contribute to exports at the local and regional level. Similarly arts companies such as theaters and orchestras can tour abroad. In addition the arts and culture may be able to promote the sales of other goods in export markets because a good image (created by the arts offering) generates goodwill. However the few studies which exist on this subject indicate that a country's arts institutions have very little if any impact on the sale of goods to other countries. For example, Abele and Bauer (1984) found that no importance was attached to sympathy for the producing country in connection with the purchase of imported goods, where price and quality were deemed to be very important factors. The impact is probably more important at the national level than at the urban level, but the empirical evidence is very sparse.

### 3.4. Development and public support for the arts

An assessment of the impact of urban and regional development on the cultural sector needs to take account of how public support for the arts changes in the course of development. Government intervention in the markets for art and cultural products is very important in many countries; for instance, in continental Europe public support makes up significant portions of total revenue for theaters, orchestras, opera houses, and museums.<sup>74</sup> The level of public support differs widely between countries and between art and cultural sectors; moreover, forms of support and the relevant level(s) of government differ across countries. To illustrate, in 1994 the per capita levels of public support of the arts ranged from \$US112 for Finland and \$90 for Germany to \$9 and \$6 for Ireland and

<sup>73</sup> For the role of consumption capital cf. Stigler and Becker (1977), for cultural discount and international trade in arts see Schulze (2003), for the application to trade in movies see Wildman and Siwek (1988).

<sup>74</sup> See, for example, O'Hagan (1998, Chapter 6) and Schulze and Rose (1998).

the US, respectively.<sup>75</sup> The support has very different importance for the various cultural subsectors – for instance, in Germany public support for symphony orchestra and theaters (*‘Kulturorchester’*) covered up to 80 percent of total revenues of these institutions [Schulze and Rose (1998)], while most musicals are not supported at all. The level of government that provides the lion’s share of cultural expenditures differs as well: in Finland, France, and Germany, for example, more than half of all support comes from *local* governments (counties, municipalities, cities), whereas Ireland, Italy, Sweden, and the UK rely more than half on *national* support.<sup>76</sup> While the level of local government support reflects local conditions, especially the state of local development, central government support is more likely to reflect the nation state’s development.<sup>77</sup> Moreover, one may surmise that countries with a large share of central government support may allocate a larger share to the capital.<sup>78</sup>

Countries differ with respect to the instruments they use to support arts and culture; hence different decision-makers will be involved and the resulting allocations are also likely to differ. For example, while direct support depends on political decisions, tax concessions give wealthy individuals and corporations the power to decide where taxpayers’ money should go. Insofar as political decisions follow voters’ preferences, they should reinforce the determinants for demand for culture including the willingness to pay for the non-market valuation of the arts and culture. However it is very difficult to draw general conclusions if politicians enjoy discretionary scope; the change in public support for the arts in the course of development depends inter alia on the institutional framework, i.e. the level of government, the socio-economic characteristics of the electorate, the initial size of support and the available instruments for support.

### 3.5. Assessment: *The influence of development on culture*

For our purposes we have taken ‘development’ to have three manifestations – it brings about technological progress which is unevenly distributed, it increases per capita income and education levels, and it increases the share of economic activity traded in

<sup>75</sup> Arts Council of England (1998) reproduced in Heilbrun and Gray (2001, p. 254).

<sup>76</sup> Ibid.

<sup>77</sup> Schuster (2002) states that in the US direct support of arts and culture at the state level is more important than at the national level. He argues, among other things, that state support will pay more attention to audiences and participation, engage more in diversity and multiculturalism, tend to support more popular culture as opposed to fine arts and be based more on political influence compared to the national support; see further Chapter 35 by Netzer and Chapter 36 by Schuster in this volume.

<sup>78</sup> This hypothesis is based on casual observation only (but is easily testable); national politicians may favor the capital in which they live more than local politicians not living in the capital, not least because institutions of national importance tend to locate in the capital. Thus a redistribution of cultural funds from local governments to the center may result in higher cultural subsidies for the capital. In Germany this is clearly the case as the Undersecretary of Culture (*‘Kulturstaatsminister’*) supports heavily central foundations, museums and cultural institutions, most of them located in and around Berlin such as Stiftung Preußischer Kulturbesitz, Stiftung Preußische Schlösser und Gärten Berlin-Brandenburg, various museums in Berlin and Bonn (the former seat of government), and Stiftung Weimarer Klassik, cf. <http://www.bundesregierung.de/Bundesregierung/Beauftragte-fuer-Kultur-und-Me-9332/Kulturfoerderung.htm> (22.10.05).

markets. Technological progress pertains to live performing and visual arts less than to the production of other goods, including industrially-produced cultural goods such as books, music and film CDs and DVDs. As a consequence the relative price of these art forms (e.g., plays, opera, concerts, unique sculptures, etc.) tends to rise, thereby reducing the demand for them through a substitution effect. At the same time, technological progress brings about increases in per capita incomes and in average educational attainment, both of which tend to increase the demand for arts and culture through an income effect. Obviously, income and substitution effects work in the same direction for industrially-produced cultural goods such as music CDs, but have opposing directions for unique art such as theatrical plays.<sup>79</sup> The net effect is undetermined a priori; it depends to a substantial extent on how governments react to an increase of relative prices. The art forms affected by rising costs are those that enjoy the largest subsidies as a share of production costs.

Technological advances in the Internet and in reproduction technologies for digital cultural products – music, films, and digital books – have led to copyright infringements and declining sales. At this point we can only surmise all the possible effects that this will have in the future. Average movie production budgets may fall as it may become increasingly difficult to recoup them as record sales decline. The complementarity between live shows and record sales and movie visits and video sales will weaken with the consequence of rising ticket prices. For less developed countries, development will also increase the share of monetized transactions which will change the cultural and artistic production from a community and leisure activity into a for-profit activity; increased division of labor will lead to the emergence of full-time artists.

For the regional culture we observe two countervailing effects – a positive income effect that tends to increase cultural expenditures and a substitution effect that tends to divert expenditures away from live performing arts due to the relative price effect. Those forms of culture and art that experience productivity gains and are not subject to Baumol's cost disease exhibit strong scale economies (recorded music and movies, digital art) and thus tend to be present on a national or even international level. Thus even though we cannot know a priori what the net effect of the substitution and income effects will be on local performing arts, there is a strong presumption that the *share* of cultural goods produced by cultural industries (in constant prices) will increase (as income and substitution effects work in the same direction). This will tend to reduce the influence of truly *local* culture.

<sup>79</sup> With rising incomes the opportunity costs of visiting the arts goes up as well, thus establishing a countervailing force. In a longer-term perspective, however, development has not only meant increasing per capita levels, but also increased leisure time thus making cultural consumption easier.

## 4. Location of arts and cultural industries

### 4.1. Delineation of the cultural industries

Before considering factors affecting the location of the arts and cultural industries it is important to consider how these industries are delineated. The cultural or creative industries can be defined as industries that mass-produce goods and services with sufficient artistic content to be considered creative and culturally significant.<sup>80</sup> The essential features are industrial-scale production combined with cultural content [Towse (2003)]. The guiding principle that is increasingly adopted for defining the cultural industries is their reliance upon copyright law to protect the creative or cultural content, i.e. their intellectual property. Thus, “industries protected by copyright” have become virtually synonymous with the cultural or creative industries and as such they have been measured for their contribution to the GDP in a number of countries. A typical list consists of advertising, architecture, the art market, crafts, design, fashion, film, the music industry, performing arts, publishing, software, toys and games, television and radio, and videos. In most developed countries in which the size of the cultural industries has been measured, their share of the GDP is around 5 percent [Towse (2003)]. In Denmark their share has been calculated to 5.3 percent of GDP, in Great Britain 8 percent, in Sweden 9 percent, in the USA 7.8 percent, in New Zealand 3.1 percent of the GDP and in Norway 3.5 percent [Haraldsen et al. (2004)].

Cultural industries have attracted special attention from a development perspective because the cultural sector in itself – especially the cultural industries – is characterized as a growth sector. The growth is caused by increasing demand for experiences, culture, events and leisure-time activities in the course of development [Pine and Gilmore (1999); Wahlström (2002)]. The growth rate of the “creative economy” (usually defined as cultural industries plus the creative and performing arts) averages about 5 percent per annum and is therefore higher than that of “traditional” manufacturing industries [Towse (2001, 2003)].<sup>81</sup> It is therefore believed that the creative industries offer good employment prospects due to their potential for growth. Besides, many cultural industries are export industries selling their products outside the local area. The cultural industries are therefore described as important producers of substance in “the new economy”, where technological improvements, computers and the Internet play an important role.

The measurement of cultural employment and earnings in this sector is, however, so fraught with difficulties that such claims are hard to verify. Thus, these figures present many problems. The official statistics are often too aggregated and do not allow for including the relevant parts of different trades. For instance, it is questionable whether

<sup>80</sup> See further Caves (2002) and Chapter 17 in this volume.

<sup>81</sup> The Norwegian study [Haraldsen et al. (2004)] has found growth in the period 1996–2001 only in what is called “performing art” or the creative core. This might be due to the Norwegian study not including computer software which is included in most other studies, and which is characterized by a substantial growth. This illustrates the definitional problems affecting these kinds of studies quite clearly.

the whole travel trade or computer software should be included. Delineations are quite different in different countries, and the classification of different areas varies considerably. Moreover, cultural industries comprise a very wide spectrum from commercial businesses to subsidized cultural institutions and non-profit organizations, and there are also many different kinds of culture with different structures, economy and development potential.

In the following sections we will trace some of the guiding principles for the location of arts and culture, depending on the economic characteristics of the institutions and individuals that comprise the cultural sector.

#### *4.2. Agglomeration economies and the location of arts and culture*

Economic activities cluster because distance, or rather the absence of it, matters. Two relevant proximities that matter and often coincide can be distinguished: proximity to market and proximity to other producers, either competitors or producers of intermediate inputs.<sup>82</sup> These reflect positive externalities in consumption or production at the local level. In other words, agglomeration economies can be due to economies of scale and scope either in production or in consumption (or both).

##### *4.2.1. Proximity to market*

Proximity to potential customers matters to cultural institutions as distance is a major determinant of people's decision to visit the institution; it also affects existence and option values.<sup>83</sup> This is relevant to live performing arts such as theaters, ballets, opera houses and symphony orchestras, and also to museums, galleries, etc. Due to indivisibilities such institutions tend to locate only in larger cities: for instance, a symphony orchestra has a minimum size which must be supported by a large enough audience to operate profitably. The same holds true for ballet companies and opera houses, and to a lesser extent for theaters or museums. Thus smaller towns should tend to have smaller and/or fewer museums and theaters. In countries that subsidize the live performing arts heavily, however, this economic rationale may not apply to the same extent. because of political interventions. For instance, in Germany there are many more orchestras per inhabitant than in many other European countries and they are much more scattered, a result of the political fragmentation that occurred in the 17th and 18th centuries. Local courts saw orchestras as prestige objects and supported them [Schulze and Rose (1998)]. This tradition has remained and even today excellent symphony orchestras are found in the German hinterland. This is clearly not the case in a country such as the US where local public support is much smaller.

<sup>82</sup> Agglomeration phenomena are central to the 'new economic geography' literature; for surveys see, for instance, Fujita, Krugman and Venables (1999), Neary (2001) and Fujita and Thisse (2002).

<sup>83</sup> See, for example, Schulze and Ursprung (2000).

If live performing arts, museums, galleries, etc. locate where their customers are, agglomeration of these cultural and artistic institutions will follow the more general agglomeration of economic activity and of people. If we take into account that larger towns and cities tend to have larger per capita incomes and better educational attainment than the hinterland, agglomeration of cultural and artistic institutions should be even more pronounced in these locations. Of course, cultural tourists are attracted more easily the larger the supply of cultural institutions and activities. That constitutes a second externality in consumption and thus a reason for cultural institutions to cluster. This effect may show even within a city where museums locate in a museums district (Vienna) or a museum island (Berlin).<sup>84</sup>

#### 4.2.2. *Economies of scale and scope in production*

While there is a demand-side explanation of agglomeration due to consumers' positive travel costs (including opportunity costs of time), there is a supply-side explanation of agglomeration as well, arising from economies of scale and scope either at the firm level or the local industries level. The concept of agglomeration economies has been defined by Kaldor (1970):

... nothing else but the existence of increasing returns to scale – using that term in the broadest sense – in processing activities. These are not just the economies of large-scale production, commonly considered, but the cumulative advantages accruing from the growth of industry itself – the development of skill and know-how; the opportunities for easy communication of ideas and experience; the opportunity of ever-increasing differentiation of processes and of specialization in human activities (p. 340).

If economies of scale or scope occur at the firm level, they lead to larger firms, but not necessarily to agglomeration of different firms. For instance, there are obvious economies of scope for a symphony orchestra in combination with an opera house or a ballet company. Economies of scale occur due to significant fixed costs. At one level these economies of scale apply to all live performing arts; since a large part of the fixed cost is maintenance and capital costs of the building and costs for technical and artistic personnel, an additional show increases overall costs only slightly. At a different level, closely-related products can be offered without much additional cost. Theaters, for instance, can have a large stage and a studio stage where they perform more experimental plays for smaller audiences.

<sup>84</sup> Cultural districts are a prime example of economies of scale in consumption. Joint location of cultural institutions may attract larger audiences as they reduce travel costs (monetary and opportunity costs) to each cultural institution. A critical mass of cultural activities may be necessary to make the visit only worthwhile. Some of the cultural districts may also have economies of scope in production. See, for example, Scott (2000), Brooks and Kushner (2001); cf. Chapter 31 by Santagata in this volume on cultural districts.

Clustering of different firms is caused by economies of scale or scope external to the firm. These agglomerations have three principal causes: labor-market economies, scale economies in the production of intermediate inputs, and communication economies on the local level [O'Sullivan (1993)]. They all refer to essential inputs for the production by cultural industries.

#### 4.2.3. Input markets

Labor market economies of scale and scope occur when firms tap a common pool of artists which are hired only for short periods of time, then to be released into that pool again to be hired by other firms. This is typical of the London market for studio musicians; a further example is the movie industry where actors, extras and stuntmen are hired only for the duration of one film or even only for the scenes they play in. After one engagement they are available for new engagements. The larger the pool of specialized artistic labor, the easier it is for a firm to find the specific qualities they look for in the artists. In turn, the more production activities there are in a given area, the stronger is the incentive for actors to move into this area – in other words agglomeration is reinforcing. Los Angeles and New York are such agglomeration areas; Los Angeles is the center for actors and directors working in the movie industry in the US, while New York has become the point of gravity for live theater and dance. In 1990, 11 percent of all performing artists lived in New York and 13.2 percent lived in Los Angeles, while the relative shares of the population were only 3.4 and 3.6 percent, respectively [Heilbrun and Gray (2001, Chapter 15)].

The above line of argument applies not only to artistic labor, but also to highly specialized inputs. Again, Hollywood serves as an example as the movie industry hires a multitude of highly specialized inputs that range from special effects animation to post-production.<sup>85</sup> As their services are required only for short periods, an economically viable production mode requires that these inputs are hired by many firms. Producers of specialized inputs cluster around the producer of the final product, but because of short-lived contracts and the high degree of specialization, agglomeration results. Thus these characteristics of the production process, vertical disintegration and product innovation have led to the need for specialized inputs, a demand served at a relatively low level of product standardization by a cluster of creative and dynamic small-sized firms. Social capability and interactive learning are the basic factors of the local expansion. Such an agglomeration creates many kinds of external benefits and synergies for the firms [Scott (2002); Garreau (1992)].

#### 4.2.4. Creativity spillovers and the location of artists

Unlike performing artists, many other types of artists do not have to be close to their consumers, nor do they rely on intermediate inputs in order to create their artistic product.

<sup>85</sup> See further Chapter 19 by de Vany in this volume.

Thus they do not face “technological” incentives for agglomeration like live performing arts, museums, or the movie industry or studio music do. Among these artists are writers, painters, composers, even sculptors. After completion of a long creative process they contact their intermediaries – literary agents, galleries – or their buyers or publishers directly and stock up on the few inputs they need. In principle they could reside in solitude and some actually have done so for extended periods of time. However many of them have opted to live close to their peers or actually with them. For instance, Montmartre in Paris used to be an artist quarter, Worpswede, near the city of Bremen, has been an artist colony in an isolated spot where painters have worked side by side. There are many more examples.<sup>86</sup> The reason is not a technological one, but rather one of mutual inspiration, in other words “creative spillovers” have led to a clustering of artists.

An institutionalized form of creativity spillovers occurs in art schools and colleges and other modes of art education which attract young artists, create an artistic atmosphere and thus provide incentives for artists to stay after their formal education has been completed. One prime example is the Bauhaus in Dessau, another one is Ubud in Bali/Indonesia, where young artists from all over Indonesia go in order to be educated. These creativity spillovers are of course not limited to painters, writers and sculptors but apply in principle to all art forms, thereby reinforcing existing incentives to cluster.

#### *4.3. The particular role of cities*

Culture may be an important element in a comprehensive urban development strategy. The literature on “the creative city”<sup>87</sup> emphasizes the importance of the arts and culture for the economic development of cities. A critical element is the relationship of urban centers and suburban regions and the hinterland; the balanced growth hypothesis states that the development of the urban center is necessary for suburban and regional development. This hypothesis has been subject to academic discussion. Especially in the US, there has been debate as to whether city and suburban growth are substitutes or complements.<sup>88</sup> Some have argued that suburbs are no longer dependent on central cities, while others have argued that central cities and their suburban areas remain closely interconnected.

What do we know about “balanced growth”, and to what degree is the vitality of a central city critical for the future of the whole region? This question is interesting from the perspective of arts and culture in urban and regional development because if arts and culture play important roles in preserving and rejuvenating central cities and core urban neighborhoods, they can be essential for the long-run health of the entire metro area and larger region. Ihlanfeldt (1995) identifies some major “sources of interdependence” that in his view link the economies of central cities and their surrounding suburbs:

<sup>86</sup> Of course large cities provide proximity to fellow artists without making this “agglomeration” visible.

<sup>87</sup> See, for example, Landry (2000) and Landry and Bianchini (1995).

<sup>88</sup> See, for example, Voith (1992, 1993), Ihlanfeldt (1995), and Glaeser (1998).

- Outsiders' perceptions of the region, which are influenced by conditions prevailing within the central city;
- Location-specific and historically unique amenities in the central cities, which are valued throughout the entire region;
- The related notion that central cities provide a "sense of place" that is highly valued not only by central city residents, but by others living in the metro area who "identify" in some way with those things that make a city a unique place to live;
- Fiscal interdependence between a central city and the rest of the region; and
- The "traditional" concept that central cities offer unique "agglomeration economies" that provide a specialized role for the central city.

Ihlanfeldt concludes that there is no empirical evidence on the quantitative significance of "perceived image" or "sense of place" effects. He argues that the best way to measure the importance of unique central-city amenities would be via an "inter-area hedonic wage or housing equation". However, he does find some empirical support for the existence of agglomeration economies; this finding is at least consistent with the possibility that central cities make an important contribution to growth, and are perhaps even engines of growth, because their compact development allows for particularly strong agglomeration economies.

As Seaman (2001) points out, ambiguity about the direction of causality is a critical limitation to our current understanding of the role of central cities in regional development, and greatly limits our ability to draw strong inferences from "simple" tests of the balanced growth hypothesis such as studies of correlations between central city and suburban economic and demographic variables. Therefore the proposition remains plausible, but only weakly empirically confirmed.

## **5. Concluding remarks: Regional cultural and economic development – a complex simultaneity**

In this chapter we have reviewed the literature on cultural and regional development. We have demonstrated that there is a complex simultaneity between cultural and economic development. It has become clear that local culture will change in the course of economic and technological development. Demand changes not only because of increased income and educational attainment, but also due to technological developments that create new art forms and open up possibilities for transmission of culture. These changes in supply conditions are complemented by differentially lower productivity gains in the live performing arts thus triggering relative price increases. How demand (and public support) will react to this price increase remains an open question; the rising income will increase demand but at the same time alternative art forms that are not subject to stagnating productivity will become more attractive.

We have seen that art and culture can play a significant role in urban and regional development, even if we focus only on the level of overall economic activity. The contribution of culture to overall development is even larger if we apply a broader concept

of development. While short-run spending impacts can be measured relatively easily, longer-run effects on location choice of mobile people and enterprises as well as on overall creativity of a region are much harder to identify and to quantify. Here theoretical concepts remain somewhat vague and empirical assessments tentative. But assessments of the economic effects of culture, whether short-term or long-term, should neither serve as a justification for, nor as evidence against, certain cultural policies. It is not the sole goal of regional cultural policy to promote economic growth in a narrow sense, nor is it even the dominant goal.

Nevertheless, from a policy perspective the effect of culture on economic development is important in the formulation of cultural policy. While it is possible at the theoretical level to localize different “transmission channels” – ways in which culture can contribute to economic development – the matter becomes very complex if is transferred to a concrete policy situation. The degree of success in a given case is dependent on a series of factors and how these factors are mixed. Among the relevant questions are the following:

- *What kinds of cultural assets are “added” into the geographical area?* The effect of additional provision of culture on urban and regional development depends of course on the cultural asset that is “added” to the current cultural environment. A festival, a theater, a museum, facilities for creative artists, a “cultural industry”, etc. will have different impact on tourism, location decisions of firms, local residents, etc. For example, a festival or a large scale museum may be important for tourism, while libraries, etc. will cater only to local residents. Cultural industries, like the production of recorded music, film, TV and videos, are mainly export industries from the regional perspective, thus making them important for employment and economic development in the local area, but of minor importance for the local residents and for tourists in the area. Obviously, even within a category of cultural asset its effect depends on the degree of uniqueness of the asset under consideration. Current research does not tell us very much about these differential effects of cultural institutions and industries.
- *What is the current level of art and culture in the area?* The effect of a specific new cultural asset depends on the environment in which it is placed, in particular on the existing art and culture in the area. We refer here to synergy effects on the supply side which are responsible for agglomeration phenomena and which depend on the structure and level of cultural activities in place. We refer also to demand effects. In particular a “critical mass” of cultural artifacts needs to be in place to attract locals and tourists from outside the area.
- *What is the state of the existing environment (location factors such as infrastructure, quality of labor, natural amenities, etc.)?* The entire environment is important for the success of a cultural institution; relevant factors include infrastructure (transport, telecommunication and informational infrastructure), tourist infrastructure (hotels and restaurants), nature and climate. Their relative importance depends on the transmission channel – if we focus on cultural tourism, it will be hotels, restaurants, infrastructure, nature, climate, etc. that are important; if we focus on

culture as a factor for attracting new residents, other factors affecting people's localization choices must be considered such as schools, houses, job opportunities, tolerance, etc. When we look at arts and culture as location factors for enterprises, it will be tax rates, infrastructure, labor availability and costs, etc. that are relevant.

In all cases the socio-economic profile of the residents will make a difference.

There is no simple formula for success. Cultural development needs to be embedded into an overall urban and regional development strategy<sup>89</sup> that takes account of the existing situation for each region and emphasizes complementarities between the different areas of regional development.<sup>90</sup> Eventually, we need a better understanding of the dynamic process of regional and cultural development based on historical analyses which would allow us to assess the incremental contribution of additional artists and arts institutions to the urban and regional economy.

Cultural economics has produced a realm of knowledge about the influence of cultural development on economic development and conversely on how economic progress shapes the cultural landscape. Yet we are still missing a convincing theory that is able to portray the complex dynamics and interdependence of cultural and economic development. Such a theory would have particular relevance to development at urban and regional levels.

**Abstract**

The aim of this chapter is to analyze the economic properties and the institutions governing the start-up and evolution of cultural districts. Cultural districts are a good example of economic development based on localized firms and local culture. The first part of the chapter (Sections 1–2) reviews the relationships between culture, viewed as an idiosyncratic good, and the Marshallian theory of industrial districts. Sections 3 and 4 of the paper present a discussion of two models of cultural districts: the *industrial cultural district* (mainly based on positive externalities, localized culture, and traditions in “arts and crafts”), and the *institutional cultural district* (mainly based on property rights assignment and symbolic values). Policy issues are analyzed in Section 5, with particular reference to the applicability of the two models of cultural districts in developed and developing countries.

**Keywords**

cultural districts, intellectual property rights, economic development, material culture

## 1. Introduction

Culture-based goods and services are identified by Scott (2000, p. 3) as being “marketable outputs whose competitive qualities depend on the fact that they function at least in part as personal ornaments, modes of social display, forms of entertainment and distraction, or sources of information and self-awareness, i.e. as artifacts whose symbolic value to the consumer is high relative to their practical purposes”. Some such goods are produced in specific and identifiable local areas; well-known international examples include Hollywood, the Spoleto Festival, the vineyards of Langhe in Piedmont, the fashion and textile district in Prato near Florence and the pottery district of Caltagirone in Sicily. These areas may be called cultural districts. They occur in both the industrialized and the developing world. In the latter case, there exist many localized agglomerations of micro and small enterprises producing culture-based goods such as jewellery, apparel, textiles, craftware, services of cultural heritage, etc.; these are potential cultural districts whose progress may benefit from the type of economic policies instituted in the well-known international cases.

In theoretical terms, a cultural district arises at the confluence of two phenomena: that of localization, as first identified by Marshall, and that of the peculiar or “idiosyncratic” nature of culture. When these two essential factors are brought together into a receptive economic environment, the basic conditions for a potential cultural district are satisfied.<sup>1</sup>

The aim of this chapter is to analyze the economic properties and institutions governing the start-up and evolution of potential cultural districts. The first section introduces the theory of cultural districts, whose basic elements as noted above are the localized production of culture-based goods and their idiosyncratic cultural nature. The following sections present a discussion of two main models of cultural districts: the *industrial cultural district* (mainly based on positive externalities, localized culture, and traditions in “arts and crafts”) and the *institutional cultural district* (mainly based on property rights assignment, symbolic values and cooperative behavior). Some policy issues relevant to both developing and developed countries are discussed in the final section.

<sup>1</sup> The use of the term “cultural districts” in North America refers mainly to urban concentrations of cultural activity which are often the focus of policies for the revitalization of a city area through the localization of performing arts services, leisure-time industries and cultural industries; these districts are not analyzed in this chapter (see Chapter 30 by Bille and Schulze in this volume). Other important examples of cultural districts not analyzed here are those that surround systems of cultural heritage involving networks of museums, temples, and archaeological remains; examples include local museum networks in France, Egyptian tombs (Old Pyramids, Saqqara tombs) or Khmer temples in Cambodia [Santagata (2002)].

## 2. The theory of cultural districts

### 2.1. Marshallian localized industries and endogenous economic growth

The first component of a theory of cultural districts derives from the work of Alfred Marshall, who was the first to focus attention on localized industry. The basic elements of his theory are outlined in his *Principles of Economics*, book IV, chapter X: “The concentration of specialized industries in particular localities” [Marshall (1890)]<sup>2</sup> and in *Industry and Trade* [Marshall (1919)].

Marshall divides the economies arising from an increase in the scale of production into *external economies*, those “dependent on the general development of the industry” [Marshall (8th ed., 1930, p. 266)], and *internal economies*, those “dependent on the resources of the individual houses of business engaged in it, on their organization and the efficiency of their management” (ibid). This distinction is crucial, because while the internal economies are essential for the development of the great factory, the external economies “can often be secured by the concentration of many small businesses of a similar character in particular localities” (ibid). In other words, industrial districts in Marshall’s analysis are normally based on external economies of agglomeration.

On the production side Marshall lists several advantages of the industrial agglomeration:

- free diffusion of ideas;
- free diffusion of information: “. . . the mysteries of the trade become no mysteries; but are as it were in the air” [Marshall (8th ed., 1930, p. 271)];
- prompt dissemination of innovations in machinery and in processes and in general organization;
- development of subsidiary trades in the surrounding areas;
- reductions in unit costs led by the introduction of highly specialized machinery and increased use of equipment; and
- creation of a constant market for skilled workers.

On the consumption side, Marshall observes that consumers are willing to travel to distant districts if they can find what they want easily and cheaply. Thanks to the relevance of economies of agglomeration, industrial districts are recognized as places where average costs of production and trade are decreasing, just as they are decreasing in the great factory thanks to internal economies of scale. Even if some drawbacks to the concentration of industry are acknowledged, such as the risk of dependence of the local economy on a single industry, Marshall’s original concept of external economies was profound and rich with potential for development.

At the end of the nineteenth century when Marshall was writing, economists were aware of the fact that the evolution of transport and the widening of the labor market would render industrial districts increasingly less competitive. The shift to mass production – whether favored or not by industrial policies of the central government – was one

<sup>2</sup> Quotations in the following paragraphs are from the 8th edition, 1930.

of the factors that ushered in the decline of some old districts such as Sheffield (UK) or Saint Etienne (France). Nevertheless, the crisis of the Fordist model of mass production that took place at the end of the twentieth century led to renewed interest in the industrial district as a good example of flexible organization and endogenous growth based on external agglomeration economies and small creative enterprises [Becattini (1987, 1989); Bagnasco and Sabel (1995); Pyke, Becattini and Sengenber (1990, 1992)].

As can be learnt from recent Italian and international experience, the presence of small firms is essential to a district, but the presence of many small firms does not in itself form a district. One of the most meaningful characteristics of a district is the interdependency of its firms: in this type of “industrial atmosphere”, frequent contact favors the exchange of specialized inputs, and continuous and repeated transactions cause information to circulate. Within the districts it is easier to find contractors to verify the quality of goods and services and to sign standardized contracts. The social habitat of the industrial districts tends to be made up of large families and of firms where the whole household are employed. Tacit knowledge, mutual trust and the accumulation of social capital are other pervasive traits of local society and culture. In this sense the Marshallian notion of “industrial atmosphere” [Marshall (1919)] implies an interdisciplinary approach involving economic, social and cultural factors. Moreover, when most of the economic and human resources are local, the economic process becomes endogenous. Of course, such evolution requires continual adaptation, but the strong advantages in providing technological innovation, sharing information, differentiating products, regulating the market and fostering cultural links have been shown to be reliable guarantees of sustainable growth [Piore and Sabel (1984)].

Thus it can be suggested that Marshall’s theory of localized industry can be given a new lease of life in contemporary economic analysis. In particular, we can apply the theory to the production of some culture-based goods which create a path to regional economic development through the growth of micro and small-sized firms which are intensely integrated within the territory and in the local community. In this sense Italian industrial districts, such as those producing glass in Murano (Venice) or woven goods and apparel in Prato or Biella, constitute an ideal model for the localized production of culture-based goods.

## 2.2. Culture-based goods as “idiosyncratic”

The second essential component of a theory of cultural districts derives from the nature of culture as a particular phenomenon, endowing culture-based goods with peculiar or “idiosyncratic” characteristics. Several such characteristics can be identified in the specific context of localized production.

First, some local cultures have originated from longstanding social and institutional structures within communities, with their specific content (reflected, for example, in the types of culture-based goods produced) often depending on local resources both tangible (mines, clay grounds, climate, water, etc.) and intangible (patronage of a court, universities, cultural centers, monasteries, etc.) [Marshall (1890); Harris (1977)]. In

other words, the local presence of appropriate natural and institutional resources together with given social structures may be at the origin of an idiosyncratic culture, peculiar to a community and transmissible between generations.

Second, culture has two profound anthropological roots: time and space. The production of a culture is indissolubly linked to a place, or in a social sense to a community and its history. As a result, certain culture-based goods have both space-specific and time-specific characteristics. Note that the more time-specific and space-specific a commodity is, the less the market mechanism is able to efficiently regulate its production and consumption. The more specialized and peculiar a good is, the less likely it is that competitive equilibrium will be optimal [Salais and Storper (1993)].

Third, although UNESCO conventions distinguish between tangible and intangible heritage, it remains a fact that so-called “material cultural heritage”, in which the intangible essence cannot be disentangled from the tangible, is not regarded as a specific and autonomous concept [Jalil Moreno, Santagata and Tabassum (2005)]. Yet some culture-based goods and services (functional objects, functional artifacts of material culture) supplied by industrial cultural districts and local communities are made up of both tangible and intangible factors, and this co-existence and union of traditional knowledge, skills and corporeality are their very substance. Examples of such production drawn from the developing world include the following:

- In Sigchos, Ecuador, a number of craftsmen produce pottery, woven goods and clothing reproducing old forms, designs and traditional colors.
- In Alepp, Syria, micro and small firms gathered in small areas of the town produce green olive soap according to a three-thousand-year-old tradition. The technology employed is ancient, the product highly standardized.
- In Lucknow, a city in Uttar Pradesh, many micro firms and creative traditional artisans, mostly women, develop the art of chikan embroidery. The pastel muslins traced by gossamer embroidery look like the ethereal raiments of fairies. “If you wear chikan, you are wearing history.”

What do these cases have in common? They all exhibit the existence of a local culture, which is the source of identity and creativity. In each case, there is a strong link between present-day production and the culture of the place.

A fourth idiosyncratic characteristic of localized cultural production has to do with creativity – its generational aspects and its role in capital accumulation [Santagata (2004)]. In one sense creativity per se is the original and specific product of a generation. In painting, in industrial design, in the motion picture industry, in the fashion market, even in the forms and decorations of pottery objects, waves of creativity marked by a generation period may be identified. The generation waves are visible in the idiosyncratic character of culture-based goods: the couple time/space has a formidable strength in creating the image and the reputation of a single generation. What was the essential nature of the industrial design produced in Milan during the 1950s? It is not re-producible tout court in the year 2005, because the ideas, the culture, the communication technologies, the marketing practices and the style have all changed. Thus, every generation has its own identity, its own pace, and its own creative vein. Fur-

thermore, culture-based goods translate creativity into valuable economic goods and services, providing competitive advantage through the accumulation of cultural capital. Cultural capital is “. . . an asset that embodies, stores and provides cultural value in addition to whatever economic value it may possess” [Throsby (2001, p. 46)]; it gives rise to a flow of services, consumed or used along with other inputs to produce further goods, having both an economic and a cultural value. Through these means creativity lends a further idiosyncratic characteristic to culture-based goods and services.

Finally, culture-based goods are idiosyncratic because tacit knowledge [Polanyi (1958); Polanyi and Prosch (1975)] is needed for their creation, production, distribution and also because personal knowledge relies on past personal idiosyncratic experience. Individual ability, tastes, lifestyles, social institutions and industrial organizations cannot be learned by mechanical transmission: personal and collective stories count.

### 3. Industrial cultural districts and clusters

When localized industries and idiosyncratic cultures as discussed above are brought together, the minimal conditions for an industrial cultural district are met. In this section, the main traits of an industrial cultural district will be examined first in theory, and then in practice with reference to two specific examples: the motion picture complex in Los Angeles and the pottery district in Caltagirone (Sicily).

#### 3.1. In theory

The principal features of an industrial cultural district can be inferred from the formula that led to the international success of the micro, small, and medium sized enterprises of the “Third Italy” in the 1960s and 1970s. These industrial cultural districts belong to the endogenous growth models based on the presence of small firms [Becattini (1989); Storper and Harrison (1991)] and the existence of basic social and cultural conditions [Bagnasco (1988)], and include a number of districts producing culture-based goods such as Sassuolo (decorated and designed tiles and pottery), Biella and Prato (prestigious wool clothes and apparel), Vicenza and Arezzo (jewellery) and Belluno (eyeglass frames). The characteristic preconditions for building cultural districts such as these are the following:

- a local community that is cohesive in its cultural traditions and in the accumulation of technical knowledge and social capital (trust and cooperation);
- a dense interaction between the cities and the surrounding country, the source of most of the active manpower working in the district’s firms;
- a significant development of increasing returns to scale and increasing returns to scope;
- accumulation of savings and the presence of strongly entrepreneurial cooperative local banking;

- a bent towards open international markets;
- public financial support along the entire chain of the creation of value;
- a high rate of birth of new firms, often of household size, as a result of social capability and interactive learning; and
- the ability to be district- and cluster-minded and to produce positive externalities in the field of design, technological innovation, managerial organization, the creation of new products, labor market flexibility and commercial distribution.

In economic terms, these characteristics mean that within an industrial cultural district the costs of the use of the market are lower than anywhere else because of the intense creation of positive externalities, tacit knowledge, the high rate of innovation, easy networking and the cost-free diffusion of information. In regard to positive externalities, two types can be identified. First is the so-called “atelier effect”; more individuals are trained in the local cultural profession than are required to meet the labor demand of the district, hence creating a resource for new entrepreneurial initiatives. Second, industrial cultural districts accelerate the rate of birth of new creative products and new processes of product differentiation. As a result, buyers are likely to enter commercial centers where they can find a vast amount of product. For instance, in the textile and apparel district of Carpi (Italy), 700 firms employ about 18,000 workers. They are therefore able to present about 100,000 models in their pattern-books each season.

Turning to questions of technology, we note that two varieties of cultural districts may be defined according to the nature of the technology involved. On the one hand, sometimes the technology is highly-developed and sophisticated, as in the textile or fashion industries. The more essential technology is to a firm, the longer or more developed the value chain. The production process is articulated into many hierarchically connected phases, and the *final firm* has the important role of organizing the whole production process. A final firm is the last element of the value chain, and is strategically significant because of its proximity to consumer preferences and choices. In this context the final firm may have incentives to buy the contractors' firms and to integrate vertically. The trend is toward a reduction in the number of firms and toward a change in the district's industrial structure.

On the other hand, some cultural districts rely on quite elementary technology; glass, jewellery or pottery production are examples. The less significant the technology, as is the case in pottery, rugs, glass, soap and perfume production, the shorter the value chain and the less the final firm per se counts. In this case each firm organizes its production and competes in sales with other local firms. Cooperation with other firms located at other points in the chain is more concentrated. Creativity thus counts more. In this context structural evolution is less evident. The growth of a firm is more strongly tied to waves of creativity, to its ability to develop collective intellectual property rights, and to expansion toward collective distributive structures. In such an environment the number of small and medium sized enterprises may increase.

### 3.2. In practice: The Los Angeles motion picture complex

The motion picture industry in the Los Angeles County is a special case of industrial cultural districts internalized in a great metropolis [Garreau (1992); Scott (2000, 2005)]. Its relevance is acknowledged worldwide "... because unlike many other case study industrial districts (Silicon Valley, Orange County, or Boston's Route 128, for example), its outputs trade on a pure cognitive register. For this reason alone, Hollywood is one of the most arresting examples of the burgeoning cultural products agglomerations that are on the rise all over the world today" [Scott (2002, p. 972)]. Furthermore, Hollywood movie production [Scott (2005); Chapter 19 by de Vany in this volume] has become a remarkable example of a well established and flexible network economy, emerging from the crisis of the studio system based on the old Fordist production processes [Christopherson and Storper (1986); Storper (1989); Scott (2005)]. Vertical disintegration and product innovation have led to the need for specialized inputs served at a relative low level of product standardization by a cluster of creative and dynamic small-sized firms (see Table 1).

The movie industry in Los Angeles also illustrates the two types of positive externality noted in the previous section. First, the atelier effect is evidenced by the fact that movie production requires the cooperation of a variety of professionals, including designers, painters, writers, photographers, craftsmen, stylists, musicians, multimedia experts, artists, wardrobe designers, tour managers and Shumpeterian entrepreneurs. When all these skills are mobilized, the sector becomes the source of a cohort of highly qualified workers. Given that around 60 percent of the labor force is freelance, an immense workshop results in which every worker is the potential creator of a new firm. Second, in addition to its ability to train new workers, the motion picture industry creates new tie-in and licensed products: books, videos and paraphernalia, thus opening a large merchandising market. This outcome is an example of the "creative product differentiation" externality.

The motion picture industrial complex in Hollywood could be perceived as a mature industry, yet the rate of birth of firms there is remarkable for such an old district: 188 new establishments appeared each year between 1993 and 1997 (with a yearly growth rate of 16.6 percent). This confirms the endogenous dynamic of this cultural district as

Table 1  
Los Angeles motion picture and video industry

Year	Number of employees	% of total employees	Number of establishments	% of total establishments	Number of establishments 1-19	% of total motion picture establishments
1993	183,783	5.2	5634	2.6	N/A	N/A
1997	188,465	5.3	6573	3.0	5984	91.0

Source: Bureau of the Census, 1998, *County Business Patterns for Los Angeles, CA*.

well as its potential capability for allowing the cohabitation of a few major studios with a large number of small sized independent firms. This is a peculiar characteristic of the Hollywood district and anticipates in practice the expected evolution of other typical clusters of culture-based firms.

### *3.3. In practice: The Caltagirone (Sicily) pottery district*

Caltagirone has been renowned since ancient times for its pleasing pottery, the elegance of its traditional design and the creativity of its craftsmen. Earth, fire and creativity, the three basic inputs of pottery production, have been furnished from time immemorial by the mines of clay, the woods and the cultural spirit enveloping the town. The pottery district of Caltagirone represents an example, among many others, of an industrial cultural district using very low technologies [Cuccia and Santagata (2004)].

This cultural district is small. It holds no more than 150 studios and laboratories, each of which corresponds in dimension to an extended family. The average size of each studio is small: not more than 180 square meters. The local community is intensely linked to the pottery production. In Caltagirone there is an historical Museum of Pottery, a regional training school for pottery handicraft, and a strong tourism industry. Two guilds organize the institutional links with the local authorities, important channels for public subsidies and for the forthcoming institution of a collective trademark.

The main structural differences with the Los Angeles case concern three aspects: the intensity of the technical division of labor, the rate of technological innovation and the range of products. The division of labor in Caltagirone is weak and the growth of technological innovation is stagnant. In fact, when the structure of production of a cultural good is elementary, such as with pottery or glass, the whole filière is performed in a number of small laboratories under the direction of lead craftsmen whose skill, flexibility and creativity are the fundamental inputs of firms which sell the same limited line of objects. Consequently, in this kind of industrial cultural district many small production units share consistent positive externalities and social practices developed within the district, but they are strongly competitive with each other. Moreover, each unit tends towards full internal integration of the creative, productive and distributive phases of the value chain. In particular, each studio tends to have a showroom in town or abroad, and a virtual site on the Internet. Finally, given the relatively limited division of labor, this kind of industrial cultural district does not develop specialized branches or new industrial activities. This in turn makes the industry more vulnerable to unexpected shocks on the demand side.

Nevertheless, two new factors seem to be affecting this scenario. Firstly, the accumulation of reputation may induce the localization on the site of new industrial activities from abroad such as industrial tile and pottery production, whose firms are interested in associating the renowned name of Caltagirone to their trademark. Secondly, web offerings – for example, the designing of a website – are usually created cooperatively, thus sharing positive externalities among a wide group of firms.

#### 4. Institutional cultural districts

The second type of cultural district to be discussed in this chapter is the *institutional cultural district*. Its essential characteristic is its grounding in formal institutions that allocate property rights and trademarks to a restricted area of production. These rights take on the meaning of *community or collective property rights*. In this sense, they legally protect the cultural capital of a community in a given area. Their protection concerns the intellectual and intangible components of the culture embedded in the goods and services produced. These rights are normally established through the introduction of a collective geographical trademark that only the local producers can exploit. Following the definition of the World Intellectual Property Organization [WIPO and ITC (2003)] we will refer to them as *appellation of origin* and *geographical indication*.

The content of the goods produced in these districts is strictly connected to the local civilization and its *savoir vivre*. Furthermore, the economic advancement of these products is naturally correlated with the local culture: the more their image and symbolic icon is identified with local customs and cultural behaviors, the more they seduce consumers in a cultural lock-in and the more their production is fostered. In this case, the importance of culture is all-inclusive, mobilizing the aesthetic, technological, anthropological and historical content of the district.

Once more, the Italian experience is emblematic. In regions such as Piedmont–Langhe and Tuscany–Chianti, the economic growth of well-circumscribed areas shows one decisive factor: the approval of legislation assigning collective property rights to the products of material culture, namely of local tradition in the eno-gastronomic sector. However, as we will see analyzing the case of the wine cultural district of the Piedmont–Langhe, to trace a positive clear-cut correlation between the establishment of intellectual property rights and the economic success of a localized industry is complex and non linear, due to the co-evolution of many causes. Nevertheless a strong indirect test exists: in recent years a host of other potential or historic districts have established collective property rights to consolidate a localized economic growth.

In the following sections we consider the institutional setting within which collective property rights are established, propose a behavioral model, and discuss a case-study example of an institutional cultural district.

##### 4.1. Institutional setting: The collective intellectual property rights

When the products are well identified, a trademark is the usual way to protect against piracy and unfair competition; this right, typical of the market for reputation [Landes and Posner (1987)], is individual in its essence. On the other hand, collective property rights are normative rules governing and protecting all the registered producers in a given place; individuals accept a supra-individual authority and the trademark becomes a local public good. So the main reason for establishing it as a collective institution is

similar to that which is at the origin of civil government: there is an increase in efficiency limiting absolute individual freedom and free-riding behavior when this may be done in a consensual setting [Coleman (1993)]. Two types of intellectual property rights may thus be distinguished: individual and firm-based or collective and community-based. Those that are communitarian or collective will be especially helpful for the start-up of a potential cultural district, for example, the *appellation of origin* (AO). This is usually the name of a village or place, and is assigned to a product whose characteristics are deeply rooted in the local social and cultural environment or territory. The entitlement to use the label "AO" offers a means of protecting the traditional practices of a specific place. The AO gives rise to an exclusive right, namely a monopolistic power which is shared among the producers located in the same protected area. Other important collective intellectual property rights are the *collective trademark* and the *geographical indication*.

The assignment of this sort of property right yields a mixed set of incentives and problems. In regard to incentives, these property rights create a monopolistic privilege through product differentiation; at the same time they allow an increase of prices and of yields, contributing to a substantial accumulation of capital, beyond that allowed by the premium price. Furthermore, they generate incentives so that producers invest in reputation and high quality of products selected through a long cultural tradition. They also lead to better control of the productive and distributive process, with an increase in the quality of the products.

However, improving the content and availability of information through labels of origin may have some drawbacks. Here we consider three potential failures.

The first, as public goods theory asserts, is the risk of free-riding behavior. The AO has the function of signaling the quality corresponding at least to the minimum standards required by the rules of registration. Sharing this signal and keeping constant the level of reputation implies a significant collective investment in spreading information and enhancing product quality. Low-quality producers can free-ride in order to get the benefits of the collective trademark, but in the long run, as will be seen below, their non-cooperative behavior will reduce the positive effects deriving from the assignment of the collective right.

The second failure is concerned with moral hazard that may arise if periodic inspections on the quality are not carefully carried out. In this case a local producer could decide to attach the collective sign to products of lower quality, confident that consumers will not appreciate the difference. This strategy will produce a lowering of the average quality of the product until more experience and information eventually reverses consumer behavior.

The third problem is the *exit option* for the better quality producers. If the relative quality of individual products increases, there could be an impulse toward the exit from the collective sign because the use of it would signal a quality that is, over a significant threshold, lower than that of the better quality firms. Thus the process of exit and the cumulative decrease in quality may develop a new reverse move toward adoption of individual rather than collective trademarks.

4.2. Modeling behavior in the establishment of collective intellectual property rights

In this section we investigate the strategies of individual producers with regard to the adoption of a collective trademark [Cuccia and Santagata (2004); Cellini, Cuccia and Santagata (2005)], using artistic ceramics as an example. The generalization to other cultural districts is straightforward.

Let us assume that in the market for pottery there are  $N$  individual firms corresponding to  $N$  craftsmen. It is also assumed that in the market there are two kinds of craftsmen:

- A number  $N^A$  of *art-oriented* craftsmen, producing high quality commodities. They invest in culture and care about the artistic nature of their production.
- A number  $N^M$  of *mass-production-oriented* craftsmen, producing standardized and low-quality/low-priced commodities. They do not care about the art of ceramics, but are only interested in market results. They do not respect the minimum quality standards required of members registered to the collective trademark.

To simplify the interaction among actors, let  $C^A$  stand for the agent representative of the art-oriented craftsmen and  $C^M$  the agent representative of the mass-production-oriented or low-quality craftsmen. Consider a game in which each craftsman can choose between two strategies: “to join” and “not to join” the collective trademark. A lack of interest in the collective trademark and hence its non-existence represents the status quo. We assume that the payoff of the art-oriented craftsman is  $\pi^A$ , while the payoff of the market-oriented craftsman is  $\pi^M$ ; the subscripts 0 and  $T$  ( $\pi_0^A, \pi_0^M, \pi_T^A, \pi_T^M$ ) denote the status quo and the adoption of the collective trademark, respectively.

The payoffs of the players in a static non-cooperative game with simultaneous strategies and perfect information are represented by the payoff matrix shown in Table 2. In the payoff matrix  $\varepsilon > 0$  denotes an externality resulting from the decision of the players about whether or not to join in the collective trademark. If both join in the trademark club,  $C^A$  will bear a negative externality because of the co-presence of the low-quality producer downgrading the collective reputation; at the same time  $C^M$  will receive a positive externality from the presence in the collective trademark of an art-oriented craftsman with excellent reputation. Payoff  $e$  denotes the result for the art-oriented craftsman in the case in which he/she does not join the trademark club while the market-oriented craftsman joins. No a priori assumption is made about the size of  $e$ .

Table 2  
Payoff matrix

To join or not to join a collective trademark		$C^A$	
		To join	Not to join
$C^M$	To join	$(\pi_T^M + \varepsilon), (\pi_T^A - \varepsilon)$	$\pi_T^M, e$
	Not to join	$(\pi_0^M + \varepsilon), \pi_T^A$	$\pi_0^M, \pi_0^A$

If player  $C^A$  decides to join the collective trademark club, his/her payoffs are:  $\pi_T^A - \varepsilon$  if  $C^M$  joins, or  $\pi_T^A$  if player  $C^M$  does not join. With his/her presence  $C^M$  generates therefore a negative externality ( $-\varepsilon$ ), since he/she decreases the average quality level that the consumer attaches to the collective label. If on the other hand  $C^A$  decides not to join, his/her payoffs are:  $\pi_0^A$  if  $C^M$  does not join (this payoff can be interpreted as the normalized level of profit in a market without collective trademark); and  $e$  if  $C^M$  joins.

As far as the player  $C^M$  is concerned, if he/she decides to join, his/her payoffs are:  $\pi_T^M + \varepsilon$  if  $C^A$  joins (in this case,  $C^M$  enjoys at zero personal costs the positive externality ( $\varepsilon$ ) generated from the adhesion of  $C^A$  to the label, since  $C^A$  is supposed to increase the average quality attached to the collective trademark); and  $\pi_T^M$  if  $C^A$  does not join. If  $C^M$  decides not to join, he/she gets a payoff  $\pi_0^M$  if  $C^A$  does not join; and  $\pi_0^M + \varepsilon$  if  $C^A$  joins, since, even if  $C^M$  cannot carry the trademark, he/she may benefit from the positive externalities such as those stemming from the great renown of a ceramic district like Caltagirone.

Considering the payoff matrix, the representative player  $C^M$  has one dominant strategy: *to join* the collective trademark. In fact, for whichever choice of  $C^A$ ,  $C^M$  will judge it convenient to join, that is  $\pi_T^M + \varepsilon$  and  $\pi_T^M$  are respectively greater of  $\pi_0^M + \varepsilon$  and  $\pi_0^M$ . Thus if entry/registering costs are not high, the market-oriented low-quality craftsmen will without doubt join.

As far as the representative player  $C^A$  is concerned, two cases may occur:

- If  $\pi_T^A - \varepsilon \geq e$ , the strategy *to join* is dominant also for him/her and the game has a Nash equilibrium in dominant strategies (*to join–to join*).  $C^M$  increases his/her payoff with respect to the status quo, while the change in the payoff for  $C^A$  will be positive or negative according to whether  $\pi_T^A - \varepsilon$  is larger or smaller than  $\pi_0^A$ .
- If  $\pi_T^A - \varepsilon < e$ , no dominant strategy exists for  $C^A$ , and the game's Nash equilibrium is *to join–not to join*. In this case  $C^M$  benefits from an increase in his/her payoff with respect to the status quo, while  $C^A$  will have a positive or negative change in his/her payoff according to whether  $e$  is larger or smaller than  $\pi_0^A$ .

The above discussion makes it clear that the assignment of collective intellectual property rights such as collective trademarks can work only under specific restrictions.<sup>3</sup> In particular the art-oriented agent is very cautious about joining a collective trademark, and his/her decision depends on the order of magnitude of the negative externality involved in his/her interaction with the market-oriented agent. Local economic policies aimed at increasing the quality of the production of market-oriented agents are the main instrument to reduce that negative externality and induce the art-oriented agent to join the collective trademark. This elementary condition is a prerequisite for the start-up of any institutional cultural district.

<sup>3</sup> For further discussion see Cuccia and Santagata (2004), Cellini, Cuccia and Santagata (2005).

Table 3  
Differentials in GDP deflator and DOC wines prices 1986–1998

Wine DOC	% growth rate of GDP deflator 1986–1992	% growth rate of wine prices: 1986–1992	Differentials: 1985–1992	% growth rate of GDP deflator 1993–1998	% growth rate of wine prices: 1993–1998	Differentials: 1993–1998
Barolo	45.22	86.2	41.0	20.66	146.2	125.54
Barbaresco	45.22	147.29	102.07	20.66	187.6	166.94

#### 4.3. The institutional cultural district: The case of the Langhe, Piedmont

The Barolo and Barbaresco wines produced in the Langhe district in Piedmont in Northern Italy were granted AO rights in 1992.<sup>4</sup> The basic economic effect of this assignment of property rights was to set off a massive process of capital accumulation. Table 3 illustrates the extensive redistribution of income that followed the assignment and enforcement of these property rights. Comparing the differentials between the GDP deflator and wine prices in the two periods before and after 1992, it can be noted that the price lead of the Barolo DOC over the general national price index was three times greater in the years 1993–1998 than in the years 1985–1992. The same impressive lead holds for Barbaresco, suggesting that during the phase of more effective enforcement of the property rights the economic environment has been at least as good as the natural one (good weather conditions).

Effects of the Langhe cultural district on industrial production processes in the region include high levels of innovation amongst small-scale enterprises, a more professional labor force, improved infrastructure and expanded exports. In cultural terms, the establishment of the district has resulted in enrichment of local quality of life through fairs and festivals linked to local cultural products and traditions, restoration of cultural heritage, use of the landscape as an economic resource, cultural dissemination through museums, cultural centers and wine cellars, development of the tourist industry, etc. To illustrate these cultural effects further, it can be noted that approximately one new cultural event was established per year in the 24 municipalities of the Langhe from 1980 to 1992; from 1992 to 2000, after the promulgation of the DOC Act, the frequency of the events permanently created increased to four/five units per year. This means that about 50 new permanent public performances have been established within eight years. So in spring 2001, for example, more than 100 shows, guided visits to castles, and public performances were available to cultural visitors to the area. Finally, in 2003 the Langhe

<sup>4</sup> DOC Act, February 10, 1992, No. 164. The legislation on wine property rights dates back in Italy since 1924, but the DOC Act No. 194, 1992, introduces for the first time a complete and enforceable protection.

region and Barolo and Barbaresco wines received the maximum score of “100” from the severe and established American review *Wine Spectator*, who titled the winter issue: “Piedmont Perfection”. Never was such a rating assigned before.

Analogous arguments may be made for the institutional cultural districts that are based on the economic exploitation of artistic and popular traditions, such as in the fields of music, arts and craft (glasses, perfumes, soaps), the figurative and plastic arts, and designed goods [Grefe (2002)].

## 5. Policy issues for cultural districts in developed and developing countries

As with all social phenomena, any definition of cultural districts and clusters remains in some sense imperfect, because it is progressively evolving along with the continuous transformations of local society and its economic structure. The two different types of cultural district that we have considered are obviously complementary and compatible. Taken together they show the potential for new paths of economic development. Nevertheless, even though the two models can be found all over the world, it is helpful to introduce a simplification. *Industrial* cultural districts can be considered an economic structure mainly operating in the developed countries, like Italy, France and the United Kingdom. *Institutional* cultural districts can be considered in perspective as an economic formula especially suitable for developing countries.

The logic behind the latter proposition is as follows. The foundation of an industrial cultural district is subject to two constraints: first, it must be superimposed onto an appropriate and adequate socio-economic structure, and second, it is a process of very long and often socially painful incubation. These constraints are likely to militate against the establishment of a traditional industrial cultural district in a developing country. Nevertheless it is not uncommon in developing countries to find clusters of small firms producing culture-based goods within an organizational and industrial frame which is something *less* than a cultural district. There are local economic forces, one or more pioneers, local and external demands, labor skills, learning effects, but what is commonly lacking is an incentive system leading the main economic actors of such a place towards more efficient ways of investing, trading, communicating and marketing their products. In short *good institutions* and *good governance* are lacking. Thus the problem becomes how to convey certain efficient institutions such as intellectual property rights into existing potential industrial clusters. One possible solution is to focus on the function of collective property rights in promoting market-oriented incentives sustaining local development. Thus the institutional model could be seen as the more appropriate strategy for establishing cultural districts in the developing world.

Thus provisional conclusion of this analysis is that there is a *policy design dilemma* concerning the start-up of a cultural district. The diffuse entrepreneurial atmosphere that accompanies the evolution of a cultural industrial district does not have an explicit starting point. Its pattern is historic-evolutionist. Institutional re-engineering is not possible.

In terms of public policy, this means that the sequence of random and unforeseeable events leading to a district's achieving a critical mass is, in practice, irreproducible. The localized social and economic environment cannot be constructed *ex ante*. What can be done, mostly in developing countries, is to influence some of the mechanisms governing a potential cultural district according to rational plans to modify individual economic incentives. This is the case for institutional cultural districts. Here local institutions may be capable of transforming a long and spontaneous process into a real and accomplished economic phenomenon. Collective property rights can serve as a vehicle for setting quality standards, increasing prices, generating income, and raising the rate of competitiveness of the potential district.

In principle the assignment of collective intellectual property rights has a double function. On the one hand, these rights are a safeguard against the illegal copying of a good, idea or logo. On the other hand, they introduce rules, standards and mechanisms for business development to a geographical area and to a community or association of producers; setting standards about the quality of the products implies the development of continuous activities of cooperation, marketing and monitoring among the local artisans and producers. Now while the first function is particularly relevant for developed countries, where the main problem is to safeguard the products of cultural industrial districts from copying, the second function is strategic for the economic start-up of micro and small firms in developing countries where the potential for local agglomerations must become effective.

The two types of cultural districts employ the same economic actors: artisans and entrepreneurs producing culture-based goods and services. Localized micro and small enterprises led by craftsmen and small entrepreneurs are common all over the world. However, due to the higher levels of technology employed, vertical and horizontal integration of firms is typical in developed countries, whereas the agglomeration of many identical micro firms prevails in developing countries. In both cases, due to the essential characteristics described above, the production function of cultural goods and services is influenced by the positive externalities deriving from a common location.

Finally, we draw attention to the evolution of cultural districts over time. We expect this to be positive in many respects: job creation, income generation, improved institutional capacity, international openness and the intergenerational transmission of creativity. However there may also be some drawbacks. As shown in the game model for establishing collective property rights discussed above, the choice of joining to collective property rights depends both on individual incentives and on collective behavior. If joining is possible, exit is possible as well. This means that if intellectual property rights are permanently assigned, the individual adhesion may be temporary, because of the exit option. The main function of a collective property right is to signal the average quality of the collective trademark, so those producers who make higher quality products are induced to take the exit option, those with lower quality stay outside. In other words there is a dynamic in the functioning of these rights which has a bottom line: under a certain quality threshold, signaling of collective intellectual property rights offers no advantage (not even to free-riders) and is thus not chosen. The exit option seems

to be the phenomenon mostly present in developed countries, whereas in developing countries the low-quality scenario may be a deterrent to the assignment of these rights.

In developing countries other possible dynamic disadvantages can be linked to the success of cultural networks. First of all, these countries often lack local enforced regulation on the use of land and landscape. Excess demand creates congestion costs leading to deterioration of tourist attractions: too many visitors, too many extraneous installations – from the construction of hotels to the privatization of public property. Second, external forces such as powerful multinational companies can destroy the local culture through new localizations for production often unrelated to the local culture, unfair competition and exploitation of the local reputation. Globalization may endanger indigenous cultures and has already led to the destruction of some. These cultural invasions can be limited only by developing policy instruments that protect local culture and related economic activities.

## 6. Conclusion

The main aim of this chapter has been to contribute to the economic theory of institutions and culture by providing some analytical suggestions concerning the use of culture as an engine for economic development. This explains the emphasis on the start-up of localized economies. In this sense the distinction between industrial cultural districts and institutional cultural districts serves as a fundamental divide to show how collective intellectual property rights work to assist the evolution of a potential district into an effective one. The institutional cultural district formula is being regarded with increasing interest by developing countries, where many potential cultural districts and networks already exist. International organizations such as the World Trade Organization, UNESCO and the World Intellectual Property Organization are becoming more and more aware of the significant role of collective property rights in assisting and promoting such cultural districts.

**Abstract**

Consumer sovereignty is taken to be the aim of policy by which the nature and form of public intervention is identified, both in order to influence the provision of and also the demand for cultural services. Such services are defined by enumeration and include creative arts, performing arts and heritage. In practice, some such services, such as museums and galleries, are publicly provided and paid for, and others, such as artists, theatre, opera and ballet companies and broadcasting receive substantial financial support in the form of grants and tax relief. The interesting question is why such support, coupled with regulatory measures to control the provision and sale of historical artefacts, is found in the arts, whereas in other forms of productive activity, such support is increasingly reduced, as instanced in privatisation measures. The answer seems to lie in scepticism by governments about the ability of consumers to choose for themselves the cultural services that they wish to enjoy and therefore the strong influence of producer interests on government policy exploiting the argument that peer group assessment is the sole guarantee of quality. The consequences of this situation are then explored with reference to both allocative and productive efficiency. Suggestions for policy changes are given seriatim and a view is taken as to how such changes might be influenced by possible future economic trends.

## 1. Introduction

This chapter tackles the difficult question of how to formulate government policies concerning the arts and culture and the problems arising in implementing them, using a simple methodology. First of all, an account is given of the nature of the analytical issues that have arisen and how they have changed in the light of developments in economic analysis since the author first considered the subject [see Peacock (1969)]. Secondly, a schematic presentation is given of the relation between the various ‘actors’ in the policy process. Thirdly, the fundamental question as to why government intervention to influence the arts and cultural activities generally is considered in some detail, before, fourthly, showing how economic analysis may aid the process of appraising actual policies.

## 2. The changing analytical scenario

The author’s first attempt at deriving policy criteria and associated policy measures for public intervention in order to support the arts was written when Paretian welfare economics was taken to be the appropriate paradigm for policy appraisal [see Peacock (1969)], although he indicated then that this paradigm had certain limitations. This article is still referred to from time to time, but much has happened in economics to make a reappraisal of this approach in order to take account of both the changes that the author feels required to make in the paradigm itself and in the light of what we now know about cultural markets and government attempts to influence them. Attempts to bring policy into a suitable normative framework frequently do not take these changes sufficiently into account.

The first important change has been the widening of the concept of economic behaviour which is embodied in the standard welfare analysis. This is particularly evident in the case of the individual utility function. Models are now commonly presented which elaborate the arguments in that function in various directions. The function is expanded to take account of the utility derived from spending on goods and services which benefit others, to allow for the satisfaction derived from one’s choice of occupation and from the esteem of one’s peer group. Some brave economists have faced the challenge offered by these hypotheses in order to test empirically their relative significance.<sup>1</sup> In the case of the arts, particular attention has been paid to the analysis of the motivation of creative artists, and, as we shall observe later, this has a bearing on the methods that are likely to be considered effective, if it is decided that they might receive some form of public support.

<sup>1</sup> Cultural economists should note in particular the masterly summary of these issues by their confrère Bruno Frey (1997) and the bearing it has on research into the behaviour of those in charge of public institutions offering cultural services, as in his examination of the motivation of those who administer museums and galleries [see also Frey (2002)].

The authors's original article paid considerable attention to arguments based on the 'publicness' characteristics of the arts and which form the basis for claims for public subsidy. The second major change affecting these arguments concerns the growing problem about how to retain the assumption of consumer sovereignty as an initial value judgment, when the responsibility for the size and structure of cultural activities fall partly on the government, once it has been agreed that the market, in some sense, fails as the guarantor of optimal provision of cultural goods.

One approach is simply to abandon the assumption altogether. This is most clearly stated in the famous Musgravian discussion of 'merit wants' [see, for example, [Musgrave \(1987\)](#)]. Different definitions of the term abound, but embodied in all of them is the idea that members of society develop preferences in common – and Musgrave quotes the important cultural example of maintenance of historical sites – which means that individuals accept a societal view of what should be done to fulfil them even though it does not fully accord with their individual assessment of their value. When such goods come to be identified, goods and services with publicness characteristics are frequently found to be important examples. In consequence, such goods have to be publicly financed but whether they require to be publicly provided is a separate matter. The interests of consumers are then no longer synonymous with consumer sovereignty and, as Musgrave argues, the latter has to be replaced by some alternative norm.

The idea of merit wants is now firmly embedded in the cultural economic literature though those who accept it, perhaps without full realisation of its implications, often make the proviso that state action is not necessarily to be entirely divorced from the articulation of individual preferences. Those public officials who are able to take unilateral action to supply merit wants cannot afford in practice to regard potential beneficiaries simply as passive reactors. Hence a useful role for the cultural economist is to devise methods for testing such reactions through suitably devised survey methods.<sup>2</sup> However, the merit wants approach raises the question as to the terms and conditions that individuals might wish to attach to the giving up of their right to choose. There are clearly circumstances in which the surrender of consumer sovereignty cannot be implemented without the consent of the governed in a democratic state. Accordingly, an alternative approach to the study of cultural policies is provided by public choice theory in which criteria are laid down for political decisions so that they simulate if not replicate a market system, as in Wicksell's attempt to prescribe the political system which would produce 'approximate unanimity' [for a full analysis of this approach, see [Peacock \(1998a\)](#)]. This approach is the forbear of studies in cultural economics which discuss methods by which the preferences of consumers are not only revealed but are operational in the sense that, within the limitations on obtaining such unanimity, consumers themselves determine the general nature of what governments are to do in their name.<sup>3</sup>

<sup>2</sup> For a comprehensive account of such methods coupled with a useful bibliography, see [Cuccia \(2003\)](#).

<sup>3</sup> For the exploration of the link between voter preferences and decisions governing public intervention to promote the performing arts, see [Schulze and Ursprung \(2000\)](#).

Before examining how far these recent analytical developments affect the presentation of the problems of formulating and implementing cultural policies, attention has to be focused on a third major change in economic analysis. The large segment of resource use controlled by government through its own spending and regulation of private allocation of resources invites the speculation that economic analysis is not suitably adjusted to examine situations where transactions regarding resource use cannot be completed through the market mechanism. It is commonly asserted by arts pundits that the main concern of economics is that of studying markets which turns them into apologists for profit-taking entrepreneurs,<sup>4</sup> thus ruling them out of consideration when it comes to analysing institutions such as museums and galleries, state broadcasting systems etc. which are managed by professionals with high ideals of public service. The economists' riposte is that non-market situations do not produce some moral transformation, though they create a different set of conditions under which individuals maximise their utility, notably the instruction to maximize profits. Moreover, in cases where public services financed out of taxation are monopolies, they allow the possibility of discretionary behaviour. In other words, where such services entail some form of exchange relationship, standard forms of economic analysis can be employed in order to arrive at conclusions about the outcome of negotiations between the parties<sup>5</sup> with appropriate empirical tests devised.

Examples now abound in the field of the arts and culture where transactions within government and between government and private institutions are involved, particularly where, as in the case of specific subsidies to individual arts companies, some form of contractual relationship has to be instituted. Bargaining theory, coupled with principal-agent analysis have become part of the standard equipment of cultural economists. This last change has altered the emphasis in the policy interests of economists and in their desire to have governments pay attention to their efforts, namely in endeavouring to measure the efficiency of government spending on the arts and how far economists can help to devise control methods which act as a substitute to market forces in promoting efficiency itself.

The implications of this changing scenario for further analysis can be encapsulated in a simple diagram. See [Figure 1](#), lifted from [Peacock \(1997, p. 15\)](#). In the lower part a conventional depiction of the welfare approach would recognize only one decision-making process by government which is some unitary being acting as an 'ethical observer' in order to implement welfare rules (e.g., devised from Paretian criteria) in the perceived interests of the community. Such a process implies the existence of publicness in the provision of goods and services, as is commonly argued in the case of cultural activities. If the amount and composition of cultural goods and services requires such

<sup>4</sup> And not only by them. I recently came across the assertion by Edward Wilson, described by the *London Times* as 'the greatest living writer on science' that economists are congenially placed on the boards of commercial companies, whereas environmentalists are associated with non-profit making foundations [see Wilson (2003)].

<sup>5</sup> For a penetrating analysis of the economics involved in such relationships, see particularly [Ricketts \(2002\)](#).

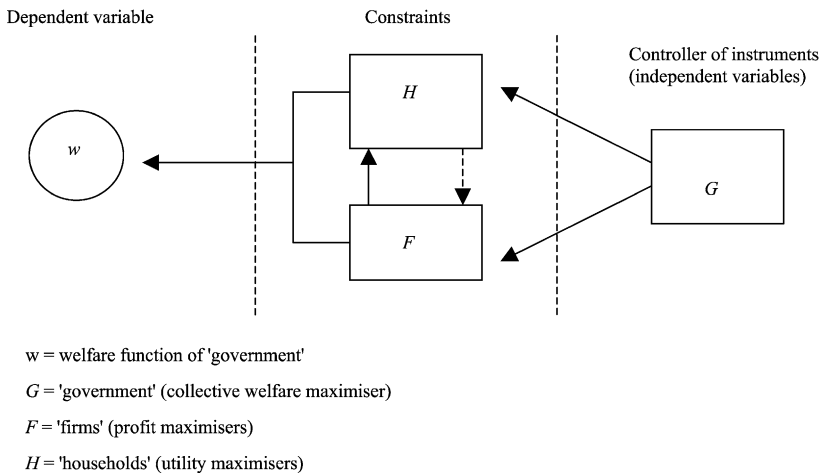

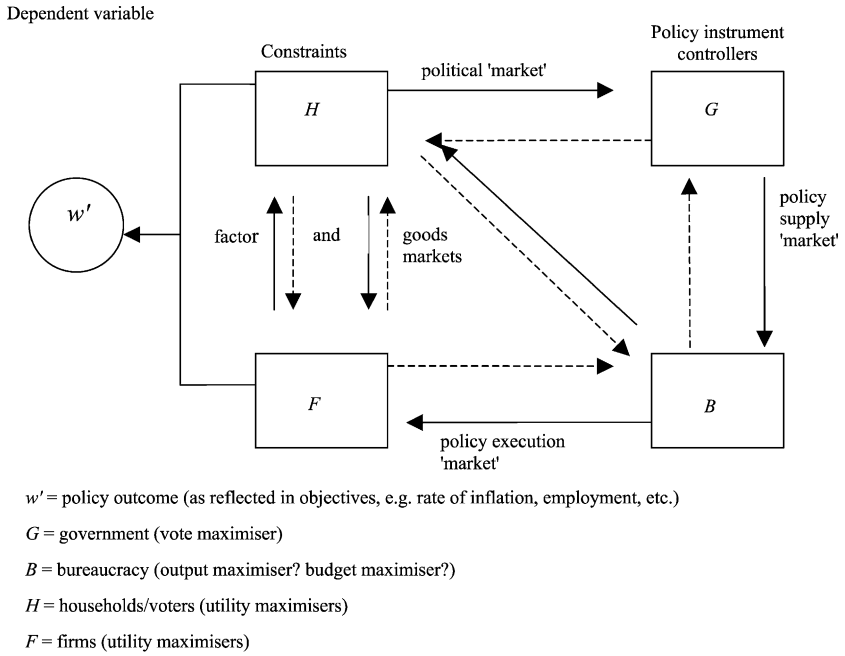

Figure 1. Scope of public choice analysis.

intervention, then the rules commonly require that the tastes and preferences of individuals are taken into account, suggesting, as in the famous Samuelson (1958) presentation of the public goods problem, some method of preference revelation, other than through voting systems. The devising of such methods is clearly of prime concern to cultural economists who accept conventional welfare economics.

Turning to the upper part of the diagram, if it is recognized that preference revelation requires public participation in the decision-making process, then, in addition to a transactions system directly between the ‘unitary being’ and the largely passive adjusting economic units, two other such systems, or ‘markets’, must be embodied in the policy paradigm. These are:

- (i) a political system for election of governments; and
- (ii) a ‘policy supply’ system recognizing the transactions process between politicians and bureaucrats.

This extends the scope of discussion of arts policy beyond defining the extent to which intervention is required on welfare grounds to the possible violation of the welfare criteria by the practicalities of implementing policy. The question as to whether these are areas in which the economists have anything useful to say, which might be denied by experts in political science and public administration, is easily answered by reference to the rapid development of public choice analysis, though some degree of persuasion still seems necessary in order to extend its scope to the world of culture and the arts. The identification of this ‘transactions chain’ brings to the fore the opportunities for discretionary behaviour and the bargaining nature of transactions between government and bureaucracy and the latter with ‘clients’ such as performing arts of companies giving ample scope for such fashionable areas of economics as principal-agent analysis.<sup>6</sup>

In Section 2 below, the policy model commonly devised to indicate the kind of policy measures used to regulate the economy is presented. This raises the question why the arts should be treated differently from other sectors of the economy, but within broadly the same normative framework – Section 3. Sections 4 and 5 contrast the policy conclusions drawn in Section 3 with actual practice. Section 6 speculates on the future role of economists in cultural policies. A short hortatory conclusion follows.

### **3. The market as allocator of resources**

Mixed economies with governments supporting the arts display definite principles of policy action in regard to intervention with the markets for goods and services. Inevitably a short account of such principles is superficial but a necessary prelude to

<sup>6</sup> The diagram might be developed, but perhaps become unnecessarily complicated, by the introduction of other instruments of political participation well known to observers of the arts field, such as pressure groups, including trade unions, NGOs and suchlike organisations who lobby not only governments but also bureaucracies. Some of these seek some special status in advising on policy matters. Much more might be said about the design of the system of political participation, in keeping with the normative rules commonly accepted in Constitutional Economics. Passing mention of some of these complications appear later in this discourse. The hatched lines are added as reminders of feedback effects which emanate from such complications.

consider why the arts should be treated in an exceptional way. The basic principle is that of Adam Smith that the sole object of production is consumption. The consumer's interest is paramount and the consumer is the best judge of his own interests – though this does not preclude consumers, but with their consent, assigning to others choices to be made on their behalf. In a free market system, the consumer can exercise some control through direct payment for such assignment. As we shall observe later, with the provision of cultural services which are not priced, notably those provided by museums and galleries, such control can only be, at best, indirect.

This principle is best invoked by choices made through markets which are characterised by competition. A primary element in government policy is to foster competition. How this is best done is an open question, but the tendency has been in recent times to place emphasis on the competitive process as a dynamic one in which the state's function is to remove barriers to entry into markets. A particular feature of current thinking is the recognition that the government itself may be a barrier to entry, leading to wide discussion of the merits of privatisation of nationalised concerns now subjected to competition, and such measures as competitive bidding for government contracts.

A policy implication of importance for cultural services is that positive intervention in the form of subsidies or grants to firms would have to be strictly limited. There could be a case made out for government general support for high risk projects embodying innovations where patent protection would not be sufficient or for risk-sharing where export performance is affected by political uncertainties. Otherwise, employment and production subsidies to specific firms should be frowned upon, as they discriminate between actual or potential competitors and may cause X inefficiency. Both effects are against the interest of consumers.

This philosophy of economic policy may also accommodate recognition of situations where not all costs incurred by firms are borne by them and not all benefits that they provide are paid for by their customers. The recognition of externalities of production and consumption may make some kind of a case for discriminatory taxes and subsidies, but one which must be compared in actual situations with alternative courses of action such as voluntary negotiation between the parties concerned and regulatory measures. The chosen course of action has to minimize reduction in the operation of market forces as the major guide to the allocation of resources.

#### **4. Cultural services and the market**

There is a marked contrast between the common relationship between government and private firms and that currently found between government and producers of cultural goods and services. It is this contrast which gives rise to a discussion of the rationale of the extensive financial help given to cultural organizations.

First, the creation of cultural works. Painters and composers are typically self-employed. They may co-operate with each other in common facilities, such as ateliers or music studios, and in protection of their rights in the sale and hire of their works, as

in the case of composers' performance rights and the promotion of *droit de suite* provisions for painters. However, it is rare that they attempt to achieve economies of scale or scope by joint production of single works, for independent control and therefore identification with a particular work is necessary for the creative artist concerned with his reputation with his peers. This consideration has a bearing on how the artist lives. The emphasis in her utility function on satisfying herself and her peers may be so strong that she will only take other paid employment as a last resort. Reliance has to be placed on outside support through patronage, long-term investment by galleries or music publishers, or, given the present concern, grants from public bodies. Success in achieving this kind of support is limited because, as is well documented, creative artists do in fact rely heavily on alternative employment, notably teaching.<sup>7</sup>

Second, the performance and presentation of works. The nearest equivalent to the market economy in this area is the commercial art market for the sale of pictures, though once again public bodies may have an influence through their purchase of contemporary art. The position is very different in the case of the performing arts. Using the narrow definition of culture adopted in this contribution, the striking feature is the organization of concerts, opera and drama as non-profit-making ventures. These can take two forms. The first is as private sector companies with charitable status which improves the opportunities of obtaining finance from the public sector either by direct subsidy or indirectly through donations attracting tax relief. The second is publicly operated concerns, such as state orchestras and opera companies, whose affairs are directed by public officials. It is relevant to mention that, in the first case, the orchestras of drama companies may consist of self-employed musicians and actors, whereas in the second, they would tend to be public employees.<sup>8</sup>

Third, the preservation and presentation of historical artefacts. The ownership of the assets regarded as of historical and therefore educational and cultural importance is a very complicated issue. It is sufficient to note that in the case of moveable assets housed in museums and galleries, a large proportion are owned by public bodies which do not require that their managers operate commercially. On the contrary, in most countries viewing days are set aside when entry is free. Direct public funding rather than entrance fees then becomes the major source of finance. The growth in interest in the past as a leisure pursuit has had the result in several countries in a remarkable growth in private bodies offering similar services but still often relying on public funding. In the case of historical sites, those owned by the public sector will normally be managed by government departments or agencies which may raise some revenue from charging admittance, but the major source of revenue will be the government purse. The public

<sup>7</sup> See particularly, Benhamou (2003) on labour market analysis of the supply and demand for creative artists, and also the sceptical view of support for artists expressed by Abbing (2003). Both articles contain useful bibliographies. An early attempt to examine the economic position of composers is to be found in Peacock and Weir (1975) who made one of the first known attempts to quantify their alternative sources of income.

<sup>8</sup> Not to forget the important profession of singer. The locus classicus of analysis of the singer's economic position is found in Towse (1993).

interest extends, however, to the preservation and presentation of artefacts which are privately owned, leading to government measures to induce or even force owners to preserve artefacts and to arrange for their public display.

Fourth, the growing influence of the media. Access to information and enlightenment on cultural matters is increasingly dependent on television and radio. There are now few barriers to the commercial operation of broadcasting, given the alternative forms of transmission now available. Many countries, however, try to exercise control over the content of programmes and actively encourage the use of broadcasting as an educational medium for better appreciation of cultural goods, known as 'public service broadcasting'.<sup>9</sup> Various measures, not necessarily mutually exclusive, may be used, including regulation of commercial broadcasting, but the most striking illustration of the setting aside of market forces appears in publicly owned and operated broadcasting services financed by some form of taxation, either from the general government budget or by some form of hypothecated revenue. In addition to the differences in motivation, in managerial structure and in ownership found in cultural services, as compared with market-oriented businesses, the link between customer and supplier in the financing of the arts in many countries is, to say the least, indirect. Of course, purchasers of cultural services do pay for them directly to the extent that suppliers rely on the box-office, turnstile receipts and the like. However, reliance on government grants brings into being a series of institutions beginning with the raising of revenue to finance them through to the allocation of funding to the relevant government department, and the governmental agencies who assess applications for grants and administer their disbursement. The position is further complicated by the use of tax relief as a method of support for cultural activities, requiring rules governing eligibility.

Therefore, alongside the question of the rationale of direct subsidies to cultural services, and their operation as government agencies, there is the further question of the consequences of this indirect method of finance for the efficient provision of the services themselves.

## 5. The rationale for state support<sup>10</sup>

Given the amount and pattern of state support indicated in Section 2 above, its rationale must be derived either from very different value premises from those adopted by economists or because there is particularly strong evidence of market failure. What appears to be the case is that even conventional welfare economics provides only a weak case for state intervention on the scale commonly found in mature economies. However, it

<sup>9</sup> The place of public service broadcasting has been extensively discussed in the UK in relation to the future of the BBC. See [Office of Communications \(2004\)](#) and [Peacock \(2004\)](#).

<sup>10</sup> This section draws on previous contributions of the author, notably [Peacock \(1998b, 2003\)](#).

is important to examine this case in some detail, if only to increase awareness of some of the ambiguities present in the interpretation of the market failure concept.

The argument may be developed as follows:

(i) *Spillover benefits to consumers.* Individual consumers may attach an option value to the arts, even though they personally do not attend arts events or view historical artefacts, notably in the form of the prestige conferred on a country or community from their existence. This argument is given a more subtle twist by assuming inter-dependent utility functions, so that individual satisfaction may be derived from the fact that others, notably their children or friends, may enjoy cultural events. To derive a case for public subsidy from this argument requires a number of assumptions. The first is that recognition of an option value does not automatically result in voluntary payments to prevent under-provision of culture. The second is that preventing under-provision on option value grounds by public expenditure presupposes that, at the margin, other possible ways by which the same end could be achieved are inferior, e.g., prestige value of international sports teams, medical research. The third is that direct subsidies to individual cultural entities is superior to other forms of subsidization.

In common with welfare analysis in general, a position has to be taken about the welfare of future generations who have no say in current decisions which affect their interests. Rather than guess or prescribe the nature of those interests, I prefer to argue that in operational terms, it is the utility that present generations derive from conferring benefits on future generations that is relevant. Put in a rather negative way, I may be uneasy at the thought that future generations, notably my immediate descendants, would disapprove of any actions of mine that would deny them access to art forms that they would enjoy. This unease might be particularly acute in the case of historical artefacts that, once destroyed, cannot be re-created. The amount and composition of artefacts to be preserved and maintained is not likely to accord with what present generations are voluntarily prepared to pay for viewing them and having them preserved, assuming that their ownership does not prevent them from doing so in the first place. This is particularly the case where charging for viewing them is impossible or prohibitively costly, as with a beautiful town square or country castle. Here again, a general case for public support is presented but it does not specify the amount and form of intervention in the market. The way in which the argument is usually developed certainly does not support the common practice by which cultural services, notably heritage, are not only produced by public agencies but are largely financed by direct grants from government, given the economist's own welfare propositions. It may be that economists on pragmatic grounds would support several of the existing practices, without having to concede that cultural policy should be driven by aims which do not accord with the consumer sovereignty. For example, granted the case for preservation of artefacts of cultural importance in order to take account of the welfare of future generations, the common practice of assigning this task to art historians, archaeologists and the like may be widely supported, given the public's problems of acquiring sufficient information on the provenance of such artefacts. At the same time, it must be realised that expert opinion represents no more

than informed judgment.<sup>11</sup> There may also be practical reasons why economists would not question too closely why heritage services should be provided by state and regional governments, even though it would be more in keeping with welfare philosophy if they were owned and operate by private concerns, albeit subject to government regulation. Apart from the fact that public buildings are frequently of historical importance in their own right, there is clear evidence that when private individuals wish to provide future generations benefits in the form of access to works of art, they may prefer to give or bequeath their property to public institutions perceived as more likely to fulfil their wishes. But the argument so far does not support any case for direct subsidies to either public or private concerns offering cultural services.

(ii) *Quality of choices.* Traditional welfare analysis finds it convenient to assume that in any comparisons of states of well-being, tastes and preferences remain constant. This neglects the strong possibility that individuals will derive utility from investing in knowledge which will improve their satisfaction, the arts being given as a prominent example. Hence the paradox that given tastes and preferences may embody a desire to change them. The Classical economists, notably Smith and Hume, argued that such investment was to be encouraged. As Hume put it, the arts “draw off the mind from the hurry or business and interest; cherish reflection; dispose to tranquillity; and produce an agreeable melancholy, which, of all dispositions of the mind, is the best suited to love and friendship” [Hume (1742)]. However, Hume at least did not believe that investment in taste would be open to all to enjoy, and it is only in recent times that the externalities derived from improvements in the quality of choices have been discerned as positive. The ‘soothing of the savage breast’ by exposure to the arts has been claimed to divert youth away from the excitements of criminality. Ultimately, the question is whether investment in quality of choices requires public support. The strongest argument for doing so is that individuals, particularly the young, under-estimate the benefits from such investment because it is only in retrospect that its benefits become apparent. The general argument may be accepted, but noticeably absent from its presentation is how much and what form state support should take. It implies some form of tied grant to individuals, such as a voucher system<sup>12</sup> recognizing that individuals should be free to choose the shape of the investment package. It does not offer support for subsidies to specific forms of cultural production.

(iii) *Spillover benefits to other producers.* It is claimed that expenditure on the creative and performing arts benefits other producers through the creation of a cultural ambience attracting skilled factors of production and, as in the case of tourism, acts as a loss-leader in attracting business from which industries will benefit. One must be clear at the outset about the connection between this spillover effect and the interests of the final consumer. If employment is at a higher level that would otherwise be the case,

<sup>11</sup> Naturally, experts find this difficult to accept. However, the point is conceded by no less an authority than Gombrich (1979), one of the most distinguished art historians of the 20th century.

<sup>12</sup> Experiments with voucher systems indicate important difficulties in implementation, quite apart from bureaucratic resistance to loss of control of the pattern of expenditure. See Peacock (1993).

then consumers as factors of production have more purchasing power – the income effect. If arts output is higher than it would otherwise be without some form of subsidy, then domestic consumers of arts services may benefit from exploitation of economies of scale or from the availability of arts events that otherwise would not take place. There has been much enthusiasm for this argument, and heavily-funded studies of the impact effect of arts expenditure in particular cities or regions. However, within a country, the extra benefits may largely be pecuniary ones, because any attempt by the use of public funding to realise spillover benefits in one area has to take account of the consequential budgetary effects, such as the reduction in overall incomes from the extra taxation or reduction in other forms of government expenditure. Pushing the argument any further would involve the introduction of interpersonal and interregional comparisons of utility. The spillover benefits could be of national importance, say in small economies with a comparatively large tourist industry. However, for any real benefits to arise it would need to be demonstrated that extra inputs of cultural goods would be the most efficient way of producing the desired results. In any case, if the benefits are perceived by producers themselves to be of material consequence, there is a presumption that they might themselves negotiate private agreements to support cultural loss-leaders.

Clearly, there is little correspondence between the forms of support derived from welfare economics incorporating consumer sovereignty as the main policy objective and the forms that actually exist. It would be wrong to conclude that this is incontrovertible evidence that prevailing systems are paternalistic. The public may be willing to assign to others choices made on their behalf because they believe that there are cadres of experts who have better insight into cultural benefits. However, that is not to concede that this superior knowledge of benefits is anything more than a set of informed value judgments and that those who make them should necessarily be in charge of cultural services in a managerial capacity. Moreover, the scope of the operation of this form of trusteeship will vary from country to country, for it is not to be assumed that public support is perceived as being the sole source of revenue even of publicly owned institutions.<sup>13</sup>

## **6. Economics and policy implementation**

The important presupposition in much of public choice analysis is that any attempt to rectify market failure may be frustrated by government failure. So far as the allocation of resources is concerned, interest attaches to the means available for the beneficiaries from public expenditure on culture to express their preferences through political mechanisms. The associated issue of considerable importance is how far the policies actually decided upon are carried out efficiently, meaning the minimization of resource use for specified levels of performance. Both matters have been extensively investigated by economists.

<sup>13</sup> For further pursuit of these questions by economists, see Johnson and Thomas (1998). The recognition of economic issues by museum directors is rare, but see Thomson (2002).

The first issue raises the question of the efficiency with which far any political system can fully express the preferences of voters. In practice one is unlikely to find, given the relatively small proportion of public budgets spent on arts, that there is strong and persistent political pressure to make it an issue which will decide the fate of national governments. However, the Swiss case is interesting for, occasionally, referenda on cultural matters have been demanded, accepted and voted upon within the cantons, this being a case where the degree of devolution of political decision-making facilities more informed debate about the issues and encourages political participation.<sup>14</sup>

Any democratic government has at least to pay lip service to public reactions to arts policies conducted in its name. The degree to which substitutes for preference revelation leading to *government* reactions are prevalent varies enormously. At the very least, public expenditure projections and audited accounts will reveal information, normally of a fairly general character, on arts financing. Commonwealth countries follow the practice of appointing trustees or some such persons who are not politicians or public officials to boards of management of state museums and galleries, but they are there to put their expertise at the disposal of the public but not as their representatives. Some protection against such appointments becoming sinecures of arts pressure groups is afforded by limiting the period of tenure. However, none of these arrangements implies that governments use an exact measure of the extent to which publicly-funded private or state providers of cultural services are implementing some careful calculation of the removal of market failure as the economist would understand this term.

The economist's skills in examining the allocation issue reveal the logical contradictions that beset arts policies, which is not exactly a way of incurring popularity with public authorities. Once policies are laid down, both in respect of principle and practical implementation, her role becomes more acceptable or at least tolerated. This is because what she has on offer is in tune with public expenditure controls in general in which economists have traditionally played a major part as advisers to Ministries of Finance. Ministries responsible for the funding of cultural institutions will be under pressure to prove that targets are clearly identified and expenditure to achieve them are minimized.

The problems of matching policy aims with this objective provides a useful example of the explanatory power of the dynamics of contracting, using principal-agent analysis. An example from arts funding may be useful here. Imagine a public funding body (pfb) for the arts contemplating the funding of a national opera company. Implicitly, such a body must first of all decide on the funding aims expressed in performance indicators, such as a given number of opera performances a year and perhaps a proviso that a given number of individual operas must be staged with one of them a new commission.

The first problem for the pfb will be to draw up a budget for the specified number of years of the 'contract', taking into account the proportion of revenue that the successful bidder is expected to raise from non-public sources. One initial strategy in an attempt to

<sup>14</sup> Cf. Frey (2002) and Schulze and Ursprung (2000).

minimize cost would be to put the contract out to tender, but alternative sources of supply may be precluded by institutional constraints, particularly if some extant national opera company is an incumbent or even run as a public institution, as with national museums and galleries. If, therefore, there is only one 'agent' offering a service, a bargaining situation is present at the outset.

The next stage would be the drawing up of a 'contract'. The devil is then firmly in the detail. The asymmetric information problem arises immediately if the sole source of information is the incumbent company or cultural institution. The more detail in the contract, the more bargaining takes place over such matters as the delivery dates for specific performances, built-in guarantees of quality of production, the contractual arrangements with singers, orchestral players, chorus etc. and administrative staff. There is an obvious trade-off between relying on trust and avoiding detailed specification – which might suit both parties – and political repercussions if rules governing public expenditure estimates are broken or bent in the process.

The logic of such a contractual arrangement requires that a monitoring system is built into the contract. The asymmetric information problem points towards periodic progress reports, and early warning given when there is a departure from its terms. This is not necessarily entirely onerous to the grantee who then has an opportunity to obtain approval for changes in the contract which may be reasonable enough in the light of circumstances beyond her control. A systematic and continuous dialogue between pfb and grantee is implied, with the former represented in some capacity on the board of management.

In commercial relationships, the non-fulfilment of a contract may be the occasion for compensation payable by the agent to the principal, though the initial contract may only specify the means by which compensation may be sought, e.g., by independent arbitration or by court action. This contingency may be covered by the possibility of insurance against loss by both parties. Such a protection for the pfb, and therefore ultimately the taxpayer, may be very limited. This is clearly demonstrated in the case of defining quality of performance within the context of a regime using performance indicators. A watertight definition of quality cannot be specified in the contract, and the way is open to extended legal argument with settlement only possible after the performance themselves have taken place.

This attempt to spell out some of the implications of a dynamic model of subsidizing arts organizations can only be the starting point for varying its assumptions. The author as a one-time chair of an Arts Council has found it useful as a *vade mecum*, but in his experience the 'noise' produced by the need for openness in public support for the arts makes it necessary to take into account further features in the bargaining process. Thus, as in most forms of public grant-giving, dissatisfied players may endeavour to alter the rules of the game, notably by coalitions with those outside the process as with the use of political feedback. Politicians are particularly sensitive to arguments that place them in the position of being regarded as cultural philistines, with the result that expenditure

on the arts receives political attention well beyond what might be expected from what is normally a small proportion of government funding.<sup>15</sup>

## 7. Conclusion: A possible future agenda

The economic environment in which arts companies and Governments that support them changes rapidly and is bound to affect the nature of the economic advice that might be useful in policies. A continuing feature of economic change in major economies has been the combination of fairly steady economic growth in which technological improvements have played a major part. These have affected, and are likely to continue to have a major influence on both the supply of and demand for cultural experiences associated with the arts; but it is the interaction of supply and demand factors which is forcibly demonstrated in the process of change. This remarkable growth in Western and newly industrialised economies has been accompanied by an increased demand for leisure and accordingly in the demand for cultural experiences. This growth has been associated with an equally remarkable increase in longevity, and also better health, so that the concentration in demand is particularly noticeable in older age groups. One would have thought that the accompanying technical changes which has affected arts production, notably rapid information flow and CD and video presentation forecasted to turn our living rooms into theatres and cinemas, would have counteracted any income effects and emptied the living theatres and concert halls, historic sites and museums and galleries. However, such changes seemed to have operated as a form of advertisement for extensive travel both to produce remarkable international mobility in cultural productions, including international exhibitions of paintings and sculpture, and in tourists anxious to enjoy cultural events in their country of origin. The growth in the concentration of artistic and cultural events generally into festivals covering a limited time span have reduced the costs of attendance to those for whom the opportunity cost of leisure may be high, notably well-off business persons. In short, we are viewing a “Globalization of Culture”.

Of course, international trade in cultural activities is nothing new, but its growing intensity means that policy has to be re-orientated. In this respect, it may reasonably be claimed that at least the technical role of the economist as an adviser to governmental bodies is likely to be increased. Already this is apparent in three areas. The first is in the impact of the growing concentration in the media, notably television, in international corporations which calls for advice on its effects on national competition policies and on its implications for public service broadcasting designed to support quality production. The second is closely related to the first, namely the impact of technology on intellectual property rights, including performance rights, which have increased the

<sup>15</sup> I have explored the bargaining framework between grant-giving bodies and performing arts companies in more detail in Peacock (1993, 2004).

demands for international action.<sup>16</sup> The third is the identification of heritage as an important source of income from cultural tourism. This last area has brought to the fore the recognition of historical artefacts as an important capital resource of developing countries. Governments have sought advice from economists on methods of evaluation of its cultural capital stock as a guide to deciding priorities in preservation. Now that the World Bank has decided that 'sustainable' environment embraces artefacts as well as physical resources, aid programmes now may include schemes for conservation. This obvious way in which economists will extend their influence in the world of cultural policy is through the study of the impact of archaeological remains on the ever-growing curiosity of tourists searching for 'pastures new'.<sup>17</sup>

Keynes looked forward to the days when economists would act and be regarded rather like dentists, more concerned with the immediate realities of improving the human condition than with impressing the public with the profundities of their statements about the good life. One suspects that Keynes's hope may be the way that cultural economics will develop in relation to its policy relevance. That will be all to the good, but the author still regards it as essential that economists will retain a watching brief on those who claim that their expertise entitles them to pride of place in policy decisions. If we do not continue to demonstrate that their judgments of value are arbitrary, then we must not be surprised if they continue to invent the economics for themselves.

## Abstract

Cultural allegiances whether inherited, imposed or chosen, affect economic activity. Many of these cultural layers – ethnic background, religion, language, ideological orientation, and artistic interests – spill over national boundaries. Cultural ideas travel the world along many routes from the Silk Road to modern electronic networks. Historically, peripatetic artists, composers and writers have responded to shifting patronage and market opportunities. More recently, firms in the cultural industries develop and produce content and distribute it as widely as the market will bear. Visual and performing arts and the cultural industries have both common and distinct international economic dimensions. In trade agreements, countries voluntarily limit their policy options in return for restrictions on the choices of the other member countries. Arguments for protection versus openness for cultural activities are more complex and nuanced than for other economic sectors because of a wide range of views on how international cultural policy affects individuals and the national culture. The inclusion of GATS and TRIPS in the WTO made the WTO a more important influence on international cultural policy than its GATT predecessor. UNESCO continues to play a complementary role. The Florence agreement (1950) encourages the free flow of cultural products and a convention addresses illicit trade in cultural property, a heritage issue. Currently, UNESCO is the focus of efforts to create a rules-based convention to protect and promote the diversity of cultural expressions, which is designed to either separate international cultural policy governance from the WTO or strengthen the bargaining position of cultural industry interests in WTO negotiations. These discussions take place in circumstances where there are serious shortcomings in the measurement of trade in cultural goods and services.

## 1. Introduction

The audience for spontaneous moments of creativity, a capella harmonies or a vivid image made in conversation, is multiplied many fold if these moments are recorded and shared. Recording and recalling have developed from drawing on the memories of troubadours and visual artists through the circulation of books, photographs, and sound recordings to the vast capacity of the Internet. In the process, content has evolved from the spontaneous to the crafted. Networks of relationships – market, cooperative, and contractual – coordinate the production and distribution of cultural products and services. Increasingly the networks are international in scope. These developments complement as well as compete with cultural activities that are local and relatively unaffected by technological change.

A possible root of “troubadour” is the Latin *turbare* – to disturb. From the beginning, the transmission of ideas and images not only increased the recipients’ pleasure and knowledge but also disturbed the relations among individuals in the importing societies and between them and their governments. The tension between those who favor stability and those who are more open to outside stimuli continues to make domestic and international governance of the exchange of cultural products contentious subjects of debate. In this chapter, we discuss international cultural economics, give a stylized account of the debate on international cultural policy, describe and analyze the international economic features of the visual and performing arts (theater, opera, ballet, musical concerts, art, etc.) and the cultural industries (publishing, cinema, broadcasting, recorded music, etc.), assess the existing governance of international trade and investment, and conclude with comments on the available statistics.<sup>1</sup>

## 2. International cultural economics

International cultural economics combines something old, international economics, with something new, cultural economics. The first ingredient, international economics, analyses the coordination by the price system of individuals (identified by their unchanging preferences) with non-labor resources and given technological opportunities. This stylized world is partitioned into countries with governments responsible for policies within their borders. Countries are usually distinguished by their factor endowments and degree of technical sophistication and not by their histories, cultures, climates, and ethnic make-up. The basic international trade model has been augmented by refinements borrowed from other areas of economics such as industrial organization or game theory. Within the basic or refined versions, researchers address how the mix of policies adopted by different countries affect trade, capital flows, movement of

<sup>1</sup> Space limits treatment of a broader definition of cultural activities that might include sports, advertising, crafts and cuisine.

people among countries, growth rates of national income, and the welfare of individuals in different countries. At their simplest international trade models are analytically challenging; at their most complex, they appear very simplistic compared to reality.

Governments negotiate and sign international agreements. The range of feasible international policy initiatives is more limited than that of domestic policy because of the absence of a world government with authority to pass international laws and establish a complementary adjudication and enforcement system. The impact of different regional or international agreements is explored in international trade theory by tracing the effect of a change in a small set of parameters, each representing a complex set of measures; for example, a single  $t$  may represent a complicated tariff schedule and set of non-tariff barriers to trade. Some international agreements are declarative of “proper” behavior. The hope is that they encourage adhering governments to conform to the embedded maxims and support the development of sympathetic norms. Traditional international economics has little to say about them. Other agreements, in particular regional and international trade agreements, constrain the policies of their members. They typically rely on a self-contained dispute settlement mechanism (DSM) that adjudicates disputes and can penalize non-compliance by a measured denial of the agreement’s benefits. The viability of trade agreements attests to the disciplining potential of denying the gains from international trade. Their social contentiousness reflects the uneven impact of trade liberalization among groups within each country and “gaming” by member countries to improve their share of the increased wealth. The governance of international trade is less “thick” than that of domestic trade because it depends on non-coercive agreements. This difference means that trade between countries within a free trade zone, for example, differs from trade within a single country.

The second ingredient is cultural economics, the unique characteristics of which are addressed by other chapters in this book. Like international economics, it has borrowed from other areas of economics.<sup>2</sup> Cultural economics also wrestles with issues that other fields of economics have largely ignored.<sup>3</sup> Not surprisingly, it stresses the importance of culture for the development of individuals. Since there is unfortunately no accepted paradigm of how to model this influence, we outline below simply those elements that play a role in our review of culture in international trade.

We assume that all individuals belong to many cultures – groups that have boundaries, sometimes fuzzy, whose members share values and related behavioral norms. Cultures in this broad sense span a spectrum. At one end are those dependent on birth,

<sup>2</sup> Some imported ideas that have been fruitful are: the provision of services with some or all of the attributes of public goods; the characteristics of markets for differentiated goods and services; auction theory; the specific human capital requirements of a cultural career; the economic role of copyright; and the measurement of contingent demand.

<sup>3</sup> Some examples are the evolution of cultural capital – the artifacts and collective memories of the past – and its impact on economic life, the implications for the future economic viability of activities like theater and opera of their limited potential for experiencing cost-reducing technological innovations, and the influence of extreme uncertainty of demand on contracting and organizational practices.

residency or parental choice. At the other end are those loosely held together by common interest or self-appointed membership (computer hackers or people of the “left” or “right”). In between are cultures that accept only a few applicants and others with relatively open memberships. Cultures can be hierarchically or democratically organized, or have no discernible formal organizational structure. Each culture partitions the world differently. From this perspective, nationality is one of an individual’s cultures. It is of particular importance because it determines the laws and regulations governing an individual’s access to other cultures. The borders of other cultural allegiances are usually not geographical but reflective of choices or endowed characteristics of individuals. Each cultural layer establishes psychic or real costs and rewards that interact in a complex way with legal constraints and market prices to shape economic behavior. Many cultures, small or large, are transnational. Their contours affect the direction and “texture”<sup>4</sup> of international exchanges of information as well as of cultural goods and services.

From an analytical perspective, membership in a culture has an impact on demand for cultural goods and services similar to the effect of capital stock on the demand for variable inputs in the short run by the firm. If membership in a culture involves significant investments in capital specific to the culture, hysteresis delays decisions of non-members to join or of members to exit.<sup>5</sup> The hysteresis impact is strengthened if the culture penalizes apostates by, for example, shunning them socially. Variations in the degree of being locked in to different cultures blur the distinction between a short and long run. Another sea anchor on change is the process governing the evolution of codes of behavior in most cultures.

Our view of international cultural economics assumes that a number of cultural partitions join with national cultures to affect individual behavior. *Rushton (1999)* discusses the tension between individualism and communitarianism. Our individuals make decisions constrained not by one association, the community, but an overlapping set of associations, some chosen and others imposed. Individuals in a sense create themselves by their choice of discretionary cultures and by how they reconcile any dissonance among the behavioral prescriptions of their personal allegiances. Some cultural allegiances facilitate reconciliation by valuing the stories, symbols and existence of other cultures. Others preach dominance over competing views and eschew compromise. The social manifestations of how individuals alter their allegiances and provide coherence to their lives are intermediated by governments and their cultural organizations. The valence of both tolerant and uncompromising allegiances is evident in some government’s willful destruction of part of its cultural patrimony and the ensuing reaction by individuals, foundations, and government agencies of other countries.

<sup>4</sup> Cultural categories and beliefs, for example, condition an individual’s view on: what is “fair” in different contexts; obligations to kin; sympathies and antipathies towards the choices and life-style of others; and the appropriate social protocols for interactions with strangers.

<sup>5</sup> See, for example, *Dixit (1992)* and *Dixit and Pindyck (1993)* for particularly clear expositions of a difficult topic, and *Schulze (1999)* for a discussion in the context of trade.

Traditional international economics generally assumes that cultural factors are insignificant in explaining behavior at least in the long run. Methodologically, international cultural economists are searching for disciplined modes of analysis to more effectively address the role of complex cultural processes and activities. International economics has the precision of a recipe but fails to include key ingredients; cultural economics puts a creative process of self-fulfillment at the center but modeling details are works in progress.

### 3. Guiding principles for international policy

#### 3.1. Differing takes

Cultural products and services from other societies have historically been treasured as tributes to the sophistication and cosmopolitanism of those who possessed them, but also feared as threats to the integrity and stability of domestic relationships. Parents would not exert costly efforts to control the radio listening, television watching and reading habits of their children if they did not think that they were important influences on development. With regard to international trade and investment, the tension between the appeal of greater diversity and a fear of its cultural consequences is reflected in a clash between two discourses, one cultural and the other economic or industrial. An early expression of the former is found in Jean-Paul Sartre's magazine *Les Temps Modernes* of 1953.

Cinema is something very different from an industry. It is a means of expression for a collectivity. The image which a country, a society, offer of themselves. That is why a politico-economic offensive which seeks to stifle this means of expression in a given country can only be compared to the forcible means which conquerors sometimes use to deprive the vanquished of their language.<sup>6</sup>

Forty years later during the Uruguay round France's President Mitterand reiterated this position.

Creations of the spirit are not just commodities; the elements of culture are not pure business. Defending the pluralism of works of art and the freedom of the public to choose is a duty. What is at stake is the cultural identity of all our nations. It is the right of all peoples to their own culture. It is the freedom to create and choose our own images. A society which abandons to others the way of showing itself, that is to say the way of presenting itself to itself, is a society enslaved.<sup>7</sup>

<sup>6</sup> Reprinted from Jeancolas (1998, p. 53).

<sup>7</sup> Speech given at Gdansk, Poland, September 21, 1993.

Similar views have been heard from ministers responsible for culture in a number of European countries as well as in Australia, Canada and the developing world. A repeated refrain is that cultural goods and services are unlike those of other industries and should be treated differently in international trade agreements. Currently, the pursuit of cultural diversity is the rallying cry for those supporting this view.

The opposing perspective is that the cultural industries, especially those that offer entertainment to the masses, are similar to other industries and should be made subject to international trade and investment agreements. The Motion Picture Association (MPA) and in particular, Jack Valenti, its leader from the 1960s to 2004, articulated this view with similar rhetorical flourishes:

Is the culture of any European country so flimsily anchored, so shakily rooted, that European viewers must be caged and blinded else their links with their honored and distinguished past suddenly vanish like an exploding star in the heavens? Our market is totally open, absolutely free. There are no restrictions, no barriers, no quotas of any kind. What is in our marketplace, however, is the most fierce kind of competition to win the eyes and ears of those who go (to) the cinema and/or watch TV.<sup>8</sup>

Both sides are largely silent about the high arts. Neither objects in principle to public support for opera, symphonies, theater, literary publishing, museums and art galleries, nor for international agreements that protect intellectual property. The major battle is over mass entertainment that has an articulate industry lobby on each side of the debate in most countries. The US government promotes liberalization while those of most other countries defend different degrees of protectionism. The opposing positions can be summarized as follows.

### 3.2. *Case for protectionism*

The nationalist viewpoint uses the following arguments. A healthy national cultural industry is necessary to assert national sovereignty and identity. Countries with small domestic markets are overwhelmed by imports from larger markets where producers can recoup their costs of production and then dump content abroad. English speaking countries are especially vulnerable to American imports, but similar circumstances apply elsewhere, for example in the case of Spanish language productions from Mexico sold into smaller Central American countries. The actions of American producers in cooperation with the American government, especially in the audiovisual sector, constitute American imperialism and result in the lessening of cultural diversity, as national industries are either unable to compete, or respond in ways that lead to a homogenization of production.

From an economic perspective it is well known that scale economies, imperfect competition and existing distortions elsewhere in the economy can justify protective

<sup>8</sup> Hearings Before the Committee on Finance, US Senate, 102nd Congress, 1st Session, 17–18 April 1991, Washington: USGPO 1991, 150 and 151.

measures. For example, [Francois and van Ypersele \(2002\)](#) have constructed a model in which the introduction of a prohibitive tariff by “France” on international movies raises economic welfare at home and in the “United States”. In the post-tariff world Americans enjoy Hollywood films with lower production values but gain from the production of American independent films that had been “crowded out” by high production value Hollywood films. French movie-goers do not lose from the barring of high production value Hollywood films, which generate no consumer surplus for viewers either in France or the United States, and gain from the consumer surplus rise when their auteur film industry expands.

Arguments about the merits of competitive markets for promoting creative activity are met by the claim that standard economic arguments for trade liberalization do not apply. The audiovisual sector is about culture not commerce, and the interests of culture, especially national culture, should prevail in international trade agreements. In order to counteract the perverse effects of unconstrained commerce, it is desirable to negotiate and implement an international agreement to preserve national cultures in an increasingly economically and politically interdependent world.

### 3.3. Case for openness

Proponents of greater liberalization stress the contribution of open markets to the efficient production and distribution of cultural products. Reliance on market forces also frees creative people from the paternalistic attentions of politicians and bureaucrats. Cultural policies often become subject to regulatory capture and are administered with a view to the interests of producers and government officials. Consumers, like schoolchildren, are told what they should watch and read, but the statistics indicate that few are paying attention to their teachers. If the political process decides that some cultural content is undersupplied, either the state can step in as it does in the case of public broadcasting, or corrective subsidies can be offered. If anti-competitive behavior undermines the efficient working of markets, competition policy should be used.

The “such-and-such-industry-is-different” argument is the rallying cry of all special interest pleading whether its spokesperson, groomed in communication skills, represents agriculture, healthcare, education or national security. Every industry is of course different. By itself the claim provides no guidance to politicians allocating the fiscal pie. In terms of economic characteristics, many industries in a knowledge-based economy have high fixed and low marginal costs but are not granted protection. Many of the special characteristics of cultural products – the non-rivalry of content, economies of scale, and agglomeration economies – enhance the case for integrating markets. That licensing prices for content are lower in small markets than larger is not dumping but its opposite – charging as high a price as different markets will bear. Protection raises rather than lowers prices. The [Francois and van Ypersele \(2002\)](#) strategic trade policy model requires assumptions that are not descriptive of the international film industry: for example, the international industry in their model must be located in the United States, the French cannot invest in the Hollywood monopoly, price discrimination cannot be

practiced, a slight increase in the ticket price of high value Hollywood films in France transforms their dominant share of audiences to a zero share, and no independent film production occurs in the United States in the absence of a French tariff.

All content wherever it is produced contains disparate philosophical and moral messages. Each individual's judgment provides the ultimate defense against being corrupted by the banal or the hate-filled book or program. Governments already act as an agent for individuals and for children by censoring material that offends the current social consensus of decency. Since the nationality of the source does not excuse offensiveness, no discrimination for or against foreign content is warranted on this ground.

### 3.4. *National cultures*

Supporters of protectionism argue that the process of globalization and American cultural imperialism are undermining national cultures. Globalization is an imprecise term. National culture in this context is much more than the laws, institutions and regulations of the country. What constitutes the much more is difficult to define. In short, it is hard to determine what the threat is and what needs protecting from pressures from abroad. National cultures are the result of past forces, many of them international, and they continue to evolve with time. If change is important to sustain viable national cultures then protectionism may impede a desirable outcome. This debate gets tied up with internal conflicts over modernization and societal changes that occur in all countries.<sup>9</sup>

Modernization has taken place as a result of a wide range of international exchanges involving goods, people and ideas. It can be illustrated by tracing the impact of imperial expansion. As well as market exchanges, conflict and tributes imposed on those conquered have provided channels of cultural influence. The empires of Rome, Spain and Britain amongst others both dispersed and absorbed technologies, architectural styles, religious ideas, cultural artifacts, and forms of government. All of the modes of cultural interaction have been criticized. Barber (1995), Gray (1998) and Tunstall (1977) are among those currently arguing that markets destroy cultural diversity.<sup>10</sup> In the opposite camp are Nozick (1974) and Cowen (2002) who contend that market economies provide a widening range of cultural choice.

How do we evaluate these conflicting positions and decide whether there is such a creature as a national culture that can be defined, protected and promoted? In general, creative people are among the first to cross national borders in search of inspiration. Writers, painters and composers, for example, draw on the creative capital of the world to provide them with ideas. Their creativity borrows from the past, reinterprets it, and contributes to diversity over time. We consider their mobility in the next section.

<sup>9</sup> Benedict Anderson (1991) examines the concept of nationhood by tracing the roots of today's nations defined geographically but made up of disparate elements that have coalesced and fragmented over time.

<sup>10</sup> Others who review the issues are Robertson (1992), Schiller (1992) and Tomlinson (1991).

## 4. International dimensions of visual and performance arts

### 4.1. Mobility of artists and diffusion of creative processes and ideas

The high arts have a significant international dimension. From classical times, with a lull in the dark ages, wealthy or politically powerful patrons have sought out and “imported” gifted writers, composers, sculptors and painters. Their experiences varied within and across these cultural activities. For example, in his early twenties Peter Paul Rubens (1577–1640) became the court painter of the Duke of Mantua where he studied the works of Titian and other Italian masters. He visited the court of Philip IV of Spain, affecting the course of Spanish baroque art. On his return to the Spanish Netherlands, he established a highly efficient studio, based on the Italian artists’ workshops that had developed in the earlier Italian Renaissance [Welch (1997)]. Catholicism and reverence of antiquity profoundly influenced his work and his life. An international commission from Maria de’ Medici, the Queen Mother of France, to commemorate her life embroiled Rubens in French politics.

Competition among patrons in the period from the Renaissance to the mid-nineteenth century foreshadowed the current rivalry among teams in international sport. Personal service contracts were the instrument of choice then as now. For example in 1809 Beethoven received an offer to be the Kapellmeister for the King of Westphalia. Three of his Viennese patrons responded by contracting to provide him with a lifetime stipend of 4000 florins to keep him in Austria. When two of the patrons defaulted, Beethoven sued. A settlement making good on the obligations and providing some adjustment for inflation was negotiated [Baumol and Baumol (2002)]. Whereas the religious impact on Rubens’ art is obvious, the cultural influences on music are less obvious; according to Solomon (2003), Freemasonry, which championed Enlightenment and anticlerical ideas, was one of the general influences on Austrian music in general and Beethoven’s in particular.

At least since the Renaissance, the cultural audience has enjoyed “conversations” about the work and lives of internationally recognized “stars” in the traditional arts. Some artists gained notoriety, contemporaneously or retrospectively, for their intense and occasionally destructive life styles. Others like Rubens lent their fame to a social or political cause. Most were not as cosmopolitan as Rubens who wrote in a 1625 letter: “Other things being equal, I regard all the world as my country, and I believe I should be very welcome everywhere” [Magurn (1955, p. 12)]. Nevertheless, almost all stars benefited from, and later became a source of, foreign inspiration, training and on occasion support. They transferred organizational innovations and aesthetic concepts and were subject to transnational religious and philosophical influences. Modern communications and transportation have enlarged the scope of international influence for subsequent artists and expanded the international reach of their predecessors’ reputations.

#### 4.2. *International trade in art and artifacts*

International art dealers sell the works of the artists that they represent from inventory or displayed works that are on consignment. Alternatively they may be commissioned by a buyer to obtain a particular piece or on hearing that something is available shop it to their list of contacts. Their clientele is a mix of galleries, corporate and governmental buyers, and private collectors. Information on the operations of leading dealers is selective and anecdotal. Considerable information, for example, is available on the career of Joseph Duveen (1869–1939) who dominated sales of European art to wealthy American patrons for many decades.<sup>11</sup> The scale of his activities was impressive:

Fifty-five of the hundred and fifteen pictures, exclusive of American portraits, in the Mellon Collection, which is now in the National Gallery in Washington, came to Mellon through Duveen. Of the seven hundred paintings in the Kress Collection, also in the National Gallery, more than a hundred and fifty were supplied by him, and these are the finest [Behrman (1951, pp. 32–33)].

Particularly valuable art and artifacts have been sold through international auction houses and dealers for over two centuries. Electronic bidding and advanced communications have widened the potential audience at auction sales. Initiatives on the Internet have expanded the reach of auctions in distributing existing works. Web sites such as eBay have developed clever protocols for auctioning a wide array of lower-priced art, collectibles, and artifacts. A number of services track transaction prices of art.

Curbing opportunistic manipulation of the identity of the artist of a work and of the provenance of the piece being sold is important for creating a more efficient international market in art. Although a painting is physically unchanged by altering the attribution, its value is significantly altered. In mid 2002, Rubens' *Massacre of the Innocents* was sold for £49,506,650 (US\$76.73 m.), a record price for a painting sold in a British auction. Since the 18th century the painting had been attributed to Jan van den Hoecke, a relatively unknown follower of Rubens. A few weeks before its owner put the painting up for sale, a Sotheby's representative identified it as an early Rubens, which dramatically changed the bidding interest in the painting (and Sotheby's fees).

With respect to the provenance of high-valued items, buyers face a risk of a suit claiming that the item was stolen or had been illegally confiscated by a government at some point in its history. One response to reduce this risk was the development in 1991 of the Art Loss Register, an international database of stolen and lost works of art, manuscripts, books, antiques and other valuable subjects. Currently, 120 thousand items that were lost, stolen or confiscated during the Second World War or subsequently are listed. The Art Loss Register's mission is the creation of an international clearance house in which provenances can be accurately traced.

<sup>11</sup> Among his clients were Hearst, Mellon, Morgan, Rockefeller, Whitney, Huntington, Frick, Carnegie, Altman, Widener, Stotesbury and Kress.

### 4.3. Touring exhibitions, multinational museums and networking

The exhibition of foreign collections of art in other countries is an alternative to cultural tourism. The piecing together of an exhibition celebrating a common theme from a number of museums and private collections and putting it on tour has become popular [Frey and Busenhart (1996, pp. 275–280)]. For example, the organizers of “Aztecs”, which visited major European cities and Tokyo from November 2003 to April 2004 consolidated over 350 pieces from Mexico and from a wide array of international museums. Ironically the exhibition could not have been held in Mexico because the foreign-owned pieces would have been seized under Mexican law, nor could it have proceeded in its full splendor outside Mexico without the permission of the Mexican authorities to allow pieces from its museums to be included. Contributors were compensated for their participation. As part of the arrangements for the London exhibit, for example, the Royal Academy of Arts donated 10 percent of its ticket revenue to the Mexican Heritage Authority.

Highly promoted visiting blockbuster exhibits such as “Aztecs” may “crowd out” collections of host museums. For example, Cannon-Brookes (1996), after acknowledging the impact of temporary visiting exhibits on local pubs and restaurants, notes that they “consume a disproportionate amount of the resources needed by the museum to discharge adequately its core functions” (p. 271). Foreign exhibits are available at a relatively low price to the host museums because the publicity surrounding a special exhibit raises the value of the items lent from private collections and the visibility of contributing institutions [Frey and Busenhart (1996, p. 294)]. The curators of the Smithsonian’s Hirschhorn Museum and Sculpture Garden have recently debated the crowding-out issue and in response mounted Gyroscope, a show mobilizing the museum’s own collection, around three themes of artistic creativity; this is the first show since the museum’s opening in 1974 that features only its own works. The blockbuster visiting exhibits also impact on incentives for regional and idiosyncratic museums to maintain their collections. Similar issues of the survivability of local creativity in the face of international competition arise in other cultural activities.

The internationalization of some large museums allows a more economic exploitation of extensive collections that might otherwise be warehoused. For example New York’s Guggenheim has been particularly active in expanding internationally,<sup>12</sup> although the “walk” has not always measured up to the “talk”. The foreign successes include the Peggy Guggenheim collection in her former home on the Grand Canal in Venice, and a joint venture with the Guggenheim Berlin to display works from its collection and those of German artists at the Deutsche Bank’s headquarters. Since the Guggenheim Bilbao, designed by Frank Gehry, opened in 1997, it has reportedly attracted over a million tourists a year. The “dry holes” included the cancellation of an agreement with the municipal government of Rio de Janeiro to build a multi million-dollar museum

<sup>12</sup> Since 2001, selected works from the Guggenheim Museum collection can be viewed online for free.

designed by French architect Jean Nouvel, and four attempts by the Guggenheim to establish a presence in Japan.

There are also gains from museums with complementary collections cooperating to stock exhibitions. In June 2000, the Guggenheim formed a long-term content alliance with St. Petersburg's Hermitage and Vienna's Kunsthistorisches Museum, which have collections focused on different periods. A less visible but important international linkage for museums and art galleries is the professional networking of administrative and managerial professionals, whereby ideas on technical matters and management are shared informally and through more formal conferences.<sup>13</sup>

## 5. International dimensions of the cultural industries<sup>14</sup>

### 5.1. Production

The international aspects of production in the cultural industries vary according to the technological characteristics of media and the content carried. Writing is a solitary undertaking that is nourished by contacts with other writers, governed by contracts with publishers, disciplined by editors, and complemented by layouts, illustrations, and printing. In contrast, large teams produce film and television programs. Members of a Hollywood film's creative and professional crews are often from different countries; shooting may occur in different venues, and post-production work may be located in still others. Television scheduling imposes tight deadlines and sequential production of episodes, which are consequently less internationalized in their production. In recorded music the organizational challenge of coordinating music, lyrics, and performances and modifying and synchronizing tracks on a master is a less complex process than producing a film. The production teams are small. International diversity is more pronounced among records than within the production of a particular record. Musical influences flow among countries in unpredictable patterns.

The cross-fertilization of ideas in all of the cultural industries is extensive. Movies are based on plays, short stories, novels and newspaper reports. Agents, guilds, industry or activity associations, and trade publications deliver information to those working in cultural activities. This information is interpreted and disseminated originally through relatively thin networks of personal contacts. Internet chat rooms have expanded networking to include strangers from all over the world who share cultural interests. What is called national music is almost always the product of different ingredients brought about by the movement of goods, people and technology. As discussed by Cowen

<sup>13</sup> For example, at the Salzburg Seminar in 1993, Schulz (1994, p. 138) recommended the adoption of budgeting for the German museum system in which the state institutions receive 90 percent plus subsidies to induce their managers "to act as their American counterparts do, in a businesslike fashion".

<sup>14</sup> Studies that treat the economics of the cultural industries include Acheson and Maule (1999a, Part 1), Caves (2000, 2003), Cowen (1998, 2002) and Sedgwick and Pokorny (2004).

(2002, pp. 21–29), this is true for Cuba specifically as well as for Latin America and the Caribbean more generally, with influences from Africa, Europe and latterly North America. In Africa, the popular music of Zaire was influenced before World War II by immigrant workers from different parts of Africa, the West Indies and China. In the postwar period, radio broadcasts and the arrival of cruise ships introduced Cuban influences, while Greek immigrants set up recording studios.

The resulting international sharing creates tensions between creators and receivers when the content is proprietary. The fuzzy boundary between what is protected by copyright and what is in the public domain is constantly being redefined by shifts in norms, copyright law, and technology. The larger the technological shock, the greater the difficulties in resolving how law and behavioral prescriptions should respond. The Internet has been a “multi-sigma” technological shock. Although the adjustment stage has just begun, the courts of many countries are interpreting the relationship of existing law to file sharing and the responsibilities of gatekeepers to police infringement, while legislators are busy amending national laws.

## 5.2. Distribution

### 5.2.1. Content

The low incremental cost of making content available to someone else makes the market for much content extend across borders. This is surprisingly true for many niche markets in the cultural industries.<sup>15</sup> As an illustration of the interplay of international cultural influences on composition and key performers, and of international commercial responses to distribute content with a relatively small market, consider the compact disc *Esteban Salas: Un Barroco Cubano del Siglo XVIII* (Cuban Baroque Music of the 18th Century), performed by the Exaudi Choir of Cuba. Salas (1725–1803), the composer of the music, was born in Cuba and ordained as a priest in the Catholic Church late in his life; the director of the Exaudi choir, Maria Felicia Perez, was trained at the Franz Liszt Music Academy in Germany; the CD was recorded in Cuba, and manufactured and distributed by a division of a German-owned multinational, BMG Music; many of the sales within Cuba are to tourists at Exaudi concerts, souvenir counters in hotels or airports, and special dollar stores; outside of Cuba, the CD is available at web music retailers and specialized record stores.

More obviously, the international market is of critical importance to mass-market content, which is often modified to cater to different cultures and national sensibilities. The producer, the licensed distributor or censors may edit content and on some occasions replace bits of the work that is shown to audiences in a particular market. The

<sup>15</sup> For example, a Canadian company, Rhombus, making cultural programming for arts channels and for cinematic exhibition (*32 Short films about Glenn Gould and Red Violin*) is briefly discussed in Acheson and Maule (1999a, p. 125).

licensing value of a work varies across national markets in response to the potential revenue. The diminution of value when rights of a television program or film from one culture are licensed to broadcasters or exhibitors in other cultures has been labeled a cultural discount [Hoskins and Mirus (1988); Hoskins, McFadyen and Finn (1997)]. Cultural discounts differ depending on whether a program or film is animated, on its special effects, and on its genre (sports, action series, space dramas, documentaries on universal topics).

Distributors are cognizant of the impact of content decisions on revenue generated in different markets in granting advances and setting contract terms. Success abroad may provide a signal of quality and enhance acceptance at home because viewers believe that domestic programming and film are often propaganda or inferior in quality. For example, Taylor (2000) reports that Eisenstein's *Battleship Potemkin* was removed from Moscow's screens shortly after its premiere in January 1926. When it returned to Moscow's cinemas that summer, "it was sold to Soviet audiences as a foreign hit".

### 5.2.2. *Uncertainty, information challenges and high promotional budgets*

Because of the high degree of uncertainty surrounding revenues and profit of a mass-market film, book or record, knowledge of market prospects has a high payoff. Experienced distributors are often in a relatively advantageous position to assess a project's prospects, a comparative advantage reflected in their critical role in the financing through advances of mass-market films, books, or records for which they have distribution rights. Successes have to generate a sufficient surplus to make the overall rate of profit attractive, given the risk.<sup>16</sup>

Distributors of mass-market content strive to persuade potential customers that they offer a more attractive "surprise" than their competitors. The surprise occurs within a set of expectations shaped by genre, the reputation of key figures, and teasing "leaks". Their success depends on seeding a favorable informational cascade<sup>17</sup> about a prospective release over its potential market. What appear to be obscenely expensive marketing, advertising and promotion (MAP) campaigns are coordinated within a short window of time in pursuit of positive "buzz".<sup>18</sup> Distributors exploit the complementary impact of arranging appearances of artists and writers on talk shows, encouraging articles and reviews in magazines and newspapers, distributing flyers, and experimenting with the proliferating counterparts of these communication channels on the Internet to distinguish their wares.

<sup>16</sup> See De Vany and Walls (1996, 2002) for analysis of these distributions.

<sup>17</sup> See Banerjee (1992) and Bikhchandani, Hirshleifer and Welch (1998) for analyses of informational cascades.

<sup>18</sup> The proportionate expenditures on production and MAP vary. Dale (1997, p. 31) suggests that a typical Hollywood film with a production budget of \$39 m. would spend \$20 m. on US advertising and \$9–11 m. in foreign advertising.

### 5.2.3. *Film and television*

Foreign films and lower budget English-language films are usually distributed through the art-house circuits in English-speaking countries. Distribution of these films is more decentralized and less concentrated in time than is the case for large-budget Hollywood films. The majors are pursuing a larger role in the distribution and financing of these films as their popularity increases. In North America, the art houses generally schedule a wide array of films into time slots over a month or two. This scheduling structure resembles that of television more than that of Hollywood films, which have their runs extended at mainstream cinemas for as long as they fill enough seats. North American viewers obtain variety among Hollywood films by choosing among cinemas on any night of the week and among foreign films by going to the tightly scheduled offerings at the local art-house cinema.

Since the 1980s video cassettes, DVDs, and digital files stored on disk have added potentially profitable links to the chain of exhibition possibilities for films. An increasing number of niche films can be successfully launched without a cinematic release. The greater capacity of DVDs and digital files has raised the value of film libraries by permitting more economical re-release of differentiated versions combined with complementary content. The costs of international distribution have been reduced at each stage in the development of home viewing options.

Digital satellite transmission provides those who live on farms and in isolated towns the same wide array of films and television programming as city dwellers. PVRs (personal video recorders) remove scheduling impediments to viewing. High definition television signals and sets reduce the gap in quality between watching a movie at home and in a cinema. The integration of these three technologies in service packages or through video on demand promises to significantly change the international distribution and exhibition of films and television programming. On the policy side, the inadvertent or conscious spillover of satellite signals from one jurisdiction to another creates international tensions that are difficult to resolve.<sup>19</sup> The time-shifting PVRs can also make advertising less efficient, putting greater pressure on subscription prices as a source of finance.

### 5.2.4. *Books and magazines*

High transportation costs of distributing books to bookstores and of returning unsold stock to publishers and inventory costs result in different arrangements for the distribution and retailing of books. Wholesalers, for example, economize on storage and facilitate ordering by retailers of books published by small houses. A multinational publisher typically has subsidiaries or joint ventures operating in the larger centers of

<sup>19</sup> For an account of the interaction between Canada and the United States on this issue see Acheson and Maule (1999a, Chapter 12).

its main language market and licensing arrangements with independent publishers for smaller centers. The subsidiaries and joint ventures cultivate productive relations with domestic authors and license among themselves and with outside firms rights to distribute their authors' books or publish differentiated versions of their books. Like the film studios, the multinational publishers have internal divisions that compete in smaller markets.

Magazine and journal publishers sell internationally. Competitive considerations provide an incentive and current technology allows magazine publishers to practice price discrimination and to bundle their offerings. Non-commercial journal publishers do the same. The American Economic Association, for example, discriminates by whether a subscriber is a student and if not, by salary, as well as bundling its three journals in different packages. One avenue for expanding magazine sales internationally is the use of split runs, editions with common editorial content coupled with advertisements targeted to different national and regional markets. National publishers who use this format across regions in their domestic market often lobby successfully to prevent foreign publishers from competing in the national advertising market with split runs. Policies designed to deter foreign split runs have generated a number of trade disputes.<sup>20</sup>

#### 5.2.5. *Music*

After the European Commission approved a joint venture combining most of the recorded music operations of Sony and BMG in August of 2004, four companies – Universal Music (French owned), Sony BMG Music (50% owned by the Japanese and German parent companies), Warner Music (American owned), and EMI (British owned) – dominate the international part of the popular music recording industry. The production and distribution structure is typically more decentralized than that of the major film studios. Universal Music, for example, has affiliates, generally wholly owned, in most music markets of any significance. The American affiliate includes large popular music labels – Interscope and Island Def-Jam – as well as smaller specialized labels dealing with classical music and jazz. Each label of one affiliate is aligned with a counterpart label of affiliates in other markets. When a label in a market area signs an artist it becomes the repertoire holder and is responsible for the cost of recording an album and for the core marketing tools – photographs, videos, etc. The repertoire holder of a release makes all the profits earned in its home market and shares in profits earned in other areas. The affiliated labels in other countries are responsible for manufacturing to serve their area, local radio campaigns, advertising, other marketing, and contracting with retailers.

Organizational innovations around this core structure are common. For example, Interscope in the United States became interested in Tatu, a singing duo of two young

<sup>20</sup> For an account of Canadian frictions with the United States over split runs and other aspects of magazine policy see Acheson and Maule (1999a, Chapter 10, 1999b, 2000, 2001a, 2001b).

women discovered by its Russian affiliate. The two affiliates formed a joint venture to be repertoire holders for Tatu. The group reached number one in ten countries including England in January 2003. A subsequent US tour has generated some commercial success and considerable cultural dissonance.<sup>21</sup> A recording artist's contractual royalty rate from sales in different areas varies systematically across international markets reflecting revenue prospects and the costs of distribution. An artist signed by an American label of a multinational, for example, receives a US basic rate of say  $x$  percent of the price for normal retail sales. For Canadian sales by the same artist, the rate is reduced to  $0.85x$  percent. For sales in major territories, which are areas in which American records generally do well, the rate is between  $0.6x$  and  $0.75x$  percent and for sales in the rest of the world, the rate is between  $0.5x$  and  $0.6x$  percent.<sup>22</sup>

An independent recording company without a worldwide network would license a promising release to the rest of the world through an umbrella deal or on a one-by-one basis. Throsby (2002, p. 15) notes that "(i)n most cases, music from the Third World has been brought to wider attention through the activities of independent record producers, standing somewhat apart from the major transnational companies". The average proportion of world sales accounted for by locally produced music, as compared to international repertoire music, increased from 58 percent in 1991 to 68 percent in 2000 (ibid, p. 5). In interpreting this statistic, it is important to keep in mind that export markets are important to independent producers. We give an example from our city to illustrate. In a 1997 interview, Peter Burnside, the head of Pacemaker Entertainment, an Ottawa firm that specializes in reissues of the works of good but not well known Canadian artists, noted that "(b)etween 80 and 90 percent of Pacemaker's sales come from outside Canada, mostly the United States and Europe" and attributed the importance of exports to "the fact that foreigners discovered Canadian acts on their own, whereas many Canadians have a negative reaction to music that they were force-fed because of domestic-content radio-play rules".<sup>23</sup>

### 5.3. Exploiting successfully promoted content across media

If content is successful in its original medium, the economic imperative is to expand the market internationally and explore adapting the concept to other media. The original initiative in cross-media successes can be a book, a film, a play, a comic strip or a musical. MAP campaigns adjust to the characteristics of each medium and their complementarities across media. Successes are typically serialized across media. A recent example is the success of J.K. Rowling's Harry Potter stories in film. Her novels have sold more than 200 million copies worldwide and have been officially translated into 55 languages. Over two-thirds of the box-office income of the first two films released,

<sup>21</sup> Sabrina Tavernise, "A bubblegum duo sets off squeals and squirms", *New York Times*, March 4, 2003.

<sup>22</sup> See Passman (1997, Chapter 13).

<sup>23</sup> Toronto, *Globe and Mail*, December 27, 1997, C6.

*Harry Potter and the Philosopher's Stone* (2001) and *Harry Potter and the Chamber of Horrors* (2002), was generated outside of the United States. The release of the films and the more recent books were tightly coordinated with promotional campaigns. Bookstores were not allowed to sell until a prescribed date and the larger ones opened at midnight of the appointed day to meet the demand from enthusiasts. On the cultural side, fundamental Christians in the United States reacted negatively to the books and film because of the central role of witchcraft, while the US Conference of Catholic Bishops were more ambivalent in their reaction.<sup>24</sup> English professors joined the debate with, for example, *Trites* (2001, p. 484) arguing that the books represented “the type of postmodern questioning of power relations traced by such theorists as Barthes and Foucault and Lacan”.

#### 5.4. *Multinationals and antitrust issues*

The ambiguity about whether or not the business practices of media conglomerates are welfare enhancing makes the application of competition policy and sector regulation in the cultural industries particularly difficult, a challenge exacerbated by the international nature of these industries. The practices include:

- block booking and blind bidding in film;<sup>25</sup>
- most-favored-nation pricing clauses in contracts between the studios and arm's-length movie channels or pay-per-view services;
- exploiting regional playback control system codes to limit DVD competition and facilitate price discrimination by, for example, preventing American DVDs from being played on machines in Australia;
- vertical integration into exhibition, pay-per-view services, and broadcasting;
- the duration and terms of contracts between artists and record companies, payola, bundling of individual songs on a CD, and the pricing of those CDs;
- author-publisher contracting, returns policy with booksellers, and the impact of chains and e-commerce on the local bookstore in book publishing and distribution; and
- cable and satellite access, bundling and pricing as well as the concentration of station ownership in local markets in broadcasting.

In addition to the impact of concentration on traditional measures of welfare, media concentration can limit the breadth and vitality of internal discourse on issues. Political reaction to this possibility is heightened if the domination is foreign. This concern may explain both the additional measures adopted to curb concentration in media industries

<sup>24</sup> Office of Film and Broadcasting, United States Conference of Catholic Bishops, June 3, 2003.

<sup>25</sup> Sedgwick and Pokorny (2004) include updated versions of influential articles on this and other aspects of studio management.

in Europe<sup>26</sup> and in other parts of the world and their relatively strong discrimination against foreign ownership.

The need for coordinated competition policy across jurisdictions has been frequently expressed and a number of agreements have been signed. The recent agreement between Japan and the European Commission (EC), for example, calls for timely notification of actions that would affect the interests of the other party, assistance consistent with its enabling law, possibility of coordination, consideration of action by the other country if that would be more effective, and protection of confidential information exchanged.<sup>27</sup> Coordinated actions have been sporadic and the political pressure to engage in retaliatory rather than cooperative competition policy actions is strong. The Working Group on the Interaction between Trade and Competition Policy of the World Trade Organization (WTO) is currently developing a multilateral framework on competition policy that is consistent with paragraph 25 of the Doha Declaration.<sup>28</sup> In pursuit of this mandate the committee began by examining compliance mechanisms for a multilateral framework on competition policy; progressivity and flexibility clauses for such a framework; ways of providing technical assistance and capacity building to developing countries; and creating an inventory of national legislation.<sup>29</sup>

EC competition policy actions have affected proposed mergers of multinational cultural industry firms. In October of 2000, AOL Time Warner abandoned a takeover of EMI after the EC expressed concern about the resulting concentration in the European music industry and with the vertical link to AOL. In approving the joint venture between Sony Music and BMG Music in July of 2004, the European Commission noted that it and the United States Federal Trade Commission had “co-operated closely in their review of the case” (EC IP/04/959). In another case with international links, the EC in 1999 extended an exemption for another five years to UIP (United International Pictures), a joint film distribution company established by Paramount Pictures, Universal Studios, and MGM. In return UIP committed to change its business plan and extend additional support to the European film industry.<sup>30</sup> In late 2000 the US Justice Department charged Sotheby’s of conspiring with Christie’s to fix auction commission rates

<sup>26</sup> Doyle (2000) investigates whether there is an economic explanation for the recent trend to relax these constraints by examining the impact of size and vertical and horizontal linkages on the profitability of British media firms.

<sup>27</sup> Agreement between the Government of Japan and the European Community concerning Cooperation on Anticompetitive Activities, July 10, 2003.

<sup>28</sup> The paragraph instructed the Working Group on the Interaction between Trade and Competition Policy to: “focus on the clarification of: core principles, including transparency, non-discrimination and procedural fairness, and provisions on hard core cartels; modalities for voluntary cooperation; and support for progressive reinforcement of competition institutions in developing countries through capacity-building. Full account shall be taken of the needs of developing and least-developed country participants and appropriate flexibility provided to address them.” Text of Doha Ministerial Declaration, November 14, 2001.

<sup>29</sup> See Report (2003) of the Working Group on the Interaction between Trade and Competition Policy to the General Council.

<sup>30</sup> EC, *Commission Renews UIP Authorisation for Five Years*, Brussels IP/99/681, September 14, 1999.

charged to sellers (“sellers’ commissions”) over a six-year period in the United States and elsewhere. The EC mounted a similar case. Sotheby’s was fined in both cases and its chairman was jailed and fined in the US case. The two firms split the payment of \$512 million in class action damages.<sup>31</sup>

## 6. International aspects common to the arts and cultural industries

### 6.1. *The new versus the old*

In the traditional arts, the new often competes with an expanding body of existing works. Only bits and pieces of the new are absorbed into an art form’s canon and acceptance is grudging. International approval helps crack this barrier to entry. As a result the collections of the great museums and art galleries of the world reflect similar views about the composition of the world’s heritage. They compete locally with contemporary venues offering avant-garde exhibits and a varied set of popular cultural shrines.<sup>32</sup> Viewing an art installation in a contemporary art gallery, for example, differs markedly from shuffling by the ordered display of Rubens’ *Life of Maria de’ Medici* paintings [Millen and Wolf (1989)] with fellow visitors to the Louvre. A contemporary museum might feature an installation that satirized this experience: visitors might be provided headsets that describe a different set of paintings from those hanging on the wall of the installation while showing the audience’s confused response on a framed video screen placed as one of the paintings in the sequence. Physical art installations are site specific and are often destroyed when the exhibit ends. Unlike Rubens’ paintings, they generally have no direct market value outside of their impact on fees to enter the gallery and their enhancement of the artist’s reputation. Virtual art installations posted on the Web are internationally accessible at a keystroke and rapidly growing in number. Installation artists hail from all over the world. The top four on Google’s list of installation artists (ordered by “hits”) as of August 3, 2003 were a Swiss living in Germany (Urs Jaeggi), two artists from the United Kingdom (Graham Nicholls and David Hall) and an American (Kenneth Rinaldo).<sup>33</sup> All are internationally recognized.<sup>34</sup>

<sup>31</sup> In *Kruman v. Christie’s* the United States Court of Appeals for the Second Circuit re (decision of March 13, 2002) ruled that foreign customers had a right to participate in a suit based on a US antitrust violation even though their own transaction was not part of US interstate commerce. This interpretation of the Foreign Trade Antitrust Improvements Act, 15 U.S.C. would have had significant consequences for the international reach of US antitrust policy. It was overruled by the Supreme Court of the United States in *F. Hoffmann-La Roche Ltd. et al. v. Empagran, S.A. et al.* (decision of June 14, 2004). For more detail of the Sotheby’s case see *Mason (2004)*.

<sup>32</sup> Some examples from the United States of popular sites seeking wider cultural canonization are Graceland, the hall of fame of baseball in Cooperstown, the boardwalk of Venice Beach, and the Haight-Ashbury district in San Francisco.

<sup>33</sup> Google’s list is at [http://directory.google.com/Top/Arts/Visual\\_Arts/Installation\\_Art/Artists/](http://directory.google.com/Top/Arts/Visual_Arts/Installation_Art/Artists/).

<sup>34</sup> For example, Rinaldo has exhibited at The Biennale of Electronic Arts, Perth, Australia; Transmediale Berlin, Germany; ARCO Arts Festival Madrid, Spain; The OK Center for Contemporary Art, ARS ELEC-

In European and North American theater, current playwrights face stiff competition for an audience from the works of Chekhov, Ibsen, Moliere, Racine, Shakespeare and Shaw. An international array of composers from the late eighteenth and nineteenth century dominates symphony programs. Similarly, the vigor of debate about the changing composition of the canon of world literature contrasts with the persisting presence of a core set of Euro-American authors. However, the relative importance of this core has been reduced in recent years by adding many more authors from African, Asian, and indigenous cultures to the current pantheon.<sup>35</sup> The cinemas of Europe have a disproportionate percentage of American films while the repertoire of American theaters and concert halls have a disproportionate percentage of works by dead Europeans. The conflict between the new and old that Swift satirized in his *Battle of the Books, A Full and True Account of The Battle Fought Last Friday between the Ancient and the Modern Books in Saint James' Library*, has spread to other media, experienced lulls, and no peace map exists. The international dimensions of that battle reflect the asymmetric importance of different countries in different media and times.

## 6.2. Openness and creativity

In the overlapping European Renaissances, artists often developed in towns or cities with a craft-industrial orientation and a trading tradition. The guilds were important in developing an apprenticeship system. They regulated the quality of work and relations among clients, and the hierarchy of masters, journeymen, and apprentices in a workshop. In some towns the guilds were protective and ran closed shops. Burke (1999, p. 69) notes:

In Florence, however, guilds did not have so much power. The Florentine governments would not allow them to force all craftsmen to join. Some artists, like Botticelli, entered a guild only at the end of their career. As a result 'foreigners' could come and work in Florence. This more liberal policy, which exposed local tradition to stimuli from outside, may help to explain Florence's cultural lead.

Although commissions by patrons dominated in this period, a secondary market for art began to develop and art dealers started to scour the world for works on behalf of wealthy patrons. The development of a market provided artists with an alternative or supplementary mechanism to patronage for making a living.

TRONICA, Austria; The Kiasma Museum of Contemporary Art, Helsinki, Finland; The Australian Center for Photography; The Chicago Art Institute, Chicago; The Museum of Contemporary Art, Chicago; The Northern Illinois University Art Museum, Chicago; The Home Show, Seoul, Korea; V2 Dutch Electronica Arts Festival, Rotterdam, Holland; Image Du Future, Montreal, Canada; Siggraph, Los Angeles; and The Exploratorium, San Francisco. See <http://www.ylem.org/artists/krinaldo/emergent1.html>.

<sup>35</sup> For example, *The Norton Anthology of World Literature*, second edition [Lawall (2003)] comes in a set of six volumes covering different periods of time. The entries, particularly in volume 6, *The Twentieth Century*, include a large number of authors from Asia, Africa, and indigenous cultures in other continents.

Many writers, professionals, and artists are part of a number of different national infrastructures. Some artists, composers, and writers seek inspiration and training abroad as Rubens did in the sixteenth century. Beckett (1906–1989) lived most of his creative life in Paris, one of the many European cities to host Joyce (1882–1941) after his self-imposed exile from Ireland in 1904. Mendelssohn composed his Scottish and Italian symphonies after visits from his native Germany in 1829–1831. Bartok, Stravinsky, and Schönberg composed in the United States after seeking asylum there. Some writers wrote in the language of their new countries. Beckett wrote many of his works first in French. Conrad and Nabokov wrote classics in English, which was not their native tongue.

Technological developments in film and television have broadened the market for the works of writers, composers, artists, directors, cinematographers and performers and increased their potential incomes. Subsidization and a high income elasticity of demand have done the same for the performing arts. As a result, an increasing number of creative and talented people make a living in the arts and the cultural industries. As the infrastructure of professionals, performers, and technical experts develops, an area may attract more custom and an inflow of specialists from other countries. The “thickness” of the infrastructure provides producers of complex projects more options and greater flexibility to adjust to unexpected events. Examples of creative centers for film production are Hollywood for the English-language film industry, Paris for the French-language film industry [Scott (1997, 2000a, 2000b)], and Mumbai [Rajadhyaksha and Willemen (1999)] for the Indian film industry. Unfortunately, policymakers’ knowledge of how to create a growth center for a cultural activity is limited. A large number of would-be production areas have wasted public monies in ambitious schemes to become the next Hollywood, Paris or Mumbai of the – pick any direction among: South, North, East or West.

The migration of foreign actors to Hollywood is well known. Among the earliest stars were British born Charles Chaplin, Canadian Mary Pickford and Pola Negri from Poland. They were followed by many others including Greta Garbo and Ingrid Bergman (Sweden), Stewart Granger, Cary Grant and David Niven (UK), Merle Oberon and Erroll Flynn (Australia), Peter O’Toole (Ireland), Lilli Palmer (Germany), Walter Pidgeon (Canada), Anthony Quinn (Mexico), and Edward G. Robinson (Romania). Such was the presence of British stars in Hollywood that a cricket club was formed. The same is true of directors: many émigrés and refugees from Europe have been among the well-known directors to work in Hollywood, including Eli Kazan (Turkey), Mike Nichols (Germany), Roman Polanski (Poland and France), and Otto Preminger (Austria). In addition, some European directors have worked for a time in Hollywood and then returned; they include Erich Pommer, head of production at Ufa in Germany, who on his return to Europe made films for Fox and RKO and was active in promoting European coproductions as a way of creating larger markets for European productions. Alfred Hitchcock produced films in both the UK and Hollywood: in the UK he worked for Paramount and in the US for RKO, Universal and 20th Century Fox. Jean Renoir spent the war work-

ing in the United States and did not make a film in France again until 1954 [Bergstrom (1998)].

### 6.3. Trade in complementary equipment, goods, and services

Technological change has also had a direct impact on the visual and performing arts. In addition to the flow of creative ideas internationally, the visual and performing arts have quickly absorbed new or superior quality media, materials, instruments and equipment from international suppliers. Suppose a friend attending a piano concert featuring an internationally-acclaimed artist asks you to guess the nationality of the performer: the large population of virtuoso pianists makes the probability of giving a correct answer low. The probability of being right would be much higher if the friend were to ask you to name the manufacturer of the piano that would be used at the performance.<sup>36</sup> The dominant manufacturers of concert pianos have distanced themselves from their competitors through innovation and quality control; they are “stars” of a different kind. The same is true in other fields serving mass markets: in an article describing the debilitating effects of digital technology and sampling on musical creativity in pop music, Tony Scherman<sup>37</sup> wrote that “(e)very generation, of course, recoils from its successor’s new sounds. Jazz was barbaric, Elvis the low point of humanity, Dylan sold out when he plugged in that Fender”. There was no need for Scherman to explain to the reader what a Fender was. On occasion, equipment becomes a collectible: a 1956 Fender owned by British guitarist, Eric Clapton, was sold at Christie’s for US\$497,000 in mid 1999 while a violin made by Stradivari in 1700 sold at the same house for US\$1,326,000 about a year later.<sup>38</sup>

Each visual and performing art requires complementary equipment. It may be an elaborate lighting system for a staged performance or a security system at the museum for protecting the precious items in a visiting exhibit. Cultural trade encompasses all of the complementary production equipment and the technology embodied within it for shaping images and sounds to satisfy local and international audiences. The linkages to other trade are more obvious in the cultural industries than in the visual and performing arts. Movies and children’s books are linked to the sale of related merchandise. The capital goods used in the production of movies, television programs, books, and records as well as in cinemas and broadcasting studios are significant export items for a number of countries. Content is the software for extensive hardware owned by the consumer – television sets, video or DVD cameras and players, sound systems, and increasingly computers, burners, and scanners. Generally speaking the countries that are significant

<sup>36</sup> A June 5, 2003 article in *The Economist*, “Making the sound of music”, lists (in alphabetical order) Bechstein (Germany), Blüthner (Germany), Fazioli (Italy), Steinway (USA), and Yamaha (Japan) as leading manufacturers of concert grand pianos.

<sup>37</sup> Tony Scherman, “Strike the band: Pop music without musicians”, *New York Times*, February 11, 2001.

<sup>38</sup> Christie’s Review 1999–2000, 257 and 91.

players in trade for related merchandise, capital goods and complementary consumer equipment differ from those that are significant players in content trade.<sup>39</sup>

#### 6.4. *Heritage tourism and festivals*

International sites, such as Angkor Wat, Machu Picchu, the Alhambra Palace, the Imperial Palace (Beijing), the Taj Mahal, and the Hermitage continue to be cultural focal points for legions of visitors. Venice remains a unique cultural complex exceeding the sum of its considerable parts, as Mosetto (1992) has explored in a thoughtful economic study. Some unique attractions face difficult tradeoffs between the benefits of cultural tourism and the stress it imposes on fragile environments.

Scheduling regularity, varied menus of events around a theme, and complementary accommodation networks and booking services make music and performing arts festivals attractive to visitors. The festivals bundle a cultural activity with other amenities of the site. Many are associated with small towns and are a welcome counter to the cultural dominance of large urban centers. Their formats are highly differentiated. A number stress the international flavor of their productions. Some are associated with training schools for the arts.<sup>40</sup> All of those that are popular locally also attract foreign visitors, sometimes to the dismay of local patrons.<sup>41</sup> Frey (1994) and Frey and Busenhart (1996) explore the economics of such festivals in more detail. Different levels of government provide significant subsidies to festivals encouraging their proliferation and expansion. O'Hagan (1992) incorporated international aspects in assessing the subsidization of the Wexford Opera Festival.

Theme parks and sites featuring stars, animated characters, themes and related fantasies associated with a major studio attract many tourists. For the large projects, success depends on the impact on contiguous real estate values bought before the project is consummated and the success of ancillary activities like hotels and restaurants.

#### 6.5. *Versioning content for language markets*

The market for instrumental music is affected by different musical cultures but not by language distinctions. There is no translation of music from one musical tradition to another but influences are integrated. When music and words are combined distinctions proliferate. Lili Marlene is a rare example of a popular song (music written in 1938) that became in the Second World War the most popular song in English with Allied troops on the western front, and in German with the Afrika Corps. When genres travel, the

<sup>39</sup> See Section 8.2 on data sources below.

<sup>40</sup> The Festival of Arts and Music in Aldeburgh, England, for example, is associated with the Britten–Pears School for Advanced Musical Studies.

<sup>41</sup> The two largest theater festivals in Canada, the Stratford Shakespearean Festival (Stratford, Ontario) and the Shaw Festival (Niagara-on-the-Lake, Ontario) report that about 40 percent of their ticket sales are to Americans; see Michael Posner, “Theatre festivals get SARS bailout”, *The Globe and Mail*, June 21, 2003.

adaptation of the language component lags behind the adoption of the music. Mathews (2000, p. 64), for example, comments on the history of rock and roll music in Japan:

Rock in Japan used to be sung in English, and a long-running argument was waged as to whether Japanese was a suitable language for rock. From Japanese bands of the 1970s mouthing songs in English whose meanings they didn't understand, to bands like the Southern All Stars in the 1980s singing in a stilted American-sounding Japanese as if to subordinate the rhythms of the Japanese language to the Western rhythms they felt to exist in rock, to Japanese bands of today, singing rock in a Japanese that sounds more or less like Japanese, we see a distinct linguistic Japanization of rock.

Knowledge of the language of the libretto broadens the audience for opera but the impact is not sufficient to make translating librettos economically attractive. The simpler and less informative expedient of providing subtitles on a suspended screen is more common.<sup>42</sup>

The leading works of a modern playwright are typically translated. Translations of fiction and non-fiction books are more common. Permission of the copyright holder in the original language is required to publish a translation, which is protected by a separate copyright. The quality of translations varies widely. At one end of the spectrum are the almost instant translators provided by some Internet search engines.<sup>43</sup> At the other are creative responses to the original works. Susan Sontag eloquently describes the role of translations in broadening the audience for literary works:

Translation is the circulatory system of the world's literatures. Literary translation, I think, is preeminently an ethical task, and one which mirrors and duplicates the role of literature itself, which is to extend our sympathies; to educate the heart and mind; to create inwardness; to secure and deepen the awareness (with all its consequences) that other people, people different from us, really do exist. [Sontag (2003, p. 15)]

Dubbing presents an additional challenge as the translation has to be synchronized with the picture. The skills of both the translator and the actor reading for the new sound track contribute to a more seamless transition from one language to another. Some countries, like Egypt, do not allow dubbed foreign language pictures to be shown;<sup>44</sup>

<sup>42</sup> They describe what is occurring on stage in brief phrases of the local language that appear on suspended screens. In Australian film director Baz Luhrmann's version of *La Boheme*, which opened in San Francisco in the fall of 2002, the teleprompter flashed "Kapow!", "Thwack!" and "@#!&%" during a mock fight scene.

<sup>43</sup> These programs are improving rapidly but the results are crude. To illustrate their current state a computer-wise colleague entered into the Google English to Italian translator "the flesh is weak but the spirit is willing". He then entered the result into the Italian-English translator and recovered "the meat is weak person but the spirit is arranged".

<sup>44</sup> See Ghoneim (2005, n. 58). Subtitling, which dates from the 1950s, "reflects the regime's objection to the presence of a foreign language being heard on national TV" that "reminds people of the era of colonialization and what followed from all the actions of fascism". He also notes that subtitling is cheaper than dubbing.

restricting foreign films to subtitles provides domestic films more protection because of the relatively low literacy rate in Egypt. Other countries will not allow pictures to be shown unless a specified amount of dubbing occurs nationally. Spain is among the countries that require foreign-language films be dubbed. According to Lluís Bonet, a film critic for Barcelona's *La Vanguardia*, "Franco instigated the practice in the 1940s, as a way of censoring foreign films, and it continues to this day".<sup>45</sup> In some instances, dubbing may improve a film; Jake Eberts, a successful producer and head of England's Goldcrest Films in its heyday, claimed this was true for the film *Revolution*.

The only thing that saved *Revolution* was that it was spectacular to look at and some of the battle scenes were breathtaking. Also, I felt that in foreign territories it might not play too badly. The one thing I couldn't stand was Al Pacino's accent, and the mixture of accents between Pacino, Sutherland and Kinski. When the film was dubbed into Spanish, Italian or German then at least the accents would be consistent and some of the dialogue might be easier to hear. [Eberts and Illott (1990, p. 578)]

At the policy level, countries vie to be the dubbing conduit for foreign films into their language market.

## 7. The governance of international trade and investment

We return now to the way in which cultural trade is governed in international, regional and bilateral agreements, as well as the proposal for a new UNESCO-based international agreement on cultural diversity that will impinge on existing commitments made by countries.

### 7.1. The GATT, GATS and the WTO

Member countries' commitments on trade in cultural goods have added to the basic obligations and rights of the original General Agreement on Tariffs and Trade (GATT 1947). Article XX(f) provides exceptions to the GATT for the protection of national treasures of artistic, historic or archaeological value. Article IV permits countries to impose screen quotas as long as they do not discriminate among contracting parties. The interests of non-United States commercial exhibitors in gaining access to popular American movies, and diplomatic pressure from the United States government and its film industry, tempered the willingness of other governments to impose film quotas that dramatically reduced imports. With the introduction of television the United States was concerned that public broadcasters would change these circumstances. It sought assurances in 1961 from a GATT working party that Article IV would not apply to trade in

<sup>45</sup> *The Economist*, December 6, 2001.

television programming. Draft recommendations were prepared but no agreement was reached. Although Article IV explicitly sanctions film quotas, other protective instruments such as box-office taxes that finance subsidies for domestic production are illegal under the GATT (Articles III and VIII).

The special mention of film in Article IV implies that in 1947 the negotiators considered movies to be a good and not a service in international trade. The rising importance of the transmission of audiovisual content by satellite or through telecommunication systems raised the possibility that these methods of trade would also be categorized as a service and GATT would not apply. Since the reduction in transportation costs would likely expand international trade, major players in the cultural industries were concerned that a rules-based regime be developed for trade in services. Some visionaries also foresaw the significant impact that the Internet would have in blurring the boundaries among the traditional cultural industries and enhancing the flow of content among countries. It was not until the establishment of the General Agreement on Trade in Services (GATS) in 1995 that a rules-based regime was developed for trade in services. The WTO incorporated the GATT with some new revisions, the GATS, and the Trade-Related Aspects of Intellectual Property Rights Agreement (TRIPS). TRIPS affected the cultural industries by extending Berne commitments (with the exception of its moral rights obligations) to a larger set of countries and specifying legal measures and enforcement obligations. If Berne had succeeded in harmonizing copyright policies and enforcement processes, creators would have been assured of a minimum level of protection through legal action against infringement of their copyright in other Berne countries. Unfortunately, this right of private action provides no protection if the other country's legislation or adjudication system fails to comply with its Berne obligations. Under TRIPS, but not under Berne, the government of the copyright holder's country can take effective action against another member country's government for not meeting its intellectual property obligations.<sup>46</sup> Similarly, service commitments under GATS are enforceable under the WTO's dispute resolution mechanism.

The GATS commits members to transparency and giving most favored nation (MFN) treatment unless a reservation is noted. A member may offer other countries market access and national treatment. Such commitments can be total or partial for each of the four modes of GATS supply: cross-border supply where seller and buyer remain in their own countries; consumption abroad, where the buyer moves to the country of the supplier; commercial presence, where the seller sets up a foreign subsidiary in the country of the buyer; and presence of natural persons, where the supplier is temporarily in the country of the buyer to supply the service. Fewer than 25 countries including the US have so far made partial or complete commitments for audiovisual services [Messerlin, Siwek and Cocq (2004, p. 32)]. In the Uruguay Round, countries with an interest in liberalization, principally the United States, accepted this lack of commitment in return for

<sup>46</sup> There have been three copyright cases adjudicated under the WTO's dispute settlement mechanism. They are listed at [http://www.wto.org/english/tratop\\_e/dispu\\_e/dispu\\_subjects\\_index\\_e.htm-bkmk31](http://www.wto.org/english/tratop_e/dispu_e/dispu_subjects_index_e.htm-bkmk31) (accessed August 6, 2004).

gaining assent to the WTO package and a promise to reopen negotiations on audiovisual trade in five years [Cahn and Schimmel (1997, p. 297)]. The resulting sectoral initiative has since been folded into the comprehensive Doha negotiations. In the process, Brazil, Switzerland and the United States responded to a request to outline members' views about governing trade in audiovisual services.<sup>47</sup> Canada and France, on the other hand, have stated that they will make no commitments on culture in the WTO until the passage of an international agreement on cultural diversity.<sup>48</sup>

It would also be possible for a waiver to be negotiated for cultural sectors under Article IX, 3–4 of the WTO Agreement, but this is highly unlikely, as three-quarters of the entire WTO membership must approve and any damaged members would have access to the WTO's dispute settlement mechanism (DSM). Carmody (1999) supports a waiver and provides a draft of a cultural waiver that would last ten years. Under the WTO as currently constituted, GATT and GATS obligations apply to cultural goods and services, respectively. What this means, when obligations differ and the activity is a mix of service and goods components, is slowly being clarified through decisions of dispute resolution panels. It is clear that when both components are present in a product, the defendant in a dispute cannot base its policy on the least constraining agreement.

## 7.2. *Other agreements*

The WTO is not the only international agreement to make reference to culture. Some of these agreements are trade related while others deal with a range of issues including cultural rights as basic rights, preservation of cultural heritage, protection of copyright, international cultural cooperation, co-production and cultural dissemination, the interests of artists and cultural creators, and the promotion of linguistic diversity. A few of the existing instruments are considered legally binding but many constitute a soft law approach to establishing international norms.<sup>49</sup>

<sup>47</sup> These are non-binding communications or "cheap talk" in game theory parlance. See Communication from Brazil: Audiovisual Services WTO S/CSS/W/99, July 9, 2001, Communication from Switzerland: Audiovisual Services WTO S/CSS/W/74, May 4, 2001, Communication from the United States: Audiovisual Services WTO S/CSS/W/21, December 18, 2000.

<sup>48</sup> See further in Section 7.3 below. Canada's position was outlined by its Heritage Minister, see <http://www.cdc-ccd.org/Anglais/Liensenanglais/frameevents.htm> (accessed August 6, 2004). France's position is stated at <http://www.diplomatie.gouv.fr/actu/article.gb.asp?ART=32971> at para.2 (accessed February 28, 2004).

<sup>49</sup> See <http://unesdoc.unesco.org/images/0013/001307/130798e.pdf> (accessed July 28, 2004). Examples of related agreements include: The Universal Declaration of Human Rights (1948); Declaration on the Rights of Indigenous People (1994); Declaration of the Responsibilities of the Present Generations Towards Future Generations (1997); Convention on the Protection of the Underwater Cultural Heritage (2001); and Convention on the Preservation of Digital Heritage (under negotiation).

### 7.2.1. WIPO

After the formation of the WTO, national copyright laws in many countries were altered to comply and the levels of protection chosen often exceeded that required by TRIPS. In addition new treaties covering copyright and neighboring rights not explicitly addressed in TRIPS were negotiated in 1996 under the auspices of the World Intellectual Property Organization (WIPO). Unlike TRIPS they lack an effective enforcement mechanism. The *Copyright Treaty* introduced two new rights – a distribution right, which leaves the issue of exhaustion to be determined by each member, and a right of communication to the public. Members must provide adequate legal protection and effective legal remedies against the circumvention of protective technological measures adopted by copyright owners. In particular, they must provide suitable penalties against removing or altering electronic rights management information from copyrighted works or distributing works that have had this information removed or changed. The *Performance and Phonograms Treaty* of 1996 generally reinforces and extends neighboring rights to cover content posted on the Internet. It creates a public performance remuneration right of performers and record companies subject to national treatment. Performers and record companies are given reproduction, rental, distribution, and the right “of making available to the public of their performances in such a way that members of the public may access them from a place and at a time individually chosen by them”. The last of these is a right to authorize downloading on the Internet. File-sharing and CD-ripping and burning have reduced the effective protection provided recorded music, films, and audio books by copyright and by any newly introduced distribution right. Public attitudes to piracy are important and they are in flux. Expenditures on lawyers and the development of new technological fences are reducing creative budgets. Out of the reactions of the industries, the public, the courts, and policy makers some *modus vivendi* as to what will be in the commons and what will be protected on the Internet will emerge. No one knows what that world will look like.

### 7.2.2. UNESCO

The United Nations Educational, Scientific and Cultural Organization (UNESCO) administers the Universal Copyright Convention, an agreement originally supported by the United States as an alternative to the Berne Convention. With the accession to the Berne Convention by the United States, the incorporation of Berne obligations (except its moral rights provision) in the TRIPS, and the new Copyright treaty of 1996, the relative importance of the Universal Copyright Convention has declined. UNESCO also administers the Rome Convention of 1961 governing neighboring rights.

In 1950, UNESCO drafted the Florence agreement to ensure the free flow of cultural products especially books. The treaty was later amended to include audiovisual materials. Over the years a number of countries ratified the Florence agreement including the UK, France and the US. The agreement has the form of a trade agreement but it lacks an

effective enforcement mechanism. In 1970 another UNESCO agreement, the Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property, was negotiated. Cultural property is defined as treasures from the past ranging from rare collections of fauna, flora, minerals and anatomy to furniture that is over 100 years old. The parties agree that there is a moral obligation to respect not only their own cultural property but also that of other countries. Members can take measures to protect cultural property against theft, clandestine excavation, and illicit export. Importing countries have obligations to deny entry to cultural property that is not certified for export from its country of origin. Members must adopt laws disciplining their museums, libraries and archives from obtaining illicit cultural property from other countries. Cultural property cannot be appropriated and exported under compulsion by an occupying force from a member country.

### 7.2.3. Regional agreements

In the founding documents of the European Union (EU), culture was not mentioned. This has not prevented individual members and the EU from being active participants in the culture-trade debate and in formulating policy. The developments are difficult to summarize. At any time, the outcome reflects the conflicting pressures of drawing a boundary around the EU to ward off American influences, and a series of borders around individual countries in the EU that want to be both European and distinct from each other. This results in lengthy discussions over whether culture should promote unity or diversity. Verbal compromises are reached such as aiming for “unity in diversity”, but they provide little policy guidance.

An important initiative was the 1989 publication of the *Television Without Frontiers* (TWF) document. TWF aimed at creating a single television Community market by setting minimum quotas for European content but allowing additional national quotas and other measures that distort trade. A 1998 review of the progress towards a single television market concluded that the “basic principle of freedom of movement has been restricted in practice”. Other trade-related European policies are the EU cultural subsidies available to content producers and distributors and the extensive use made of coproduction treaties for films and television programs. EU trade negotiators have a mandate to act on behalf of member countries after receiving authorization from the Council of Ministers. According to the Treaty of Nice, in force since 2003 and covering sensitive service sectors that include audiovisual services, the Council of Ministers has to have unanimity from member countries to enter into and to conclude negotiations. Thus each country has a veto on conclusion for sensitive sectors. For all other sectors a qualified majority is required to conclude the negotiations.

The North American Free Trade Agreement (NAFTA), contains provisions relating to cultural trade between Canada and the United States that were previously contained in the bilateral free trade agreement between those two countries. There are three components: an exemption for specified cultural industries; a provision for retaliation; and a list of exceptions. The exemption and retaliation provisions represent a compromise that

is read differently by the two countries. Canada stresses the exemption and the US the possibility of retaliation. To date the wording has not been tested in a formal dispute, in part because neither side is certain whose interpretation would prevail. When disputes have arisen, as in the periodical case,<sup>50</sup> they have been taken to the WTO or settled in the political arena through negotiations between the two countries. Culture was treated as any other sector by the United States and Mexico. Canada made no commitments on cultural trade to Mexico.

Other trade agreements, actual and under negotiation, incorporate special provisions for culture. For example, the agreements between Canada and Chile and between Canada and Israel both include an exemption for measures taken by each country with respect to the cultural industries; no provisions for retaliation are included. In the ongoing negotiations among 34 countries for a Free Trade Agreement of the Americas (FTAA), some countries are seeking a cultural exemption.

As noted earlier, co-productions (the formation of bi-national and multinational funding and production teams) have been a typical mode of operation for the audiovisual industry. These have led to countries signing bilateral (and sometimes trilateral) co-production treaties for film and television programs that depart from MFN since they give preferences to some countries over others. Parties to a co-production treaty often benefit by having access to subsidies and to qualifying as national content in the other treaty country or countries. In addition, countries have bilateral investment treaties (BITs) for foreign investment that may contain wording specifically directed at the cultural industries. The failed negotiations for a proposed Multilateral Agreement on Investment (MAI) aspired to replace these numerous agreements. The draft agreement would have contained wording that addressed cultural concerns; a French proposal would have exempted culture.

For those favoring special treatment for culture, the cultural exception/exemption route, as discussed by Cahn and Schimmel (1997), has been the means chosen to date, but there is growing recognition that this has not achieved the desired level of protection

<sup>50</sup> In 1996, consultations failed to resolve concerns of the United States government that the following Canadian policies – a prohibitive excise tax on split-runs of magazines (editions with largely the same editorial content but advertisements focused on different markets), a prohibitive tariff measure restricting the importation of split-runs, and subsidized postal rates to domestic publications – violated Canada's WTO obligations and a complaint was referred to a WTO panel. A panel decision that was modified on appeal (see WTO, WT/DS31/R, March 14, 1997, and WTO, WT/DS31/AB/R, June 30, 1997) resulted in the Canadian excise tax, the tariff and the structure of the postal subsidy not complying with GATT. Canada repealed the tariff, changed the form of the postal subsidy, and passed *The Foreign Publishers Advertising Services Act*, which would have achieved the same goal as the excise tax while in the Canadian government's opinion complying with its WTO obligations. The United States considered the last step inadequate. A negotiated modification of the Canadian legislation followed, which provided, inter alia, for a staged increase in the limits of Canadian-oriented advertising permitted before a foreign magazine would be subject to the law and modifications to the income tax treatment of advertisements in split runs, a policy that had not been part of the original complaint. For a discussion of the complex interaction between the United States and Canada over the latter's magazine policy see Litvak and Maule (1974), Acheson and Maule (1999a, Chapter 10, 1999b, 2000, 2001a, 2001b).

in either the WTO or regional and bilateral agreements. An initiative is now underway to promote an international agreement on cultural diversity that would offset the liberalizing commitments of trade and investment agreements.

### 7.3. *An international agreement on cultural diversity*

The initiative for an international agreement on cultural diversity has emerged from discussions of a group of like-minded countries concerned over the competition facing their cultural industries and the likelihood that domestic protectionist policies would be challenged under trade agreements. Those drafting a proposed international agreement have stressed the loss of cultural diversity as motivating their actions.

While several draft agreements have been in circulation since 2000, the most recent official version, released in June 2005,<sup>51</sup> results from a UNESCO initiative to develop by the fall of 2005 a convention on protecting and promoting the diversity of cultural expressions. The draft wording reveals the difficulties faced in a number of areas, in particular the determination of what constitutes cultural diversity, as well as the rights and obligations of members of the convention, and the determination in draft Article 20 of how it will relate to commitments made by countries in other international agreements such as the WTO.

Proponents claim that cultural diversity is a *per se* value and a prerequisite for the existence and functioning of the market. They believe that openness results in a great reduction of cultural diversity, retards cultural innovations, and safeguards markets not cultures. The protection sanctioned by a cultural diversity accord would preserve local cultures and their languages. The openness of the current system is responsible for the number of spoken languages that are in danger of extinction.<sup>52</sup> Those who are not persuaded argue that cultural diversity defies effective measurement. As a result, there is no basis to judge whether cultural diversity is declining or what policies promote it. Neither protection nor openness is inherently pro or anti market. By favoring domestic commercial sources, protection does not challenge the existence of the market but redirects it and in the process typically generates fewer benefits to consumers. Cultures and the relations among them are constantly evolving. Some cultures are remarkably resilient in maintaining their distinctiveness from the ubiquitous influences of mainstream cultures.<sup>53</sup> Conceiving and implementing effective governmental measures to arrest the

<sup>51</sup> [http://www.cdc-ccd.org/Anglais/Liensanglais/nouveautes\\_eng/Texte\\_revised\\_Unesco\\_Eng.pdf](http://www.cdc-ccd.org/Anglais/Liensanglais/nouveautes_eng/Texte_revised_Unesco_Eng.pdf).

<sup>52</sup> We are indebted to a communication from Professor Santagata clarifying the concerns of those in favor of a cultural diversity instrument. For a discussion of the pros and cons of a cultural diversity instrument see Acheson and Maule (2004), Benhamou (2004), Iapadre (2004) and Van der Ploeg (2004).

<sup>53</sup> Consider a North American example with European roots. The University of Waterloo in Canada anchors an advanced engineering and scientific complex of higher education, firms, and research centers. The university is also at the center of an old and thriving Mennonite community that eschews worldliness. Old order sects within this community have preserved a dialect of German despite their immersion in an English-speaking environment. The tolerance of a modern secular economy has posed less of a threat to their preservation of language and culture than religious intolerance did in an earlier Europe.

decline of cultures (and their languages) lacking that resilience has been extremely difficult within a nation state.<sup>54</sup>

In preliminary discussions leading up to the UNESCO draft, proponents have suggested that members can self-define what their rights and obligations should be. This makes it difficult to resolve cases where the exercise of one country's rights harms another's. The convention may end up as a declaratory statement, in which case it will make little progress in resolving cultural trade disputes, other than expressing the desires of the signatory countries. An alternative motivation of the proponents may be to persuade WTO members not to make further commitments on audiovisual services in GATS negotiations, thereby maintaining the limited level of liberalization in this sector. Meanwhile trade in cultural goods will remain subject to the GATT. Any progress on such a convention will require the participation of the leading countries involved in trade in cultural products. They will need to be persuaded that a separate convention is preferable to the present commitments contained in the WTO. Aside from the US, countries such as Germany, China (Hong Kong), the Netherlands and the UK have media enterprises whose interests are in maintaining open markets. Even countries with governments of a protectionist bent, such as Australia, Canada and France have business interests that are supported by export activities and would be harmed by trade restrictions.

Progress at the international level on cultural trade negotiations for goods and services is now taking place on two tracks, in the WTO and UNESCO. At some point these must merge for progress to occur. Underlying this process is rapidly changing technology that is making it difficult to enforce any internationally agreed commitments. For those who view openness as promoting cultural diversity, as discussed above, this may be a welcome outcome.<sup>55</sup>

## 8. Measuring trade

### 8.1. Measurement problems

Culture is traded as both a good and a service. In some cases both categories can apply, as in the case of a CD carrying a musical composition. Because of the variety of items

<sup>54</sup> Consider an indigenous North American example. According to the Ethnologue website [http://www.ethnologue.com/show\\_country.asp?name=Canada](http://www.ethnologue.com/show_country.asp?name=Canada) (accessed November 30, 2004), there are at least 9 languages – Abnaki (Western), Chinook Wawa, Haida (Northern), Han, Munsee, Sechelt, Tagish, Tahltan and Tuscarora – in danger of extinction in Canada. International treaties do not restrict the Canadian government's policy responses in this area. The paralysis about what to do reflects the lack of economically viable responses.

<sup>55</sup> For the case that the proponents have failed to establish any enforceable rules see Acheson and Maule (2004) and references therein. For informative comments on that paper see Benhamou (2004), Iapadre (2004) and Van der Ploeg (2004).

traded and differences in organizational and contractual arrangements in the various cultural sectors, data collection, especially for services, often requires the use of special surveys. In this section we survey, with selective examples, the types of issues faced by those collecting and interpreting these data.

Data sources differ between reproducible items such as books, films and music, non-reproducible items such as visual art originals, and activities such as cultural tourism. Items in the first category can either be sold as physical objects, or the rights to use the content may be licensed to a number of persons. For example a book can be sold to a foreign library or person, or the rights to publish a book may be contracted with a foreign publisher. A painting may be sold to a foreign buyer by a gallery or through auction. In these cases a physical object is traded but for those collecting trade data the source of information will differ. The secondhand market is the location of much information for non-reproducible art; some may be collected from public auction houses but other transactions may not get recorded.

Other differences occur due to the location of seller and buyer. In some instances both will remain in their own countries while completing the transaction – the electronic transfer of a manuscript to a printer, for example. In others, the buyer travels to the seller such as when tourists visit museums, historic sites, exhibitions and performances, or the seller travels to the buyer in the case of a soprano or baritone contracted to perform abroad. The establishment abroad of foreign subsidiaries, such as cinemas is another means of servicing foreign markets. Each of these alternatives reflects a GATS mode of supply. Negotiators have an incentive to develop statistics to measure their importance in cultural trade.

UNESCO distinguishes among tangible, intangible and material culture. We have stressed the importance of the international spread of cultural ideas, which are intangible, but measuring their importance remains subjective and is likely to remain so. There is more promise that the measurement of trade in services (which are immaterial) will improve significantly under the stimulus of WTO negotiations. The best existing statistics, such as they are, measure trade in cultural goods, which are material.

New technology can create measurement problems. Visits by foreigners to museums are recorded as tourist expenditures in the balance of payments, i.e., as an export of services. The same museum or a gallery may be visited in virtual form on the Internet for free. If a credit card payment is made for downloading a digital print from a museum shop, it should appear as a service export but will likely not be recorded. Subsequent file sharing of print and audiovisual work in digital format between individuals in different countries for which no payment is made will also be unreported. The same is true when consumers gain free access to foreign newspaper, periodical and broadcasting websites. Executives of Torstar, publishers of Canada's large circulating daily newspaper, the *Toronto Star*, testified before the (Canadian) Senate Standing Committee on Transport and Communications that "The *New York Times* alone has more Canadians registered to its website than the *Toronto Star* has subscribers".<sup>56</sup> Much

<sup>56</sup> Torstar Corporation Brief to the (Canadian) Senate Standing Committee on Transport and Communications, February 16, 2005 at [http://www.thestar.com/static/PDF/050216\\_senate\\_brief.pdf](http://www.thestar.com/static/PDF/050216_senate_brief.pdf), p. 17. Worldwide,

of what has value and constitutes international exchanges currently escapes measurement.

Another form of measurement is the documentation of existing policies and estimates of their effects. In 2002, we participated in an IAI-HWWA conference in Hamburg in which researchers described the array of national policies impacting on audiovisual trade of seven countries: Canada, Egypt, France, Germany, India, Italy and the United Kingdom. The remit included developing a measure for the impact on audiovisual trade of the policies of each of these countries. A number of different approaches were taken to arrive at an informed guesstimate.<sup>57</sup>

## 8.2. Data sources

Cultural statistics of any kind are of generally poor quality, and this includes those recording trade. Part of the problem is deciding what activities should be covered and part in determining how to collect the statistics. UNESCO is a starting point but, as Goldstone (2003, p. 177) notes, the list of activities omitted from the World Culture Reports of 1998 and 2000 is lengthy. These reports only publish those aspects of world culture that are readily available. For 2000, the report contains two tables (pp. 348–355) showing cultural trade for about 150 countries for 1980 and 1997. There are numerous blank entries especially for countries in Africa, Asia and the former Soviet Union. South Africa and Jordan, for example, report no entry in any category. Those countries that do report include only goods – in particular books, newspapers, newsprint and periodicals, typewriters, word and data processors, music related goods, cinema and photographic equipment, radio, television and VCRs, visual arts, antiques and sporting goods. These statistics suggest that for most of the industrialized countries over half of cultural trade in 1997 was in typewriters and word and data processors.

According to Ramsdale (2001) who undertook a study for UNESCO based on the UN's Commodity Trade Statistics on trade in cultural goods, developing countries as a group experience a trade surplus. For the developing countries in 1998, cultural exports exceeded imports (US\$51.8 billion and US\$44.4 billion, respectively), whereas in the developed countries the reverse was true (US\$122.5 billion in exports and US\$169.3 billion in imports). The study also notes “the developed countries were net exporters in the categories of printed matter and literature and cinema and photography, while the developing countries were net exporters of fast moving goods like radios, televisions, sporting goods and games, and recorded music” (p. vi). While the balance of payments position varies among developing countries – Malaysia has a surplus of US\$5.7 billion, Mexico US\$5 billion and China US\$13.3 billion – as a group they have a considerable stake in further trade liberalization, contrary to the views of those advocating increased cultural

the *Economist* (June 18, 2005, p. 52) reports users of news websites have increased from 1.6 million in 2000 to 7.8 million in 2005.

<sup>57</sup> See Guerrieri, Iapadre and Koopmann (2005).

protectionism. Recorded trade among less developed countries is low but pirated trade, particularly in music in Africa, appears from unofficial accounts to be significant.

Reliable information on trade in cultural services is sparse although initiatives are underway to fill this deficiency. In its annual *Review of International Trade Statistics*, the WTO summarizes the data available for three categories of services, transportation, travel and other commercial services. Data on trade relating to culture involving audiovisual services and copyright are part of other commercial services. An analyst interested in trade in these activities would require finer distinctions than presently exist.

Government publications of trade statistics typically cover both cultural goods and services but each country survey does not necessarily include the same items. National and international industry associations typically pick from an assortment of official and other surveys to describe a cultural industry including its foreign activities. For example in Canada, The Nordicity Group in conjunction with the federal government and industry conducts an annual survey of the film and television production industry which includes a figure for the "export value" of the industry that does not conform to the concept of exports recorded for balance of payments purposes; export value in this case includes the value of foreign location-shooting in Canada based on surveys of provincial film commissions. Some of these are domestic expenditures and some are already included as tourist expenditures for meals and accommodation and give rise to double counting in terms of export revenues. The survey does not attempt to report on an equivalent "import value".

Schulze (1999, p. 114) reports on trade in categories of non-reproducible and reproducible art using the 4-digit standard international trade classification (SITC): SITC 8960 (Works of art, collectors pieces and antiques for non-reproducible art); and SITC 8983 (Gramophone records and similar sound recordings for reproducible music); and SITC 8921 (Books, pamphlets, maps and globes, printed matter for reproducible literature). These categories are not limited to art in a narrow sense nor are data available for royalties associated with this goods trade. Ginsburgh (2003) uses data collected from auction houses to analyze international art prices. Other data are found in trade journals and the reports of industry associations that tend to be national and have their own particular mandate to pursue, such as measuring the loss of revenue due to piracy, the loss of jobs due to foreign location shooting, or the screen time devoted to foreign as opposed to domestic films. In the case of piracy, much is unreported or at best "guesstimated". For motion pictures, records and music, entertainment software and books in 2002, the International Intellectual Property Alliance estimates losses of US\$6 billion assigned to over 50 different countries.

Overall the trade data landscape is bleak if the researcher is looking for reliable, consistent and comparable data. What to do? Some help is on the way for measuring services trade resulting from the implementation of the GATS and the organization of data according to its modes of supply. Commercial presence (Mode 3) describes servicing the foreign market through a domestic sale by a foreign subsidiary. It is the only GATS mode that does not have a direct balance of payments impact, although previously the foreign subsidiary may have purchased rights from the parent company

through a Mode 1 transaction. Mode 3 is particularly important because controls on foreign ownership are widespread in the cultural industries. Almost every country imposes ownership constraints on obtaining broadcast licences. In other sectors, the ownership pattern is irregular and affected by historical influences. Canada, for example, has ownership restrictions on bookstores but none on record stores or video rental outlets.

At the national level, there are attempts to establish and coordinate the activities of so-called cultural observatories in different countries to compare policies and measure activity levels. These have been talked about for a number of years and are still some way from providing useful comparisons. Meanwhile technology is changing and altering the form of the activities that need to be measured. The absence of reliable uniform official data suits some parties. When trade disputes occur, reference can be made to particular surveys and used opportunistically to support some desired position.

## **9. Conclusions and suggestions for further research**

Modifying traditional models from international economics by incorporating some economic characteristics of cultural activities and industries – the public good attributes of content, the nature of the medium, degrees of copyright protection and scale and scope economies in production and distribution, for example – is difficult. Incorporating other economic attributes such as the nature of uncertainty faced and how creative processes respond to it is even more difficult. Understanding the mutual impact among the accessibility of cultural products and services and the evolution of individual and communal culture is the most difficult. Not surprisingly given the early stage of development of international cultural economics and the challenges faced, there are many empty boxes for researchers to fill in these categories.

We began this chapter by contrasting the rigor and suspected sterility of international economics with the mushiness and potential fecundity of cultural economics. Making the latter more rigorous is important for the future role of cultural economics in the discipline. Integrating effective models of cultural influences on tastes into international trade will contribute to the relevance of international economics and enhance its effectiveness as a guide for international governance. The political debate on the impact on culture of international openness versus protection begs to be informed by clarification of the economic and cultural forces at play and disinterested analyses of the economic impact of alternative policies.

In our discussion of the international aspects of the high arts and cultural industries, brief examples illustrated the processes by which techniques, aesthetic views and organizational ideas were diffused through collaboration and creative networks. Space considerations limited the number of examples and the detail provided. The international linkages in other cultural activities or industries would have similar contours but would differ in detail because of their unique technological and production characteristics. We would have preferred to cite more detailed economic narratives and histories to illustrate the themes and we hope that future researchers will fill this near void.

New content displaces and complements the old in a complex manner across cultural activities and industries. Similarly new technologies frequently inspire creative adaptation rather than destruction of the old ways of doing things. The phonograph and radio did not destroy live concerts but rather changed their role in the world of music. The organizational responses induced by the advent of new technologies in the cultural industries deserve more academic interest. A current case in point is the changes in the international music industry that have occurred and may occur because of file swapping and CD burning.

International markets and distribution networks have been instrumental in dispersing art, prints, artifacts, rights and the ideas that influence their value around the world. Museums make decisions conditioned by the interaction of the entrance fees charged to citizens and visitors and support received from domestic and international patrons and governments. Television programming is available from around the world in bundled services that depend on a mix of fees, advertising revenues, and government financing to remain viable. Films raise revenues by exploiting demand across different “windows” over time and space. These organizational adaptations to financing imperatives are a small sample of other industrial and non-profit organizational research issues that merit further research. It is hard to believe that graduate students would not find it fulfilling to apply modern research tools to any of these areas, but the direction of research is difficult to predict. We expect to be as surprised by the directions of future research in international cultural economics as moviegoers are by what is currently playing at their local cinema.

## Abstract

No good comparable data on sizes of cultural sectors of the countries of Europe exist. Still, local and national governments of Europe spend substantial resources on culture and cultural sectors contribute significantly to employment and national income. After briefly describing special features of cultural goods and clarifying some misconceptions about the value of culture, valid and invalid arguments for subsidizing culture are discussed. Although it is easy to justify government support for preservation of heritage, this is more difficult for the performing arts. Due to changing technologies and advent of E-culture classic public-good arguments for government intervention in broadcasting and other cultural activities become less relevant. Different institutions lead to different cultural landscapes. Theories of delegation suggest delegating the judgement on artistic qualities and execution of cultural policy to an independent Arts Fund, with the Minister of Culture concentrating on formulating a mission for cultural policy and making sure it is implemented properly. Insights from the theories of local public goods and federalism are applied to the making of cultural policy in Europe. Different approaches to international cultural policy in Europe are discussed. The overview concludes with lessons for the making of cultural policy in Europe.

## 1. Introduction

In Europe the market and the arts are often unhappy bedfellows. Many music lovers believe that only subsidized symphony orchestras and classical music ensembles perform good music. Commercial orchestras and musical ensembles may perform musicals, operettas and the popular operas of Verdi, Puccini, Rossini and Wagner or play classical music for the millions, but they will not play difficult or more esoteric pieces of classical music for fear of frightening away the public. If they do, they will lose money. Similarly, many argue that only subsidized theater will stage the more difficult and artistically valuable theater repertoire; commercial theater will concentrate on the lighter stuff such as comedy, cabaret or Christmas pantomimes. Commercial theater in the West End of London can survive due to millions of tourists that understand the English language, but this is unlikely elsewhere in Europe. The big London museums such as the Tate, the Tate Modern and the British Museum can also survive with less subsidy than in other European towns. Still, top museums in the European capitals thrive on one old master, for example, the ‘superstars’ Velasquez in Madrid’s Prado, the Mona Lisa in the Louvre or Rembrandt’s Night Watch in the Rijksmuseum of Amsterdam. Of course, a museum that strives to show and maintain a large and varied collection and undertake research needs a larger subsidy. Exposition centers (e.g., the Kunsthal-concept) may be able to thrive commercially or on little government subsidy.

From the Renaissance onwards cultural production in the Low Countries moved to satisfy demands of ordinary people. In contrast, Italy followed the judgement of Vasari and other independent taste critics. In a similar vein John Stuart Mill said “the uncultivated cannot be competent judges of cultivation. Those who most need to be made wiser and better, usually desire it least, and, if they desire it, would be incapable of finding the way to by their own lights”.<sup>1</sup> Today much of the cultural elite of Europe finds commercial culture suspect and argues that subsidies for high culture are essential. Yet even though national, regional and local governments of Europe hand out sizeable cultural subsidies, the belief in the contradiction between market and quality appears to have diminished; some countries now require cultural organizations to bring in a minimum amount of box office receipts and sponsorship income.

Nevertheless commercial culture offers many marvels throughout Europe. In the past this was true as well. William Shakespeare wrote his best work for the people’s theater and managed to pull in the crowds in a fiercely competitive environment; that this is still true is illustrated, for example, by Baz Luhrmann’s film of Shakespeare’s *Romeo and Juliet* with popular stars Leonardo DiCaprio and Claire Danes in the lead roles. Contemporary Europe has excellent museums that flourish without any subsidy at all. There are commercial theater productions whose quality of performances is at least as good from a high-culture point of view as that of subsidized theater groups. There is a growing number of cultural entrepreneurs who reject subsidies, preferring to succeed

<sup>1</sup> Quoted in Blokland (1997, p. 89).

without the bother and humiliation of going through awkward committees to get subsidy. On the other hand, much of subsidized culture does not realize that they will lose significance unless they reach out to new and more diverse audiences and make use of modern marketing techniques. The subsidized arts cater largely to white educated audiences and not to the huge influx of immigrants in many parts of Europe. In addition, technological advances change the character of many cultural goods and question the rationale of government support for the arts. Why (if at all) and how should the government subsidize production and showing of contemporary arts? Why and how should it finance the collection, upkeep and display of cultural treasures? How does the political process influence public support for the arts?

Cultural pessimists criticize the 'market', because it encourages a money-oriented and culturally impoverished way in which people live together. They fear a world where people, artists and cultural organizations are merely treated as buyers or sellers of goods and services. The market demands purchasing power, not background, education or culture. Who pays, joins in. Market forces dumb down expressions of high culture in order to get mass attention. Culture thus becomes part of the entertainment industry. These critics prefer culture to be expressed in ivory towers for refined elite audiences that make an effort to understand what it is all about. Using economics to understand cultural policy is considered philistine. Ministers of Culture are treated with contempt unless they bring more cash. Cultural pessimists share with medics the zealous emphasis on professional autonomy. Professionals, not politicians must decide which artistic expressions are worthy, although professional autonomy must not be abused for rent seeking.

Economists argue that the market mechanism may generate higher welfare than central planning, and that this may apply to the allocation of arts subsidies. Cowen (1998), for example, argues that the market produces a great variety and quality of culture, not just homogeneous pulp. It produces plenty of low culture, but that is what many people want and the market does produce high culture niches for the elite. Globalization and the Internet allow economies of scale and enable the market to produce diversity and variety. Robbins (1963) and Peacock (1969) derive the case for cultural policy from concern with the public interest and the need to correct markets that fail to deliver Pareto-optimal outcomes. Public goods, externalities, natural monopolies, information asymmetries and frictions thus need to be considered. One also needs to consider equity, and non-economic issues such as distinction, connectivity, security and internal motivation. Some shy away from government interference as this may conflict with creativity or, worse, artistic freedom. 'State Art' has connotations with the Third Reich, some dictatorships today and even present-day Italy. Culture may be better served by socially responsible entrepreneurs and by civic responsibility, which has a long tradition in the US and Europe. Grampp (1989) rejects even this. He claims that the public interest is not served by cultural policy at all, since subsidies only serve the self-centered interests of members of a passionate minority. Regardless of whether he is right, we must reckon with market *and* government failures in the making of cultural policy.

Europe has different systems of cultural policy, each with its own merits and distortions. In this chapter we distinguish the state-driven bureaucratic systems in, say, France

or Italy from the arm's-length approach of the UK, Netherlands and Scandinavia. We differentiate the UK with an independent Arts Council and no ministerial responsibility from countries such as the Netherlands with an independent Arts Council and ministerial responsibility.<sup>2</sup> Finally, we point to Germany, which has almost no federal cultural policy and delegates most of the making of cultural policy to the Länder. In assessing these various systems we adopt a political-economy perspective and make use of the theories of delegation and of local public goods, clubs and federalism. Before that can be done, however, we must understand the nature of cultural goods and the arguments for subsidizing cultural activities.

The layout of this chapter is as follows. Section 2 presents indicators of the different sizes of cultural sectors in Europe. Section 3 discusses the nature and value of cultural goods. Section 4 considers how technical innovation and Baumol's cost disease affect the case for cultural subsidies. Section 5 shows how the way of allocating cultural subsidies affects quality, diversity and popularity of culture in Europe. Instruments vary from tax incentives and other privileges to direct grants for cultural activities. Section 6 discusses subsidy allocation by grant-giving arts councils, advisory arts councils and bureaucrats. Lobbying and rent seeking are considered. The crucial questions are which powers should be delegated and what mission, guidelines and criteria should be used. Section 7 discusses the principle of subsidiarity and applies the theory of local public goods, clubs and federalism to cultural policy-making in Europe. This analysis helps to explain cultural competition between regional governments and sheds light on federalist systems such as Germany. Section 8 discusses approaches to international cultural policy in Europe. Section 9 concludes.

## **2. Indicators of size and participation for cultural sectors in Europe**

### *2.1. Cultural employment*

Table 1 presents estimates of employment in cultural enterprises in 2002 including non-cultural occupations, and groups them according to the NACE-classification.<sup>3</sup> Employment in the cultural sector amounted to about 3.9 million working persons in Europe (excluding Poland and Malta); 3.5 million in the EU-15, representing 2.1 percent of the working population. Employment in cultural enterprises was relatively high in Denmark (2.6 percent), Sweden (2.7 percent), Finland (2.9 percent), the Netherlands (2.5 percent), Ireland (2.4 percent) and the UK (2.8 percent). It was relatively low in southern Europe; e.g., Italy (1.4 percent), Spain (1.7 percent) and Portugal (1.2 percent). More

<sup>2</sup> In this latter case the Arts Council recommends, but the Minister of Culture decides and is held responsible by the parliament.

<sup>3</sup> We use the statistical classification of economic activities in the EU (NACE) for cultural activities in Table 1 and the international standard classification of occupations (ISCO) for cultural occupations in Tables 2 and 3.

Table 1  
Shares of employment in cultural enterprises in Europe in 2002 (percent)

Total	100	100	100	100

*Source:* Definition and Production of Harmonized Statistics on Culture in Europe, Chapter 2: Employment in cultural activities (2002), Eurostat, February 2004.

than half of people employed in the cultural sector had an artistic or cultural activity. Table 2 uses the ISCO-classification and looks at cultural occupations only. In 2002 there was about 2.9 million people working in cultural occupations in Europe, 2.5 million in the EU-15, 0.1 million in the EFTA and 0.3 million in the new EU countries. This represented 1.5 percent of the employed working population of Europe, albeit slightly less in new EU countries. The share of cultural occupations in total employment was particularly high in Sweden (2.3 percent), Finland (2.1 percent), Denmark and the UK (1.9 percent), the Netherlands (2.0 percent), and Spain (2.2 percent). The shares in France (1.2 percent), Belgium and Austria (1.3 percent), Luxemburg (1.0 percent), Germany (1.5 percent), Greece (1.4 percent) and Portugal (0.7 percent) were lower than the EU-average. These figures refer to both commercial and subsidized cultural employment.

Table 3 gives the shares of the various types of cultural occupations in Europe for the year 2002. The largest category is writers and creative or performing artists (45 percent). The second largest group in the EU-15 and EFTA is artistic and entertainment associate professionals (25 and 34 percent, respectively), but in new EU countries the second largest group is information professionals including archivists and librarians (21 percent). Shares of various cultural occupations do not vary much across countries of Europe. A large fraction of cultural occupations is in the commercial sector.

Benhamou (2000) empirically explains growth in employment in the audiovisual and performing arts for France and Great Britain during 1981–1992. The two main explanatory factors were a growing number of people with cultural occupations working in cultural industries, and structural changes in the labor market (more flexibility, fragmentation of work opportunities). The Enterprise Allowance Scheme contributed to higher self-employment in Britain while the specific social security benefits for artists led to higher temporary employment in France. As more comparative data become available from Eurostat, more research on shifts in cultural employment in Europe will be possible.

Architects	12	9	7	11
Total	100	100	100	100

*Key:* Information consists of archivists, librarians and related information professionals (ISCO 243). Creation and performance are writers and creative or performing artists (ISCO 245). Image and sound correspond to photographers and image and sound recording equipment operators (ISCO 3131). Art and entertainment are decorators and commercial designers (ISCO 3471), radio, television and other announcers (ISCO 3472), street, nightclub and related musicians, singers and dancers (ISCO 3473), and clowns, magicians, acrobats and related associate professionals (ISCO 3474). EFTA includes Iceland, Norway and Switzerland. New EU are the new countries joining EU in 2004: Czech Republic, Estonia, Cyprus, Latvia, Lithuania, Hungary, Malta, Poland, Slovenia, Slovakia and Bulgaria.

## 2.2. Public cultural expenditures

Throsby (1994) suggests that public cultural expenditures varied from 0.02 percent of GDP for the US to 0.14 percent for the UK and 0.21 percent for Germany. Little reliable data for Europe exist, however, on a comparable basis. Preliminary indicators on total gross public cultural expenditures have been published for Austria, Finland, France, Germany, Italy, the Netherlands and Spain. Per capita public cultural expenditures are highest in France (180 euro), Austria (179 euro) and are highest in France (180 euro), Austria (179 euro) and the Netherlands (174 euro). For most EU countries it is hard to distinguish between *gross* and *net* cultural expenditures and between *current* and *capital* expenditures. It is difficult to single out receipts earmarked for cultural sectors and to avoid double counting transfers to lower levels of government. The reliability of figures on cultural expenditures at municipal and local levels is further hampered by classification problems.

Table 4 presents national, regional and local public cultural spending for three European countries, namely Finland, the Netherlands and Spain. The data are not comparable and there are considerable gaps: the Finnish data exclude subsidies for public broadcasting, whereas Dutch data include these subsidies; the data exclude cultural subsidies from other ministries than the ministry of culture and media, contributions from government regulated sponsors such as national lotteries, and tax subsidies for maintenance of monumental buildings; the data also exclude risk capital for film ventures, purchase of works by living visual artists, etc. Data collection also suffers from organizational

*Key:* Finnish data only refer to current expenditures, but Dutch and Spanish data do include capital cultural expenditures.

*Source:* Task Force on Cultural Expenditure and Finance, Eurostat, October 2002.

problems, lack of a systematic framework and changes in accounting conventions. Despite these problems, the data suggest that it is wrong to focus attention on cultural spending by national governments alone. In Finland, the Netherlands and Spain national-level expenditures made up only 58.6 percent, 50.4 percent (only 32.3 percent if the public broadcasting bill of 732.5 euro is excluded) and less than 28 percent, respectively, of total public cultural spending in the years shown. Cultural spending by the regions/provinces and the municipalities is thus very important. In Germany with almost no federal cultural budget this is even more the case.

Bille, Hjorth-Andersen and Gregersen (2003) describe the efforts of the Nordic Contact Group for Cultural Policy Research to arrive at a joint Nordic common standard for data classification. They stress the difficulties in defining what exactly is meant by cultural policy. Is it only subsidized culture? Does it include teaching of literature or drawing in primary schools, preservation of heritage or valued added in the pop

music industry? Apart from libraries and newspapers the Group did not arrive at a common standard for data classification; public spending on the creative arts, theater, music and dance, film and media, libraries, museum, archives, etc. were included, but public spending on cultural education, radio and TV and capital items were not. With these definitions, culture's share of gross domestic product during the last quarter of a century was shown to have remained practically the same in Denmark, Finland, Norway and Sweden, namely 0.5–0.6 percent. Economic growth has thus led to an expansion of cultural budgets in real terms.

Little has been done to explain public cultural expenditures from a macroeconomic or political economy perspective as has been done for general government spending, for example, by [Alesina and Perotti \(1995\)](#). However some studies do explain spending on particular forms of culture. For example, [Krebs and Pommerehne \(1995\)](#) empirically examined political and other determinants of public support for the performing arts. [Schulze and Rose \(1998\)](#) analyzed funding of the 'Kulturorchester' in the various regions of Germany. Orchestras are heavily funded in Germany: 94.6 percent of public subsidy comes from local communities or municipalities and more than eighty percent of orchestra funding (compared to 4 percent for the US and 20 percent for Japan) comes from direct public subsidies. Germany has a very high density of orchestras (1 for every 0.6 million citizens) compared with Great Britain (one for every 4 million citizens) and the US (one for every 1.6 million citizens). Local politicians and local circumstances play a key role and decentralization of culture is even anchored in the German constitution. Schulze and Rose found that regional public funding of orchestras in Germany increased with the size of the population in the Länder. Larger towns also had bigger orchestras, but surprisingly the proportion of higher educated people had no effect on German funding of orchestras. The level of orchestra support depended positively on the size of the overall and the cultural budget and negatively on the level of public debt. Schulze and Rose also found that conservative and liberal politicians tend to support classical orchestras more than Social Democratic and Green politicians do.

A further example is that of [Getzner \(2002\)](#), who analyzed determinants of total public cultural spending in Austria during 1967–1998. He found that cultural spending, gross domestic product and the relative price indices of gross domestic product and government spending are co-integrated. The ratio of cultural spending to gross domestic product may vary in the short run, but rises steadily with gross domestic product. Cultural goods seem to have income elasticities greater than one, which lends support for Wagner's law of 'the growth of state activities' as described in [Peacock and Scott \(2000\)](#) and [Frey \(2000\)](#). Public cultural spending also rises with the price index of government spending (which is evidence for Baumol's cost disease). The relative importance of cultural spending thus grows over time as the national income grows. In contrast to [Schulze and Rose \(1998\)](#), cultural spending in Austria thus seems relatively unaffected by the ideology of the ruling political parties or by 'wars of attrition' between political parties described by [Alesina and Drazen \(1991\)](#). As new data become available, comparative econometric studies into the determinants of cultural spending in European countries will become more feasible.

Table 5  
Cultural subsidies per visit and box office receipts in the Netherlands

Performing arts and museums (number of institutions)	Subsidy per visit (average 1994–1997)	Proportion box office receipts to subsidy in 1997
Dance (12)	48 euro	18:82
Symphony orchestra's (10)	41 euro	24:76
Baroque orchestra's (4)	3 euro	82:18
Musical ensembles (17)	16 euro	36:64
Opera (3)	120 euro	22:78
Operette (1)	40 euro	22:78
Theater (27)	49 euro	14:86
Youth theater (13)	25 euro	18:82
Mime (6)	41 euro	14:86
Puppet theater (4)	12 euro	37:63
Scientific musea (4)	56 euro	3:97
Arts musea (4)	7 euro	30:70
Culture historical musea (15)	13 euro	19:81

Source: van der Ploeg (1999).

Public spending on culture contrasts with income from box office and sponsors. For example, Table 5 relates art subsidies in the Netherlands to box office receipts during the mid 1990s. Over this time the state subsidized every opera seat (not counting contributions to costs of concert hall and orchestra) on average by 120 euro. Dance needed less, 48 euro. Theater seats received an average subsidy of 49 euro; seats in concert halls received 41 euro. Each museum visit was subsidized to the tune of 11 euro, a lot less. More accessible forms of culture needed less subsidy than more elitist cultural expressions. Orchestras playing popular music of the 18th century, Baroque orchestras and operettas thus needed less support than opera or symphony orchestras. Paintings of Van Gogh are loved throughout the world, so the Van Gogh Museum needed less subsidy per visit than other museums.

### 2.3. *Size of creative sectors*

Collection of employment and income data on the creative industries at a European, national and regional level does not exist on a systematic basis, in contrast to many other sectors of economic importance; it is thus difficult to conduct comparative research on the size of the cultural sectors or of the creative industries of Europe. Collection of such data deserves high priority. In the absence of comparative data, we simply refer to two examples of independent measurement of the size of the creative industries for particular countries. First, for the UK, the Department of Culture, Media and Sport [DCMS (2001)] suggests that the share of creative industries in the UK gross domestic product is about 5 percent, while employing 1.3 million people. Second, García, Fernández and

Zoffo (2003) present statistics of the contribution of creative cultural and leisure industries to employment and national income for the center, sectors and regions of Spain. They find that they contribute about 4.5 percent of the gross national product and give work to 7.8 percent of Spanish employees of which only a tiny fraction relates to publicly financed culture. About 70 percent of value added is taken up by the performing, musical and audiovisual arts and publishing and printing. Most of it is concentrated in Madrid and Catalonia.

#### 2.4. Cultural participation

The Euro-barometer surveys<sup>4</sup> give a rough comparison of cultural participation in Europe. The Nordic countries and the Netherlands seem to be ahead in use of PCs and the Internet, while southern and East-European countries lag behind. The people of Nordic and Baltic countries, the Czech Republic and the Netherlands read more books and newspapers than the EU-average. Reading in Mediterranean and Eastern-European countries is below the EU-average. A similar picture emerges for visits to cultural institutions and artistic activities. It will be interesting to study the influence of variables such as education level, age and gender on participation once Eurostat makes these data available. In the mean time SCP (2001) offers a partial comparison of participation in various cultural activities based on national surveys in nine European countries – see Table 6 and Bína (2003). In all countries the less educated show less interest in traditional forms of culture *and* popular culture (e.g., pop concerts); in other words, cultural

Table 6  
Cultural participation in eight European countries

interest does not seem to depend so much on whether it is high or low culture, but on whether the participant is better educated or not. This suggests that cultural education at young ages may overcome some of the inequality gap in cultural interest and cultural participation. The decline of interest for traditional culture particularly affects young people in the Netherlands, even though the rise in educational levels is similar to elsewhere in Europe. However, comparative data on cultural participation are needed before such judgements can be made more firmly.

## 2.5. Museums

The European Group on Museum Statistics (EGMUS) collects available data on museums in Europe. Since national museum surveys are conducted very differently in different countries, present data are not comparable. However, EGMUS has now designed a common core of questions to be inserted in or extracted from national surveys, in order to guarantee comparability at the European level. Some partial comparisons can be deduced from the data presented in Table 7. For example, Norway and Sweden have a large number of visits per 1000 inhabitants, followed by the Netherlands, the UK

Germany, France and Spain. Citizens of Italy, Portugal, Luxemburg, Latvia and Romania visit museums rather less than elsewhere. Museums throughout Europe often have free admissions and entry fees make up only a relatively small fraction of total museum income. Most countries have many public and private museums covering art, archaeology, history, ethnology, science and technology. The Nordic countries, Latvia and the UK have a relatively high percentage of the population that has visited a museum while museum participation in France, Spain, Italy and Portugal is below the European average.

### 3. Cultural goods and services

#### 3.1. *Special features*

Cultural experiences can be aesthetic, touching, memorable and mind baffling. They may even make people think differently about life. In contrast, instant entertainment may be fun but the touching and baffling effects fade away quickly. However, it is important to understand that cultural experiences are also normal economic goods with substitutes (sport, family dinners) and complements (newspapers, magazines, transport, etc.). In fact, most cultural goods and services have, in varying degrees, both private good (rival, excludable) and public good (non-rival, non-excludable) properties. The latter may derive from generalized or local community benefits supposed to arise from the arts or simply from externalities. If non-market benefits exist, free markets will under-provide cultural goods and services due partly to free riders not wishing to pay, and thus subsidy may be warranted.

Other chapters in this volume explain this in more detail, but it may help to give a few examples. Pay-TV and, to a lesser extent, visits to the performing arts or museums are private goods. One can internalize all benefits, so prices reflect true costs, the market functions and no subsidy is required. If performing arts and museums generate positive educational externalities,<sup>5</sup> they may have some public good aspects and merit some subsidy. However, if congestion costs are large due to noisy, uninterested people destroying the enjoyment of others attending an open-air concert, the public good aspect is diminished and a (higher) fee must be charged. Maddison and Foster (2003) estimate that the congestion cost imposed by the marginal visitor to the British Museum is eight pounds.<sup>6</sup> The pure public good case for performing arts and museums is thus not obvious. On the other hand, the marginal cost of the enjoyment of an extra person is zero for broadcasts of radio or TV and monumental buildings. Though jamming can exclude people from broadcasts, it does not make economic sense. Similarly, it is

<sup>5</sup> For example, De Swaan (2001) argues that language is a public good. Drama, literature and film may thus justify subsidy despite being excludable, rival goods.

<sup>6</sup> Based on valuation data collected before realization of the Museum's Great Court by Norman Foster.

difficult or costly to charge passers-by for the benefits of restored heritage or splendid architectural design. Furthermore, projects like the Guggenheim museum in Bilbao designed by Frank Gehry or the Centre Beaubourg designed by Renzo Piano and Richard Rogers may pull in tourism, scarce knowledge workers and new business to Bilbao and the depressed Les Halles area of Paris. Another example of such a city externality might be the building of the largest trade fair in Britain in Birmingham partially in response to the City of Birmingham Symphony Orchestra and to the relocation of part of the Royal Ballet there. Thus open-channel radio and television and maintaining heritage may have public good aspects and may deserve subsidy.

Rapid technological innovation changes the nature of cultural goods. In the past one could record fine classical music on a cassette from radio or a record, but quality was not perfect. Today consumers get their favorite music from Napster-like sites. The quality is very good. CDs are rapidly changing from rival (private) to non-rival (public) goods. Record companies find it tougher to make profits and may invest less in CDs, while extra income from concerts, books, interviews, merchandise and other related activities is becoming more important for performing companies. These technological advances, together with the Internet, globalization of the arts market and Baumol's cost disease all contribute to a shift from unique, autographic art to reproductive, allographic art. The trend towards specialization and division of labor implies that artists make designs and others produce, reproduce and distribute the art object to the public at large. Examples are books, CDs, records, lithographs, posters, photographs, DVDs, CD-ROMs and pay-per-view TV. This shift has lowered prices and increased accessibility of classical and contemporary art for large sections of society. Similarly, there has been a shift from physical cultural experiences to the Internet, where websites of libraries, museums, archives and performing arts companies enable access at any time and any place in the world at almost no cost. Yet just as the extra demand for DVDs has not undermined demand for cinema, free virtual cultural expressions on the Internet do not seem to have eroded demand for seeing physical displays of culture. Finally, there has been a shift in colleges of art from autonomous, subsidized art to applied, commercial arts such as fashion or design. These graduates prefer empowerment (loans for tools, etc.) to income support.

Some culture is produced under increasing returns to scale and winner-takes-all markets. Harris and Vickers (1985) show that there is over-investment in new technologies if different firms race to be the first to get the patent. But if patent markets work badly, there is under-production of cultural goods; in the Internet age it is harder to protect property rights on creative expressions and this may discourage artists to produce. Rengers and Plug (2001) build on Throsby (1996) and estimate a joint model of the choice of visual artists to opt for subsidies or market funding of their work. They show that subsidizing the visual arts through grants and commissions enhances the winner-takes-all tendency for the market at large.

High culture differs from instant entertainment. First, culture is an acquired taste. Preferences for cultural consumption are not given, but shaped by education and experience. Rather than saturation described by Gossen's second law of diminishing marginal

utility, cultural goods show *over time* increasing marginal utility. The hundredth literary book one reads gives more satisfaction than any of the previous books, since the frame of reference will be bigger; the latest concert of Bach music impresses more than previous ones, since one gradually discovers the unifying themes in Bach's oeuvre. Furthermore, culture is a memorable experience; seeing *Hamlet* at a young age can lead to lifelong memories.

Second, Bourdieu (1979) argues that high culture has snob appeal. When the masses start appreciating some forms of high culture, the elite loses interest and moves on to other forms. It is akin to the theory of clubs where the utility of particular cultural goods falls if more people enjoy them. Baumol and Bowen (1966) noted that audiences for the performing arts in the US and UK consist mainly of middle-aged people, professionals, managers and white-collar workers with high education and high incomes. Throsby and Withers (1979) found similar profiles for Australian and US audiences. SCP (2000) finds for the Netherlands a diminishing interest for classical art of people between 16 and 40 years and growing interest among older people. Prieto-Rodríguez and Fernández-Blanco (2000) use the Spanish *Structure, Conscience and Class Biography 1991 Survey* to estimate a bivariate probit model to characterize the average profile of audiences for classical and popular music. Both groups seem to have an 'innate' taste for music, suggesting that music lovers are 'omnivores' who enjoy classical and popular music. Education, cultural backgrounds of parents and occupational status have strong positive effects on classical music listening for young adults (30–45 years), but not on popular music listening. Sintas and García Álvarez (2002) analyze social consumption of culture by Spanish people using both Bourdieu's 'distinction hypothesis' and Lancaster's (1966) theory of characteristics of products. They conclude that culture in Spain has symbolic value associated with social class and allows people to express and distinguish themselves. Nevertheless, the rising education level since the Civil War has not increased consumption of high culture proportionally.

Yet even if only a minority values high culture, the government may wish to encourage the majority to have an interest in it. Such paternalism overrules consumer sovereignty. However, Bille (1997) shows that the Danish public is willing to pay at least as much as the Royal Theater in Copenhagen receives in public subsidies, even though the visitors comprise only 7 percent of the population and are richer and better educated. This suggests that many people are happy to support the arts even if they do not visit themselves. If so, there is no need for paternalism, since people attach option or other values to performing arts; enjoy reading critical reviews or watching recordings of performances; value the derived benefits for television, the film industry, cultural education, cultural heritage and traditions; and appreciate the international prestige.<sup>7</sup>

A final special feature of cultural goods and services is that their enjoyment takes time. This means that the full cost includes forgone after-tax wage income as well as the cost of ticket and travel. Hence the elasticity of demand is less sensitive to the change in

<sup>7</sup> See also Frey and Pommerehne (1989).

the ticket price, especially for higher earners. This offers scope for price discrimination where venues try to charge high earners with little spare time more.

### 3.2. *Value of culture*

Throsby (2001) explains the aesthetic, decorative, spiritual, social identity, historical, symbolic and authenticity value of art. Art also has use, exchange, store, status, option or bequest value. Some argue that the value of arts is (like human life) infinite. Noonan (2003) offers an instructive meta-analysis of many empirical contingent valuation studies of willingness to pay for cultural goods varying from local TV, opera and UNESCO World Heritage Sites. On the latter Maddison and Mourato (2001) study willingness to pay for Stonehenge and Carson, Mitchell and Conaway (2002) do the same for the Fés Medina.

Arts Councils often use ‘quality’ as the prime criterion. But who decides what ‘quality’ is? Is it artists themselves, expert members of an arts council, art critics or the public? Is culture the Western canon of established high culture or the culture offered by newcomers and other civilizations? Is ‘quality’ high culture or dumbed-down culture? Does quality only emerge in the confrontation with a public? The optimal level of quality requires the marginal cost to equal marginal benefit of quality. Maximum quality occurs where government ensures zero marginal cost of extra quality, but that is not necessarily socially optimal.

Stocks of cultural goods need an intertemporal approach to value. A crude estimate by directors of Dutch museums of the market value of their collections was – depending on the current prices of Van Gogh paintings – 20 billion euro. Only about 5 percent of museum assets are on display, the rest is in storage; nevertheless, museums strive for bigger collections and buildings. Bookkeeping of museums ignores the opportunity cost of their collections in their accounts. Museums act as if their collection, their most important production factor, is almost free. Hotelling’s arbitrage principle for exhaustible resources suggests that one is indifferent between selling the assets and investing the proceeds on the one hand and keeping and displaying, lending or storing the collection on the other. Thus the following calculation could be performed: expected net gains in the value of the collection *plus* net gains from exhibiting the collection on a permanent or temporary basis *plus* returns from loaning the collection to other museums, companies or the public *plus* gifts from sponsors, donors and friends to help with purchase of new items and exposition *minus* cost of storage *minus* rate of depreciation and wear and tear of the collection *EQUALS* the opportunity rate of return (the market rate of interest) *minus* subsidies for the collection from local or national governments.

If there is an interested and fee-paying public, it may pay to exhibit items. Otherwise, it may be better to store them. Since curators have a strong incentive to use funds on storage and research, Frey (2000, Chapter 3) argues for increasing incentives for collection mobility (nice for regional museums with lesser collections), regulated sales of objects and exhibitions. The opportunity costs, roughly 1 billion euro at a 5 percent interest rate, are much larger than the subsidies museums receive. Yet they do not fea-

ture in the cost–benefit analysis of museums, so there is little incentive to make use of valuable collections. Making these costs transparent would improve the management of museums and may resolve the potential conflict of interest between curators who want to study and protect, *and* exposition managers and the public who want the collections to be on display.

#### 4. Valid and invalid arguments for subsidizing culture

##### 4.1. Convincing arguments

First, there is a strong case to invest in cultural awareness and cultural education of children, especially for developing a taste for cultural experience goods that leave a lasting impression rather than instant entertainment. It is important not to force high culture upon school children, but to let them have a say in what they want to enjoy and discuss. One possibility is to give vouchers, so children can go four to six times a year to a museum, film, theater play, dance performance, concert or opera. National and local governments in Europe give cultural organizations special subsidies for developing special activities for young people. For many children cultural education is their only chance to develop an awareness of and taste for high culture. The main rationale for subsidizing cultural education is that, as noted above, culture is an acquired taste and an investment in the future social stock of cultural capital.

Second, as subsidized high culture is primarily enjoyed by higher socio-economic groups, there is a case for bringing high culture to the rest of the population. By bringing high culture to public parks, pop temples, libraries, community halls, shopping precincts, etc., one can reach out to new and more diverse audiences. This would also provide a genuine experience as discussed in [Pine and Gilmore \(1999\)](#). The action plans of central and local governments of the UK and the Netherlands allow for interesting experiences in the twilight zone between high and low culture. Examples include serious theater and ballet at pop festivals, school children rapping with symphony orchestras, pop artists from immigrant countries backed up by symphony orchestras, the staging of Wagner's *Ring* in central parks, poetry on billboards, etc. These action plans force the arts to make their output more of a non-rival, non-excludable good and less of a luxury good, so there may be a case for government subsidy.

Third, there often is a case for stimulating demand rather than supply of cultural goods. For example, the Netherlands has shifted from income support for artists to interest subsidies for buyers of contemporary visual art. Artistic Programming Funds may encourage provincial venues to program more adventurous avant-garde culture. It takes time to cultivate an audience. Also, it is worthwhile to have a longer run for successful productions. Giving a 'bums on seats' premium to the performing arts provides greater incentives for drawing bigger audiences and generating income from the market.

Fourth, since non-rival and/or non-excludable cultural goods are public goods, the market will fail to deliver them at a socially optimal level, and government should step

in with subsidies, tax incentives, regulation or public sector provision. These public cultural goods should be provided according to the rule of [Atkinson and Stern \(1974\)](#), who propose that the sum of marginal benefits of culture to all people in society *equals* the relative price of cultural goods *times* the marginal cost of public funds *minus* the effects of cultural goods on the tax base. The well-known Samuelson rule states that the sum of the marginal benefits of cultural goods expressed in resource units must equal the relative price of cultural goods. The Atkinson and Stern rule modifies this in two ways. First, the cost is raised, as they are financed by distortionary taxes. This extra cost is high if the wage elasticity of labor supply is high and pre-existing tax distortions (e.g., the tax rate on labor) are high. Second, making cultural goods more widely available may make people enjoy them more and work less hard and pay fewer taxes. This erosion of the tax base raises the cost of public goods. In fact it may be more likely that more cultural goods will attract more high-skilled workers, businesses and tourists and thus raise tax revenues; obviously, this would lower the marginal cost of public goods. In sum, the demand for public cultural goods relative to private goods will be large if the costs of cultural goods is low (e.g., due to supply subsidies or tax facilities), if the marginal cost of public funds is low (i.e., if labor supply is inelastic and the tax rate on labor is low), and if cultural goods have a positive impact on economic activity.

There is a danger that expert advice on allocation of subsidies will be biased in favor of established cultural organizations, hence it is important to ask the Arts Council or the Arts Fund to make room for new cultural initiatives and support applications that appeal to new and more diverse audiences. An extra requirement may be that the performing arts should obtain at least a certain percentage of their income from the box office. For example, in the Netherlands cultural organizations must obtain at least 15 percent from outside income. [Table 5](#) shows that this is easily satisfied for the well-loved classics played by the baroque orchestras and to a lesser extent by the symphony orchestras, musical ensembles, opera and puppet theaters, but dance, theater and mime may have difficulty in satisfying this requirement. The Dutch public pays only a small part of the true cost of the performing arts; people may find an opera ticket expensive, but rarely realize that it is only 22 percent of the full cost. Similarly, people may not realize that they only pay 14 percent of the full cost of a theater ticket. Such high subsidies may be hard to justify, since performing arts are neither non-rival nor non-excludable and thus do not qualify as public goods unless one relies on the social cultural capital argument. In particular, the social value of theater may derive from keeping the language alive.

Fifth, there is a strong case for government subsidy for cultural goods with existence, option or intergenerational value, especially if they contribute to the social stock of cultural capital and are shown to the public. This applies to subsidizing restoration and maintenance of monumental churches, farms, castles, bridges, locks and landscape values. It also applies to other heritage such as archives of history, photographs, films and performing arts, libraries, museums and archaeological treasures, particularly if they are on display to the public. Each of these adds to the social stock of cultural capital and, if they deteriorate, harm is done to the welfare of future generations. The option value argument says that, even if one never visits certain parts of the country, one does not want

the heritage in those parts to disappear. Some argue that the opera provides option value and adds to the social stock of capital as well. Obviously this is also true for funding research and development in the arts, especially as fundamental innovations in the arts are very difficult to protect through patents and/or author rights.<sup>8</sup> There is also a strong case for government support for architecture, spatial planning and arts objects in public spaces, because these clearly add to the social stock of cultural capital and often to civic pride as well.

Sixth, failures on the supply side may merit government intervention. Cultural goods industries may have difficulties in being set up, so there may be a case for temporary subsidy. This is the infant-industry argument. Since many poor countries often have a rich and unique cultural tradition in both visual and performing arts, there is a case for temporary cultural aid in economic development programs. This may boost tourism, yield foreign currency and act as a lever for sustainable growth [UNESCO (1998)]. Tibetan horn players, Balinese dancers and Cape Verdian singers have unique selling points, which can be popularized through the global media, modern reproduction methods such as CDs and DVDs and live performances. These artists can help brand their own country, like the Beatles and Abba did, and thus boost their economies.

Finally, the market tends to avoid risk unless high profits are expected. Avant-garde cultural activities face bigger credit-market constraints than more profitable, run-of-the-mill cultural activities (musicals, cabaret, bestsellers, etc.). The government should thus stimulate the provision of risk-bearing capital for risky cultural activities that are regarded as valuable. Government-funded participation companies may help getting risk-bearing capital from the market, especially if combined with fiscal incentives. Governments can also stimulate cultural investment by granting interest rate incentives for cultural projects. Friends of a particular museum or theater may then be willing to lend money in the form of soft loans.

## 4.2. *Unconvincing arguments*

### 4.2.1. *Demand-side arguments*

A popular argument is that demand for cultural goods depends on their supply and that the government should thus subsidize supply, otherwise people will never know the value of cultural goods that may never materialize. For example, without subsidies for the opera, people may never know that Gluck's work existed and thus demand will not occur. Still, this does not justify subsidizing supply of high culture unconditionally. It does suggest a boost to the demand for high culture through cultural education, vouchers for parts of the population that normally do not go to expressions of high culture, action programs reaching out to new and more diverse audiences, and programming subsidies.

Another fallacious argument is that cultural goods should be affordable to everyone and not only to rich art lovers; the cultural lobby typically argues that one should lower

<sup>8</sup> See the Schumpeterian arguments in Wijnberg (1994, 1995).

the price for everybody by subsidizing these cultural goods. However higher-income consumers profit much more from these subsidies than lower-income consumers. The dead-weight burden of lump-sum subsidies for the supply of cultural goods may be very high. It is much more efficient to boost demand among lower-income groups or children through education, vouchers, action programs or other means. This is a more effective way to ensure that people can choose themselves which culture they want to experience. If one is concerned about a tendency for middle-of-the-road taste at the expense of avant-garde and high culture, teachers and programmers of venues might try to gently cultivate a taste for experience goods. Note that supply subsidies allocated by committees of experts typically stimulate high culture for the elite; although this seems in line with the moral ideas of Thomas Aquinas that the prominence of someone's position in the community should imply a larger share of the common goods, this medieval view is hardly endorsed today.

Yet another fallacious demand-side argument is that price increases lead to even bigger falls in demand and thus to fall in revenues, hence supply subsidies must be given. This is unconvincing, since demand for cultural products is often inelastic so raising prices does raise revenues. If this means that concert halls, theaters, etc. are not fully utilized, there is a better case for boosting demand rather than supply for concerts, theater, etc.

Finally, a popular argument for granting government subsidy is that cultural goods are merit goods; if society demands an insufficient amount of these goods even though it can afford them, the government should subsidize them. Although this paternalistic argument may justify subsidizing cultural education, it is not a convincing one in support of across-the-board cultural subsidies.

#### 4.2.2. *Supply-side arguments*

A popular argument is that cultural goods are produced under decreasing average costs, so subsidy is needed to ensure full utilization of concert halls, theaters, museums, etc. and ensure profitable operations. This argument is unconvincing. If venues do not pull in audiences, they can experiment with cheap last-minute tickets and spend more time and effort on marketing. This phenomenon provides a case for stimulating demand through education, vouchers, action plans and programming subsidies, not for extra supply subsidies. Another unconvincing argument is that culture contributes to employment, especially in an economy with a tight labor market. But the government is not obliged to provide orchestras, theater companies, etc. in sufficient numbers simply to employ all art graduates. Nevertheless the employment argument may be valid for certain professions (e.g., restoration) if one fears that otherwise valuable skills will be lost for future generations. However the fact that many artists are poor is not a valid argument, except insofar as one should assist all poor people regardless of their occupation.

The performing arts and other cultural goods are labor intensive and thus suffer from Baumol's cost disease.<sup>9</sup> The argument that this justifies government subsidy to the performing arts is unconvincing, since increases in productivity elsewhere in the economy gives rise to huge increases in purchasing power; if people value this labor-intensive culture, they will use their new riches to pay for it. With Cobb–Douglas preferences, the ratio of output of cultural goods to other goods dwindles away and prices of cultural goods rise at the rate of technical progress in the rest of the economy, but absolute levels of employment and output in the cultural sector remain constant. In other words jobs in the cultural sector are not destroyed since technological progress elsewhere boosts purchasing power just enough to maintain spending on culture despite rising prices of culture. In fact, there are two good reasons why the share of culture in national income may grow and the arts will flourish, even without more government support. First, food, drink, shelter and health are necessary goods while culture is a luxury good. With non-homothetic (e.g., Stone–Geary) preferences the budget share of the arts will rise over time as people grow richer. Second, an elasticity of substitution between culture and other consumption goods of less than unity will generate a budget share of culture that rises over time as well. With an inelastic demand for culture, sufficient revenue will be generated to compensate for rising costs.

In any case, Baumol's cost disease leads to offsetting trends. The rise in the relative price of labor-intensive cultural expressions causes a shift towards less labor-intensive culture. For example, a vocal artist may not be accompanied by a symphony orchestra but by a chamber orchestra or even by a computer. Technology may induce new economies of scale and substitution in consumption, as evidenced by the popularity of the CD, video, DVD or poster as a substitute for the concert, film, theater play or painting, respectively. The possibilities for an artist of operating on a world market have grown enormously with the advent of globalization and the Internet.<sup>10</sup> Note however, that Baumol's cost disease causes a shift from art for the elite to art for the masses, and may induce dumbing-down at the expense of diversity and experiment; if so, there may be a case for subsidizing innovation, experiment and diversity in the arts.

## 5. Quality versus popularity in cultural funding in Europe

### 5.1. *Different ways of funding culture*

There are three ways of supporting the arts. First, one can grant privileged positions possibly in exchange for satisfying certain requirements from the government. For example, public broadcasting organizations almost everywhere in Europe get first right

<sup>9</sup> See further in Chapter 15 by Brooks in this volume.

<sup>10</sup> Note that all of these developments can lead to the emergence of superstars; see the classic Rosen (1981) and Chapter 25 by Adler in this volume.

in the allocation of air space for TV and radio on top of a hefty subsidy; in return they program certain (minimal) amounts of information, education, arts and culture. Commercial broadcasters in Europe (apart from the UK) have more freedom. Another example is the fixed book price used in much of continental Europe (Austria, Denmark, France, Germany, Greece, Italy, the Netherlands, Portugal and Spain), where booksellers are granted monopoly power for each book that is published.<sup>11</sup> This leads to higher prices, lower sales and lower welfare, as shown in [Figure 1\(a\)](#). Critics also argue that the fixed book price is bad for low-income consumers and hurts the democracy of culture. On the other hand others stress that books are heterogeneous goods, produced and sold under monopolistic competition; they argue that the agreement allows for cross-subsidies from bestsellers towards less popular books and results in a more diverse supply of book titles and bookshops. This cross-subsidy argument is unlikely to be valid if bestsellers are highly price elastic and thus permit little monopoly power, while less popular books are price inelastic and allow a lot of monopoly power. In these circumstances the agreement induces substantial welfare costs. This may happen if bestsellers are easily digestible, require little time to read and have higher price elasticities while, say, poetry readings demand a lot of time and thus have lower price elasticities. In any case, a lot of energy and time is spent on defending the fixed book price agreement. This leads to wasteful rent seeking as discussed in [Tullock \(1980\)](#).

Many privileges and monopoly positions granted by European governments are eroded by technological change. For example, the fixed book price agreement may be undermined if people order books on the Internet through amazon.com and other virtual book suppliers. [Hjorth-Andersen \(2000\)](#) documents how the advent of new printing technology and new media have cut costs and led to an avalanche of new book titles in the Danish book market. Although it is much easier to get a book published for an author, turn-round of books has increased enormously and it is much more difficult to attract large groups of readers. In the broadcasting field, digital cameras and recording and editing equipment make low budget radio and TV possible, while the monopoly of public and commercial broadcasters is challenged by the arrival of the Internet, digital frequencies and narrowcasters. The Danish Dogma group as well as the recently killed film producer Theo van Gogh show that it is possible to make low-budget films with digital, hand-held cameras.

Second, the tax system and price subsidies can be used to grant demand price or supply price subsidies.<sup>12</sup> For example, the UK and Ireland do not allow fixed book price agreements but do have a zero VAT on books. Many countries in Europe exempt tickets for museums and the performing arts from VAT as well. The Netherlands has interest-free loans for buying visual arts. Almost all countries of Europe allow tax deductions for restoring monuments. [Figure 1\(b\)](#) shows that each of these price subsidies lowers prices at the gate and boosts output of culture. Since culture takes time to enjoy, the effective

<sup>11</sup> See [van der Ploeg \(2004\)](#) and [Chapter 21](#) by Canoy, van Ours and van der Ploeg in this volume.

<sup>12</sup> We abstract here from tax deductions to philanthropists, which are more prevalent in the US than in Europe.

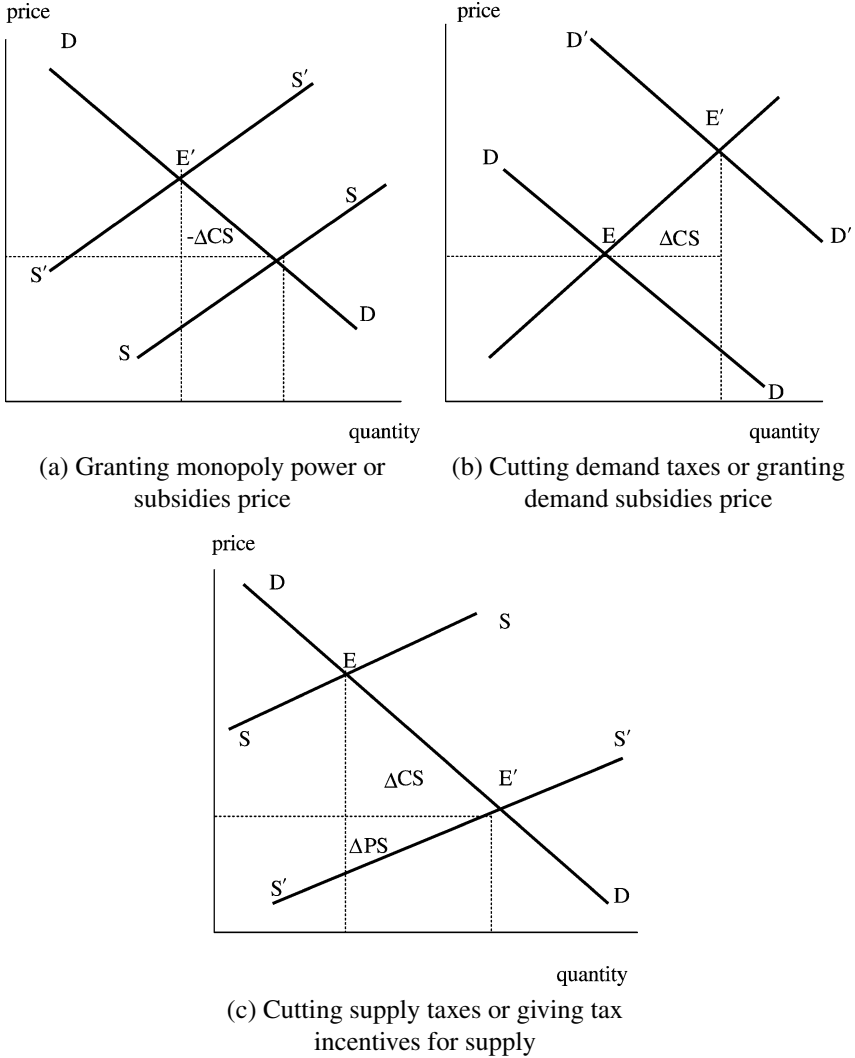

Figure 1. Incidence of different types of government intervention in the cultural sector. Key:  $\Delta CS$  and  $\Delta PS$  refer to the change in the consumer surplus and producer surplus, respectively.

demand elasticity is likely to be small. In that case, punters benefit a lot by having to pay substantially less while suppliers of cultural goods do not benefit much, especially if the price elasticity of supply is large. The potential welfare gains from the demand price subsidy, measured by consumer and producer surpluses, is then not very large and may well be negative if one takes account of the welfare costs of raising tax revenues to finance the subsidy. Figure 1(c) indicates that boosting supply through *supply price*

subsidies lowers prices and raises volume. For example, Ireland is well known for its tax incentives for producing films. This allows the production of more Irish films, and the lower prices for the public boost demand as well.

In principle, there is no difference in using demand or supply price subsidies in competitive environments. If demand is very inelastic and supply elastic, most of the benefit of the supply price subsidy is shifted to consumers while demand is not boosted very much. In that case, there is not much point in supply price subsidies. Although most cultural tax incentives apply across the board, it makes sense to avoid dead-weight losses by trying to target these instruments at the most needy projects; for example, interest-free loans might only apply to living visual artists; film incentives might require films to have substantial European contents; and deductions for monuments might only be obtainable if the property is indeed a valuable, historic monument. Also, if one wants to help low incomes with cheap opera tickets, one must avoid giving unnecessary subsidies to those pundits who can afford the true cost of opera. The welfare losses from these unnecessary subsidies are higher if demand and supply are more inelastic. One should avoid substitution, so cultural producers should not receive subsidies for activities they would have done anyway without subsidy.

Third, public support for the arts in Europe comes mainly in the form of *supply volume* subsidies allocated on the basis of advice of cultural experts as, for example, in the UK, the Netherlands, Belgium and Scandinavia. In France and Italy civil servants seem to play a bigger role. The positive effect on volume is partially offset by the negative effect of lower prices on supply, particularly if the demand elasticity is small and the supply elasticity is large. Supply volume subsidies can be better targeted and thus cause less dead-weight loss. However, such subsidies are allocated by civil servants, committees of experts or politicians, which causes wasteful lobbying and rent seeking. Committees of experts may also induce a bias towards 'arts for artists' and the elite, but extremes of the cultural spectrum may benefit. Some therefore have a preference for generic demand-price subsidies that lean with the market. The government then changes from participant to one who ensures a level playing field among cultural producers. This may induce median voter outcomes that reinforce middle-of-the-road culture. Indeed, Urratiaguer (2002), building on Throsby (1990) and Abbé-Decarroux (1994), finds that quality as judged by experts or drama critics or indicated by the artistic reputation of manager-directors are poor explanatory variables of the demand for subsidized theater in France. The main factor explaining demand seems to be the reputation of the theater company. This empirical work suggests that middle-of-the-road programming and bigger audiences may follow after a shift from supply-volume grants to demand-price subsidies.

## 5.2. *Programming diversity and funding of TV*<sup>13</sup>

The question of quality vs. popularity in European cultural policy is especially relevant in the field of television. To analyze the effects of financing modes on programming di-

<sup>13</sup> For a discussion of the rationale for the license fee, see O'Hagan and Jennings (2003).

versity and welfare, a framework of monopolistic competition is needed. The pioneering contribution of Spence and Owen (1977) shows that any private system of finance biases against programs that have a low own-price elasticity of demand ('minority taste programs') and that are expensive to produce. The price fails to fully reflect the average intensity of preferences for certain programs and, given fixed costs, such programs are not produced. This bias occurs with pay-TV, but is worse if programs are financed via advertising revenues. The latter produces fewer programs and leads to a less diverse menu of programs than pay-TV. As the cross-elasticity of substitution among programs increases, advertising is more likely to approach a second-best structure than pay-TV. Many countries of Europe have cable-TV. It is important to permit advertising on pay-TV, make sure the cable operator allows entry of other suppliers of programs, and ensure open entry with elastic supply of channels. Doyle (1998) extends the analysis and considers various regulatory instruments (such as direct instructions to channels on programming minimal amount of culture, arts and education and a tax on profits). Chae and Flores (1998) argue that certain characteristics of TV programs such as the extensiveness of the market, makes them more likely to be broadcast than shown on pay-TV. Bourreau (2003) analyses the trade-off between mimicking and counter-programming. He shows that profile differentiation is higher under pay-TV than under advertising support where competition on price is infeasible. He also shows that program quality is higher under advertiser support than under pay-TV. These studies ask the right questions and they also apply to other areas of culture. Of course, in contrast to the US, Europe finances a lot of public broadcasting. These studies justify governments doing this if they make possible the production and broadcasting of more expensive TV-programs that cater for special niche audiences. That is something the market can only deliver in the form of narrowcasting. To ensure the diversity of programs of public broadcasts, Germany relies on representative viewers' committees, the UK on detailed program requirements, and the Netherlands on diverse broadcasting corporations corresponding to liberal, catholic, protestant, social-democratic, libertarian, or evangelical pillars. The UK limits the entry of commercial broadcasters and forbids the BBC from advertising. In return for monopolistic advertising profits Channel 4 and ITV face extensive programming requirements.

## **6. The arm's length principle: Institutions matter**

### *6.1. Institutional structures*

Europe has three basic systems of allocating subsidies to cultural goods. The French and Italian systems are top-down and state-driven, so bureaucrats and politicians decide. This is not very transparent with plenty of scope for lobbying and friends' politics, with prestige projects standing a better chance and with unpleasant connotations of state art. At the other end is the British system; the government allocates a budget to the Arts Councils and leaves them the responsibility for allocating subsidies. The UK Arts

Councils operate as an independent Art Fund, so it is hard for the British government to set priorities and formulate criteria for allocating subsidies. The British system has clear advantages: less room for political lobbying and rent seeking and no danger of the state trying to impose its taste on the cultural sector. The disadvantage is that the government has little room to influence the direction of cultural policy.<sup>14</sup>

The Netherlands uses an intermediate system, which has an independent Arts Council that gives experts' advice on artistic merit and on how budgets should be allocated. The main difference from the British case is that it is the Dutch Minister of Culture and not the Arts Council that takes the final responsibility for the allocation of cultural subsidies. The government operates at arm's length and does not judge the artistic quality of different cultural activities and organizations, but there may be political and managerial reasons for deviating from the advice of the Arts Council. The government attempts to set the rules of the game well in advance, so announces in a White Paper the framework (priorities, criteria and budgets) that the Arts Council needs to adopt in their advice on the allocation of subsidies. The main advantage of this system is that the government can shape cultural policy without meddling in artistic judgements about individual cultural activities and organizations. However, with ministerial responsibility, there is maximum scope for political lobbying and rent seeking. Winners claim their subsidy and get on with making theater, opera, dance or whatever, while losers find plenty of opportunity to make their case in the media. Parliamentarians who want to distinguish themselves by associating themselves with the arts further reinforce this. The result is that it is easier to lobby for extra budget for the arts than for science, where the research councils allocate the subsidies and there is no ministerial responsibility.

The Arts Council system relies on committees, which are subject to well-known problems of committee decision-making [Tullock (1971)]. There is a danger that arts council meetings are long and dull, suffer from comment pollution and members merely proffer personal opinions without getting to grips with the issues concerned. It is thus important to give committees of cultural experts clear criteria and priorities. Debate concentrates on the victims, so cultural policy tends to be incremental and catering for the status quo. Klamer (1996) argues that politicians will lose the rhetoric arguments, since the cultural sector is much better able to make its case. It is thus crucial that the government clearly lays down the rules of the game as well as criteria and priorities in advance of the applications for subsidy and refrains from making artistic value judgements about individual cultural expressions. Otherwise, it may succumb to pressure to overthrow negative artistic judgements of the Arts Council, setting a legal precedent to other cultural organizations to have their subsidies reinstated in court.

Each system for the allocation of cultural subsidies has different drawbacks. Stimulating demand across the board carries little danger of rent seeking and lobbying and avoids protection of the status quo, but suffers from dead-weight losses and bias towards middle of the road culture. The French or Italian system suffers from top-down

<sup>14</sup> Delegation of cultural tasks to an Arts Fund or the Arts Council is known as the arm's length principle.

behavior, lobbying, rent seeking, political and bureaucratic favoritism, and a bias towards prestige projects. The British system does not suffer too much from lobbying and rent seeking, since it avoids the taste of politicians and bureaucrats influencing individual decisions. Both the British and the Dutch system are transparent. The Dutch system allows more room for the government to shape cultural policy without trying to influence artistic judgements, but suffers from political lobbying and rent seeking. The Dutch government has made a determined effort to give more room for diversity and innovation. It also has given a clear mission to the Arts Council. In any system it is important to keep the cultural sector on the ball by ensuring a competitive field with free entry. This requires equal access to cultural subsidies for everybody, but may also be helped by vouchers, performance contracts and benchmarks. One can stimulate cultural entrepreneurship by defining ends and performance indicators while allowing for the costs of targeting. The government should use the right sticks and carrots and avoid destroying intrinsic artistic motivation. Attention should be paid to how to manage cultural institutions and guidelines for cultural governance. Unfortunately, board members of cultural organizations are often older white men from the banking sector and big business. To be in touch with new and diverse audiences, one must look for more representative boards of supervisees.

## 6.2. *Delegation and control*

Recent theories of delegation and control can be used to explain whether non-elected bureaucrats or art experts or elected politicians should take responsibility for shaping cultural policy and allocating funds to cultural organizations. Hart, Schleifer and Vishny (1997) analyze whether public services such as prisons should be delegated to private business or under control of politicians. Dewatripont and Tirole (1999) discuss the use of advocates for policy makers, while Dewatripont, Jewitt and Tirole (1999) consider career concerns rather than explicit contracts as a motivation of government agencies. Maskin and Tirole (2004) study career concerns and non-accountable agents with intrinsic motivations. Alesina and Tabellini (2004) build on these contributions to explain whether tasks should be given to bureaucrats or politicians. From a normative perspective they show that politicians are better suited to particular tasks than bureaucrats if:

- differences in performances are due to effort rather than to individual talent or technical ability;
- preferences of the electorate and parliamentarians are unstable and uncertain, so flexibility is valuable and the task or mission of bureaucrats cannot be specified ex ante while politicians are accountable and can ex post be voted out of office;
- time inconsistency is unlikely to apply;
- politicians cannot strategically distort policy choices in favor of short-term objectives at the expense of long-term welfare;
- the stakes of organized interest groups are small and the legal system is poorly designed, so corruption is widespread; and

- side payments to compensate the losers are desirable and relevant or bundling of policies is crucial to obtain majorities in parliament.

Epstein and O'Halloran (1999) argue that the degree of delegation is chosen so as to maximize the benefit to politicians. Alesina and Tabellini (2004) argue that in these circumstances politicians want to keep those tasks that generate substantial rents, campaign contributions and/or bribes and all kinds of redistributive tasks. However, Fiorina (1977) points out that politicians delegate tasks that have a high risk of policy failure so that bureaucrats can be blamed. Monetary policy requires sophisticated skills, has relatively few distributional effects and suffers from time inconsistency problems. Also, the electorate's preferences for low inflation are stable and not controversial and recessions can be blamed on central bankers. As in Rogoff (1985), there is a clear-cut case for delegating monetary policy to an independent central bank. Similar arguments apply to regulation of utilities. In contrast, foreign policy should not be delegated to bureaucrats as preferences change a lot and it is difficult to ex ante specify the goals. Redistributive policy should not be delegated either, since politicians may want to capture some of the associated rents.

What are the implications of these studies for the delegation of cultural policy? Which tasks in the domain of cultural policy should be given to the Minister of Culture, parliamentarians, bureaucrats and art experts? Many of the insights of the theory of delegation apply. Being popular and winning elections in the short run motivates politicians; bureaucrats at the Ministry of Culture are motivated by career concerns and have a longer-term perspective; art experts are motivated by their standing and reputation with their peers in the cultural sector, and they also want to be seen to be independent of political pressure. Cultural subsidies generate substantial rents. Many politicians like to be seen to be a patron of the arts and around election time are happy to call on 'friends' in the arts to lend their theaters and to help during the campaign. But they are unsuited to decide on the exact allocation of funds; bureaucrats who make use of the advice of expert judgement on artistic quality do this better. Yet many politicians do not resist the temptation to interfere in the allocation of funds to please electoral lobbies and engage in redistribution from, say, the rich metropolis to culture-starved regions. This is particularly prevalent in a system with ministerial responsibility. There is often pressure from the parliament to focus on short-term benefits of cultural subsidies with no concern for the long run; building a new theater or opera house generates short-term prestige, but without making funds available for ambitious programming it is unclear whether it will contribute to a thriving cultural climate. The making of cultural policy suffers from very serious time inconsistency problems. This should not be mistaken for varying or unstable cultural preferences. The first five of the normative reasons described above thus strongly argue in favor of the arm's length principle in the making of cultural policy, and although it is true that the Minister of Culture can package cultural policies and make side payments to obtain a majority (see the sixth reason), the financial and cultural experts of the Arts Council can do that as well.

Nevertheless, delegation of the execution of cultural policy to an independent Arts Fund does not deny a role for the Minister of Culture. It is crucial that he or she specifies

a clear yet broadly defined mission for the Arts Fund, stating its priorities and criteria and also the available budgets; the mission could state, for example, that more funds should go to cultural education, vouchers, cultural diversity, the regions or international cultural policy, but not to which particular cultural organizations unless no judgement of artistic quality is involved. The Minister of Culture should not be allowed to change the rules of the game halfway through the complicated process of granting subsidies or to decide on subsidies for individual cultural organizations, but should ensure that the Arts Fund acts according to the objectives stated in the mission and only interfere if the Arts Fund deviates from the mission. Carpenter (2001) argues that the rise of the regulatory state offers bureaucrats the chance to decide as well as to implement legislation. This also applies to Arts Councils and Arts Funds. They can count on generous space in the press and are able to obtain support for their case. In the absence of a strong and visionary Minister of Culture, there is a danger that the Minister of Culture simply rubberstamps the proposals of the Arts Council or Arts Fund.

Granting cultural subsidies by the above means is not the only option. Another system is to allocate cultural subsidies by referendum as in Switzerland. For example, Schulze and Ursprung (2000) analyze a public referendum for the Zurich Opera House. However governments of the European Union have not used referenda in cultural policy.

### 6.3. Analytical example of delegation of cultural policy

The above argument can be analyzed formally as follows. Suppose policy output  $Y$  is given by the sum of the policy maker's unobservable talent or ability  $A \sim N(A_M, \sigma^2)$ , the policy maker's effort  $X$ , and noise  $\varepsilon \sim N(0, \tau^2)$ , that is  $Y = A + X + \varepsilon$ . Bureaucrats and experts want others to have a good perception of their ability, so their reward is  $E[E(A/Y)] = A_M + \beta E[A + \varepsilon + X - E(X) - A_M]$ , where  $\beta \equiv \sigma^2 / (\sigma^2 + \tau^2) < 1$  is the signal-to-noise ratio. If costs are convex in effort, i.e.,  $C(X)$ ,  $C' > 0$ ,  $C'' > 0$ , the Arts Council chooses effort level  $X = C'^{-1}(\beta)$  and puts in less effort if there is a lot of noise relative to the variance of talent. With imperfect monitoring, bureaucrats and art experts put in too little effort which causes a loss of welfare. A Minister of Culture is concerned with re-election, so his or her reward is  $\text{Prob}[Y > A_M + E(X) + \varepsilon]$ . This implies rational voters, who assume that the alternative to the incumbent is a politician with average talent and who in equilibrium puts in the same effort as the incumbent. It follows that the Minister of Culture sets  $C'^{-1}(X) = 1/\sqrt{[2\pi(\sigma^2 + \tau^2)]}$ . Imperfect monitoring ( $\tau > 0$ ) reduces effort of both the Arts Council and the Minister of Culture. However, more uncertainty about talent boosts effort of the Arts Council and cuts effort of the Minister of Culture. The Arts Council experts are motivated by career concerns and fully internalize benefits of higher expected ability. The Minister of Culture wishes to secure re-election. It follows that bureaucrats and art experts are better suited for tasks requiring special abilities or technical competence that not everyone (and a Minister of Culture definitely not) is likely to have. They are not more gifted than the Minister of Culture, but that they have stronger incentives to be gifted.

Assume now perfect monitoring and that cultural policy is concerned with two tasks: facilitating a diverse spectrum of cultural activities of high artistic quality ( $Q$ ) and promoting participation of large and diverse audiences ( $P$ ). The success of achieving these tasks is determined by effort  $X_i$ ,  $i = Q, P$ , and ability  $A$  of the person who makes cultural policy, so  $Q = A + X_Q$  and  $P = A + X_P$ . The costs of the efforts of the policy maker are additive and convex,  $C(X_Q + X_P)$ ,  $C' > 0$ ,  $C'' > 0$ . Ex ante the electorate is uncertain about whether it prefers more artistic quality or more participation. It has utility  $U[\delta Q + (1 - \delta)P]$ , where  $\delta = 1$  with probability  $p$  and  $\delta = 0$  with probability  $1 - p$ . The Minister of Culture formulates in a White Paper the mission or task of the Arts Council, say  $Y \equiv \lambda Q + (1 - \lambda)P$  with  $0 < \lambda < 1$ , and defends this in parliament before asking the Arts Council to use it. The mission of the Arts Council is not contingent on the realization of the preferences of the electorate  $\delta$  (i.e., it is an incomplete contract) and thus does not follow the whims of the voters. The experts on the Arts Council are concerned with the perception of their ability, hence their reward is  $E[E(A/Y)] = E[A + \lambda X_Q + (1 - \lambda)X_P - \lambda E(X_Q) - (1 - \lambda)E(X_P)]$ . If  $p > 1/2$ , it is optimal to ask the Arts Council to focus completely at artistic quality  $Q$  (i.e.,  $\lambda = 1$ ). The optimal strategy, as far as the Arts Council is concerned, is to set  $X_P = 0$  and  $X_Q = C'^{-1}(1)$ . By giving the Arts Council a fixed mission, society is stuck with the risk that they cannot respond if ex post cultural participation is important as well. The Minister of Culture can respond to changing preferences (i.e., the realization of  $\delta$ ) and devotes effort only to the task ex post preferred by the electorate. This advantage is not so strong if voters are not too risk averse and relative certain about their ex post preferences. In that case it is best to let the Minister of Culture set the mission of the Arts Council.

## 7. Subsidiarity, local cultural clubs and federalism

To determine the best level (local, regional, national or international) for the making of cultural policy, the subsidiarity principle employed by the European Union is useful. This implies that it is best to conduct cultural policy at as low a level of government as possible, because politicians at the local level are better informed about preferences of their electorate and are more readily rewarded and punished than politicians at a national or international level. However, culture thrives best in a competitive climate so it may be better to allocate part of the subsidies at a national or international level; this would ensure that the quality of, say, a local symphony orchestra is judged against symphony orchestras in other regions and would require cultural policy at a higher level of government. One reason for cultural policy at an international or national level is that some culture generates by its very nature positive cross-border externalities. In addition there may be substantial economies of scale; for example, small countries make do with one big opera house.

The theory of local public goods surveyed in [Rubinfeld \(1987\)](#) and [Scotchmer \(2002\)](#) points out the importance of migration between local jurisdictions. This has obvious

applications to the making of a cultural policy in Europe, in particular in the Länder of Germany. Tiebout (1956) argues that the provision of local public goods can be viewed as an efficient competitive market for private goods where people reveal their preferences for these public goods by ‘voting with their feet’. Efficiency requires perfect information, costless migration, and no cross-border externalities; it also requires each jurisdiction to be large enough so there are enough people to produce the local public good at minimum average cost. Free entry of people is a very strong assumption. Nevertheless, one does see more skilled and educated people migrating to bigger cities (London, Barcelona, Paris, Berlin and Amsterdam) with a bigger supply of local cultural goods, while provincial towns are starved of their potential audiences and find it more difficult to support high culture. The optimal size of a jurisdiction is small if preferences are homogenous for each region, cross-region spill-over effects are small and economies of scale are unimportant.

The club model of local public good provision trades off economies of scale versus externalities arising from congestion. Groups of people with similar incomes and similar preferences arrange themselves in a club. The Tiebout model allows citizens to have different incomes and uses a local property tax to finance local public goods. Cultural public goods have an impact on land and property values. Building a theater, opera house or museum makes neighborhoods more attractive places to live and attracts citizens who pay higher local taxes and push up land and house prices. An interesting direction of future research in cultural economics is to analyze the effects of local cultural infrastructure and activities on land and house prices and to estimate the demand for these goods in terms of local socio-economic characteristics and local and inter-governmental support. The use of micro data on cultural demand seems particularly promising. Such demand studies should focus on different attributes (e.g., international reputation versus popular appeal) of the local cultural goods. A crucial complication is how to aggregate preferences, since people differ very much in their taste for culture. Bergstrom and Goodman (1973) show that under certain strong conditions one can postulate a simple majority-rule political process by estimating demand for public goods based on a median-voter model.<sup>15</sup>

An important issue for Europe is whether local governments should balance their budget, what local public goods should be provided locally, and whether and how revenues ought to be shared between levels of government. The literature on fiscal federalism and multiple layers of government attempts to give answers to these questions. It is doubtful whether there are good economic reasons for conducting cultural policy at the level of the European Commission; a large part of the Commission’s cultural budget is devoted to prestige projects such as the Cultural Capital of Europe with little international spill-over effects, and much of the cultural exchange that is supported is hampered by costly bureaucratic procedures. Since not all countries of Europe adhere to the arm’s

<sup>15</sup> Rubinfeld (1987) discusses the empirical aspects of estimating such demand functions for local public goods and the Tiebout model in some detail.

length principle, it is difficult to avoid political intervention. Topics that are of a European nature (e.g., competition policy, trade policy) are typically not the responsibility of Ministers of Culture. The European Councils of the Ministers of Culture have very tiny agendas and serve mainly the purpose of symbol politics.

## **8. International cultural policy: Different approaches in Europe**

Most countries of Europe make an effort to develop international cultural policy – i.e. cultural policy involving or directed towards other countries, including developing countries. Typically, such policy is the responsibility of both the Ministry of Foreign Affairs and the Ministry of Culture.<sup>16</sup> In some cases the international positioning of culture is done with the departments responsible for media and sport (UK), education (Finland), sciences (Austria), sport and tourism (Ireland), or communication (France). In some countries cooperation between the two key ministries has resulted in a central institute for international cultural exchange (Denmark, the Netherlands) and in others these ministries work together on a continuing basis (France, Finland). In others the Ministry of Foreign Affairs takes the lead (Austria, UK and Sweden) and may make use of cultural institutes abroad (such as the British Council and the French, Swedish or Finnish Institutes). Sometimes the Ministry of Culture is primarily responsible (Hungary) and elsewhere there are discussions leading in that direction (Ireland, Sweden). In some cases international cultural policy is shaped in collaboration with the regions (UK). Most countries engage in bilateral and multilateral cultural treaties (in particular France with its many cultural specialists and *Alliances Françaises*) and join forces regionally (e.g., the Nordic Council, Finland with the Baltic countries). They also develop international cultural policy together with the Council of Europe, the EU and UNESCO.

Different definitions of international cultural policy formulation are used. Most countries use a very broad concept of culture (Denmark, Finland, France, Austria, UK and Sweden). Some of these countries tie international cultural policy closely with development policy (Sweden, Denmark and Finland) or with efforts to stabilize regions such as the Balkans (France, Austria and UK). International cultural policy often pays considerable attention to education (Finland, France and UK) and boosting creative industries (Denmark, Finland, Sweden, UK and France). Other countries employ a narrower concept focusing at the arts, heritage and libraries (Ireland, Hungary).

In all countries one of the goals of international cultural policy is to help home cultural organizations to travel abroad. With a certain degree of national pride countries want to promote their own culture abroad and gain mutual respect for each others' culture. These forms of cultural diplomacy may help to further other objectives of the Minister of Foreign Affairs, e.g., to help to win foreign contracts for home enterprises.

<sup>16</sup> See, for example, Annalin (2003) and the website [www.culturalpolicies.net](http://www.culturalpolicies.net).

The UK seems to have the biggest emphasis on economic interest. If this is the case, international cultural policy formulation is best seen as a side-kick of foreign affairs and has little to do with inducing a thriving international cultural exchange. From the point of view of the cultural sector it may be better to leave the initiative with the Minister of Culture. Then priority may be given to the highest artistic quality of culture offered abroad rather than popular expressions of culture geared towards other motives than the arts. It also seems more likely that priority will be given to fund and attract foreign expressions of culture that are not offered at home, e.g., Third World music, Berber culture, Bombay films, etc. (Denmark, France, Sweden and the Netherlands). This added diversity has intrinsic value for the cultural climate of a country. Another reason is that it encourages more competition among home producers of culture, which also leads to a more thriving cultural climate. From this perspective some countries host the best foreign young visual artists, film directors, architects, musicians, etc. if they are judged to be of higher merit than home-grown talent. Not all countries agree (France).

It is important to measure the effects of international cultural policy. Although this has not been done on a systematic basis, casual evidence can be assembled. For example, promotion of Swedish and French music abroad seems to have been successful; in France music sales abroad rose from 1.5 million items in 1992 to 39 million items in 2000, even though the French government probably judges this spectacular growth insufficient to counter the dominance of the Anglo-Saxon music industry. France also strives to promote its films, TV and radio programs abroad, again with some success. Denmark has shown considerable success abroad with the films of its Dogma group, while Finland obtains similar results in music, design and dance. It is not only Britain that is trying to promote a 'cool' image; Austria also wishes to change towards a more modern image, building on the popular music of Kruder and Dorfmeister, for example. Both countries make use of branding, corporate identities and joint marketing approaches to promote their culture abroad.

There is a heated debate about whether one should adopt protectionist cultural policy or not. Some countries find it better to empower artists, so they can compete on international markets (UK, the Netherlands). Other countries (led by France) disagree strongly and rationalize their protectionist tendencies with the goal of promoting cultural diversity. This goal is not controversial if it involves using special instruments to sell French films, books or music outside France, offering ethnic minorities the chance to express their culture, or bringing in more non-European culture within national borders. However, it is controversial if it boils down to keeping as much culture as possible from the US out of Europe. Although there may be a case for promoting own-language products and blocking foreign-language products, this is generally a dangerous route to take and is often in direct conflict with the objectives of liberalizing international trade.<sup>17</sup>

<sup>17</sup> For further discussion of these issues, see [Chapter 33](#) by Acheson and Maule in this volume.

## 9. Summary and conclusions: Some lessons for cultural policy-making in Europe

The governments of Europe believe that culture cannot be left to the whims of the market. They argue that culture is an experience good, takes time to enjoy and appreciate, and has strong social externalities. It is therefore unpalatable if only the cultural elite enjoy culture, because culture is like language, in essence a social phenomenon. If culture is non-excludable and/or non-rival, it is a public good. Culture has social value, but it also has existence value, innovation value, option value and intergenerational value. None of these factors are properly internalized by the market.

The challenge for most European policy makers is to boost high culture, including the synergies with low culture, and strive for a democracy of culture by making sure that more people have the competence to appreciate and understand cultural expressions. Democracy of culture is not concerned with dumbing-down high culture, but with making high culture available and accessible to broader, new and more diverse audiences. This enhances the public good character of culture. Furthermore, cultural expressions only become meaningful if they are confronted with a critical audience. Culture has to compete with many other leisure activities, which explains why cultural participation over the last quarter of a century has been stable while the level of education has risen substantially.<sup>18</sup> Culture in Europe has become a more normal, integral part of an omnivore diet of excursions, holidays, visits to leisure parks and even sport. High culture in Europe faces the danger over the next few decades of becoming marginalized as the leisure industry becomes even more professional, the young invest less and less in cultural competence, the circle of genuine art lovers becomes smaller, and culture is to be found more often only in places of entertainment. Hence, governments of Europe work on a cultural policy that stimulates cultural education for school children, develops a taste for cultural goods that make a lasting impression, brings high culture to where ordinary people are (parks, squares, pop temples, etc.), boosts the programming and demand for high culture, finances cultural expressions that are non-excludable and/or non-rival or has social, existence, option or bequest value, and provides room for experiment and research and development.

Governments should avoid dead-weight losses and substitution, on the one hand, and lobbying and rent seeking on the other hand. If subsidies to art producers are allocated by committees of experts (as on arts councils), there is a real danger of art for the sake of art and an erosion of the public support for the arts. The French model is less attractive than the Dutch or British model, because it gives too much influence to bureaucrats and politicians and prestige objects. The Dutch model allows a greater possibility for shaping cultural policy than the British model, but is more susceptible to lobbying. One should keep the committees of experts small, appoint the experts for periods that are not too long, and allow interested laymen on the committees as well. Since the task of deciding on the artistic merit and financial needs of different cultural organizations

<sup>18</sup> See van den Broek and de Haan (2000).

is a difficult task, and since lobbies in the cultural sector are strong and politicians tend to focus on the short term and act in a time-inconsistent fashion, recent theories of delegation suggest it is best to delegate the execution of cultural policy to an independent Arts Fund while the Minister of Culture is restricted to setting out a mission with clear priorities, criteria and budgets and making sure the Arts Fund adheres to the mission.

Demand-oriented subsidies such as vouchers, interest free loans, matching grants, public-finance partnerships, etc., stimulate the cultural sector to produce art for which there is a demand in society. The danger with this is that safe, boring, better-known art wins over innovative art. Hence, special facilities are needed to stimulate experimental art and research and development.

The performing arts are labor-intensive and, like education, health care and the police, suffer from Baumol's cost disease. Productivity growth in the arts lags behind other sectors, resulting in relative price increases and greater pressure for bigger subsidies. Still, the newly-found riches of technical progress elsewhere lead to extra demand for culture, especially if culture is a luxury good. There may be a shift from unique to reproductive art expressions, from small-scale to large-scale productions and from labor-extensive to labor-intensive productions. In addition, since the performing arts are good at lobbying, this may take up a growing proportion of the total culture budget at the expense of other cultural needs. This is somewhat of a paradox, since the performing arts are much less a public good than reproductive art forms, the more so if subsidies for the performing arts profit a highly educated, high-income minority living in the big cities. Hence, governments should be careful to provide sufficient funds for cultural causes that benefit current and future generations such as monuments, archaeology and museums.

Governments in Europe should avoid addiction to cultural subsidies and sustaining the status quo by allowing equal opportunities for newcomers and having a level playing field. In the Renaissance there was fierce competition between producers of art and also some degree of specialization. Today a healthy dose of domestic and foreign competition and more market-oriented support from governments can be important drivers bringing about a revival of the creative and innovative arts sectors of Europe.

**Abstract**

American cultural policy is made and executed by multiple governmental entities, with a large part of direct public expenditure coming from sub-national governments rather than the central government. Much the largest share of government support is provided by tax concessions for gifts to not-for-profit enterprises that are the predominant producers of the subsidized arts, and by tax concessions to private owners who agree to preserve their heritage buildings and sites. The multiplicity of government decision makers and the reliance on “arms-length” relations between government and not-for-profit private providers of cultural services results in cultural policy that appears to be and is incoherent, but is characteristic of American public policy in many spheres.

## 1. Introduction

A standard definition of policy is “a definite course or method of action selected to guide and determine present and future decisions” (Merriam-Webster Dictionary Online, 2001). In that sense, there is not and never has been a clearly articulated cultural policy in the US. Instead, there is a very large number of distinct policy measures and proposals, often contradictory and poorly articulated. To some extent this is a consequence of the organizational pluralism that characterizes American government: the large and varied roles played by sub-national governments, and the pluralism within central and sub-national units of government. It is extremely rare that a single organizational entity within the federal government, and to a slightly lesser extent the state governments, has exclusive responsibility for a major area of public policy, from national defense to culture. A list of sources of direct federal government support of the arts and humanities in 2001 includes 17 different organizational entities as direct financial supporters of the cultural sector [Seaman (2002, p. 26)].

American cultural policy, then, comprises the collection of public-sector actions that affect the production and consumption of cultural goods and services. It also relates to how those actions have changed over time. But in fact, despite noisy controversy during the 1980s centering on the National Endowment for the Arts, cultural policy in the United States has been rather stable over the past century or more. There has been modest direct government financial support<sup>1</sup> of the arts and culture, and that support has increased at a moderate rate. Most of the increase has been in the form of steady increases in the budgets of cultural organizations that are government enterprises: federal, state and local government museums, non-commercial television and radio stations owned and operated by state and local government and by state universities, and so on. Public expenditures for heritage protection have also risen.

## 2. A brief history

The first museum in the United States was created by the New-York Historical Society, founded in 1804 in Federal Hall (where the first president of the United States was inaugurated in 1789). The Society’s collections included a large number of paintings by leading American painters, and 485 watercolors of birds by John Jay Audubon, a major figure in American painting in the first part of the 19th century. However, American cultural policy at the national level had an important but isolated founding moment in 1836. James Smithson, a successful British scientist, had drawn up his will in 1826, naming his nephew as sole heir. The will stipulated that, should the nephew die without heirs (as he did in 1835), the estate should go “to the United States of America, to

<sup>1</sup> “Direct government support” means grants of government funds, rather than tax preferences for private gifts to non-profit cultural organizations or exemption of such organizations from general taxes.

found at Washington, under the name of the Smithsonian institution, an establishment for the increase and diffusion of knowledge among men” [*Smithsonian Institution Libraries* (2002, p. 1)]. The motives behind this remain mysterious. Smithson died in 1829 leaving a legacy worth more than \$500,000. In 1836, Congress accepted the legacy, not without angry dispute, and eight years later established the Smithsonian Institution. The beginning collection was a scientific not artistic one, consisting of the thousands of plant and animal specimens brought back by the United States Exploring Expedition of 1838–1842 to the Pacific and the Antarctic.<sup>2</sup>

There were no further actions by the Federal government for decades to follow, apart from the commissioning of large paintings and sculpture (mostly bad but indubitably heroic) for the Capitol building that was under construction during the middle of the 19th century. For the country as a whole, the history really begins later in the century, outside the national capital, with the founding of the first large museums<sup>3</sup> and performing arts companies in major cities. Most of them were private not-for-profit entities, but there were also some state and local government museums (often historical museums) as well as Federal museums in Washington, the latter meant to entertain visitors to the capital<sup>4</sup> as well as to serve the educational missions customary to museums. Support for all these organizations was greatly reinforced after 1913 when personal income and death taxation began, with essentially unlimited deductions for “charitable gift deductions”, defined to include (among other things) cultural activities conducted by not-for-profit entities.<sup>5</sup> Government-owned cultural institutions have continued to receive private gifts of money and works of art. For example, the National Gallery of Art in Washington was created following a gift from Andrew Mellon, a billionaire who shortly before the gift was made was the Secretary of the Treasury; it is a Federally-supported museum and receives large private gifts of cash and works of art. Indeed, the differences between government-owned and private not-for-profit museums in regard to their financing and governance are sometimes obscure, and often matter little in practice.<sup>6</sup>

In the last three decades of the 19th century, art museums opened in a number of major cities, including New York, Boston, Brooklyn, Chicago, Cincinnati, Detroit,

<sup>2</sup> This expedition’s story is recounted in *Gurney* (2003) and *Philbrick* (2003).

<sup>3</sup> See *Meyer* (1979, pp. 17–36).

<sup>4</sup> The city was directly governed by the national Congress until well after World War II, with the House of Representative’s “District Committee” acting as the city council, approving the budgets of the city officials (who were Federal employees), determining the local tax rates, and deciding upon all policies applicable to the city.

<sup>5</sup> These tax preferences apply to a wide range of charitable gifts. Deductions are unlimited with respect to transfers at death (that is, bequests may reduce the taxable estate to zero). The value of gifts during one’s lifetime that can be deducted in any one year is limited to a stated percentage of before-tax income, but the non-deductible portions may be deducted in future years. The portion of the value of the gift reflecting capital appreciation over time is not taxed at the time of the gift at all.

<sup>6</sup> In sample surveys conducted by the American Association of Museums in 1999 and 2003, more than one-fourth of the respondents reported their governing authority as state or local governments, including state and local government colleges and universities. Nearly all others were operated by non-profit organizations.

Philadelphia, Pittsburgh, St. Louis, San Francisco, and Washington.<sup>7</sup> The organizers were well-off businessmen and the museums were private non-for-profit enterprises. But in most cases, the city government provided land and/or money to build and support the new museums. For example, the New York City government in the 1870s provided \$500,000 of the construction costs of the newly-established Metropolitan Museum of Art.<sup>8</sup> Interestingly, most charged non-trivial admissions fees, but had days with no charges at all. [Smolensky \(1986\)](#) demonstrates conclusively that the motivating rationale for establishing these museums was to exploit the educational value – or externality – of museums for ordinary residents of these cities. The organizers were persuaded that museum attendance was a worthy educational exposure for working people. Both state and local governments at this time and for a few decades afterwards also created historical and natural history museums, but usually with relatively little local government financing. But otherwise neither state nor local governments were significant as cultural patrons, save for what was done at the state government universities.

Direct government production of cultural goods and services has remained relatively small; indeed, it is relatively less important today than a century ago. There were two short-lived exceptions to this. In the Great Depression of the 1930s, a large number of artists were temporarily employed as artists, an almost accidental by-product of Federal work relief programs. A similar though much smaller such program existed for a few years in the late 1970s, as a Federally-financed counter-cyclical measure. In both cases, cultural activities were favored objects of publicly-financed counter-cyclical programs simply because at almost any time many cultural workers are not fully employed and have the low incomes that qualify them for these programs. Moreover, most cultural workers at any given time have well-developed projects that they can pursue, if financed. That means that the time between the passage of the law and the start of program operations tends to be short, relative to the lead time needed for most other projects.

By the early 1960s, establishment people persuaded politicians that direct monetary support from government, in the form of grants to not-for-profit cultural organizations, was essential to the local and national well-being. [Baumol and Bowen \(1966\)](#) appear to have made the single most persuasive intellectual contribution to this sea change in American cultural policy. They provided a market-failure case for subsidy. Their analysis of slow productivity increases in the performing arts, far less than increases in labor costs in the economy as a whole, forecast increasing financial distress for the sector, a forecast that was readily comprehensible by political leaders and the public at large. The amounts of money provided increased rapidly for a few years after 1965 when the National Endowment for the Arts and the National Endowment for the Humanities were created. Government funding of the Endowments peaked in 1980 (in current dollars), was cut sharply during the 1980s and has grown unevenly at modest rates since then.

<sup>7</sup> Some museums that opened during this period were financed and operated by individuals and families, such as the distinguished Isabella Stuart Gardner Museum in Boston. They eventually were converted into private, not-for-profit museums.

<sup>8</sup> [Jackson \(1995, p. 755\)](#).

Soon after World War II, the New York City government began to provide substantial support to a few major cultural institutions that were in serious financial difficulties. Initially, the rationale was that these institutions were located on City-owned land and/or in City-owned buildings. The first institutions so subsidized had immediate financial problems. The program evolved into one in which 30-plus institutions now receive annual support in the city budget to pay for some or all of the costs of building maintenance and operation, including security costs. The annual budget for this has been approximately \$120 million for some time.

The New York City local government arts agency example has been emulated in other American cities. The number of such agencies has been estimated to be more than 2000, an estimate that includes many private, not-for-profit (rather than governmental) agencies which receive little cash support from local government. The governmental agencies in the fifty largest cities spent \$350 million in the financial year 2001, of which \$306 million came from local government funds; New York City alone accounted for roughly 40 percent of the latter total.<sup>9</sup> Most of those agencies receive part of their public funding from the proceeds of special local taxes, such as hotel room occupancy taxes [Americans for the Arts (2001)]. In a National Endowment for the Arts publication, the local arts agencies are described as “primarily concerned with creating opportunities for artistry to occur” [NEA (1988, p. 394)] by sponsoring festivals and special exhibitions and providing housing for creative events. Some do provide operating support for long-existing cultural institutions, but at levels far below those in New York City. Also, there are cases in which local governments have issued bonds to finance, in part, new or expanded buildings such as concert theaters and museums.

In the 1960s, the New York State government created an arts council, roughly modeled on the UK Arts Council, to provide continuing support of operating budgets of large and small cultural institutions in the state; that concept became a reality in the 1970s when the state arts council budget was sharply increased. Meanwhile in the early 1960s American advocates for the arts also used the Arts Council of Great Britain as a model in pressing for national government provision of direct cash support of cultural institutions and cultural activities. They argued that the national government, which for years had been providing base-level financing of museums and other cultural activities in Washington, should now extend its financial support to most established and to-be-created performing arts companies and art museums. They proposed a new National

<sup>9</sup> It appears, from data in *Americans for the Arts* (2001), that total expenditure of public funds by local arts agencies in smaller cities in the financial year 2000 was modest. However, Cordes (2004, p. 205) suggests that arts spending by local government may have been equal to two to three times the total state government spending through state arts councils in 1999. That would mean local government support of between \$800 million and \$1.2 billion, implying that local governments *outside* the 50 largest cities were spending, per capita, two to four times as much as those in the big cities. This is highly implausible. It implies that the mean arts support (in total amounts of money) in smaller cities is higher than the mean for the cities ranking 2nd to 49th (that is, excluding New York). It may be that the source cited by Cordes includes non-governmental funds raised and spent by local arts councils, and also includes local arts councils that are entirely non-governmental.

Table 1  
Federal appropriations to the National Endowment for the Arts. Fiscal years 1965–2003<sup>1</sup>

Fiscal year	Appropriation in millions of current dollars	Appropriation in millions of 2000 dollars <sup>2</sup>
1966	2.9	12.5
1970	9.1	33.1
1975	80.1	210.8
1980	154.0	285.0
1985	163.7	234.8
1990	171.3	210.0
1995	162.3	176.2
2000	97.6	97.6
2003	115.7	109.2

Endowment for the Arts (NEA), and a parallel National Endowment for the Humanities (NEH) to support other cultural activities. The NEA would also provide support for other fields such as literature and the visual arts in which individual artists were the dominant form of activity. In the event, the total amount of Federal money provided for the NEA was far too small to permit so ambitious a role, even in the late 1970s when the funding of the Endowment in real terms was at its peak (see Table 1).

Yet another federal government intervention into cultural matters was the creation and funding of the Corporation for Public Broadcasting in 1968 to help support the rapidly increasing number of non-commercial radio and television stations known as “public broadcasting”. A large percentage of the on-the-air time of these stations is devoted to cultural programming. Most public radio stations are operated by universities, while the predominant operators of the public television stations are non-profit organizations and state governments. The entire system had revenues of \$2.3 billion in 2002, 43 percent from government (mostly state and local) and 57 percent from individuals, corporations and foundations.<sup>10</sup>

### 3. The role of the arts councils

#### 3.1. What the arts councils do

Apart from the New York City program, the programs of the NEA, the state arts councils and the local government arts councils are similar in design. None has sufficient funds

<sup>10</sup> [www.cpb.org/pubcast#whopays](http://www.cpb.org/pubcast#whopays), November 2004.

to support a major share of the operating costs of cultural institutions, nor to make large capital grants for buildings or acquisition of works of art. Instead, they support selected projects that applicants propose, such as special exhibitions at art museums, the commissioning of a new work by an orchestra or opera or theater company, improvement of climate control systems, art festivals, projects designed to expand the audiences for whatever it is that the applicant does, or part of the costs of expanded touring programs. Those projects must be consistent with the applicants' overall programs, and the grants ordinarily provide only a portion of the full costs of the proposed projects.

In the early days of the NEA, one of its distinctions was making grants to individual artists in numerous fields such as literature, the visual arts, music composition, and choreography. As discussed further below, the grants were often controversial, because some resulted in the production or presentation of work that was offensive to audiences and/or politicians or work that was ridiculed by critics as well as audiences. As a result, grants to visual artists were ended in the 1980s and grants to individual artists in other programs were reduced or eliminated. However, some of the state arts councils continue to make grants to individual artists, often by subsidizing organizations that actually make the choice of grantee.<sup>11</sup>

In the operation of most arts councils (New York City is again the major exception, where most of the money goes to cultural organizations on a list that is specified in advance and seldom changes), the council and its staff have broad discretion in making grants. However, in addition to voting money to the state arts council to use at its discretion (subject to some general restrictions), state legislatures often specify grants in detail. These so-called "line-items" in state arts agency budget allocations usually reflect the preferences of the more important members of the state legislature, who are convinced that the state arts council will not look with favor on projects thought to be highly popular in a particular legislative district; these often involve grants to build a named building or concert hall. "Line-items" tend to account for larger percentages of the total amount allocated to the state arts councils in recession years when the regular allocation to the arts council has been reduced. For example, line-items comprised 5 or 6 percent of the total in the middle-1990s (in 14–16 states), but 13–17 percent in 1999–2001, when they appeared in 20 or more states [[National Assembly of State Arts Agencies \(2001b\)](#)].

It is to be expected that most of the interventions by government cultural agencies will be on the supply side. Inevitably, most requests for funding are made by suppliers or would-be suppliers rather than consumers. But in the presence of very strong demand, private entities will respond and Baumol's disease will be irrelevant, as the evidence from the popular arts shows. This is so obvious that long-term development of audience demand is invariably a policy objective. Nonetheless, Endowment grants have mostly

<sup>11</sup> Some state constitutions prohibit gratuitous gifts of money to individuals and for-profit firms, which requires the use of non-profit intermediaries if grants to individual artists are to be made. A policy decision not to make grants to individual artists avoids that complication and also the political difficulties experienced by the NEA.

gone to expanding supply. For example, both the Endowment and major foundations have made grants to support new compositions of serious music, in face of the reality that few compositions ever have even a single performance.<sup>12</sup> Nevertheless, some of the state arts councils have made, and continue to make, grants that foster demand, such as developing new ways of marketing performances and distributing tickets.<sup>13</sup>

### 3.2. *The National Endowment for the Arts*

#### 3.2.1. *Development of programs*

After its establishment in 1965, the new Endowment quickly became a marginal supporter of the well-established cultural organizations, and a more significant supporter for arts disciplines that had barely existed when the Endowment was created, notably dance. In 1960, there were very few permanent dance companies in the US, and only a few dance performances each year outside the few cities that had dance companies in residence, notably New York and San Francisco. The Endowment very early in its life created a “Dance Touring Program” that relied on consumer choice rather than on centrally-made decisions as to which dance companies to support. That program provided managers of venues such as theaters at colleges and universities with inducements to schedule more dance, by offering them a long list of companies from which to choose and by paying one-third of a stipulated fee for a dance company’s visit. Not surprisingly, since all the ticket revenue belonged to the theater operator, dance companies that filled the seats were invited back [Netzer (1987)]. The Endowment also greatly strengthened the regional non-profit theater companies and the regional opera companies, as the data on the growth of theater and opera companies, revenue and attendance in Table 2 show.

In addition to the relatively small amount of money spent by the Endowment each year, it has exerted some leverage. A grant from the Endowment could be used to certify – for other donors – that the organization had demonstrated its worthiness. At the very least, recognition by the Endowment lowered search costs for other would-be donors. Moreover, the Endowment in making grants does so for specific projects, not for the cultural organization as such. It also requires that its grants be matched by funds from other sources, which could increase private giving. Such “crowding in” is unlikely to have been very successful, because any funds that the recipient organization has can be applied to the match.<sup>14</sup>

<sup>12</sup> O’Hare (1980) and Felton (1978, 1980) examined possible ways of encouraging composers to devote more time to composing rather than in more remunerative work like teaching.

<sup>13</sup> One celebrated project was the New York State Arts Council’s TKTS ticket booths in Times Square which distributed unsold tickets to Broadway shows at half-price or less on the day of the performance.

<sup>14</sup> See further in Section 6.3 below.

Table 2  
Live performing arts, 1980–2000. (Revenue in millions of dollars. Attendance in millions. Data are for seasons ending in the year shown)

<sup>1</sup>Companies reporting to Theatre Communications Group, New York, NY. The number reporting almost doubled over this period.

<sup>2</sup>Companies reporting to Opera America, which increased from 79 to 98 over this period.

<sup>3</sup>Prior to 1995, covers 254 US orchestras; beginning 1995 covers 1200 orchestras. The additional orchestras are much smaller than those previously covered.

### 3.2.2. The “culture wars”

Another role of the Endowment was an unhappy one: it has been something of a lightning rod. Its existence demonstrated a Federal government commitment to the arts and culture, but also provided a target for criticism of expenditures that were more conspicuous than other Federal cultural outlays like support of the Federal museums. Such criticism led to what journalists have called “the culture wars” [Marquis (1995)] which began in 1981. They arose as follows. By the late 1970s, the NEA was making (necessarily very small) grants to virtually every non-profit organization in a given discipline each year. It had programs in disciplines that had been flourishing commercially with-

out subsidy such as crafts, folk arts, musical theater and architecture. In making specific grant choices, the NEA gave complete discretion to its discipline panels which were composed of artists in the field; this process was especially hazardous in making grants to individual artists. Until the program of grants to individual visual artists was ended, the Endowment was under continual political attack. Its survival was in question at numerous points in the 1980s and 1990s, often because of grants to allegedly “obscene” recipients. The Endowment’s defenders cited a variety of reasons why these attacks were wholly irrational and hurtful to the public good. But in 1990 the US Congress inserted in the law governing the Arts Endowment the requirement that the Chairperson of the Endowment ensure that the judges of grant applications take into consideration “general standards of decency and respect for the diverse beliefs and values of the American people”, a requirement upheld by the US Supreme Court.<sup>15</sup> This was greeted with outrage by the “artworld”. Rushton (2000) has laid out the various rationales for public funding of the arts and has concluded that the decency-and-respect requirement is consistent with each such rationale.

The major consequence of the long controversy was the end of most grants to the visual arts. Also, there have been important changes in the ways that the Endowment makes grant decisions. It is no longer organized along disciplinary lines – dance, theater, music, museums, etc. – but by major purpose.<sup>16</sup> A second major internal change was reaffirmation in words and in practice that final decisions are not to be made by panels and/or program directors: they are made by the person chairing the Endowment, as is done in the US Federal government generally.

There have been noisy controversies and political threats to the continuation of direct government support on occasion since 1980 at the state government level, as well as at the Federal level. The NEA’s funding in recent years has been equal to or less than its funding in 1980 in current dollars (see Table 1), but because of increased funding of other Federal agencies – including the Federal museums and the Corporation for Public Broadcasting – total Federal spending for the arts and culture has increased somewhat. However, its composition has changed considerably, in the direction of limiting the discretion of the agencies and eliminating subsidy of some cultural activities. One example is the end of Federal support for virtually anything that can be described as contemporary visual arts, which flourish despite this. Artists and their advocates often decry what they see as increasing reluctance to support anything unconventional on the part of the government agencies that provide direct cash support to cultural organizations. Almost any change in the staffing or internal organization of those agencies is viewed as another shift toward the conventional.<sup>17</sup>

<sup>15</sup> The Court noted that the Endowment’s limited budget requires that it reject the majority of applications and that some will be rejected on the grounds of content.

<sup>16</sup> The Humanities Endowment has been so organized from its inception.

<sup>17</sup> See *New York Times*, October 5, 2002.

### 3.3. State arts councils

Following the reduction in NEA funding during the 1990s, a considerable percentage of the funds nominally appropriated to the Endowment is now passed on directly to the state arts councils, which since the 1980s have existed in every state. The state arts councils became the new hope for sustained government support of cultural organizations, a hope based in part on the example of the New York State council, which set out to provide significant budgetary support to almost 100 “major” organizations, as well as marginal grants to small ones. Although the New York council’s funding has been far below its 1974 peak in real terms since then, state government support (from all states combined) has been much larger than National Endowment funding for some years. The total for all states reached nearly \$300 million by 1990, when the National Endowment’s budget for programmatic grants was less than \$200 million.

Nonetheless, the state arts councils have not been reliable base-level supporters of cultural organizations. This is because there is considerable volatility in their budgets. In the 13 financial years<sup>18</sup> between 1991 and 2003, a period including two recessions and the extraordinary mid-1990s boom, aggregate legislative appropriations to state arts agencies declined in six years, including the recovery year 1993 and the high boom year 1996. There were years of decline in every state, and in an average year in this period declines occurred in 19 of 50 states. Often the year-to-year declines were more than 25 percent. In a few cases, the budget was reduced to zero, and the agency rebuilt in later years on a much smaller scale. The average annual growth over the 13 years was 1.6 percent.<sup>19</sup> There had been similar although less pronounced instability in the 1980s [Netzer (1992a)].

There have been efforts to explain the large variation among states in state government support of the state arts councils measured in both total funds and dollars per capita terms. These efforts are summarized in Heilbrun and Gray (2001, pp. 283–285). The most exhaustive analysis was done by Schuster (1989). For the 14 states for which he could find data suggestive of the demand for funding – the size of audiences, the number of not-for-profit arts organizations and the number of resident artists in the decennial Census year – those variables explained 76 percent of the interstate variation. Dropping the audience size variable, the 50-state equation explained only 10 percent of the variation, and no independent variable was significant. Netzer (1992a) subsequently found that states in which state tax revenue is relatively high tend to spend more for the arts, but the relation was not a strong one. The variation seems idiosyncratic.

<sup>18</sup> Nearly all states begin their financial years on July 1.

<sup>19</sup> Calculated from data in the following publications of the National Assembly of State Arts Agencies, the trade organization for the state arts agencies: Legislative Appropriations Annual Survey, 2000; Legislative Appropriations Annual Survey, 2001; Legislative Appropriations Annual Survey, 2002; Legislative Appropriations Annual Survey, 2003; State Arts Agency Funding Sourcebook (1966–2001 data).

## 4. Direct support for the arts and culture

### 4.1. Levels of support

Total direct government support of the arts and culture in the year 2000 was \$3 billion as shown in Table 3. The “arts council” organizations accounted for a little over one-third of this sum, reflecting the substantial fluctuations in their funding at federal and state government levels over time. For the federal Endowments, this variability reflects the political controversy surrounding the Arts Endowment beginning in the 1980s, as discussed above. For the state arts councils, it reflects budgetary pressures confronting state governments during recessions. In contrast, direct government support for the museums that governments own and operate has increased steadily, as has support of public broadcasting; together these avenues account for more than 60 percent of total funding by the federal government and by the states. More than 80 percent of Federal support goes to those two activities and the heritage programs of the National Park Service. An obvious explanation for these figures is the reality that government departments have well established bureaucracies, located close to the places where budget decisions are made. These organizations are likely to have budget increases over time that parallel the increases enjoyed by other departments and agencies of that government, unlike arts councils that give public money to “outsiders”.

A particular avenue of direct government support for the arts and culture is support for non-profit organizations. Tables 4 and 5, based on different sources of data, show the relative importance of government grants to non-profit organizations that produce cultural services. Table 4 is based on the Economic Census of 2002.<sup>20</sup> Table 5, showing data for the year 1999, is based on inspection of returns filed with the Internal Revenue Service annually as a condition of Federal tax exemption. There are large differences in the data in the two tables, especially for museums.<sup>21</sup> But both show that government grants are small percentages of total revenue for all types of non-profit cultural organizations.

There is one strategic intervention in cultural policy with a very high benefit–cost ratio. It is the Federal government’s indemnity insurance for exhibitions of artworks and artifacts borrowed from other countries by US museums, or lent by US museums for exhibitions in other countries. The insurance may also include works lent by US museums for exhibitions within the US if the exhibitions also include works borrowed from other countries. In other words, the program covers virtually any exhibition that includes valuable works. The total amount of this insurance that may be outstanding at any one time

<sup>20</sup> The Economic Census is conducted every five years; in categories in which non-profit organizations are important, data for firms not subject to Federal income tax are shown separately. Although filing returns for this Census is not compulsory, there are indications that compliance rates are high, for both tax-exempt and taxable firms.

<sup>21</sup> In the periodic financial surveys conducted by the American Association of Museums, the response rate has been quite low. It appears that many large museums do not respond, even to surveys that seem to be in their interests.

Table 3  
Direct government support of the arts and culture, 2000 (in millions of dollars)

	Federal	State	Local	Total
Total, all levels of government	1158	1080	820	3058

Other	22	2	11.9

Data from annual reports filed with the US Treasury Department as a condition of exemption from Federal income tax, and summarized in Table 8.1 of Cordes (2004).

is \$8 billion. The maximum insurance coverage for a single exhibition is \$800 million, and the insurance deductibles are very low, so that as much as 99.9 percent of a large loss is recoverable. The purpose of the program is to permit the borrowing of works for which no commercial insurance cover can be had and to permit very large savings in insurance premiums in cases where commercial insurance coverage would have been feasible. From 1975, when the program began, until October 2003 these savings are estimated to have been \$157 million for 713 exhibitions. In 2003, 62 exhibitions opened with this indemnification.<sup>22</sup> It is a low-cost intervention, given the physical care that is taken in mounting any major exhibition. There is no dispute about this program.

The United States is unusual in the very small extent to which the state pays for the professional training of artists. Logically this could be expected to lead to a failure to exploit available talents. Although some state government universities have such programs, a considerable number of the most illustrious programs are in private universities and conservatories with very high fees that surely deter some people from pursuing the path into an artistic career. In addition, some of the private conservatories and dance schools, including the most illustrious, regularly live close to the edge financially, and occasionally there are failures. Government assistance to the conservatories to assure their continued existence would be another not very high-cost intervention.

The state universities and colleges play an important part in developing audiences for the performing arts through their role as presenters of touring companies; this role is essential to the financial survival of large numbers of performing arts groups, especially dance companies, for some of which touring may account for 95 percent of their earned income. It is inconceivable that the development of a national audience for dance, which was limited to a very few cities before 1960,<sup>23</sup> could have occurred without the existence

<sup>22</sup> [www.nea.gov/grants/apply/Indemnity/Intro.html](http://www.nea.gov/grants/apply/Indemnity/Intro.html).

<sup>23</sup> Kendall (1983) recounts the progress of dance in the US in the course of celebrating the contributions of the Ford Foundation to that progress.

of numerous institutions capable of both physical presentation and financial guarantees to fledgling dance companies.

#### 4.2. *The case for direct subsidy by subnational governments*

In American politics, the case for direct subsidy for the arts is made almost entirely on narrow utilitarian grounds, with little attention to the positive externalities that cultural economists write about. The argument typically is that subsidies for arts and culture by state and local governments have very large and favorable impacts on local economic growth. Under some conditions this can be true, notably when the cultural attractions are numerous and famous and people actually travel to that city mainly or partly because of them. But there are few instances of a Venice or Paris among the hundreds of American places to which the argument is said to apply. In many American cases, the economic impact argument is no more than dissembling in a noble cause [Seaman (1987)]: the cultural attractions are substitutes for other local consumer goods rather than exported services. Even for New York, where a plausible economic-impact case has been made for cultural subsidies [Port Authority of New York and New Jersey (1993, 1994)], extravagant claims sometimes are made regarding the alleged local economic impact of government cultural subsidies. A letter to the editor from the head of the main arts advocacy group in New York City that was published in *The New York Times* [Bourscheidt (2002)] asserts that “In return for \$100 million in city support, non-profits arts groups generate \$5 billion in economic activity”. Studies of the local economic impact of the arts in the US usually make generous claims, but few claim a 50:1 multiplier.

Nevertheless, local cultural goods can be a significant contribution to the local quality of life, a proposition that makes the dominance of state and local financing of cash subsidies to culture, in contrast to the minimal role of the Federal government, congruent with American values rather than an indication of American hostility to the arts and culture. A considerable fraction of local government subsidy is used to support the most important local cultural institutions, including venues for first-rank visiting artists as well as local artists and supporting players.

Advocacy groups sometimes note an important and plausible goal of increased subsidy, namely to enable individual artists to devote less time to non-artistic labor and more time to artistic labor. It is well known that most artists hold multiple jobs. For example, in a NEA survey of choreographers, Netzer and Parker (1993, p. 47) found that the mean number of hours per week that was devoted to the first of two or more jobs other than choreography was 23.6 hours, and there was a negative relation between working in non-choreography jobs and the number of new works produced.<sup>24</sup> Throsby (1992, 1994) has formally modeled artists’ three-way labor market choices,

<sup>24</sup> Such supply-side intervention seems appropriate for dance. Each season mounted by any respectable American dance company is expected to include some new works. Many dance companies include European cities in their tours (which are essential to their financial stability), and managers of these companies appear to be convinced that the tour must include new works if it is to be invited to perform in subsequent

among artistic labor, non-artistic labor and leisure. Any policy measure that increases the hourly earnings from artistic labor will stimulate a shift in the supply curve away from non-artistic labor in favor of artistic labor.

Another cause popular with advocates is less plausible. It is asserted that because uncompensated and voluntary cultural activities, notably in music and theater, appear to be large and increasing, direct cash government subsidies to professional cultural activities should increase. The reasoning appears to be this: if the sector flourishes with so little subsidy, imagine what the sector would be with more subsidy [McCarthy et al. (2001)]. However, it seems equally plausible that increased subsidies might result in a reduction in uncompensated voluntary labor, as has been the case with many activities in the US in the past thirty years. A notable example is the sharp decline in uncompensated work by parents and others in the state schools, accompanied by a large increase in paid staff such as school crossing guards.<sup>25</sup>

A new version of Baumol's "cost disease" is a recent addition to the advocates' case for more subsidy. McCarthy et al. (2001) forecast declines in the output of professional performing arts groups in middle-size American cities because of increasing costs of production and sluggish growth in direct government subsidy. The analogy is with the recent history of professional league sports in the US and some other countries. In these sports the top-ranked divisions and teams are extraordinarily successful enterprises, in large part because of television revenue, while lower-ranked divisions and teams languish financially and often collapse; those that survive do so by means of subsidies from the more successful enterprises and sale of athletes' contracts to the successful teams. In reality, in the performing arts in smaller cities the financial problem is much less severe because the companies are less ambitious in their programming and often operate with a mixture of paid professional staff and unpaid amateur artists, and volunteer non-artistic staff. That mix of paid and unpaid, professional and amateur labor was the operating mode for most performing arts companies outside the largest US cities as recently as 1960.

However questionable some of the arguments made by advocates, it is entirely legitimate for those with strong preferences for cultural goods and services to attempt to persuade others that the public goods generated by subsidies to cultural activities and organizations are real and large. As Bruno Frey has long argued, when the political decisions are made at the local rather than central government level, there can be more confidence in the process of public choice, especially when the decision process is by direct individual choice. By voting positively on the issue in an election, voters are indicating that they believe the various external benefits such as option value, bequest value

years. In contrast, American orchestras and opera companies rarely perform new works. O'Hare (1980) calculated that most new compositions are never performed; Heilbrun (2001) documents the declining diversity of American opera companies over the period 1982/83–1997/98.

<sup>25</sup> The question of substitution of paid for voluntary labor is examined in numerous papers dealing with "crowding out" in the provision of health care and social services.

and prestige value are real enough to warrant payments of taxes. Frey's (1999) argument suggests that one of the strengths of American cultural policy is that most direct subsidy to the cultural sector is provided by state and local governments rather than by the national government. The national government's main roles are to handsomely support the operations of national cultural institutions in the nation's capital, to provide physical protection for a large number of heritage sites and buildings, and even more importantly, to provide indirect support through tax preferences to private givers, thus leaving decision-making about each gift highly dispersed among thousands of private parties.

## 5. Indirect support for the arts and culture

### 5.1. Levels of support

Indirect support of the arts and culture through the tax system is of considerably larger magnitude than direct subsidy. "Private contributions to arts, culture and humanities"<sup>26</sup> have been in the \$10–11 billion range in recent years, as shown in Table 6. A conservative estimate is that the cost of these gifts to the public sector, in terms of the reduced revenue from income and wealth-transfer taxes, is \$4 billion annually. Income tax credits for preservation of privately-owned historic structures amounted to \$9.2 billion over the years 1978–1997 [Listokin, Listokin and Lahr (1998, pp. 433–439)]. Also, there is the exemption from local property tax of land and buildings owned by not-for-profit cultural organizations, an exemption dating back to the early 19th century [Diamond (2002)]. This exemption is not important for most types of cultural entities, but only for those that own valuable land and buildings. Logically it should encourage cultural organizations to over-invest in land and buildings, but museums are the only type of not-for-profit cultural enterprise for which land and buildings are crucial and expensive factors in the organization's production function.

Not-for-profit entities are exempt from corporate income tax in the US by definition, i.e. any excess of receipts over expenditure in a given year cannot be appropriated by the "owners" of the enterprise. There is a Federal tax on "unrelated business income" of not-for-profit organizations, but this is defined in a manner that results in infrequent and very small payments by only a small minority of not-for-profit entities. In countries with value added taxes, the treatment of not-profit-organizations' receipts under VAT is of considerable importance. The US counterpart – state and local government taxes on retail sales of goods and services – are imposed at rates that are considerably lower than most VAT rates, and the receipts of not-for-profit cultural organizations from admissions charges are never subject to these sales taxes; their receipts from sales of food and drink and other merchandise also largely escape sale taxes. Thus, the tax exemption that matters is the ability of donors to deduct the value of gifts from income and wealth-transfer taxes.

<sup>26</sup> That is a considerably broader category than "non-profit performing arts and museums".

Table 6  
Private philanthropy for the arts and culture, 1980–2000 (in millions of dollars)

Source and allocations	1980	1985	1990	1995	2000

From individuals	2.8	4.4	7.3	9.2	9.7

Source: Statistical Abstract of the United States, various years; in some places, estimates have been made by the author.

<sup>1</sup>Roughly 5% of all charitable contributions are not allocated are by recipients in the data source.

## 5.2. Criticisms

The income and wealth-transfer tax preferences for charitable gifts date from 1913, when Federal government taxation of income and wealth transfers began. They have been criticized, mainly on the grounds that deductibility for tax purposes transfers decision-making power regarding the allocation of resources in matters of public concern from government to givers, in proportion to the size of their gifts. Gifts to the arts and higher education are notoriously dominated by gifts from rich donors, unlike gifts to churches.<sup>27</sup> However, the prevalent American view of subsidy in this form appears to be that it is the ultimate decentralization of choice regarding who and what is subsidized. Americans generally see this not as the rich deciding on who and what receives subsidy at government expense, but as the only practical way to shift the decision-making from bureaucracies and politicians to a vastly larger number of individuals. Moreover, because gifts to culture are so heavily concentrated among the rich, there is some measure of progressivity in incidence, probably more so than is the case with respect to direct cash subsidies from government [Netzer (1992b)].<sup>28</sup>

<sup>27</sup> See Feld, O'Hare and Schuster (1983) and Chapter 36 by Schuster in this volume.

<sup>28</sup> In the volume that includes Netzer (1992b) two of the discussants, Estelle James (pp. 244–255) and Henry Aaron (pp. 237–243), argue that several papers including the Netzer paper may overstate the redistributive effects of income and wealth tax deductibility by not explicitly taking into account the likely low price elasticity of demand for some of the services subsidized by charitable contributions (notably for cultural goods and services) on the part of lower-income households. The subsidies probably do not increase their consumption of cultural goods by very much. The proportion of audiences that are low income households is, therefore, a poor measure of the distribution of the benefits from tax-deductible gifts. However, Aaron notes that in the performing arts, the wage subsidies to artists financed by tax-favored charitable contributions probably are real and significant.

## 6. Economic issues in support for the arts

### 6.1. Market failure and willingness to pay

The great majority of Americans tolerate, even take pride in, occasionally consume, and often join as amateurs in the production of, cultural goods and services. But they evidently do not consider increases in the supply of professionally produced cultural goods to be sufficiently important to warrant them paying more than infinitesimal amounts of taxes to directly support culture. This attitude is comfortable in part because cultural output has been increasing for some time at a rate equal to or greater than the increase in total consumer expenditure, in the absence of large subsidies from tax-derived public revenue as was seen in Table 2.<sup>29</sup> Attendance data for performing arts organizations and museums are an indication of this increase in output. Moreover, surveys of “public participation in the arts” done by the US Census Bureau for the National Endowment for the Arts every five years beginning in 1982 suggest that between one-third and one-half of adult Americans who are university graduates attend at least one performance a year of both plays and classical music and well over half visit an art museum at least once. Even for opera and ballet, that proportion is 10–15 percent [US Census Bureau (2001, Table 440)].<sup>30</sup>

The essential argument for subsidy to the cultural sector in one form or another is that there are a number of classes of external benefits that will not be realized in purely market transactions [Frey and Pommerehne (1989, pp. 16–30)]. The magnitude of the external benefits and how those are valued by the individual or the collective decision-making entity – a country, province, or city – should determine the extent of subsidy. Frey suggests that the impact of government subsidy on creativity and the quality of artistic output is affected by “what kind of state” provides the subsidy, arguing that a decentralized and democratic state is likely to better than a centralized and authoritarian state [Frey (1999, pp. 72–75)]. Frey and Pommerehne (1995) make a case for direct democracy – voting in referenda – using the Swiss experience. The alternative, given that decision by referenda is unusual except in Switzerland and some places in the United States, is the contingent valuation method, using a variety of indirect approaches.

### 6.2. Direct vs. indirect support

In the *Journal of Cultural Economics*, November 2003, eight papers evaluate contingent valuation in the arts itself. Noonan presents a meta-analysis of more than 100 such

<sup>29</sup> Relative prices of tickets for the listed performing arts appear to have risen considerably over the period, which suggests that the price elasticity of demand is low, while the income elasticity is moderately high. However, Felton (1992) found, in an analysis of 50 performing arts companies, a considerable degree of variation in price elasticities among the companies and some suggestion that higher prices may be thought by many consumers that they are indicators of higher quality, as Throsby (1983) proposed.

<sup>30</sup> There has been some skepticism about the response to the surveys, to the effect that they seem benign exaggerations. Earlier surveys showed even higher percentages and seemed inconsistent with estimates of total paid attendance at professional performances [cf. Netzer (1986, 1992b)].

studies. In concluding papers, Epstein (2003) and Throsby (2003) tell readers that despite the drawbacks of the approach, its use is a “regrettable necessity”. Tax reductions to encourage individuals to make gifts of money and art works arguably reduce the error inevitable in contingent valuation methods. In arithmetic terms this must be true, because the value of the gifts themselves represent direct valuation of externalities by donors; it is only the portion of the gift that represents tax forgiven by the state that requires contingent valuation. The lower the marginal tax rate confronted by individual givers, the smaller the amount of externalities whose economic value is unknown.

There is an extensive literature about American “tax expenditures”, that is, using tax concessions rather than direct spending of public money to subsidize activities considered desirable in some sense, beginning in the 1970s [Surrey (1973)]. Much of it is not very relevant to the economics of art and culture. Nevertheless for at least 50 years public finance economists have argued that the broader the coverage of income and/or wealth by a tax, the less the excess burden or deadweight loss – i.e. the economic distortion caused by payment of the tax itself – because the excess burden is a function (most likely exponential) of the marginal tax rate confronting taxpayers [Auerbach (1985)]. Exemptions, deductions and other exclusions from the tax base must cause marginal tax rates to be higher. That would suggest that generous deductions allowed in calculating tax liability will increase the marginal tax rate and thus the excess burden.<sup>31</sup> However, if the alternative is outright subsidy, the marginal tax rate must be even higher because the size of the budget is increased by the direct subsidy relative to gifts by taxpayers, unless this exercise begins by assuming a marginal tax rate of 100 percent. If the highest marginal income tax rate is 40 percent, as it is in the United States, then the 60 percent of the gift that is paid entirely from the taxpayer’s own resources reduces the deadweight loss from taxation, compared to a direct expenditure of government funds of the same amount in the form of subsidy.

### 6.3. *Crowding-in or crowding-out?*

During the early life of the NEA, there was considerable concern among the managements and governing boards of large and prestigious cultural organizations, especially museums, that direct Federal government support might reduce private philanthropic donations to their organizations. There is a considerable economic literature on the possible “crowding out” of private money and voluntary labor by incremental government spending for parallel purposes.<sup>32</sup> Some of this focuses specifically on cultural activities and organizations. Earlier work addressed the issue of the possible negative effect on donor motivations; almost all, like Abrams and Schmitz (1978), found that there was

<sup>31</sup> A commonly used rule of thumb is that the excess burden of the Federal income tax at the rates prevailing since 1986 is 1.6 times the tax collected.

<sup>32</sup> There is an even larger literature on the possible “crowding out” of private investment and consumption spending by government macroeconomic measures.

some crowding out but that it is not complete, implying that donors view government grants as imperfect substitutes for private giving.

Borgonovi and O'Hare (2004) approached the issue somewhat differently, employing both econometric and interview data to examine crowding (crowding-in as well as crowding-out) at the level both of individual institutions and of the cultural sector as a whole. Their interviewees (managers of cultural institutions and foundation donors) almost uniformly disputed the notion that there is any crowding in, although there was some in the early history of the two national Endowments. Their econometric model used data for the period 1955–1999. The empirical results suggest that Endowment grants do not have significant effects on grants received by individual organizations institutions or by the sector as a whole.

Some work has addressed the effect of grants on fund-raising activities by charities; the usual finding is that there have been significant reductions in spending for fund-raising caused by government grants. Andreoni and Payne (2003) analyzed panel data for 233 non-profit arts organizations and 534 social services organizations over a 10-year period, with fund-raising expenditures averaging more than 10 percent of their total revenue from contributions, an average that is stable over the period. They found that an increase in government grants of \$1000 on average reduces fund-raising expenditure by \$264, a decline of 52 percent. Conceivably this could be efficient if the deadweight loss of fund-raising is greater than the deadweight loss of taxation. If not, then the efficient outcome might be a requirement that for the grant to be continued or increased there must be evidence of increased fund-raising spending. American foundations frequently condition grants on just this.

## 7. Heritage policy

### 7.1. *Public sector role in heritage protection*

Heritage policy in the United States, in sharp contrast to public policy with regard to the arts, is supported by considerable direct public financing, much of it by the Federal government, as well as by generous tax incentives. In part this may be because the supply of physical heritage sites and artifacts is relatively small, so that protecting a large fraction of them is not very costly. Many are not located in cities, so the opportunity costs in the form of possible alternative high-value uses are also low for the most part.

The physical heritage outside museums in the US consists largely of historic buildings and sites. Unlike most countries in Western Europe, there is not a vast supply of paintings and sculpture in public places or in small churches, of a quality and significance that makes them part of the commonly accepted national heritage, however costly it may be to protect them. Indeed, in the US much of the sculpture in public places is arguably not highly regarded either by ordinary people or by experts, and often can be suitably restored at relatively modest cost when the need arises. Many historic structures are built of wood rather than masonry, and thus suffer the disadvantage of deteriorating

more quickly. But the offsetting advantage is that the deterioration is usually easier to repair, skilled carpenters being much more numerous than skilled stone-cutters in the US where more than 75 percent of the housing stock consists of wooden buildings. A large majority of protected historic sites managed by government agencies are predominantly open space with a few wooden structures.

Therefore the issues surrounding heritage policy in the US do not include the concern that there may be too much officially designated heritage and too rapid a growth in the number of such designations, as Françoise Benhamou (1996, 1998) has suggested is the case in France and the United Kingdom. No doubt the same is true in much of the rest of Europe; even with conservative hypothetical illustrations of the value of heritage structures and artifacts in these countries, the annual costs of offsetting physical capital consumption could be a large fraction of GDP, for example, in Italy [Netzer (1998)].

As noted above, the public sector's role in heritage protection in the US is substantially larger than in the arts per se. This role is administered in a number of ways. For example, the National Park Service (a bureau of the Department of the Interior) includes in its natural resource protection mission the protection of historic places, sites, trails and monuments, most of them battlefields (or related otherwise to wars fought in North America), important places in the exploration and settlement of the American West in the 19th century, and sites significant in the 17th and 18th century that illustrate aspects of the workings of the economy. The Park Service owns and manages more than 250 such places, at an average annual cost of at least \$1 million, devoting more than 10 percent of its annual budget of \$2.0 billion to these efforts.<sup>33</sup> There also are state and local government efforts to preserve historic sites but it has been the practice to persuade the Federal government to assume ownership and responsibility for historic preservation involving sites with limited private uses wherever possible.

## 7.2. Heritage tax incentives and regulation

As in the arts, there is substantial indirect assistance to heritage protection in the form of tax incentives. There is a National Register of Historic Places, and owners of buildings located in places that are in the Register are eligible for tax credits for preservation work. The Register began in 1968 and contains more than 65,000 listings of places, each of which may have many buildings whose owners can take advantage of the tax savings. The main Federal tax incentive program, which began in 1978, had provided tax credits that reached \$19.2 billion by 1997. It is estimated that there are three million privately-owned structures included in Federal, state and local government registers [Listokin, Listokin and Lahr (1998, pp. 433–439)].

Another aspect of protection of heritage is the regulation of what private property owners may do to their properties, if those properties have been designated historical “landmarks” or “monuments” or are located in historical districts so designated by local

<sup>33</sup> [www.data2.ipc.nps.gov/parksearch/atoz.cfm](http://www.data2.ipc.nps.gov/parksearch/atoz.cfm).

governments (the generic term is “local historic preservation district”). In 1955, there were 20 such districts; the earliest were the Georgetown section of Washington, the Vieux Carré in New Orleans, “Historic Charleston” (South Carolina) and Beacon Hill in Boston. Twenty-five years later, there were more than 800, and more than 2000 by 1996 [Listokin, Listokin and Lahr (1998, pp. 438–439)]. In these districts, changes to the exterior of buildings require permission by an official agency, in order to preserve the historic exterior appearance of the buildings and to prevent demolition and replacement by new structures whose appearance is inconsistent with the architecture that characterizes the district.<sup>34</sup> Owners of buildings in the districts can claim “economic hardship” but this is often hard to demonstrate; in New York small buildings like churches located in high-demand areas often can sell the development rights (to build much higher buildings on a nearby site outside the historic district) at high prices.<sup>35</sup>

In addition, historic district designation is often thought to be accompanied by large increases in property values, much larger than in the remaining areas of the city. However, the literature on this shows mixed results, which is to be expected in the light of the substantial variation in real estate markets across the country. Early studies compared price level changes in designated historical districts with price level changes in other parts of the same cities, without rigorous controls for other differences between historic and other districts [Scribner (1976); Gale (1991)]. Subsequent studies used the hedonic pricing method to isolate the implicit price of the attribute of being in a historic district. Asabere and Huffman (1994) found substantial price increases in Philadelphia associated with both historic facade easements (which essentially give away the owner’s discretion in making facade changes) and being in a historic district. Coulsen and Leichenko (2001) found net positive effects on property values of houses in Abilene, Texas in a Census tract with historic houses, relative to tracts with no historic designation.

The most persuasive study is that by Noonan (2004), who examined 73,000 sales of residential property in Chicago in 1990–1999.<sup>36</sup> The initial finding was that landmark designation had a strong effect on sales prices, adding between 6 and 15 percent. However, Noonan then used the repeat-sales approach, an approach familiar to cultural economists who have used it in analyzing price trends for paintings and other works of art over long periods. The approach controls for unobserved property characteristics, as it does for the uniqueness of a work of art. Using this method, Noonan found that landmark designation in Chicago did not have positive price effects, and may even have had negative effects on price appreciation over time.<sup>37</sup>

<sup>34</sup> Although there are districts characterized by a cluster of cultural activities, historic districts are mostly a celebration of architecture, rather than the “cultural districts” discussed in Chapter 31 by Santagata in this volume.

<sup>35</sup> If “economic hardship” can be demonstrated, the action can be construed as a “taking” of private property for public use. US Constitution requires that owners be compensated for their losses when this occurs.

<sup>36</sup> Cited with the author’s permission.

<sup>37</sup> Public property tax records in New York suggest that residential property prices in historic districts have risen far more rapidly than in the rest of the city, since the districts were designated. This is no doubt partly

Conceivably, if there are substantial increases in market values occasioned by historic designation, local property taxes, which are based on market value in American law, will rise. But such increases in taxable property values are not the general case, since in most cities local government valuers are hesitant to do this. Moreover, the Federal income tax law has been interpreted by courts to permit very large deductions from taxable income and thus income tax payments when property owners grant “easements” to a not-for-profit organization under which no change in the external appearance of the building can be made without the consent of the holder of the easement – which consent is rare. The US Tax Court has found in several cases that giving away that particular property right reduces the market value of the property by 11 percent, which has become the standard tax rule. However, when the historic designation of a district is associated with very large increases in the market value of property in the district, strengthening the rules against changes in appearance will increase, not decrease, market value.

### 7.3. Heritage valuation

A study by Frey and Oberholzer-Gee (1998) is one of the relatively few efforts to address the question of the evaluation of the benefits of heritage protection. Where a more-than-nominal admission price to the building or site is charged, the immediate benefits to those who pay the charge has been revealed. But there is much protected heritage for which charging is entirely infeasible or feasible for limited aspects of the building or site only. Most protected heritage also provides option and bequest value. Possible approaches to measurement of these externalities include contingent valuation, hedonic pricing in the markets for real property, cost–benefit analysis and the travel-cost method. However, the approach preferred by Frey and Oberholzer-Gee is direct democracy, i.e. voting in referenda on specific projects and their budgets. That is common in Switzerland, and occasionally happens in the US for arts projects but not for heritage purposes.

Navrud and Ready (2002) examine the application of various techniques used for environmental policy evaluation to the evaluation of cultural heritage, including the travel-cost approach, which was developed in the 1950s by Marion Clawson and Jack Knetsch as a means of valuing the protection of places of natural beauty in the US, notably national parks in the West and South [Clawson (1959); republished in 1992]. One pragmatic advantage of the approach is that there are good data on travel costs provided by Federal and state government transportation departments, including estimates of the value of time devoted to travel. The approach seems appropriate because much of the protected American heritage is in places that are visited by people who live at some distance from these sites. If these visits had not occurred, physical decay and transformation to other uses would have caused many heritage sites to have been lost

explained by the tax law provision that severely restricts taxable value increases over time on 1–3 family houses, the prevalent type of property in numerous New York City “landmark districts”. Thus, their market values are not reflected in property tax payments. (This is based on a survey by the author.)

during the many years before governments took an energetic role in their protection. It is perhaps surprising that there has been little use of the travel-cost approach in the valuation of heritage in remote sites. One such use is described in [Poor and Smith \(2004\)](#). The heritage site in question is a restored 17th century settlement that was the initial English settlement in Maryland, relatively remote from the larger cities of the region. It is on no main travel route and accessible only by automobile. The value estimates in the alternative forms of their equations vary considerably, but they do support some policy suggestions. Price elasticities were found to be quite low and income elasticities negative, suggesting caution in up-scale advertising.

## **8. Further research**

There has been very little written about how the peculiarly American aspects of cultural policy – notably the heavy reliance of the arts on a revenue stream consisting largely of earned income and private gifts stimulated by tax incentives rather than direct government financial support – affect the composition (rather than the level) of cultural output. For example, “block-buster” museum shows have become the dominant element in arranging exhibitions at major American art museums. Arguably, the block-buster substantially increases revenue from admission charges and generates more and larger private gifts to museums. If so, the result must be to increase the amount of time and space devoted to such exhibitions and to reduce the time and space devoted to exhibitions from the museum’s own collections, compared to the experience in countries with quite different policy regimes.

Similarly, the dependence of American dance companies on revenues from touring in Europe may be a consequence of the negligible level of direct government financial support available at home. Also, there may be programmatic effects of the heavy reliance on sub-national government entities for financial support. The answer to this latter question requires better information on just what local governments actually do in their subsidies to cultural output.

It has been argued that the for-profit sectors in the arts depend heavily on the creativity of the non-profit sector. This is obvious in theater and cinema but less so for other disciplines. The rents generated by this use of material and ideas usually are captured by individual creative people, not by the non-profit companies. Little systematic research on this topic has been done. Also, little is known about the consequences for cultural output (as well as for the size of potential audiences) of the lack of exposure to art and music of children in the great majority of the public elementary and secondary schools.

## **9. A concluding observation**

Like the other chapters in this volume, this one seeks to explain the cultural policy choices in the US as if they had been products of economic analysis, specifically in

terms of market failure. Zimmer and Toepler (1999) challenge that approach. They argue that neo-classical market failure arguments fail to take into account historical and institutional factors that exist in every country, and that lead to quite distinctive cultural policies: “while market failure provides a strong argument why government should intervene, it fails to explain international variations in the extent of public support” (p. 46). Or international variations in the institutional arrangements through which cultural policies are implemented. Their argument is a persuasive one.

## Abstract

Cultural policy discussions are increasingly concerned with the creation and restructuring of tax incentives; thus, cultural policy and tax policy are becoming more and more intertwined. With the widely held perception that there has been a general decrease in the availability of direct public resources for culture, a search has begun for other sources of support and for ways to provide incentives for those other sources. Moreover, with the growth in the use of forms of decentralization, désétatisation, and devolution in cultural policy, increased attention has been paid to tax policy as a way of spreading decision making over public resources more broadly. Thus, there has been a rise in the use of tax policy to provide incentives for what is considered to be desirable behavior vis-à-vis the arts and culture, particularly though not exclusively with respect to its nonprofit component. It has been clearly documented that the indirect aid embedded in various taxes forgone by the various levels of American government are a much more important source of financial support than are the government programs of direct support and that foremost among these is the deductibility of charitable contributions. As a result, many countries have begun to pay more attention to the “American model” of cultural support with its high level of reliance on private donors and its attendant tax incentive structure.

Adopting a “tax expenditure” perspective, this chapter begins with a summary of the existing literatures on tax policy in cultural policy. It then proceeds to a consideration of the accumulated evidence with respect to the effects of tax exemption: the price elasticity of giving; the income elasticity of giving; the differences between individual and collective decision making with respect to distributing public resources to the arts and culture; the kinship between tax incentives and matching grants; the economics of tax incentives for corporate contributions; the incidence of tax incentives in comparison to the incidence of direct support; and the extent to which tax incentives promote crowding out or crowding in behavior with respect to other revenue sources. While most research has been focused on American tax incentives for charitable giving, some studies do exist for other countries, and their results are summarized where available.

For the moment, the econometric results depend substantially on the model specification and the type of dataset used. For those who would argue in favor of tax-based incentives, at least with respect to charitable donations, there is considerable evidence

in support of the view that such incentives would have the desired economic effects. But those who are dubious about the net effects can also find evidence to support their arguments. Despite the ambiguity of the econometric evidence in the United States, the use of tax-based incentives is proliferating. A set of contemporary international examples suggests (i) that indirect aid is the terrain in which many of the most interesting innovations and variations in the funding of the arts and culture are taking place, and (ii) that this proliferation is more likely due to the influence of politics and advocacy than to the influence of reasoned analysis.

## 1. Introduction: Tax policy as cultural policy

Most analytic attention to cultural policy has been paid to direct policy, and rightfully so, since government's cultural agencies and the policies, programs, and projects that they oversee are a visible and important component of cultural policy. But over the past twenty-five years or so, considerable research in the cultural policy arena has demonstrated that indirect methods of government involvement also figure importantly in the cultural policy mix. Unemployment or other social welfare rules and how they interact with employment practices in the cultural sector are cases in point, but first among these is the contribution that tax policy makes to cultural policy.

Tax policy is of interest for four primary reasons:

- *The use of tax policy to provide incentives for what is considered to be desirable behavior in the arts and culture, particularly though not exclusively within its non-profit component.* Nonprofit arts and cultural organizations might benefit from a wide variety of favorable tax provisions: they might be exempted from property tax,<sup>1</sup> from sales taxes on purchases they make, or from paying income tax on any surplus revenue they realize in a taxable year (as long as that surplus is reinvested in the mission of the organization); a donor might be able to benefit from tax provisions that reduce the donor's cost of private giving to the cultural institution. Individual artists might also benefit from various tax provisions: they might be exempted from state income taxes or state sales taxes under certain circumstances; they might even benefit from a national income tax exemption, as is the case for creative artists in Ireland.<sup>2</sup> Corporations in the cultural industries might benefit from special tax breaks of their own: reduced VAT rates on the products they produce, tax credits to encourage certain types of investment, or the like.
- *The use of special dedicated taxes as a source of revenue for the arts and culture.* Recent debates in cultural policy have seen an upswing in the call for dedicated sources of public revenue for the arts and culture. In large part this has been fed by an increase in the number of state lotteries and a relatively successful attempt to make this new source of public revenue palatable to voters – to garner political support, lottery revenues are dedicated to favored “good causes”. But there are other, nonlottery examples as well. The creation of the Colorado Scientific and Cultural Facilities District, a six-county special taxation district within which an additional one-tenth-of-one-percent sales tax is collected to support scientific and cultural facilities, is a case in point [Martell (2004)].
- *A desire to ensure fairness of tax treatment within the arts and culture as well as across sectors.* Here the primary concern is the extent to which tax policy interacts in an unusual way with the sector under consideration. To take but one example, because of the sporadic and unpredictable nature of the income of authors,

<sup>1</sup> An excellent discussion of property tax exemptions is contained in Brody (2002).

<sup>2</sup> A comparative survey of the tax treatment of individual artists in various European countries is contained in Munnely (1986).

playwrights, or composers, it may be good public policy to introduce income averaging, allowing spikes in income to be spread over longer periods of time and thereby ameliorating what might otherwise be an unacceptable tax burden.

- *A turn away from direct forms of support to indirect forms of support as a political strategy.* As public budgets have become more restricted and as direct support for the arts and culture has experienced moments of controversy, less visible forms of government support have become more attractive to the sector as well as to politicians.

Moreover, tax policy in particular and indirect aid more generally are the terrains in which many of the most interesting innovations in the public funding of arts and culture are taking place.<sup>3</sup> Here more than in direct aid is where experimentation and variety can be found. At the biennial meetings of the Association for Cultural Economics and of the International Conference on Cultural Policy Research, as well as in the pages of their respective journals, the *Journal of Cultural Economics* and the *International Journal of Cultural Policy*, it is clear that all over the world policy discussion is increasingly concerned with the creation and restructuring of tax incentives (though ownership and operation of state cultural institutions and direct support through grants and operating subsidies continue to be favored modes of support in many countries). As a result, it has become quite difficult for individuals and organizations in the cultural sector to keep track of all of the tax incentives for which they might be eligible and of all of the tax provisions that might impact them.<sup>4</sup>

Even with this brief introduction, it is clear that the topic of “tax policy as cultural policy” is a vast one with many corners worthy of sustained exploration and analysis. Indeed, *any* tax regime might be the subject of a simple yet revealing analysis: to what extent does this current form of taxation or this tax provision advantage or disadvantage the cultural sector? And to what extent could this tax regime be modified to provide desirable benefits to the sector? At what cost? Much of the discussion concerning the intersection between tax policy and cultural policy is concerned with precisely the question of the extent to which tax policy affects cultural policy. Put another way, much of the discussion of the contribution that tax policy can make to cultural policy is focused on the first point above: To what extent can tax policy be used to provide effective incentives for desirable behavior vis-à-vis the arts and culture?

Taxes play a role in many corners of cultural policy:<sup>5</sup> tax provisions are used in an attempt to attract artists to become part of urban redevelopment efforts [Schuster (1999)] or more broadly at a national level to support a particular group of artists, as

<sup>3</sup> See, for example, Schuster (1999).

<sup>4</sup> This has given rise to taxation catalogues. Simmonds (2001) is an example of such a guide for the arts in the UK; Staines (2004) provides one for artists and promoters operating in Europe; and Simon (1987) and Facchina, Showell and Stone (1993) provide useful cross-sector catalogues for the United States.

<sup>5</sup> For a broad summary of tax incentives for nonprofit organizations in the United States, see Simon (1987), but note that this extensive summary does not include any discussion of tax incentives for profit-making organizations in the cultural field.

occurs in Ireland [Coffey (1998)]; they are used to lower the relative costs of certain cultural goods and services as compared to other goods and services – lower VAT rates on the purchase of books are a case in point [Rouet (1999)]; they are used in addition to regulation and outright purchase to provide an incentive to keep artworks considered part of the national patrimony within national borders [McAndrew and O’Hagan (2000); O’Hagan and McAndrew (2001, pp. 49–50)] or to make donations to national museums in lieu of taxes more attractive than sale [Council for Museums, Archives and Libraries (2002, p. 10)]; and special dedicated taxes are implemented to serve as a supplementary source of support for the arts [Schuster (1996, 2001); Martell (2004)]. These examples are only the tip of a very large iceberg.

But one area of tax policy has generated more interest in cultural policy – and in governmental policy vis-à-vis the nonprofit sector more generally – than any other: the tax treatment of donations to cultural and other nonprofit organizations. This topic has reached its preeminence because of the fact that, in an era of what appear to be increasingly limited public resources, many countries have begun to pay more attention to the “American model” of cultural support with its high level of reliance on private donors, particularly individuals but also corporations and private nonprofit foundations.<sup>6</sup> It has been clearly documented that the indirect aid embedded in various taxes forgone by the various levels of American government are a much more important source of financial support than are the government programs of direct support [Feld, O’Hare and Schuster (1983)], and that preeminent among these is the deductibility of such contributions.

Thus, in order to maintain some focus in the current chapter, I will concentrate my attention on tax provisions with respect to charitable donations and their incentive effects. I will make reference to examples drawn from other components of tax policy where appropriate, as well as to the broader issues that tax policy raises when it intersects with cultural policy, but I will not be able to provide a comprehensive overview of this very large field. Restricting my focus in this way has one further advantage: this is where the data are probably the best – though only in certain national contexts – and where, to date, the analysis has been the most complete.

But before I turn almost exclusively in this direction, let me turn first to a summary of the current state of the art with respect to the cultural-policy-based literature on tax policy.

<sup>6</sup> A general misimpression about the sources of revenue for American cultural organizations deserves to be clarified here. As a rough rule of thumb, American cultural organizations receive approximately 60 percent of their revenue from “earned” sources of revenue – ticket sales, subscription sales, memberships, and sales through shops, cafes, publishing operations, and parking facilities. The remaining 40 percent is in the form of “unearned” revenue. Typically three quarters of this unearned income comes from the private charitable contributions of individuals, with the remaining one-quarter coming from corporations, foundations, and the government. Thus, while there are always exceptions to such a generalization, the most salient characteristic of this revenue profile is the importance of private contributions from individual supporters of the organization. They provide an average of 30 percent of the total revenue of the organization. But, as we shall see, this 30 percent is made up of two portions: truly private after-tax donations and the taxes that have been forgone through public policy.

## 2. The literature on tax policy in cultural policy

### 2.1. The early literature

The first recognition of tax policy as an important complement to direct aid in cultural policy (at least in the United States) came at about the same time as the primary governmental cultural agencies – the National Endowment for the Arts and the National Endowment for the Humanities – were being created. Thus, from the very beginning a mix between direct and indirect aid was under discussion. August Heckscher's 1962 report in which he recommended that President Kennedy create an "Advisory Arts Council" made numerous recommendations for changes in tax law aimed at increasing government assistance to the arts [cited in [Netzer \(1978\)](#)]. Several reports that were released about the time that the National Endowment for the Arts was created also argued for an increased use of indirect subsidies, presumably to counteract the fears of overcentralization that accompanied the creation of the new agencies.<sup>7</sup> In each of these reports tax policy played only a minor role. To the extent that these documents paid attention to this area, they were all exhortatory; the fundamental lack of reliable data made it virtually impossible for them to be analytic in any meaningful way.

In 1973 the Commission on Private Philanthropy and Public Needs (colloquially known as "The Filer Commission" after its chairman), a privately funded citizens' panel, was formed to study the role of philanthropic giving and voluntary public-oriented activity in the United States. This effort which resulted in the publication of five volumes of working papers and reports [[Commission on Private Philanthropy and Public Needs \(1977\)](#)] is still the most ambitious attempt to understand the dynamics of the American nonprofit sector and its relationship to the state. Only one twenty-two page paper in its more than 3000 pages dealt with the nonprofit arts [[Hightower \(1977\)](#)]. While carefully documenting the importance of various sources of support to arts organizations, this paper was remarkably silent on the behind-the-scenes role played by tax law. This is especially striking since one entire volume of the commission's papers dealt directly with a myriad of questions concerning tax provisions. In retrospect, it seems clear that the arts sector was not yet focused on the actual contribution that tax policy was making to its financial health, even as others outside the sector were beginning to sense an accumulation of interesting research questions and policy issues surrounding both existing and proposed tax laws.

In the mid to late 1970s some sustained attention began to be paid to tax policy questions in Europe. Ignace Claeys Bouuaert was commissioned by the Commission of the European Communities to compile three comparative reports on taxation issues in cultural policy among the European Economic Community (EEC). These reports dealt with the tax treatment of cultural organizations and contributions to those organizations

<sup>7</sup> See [Toffler \(1965, pp. 182–208\)](#); [Rockefeller Panel Report \(1965, Chapters 4 and 5, pp. 120–121, 138–143\)](#); and [Baumol and Bowen \(1966, Chapter 13 and pp. 348–356\)](#).

[Bouuaert (1975)], the tax treatment of cultural workers in the EEC [Bouuaert (1977)], and the tax treatment of historic properties [Bouuaert (1979)]. Each of these reports is a cross-national catalogue describing the national legislation in force in the EEC countries at the time. In each case Bouuaert struggled with the fact that a satisfactory set of categories to describe various taxation regimes had not yet been developed within the arts and culture, and the result was an ambitious though incomplete survey of the state of the art at the time.

## 2.2. Tax expenditure analysis

The publication of Stanley Surrey's (1973) book *Pathways to Tax Reform* marked a clear methodological and analytic divide in the study of tax incentives. Surrey argued that indirect government action, particularly the indirect action embodied in tax incentives, could and should be compared to direct aid; forgone taxes should be analyzed as a government "expenditure" in much the same way that direct outlays would be analyzed, and the two approaches should be compared to understand their respective attributes and their respective advantages and disadvantages. He coined the phrase "tax expenditure analysis" to describe this approach. A decade later, one of the most comprehensive analytic studies of the relationship between tax policy and cultural policy was commissioned by the Twentieth Century Fund as part of a series of books on support for the arts and culture in the United States.<sup>8</sup> *Patrons Despite Themselves: Taxpayers and Arts Policy* [Feld, O'Hare and Schuster (1983)] was the first study to attempt a tax expenditure analysis for a single sector of the economy rather than across a taxation instrument, and its importance goes well beyond the arts and culture.<sup>9</sup> Perhaps still the best known and most widely cited treatment of tax questions in the arts and culture, *Patrons Despite Themselves* remains a standard reference work despite the fact that the American tax context within which it was written has changed significantly, particularly with respect to marginal tax rates.

Feld, O'Hare and Schuster demonstrated that in the United States the indirect aid to the arts and culture that was embodied in various tax exemptions and reductions dwarfed direct aid to the arts and culture. For 1973 – their reference year<sup>10</sup> – they estimated that

<sup>8</sup> This set of studies makes for interesting reading, particularly if one places each volume within its historical context. Feld, O'Hare and Schuster (1983), mentioned in the text above, provided the *indirect* aid complement to Netzer's (1978) Twentieth Century Fund study of *direct* government aid to the arts in the United States, which focused on the National Endowment for the Arts and the state arts councils. In addition, Meyer (1979) was asked to consider policy in relation to art museums; and Banfield (1984) took up the question of public policy vis-à-vis the visual arts.

<sup>9</sup> As far as its authors are aware, it remains the only such comprehensive study for a single sector.

<sup>10</sup> The reference year was 1973 because it was the year for which the Commission on Private Philanthropy and Public Needs conducted the National Survey of Philanthropy, systematically collecting data for charitable contributions that allowed for the separate identification of the sectors to which the surveyed donors had made their contributions. In the words of Christopher Jencks (1987, p. 324), this survey "was the largest and most

indirect aid to the arts and culture in the form of forgone taxes was nearly two-and-a-half times the amount of direct governmental aid.<sup>11</sup> But, more importantly, they raised a number of policy questions inherent in supporting the arts and culture through tax exemptions rather than directly. First, they demonstrated that there was an important interaction between donor tastes, their income levels and therefore their marginal tax rates, and their relative propensity to give to the arts and culture as opposed to other charitable sectors. This, they argued, has led to a distortion of the public policy elements of a tax-exemption-based support policy. Moreover, they pointed out the degree of influence that had been accorded individual *private* donors in the allocation of what could be construed as *public* resources.<sup>12</sup> They cited many instances in which the general taxpayer was being asked to pay, in part, for the rather idiosyncratic results of the decisions made by individual donors. The important analytic point here is, of course, not solely that the decisions of an individual donor might be idiosyncratic. The decisions made in a direct aid system might also be idiosyncratic in the sense that they too might not be in line with accepted public policy. The question is whether one system of providing public assistance achieves systematically better results than does the other when measured with respect to articulated policy.<sup>13</sup> Still, public sector idiosyncrasies in decision making arise because of bureaucratic or political failures that presumably can be corrected through vigilance and institutional design; the idiosyncrasy of private decisions is inherent and cannot be as easily corrected.<sup>14</sup>

With respect to the property tax, Feld, O'Hare and Schuster (1983) argued that the net results of existing tax incentives was to fuel capital intensity among nonprofit organizations, making buildings and land inexpensive relative to other uses of their resources.<sup>15</sup> They demonstrated how changes in tax law could have perverse effects on arts organizations – museums, for example, would find themselves opposing tax reform behind the scenes because it was in their interest to keep marginal tax rates as high as possible, thereby keeping the marginal price of charitable donations lower and more attractive to donors. They also outlined how, at the heart of many tax exemptions, private interests were continually in tension with public policy.

detailed survey of giving ever conducted in America". But note that Jencks has criticized this source of data for possibly overestimating charitable giving among high-income individuals who itemize their deductions and underestimating charitable giving among low-income itemizers.

<sup>11</sup> As we will see below, more recent estimates have arrived at even more dramatic ratios for the United States.

<sup>12</sup> Elsewhere in this volume Dick Netzer argues that the degree to which tax incentives are taken up by donors in the United States may provide the best available estimate of taxpayers willingness to pay for the arts and culture out of public resources. In this regard, he argues, this estimate may even be superior to contingent valuation studies.

<sup>13</sup> See King and Blaug (1976) for an interesting example of evaluating direct aid in this manner.

<sup>14</sup> I am grateful to Victor Ginsburgh and David Throsby who made these points in response to a draft of this chapter.

<sup>15</sup> This theme is further explored by Vladeck (1976).

Table 1  
Revenue sources for American art museums, 1988

	Revenue (\$ millions)	Percentage	Adjusted percentage*	Notes
Operating revenue (earned income)	122.4	14.0%	14.0%	
Private support (contributed income)	235.0	27.0%	15.0% (12.0%)	Private portion Tax expenditure
Value of art donated	77.3	8.9%	2.3% (6.6%)	Private portion Tax expenditure
Total direct federal support	95.7	11.0%	11.0%	
Total direct state and local support	168.7	19.3%	19.3%	
Total indirect government support			18.6%	
Endowment income	173.0	19.8%	19.8%	
Total	872.1	100.0%	100.0%	

Source: Fullerton (1991).

Notes: Calculations are based on data from 155 arts museums surveyed in 1989 by the Association of Art Museum Directors.

\*Adjusted percentage reports percentages after adjustments have been made for the appropriate accounting of the tax expenditures embedded in charitable contributions.

There have been other more recent attempts to estimate the relative role of forgone taxes in support of American cultural institutions. Some have looked at a specific set of cultural institutions, basing their estimates on the limited data available from those institutions. For example, Fullerton (1991, pp. 198–199), focusing on art museums and using 1988 data, estimated that 18.6 percent of the operating income of American art museums was comprised of the value of forgone taxes on contributions of cash and the value of capital gains taxes forgone on gifts of appreciated art work (Table 1). Thus, by his estimate indirect federal aid for museums was one and a half times direct federal aid (11.0 percent of total revenue on average). Thus viewed, public support for these museums actually comprised an average of 48.9 percent (18.6 + 11.0 + 19.3) of total revenues. Put another way, over a third of the benefit provided by the public sector was provided through the forgone taxes embodied in tax expenditures:  $(12.0 + 6.6)/48.9 = 38$  percent.

But even this analysis underestimated the overall benefit of federal tax exemptions because it included neither the nontaxation of net operating revenues nor tax exemptions related to restricted donations to endowment, nor did the analysis make any attempt to estimate state or local tax expenditures – for example, neither the value of property tax exemptions nor exemptions from sales taxes on museum purchases nor state tax incentives for charitable contributions were considered. And note further that the 155

museums considered here included five large government art museums, which are the exception rather than the rule in the United States. If they were removed, the implicit subsidy for private museums would be seen to be much larger than direct government spending.

Other studies have tried to look at the arts in the aggregate, deriving their estimates in a variety of ways using new partial datasets that have become available on aggregate charitable giving by sector. Most recently, Brooks has written several short papers that explore some of these themes with more recent data. He has estimated that in 1999 the ratio of indirect to direct funding at the federal level (calculated by estimating the forgone federal taxes in charitable giving to arts and cultural organizations and comparing that figure to the federal appropriation for the National Endowment for the Arts) was \$14 indirect : \$1 direct [Brooks (2003a)].<sup>16</sup>

While this estimated ratio can be criticized on a number of grounds – the numerator may be overestimated because it relies on data provided by the American Association of Fund Raising Counsel which has every reason to be generous in its figures, and the denominator is undoubtedly low because there is far more direct federal aid to the arts than that aid included in the budget of the National Endowment for the Arts – it does suggest that the relative importance of indirect aid in the form of forgone taxes has increased dramatically. Note also that, as was the case with the Fullerton study cited above, Brooks makes no attempt to include estimates of the influence of property tax (or other state and local) exemptions. Contrast this to Feld, O'Hare and Schuster (1983) who did include such estimates, though they are now quite outdated.

### 2.3. Other issues in tax policy

Even beyond strict tax expenditure analysis, Schuster has been the most consistent contributor to the (American) literature on the role of tax policy in cultural policy. In several papers he has taken a look at tax incentives through a comparative perspective: he compares the American charitable deduction to the traditional British deed of covenant system of providing a tax incentive for charitable contributions [Schuster (1985a, 1989a)]. These papers provide a defense of the merits of the traditional British system, even as it was being gradually moved toward the American system of incentives and its own policy merits were being watered down. Building on the earlier work of Bouuaert (1975, 1977, 1979), he demonstrates [Schuster (1986)] that, contrary to popular wisdom, American style incentives for charitable contributions had already been implemented in a number of Western European countries and that other countries

<sup>16</sup> In an unpublished analysis, Brooks estimates that "... [T]he ratio of private to public dollars to the arts varied over the 90s from about 12:1 to 19:1. In general, it's increasing. Assuming reasonable marginal federal tax rates, indirect federal aid outweighs direct federal aid by about 15:1. Getting the total indirect/direct ratio is harder because imputing state and local taxes is [difficult]. But I figure it's about 6:1." (Arthur Brooks, e-mail correspondence with the author, February 2, 2002.)

had gone far beyond the United States in inventing tax provisions to pursue various aspects of cultural policy, most particularly with respect to the treatment of both movable and immovable heritage resources. He also demonstrates that the take-up of these provisions by the citizens of these countries has been far less than has been the case for such exemptions in the United States.<sup>17</sup> He has also advanced a broad set of propositions concerning the use of tax incentives in the arts and culture [Schuster (1987)]; in this paper the focus is on the inherent dilemmas in supporting the arts and culture (as well as other sectors more generally) that occur when providing support through indirect rather than direct means.

Most recently Schuster (1999) has revisited the field of indirect aid to the arts as part of a commemoration of the twentieth anniversary of the publication of Dick Netzer's book, *The Subsidized Muse*. In this paper he points out that much has changed as other countries began to take up the cause of American-style tax incentives, but that what has changed most is governments' willingness to craft narrowly defined and targeted tax incentives. Moreover, while tax incentives have previously been used to provide a wide swath of benefits to broadly defined groups of recipients, more recent incentives have been more carefully crafted to target specific policy goals and to assure that those benefits are limited to intended beneficiaries. Such targeted incentives seem particularly well suited to overcoming resistance to behavior change, as will be seen further below.

While much of the discussion of tax policy that emanates from the cultural field is often based in advocacy more than in analysis, an occasional thoughtful contribution is made from within the field. Stephen Weil, a lawyer and museum administrator, is one such contributor. In a 1991 paper he explores the politics of tax reform in the United States and its relationship to the maintenance of indirect government aid to the arts [Weil (1991)] and mounts a spirited defense of tax incentives, particularly the charitable deduction, as a preferred way of structuring government support.

Another component of the tax literature in cultural policy focuses on the tax treatment of the donation of appreciated property, particularly the donation of paintings to museums in the United States. A lot of ink has been spilled on the comparative tax treatment of collectors and artists with respect to the donation of works of art, but most of this literature counts as straight advocacy rather than considered analysis.<sup>18</sup>

The particular problems related to heritage resources and the solutions that might be offered by various tax incentives have also commanded some sustained attention.

<sup>17</sup> Indeed, an increasingly large number of countries, particularly in Western Europe, have implemented American-style deductions for charitable contributions. [See also Weisbrod (1991); International Center for Not-for-Profit Law (2002); Inkei (2001); International Federation of Arts Councils and Culture Agencies (2003).] These tax regimes differ considerably with respect to floors, ceilings, and approved recipients of deductible donations, but the basic principle nearly always remains the same: a contribution for charitable purposes may be deducted from one's income before calculating the income tax that one owes. The exceptions are those countries that have opted for tax credits instead of contribution deductions (see below).

<sup>18</sup> Compare, for example, Hawkins (1988) with Feld, O'Hare and Schuster (1983, pp. 11–16, 44–48, and 220–223) and Fullerton (1991, pp. 206–207).

Alvarez (1988), Schuster (1986), and Netzer (1997) provide overviews of the relationship between tax policies of various types and preservation and conservation. Fogelman (1990) considers how the United States might adopt a set of tax rules that would foster preservation of the heritage based on the British system for protecting the national heritage. Schuster, de Monchaux and Riley (1997) discuss tax incentives in the context of a fuller presentation of the range of government tools used in preserving the built heritage. Interestingly, this cultural subfield, more than others, has led to the broad publication of information leaflets by governments seeking to explain the application and enforcement of the relevant tax rules and tax incentives. Finally, in his overview of economic policy issues in the arts O'Hagan (1998, pp. 104–130) devotes a chapter to questions of taxation. This chapter provides a summary and update of what is known about the role of taxation in cultural policy. Notably, it includes a section on the value added tax (VAT), which has been underemphasized in other work (including the current chapter).

#### 2.4. Putting tax policy back on the cultural policy agenda

Two factors have recently focused attention firmly back on tax policy. First, with the widely held perception that there has been a general decrease in the availability of direct public resources for culture, a search has begun for other sources of support and for ways to provide incentives for those other sources. Second, with the growth in the use of forms of decentralization, désétatisation, and devolution in cultural policy [Boorsma, Hemel and van der Wielen (1998)], increased attention has been paid to tax policy as a way of spreading decision making concerning public resources more broadly, since benefits in the form of forgone taxes follow the disaggregated decisions of individuals or organizations. Together, these factors have once again turned the field's attention toward cataloging and understanding the tax regimes currently in effect in various countries with one eye toward finding models of effective implementation and the other toward reconciling and integrating different regimes across countries.<sup>19</sup> Thus, the most recent contributions to the literature on tax policy and cultural policy are studies completed by the Regional Observatory on Financing Culture in East-Central Europe (the "Budapest Observatory") for the Council of Europe [Inkei (2001)] and a comparative study completed by the staff of the International Federation of Arts Councils and Culture Agencies (2003). These reports are, in turn, part of a broader literature that has focused on developing civil society with a strong nonprofit sector, particularly in Central and Eastern Europe. Thus, careful attention is being paid to the development of appropriate legal structures in these countries [International Center for Not-for-Profit Law (2002)].

Inkei (2001) captures nicely the current perspective of the field with respect to research on tax-based incentives in cultural policy. It is wary of individual and corporate influence, and laments the passing of high levels of central government support, but

<sup>19</sup> Much of the activity in this regard has been in the European Union, focused on facilitating the flow of artistic workers across national boundaries.

it also mixes optimism and advocacy with a healthy dose of skepticism. Inkei's report focuses on the tax treatment of corporate support with much less discussion of individual support, reflecting this report's emphasis on Central and Eastern Europe where it is believed (hoped?) (feared?) that corporations will provide the first important entrée to private support. Accordingly, the report carefully distinguishes between sponsorship – a commercial transaction – and a donation – a charitable gift – in the Anglo-American tradition, a distinction that is critical to maintain when trying to untangle current laws and procedures (sponsorship, for example, usually incurs VAT because it is construed as a purchase of a service, while donations do not; sponsorship may also cause a taxable “profit” for the organization in receipt of the sponsorship). In certain national contexts the tax treatment of corporate sponsorship looms large in cultural policy, as corporations move more and more sponsorship money into the arts and culture and as countries search for ways to get corporations to pick up an increasing proportion of cultural support.

Because private support for culture is a small part of private support to all kinds of charity and nonprofit causes, governments and social scientists tend to address the issue of private support to culture in the wider contexts of philanthropy, charity, the development of civil society, and the definition and regulation of nonprofit organizational forms. Inkei (2001) provides a rough estimate that internationally perhaps 10 percent of private philanthropy flows to culture. This estimate seems generous given that a much more reliable estimate for the United States calculates that in 2001 5.7 percent (\$12.14 billion) of total contributions to nonprofit organizations (\$212.0 billion) went to the arts, culture, and humanities [AAFRC Trust for Philanthropy (2002, p. 11)]. It is possible that because national laws restrict tax incentives to a narrower range of recipients and that cultural organizations are often designated recipients, the relative portion of tax-incentive-eligible donations flowing to the arts and culture is higher elsewhere. It is also possible that the arts and culture are used as the wedge sector to argue for tax incentives, thus becoming at least for a while one of the few sectors to benefit.

Whatever this proportion, one of its implications is that less analytic attention has been paid to the cultural sector (or, for that matter, to any particular sector) than has been paid to the economics of philanthropy as a whole.<sup>20</sup> Thus, much of the work that I am forced to rely upon later in this chapter will be based in the broader literature of tax policy with little reference to cultural policy. Moreover, much of what one sees in the arena of indirect aid can be better explained through political science than through economics. Nevertheless, economics remains a critical tool of analysis.

### 3. The purpose of tax policy vis-à-vis the arts and culture

Tracking the impact of tax policy on the arts and culture would be simplified if tax law had a single objective. But, as he points out in his remarkably succinct article on the

<sup>20</sup> See further Chapter 37 by Katz in this volume.

theory of the tax law treatment of nonprofit organizations in the United States (and, by extension, elsewhere), *Simon (1987)* identifies what he calls the four main functions of tax law: a financial support function providing assistance to the nonprofit sector; an equity function embodying the principles of fairness, redistributive equity and the pursuit of the public interest through the resulting incentives; a police function assuring that trustees, organizational managers, and donors are operating broadly within the public interest; and a border patrol function assuring that distinctions between the nonprofit sector and the for-profit and governmental sectors are clearly defined. But all of these are, of course, ancillary functions of tax law, the primary function being the raising of revenue for public purposes. Here is where the question of tax policy gets tricky because on the one hand there is a desire to make tax revenue collection as clean and straightforward as possible, yet on the other hand there is a desire that grows out of the concerns of various sectors of policy such as cultural policy to use tax policy as a locus for providing incentives or disincentives.

### *3.1. Defining the tax base v. providing incentives*

At the heart of any policy concern vis-à-vis tax law is a concern about incentives: what economic behavior has been given an impetus and how well has that impetus worked? But here lies a fundamental debate that has always affected – and continues to affect – the framing and analysis of tax policy. What appears to one person as a tax incentive, appears to another merely as a way of defining the base upon which taxes are to be collected. Where one comes down in this debate has shaped rather dramatically how one feels about the use of tax law in this manner.

In the United States the Second Revenue Act of 1917 provided for the deduction from income of donations made to charitable organizations. This was done for several intertwined reasons [*Wallace and Fisher (1977, pp. 2131–2132)*]. The act substantially increased income tax rates to fund America's involvement in World War I – the income tax itself had only been implemented a few years earlier. Yet there was a fear that this tax increase would curtail private support of public charities. It was argued that if private funding were to decrease considerably, the public sector would have to step in with increased support. At the same time it was also argued that charitable donations came from whatever surplus an individual felt that he or she had in income and that taxation would unduly limit that surplus, which might otherwise be deployed to public good through charitable contributions. Others argued that an income tax without a deduction would have the effect of imposing a tax upon the charitable recipients themselves, as donors would give less than would otherwise be the case because of the increased taxation on income. These arguments all amount to more or less the same thing, arguing in essence that the charitable deduction was actually a “hold harmless” provision, leaving charitable contributions untouched by income taxation. Some others went so far as to assert that individuals should not be taxed on that part of their income donated to charity, arguing in effect that income tax should only be imposed on consumable income.

These ideas about tax deductibility for charitable contributions persist in much of the discussion today. And they all lead to more or less the same place – the conclusion that the charitable deduction is best framed and best understood as *tax-base defining* rather than as an *incentive*, effectively taking questions of the actual incentive effect off the table.<sup>21</sup>

Still, this conceptual debate has raged for decades, particularly since the work of the [Commission on Private Philanthropy and Public Needs \(1977\)](#). Volume IV of its published research papers provides a useful summary of this debate, as does [Simon \(1987, pp. 73–76\)](#).<sup>22</sup> But the battle was most directly joined with the publication in 1973 of Surrey's book, *Pathways to Tax Reform*. As has already been mentioned, in this volume Surrey laid out the process of "tax expenditure analysis" in which he analyzed taxes forgone by the federal government for reasons unrelated to the purpose of the tax instrument itself as carrying the same fiscal and incentive effects as direct government expenditures. He also argued for the regular compilation of a "tax expenditure budget" which would detail the amount and the purposes of various forms of forgone taxes, a practice that has been adopted by the federal government as well as by many states.<sup>23</sup> This book, a seminal contribution to the analysis of the differences between direct and indirect government aid, shaped much of the later research, including [Feld, O'Hare and Schuster \(1983\)](#).

From an economic point of view, however, this philosophical debate is something of a diversionary tactic, obscuring the fact that changes in the various parameters of tax law – marginal tax rates, income brackets, income averaging provisions, and floors and ceilings on deductibility, not to mention outright changes in rules on deductibility – inevitably act to change the attractiveness of donations at the margin. In a system that allows the deduction of charitable donations from income before calculating the tax owed, an increase in marginal tax rates will make a charitable donation look less expensive (i.e., more attractive) to a donor. And a provision that would allow charitable deductions to donors who otherwise would only take the standard deduction (i.e., not itemize their deductions) would make charitable donations less expensive for taxpayers who take the standard deduction. On the other hand, a decrease in marginal tax rates would make donations more expensive (less attractive) for donors who itemize their deductions. Thus, whatever the origins of the tax provisions under consideration, there is considerable analytic leverage in understanding their incentive effects. One need look

<sup>21</sup> They also lead logically to the conclusion that a *deduction* from income rather than a *credit* against taxes is the appropriate way to structure this "hold-harmless" provision.

<sup>22</sup> See also the sources cited in [Feld, O'Hare and Schuster \(1983, footnote 8, p. 244\)](#).

<sup>23</sup> Tax expenditure budgets, where they exist and are done well, can be a boon for cultural policy researchers who are looking at the indirect side of government policy. In a recent report on the cultural policy of the State of Washington, for example, [Schuster et al. \(2003\)](#) benefited greatly from Washington's careful and detailed tax expenditure analyses [[Taylor \(2000\)](#)], but not all states make it their business to collect such detailed information. [Mikesell \(2002\)](#) provides a nice summary of the state of the art in tax expenditure budgets at the state level.

no further than to the furious lobbying emanating from the charitable nonprofit sector at moments of tax reform to understand that they see the question of receiving the benefit of forgone taxes primarily, if not exclusively, through the lens of incentives.

It is not then too large a step to evaluate the flow of forgone taxes in much the same way that one would evaluate direct subsidy; indeed, one can usefully consider forgone taxes as the functional equivalent of government subsidy. And, as [Simon \(1987, p. 75\)](#) points out, no less an authority than the US Supreme Court in a 1983 decision came down on the side of interpreting tax exemptions as subsidies: “[T]ax exemptions and tax deductibility are a form of subsidy that is administered through the tax system . . . [with] much the same effect as . . . [or being] similar to cash grants . . . [thereby constituting an expenditure of] public moneys.”<sup>24</sup> In more recent decisions, however, the Supreme Court has been inconsistent in this view, particularly when it comes to tax provisions affecting religious organizations, for which the constitutional principle of separation of church and state makes it more difficult to sustain the idea of tax provisions as incentives.<sup>25</sup>

Still, the debate between incentive provision and tax base definition has not entirely gone away.<sup>26</sup> And one would do well to remember that it is not yet true that “incentive” is seen as a neutral term in all national contexts. For example, [Inkei \(2001, p. 1\)](#) points out that while it is perfectly logical for the phrase “tax incentive” to be used to characterize such fiscal mechanisms in many countries, in some parts of Europe (particularly Central and Eastern Europe) this way of framing these policy mechanisms is somewhat controversial: “There is a feeling . . . that these approaches imply that the government is simply ‘bribing’ taxpayers to giving ‘protection money’ to culture.” Thus, the concept of tax forgiveness as an incentive as opposed to a base-defining provision remains controversial.

### 3.2. *Individual v. collective decision making*

Somewhat less evident in the debate about the effects of tax incentives is a question about the properties of various decision-making mechanisms in public policy. The trade-off between implementing policy through tax incentives as compared to more direct means can also be seen as one between individual and collective decision making. Few authors have addressed this trade-off head on [[Schuster \(1996, 2001\)](#)], and none except [Feld, O’Hare and Schuster \(1983, pp. 104–129\)](#) has brought any empirical analysis to bear on this question. Generally speaking, the use of tax incentives values individual over collective decision making: individual donors not only decide how their private net-of-tax contribution is to be allocated, but they are also accorded the right to make the same decision with respect to the forgone taxes in the transaction; museums and

<sup>24</sup> *Regan v. Taxation Without Representation of Washington*, 461 US 544-5 (1983).

<sup>25</sup> I am grateful to Alan Feld for pointing this out to me.

<sup>26</sup> See, for example, [Yarmolinsky \(2000\)](#).

other cultural institutions that own property in effect make their own decisions as to how much of a property tax exemption to take advantage of by their decisions concerning how to treat their land and buildings; and so on.

The policy-analytic task here is to compare the important attributes of one support system with another. The problem is disentangling the implications of the various decision-making mechanisms in use. Consider first direct aid. In the American context it is often assumed that the appropriate collective decision-making mechanism in direct funding of the arts and culture is peer review, in which a panel of one's peers evaluates and chooses among competitive applications for support.<sup>27</sup> But peer panel review is not the only form of collective decision making that is used. In some situations formulas are used to determine funding amounts; in others legislatures use line-item budgeting, thereby making funding decisions themselves; in still others the staff of cultural agencies make these decisions; and in yet others public referenda are used to determine the allocation of public resources [Frey and Pommerehne (1989); Frey (2000, pp. 115–129)]. Because of the intermingling of funds that arrive through a variety of mechanisms, in the end it becomes nearly impossible to separate the effects of one type of direct decision making from another. Nor are tax-incentive-based funding schemes the only form of individual decision making: publicly-funded vouchers by which individuals are given the ability to distribute collective resources according to their own preferences are another example,<sup>28</sup> matching grants are another, and self-directed allocations of a portion of one's tax payments yet another [Vajda and Kuti (2002)].

It may be that a society has an inherent preference for one type of decision making over all the others. Implicit in the move toward greater private influence in arts funding decisions is the assumption that the decentralized decisions made by a wide range of individuals would lead to results that would be superior to any of the candidate collective decision-making mechanisms. In other words, there may be a policy preference for a particular form of decision making, a preference that might outweigh any concern about economic effectiveness. Of course, one might also be concerned about exactly *what* decisions are made under each form of decision making. Do they align themselves with articulated public policy, or do they diverge from that policy, forcing public policy to compensate in some manner? Many of the idiosyncratic stories that are told about the eccentricities of individual donors to cultural institutions are evidence of this concern [Feld, O'Hare and Schuster (1983, pp. 130–178)].

Thus, as we turn to narrowly economic questions in the next section, it is important to remember that the *economic results* of any particular form of public support are not the

<sup>27</sup> Some attention has been paid to the attributes of peer panel review in cultural funding [Wyszomirski (1990); Independent Commission (1990); Galligan (1993); Brenson (2001)], though more attention has been paid to it in the field of science funding. There is much more work to be done here.

<sup>28</sup> With respect to vouchers, Schuster (1994) discusses the success of the Wintario Halfback Program, a voucher program in which losing lottery tickets in a dedicated lottery became vouchers at half their face value. With respect to matching grants – and their close affinity with tax incentive schemes – see Schuster (1989b).

only outcome of policy concern. We might value *particular forms* of decision making over others as a matter of policy, particularly if a comparison of *what* decisions are made under those various forms of decision making indicates that particular ways of arranging the system act more effectively to pursue articulated policy.

#### 4. The economic effects of tax exemption

##### 4.1. Introduction

The key economic question in considering the effects of tax deductions and credits lies in the cost–benefit analysis of that effect. Do the benefits to the public outweigh the costs? Once all of the other philosophical matters concerning direct versus indirect aid are resolved, this is the one question that remains. This section considers tax exemptions for charitable donations as but one example of tax exemptions vis-à-vis the nonprofit sector. The focus will be on charitable giving by individuals because, in the United States at least, individual charitable giving is a much more important source of support than are other sources of donations (Table 2); in 2001 individuals accounted for more than three-quarters of total charitable contributions (and an additional 8 percent through bequests).

These data reflect the importance of private initiative and the nonprofit sector in the provision of the arts and culture in the United States. Clotfelter (1985, p. 1) makes this point quite clearly:

“Although the interrelationships that have evolved between government, nonprofit institutions, and the legal structure are the result of hundreds of years of complex social development, it seems by no means accidental that this special reliance on nonprofit institutions and . . . favorable tax provisions have developed side by side.”

Table 2  
Total charitable contributions in the United States, 2001

	Contributions to all charitable organizations (\$ billion)	Percentage
Individual donors	\$160.72	75.8%
Bequests through estates	\$16.33	7.7%
Foundations	\$25.90	12.2%
Corporations	\$9.05	4.3%
Total	\$212.00	100.0%

Source: AAFRC Trust for Philanthropy (2002, p. 169).

Note: Unfortunately *Giving USA 2002* [AAFRC Trust for Philanthropy (2002)] does not provide sufficient information in its summary report to reconstruct comparable percentages for giving to the arts, culture, and humanities.

#### 4.2. *The price elasticity of individual giving*

The key to addressing the tax effect of an exemption for charitable donations is to notice that the tax incentive decreases the marginal price of giving: with no tax incentive it costs the private donor \$1.00 in after-tax income to get \$1.00 to a charity, but with a tax incentive it costs only \$1.00 times one minus the applicable marginal tax rate.<sup>29</sup> Seen from this perspective, the fundamental question is whether, in the presence of the tax incentive, total private net-of-tax giving goes up by more than the amount of forgone taxes. This reduces to a question of the price elasticity of giving: what percentage change in giving is engendered by a one percent decrease in the price of giving? In the literature this has been termed the “treasury efficiency” of the tax incentive.<sup>30</sup>

Economic theory would predict the sign of the price elasticity of giving to be negative – an increase in the price of giving at the margin is expected to result in a decrease in the total contribution.<sup>31</sup> But the question of whether or not that elasticity will be less than  $-1.0$ , the boundary between elasticity and inelasticity, is an empirical one. If the absolute value of the elasticity is greater than one, giving is price elastic – it more than responds to changes in the marginal response – and the total contribution increases by more than the tax expenditure alone. In other words, the tax expenditure has sufficiently leveraged increased private funds to justify the cost of the incentive. It is this potential that makes tax incentives for charitable donations an attractive proposition for governments: the possibility that a tax incentive will actually increase the revenues flowing to the favored sector in an amount that is greater (and, hopefully, much greater) than the forgone taxes.

As one might imagine, economists have attacked the estimation of the price elasticity of giving with considerable energy and ingenuity. Unfortunately, even after some forty years of research on this question a clear consensus has yet to emerge. In the earliest summary of the existing research of which I am aware, Clotfelter (1985, pp. 56–63) summarized sixteen economic analyses of charitable contributions in the United States. While the earliest of these, conducted in the 1960s, estimated low price elasticities – negative but with an absolute value of less than one – many later studies returned price elasticities that were negative and with an absolute value greater than one, suggesting an emerging consensus that charitable contributions were price elastic and did respond (at least in the United States) as had been predicted and hoped. Fullerton (1991), in his attempt to apply the accumulated research findings on tax incentives to arts museums, concurred:

<sup>29</sup> In a regime based on a tax deduction, this is simply one minus the donor’s marginal tax rate; in a tax credit system, it is one minus the rate at which the credit is being offered.

<sup>30</sup> A clear and concise summary of these and other issues is contained in Cordes (1999).

<sup>31</sup> One needs to be particularly careful in interpreting the accumulated literature on this point because some authors either have neglected to carefully record these negative signs or have chosen to represent the price elasticity with respect to marginal tax rate rather than with respect to price. Thus, negative signs in some studies have the same meaning as positive signs in others. In this chapter, I have chosen to maintain the use of negative signs by focusing on the price elasticity of giving.

Figure 1. Components of the total contribution.

“Early research tended to find elasticities less than 1 [in absolute value] . . . but more recent work has found larger responses . . . These price elasticity estimates are all close to each other, especially considering the substantial differences in the nature of the data and the level of aggregation. More recent research concludes that the price elasticity of charitable giving is greater than 1 [in absolute value], though perhaps not much greater than 1. This implies that donees receive more than the government loses in tax revenue” (p. 212).

But then methodological questions were raised. In 1990 Steinberg summarized a new set of studies using panel data rather than cross-sectional or time series data in their estimates. These studies tended to conclude that giving was inelastic with respect to price, rather sobering news for the proponents of tax incentives. In a more recent summary Steinberg (2003) makes reference to ten more cross-sectional studies and eight more panel studies, concluding that the earlier pattern continues to hold, with cross-sectional data suggesting price elasticity, and panel data suggesting inelasticity.<sup>32</sup> In a recent paper not summarized by Steinberg, Tiehen (2001) uses an intermediate dataset: a cohort panel constructed from a series of household surveys on charitable giving. Her estimates of the price elasticity vary between  $-0.9$  (somewhat inelastic) and  $-1.1$  (moderately elastic). Thus, the debate continues.

To understand more fully the implications of these results, it is useful to return to Feld, O’Hare and Schuster (1983). They approached the analysis of charitable contributions in the presence of tax incentives by carefully disaggregating the total charitable contribution into its component parts (Figure 1): The “base gift” is the gift that a donor would have made in the absence of any tax incentive. The “total contribution” is the total gift that she would choose to make in the presence of the tax incentive. The components of the total contribution include the base gift plus any “tax expenditure” that has been realized in the transaction plus any increase that might have occurred in the

<sup>32</sup> Steinberg (2003) points out that there has been some suggestion that the disparity between these two approaches may be partially due to misspecification of the error distribution in panel studies rather than in analysts’ ability to control for unobservable individual-specific effects with panel data [Barrett and McGuirk (1992)].

Table 3  
The components of individual charitable giving, United States, 1973 (\$ millions)

	Private contribution		Tax expenditure	Total contribution
	Base gift	Induced gift		
Total charitable giving	\$12,027 69.0%	\$840 4.8%	\$4570 26.2%	\$17,437 100.0%
Giving to cultural institutions	\$118.56 36.6%	\$24.04 7.4%	\$181.6 6.0%	\$324.2 100.0%

Source: Feld, O'Hare and Schuster (1983, p. 43) analysis of data from the Commission on Private Philanthropy and Public Needs, National Study of Philanthropy, 1974.

Notes: Estimated tax expenditures do not include capital gains forgone on gifts of property.

A price elasticity of giving of  $-1.24$  as estimated by Feldstein (1975a) is used for all income classes of donors and all charitable sectors to arrive at these estimates.

donor's private net-of-tax gift; this last component can usefully be referred to as the "induced gift". The sum of the base gift plus the induced gift is the donor's total "private contribution".

What would be most desirable (and expected) would be for the induced gift to be positive, indicating that the tax exemption is working as intended, but it is also possible that the induced gift will turn out to be negative, indicating that the donor has taken advantage of the tax expenditure to reduce her private contribution below the base gift.<sup>33</sup>

Feld, O'Hare and Schuster (1983) estimated separately the base gift, the induced gift, and the tax expenditure components of total giving to all charities and total giving to cultural institutions. This is the only attempt of which I am aware in either the arts literature or the more general literature on charitable contributions to make such estimates. Using data from the 1974 National Study of Philanthropy and an estimated price elasticity of  $-1.24$  for all income classes and for all charitable sectors – an elasticity chosen to represent the apparent academic consensus on the price elasticity at the time in which they were working – they arrived at the set of estimates shown in Table 3. Note, however, that these estimates are for a year in which marginal tax rates were much higher than they are now in the United States and that they are based on a dataset that has been criticized [O'Hagan (1998); Jencks (1987)].

While too outdated to provide much insight into the working of American tax incentives some thirty years later, this table is at least helpful in highlighting an issue that has not received sufficient treatment in the literature on the use of tax incentives in public policy: the leveraging effect of the tax incentive. The estimates in Table 3 indicate that in 1973 it took a tax expenditure of nearly \$4.6 billion to induce additional private giving of \$840 million, a ratio of 5.44:1.00. In other words \$5.44 in tax payments

<sup>33</sup> The induced gift might also turn out to be zero, indicating that the donor has simply increased her contribution by the amount of the forgone taxes, leaving her with the same private net cost for the total contribution.

were forgone for every additional private donation of \$1.00 to charity. To be sure, the \$5.44 went to charity as well, directed by the donor within whose contribution it was included, but a critical question remains: Is it necessary to forgo \$5.44 to get \$1.00 to flow (and an additional \$6.44 to arrive), or are there other ways to structure an incentive that would accomplish the same result at lesser public cost?<sup>34</sup> Because donors to the arts and culture have higher incomes than the average donor to charity, these figures are even more extreme for culture. A tax expenditure of \$181.6 million resulted in an additional induced private gift of \$24.04 million, a ratio of 7.55:1.00. Thus, in the field of the arts and culture \$7.55 in taxes were forgone in order to get each additional \$1.00 to flow in private contributions.

#### 4.3. Tax incentives as matching grants

Framed in this way, a tax incentive for charitable contributions looks very much like a matching grant. Indeed, this is the whole premise of tax expenditure analysis: that tax breaks can be construed and evaluated as though they were direct aid programs. It is therefore instructive to look at the practice of matching grants to support the arts and culture, an attribute of cultural support that is also seen to be American in origin.<sup>35</sup> Without turning in another analytic direction entirely, suffice it to say that when government agencies (or legislatures themselves) have implemented matching grants, they have tended to design them with leveraging ratios such as \$1.00 public money to \$1.00 “new” private money or \$1.00 public money to \$2.00 “new” private money. I am unaware of any that have been designed at anything near the \$7.55 public money to \$1.00 “new” private money ratio implicit in the tax incentive system for the arts and culture as analyzed by Feld, O’Hare and Schuster summarized above. Such a program design, if explicit, would be open to criticism as a poorly designed use of public money if its actual goal were to leverage increased private resources.

An economist considering the design of matching grants would of course focus on many of the same questions addressed here. What is the level of private giving in the absence of the matching grant (the “base gift”)? How much “new” money is attracted from other sources to the arts and culture that would not otherwise have come in the absence of the offered match (the “induced gift”)? How much does the public sector have to give up – this time in direct expenditure – to get the change in giving (the “tax expenditure”)? And finally does the use of more decentralized individual decision making in

<sup>34</sup> A more recent study by Price Waterhouse, cited by Brody and Cordes (1999, pp. 146–147), simulates the changes to total charitable contributions that would occur if the tax deduction were removed completely. Under the assumption that donations are “fairly responsive to changes in the after-tax cost of giving”, they estimate that this would reduce private giving by 32 percent including both the induced gift and the tax expenditure. While they present estimates by subsector, their estimates are arrived at by simply applying this 32 percent decrease to each of the subsectors of charitable giving, a not entirely satisfactory approach.

<sup>35</sup> For a fuller discussion of matching grants than is possible in the current chapter, see Schuster (1989b, 2001). McDaniel (1977) provides a nice presentation of how a more explicit matching grant system might be designed to replace the charitable deduction.

the matching grant system make it preferable from the public policy point of view? On these questions, [Eckel and Grossman \(2003\)](#) have conducted an experiment to ascertain how individuals respond to a subsidy structured as a rebate as compared to a mathematically equivalent one structured as a matching grant; they find that “contributions are significantly higher with matching subsidies than with rebate subsidies” (p. 681). If these results can be replicated, they suggest yet another reason besides transparency for restructuring indirect aid as direct aid – such a switch may also be more effective from a treasury efficiency point of view.<sup>36</sup>

#### 4.4. *Price elasticities by charitable sector*

Do different charitable sectors face different price elasticities of giving? [Feldstein \(1975b\)](#) has estimated price elasticities for various sectors, though not for the arts and culture (column 1, [Table 4](#)). Interestingly, giving to religious organizations is inelastic with respect to price whereas giving to each of the other sectors is price elastic. This is sensible, as support of the church is considered more as an obligation than as a voluntary contribution in many sectors of society. Moreover, many donations to religious organizations are more concentrated among low-income individuals (including individuals who take the standard deduction rather than itemizing their deductions and for whom any charitable exemption provides no incentive) than are donations to other charitable sectors. Giving to cultural organizations, on the other hand, is likely to be most similar to giving to other sectors favored by higher income individuals such as educational institutions or hospitals. If this assumption is true, then [Feldstein’s](#) work suggests that a one percent decrease in the price of giving should result in more than a two percent increase in giving to cultural organizations.

#### 4.5. *The income elasticity of giving*

The price effect is accompanied by a second effect – the income effect – which also must be accounted for. A decrease in the price of giving is accomplished through a decrease in the donor’s marginal tax rate. If the donor’s marginal tax rate decreases, his taxes decrease and his net after-tax income therefore increases. As a result, the donor’s contribution may go up. Thus, one also needs to model the income effect on donations.

[Feldstein \(1975b\)](#) has estimated that giving is only elastic with respect to income for educational institutions and hospitals (column 2, [Table 4](#)). But because his data do not allow the separation of arts and cultural organizations, it is difficult to apply his results to this sector. I am unaware of any other attempts to disaggregate income elasticities by charitable sector, so there is little further information concerning what the impact of income changes might be on donations to the arts and culture.

<sup>36</sup> But note that in the United States, depending on the design of particular funding programs, charitable donations may be eligible for a tax incentive *and* attract a matching grant, thus providing an even greater incentive for giving.

Table 4  
Price elasticity of giving, various charitable sectors

Type of donee	Price elasticity of giving	Income elasticity of giving
Religious organizations	-0.49	0.63
Educational institutions	-2.23	1.22
Hospitals	-2.44	1.08
Health and welfare	-1.19	0.85
All others	-2.63	0.65

Note: Negative signs have been added where necessary to be consistent with the mode of presentation in this chapter.

In a summary of sixteen economic analyses of individuals' total charitable contributions in the United States, Clotfelter shows that while the earliest (pre-1970) study of charitable giving estimated income elasticities of giving well over 1.00 – from 1.31 to 3.10 depending on income class – later studies have generally estimated positive income elasticities but ones that are less than 1.00 [Clotfelter (1985, pp. 56–63)]. Steinberg (1990) summarizes an additional 24 studies that benefit from new methodological approaches and the availability of new datasets, particularly panel data. In these studies, income elasticity is uniformly positive but nearly without exception less than +1.00, indicating that charitable giving is inelastic with respect to income.

Apart from price and income elasticities, the literature on tax incentives also includes studies of other independent variables such as the donor's income level, her educational level or her relationship to the recipient organization to determine what their effect is on charitable giving. Other studies focus on alternative dependent variables to look at other effects of tax provisions. One vein of this research is concerned with the impact of tax law on charitable bequests, another has looked at how changes in tax law affect the timing of donations, and yet another asks about the relationship between volunteering and making contributions – to what extent do changes in tax law lead to changes in the relative amount of time dedicated to volunteering, and how do those changes interact with changes in charitable donations? Steinberg (2003) provides a short summary of the relevant results on each of these questions.

#### 4.6. The economics of corporate contributions

Some econometric work has been done on corporate contributions. Though the impact of these contributions in the United States is considerably less than the impact of donations by individuals – as we have seen, corporate donations were only 4.3 percent of total charitable giving in 2001 as compared to 75.8 percent for individual giving – it is worth considering the available findings because of the general (false) impression that

Table 5  
Income elasticities for corporate contributions by charitable sector

	Art	Civic	Education	Health	Total
Linear model	+0.82	+0.58	+0.66	+0.24	+0.56
Double log model	+0.80	+0.75	+0.97	+0.82	+0.85
Full Box-Cox model	+0.86	+0.78	+0.92	*	+0.81
Single Box-Cox model	+0.80	+0.75	+0.94	+0.78	+0.84

Source: Navarro (1988, pp. 71–72).

\*The model failed to converge for this category.

corporate donations do (and must) play a critical role in a tax-incentive-based support system.

In the United States, charitable contributions by corporations are deductible from income prior to calculating taxes owed in much the same way that an individual's contributions are deductible. The primary differences are that corporate tax rates are much lower than the highest marginal tax rates for individuals and that ceilings on contributions are lower. Generally speaking, models of charitable corporate giving do not focus on the individual firm; rather, they use data aggregated by industry groups or by corporations as a whole. Once again, Clotfelter (1985, pp. 203–205) provides a summary of the results of a set of studies that have used a wide variety of mathematical forms and data sources. The two studies that are based on time-series data estimate price elasticities ranging from  $-1.03$  to  $-2.00$  depending on the model specification, suggesting that charitable organizations receive more in contributions from corporations than the government forgoes in taxes. These two time-series studies disagree on the question of the income elasticity of corporate giving: one estimates income elasticities in the  $+0.53$  to  $+0.63$  range, but the other estimates income elasticities that are greater than  $+1.00$ . Once again, cross-sectional data produce different results from time-series data. For a wide variety of cross-sectional studies with a wide range of model specifications, the income elasticity is estimated as being positive, but lower than  $+1.00$ .

Navarro (1988) also takes a look at the income elasticity of corporate contributions. First, he summarizes earlier studies – many of the same ones summarized by Clotfelter (1985) – that calculated income elasticities ranging from as low as  $+0.03$  to as high as a surprising  $+2.37$ .<sup>37</sup> Navarro's work is one of the few attempts to disaggregate elasticities by sector (Table 5).

According to his linear model, “only the arts category appears to be at all elastic” but with respect to each of the other model specifications, corporate contributions appear to be similarly moderately elastic across all charitable sectors. He concludes (p. 73):

<sup>37</sup> One study even reports a negative income elasticity in one of its ranges of  $-0.27$ !

“The finding that corporate contributions are moderately income-elastic has implications for both the philanthropic sector, which relies on corporate largess, and for the federal government, which has some responsibility to meet welfare needs. For the philanthropic sector, this finding means that charitable organizations and their recipients are as exposed to variations in the business cycle as for-profit institutions. This vulnerability underscores the need for aggressive fundraising efforts, particularly during recessionary times. For the federal government, this finding would appear to vitiate the argument that corporations, rather than the federal government, can be relied upon to meet social welfare needs in times of recession or depression.”

An analytic understanding of corporate charity is further complicated by the rise of corporate sponsorship, particularly in the field of the arts and culture. It is helpful to keep clear the distinction that is generally drawn between corporate *sponsorship* and corporate *philanthropy*. Corporate sponsorship is the expenditure of corporate funds to advance the image of the corporation; typically, it is not tied to the sale of particular products or services but is part of the corporation’s advertising expenditures (and therefore typically deductible without limit from the corporation’s income before calculating taxes). Corporate philanthropy on the other hand is given with no expectation of a return to the corporation other than increased goodwill; corporate philanthropic contributions are only deductible from income to the extent allowed by national laws (which vary widely on this question).

Any number of countries that have moved to introduce tax-based incentives for private support for the arts and culture have begun with incentives targeted at corporations rather than at individuals. This seems to have been done for two reasons: first, an attempt to model themselves after the “American system”, which is widely (mis)perceived to be primarily constructed around corporate support, and second, a belief that corporations provide the easiest place to begin to attract increased private support, a belief which in turn has led to an emphasis on sponsorship rather than philanthropy. These countries have concluded that such a system has to be built on clear self-interest – in this case the self-interest of the corporate donor. This has led to considerable confusion between the ideas of “sponsorship” and “philanthropy”, so much so that in many countries “sponsorship” has been adopted as the more general term to describe both types of support. Not surprisingly, this has created nagging analytic problems for researchers trying to untangle the economics of corporate support.<sup>38</sup>

#### 4.7. Studies of charitable giving in other countries

To what extent are the American results summarized here replicated in the other countries that now provide tax incentives for charitable contributions in one form or an-

<sup>38</sup> See Schuster (1985b) for a discussion of this issue.

other?<sup>39</sup> Most of these countries have adopted the income tax deduction following the American system, though often with more restrictive limits on the class of eligible recipients and on the minimum and maximum donation for which a tax benefit can be realized. This system allows a donor to deduct her charitable contribution from her income before calculating the income taxes that are owed. As has already been suggested above, in such a system the donor's incentive is a function of her marginal tax rate, which in turn is a function of her income; thus higher income donors benefit from higher price incentives. Other countries including Canada (which has systematically been replacing deductions with credits), Hungary [Vajda and Kuti (2002, p. 4)], and Israel make use of the tax-credit system of providing incentives. This system establishes a particular percentage at which the credit will be offered. In effect, the donor multiplies that percentage by her charitable contribution and then deducts that credit from her tax bill. In such a system, the price incentive is the same for all donors eligible for the credit. Finally, several countries including the UK, Ireland, and Denmark make use of a third system, the deed of covenant, which allows charities to recoup taxes already paid to the government by a donor when a donation is actually made [Schuster (1989a)].<sup>40</sup> Some specific examples of the international move towards tax-based incentives are discussed in Section 5 below.

Studies of the effectiveness of these systems have been undertaken in several countries.<sup>41</sup> In two early studies, Hood, Martin and Osbert (1977) analyzed Canadian giving, while Pacque (1982) analyzed giving in the Federal Republic of Germany. In both cases their price elasticity estimates were broadly consistent with those estimated for US data. But later studies for the UK and Canada have concluded that giving appears to be price inelastic in these countries [Steinberg (1990, p. 74)]. Using UK data Jones and Posnett (1990) found that the price of giving was a large and statistically significant determinant of *making* a charitable gift, but it was not determinant of the *size* of the gift.<sup>42</sup> Two recent studies of charitable giving in Singapore – Wong, Chua and Vasoo (1998) and Chua and Wong (1999) – report price elasticities that are quite high, especially if those donations are given to organizations that are members of the Community Chest, which itself

<sup>39</sup> A number of summaries of tax incentives by country have been published, though they are generally incomplete and often suffer from poor descriptions of the tax provisions actually in force. See, for example, Weisbrod (1991), International Center for Not-for-Profit Law (2002), Schuster (1986), and Inkei (2001); the last two are particularly concerned with tax incentives as they impact the arts and culture. The International Federation of Arts Councils and Culture Agencies (2003) has also undertaken a survey of research on the encouragement of philanthropy in the arts; this survey is available on their website ([http://ifacca.org/en/organisation/page04\\_research.html](http://ifacca.org/en/organisation/page04_research.html)) and is updated as further information becomes available.

<sup>40</sup> More recent changes in tax law in the UK include elements of the American charitable deduction, which have been implemented on top of and in addition to the more traditional structure of the British deed of covenant.

<sup>41</sup> I am grateful here to Steinberg (1990) who provides much of this summary.

<sup>42</sup> But note that this study was of a rather different system of offering tax incentives – the deed of covenant – so it is difficult to apply these results to a system reliant on charitable deductions. For a detailed discussion of the deed of covenant, see Schuster (1989a), but note once again that a variety of other tax-based incentives for charitable giving have been added to British tax law since 1989.

serves as an additional source of charitable contributions to nonprofit organizations. On the other hand, in these studies donations are estimated to be relatively inelastic with respect to income.

#### 4.8. *Who pays and who benefits? The question of incidence*

The question of who pays for and who benefits from government support for the arts has been the topic of considerable debate but little actual research. In the words of Feld, O'Hare and Schuster (1983, p. 71): "[T]wo inconsistent views concerning the arts have developed: (1) cultural institutions represent a gift from the rich to the rest of society, and (2) all of society pays to support an entertainment for the rich." As we will see, the limited research on government support for the arts more generally and on indirect support through tax incentives more narrowly suggests that neither is the case. Three sources inform this debate: Feld, O'Hare and Schuster (1983, pp. 71–103), Netzer (1992), and, in a rather different manner, Cordes (2004). What is surprising about the results of these studies is that, despite findings that seem to be beneficial to the nonprofit arts, the field has not picked up on them.

Feld, O'Hare and Schuster worked with four datasets that in retrospect appear to be rather primitive: the 1975 *Americans and the Arts* survey by the National Research Center of the Arts, a subsidiary of Louis Harris Associates; the 1974 *National Study of Philanthropy* commissioned by the Commission on Private Philanthropy and Public Needs; the 1974 Ford Foundation report, *The Finances of the Performing Arts*; and the 1975 report, *Museums USA: A Survey Report*, commissioned by the National Endowment for the Arts from the National Research Center of the Arts. Paying careful attention to a number of analytical matters – drawing a distinction between visitors and visits, handling students differently from other adults, distinguishing between direct aid and the three components of charitable contributions (the base gift, the induced gift, and the tax expenditure), and using a set of commonly held benchmark assumptions about the incidence of the various sources of support – they were able to compare the incidence of indirect aid to direct aid to total income and to construct what is arguably still the most complete look at the question of incidence in arts funding, albeit an outdated one.

To those who paid attention the findings were astonishing:

"The existing system is mildly redistributive, transferring relatively small amounts of benefits down the income scale . . . On balance, income to the arts is paid for disproportionately by the very wealthy and is enjoyed more by the moderately wealthy and the well educated" (pp. 102–103).

"[T]ax expenditures redistribute benefits in roughly the same way as does the entire arts institutions' support system" (p. 94).

"[M]oving even significant amounts of current art support from the charitable deduction to any of the alternatives would not significantly change the distribution effects of the whole system" (p. 102).

Taken together these findings suggested that the arts funding system, both in its entirety and with respect to its various components, could not be criticized for being regressive, the result that the field most feared would emerge from any incidence analysis. But note that Feld, O'Hare and Schuster were working at a time when the marginal tax rates were significantly higher than they have been since. It is quite possible that this snapshot of incidence is no longer accurate, yet at least one other study suggests that the main conclusions still pertain.

In the early 1990s Dick Netzer was invited to revisit the question of incidence in arts funding in an edited volume that was to focus on this question across a number of nonprofit sectors. The resulting paper [Netzer (1992)] was able to take advantage of newer, more reliable datasets: the 1985 Survey of Public Participation in the Arts, commissioned by the National Endowment for the Arts, provided higher quality data on the recipients of benefits, and the 1985 Census of Service Industries provided a steadily improving source of data on the income profile of nonprofit organizations. Like Feld, O'Hare and Schuster, Netzer was careful to distinguish between the incidence of direct aid and indirect aid, though his analysis was not quite as disaggregated as the earlier study.

Netzer pointed out that redistribution is seldom a major goal of arts funding, and he took a rather skeptical view as to how the historical evolution of cultural institutions might affect how they actually function in this regard:

“[T]he redistributive goal from the outset often was very secondary to the primary goal of establishing clubs to make possible cultural experiences that would be enjoyed, if not solely by the very rich who were the initial organizers and backers, then by the relatively educated and affluent upper-middle-class” (p. 174).

Though not quite willing to conclude that the system is mildly progressive, Netzer's findings agree with Feld, O'Hare and Schuster:

“[T]he output of the arts and culture subsector of the nonprofit sector is consumed mainly by individuals and households whose income, wealth, and social attributes are well above the national averages. In this, the subsector is like its close relative in the nonprofit world, higher education. Like higher education, the distributional effects of the subsidies to the subsector would be considered objectionable by many people, were it not for the positive external benefits the subsector is believed to generate” (pp. 186–187).

“The bulk of the benefits of the activities of nonprofit arts and cultural organizations are realized by people in the upper half of the income distribution, but the frequent allegation that support of the subsector from tax funds and tax-deductible gifts is a transfer from those in the middle of the income distribution to those at the top of the distribution is a caricature” (p. 202).

More recently Cordes (2004) has conducted an “incidence analysis”, but one of a somewhat narrower sort. Working with data from the 1997 Economic Census and data from Internal Revenue Service Form 990 (a form required of over 7000 nonprofit arts

organizations) as collected and analyzed by the National Center on Charitable Statistics, he disaggregates the various sources of income (though it appears that he neglects to separate out the induced gift) in order to construct a picture of what types of institutions receive what types of income and in what amounts. Thus his approach to the benefit side of incidence focuses on type of organizational recipient rather than going one step further to try to associate audience volumes and demographics with organizational type.<sup>43</sup>

In asking how the benefits of public support, both direct and indirect, are distributed among arts organizations – an interesting public policy question in its own right – Cordes focuses on the age, the budgetary size, and the type of arts organization. His conclusions include the following:

“In terms of breadth of coverage, and also effective subsidy value, the charitable tax deduction remains as the single most important source of subsidy for most nonprofit arts organizations . . . A disproportionate share of total direct and indirect arts subsidies are [sic] estimated to be received by some arts providers, which, apart from art museums, do not include organizations engaged in providing what some might describe as ‘high art or culture’ . . . On balance, the overall pattern of subsidies seems neither to favor nor to penalize the entry of new nonprofit arts providers” (p. 229).

“The system provides larger total effective subsidies to larger than to smaller organizations” (p. 231).

Taken together, these three studies suggest that the system of arts support in the United States, largely based on the forgone taxes embedded in various tax incentives, cannot be faulted for its incidence. To be sure, one would not design the current system to pursue a goal of redistribution. Still, a number of interesting attributes of the funding system are revealed by incidence analysis, attributes that various policies might find attractive. Nevertheless, there is still considerable work to be done to research fully the question of incidence in the funding of the arts and culture.

#### 4.9. *Crowding in or crowding out?*<sup>44</sup>

Finally, the question of whether or not government support for the arts “crowds in” or “crowds out” other sources of support is another question that is typically asked of direct support but that can just as easily be asked of indirect support through the tax system. One of the main arguments often advanced in favor of direct government support to the arts and culture in the United States is that it provides a “Good Housekeeping Seal

<sup>43</sup> This paper also contains more recent set of estimates of tax expenditures for the arts and culture: Cordes’ conclusion is that roughly two-thirds of estimated total support of nonprofit arts and cultural organizations is in the form of tax incentives and preferences.

<sup>44</sup> For further discussion see [Chapter 35](#) by Netzer in this volume.

of Approval” to the recipient organization;<sup>45</sup> such recipients, it is claimed, can then use that seal of approval to attract other donations, particularly private donations taking advantage of tax incentives. In this view, direct public support can “crowd in” private support. Others have argued that the more support the government provides through direct means, the less private donors will see the need for their own donations. In this view, direct public support can “crowd out” private support. Either way, the result is of importance in an era in which direct government support is generally being rolled back.

What is the evidence in either direction? Once again, Steinberg (1991; 2003, pp. 284–285) provides useful summaries.<sup>46</sup> In his 1991 survey article he found that the available evidence and the accumulated research results suggested that there was modest and statistically significant crowding out, at least with respect to governmental social service expenditures. In his 2003 article (p. 284), he concludes, “New studies generally concur with the consensus of earlier studies that donations will replace only a small fraction of governmental cutbacks.” In other words the crowding-in effect is limited, at best. But he also points out that evidence suggesting a crowding-in effect is appearing from time to time with respect to certain charitable industries.

Several studies have focused on the arts and culture, and their results have made important contributions to the broader literature on crowding in and crowding out. Using data from the unpublished American Association of Museum’s 1989 Survey of Museums, Hughes and Luksetich (1999) consider the relationship between funding sources for art and history museums; they find evidence of crowding in. Their initial specification suggests that each \$1.00 of support to art and history museums from federal government sources results in an increase in private support – including individual, corporate, and foundation support – of more than \$9.33. An alternative nonlinear specification also supports the conclusion of crowding in – in this model each additional \$1.00 of federal funding results in additional private support of \$10.88 – but the crowding-in effect only stimulates private giving up to a certain point at which crowding out begins to take over. They attribute much of the observed crowding-in effect to the heavy use of matching grants in federal funding, which ties federal support to co-financing from other sources of support. In addition they cite evidence that increased federal support may cause some displacement of state and local government support. Finally they show differences across museum subsectors, concluding that decreases in federal funding would be likely to have a greater impact on art museums than on history museums as lower levels of government and private contributors adjust their giving to such decreases. Focusing even more narrowly within the cultural sector, Kingma and McClelland (1995) report crowding out with respect to donations to (nonprofit) public radio stations. They estimate that for this cultural subsector a \$1.00 increase in government support results in a \$0.15 decrease in donations.<sup>47</sup>

<sup>45</sup> The reference here is to *Good Housekeeping*, a popular American magazine that awards its “Seal of Approval” to goods and services that it determines to be of particularly high quality.

<sup>46</sup> A broader survey of “motivation crowding theory” is provided by Frey and Jegen (2001).

<sup>47</sup> See also Kingma (1996).

Brooks has written a series of papers exploring these questions in various segments of the arts. Using 1995 data on 91 public radio stations in the United States, he finds that public funding to these radio stations has a positive impact on private giving, but that this impact rapidly decreases as the level of government subsidy increases [Brooks (2003b)]. This analysis also suggests that increases in state tax rates correspond to significantly higher donation levels.<sup>48</sup> Brooks has also explored these questions using data on American symphony orchestras [Brooks (1999, 2000b)]. The first of these papers, using data from five major American symphony orchestras over twelve seasons, concludes that there is no causality in either direction. In the other paper Brooks uses American Symphony Orchestra League data for 253 symphony orchestras over eight concert seasons (1984–1991). Here a different model specification leads to a more nuanced result (p. 461): “At low levels of government funding, philanthropy might be encouraged, but beyond a certain point crowding out begins.” In another paper Brooks (2000a) considers four different charitable sectors; using federal spending on arts and culture from 1966–1997 he fails to produce a statistically significant result, though the results do show modest crowding in. Brooks attributes the ambiguity of these results to the fact that the dataset included only federal funding and not state funding, thus introducing a possible omitted-variable bias.

For the moment, the most responsible conclusion with respect to the crowding-in/crowding-out debate is the observation by Brooks (2000a, p. 213) that “the relationship between government subsidies and private philanthropy is highly dependent on the subsector, the level of government involved, and the specific dataset used in the analysis”.

#### 4.10. Conclusion

Much the same might be said of the broader literature surveyed above concerning the economic effects of tax incentives for charitable contributions: the results depend substantially on the model specification and the type of dataset used. For those who would argue in favor of tax-based incentives, at least with respect to charitable donations, there is considerable evidence in support of the view that such incentives would have the desired economic effect. But those who are dubious about the net effect can also find evidence to support their arguments. It is also clear, though not explicitly explored in the summaries that have been provided here, that cultural proclivities tend to be very important. If one looks at behavior in the aggregate rather than behavior at the margin, it is quite clear that in some countries, particularly the United States, there is a much

<sup>48</sup> Note, however, that the number of states that explicitly provide tax incentives for charitable giving is relatively small and that the effect of a state incentive is diluted by the structure of the federal income tax law. According to one report, only five states provide explicit incentives for charitable contributions in state income tax, but twenty-eight additional states simply adopt the federal deductions, which include a deduction for charitable contributions [Russell (2001)]. The interaction between federal and state tax incentives for charitable contributions is discussed further below (cf. footnote 65).

stronger tradition of private support for the arts and culture. When studying the data for other countries, it is necessary to keep in mind that despite the existence of tax-based incentives, the degree to which those incentives are taken up is a function of the extent to which the provision of the arts and culture is seen to be a private responsibility or a mixed government-private responsibility. Future research might do well to try to model these differences – for example, for a country like Canada where tax law is national but where there are important differences in charitable behavior between the French-speaking province of Québec and the English-speaking provinces. (These differences are even mirrored in the actual structure of government arts funding across the provinces.)

Despite the relatively ambiguous evidence on the effectiveness of tax-based incentives for charitable behavior, it is clear that there has been a strong international movement toward the provision of such incentives, often based on the American system of so-called “income tax deductions”.<sup>49</sup> In the final section of this chapter, I turn to a discussion of the proliferation of tax-based incentive schemes for the arts and culture throughout the world.

## 5. The international move toward tax-based incentives

Despite the ambiguity of the econometric evidence in the United States, the use of tax-based incentives is proliferating in other countries, not only to provide an incentive for increased private support in one form or another, but also to target a wide variety of specific cultural policy goals [Schuster (1986)]. Many countries now have such tax provisions, mostly providing income deductions, but some structuring the incentive as a tax credit.<sup>50</sup> There is considerable experimentation with the parameters of these incentives; floors, ceilings, “superdeductions” (deductions that are set at more than 100 percent of the actual contribution), and various forms of administrative oversight have all been adopted. Many countries are experimenting with a wide variety of tax-based incentives that go well beyond the realm of private individual or corporate philanthropy.<sup>51</sup> I have argued elsewhere [Schuster (1999)] that indirect aid is the terrain in which many of the most interesting innovations in the funding of arts and culture are taking place, though because of their hidden nature in the tax code they are not often recognized as such. In this proliferation one more often sees the influence of politics and advocacy than the influence of reasoned analysis. These points are most clearly illustrated through contemporary international examples; several will suffice.

<sup>49</sup> The widespread use of the unfortunate phrase “income tax deduction” in the United States has led to considerable confusion in other countries as to how the American charitable deduction actually works. As we have seen, it is structured as a *deduction from income* prior to calculating one’s tax liability, not as a *deduction from one’s taxes* (which would be more precisely described as a tax credit).

<sup>50</sup> For an argument in favor of the replacement of deductions with credits, see Feld, O’Hare and Schuster (1983, pp. 216–220).

<sup>51</sup> For fuller though somewhat outdated discussions of these themes, see Schuster (1986, 1987, 1999).

### 5.1. Chile

The 1990 Chilean *Ley de Donaciones Culturales* (Law for Cultural Donations) is an example of tax legislation specifically designed to stimulate increased donations to the arts by private corporations;<sup>52</sup> it established a unique and limited form of tax incentive that might be described as a “monitored tax credit” (to distinguish it from an automatic tax credit). The intent is to provide an incentive for the private sector to make donations for cultural projects by having the state “share” the cost of approved projects. In order to take advantage of this cost sharing a potential donor, in collaboration with the proposed recipient cultural organization, must present a detailed project proposal to a committee created to certify private donations. The proposal must meet a set of criteria for acceptability. If a project is approved, the corporate donor is allowed a 50 percent tax credit on the corporate donation.<sup>53</sup> In this manner, the state contributes half of the project’s cost – but in the form of forgone taxes. The state never has to write a check or make a grant, but it is able to determine acceptability on a case-by-case basis. In all publications, posters and other publicity related to the project, both the donor and the recipient must mention that the project has benefited from tax benefits under the *Ley de Donaciones Culturales*, making explicit the fact that the project is being supported in the form of taxes forgone by the state. Moreover, when the project involves exhibits of artistic or historic objects or performances, the recipient organization must certify that the exhibit or performance will be open to the general public with free admission. Thus a rather high level of public benefit is insisted upon in order to take advantage of this form of co-financing. This is a public policy attribute that does not often appear in tax-based legislation for the arts and culture.

### 5.2. Australia

In Australia, the Department of Communications, Information Technology and the Arts administers three different tax incentive programs, all of them of relatively recent vintage: the Register of Cultural Organisations, the Cultural Gifts Program, and the Cultural Bequests Program [Penhallurick (1998)].<sup>54</sup>

The Register of Cultural Organisations allows qualifying cultural organizations to offer donors the incentive of a charitable deduction. Much as in the United States, an Australian donor is allowed to deduct from taxable income donations of cash or of property<sup>55</sup> that are made to nonprofit organizations appearing on the register.<sup>56</sup> The

<sup>52</sup> The text of the law is available in *Diario Oficial de la Republica de Chile*, No. 33,706, 28 June 1990, p. 7; and the regulations concerning its implementation are available in *Diario Oficial de la Republica de Chile*, 12 February 1991, p. 3.

<sup>53</sup> Total annual credits for a corporate donor are limited to 2 percent of the corporation’s taxable income.

<sup>54</sup> For current information on these programs, consult the Department’s website: [www.dcita.gov.au](http://www.dcita.gov.au).

<sup>55</sup> Under this scheme donations of property are limited to property that the donor acquired within 12 months of the donation, and the deduction is limited to the purchase price or the current market value, whichever is smaller.

<sup>56</sup> This principle applies equally to individual donors, corporate donors, and trusts and foundations.

interesting component of this scheme is the explicit registration of eligible cultural bodies. These organizations must have as a principal purpose the promotion of literature, music, the performing arts, the visual arts, craft, design, film, video, television, radio, community arts, Aboriginal arts, or the movable heritage. They must be organized in a manner that is considered appropriate under Australian law, have a main purpose that is cultural, and maintain a separate fund for the receipt of public donations that must be used exclusively for the cultural purposes of the organization. Finally, to be entered into the register, organizations must be approved by the Minister and by the Treasurer. The register, established in 1991, is primarily made up of music and other performing arts organizations; public art galleries, museums, and libraries are covered by the Cultural Gifts Program and are not part of this register.

The Cultural Gifts Program (formerly the Taxation Incentives for the Arts Scheme) provides an incentive for gifts of significant cultural items to public arts galleries, museums, and libraries. Under this program a donor is entitled to a deduction from taxable income for the market value of the gift. Two valuations by approved appraisers are required, and the donor can claim the average of the two values as the deduction. The Commissioner of Taxation can adjust or disallow the deduction if the gift is given with conditions that prevent or delay the receiving institution from having clear title, custody, and control over the item or that involve a material benefit to the donor. Materials describing the program make it very clear that the Australian Government considers this to be a tax expenditure and even estimate the extent of that expenditure: "... the policy objective of the program is to attract significant cultural material into public collections and ... gifts are funded by the Government through the donor's tax deduction (estimated to be about 40 percent of the value of the gift)".<sup>57</sup> Gifts of cash to these public collecting institutions can also be deducted from income prior to calculating one's taxes.

The Cultural Bequests Program operates as a supplement to the Cultural Gifts Program. It is designed to encourage private collectors to bequeath nationally significant cultural items to public art galleries, museums and libraries by allowing the value of the bequest to be deducted from one's estate and by exempting the bequest from capital gains tax. This program is unique in that it goes one step further in limiting the tax expenditure by placing a limit on the total value of bequests that can be authorized annually. This limit, set at 5 million Australian dollars per year, constrains the amount of forgone taxes that can be spent via this tax expenditure and creates a situation in which the government may have to consider and decide among competing applications.<sup>58</sup>

Taken together, these programs provide an unusually constrained set of tax-based incentives. The Australian government through its registration, approval, and review

<sup>57</sup> See the Department's website listed above.

<sup>58</sup> A more refined limitation scheme apparently exists in Italy. *Trupiano (2002)* suggests that in Italy the deductibility of donations is limited through a ceiling *for each taxpayer* – individual or corporate – *and in the aggregate*. If, in any year, total donations exceed the aggregate limit, a "tax" is charged on the recipients of deducted donations in proportion to the total donations received by the organization.

mechanisms exercises a relatively firm hand on the system to assure that it operates within the grain of public policy in a way that other more automatic tax incentives find it difficult to do.

### 5.3. Singapore

Surprisingly, the idea of a “superdeduction” – one that provides a deduction of more than 100 percent of the value of the contribution – seems to be gaining some traction in several countries, perhaps because in certain societal and cultural contexts it is felt that an extra incentive is required to prime the pump in a system that has not heretofore had a tradition of individual or corporate support, or perhaps because advocates on behalf of the cultural sector have been particularly effective in promoting their own self-interest. In Australia, the Victorian Arts Minister has called on the Federal Government to implement a 125 percent deduction for gifts of new contemporary art works to public collecting museums [Coslovich (2002)]; Iceland is considering a provision that would allow a 200 percent income deduction for charitable contributions [Einarsson (2004)]; and even in the United States at one point the President’s Committee on the Arts and Humanities proposed that donations to the arts and culture be afforded a 150 percent tax deduction. The justification in the latter case was little more than that the arts were particularly worthy.

In Singapore, the Ministry of Finance’s 2002 Budget contained a set of tax measures to promoted philanthropy, including a superdeduction:<sup>59</sup>

- all cash donations made to Institutions of a Public Character would be eligible for a double tax deduction;
- donations made to those Institutions of a Public Character which offer naming opportunities to donors in return for their financial support would be eligible for a single tax deduction but not for a double deduction;
- any excess donations above the annual ceiling made by individuals or corporations could be carried forward for up to five years so that the incentive is not lost;
- the amount that an organization may spend for fundraising purposes is capped at 20 percent of the funds raised.

At the same time, the National Arts Council set up a system of Special Accounts to assist arts organizations in receiving tax-exempted donations. Donations are to be deposited into these accounts for the use of the various recipient organizations. While the reason for the creation of such a middleman organization is unclear, several elements in the legislation suggest possible explanations: (i) funneling deductible donations through the National Arts Council may help assure that the donations would actually be used for the projects and purposes for which the donor intended them; or (ii) the fact that the

<sup>59</sup> For the information on Singapore, I am grateful to Siu-Yuin Pang, Senior Manager of the Singapore Symphony Orchestra. Details are available from Ministry of Finance (2002). Note that not all of the tax measures proposed in that budget are summarized here.

National Arts Council is responsible for issuing receipts for these donations relieves the organizations of that burden, but also helps monitor the system to be sure that deductible donations are being made within the parameters of the law.

The notion that a special institutional structure might be necessary to serve as the conduit for charitable contributions shows up in several of the above examples. Such a structure has also been proposed by those considering how American-style incentives might be applied in other national contexts.<sup>60</sup> The creation of such new institutional structures, which to American eyes appears wasteful of resources, is an attempt to balance the provision of incentives with the requirement for extraordinary measures to prevent abuse.

#### 5.4. France

In December of 2002 Prime Minister Jean-Pierre Raffarin announced twelve measures to reform the treatment of charitable contributions and foundations in France [Morel (2005)]. The proposed measures included “better” tax incentives for both individual and corporate donors, more favorable tax treatment for foundations, and simplification of the rules governing the creation and operation of “public utility foundations”. The tax proposals were swiftly reviewed and amended by Parliament, and the law<sup>61</sup> was adopted on August 1, 2003 [Ministère de la Culture et de la Communication (2004)]. The changes in tax law embodied in this legislation were made because of a general sense that the preexisting incentives embedded in French law were not sufficient, particularly those related to corporate patronage. Prior to this legislation corporate patronage was deductible from corporate income; because the corporate marginal tax rate was 33.3 percent at the time, this provision set the price of giving at 0.667. The new legislation has replaced the tax deduction with a tax credit at 60 percent, thus lowering the price of giving to 0.40.<sup>62</sup> In effect, this legislation created a superdeduction for corporate charitable contributions.

It is too soon to know what effect this change in incentives has had, but it would seem reasonable to suggest that, given the high levels of government support for the arts and culture in France, one would not expect to see the sort of dramatic change in corporate giving that the legislation hopes for. The incentive interacts with the culture of giving of the country in question, with the result that the same incentives will have very different effects in different places.

<sup>60</sup> See *Borgonovi and O’Hare (n.d.)* for an example based on a consideration of how American-style tax incentives might be applied in the Italian context.

<sup>61</sup> *Loi du 1er août 2003 relative au mécénat, aux associations et aux fondations.*

<sup>62</sup> The new legislation also increased the limits on corporate charitable contributions that could benefit from these tax incentives from 2.25 or 3.25 per thousand of the company’s turnover (depending on the type of beneficiary) to 5 per thousand of turnover. These limits were accompanied by carryover provisions so that donations beyond the limit would be eligible for preferential tax treatment in a future year.

### 5.5. United States

In the United States over the past ten years there has been a movement to create state arts endowments. For the most part these endowments are intended to be separate from the preexisting state arts council in the hope that they will provide additional public and private resources for the arts and culture. They have often been created to serve a broader range of artistic, cultural, and heritage initiatives. The fiscal mechanisms that have been used to fund these endowments vary widely [Rafool (2004)], but several make explicit use of state-level tax incentives. Here we consider three examples drawn from the states of Oregon, Wisconsin and New Jersey.

Donations to the Oregon Cultural Trust are eligible for a 100 percent tax credit up to an annual limit of \$500 for individuals and \$1000 for households. Corporations are eligible for an 80 percent tax credit on an annual maximum of \$2500 in contributions.<sup>63</sup> These incentives are available only when the donor contributes an equivalent amount to a qualifying Oregon nonprofit cultural organization in the same year. The result of a 100 percent tax credit, of course, is that a donor making a donation is simply directing that contribution from his or her tax bill to the Cultural Trust; put another way, within the limits on eligible contributions the price of giving is zero. What is the rationale behind such an offer? This tax incentive structure well illustrates the politics of such provisions. While eager to have more revenues available to them, cultural organizations are wary of the creation of such new institutional funding mechanisms because they fear that they will be placed into direct fund-raising competition with the new intermediary. The proposal for a 100 percent tax credit is intended to remove this fear and to remove political opposition. But a 100 percent tax credit can be an expensive proposition for the state, so it is accompanied by ceilings on its use.

While the 100 percent tax credit remains in place in Oregon, it has had a more difficult time in other states. When it was originally proposed, the Wisconsin Artistic Endowment Foundation was to be the beneficiary of a 100 percent state income tax credit up to a limit of \$50 on individual contributions and \$500 on corporate contributions.<sup>64</sup> When the Department of Revenue said that it would lose a lot of revenue because of this provision, the legislature knocked the credit down to 25 percent (though this was still considerably more generous than the tax incentive for giving to other charitable sectors, which was at the state's marginal income tax rate of 5 percent). Under pressure from the other charitable sectors as well as from state budgetary considerations, the governor ultimately took the effective credit down to the 5 percent level, and as a result the momentum for getting the Wisconsin Artistic Endowment Foundation up and running has evaporated.

At first glance, the funding model for the New Jersey Cultural Trust appears to be rather different. The State of New Jersey will match on a 1:1 basis private donations

<sup>63</sup> In subsequent years, the incentive for corporate donations was limited further.

<sup>64</sup> This account is based upon personal communication with George Tzougros, Executive Director of the Wisconsin Arts Board, 13 October 2004.

made directly to the Cultural Trust or private donations earmarked for the endowments of specific cultural groups. In either case the match is paid to the Cultural Trust and is used to build up its corpus. A floor of \$10 million per year in state match was established. Any organization that receives a donation of more than \$100,000 toward its endowment automatically qualifies for a grant of 20 percent of the match paid to the Cultural Trust. But remembering the similarity between matching grants and tax incentives, this funding model is the rough functional equivalent of a 50 percent tax credit against state income taxes. The question is the extent to which the potential donor actually perceives this program as essentially doubling his or her contribution. This depends a lot on how the program is marketed, though admittedly there must be a perceptual difference between writing the entire check (and knowing that a tax credit has made it possible/attractive for you to give more than otherwise would have been the case) and writing a check that is only half the value of what the Cultural Trust will receive.<sup>65</sup>

### 5.6. Romania

Legislation proposed in Romania has taken up a somewhat different issue in corporate giving. In 1992 the Parliament of Romania circulated a draft Law on Sponsorship for comment, as part of a process seeking to regularize the nonprofit sector and provide incentives for contributions to that sector. Although the legislation did not distinguish between sponsorship and philanthropy, the draft law proposed to distinguish between sponsorship undertaken anonymously from that undertaken with recognition provided to the sponsor.<sup>66</sup> The former would benefit from a more generous tax-incentive: both forms of sponsorship would be deductible from total income before calculating taxes owed, but in the case of anonymous sponsorships, an *additional* tax credit was proposed which would vary between 0.5 and 1 percent of the amount of the sponsorship, depending on characteristics of the sponsor. The principle behind the additional incentive was that purer motivation would be more highly rewarded, a result that reveals an underlying uncertainty and suspicion of tax-based incentives and how they might be captured to advance individual interests in a tax system in which they have not heretofore been a recognized component.

<sup>65</sup> There is one other issue pertaining to state tax law that deserves mention here. In the United States state tax payments are typically deductible from the taxpayer's income prior to calculating one's federal income taxes. The result is that a substantial portion of any tax incentive that is realized as part of one's state tax payments is clawed back by the federal government: taking advantage of a state income tax incentive lowers your state income tax, resulting in a decrease in the deduction you can take on your federal tax form for state income taxes; this raises your federal income taxes in the following year.

<sup>66</sup> The Parliament of Romania, draft, *Law on Sponsorship*, 1992(?): Article 5, ¶4; Article 6; and Article 7. One should be careful about attempting to divine too much intent from this proposal because of the confusion within the draft law itself among various types of "sponsorship". Apparently, the crafters of the law were trying to incorporate in the one term "sponsorship" three different types of financial transfers from both individual and corporate contributors – charitable contributions for ongoing, unspecified expenses; contributions intended to support a particular project; and sponsorship that was more narrowly intended to promote the name, trademark, or image of the sponsor.

### 5.7. Conclusion

Taken together, these examples demonstrate that many jurisdictions, whether national or sub-national, are looking at tax incentives that go well beyond what might be considered “natural” incentives linked directly to the marginal tax rates in force. They are all based on the conviction that tax incentives will actually work to increase the level of total contributions, but they also seem to be based on an assumption that a simple deduction will not prove to be a sufficient inducement. The question becomes how high does that inducement have to be to get the desired result and will that inducement ultimately prove too expensive?

## 6. Summary and concluding remarks

The point of concluding this chapter with these international examples is at once simple and complex. The general yet only ambiguously-supported belief in the effectiveness of American-style tax incentives has led to a wide proliferation of such mechanisms elsewhere. Often they are modeled on the American deduction, but not always. Some countries have opted for a credit rather than a deduction; some have implemented more restrictive maxima or minima; some have included superdeductions; and some have put in place institutional structures to monitor the system and prevent what they perceive as abuse or the potential for expensive over-use. But they are all linked in their desire to provide a certain type of incentive, an incentive for increased individual or corporate support which may well be seen as a long-run way to ease pressure on government support.

In addition to continuing research on the economic effects of tax-based incentives to refine further our understanding of those effects, there is also a need for comparative research on the forms of incentives and their relationship to various national contexts. Why have particular forms of incentives arisen in certain countries but not in others? What difference does variation in various parameters make in the operation of these tax laws? What are the comparative politics of tax-based incentives? And, finally, while researchers have much to learn from the broader research on tax-based incentives for nonprofit charitable organizations and their various sources of support, sector-based research would also be of interest. Feld, O’Hare and Schuster (1983) pointed out that changes in tax law will not affect all charitable sectors equally because the demographics of those who choose to fund the arts and culture are different from those who choose to fund other sectors. Is there an appropriate set of tax-based incentives for the arts and culture, one that would be justifiably different from the set available to another sector? Several of the examples cited above seem to be based on that premise. But the central analytic question remains: To what extent have they realized their promise?

## **Abstract**

Charity on the English and early American model must be distinguished from philanthropy as it developed in America at the turn of the twentieth century. Philanthropy aims at the systemic eradication of social ills rather than, as does charity, at their amelioration. The general purpose philanthropic foundation became the standard vehicle for effecting this purpose, and made significant contributions to a variety of fields until the Great Depression, though funding for the arts was fairly limited. Much of the role of foundations was assumed by the federal government as it expanded in power and scope after World War II, often adopting the foundation *modus operandi* as its own. Partly as a result, foundations began to support the arts and culture, and when corporate philanthropy emerged in the 1950s it was also often aimed at the arts and culture. The National Endowments for the Arts and Humanities have been responsible since 1965 for the central government contribution to these fields. Recent changes in the foundation sector include the growth in the number of new, very well endowed foundations; the emergence of conservative foundations; a contraction in the scope of foundation funding, including fewer and smaller grants to the arts and culture; and the rising number of community and family foundations. American philanthropy is undoubtedly responsive to government policy and economic cycles, but there remains despite vicissitudes a unique affinity for philanthropy in the United States, perhaps explained in part by the relative weakness of the American state. In Europe, a different historical tradition and legal framework has given rise to different forms of support for the arts and culture, with a greater role for the state. Recent trends, however, suggest that non-American philanthropy is coming to resemble philanthropy in the United States.

## 1. Philanthropy and the arts in the United States

### 1.1. *Origins: From charity to philanthropy*

In English, and in the United States, “philanthropy” remains both a technical and a general term, and its technical meaning is imperfectly understood both by most practitioners and by the general public. The term is probably best understood in its historical context, and especially in opposition to the concept of “charity”, the duty to take care of the poor, the ill, and the otherwise unfortunate in society.

Charity in the American colonies was influenced in some respects by the practice of charity in England. For instance, England’s Poor Relief Act of 1601 had placed certain charitable responsibilities in the hands of municipal authorities; some early American charity took the same form, especially in New England, though municipalities would usually farm out the actual care of the needy to whoever could do it most cheaply. But at the same time, the Church of England (and the other Christian denominations), both played a charitable role itself and imposed upon its better-off members the duty to share their wealth with the unfortunate of the faith; so in some regions of America – like Anglican Virginia – parishes and their parishioners were charged with the care of the poor and needy.<sup>1</sup> But while Elizabeth’s Statute of Charitable Uses of 1601 (a statute now under revision in the United Kingdom) had begun to formalize the legal status of charity and especially of charitable trusts in England by delimiting what qualified as charitable activities, the instability and variability of colonial law provided an at best unfavorable environment for charity in America [Tomlins and Mann (2001)]. After the Revolutionary War that environment, especially outside New England turned openly hostile to charity for several decades, perhaps influenced by Jefferson’s warnings against “un-republican” organizations. In Virginia, the Anglican Church was disestablished and its assets seized, and Pennsylvania annulled the Statute of Charitable Uses.

But American impulses towards voluntarism and charity would not be thwarted, and the controversies that resulted required the intervention of the Supreme Court, which ruled, though not wholly unambiguously, in favor of those impulses in 1819 and 1844 (in the *Dartmouth College v. Woodward* and *Vidal et al. v. Philadelphia* cases). Still, the Court left enough unsaid for two divergent legal approaches to charity to develop. In New England, the law not only allowed charitable activities but encouraged them through tax exemptions [Wright (1992)]; but most other states limited the sorts of activities could pass as charitable, and did little to promote them [Zollmann (1929)]. As a result, charitable activity tended to thrive in the Northeast and upper Midwest, and to do less well in other areas.

Alongside this more permissive legal environment, a concatenation of developments was preparing the way for the dramatic expansion of the general idea and the legal definition of charity in the very late nineteenth century, with the development of the modern

<sup>1</sup> On early American charity, see Trattner (1999) and Katz (1996); on early English charity, see Jordan (1959) and Owen (1965).

conception of philanthropy.<sup>2</sup> The professions were developing associations to uphold occupational standards; large benevolent associations were coming to be run by salaried administrators instead of volunteers; national-scale issues like slavery, immigration, and black migration northwards were nationalizing public life, a process enhanced by the increased ease of communication that followed the federal government's reorganization of the postal service and its control over interstate commerce; the United States Sanitary Commission's efforts on behalf of public health on Civil War battlefields demonstrated the efficacy of scientific expertise, and then discharged into the medical community a body of scientifically minded experts concerned with dealing with the causes of disease and suffering instead of their symptoms; research universities were beginning to thrive; and the establishment of the National Conference of Charities and Correction emblemized, more generally, the professionalization of social welfare and the shift from the alleviation of social problems to their systematic solution.<sup>3</sup>

At the same time, the great entrepreneurs of the Era of the Robber Barons were amassing fortunes of unheard of sizes. These capitalists were all Christians, and most of them believed fervently that their Protestant faith required them to steward their wealth, and to use some considerable part of it for the benefit of others (though Carnegie's "Wealth" of 1889 is a remarkably pragmatic and secular document). They had always been charitable – Rockefeller had tithed the first dollar he ever earned as a boy. The difficulty for those captains of industry interested in social problems was that they were amassing liquid wealth more quickly than they were able to distribute it charitably. The charity they were able to practice was necessarily retail, and both their sense of social obligation and the amounts of money at their disposal required that they develop a wholesale process for distributing their rapidly accumulating riches.

The first instinct of these innovators was to imagine how they could expand and be more efficient in the charitable work they were already engaged in. But what really set them apart was their realization that the challenge was not merely or even primarily technical, but conceptual. For charity addressed the needs of individuals and responded to specific needs, whether of income, health or education. Even if charity could meet such needs on a continuing basis, it would do nothing to extirpate the underlying problems. Giving alms would not address the causes of poverty, nor would the provision of shelter and medicine eradicate disease. These modern businessmen (though the Russell Sage Foundation, one of the earliest and most ground-breaking foundations was established by a businessman's widow) wished to apply their wealth to the discovery of the underlying causes of personal distress, and to the formulation of strategies to rid their country and the world of such systemic scourges [Hammack and Wheeler (1994)].

<sup>2</sup> While charitable activities had sometimes been denominated "philanthropy", that term was widely and non-specifically used to describe generous or benevolent behavior; in the antebellum United States, for instance, those who opposed the institution of slavery were frequently described as "philanthropic".

<sup>3</sup> For reviews of these developments, see Hall (2003), Lubove (1965), Bremner (1996) and Karl and Katz (1981).

This was the origin of the modern idea of philanthropy. It emerged from a general context in which confidence was building that science and technology could provide tools to address social problems in radically new and effective ways. And it drew on the intellectual and business experience of the great capitalists, who had after all made their fortunes by innovating organizational strategies (especially the vertical integration of related extractive and manufacturing industries) and by employing the intellectual resources of the second scientific revolution (which was being so successfully managed by the emerging system of research universities). The insight was that these new techniques could be deployed to solve social, economic and medical problems just as effectively as they had served Standard Oil or United States Steel.

### 1.2. *The emergence of the philanthropic foundation*

The institutional embodiment of this philanthropy was the private philanthropic foundation. But the legal and political difficulties of establishing foundations were considerable. The rule against perpetuities militated against trusts (of which foundations were a type) enduring indefinitely, with the result that their capital never vested to their beneficiaries [Friedman (2000)]. And as Katz, Sullivan and Beach (1985) has shown, the laws of New York State, where much Robber Baron wealth was concentrated, were unfriendly to philanthropic foundations. Nonetheless, by the early 1900s several large foundations or foundation-like entities had successfully been established, and while Rockefeller's endowment of the Rockefeller Foundation with \$100 million and wide discretion to promote "the well-being of humankind throughout the world" (well, "mankind" in the early days) prompted a public outcry reminiscent of the populist 1890s, the Foundation was duly chartered by the state of New York in 1913 [Johnson and Harr (1988)]. The chartering cemented legal approval for a new sort of trust, with an indefinite class of beneficiaries and a very general purpose. In short, they created what Americans now call the private philanthropic foundation.

There was a calculated reason for the generality of purpose of these institutions. English law had always looked askance at over-specificity of purpose in trust, on the grounds that narrowly defined trust instruments would inevitably become impossible to carry out as social conditions changed over time (though the doctrine of *cy pres* helped resolve some such difficulties). The philanthropists understood the need for timeliness and flexibility from their experience in industrial management, and they sought to build it into their philanthropic foundations by appointing governing boards – trustees – whose principal duty would be constantly to refine the particular and immediate purposes of the foundation, consistent with its general commitment to the development of research-based solutions to the most urgent problems of the country and the world. They would do this through proactive grantmaking based on the payout of some substantial portion of the annual income of the trust. Such flexibility was less important for those foundations established with time limits for spending down their assets trusts, such as the Rosenwald Fund. Julius Rosenwald, the Sears Roebuck mail order magnate, endowed

the fund with more than \$20 million in 1927, on condition that it expend the funds within twenty-five years of his death. In the event, it took the Fund only sixteen years.

The model of the general purpose foundation, then, was established by the time the United States entered World War I, and it flourished during the 1920s. A significant number of private philanthropic foundations were established between the end of the Great War and the onset of the Great Depression. They were devoted to a wide variety of purposes, but the majority focused in various ways on education, medicine and public health, and international affairs. Considerable investment was made in addressing the “American Dilemma”, the role of race in modern democracy, and in fact Gunnar Myrdal’s book *An American Dilemma: The Negro Problem and Modern Democracy* was commissioned by the Carnegie Corporation.<sup>4</sup> There was relatively little focus on economics and the economy, since the new foundations were constantly subjected to the criticism that they were thinly disguised efforts by the rich, having sequestered their wealth from taxation, to influence public (and especially economic) policy. But some indirect investments were made by funding and or establishing intermediary organizations like the National Bureau of Economic Research, the Brookings Institution and the Social Science Research Council, by supporting the private natural resources planning efforts of both Herbert Hoover and Franklin Delano Roosevelt. Although the Carnegie Corporation did engage in some arts grantmaking (mostly in arts education), in the 1920s and 1930s, by and large the private foundations had little interest in supporting the arts and cultural sector. And then the problems of the Great Depression dwarfed the resources of the foundations and further de-prioritized cultural philanthropy, and World War II saw much of the expert staff members recruited into the war effort.

Also in this period, another sort of foundation emerged that would prove to be extremely important as the century wore on – the community foundation. As Howard (1963) documents, the first such foundation – the Cleveland Foundation – was established in Ohio in 1914. It was based on the traditional premise that “charity begins at home”, though the community foundation was as scientifically philanthropic as it was charitable, both in its methods of amassing funds and strategic approach to giving. The community foundation enjoyed the same legal status as a private foundation, but its assets were donated by wealthy members of its community and were intended to benefit that community specifically. The community foundation enabled local donors to gain the tax advantages and some of the leverage of private foundations without the expense and responsibility of establishing their own private foundations. Community foundations had their own boards, populated with a mix of local notables, mostly businessmen, but also with other sorts of prominent and knowledgeable citizens. The community foundations funded a wide range of community activities, and doubtless had a broader impact on local life, especially in cultural institutions and activities, than private foundations, at least until fairly recently. At about the same time, there developed (also in Ohio) a related but more conventionally charitable institution with a local

<sup>4</sup> See Lagemann (1992).

focus – the Community Chest. This institution has since had several forms (and it is now called the United Way), but the basic idea was to provide workers with the ability to “check off” (permit the employer to deduct regularly from the employee’s paycheck) amounts of money that a central organization in the community would distribute to a selected group of charitable, that is non-profit, organizations providing services to the local community [see Crane (1992); Brilliant (1992)].

### *1.3. The development of federal government “philanthropy”*

As is well known, the government of the United States emerged from the Revolutionary period as a designedly and adamantly weak state. The fundamental premise of the Constitution of 1787 was that powers not specifically granted to the national (“federal”) government were reserved to the governments of the states, or to the people. This was partly a clear principle of finance, and the budget of the federal government remained miniscule until the coming of Civil War in the mid-nineteenth century forced increases in revenue collection and military-industrial expenditure. Direct taxation was low at all levels, and was not an important federal source of revenue until after the passage of the Sixteenth Amendment in 1913. The division of functions between the federal government and the states meant that the latter had virtually sole responsibility for the police powers of the state – the health, safety and welfare of the people. Since charity was, as we have seen, very much a local issue until the late nineteenth century, both charity and (relatedly) cultural activity were either outside of any governmental jurisdiction at all or under the jurisdiction of state governments. As Alexis de Tocqueville pointed out so eloquently in the 1830s, most local cultural activity was supported by volunteerism and charitable giving. This is of course still the case to a remarkable extent.

But, of course, the power of the federal government has grown enormously, driven both by the demands of waging two wars (even before the United States declared that it was perpetually at war), and by the dramatically enlarged social and economic agendas that began during the Great Depression, reached a high point during the presidency of Lyndon Johnson with “The Great Society”. Despite the best efforts of successive late twentieth century Republican and Democratic administrations, it is still with us. The growth of the federal state (measured in terms of the proportion of GNP expended upon it) and the enlargement of the jurisdiction of the national government have been accompanied, not unsurprisingly, by its involvement in what look very much like philanthropic activities. Two points are worth noting. First, much of the thinking behind Roosevelt’s New Deal was heavily influenced by philanthropically funded research; the foundations, in other words, helped ease the federal government into their realm [Critchlow (1985)]. Second, New Deal activism, at least, actually encouraged philanthropy both because its very progressive tax rates encouraged charitable contributions, and because government policy depended for its implementation on the private infrastructure that philanthropy succored and in part constituted.

The practice began with the federal government’s response to the demands of World War II, when it became for the first time the dominant funder of scientific research.

The first step was federally supported military research, such as the Manhattan Project to develop atomic weapons. Subsequently the federal government became the funder of first resort in science and medicine in general; crucial in this regard, as Brownlee (1996) has shown, was the establishment of an almost universal mass income tax in 1943. At the end of the war, for the first time government “foundations” were established to drive the rapidly growing private research establishment: the National Science Foundation was established in 1950, and while the National Institutes of Health had been around in some form since 1897, it got its current name in 1948 and substantial financial support in the 1950s. These public agencies were dependent upon annual federal appropriations, and legally were quite unlike private foundations. What the government took from the “real” foundations was an approximation of their grantmaking procedures and their sectoral research planning strategies. Huge numbers of tax dollars (by historical standards) were invested in this enterprise, and one of the interesting effects of government “philanthropy” was the self-imposed necessity of private foundations, even the largest, to reposition their funding strategies in relation to what the government was and – especially – was not doing. Private foundations increasingly became niche players in relation to the total universe of research funding.

#### *1.4. The impact of foundation philanthropy on art and culture*

As already noted, American philanthropy paid little attention to art and culture in its first few decades. But changes in federal tax laws in the 1930s and 1940s stimulated a second wave of large private foundation creation – the Ford Foundation and Lilly Endowment, for instance – and in the post-war era several of these institutions identified culture as a promising area for philanthropic investment. This probably resulted in part from the need to move away from investment areas coming to be dominated by public funding, but also because of the emergence of new trustees with new interests and new views of the appropriateness of certain types of foundation funding. The arts and culture sector was democratizing itself in an era of rapidly expanding audiences, repertoires, and artists, and this made it easier for private foundations, always sensitive to allegations of elitism, to support it. By the 1960s and 1970s, first the Rockefeller and then, especially, the Ford Foundation had begun significant programs of cultural philanthropy. In the 1980s and 1990s, newer large foundations such as the Pew Charitable Trusts and the Wallace Funds entered the field, and there are now a number of newer foundations sufficient to support the creation of an umbrella organization of arts and culture funders, Grantmakers in the Arts, which organizes annual conferences and publishes their proceedings, and also produces research on philanthropic support for the arts and culture [Renz and Atlas (2000)]. The sum total of foundation support for the arts and culture, however, is quite small when compared either to private charitable donations or to state and local cultural funding, and it has fallen off dramatically in recent years [Focke (2001)].

### *1.5. Corporate philanthropy and art and culture*

The record of corporate philanthropy, another post-war American innovation, is similar. United States business corporations, like business firms everywhere, are institutions that seek to amass profits for productive re-investment or to distribute to shareholders if they have them. Milton Friedman (1997) and many other economic thinkers have gone out of their way to make clear that distributions of profits for other purposes, especially for philanthropic purposes, are ill-advised and inappropriate. It was only in 1935 that the Revenue Act made corporate donations to philanthropy tax-deductible, and since an important legal decision in 1948 they have become common practice [Muirhead (1999)]. The dominant rationale for corporate philanthropy, as Himmelstein (1997) puts it, has of course been that certain sorts of gifts “do well by doing good” – they benefit not only the donees, but also the business interests of the donor corporations. As corporate philanthropy became more and more common in the 1960s and 1970s, it tended to be directed at the communities in which a firm’s plants were located and its employees lived. Firms also developed matching gift programs through which charitable gifts of employees to universities and other non-profits were matched dollar for dollar by the corporation, both encouraging employee charitable behavior, and giving substantial satisfaction to charitable employees. The sums involved, however, are typically not large proportionate to earnings. Over the past fifty years they have generally ranged between 1 and 2% of pretax earnings – though for large firms such sums are non-trivial contributions. In the late 1970s industrialists in the upper Midwest led a movement to encourage corporations to boost their philanthropic giving to 5% of pretax profits, but the effort failed. In fact, in the 1980s and 1990s general levels of corporate philanthropy fell, and grant-making became more and more closely tied to corporate marketing strategies, and thus managed by the marketing and public relations arms rather than by corporate contributions offices of the firms [Porter and Kramer (2002)].

Much corporate philanthropy has gone to the cultural sector, mainly because support of the arts has appeared an attractive, uncontroversial way for industries with severe public relations problems to present themselves in a welcome positive light to the public. It is not surprising that the tobacco products industry led the way, with Philip Morris taking the sectoral lead. The first years of the twenty-first century have seen an unexpected rise in corporate giving: it amounted, according to Raymond (2003) to about 12 billion dollars in 2002, an increase of 10.5% over 2001 (in which an increase over 2000 occurred). But this was perhaps an anomalous development – the 1990s saw a fairly substantial decline in corporate philanthropy [Chronicle of Philanthropy (1999a, 1999b)].

### *1.6. Government cultural philanthropy: The endowments*

The federal government’s approach to the arts and culture has never flowed from a formed notion of cultural policy.<sup>5</sup> It took Congress more than ten years to decide

<sup>5</sup> See further Netzer’s Chapter 35 in this volume.

whether to accept James Smithson's gift to establish the Smithsonian Institution in Washington; and thereafter federal appropriations helped sustain and expand its vast (and arguably haphazard) complex of museums and research activities, far beyond what its donated trust funds could have provided by themselves [Oehser (1969); Burleigh (2003)]. A similar process took place with the Andrew Mellon endowment that began the National Gallery of Art in the capital city. The federal government encouraged individual Americans to support the arts and culture by means of the tax code, but it did little until the 1960s to provide directly for the sector (except, perhaps, for the Works Progress Administration's incorporation of visual and performing arts into its programs). But, to the surprise of many observers, years of lobbying by arts and cultural organizations (and individuals) resulted in the creation of federal cultural grantmaking agencies in 1965. In that year, in a characteristically Great Society mood, Congress passed an act establishing a National Foundation for the Arts and Humanities, comprised of two separate Congressionally appropriated "foundations", the National Endowment for the Arts, and the National Endowment for the Humanities. The authorizing legislation justified the two unendowed "Endowments" by reference to the importance of culture in strengthening democratic society, but the actual appropriations in the first years were very small [Netzer (1980)]. After all, the United States had never had a federal ministry for culture, for the very good historical reason that the Constitution never contemplated the possibility that the federal government would have responsibility for cultural activities of any kind; such activities and institutions were clearly intended to be within the jurisdiction of the states and localities.

The idea of having some sort of coordinating council to oversee them endowments (picking up on the original legislative plan for a National Foundation for the Arts and Humanities) was never implemented. Each Endowment has a presidentially-appointed Chair, subject to confirmation by the Senate, and the Chairs of each Endowment have significant discretion in grantmaking, although by statute each must work with a presidentially-appointed National Council. But the humanities are institutionally separated from the arts, mainly because "culture", the more general term, is considered such a dangerous concept in the United States when it comes to state action. Very few of the Chairs have been independently distinguished and politically strong, and the National Councils have frequently not been selected for the professional distinction of their members. Politics has usually been the rationale for making such appointments.

Under the leadership of the arts activist Nancy Hanks, the NEA began to receive substantially increased appropriations during the Nixon administrations in the early 1970s, and after: NEH was granted \$2.9 million in 1966, and less than \$8.5 million in 1969 when Hanks took the helm, but the NEA received about \$100 million in 1977, when she died [National Endowment for the Arts (2004)]. The NEH started off garnering about \$6 million in 1966, and also received about \$100 million in 1977 [Katz (2001)]. Each endowment increased the range of its funding, the NEA providing support both to individual artists and to leading performing arts organizations, while the NEH supported both individual scholarship and individual cultural institutions such as independent research libraries and historical societies. In real dollars, the Endowments reached their

highest appropriations levels in the very early 1980s, but neither ever broke the \$200 million mark even in the mid-1990s, the period of their greatest appropriations in nominal dollars. Support on this scale did not match to the annual total investments of private philanthropic foundations and individual donors, and they were even dwarfed by public funding at the state and local levels.

Furthermore, during the George H.W. Bush administration the worst fears of those who had opposed federal funding of culture on the grounds that it would politicize cultural affairs were confirmed. The so-called Culture Wars prominently involved the attacks of political and religious conservatives on the funding of individual artists. Congressmen and Senators wanted to know why NEA had supported allegedly homophobic and anti-Christian art, and comparable (though more restrained) conflicts emerged in the humanities. The result, as Zeigler (1994) and Marquis (1995) have shown, was the elimination of NEA individual grants to artists, and in general a movement away from the production of “high” art and support of traditional arts institutions to the funding of more popular and local forms of art. Partly in response to these crises, both endowments have come to serve in part as pass-through funders to state arts (and humanities) councils, which regrant these funds, mostly to local organizations.

But by the mid-1990s, and especially after the massive cutbacks of 1996, more and more federal money that might have gone to the NEA and NEH was passed directly through to state councils. Only a few of the humanities councils were simultaneously funded by state governments, but almost all of the arts councils received enormously more money from their states than from NEA. This was in part a continuation of the historic American preference for state rather than federal cultural policy, but of course it rendered the councils subject both to annual variations in state tax revenues, and to the vagaries of state politics, or both. For instance, state funding for the California Arts Council dropped from \$32 million in 2000–2001 and from \$29 million in 2001–2002, to \$1 million in 2002–2003 [Winn (2003)]. The message here is clear. As we enter the 21st century, philanthropy remains a significant source of the external support of cultural institutions and activities – although it trails far behind state and local public funding. Like all U.S. non-profit institutions since the Reagan revolution, cultural institutions increasingly will have to sustain themselves by means of earned revenues.

### *1.7. Philanthropy in the early 21st century*

Returning now to philanthropy proper in the United States, it is interesting to observe how little major institutional change has occurred, although there have been profound changes in broader philanthropic behavior. The fact is that the major institutional players remain private philanthropic foundations and community foundations, each of which has to be seen in the context of changing federal policies and priorities, since the philanthropic sector has always been an inherently reactive sector.

The number of private philanthropic foundations continues to grow, and the most remarkable change is the creation of new foundations with exceptionally large endowments. In 2004, according to the [National Center for Charitable Statistics \(2004\)](#), the

United States boasted almost 2000 private foundations with assets of \$25 million or more. This is a function of the dramatic creation of individual wealth in new industries, especially information technology, coinciding with federal tax policies favorable to the creation and retention of wealth. The most dramatic example has to be the Bill and Melinda Gates Foundation, founded only in 2000, and recently enhanced by a gift of more than \$3 billion by its founders. This makes the Gates Foundation, by any measure of historical economic value, the wealthiest foundation in the history of the United States. It has been fascinating to watch the Foundation, originally run in an intimate and informal fashion by Bill Gates' father and one of his business associates, swiftly take on the organizational form and grantmaking styles of older large philanthropic foundations. The same has been true of the Open Society Institute established in 1993 by the hedge fund manager George Soros: for many years Soros tried to direct the complex of foundations he established around the world by himself, but the major Soros foundation now looks more like the Ford Foundation than the donor seems to have intended.

The iron law of what, following DiMaggio and Powell (1983), might be called "philanthropic institutional isomorphism" has taken over for both the Gates and Soros foundations. The new foundations, accelerating a process begun in the 1970s, are changing the structure and dynamics of foundation giving, making for a more distributed philanthropic foundation system. Many of the new large foundations are in the Midwest (for instance, the Ewing and Marion Kaufman Foundation in Kansas City) or, more likely, on the west coast (for instance, the Hewlett and Packard Foundations). But the new foundations also take on new sorts of objectives, sometimes (but not always) reflecting the interests of their donors: the Gates Foundation seems to reflect very strongly the emerging philanthropic interests of Bill and Melinda Gates, and the Packard Foundation reflects primarily the interests of the late Lucille Packard; interestingly, the Hewlett Foundation seems to have developed a quite independent agenda of its own.

Another significant development, this one also originated largely in the 1970s, has been the emergence of self-consciously politically conservative foundations. Foundations such as Olin, Smith Richardson and Bradley have constructed grantmaking programs aimed at stimulating, institutionalizing and disseminating conservative ideology, both by funding university programs (for instance, in law and economics), colleges (conservative alternative student newspapers and organizations), publications (Liberty Fund) and think tanks (Heritage Foundation, American Enterprise Institute, Cato Institute). They have organized their own cross-institutional trade association (Philanthropic Roundtable) to compete with the establishment Council on Foundations and Independent Sector. They have criticized the mainstream liberalism of the foundation world, causing both surprise and consternation among the older foundations, which apparently did not realize that they were liberal, a bit like Moliere's *bourgeois gentilhomme*, who did not know that he was speaking prose. What has particularly characterized the management of the conservative foundations has been the exceptional clarity and focus of their programs, and their result orientation [see [National Committee for Responsive Philanthropy \(1997, 2004\)](#)].

The older and more mainstream foundations would deny it, but it is likely that the most important recent change in foundation behavior has been a movement to imitate the management strategies of the conservative foundations. Over the past decade a series of new foundation management rationales have developed, and along with them a consultant industry (mainly drawing on business school models and experience). The new calls are for “effective”, “strategic”, or “venture” philanthropy, and each of these is essentially a business management point of view. Of course philanthropic foundations, from the very start, have always had investment strategies, and they have always desired to be effective, but their styles were more patient, relaxed and generous. After all, by the 1920s foundations were already developing “programs” or investment areas, and appointing program officers to manage these areas. They were frequently proactive, and worked closely with their chosen grantees. According to Kiger (2000), they also tended to work with limited numbers of grantees, those in whom they had the most confidence, and whose work they could monitor closely.

I could argue that the recently emerging foundation management strategies are only nominally different from the historic model of foundation management, but in fact it seems that something quite distinctive is taking place. The changes are more in the attitudes of managers than in the techniques they use. What is now evident in many of the large U.S. philanthropic foundations is an impatience with what is said to have been the chaotic and languid styles of post World War II foundations – too many programs, too little monitoring and evaluation of grantees and these programs, too much forbearance with grantee hijacking of previously agreed upon goals and strategies, and too little measurable success. Success is now defined in a much more matter of fact fashion, related to a new preoccupation with short-term impact on specific (and sometimes narrow) policy goals. There is less tolerance for ambiguity and uncertainty, and less patience with longer-term projects. Corollary to these attitudes is impatience with research, especially basic research, into underlying causes, the signature insight of the original philanthropists, and a loss of confidence in universities as the most effective sites for carrying on philanthropic programs.

Today many foundations are narrowing their focus, limiting the range of their programs, demanding short-term, measurable deliverables contracted up-front with grantees, and holding grantees strictly accountable for what they do and do not do [see Porter and Kramer (1999); Rimel (1999); Center for Effective Philanthropy (2002)]. At the “venture” end of the new philanthropy, the entrepreneurial techniques of venture capital are being applied [Letts, Ryan and Grossman (1997)]. Donees are analogized to start-up firms, donors partner with them, establishing specific and measurable benchmarks, and continuing their investments only if periodic goals are met. A few foundations have carried these notions quite far, some of them restricting themselves to a single program, and most significantly altering the range of their substantive programs in line with these principles. The result appears to be a retreat from research, from long-term programming, from goals that cannot be quantitatively measured, and from programs that do not promise hard-edged social/economic results.

Given the changing nature and direction of the new governing attitudes in foundation management, it is not surprising that arts and culture funding is less and less prominent on the agendas of the large foundations. As [Renz, Lawrence and Smith \(2004\)](#) show, foundation support for the humanities, for instance, slipped as a proportion of overall foundation giving between 1992 and 2002, from about 2.5% to just over 2%, though more foundations made humanities-related grants. There is no longer a single major philanthropic foundation that identifies the funding of mainstream domestic arts and cultural institutions and activities as a significant investment area other than the Andrew W. Mellon Foundation. Where arts funding continues, it is normally thought of as subordinate to larger policy goals.

Consider what has happened at the Rockefeller Foundation. In the period after World War II, Rockefeller emerged as one of the largest funders of art and culture, operating through a Division of Arts and Humanities. The Division was always relatively poor in resources, compared to health and other more central Foundation concerns, but it leveraged its resources and had an important impact in the cultural sector. The Division was always precariously situated, but it was reinvigorated by a humanist Foundation President for a period of time, and survived a public-policy-oriented President. But recent President, a development economist, attempted to transform the entire organization into a vehicle for assisting disadvantaged groups, especially in the Third World. The Arts and Humanities Division was therefore reinvented as the Division of Creativity and Culture, and much of its thrust redirected in line with the new overall direction of the Foundation. It is not clear that the Division will survive the newest President. For example, the [Rockefeller Foundation \(2003\)](#) describes the desired result of its Creativity and Culture endeavors as “to enhance the well-being of societies and better equip them to interact in a global and dynamic world”. Relatively little of the Division’s resources are currently invested in any kind of conventional support and development of the domestic cultural sector. But despite these changes, Rockefeller is still an arts funder, and that is something that can now be said about only a handful of large private foundations. For the moment, there have not been major changes in corporate philanthropy with respect to the cultural sector. Expenditures continue at relatively low levels, programming remains tightly correlated to marketing goals, and corporate engagement with the sector is mostly reactive.

What has changed most in the philanthropic sector, however, is the remarkable expansion of both community and family foundations. There used to be a relatively small number of community foundations, mainly based in the major urban areas. But now even smaller towns and cities have established local community foundations, as have large and small regions of the United States; the total number of community foundations was estimated by the [C.S. Mott Foundation \(2001\)](#) to be 600 in 2000, and accelerating. This means that a much larger and more diverse population of donors, ranging from those of comparatively modest means to the superrich, now contributes funds for regranteeing in their communities. A significant recent innovation in management of community foundations, as in the United Way organizations, is in “donor-advised” funds. The pitch to new donors has been that they do not have to defer to the allocational

decisions of the trustees of community foundations, but can play an active role in determining the use of the funds they have contributed. Frequently this has meant that donors set up funds to be used for quite specific purposes, in health, social service, and sometimes in culture. This has helped to stimulate a tremendous surge of investment, much of it centrally managed in particular communities.

A significant recent development is the growth in popularity of donor-advised funds (DAFs). These philanthropic instruments have been available since the 1930s, but have only become prominent since the early 1990s. Some of them – those managed by commercial investment firms such as Fidelity Funds – compete with community foundations. It is too soon to evaluate their impact on broader patterns of philanthropic investment, but it is already apparent that they are becoming major players. [Luck and Feurt \(2002\)](#) estimated that in 2000, just the assets of DAFs managed by community foundations (that is, excluding those managed by for-profit firms) totaled more than \$5 billion. While we do not have the data to assess the range and extent of their sectoral investments, it seems that they have not yet had a major interest in the cultural sector.

This cannot be said of the other major change on the philanthropic scene at the turn of the twenty-first century – the explosion of family foundations. The “family” foundation is of course not new. It could be said that the Rockefeller Foundation and the Carnegie Corporation were among the first family foundations, but of course these institutions evolved into general purpose foundations managed primarily (or in the case of Carnegie, entirely) by others than relatives of the donor. These days when we talk of family foundations we refer to those whose trustees are entirely (or primarily) members of the donor’s family – and of course by the donor him or herself. Family foundations, many of them extremely small, number in the tens of thousands [[Foundation Center \(2005\)](#)]. In many cases they are really little more than unstaffed or thinly-staffed emanations of individual philanthropists. Given the remarkable creation of individual wealth in the United States in the 1990s, it is not surprising that thousands of family foundations have been newly-established, but it is quite surprising, given the earlier history of foundations, that so many extremely large family foundations have been established. Some of them, as already mentioned, like the Bill and Melinda Gates Foundation, quickly developed into more highly organized, fully-staffed and rationalized general (or broadly-purposed) foundations, but others – such as Gordon Moore’s Gordon E. and Betty I. Moore Foundation – have remained highly personalized donor-driven foundations, at least so far.

We are still, in effect, in the first decade of what many are calling the “new” philanthropy in the United States, and we do not yet have enough data to be sure what the impact of new institutions and new strategies is. I have suggested elsewhere that there is less new about the new philanthropy than the claims of its enthusiasts suggest [[Katz and Stacey \(2004\)](#)]. And it is worth noting that these claims come largely from the rapidly growing new field of for-profit philanthropic consultants, the bulk of them in or recently spun-off from business consulting firms such as McKinsey and Bain. But even I am pretty sure that there is something more than novel rhetoric at play.

My guess, without a full analysis of the available data, is that the combination of rapid expansion of the community foundation sector, the burgeoning of donor-advised

funds (both in the non- and for-profit sectors) and the proliferation of family foundations is substantially changing the dimensions of philanthropic giving, the composition of donee communities, and the relations between donors and donees. It is always difficult to analyze change while it is taking place, but my sense is that we are currently living through a truly significant transitional era in the history of philanthropy in the United States. If nothing else, there is considerably more philanthropic capital in play, and there is an equally significant increase in the number and character of players. And all of this is taking place on a truly continental basis, changing the map of philanthropy from one that twenty-five years ago was focused on the Northeast, the upper Midwest, California and the Pacific Northwest.

### *1.8. Philanthropy, economy and government policy*

I have just suggested the changes within the philanthropy, but I would also like to stress the obvious fact that the philanthropic sector has always developed interactively with major state policies and with the general economy. Other essays in this volume will deal with tax policy, for instance, but I hope it is obvious that both overall rates of income taxation and tax policies specific to both foundations and individual giving have specific and fairly predictable impacts upon philanthropy.<sup>6</sup> The current proposals for elimination of inheritance taxes, for instance, have stimulated both general and scholarly debate over what their legislation might do to the propensity of the wealthy to transfer wealth to their families rather than to the larger society. Likewise, the much heralded explosion in the intergenerational transfer of wealth, if true, is bound to have a measurable impact on philanthropic investment, and probably upon the styles of investment as well [see [Schervish and Havens \(2002, 2003\)](#)].

Moreover, changes in federal social policy have an impact (often hard to measure) on philanthropy. After the election of Ronald Reagan in 1980, Republicans and conservatives demanded (and achieved) steep reductions in the federal social budget, while at the same time calling for the private charitable sector to take up the slack left by the retreat of the state. That did not happen to the hoped-for extent, but cutbacks in federal funding certainly did redirect both individual and institutional philanthropic investment, particularly in the service-providing sector [[Salamon and Abramson \(1982\)](#)]. And, as I have already mentioned, it forced non-profit institutions to try to generate earned income. These were among the forces that compelled museums to expand their gift shops, to rent out their facilities for social occasions, and to mount more spectacular blockbuster exhibitions in order to augment dwindling philanthropic and municipal financial support. To this extent the cultural sector behaved much like those service-providing non-profits that began to charge clients for what had previously been free services.

The conservative political movement in American national politics that took off with the Reagan administration was continued by George H.W. Bush and his son – and it

<sup>6</sup> See further Schuster's [Chapter 36](#) in this volume.

was the elder Bush who tried to stimulate private giving by describing in a 1988 speech the “1000 Points of Light” making positive impacts in their local communities. But it has seldom been noticed that the emphasis on private charitable and philanthropic involvement was emphasized nearly as much by Bill Clinton and his centrist Democratic administration. It was on Clinton’s watch that the first ever White House conference focusing on charitable giving was held [[Chronicle of Philanthropy \(1999a, 1999b\)](#)]. But it is not only social politics that drive the interest of the state in the philanthropic sector. Roughly every ten years since World War I the federal Congress has launched noisy investigations into the behavior of the philanthropic sector, and we are currently at the beginning of such an episode. In 2004 the Senate Finance Committee investigated a wide range of alleged foundation abuses, ranging from excessive expenditures for foundation staff, trustees and administration to suggestions for legislating requirements for board meetings and oversight of foundation affairs [[Grassley \(2004\)](#)]. This should remind Americans that what they have taken to calling the Independent Sector (usually called the Third Sector in Europe and the rest of the world) is not so completely independent.

Such government policies and activities – aside from the policies restricting the size, scope and funding of the Endowments for the Arts and Humanities and changes in Internal Revenue Service regulations governing charitable donations – do not ordinarily have a direct, specifiable impact on the cultural sector. Mostly, the impact (or lack of impact) of philanthropy on culture comes from alterations in foundation and individual donor behaviors and preferences, and these alterations are mostly endogenously generated. Culture is truly a part of the larger philanthropic and non-profit sector. The problem, if there is one, is that it is not a very large part of the sector. My hunch, though, is that there is much more philanthropic support than arts and cultural advocates, such as Americans for the Arts, admit. It is hidden in individual and donor-advised gifts that are not adequately publicly reported.

### *1.9. The American affinity for philanthropy*

Why do Americans give? A great deal has been written on motivations for philanthropic behavior in the United States, but general explanations are not of much help in understanding the instinct to give to a particular cause. The interesting issue is the distinction between charitable motivations, presumably similar across national and cultural borders, and the propensity to philanthropic activity [see [Ilchman, Katz and Queen \(1998\)](#)].

Philanthropy seems to me a distinctly American phenomenon, although of course it is now being appropriated and adapted in other (mostly post-industrial) national cultures. The usual explanation, tax avoidance, does not take us very far in understanding the phenomenon. The earliest twentieth-century philanthropic foundations were after all created before the federal government was permitted to tax individual income, following the passage of the Income Tax Amendment in 1913. There had been state income taxes since the Civil War, but the rates of state taxation were very low. Indeed, when John D. Rockefeller, Sr. was considering forming his foundation during the first decade of the

twentieth century, he instructed his lawyers to investigate state rates of income taxation. Their response was that it did not matter in which state the foundation was chartered since state taxation was so low as not to be a factor in the decision as to where to incorporate. Taxation became more of an issue by the 1930s, with the passage of federal gift and estate taxes. Both the Ford Foundation and the Lilly Endowment were created at that time explicitly as tax avoidance measures, but neither was funded for many years. There is some evidence that declines in marginal rates of taxation produce declines philanthropic giving, but the effect is not strong. Taxation is clearly an incentive to engage in tax-deductible behavior, but it is hardly the only motivation and I doubt that it is the major factor.

Much more important, I would speculate, is what I would call the American philanthropic instinct. This is distinctly not a specifically altruistic instinct, but rather a desire to contribute to the improvement in the conditions of human existence. The philanthropist may or may not share the belief of Andrew Carnegie and John D. Rockefeller, Sr. that his religious duty was to discover the underlying causes of illness and misery in order systematically to address them. There is no doubt that Protestant religion was a strong component in the belief systems of many of the early philanthropists, and religion may well still play a motivational role in American philanthropy. But it is unlikely to be the dominant motivation, and it plays no role whatsoever for many givers. The deeper and more pervasive instinct is the one first clearly demonstrated by the first generation of American philanthropists, and it relates to a generalized commitment to make the world a better place for all.

Clearly urge to make the world a better place is not unique to one country. But historical conditions have given it a peculiar salience and form of expression in the United States [Katz (2003)]. It doubtless found its origins in a people living in a country with a weak state tradition, one in which there was little history of the state (especially the national state) “doing good”. The early philanthropists feared the state, and worried especially that the state in America would move in the direction of European welfare states of the late nineteenth and early twentieth centuries. The answer was for individuals to take up the responsibility that Europeans assigned to the states, and to retain the wellsprings of reform in the private sector [Karl and Katz (1981)]. Times have changed and government in America has grown, but the significant emphasis of the conservative movement of the last generation in American politics shows just how tied the rhetoric of American philanthropy is to state-replacing activities. I doubt most American philanthropists are self-consciously state-replacers in any explicit sense, but their instinct to imagine and support the non-profit engines of human betterment derive from the original Carnegie–Rockefeller tradition.

## **2. Philanthropy outside the United States**

I want to conclude with a few remarks about the arts, culture and philanthropy elsewhere in the world. I have focused on the United States both because American philanthropy

is what I study, but also because private cultural philanthropy is vastly larger and more significant in the U.S. than elsewhere in the world. Though I do not think there are statistics to rely upon, it is hard to imagine that the sum total of private financial investment in culture in the U.S. is not larger than that in all other countries combined. Even if that assertion is too extreme, it is absolutely clear that no other single nation comes close to the level of private philanthropic investment in culture currently existing in the U.S. [Salamon and Sokolowski \(2004\)](#) have shown that the philanthropic giving of the United States outstrips that of most rich countries (even when donations to religious bodies are excluded), and the tradition of state support for the arts and culture in European countries has tended to depress private giving to the sector. Of course, what is interesting is the extent to which so many other nations are moving in the direction of the United States, frequently dramatically, as the size of their state sector declines and as they pursue self-conscious policies of privatization in their cultural sector.

History has made the difference, and here I will use Europe as the example. As art and culture developed from, say, the Renaissance, they took root in and were supported by patronage – the gifts and protection of the wealthy and powerful. These included the church and the politically powerful, but much early patronage was provided by individuals – it came from kings and princes and barons and cardinals and state ministers and merchants. There was of course a coincidence of private wealth and public power in pre-modern times, and at least from the fifteenth century the wealthy and powerful felt it both their duty and their prerogative to support artists, writers, craftsmen and other producers of culture and cultural institutions such as schools and cathedrals. The aim of the patrons was to glorify themselves and their families. But of course the maintenance and glorification of the Catholic Church was an equally important motivation. And this complex system of private patronage remained in place well into the nineteenth century.

But it had begun to be supplanted by the state and the state church from the sixteenth century forward. An obvious example was abolition of the English monasteries by Henry VIII, and the consequent necessity of the Crown to provide for institutions of religion and education [[Jordan \(1959\)](#)]. Such tendencies increased with the rise of parliaments in the Netherlands and England in the seventeenth century, and by the time of the French Revolution the emerging nation-state (with or without a king) had tended to take over church and crown responsibilities for cultural patronage. This was not entirely a self-conscious or explicit decision on the part of the state, but rather a reflection of democratizing nations espousing strong notions of state power to do publicly what had previously been done by the nobility, the crown and the church [see [Adam \(2004\)](#)]. The patron-state emerged over the course of the nineteenth century, assuming the dominant responsibility for education, state religion and arts institutions such as libraries and museums. In federal states, such as Germany, these patronage functions were frequently distributed regionally, according to local traditions of federalism, but they were ordinarily conceived of as state functions by Europeans [see [D'Angelo \(2000\)](#)].

As the twentieth century began, these forms of state support persisted, though they were less frequently conceptualized as patronage proper. They became institutionalized

in (state and federal) ministries of culture, the official expression of the responsibility of the state for cultural institutions and cultural policy. And both of these developments were quite different from the emerging tradition of the privatization of culture in America. If the state was to collect tax monies for culture, it asserted the right to set the policies according to which they would be given. And across Europe, but especially on the continent, the state was a generous funder of culture, sometimes with a light imposition of policy and other times with a heavy hand (the national socialist movements, for instance). On the other hand, American museums and other major cultural institutions were founded almost entirely by private wealth in the late nineteenth century, and that pattern continues – with some important exceptions – to this day.

But by the 1970s the attack on the welfare state in Europe, led by Margaret Thatcher in the United Kingdom, focused the attention of government on methods of shifting the burden off the backs of taxpayers. Privatization emerged as the obvious solution, along with a stiff dose of neo-classical economics and economic policy. In effect, Britain began a policy of Americanization of the political economy that still drives most change in state policy across the world, and certainly in Europe. The trend has apparently hit hard in the cultural sector there. To some extent non-tax alternatives, especially lotteries, have emerged to take up the space left by a receding patron state, but the larger move has been to encourage the privatization of cultural institutions, whether by their severing their ties with the state, or by finding additional non-state sources of revenue; the current debate in the United Kingdom and in most of the Commonwealth countries about the raising of student tuition fees is just one instance.

But, perhaps independently, something like a U.S. philanthropic sector has been emerging on the continent (and also in Latin America, Japan, and elsewhere). The movement has been aided in some countries by legislative action to provide tax incentives for individual charitable giving, but also by policies favorable to the establishment of non-governmental organizations (analogues to American non-profits) and to the creation of legal novelties, philanthropic foundations [*The Economist* (2004)]. There are now considerable numbers of both private and corporate foundations in Europe, though the financial levels at which they operate are modest by American standards. Still they are part of what appears to be an inexorable rollback of the state and an expansion of the use of private wealth for public purposes.

I am not sure that we can tell with any precision what the specific impacts on this move to private support have meant for the cultural sector in Europe. Certainly there have been cries of distress from universities, opera companies, museums and other cultural institutions that sound a good deal like similar noises being heard in the U.S. But it is not clear, at least to me, what degree of financial impact, sorts of structural modifications or alterations in cultural content are coming into existence. It is hard, though, to imagine that there will not be some important implications for the cultural sector.

### 3. Conclusion

What seems obvious, when all is said and done, is that the winds of change are blowing. Although in vastly different ways, the state is retreating from culture everywhere – although at the same time it remains everywhere a significant player on the cultural scene. In the United States we are in a transitional phase in which levels of real and potential philanthropy are rising dramatically, the state has abandoned even the modest policy claims it briefly asserted in the 1960s and 1970s, and yet the cultural sector feels that it is caught in a situation of severe shortage of funding. In Europe, the philanthropic sector expands as privatization proceeds apace, yet the state is not prepared to abandon its responsibility for cultural policy. We are probably in Act III of a five-act play, and it is much too soon to know how the plot will unfold.

## ACKNOWLEDGEMENTS

In September 2004 an authors' conference was held at Princeton University at which most of the chapters contained in this volume were presented. Contributors benefited enormously from the interchange and discussion at this conference and this assisted greatly in the process of revising chapters for publication. We wish to express our thanks to the Industrial Relations Section at Princeton, and especially to Orley Ashenfelter and Alan Krueger, for their invaluable support in making this meeting happen. We are also grateful to the Belgian Fonds National de la Recherche Scientifique, the Belgian Central Bank (Banque Nationale de Belgique) and the Department of Economics at Macquarie University, Sydney, for their financial assistance.

We also wish to thank Laura Billington for her help in the preparation and editing of this volume.

Victor Ginsburgh  
David Throsby  
*November 2005*

# CONTENTS OF THE HANDBOOK

## VOLUME 1

### PART 1: INTRODUCTION

#### *Chapter 1*

Introduction and Overview

DAVID THROSBY

### PART 2: HISTORY

#### *Chapter 2*

Art and Culture in the History of Economic Thought

CRAUFURD GOODWIN

#### *Chapter 3*

The History of Art Markets

NEIL DE MARCHI AND HANS J. VAN MIEGROET

#### *Chapter 4*

The Evolution of Music Markets

F.M. SCHERER

### PART 3: VALUE

#### *Chapter 5*

Defining Cultural and Artistic Goods

ROGER MCCAIN

#### *Chapter 6*

Value and the Valuation of Art in Economic and Aesthetic Theory

MICHAEL HUTTER AND RICHARD SHUSTERMAN

### PART 4: LEGAL ISSUES

#### *Chapter 7*

The Economic Analysis of Art Law

WILLIAM M. LANDES AND DANIEL B. LEVINE

*Chapter 8*

Copies of Artworks: The Case of Paintings and Prints

FRANÇOISE BENHAMOU AND VICTOR GINSBURGH

*Chapter 9*

Copyright, Art and Internet: Blessing the Curse?

PATRICK LEGROS

*Chapter 10*

Censorship versus Freedom of Expression in the Arts

TUN-JEN CHIANG AND RICHARD A. POSNER

## PART 5: CULTURE AND THE ECONOMY

*Chapter 11*

The Arts in the “New Economy”

WILLIAM J. BAUMOL

*Chapter 12*

Culture and Economic Performance

MARK CASSON

*Chapter 13*

Culture and Economic Development

PAUL STREETEN

## PART 6: CONSUMPTION AND PRODUCTION

*Chapter 14*

Empirical Studies of Demand for the Performing Arts

BRUCE A. SEAMAN

*Chapter 15*

Nonprofit Firms in the Performing Arts

ARTHUR C. BROOKS

*Chapter 16*

Creativity and the Behavior of Artists

WILLIAM D.A. BRYANT AND DAVID THROSBY

## PART 7: CULTURAL INDUSTRIES

*Chapter 17*

Organization of Arts and Entertainment Industries

RICHARD E. CAVES

*Chapter 18*

**The Media and Advertising: A Tale of Two-Sided Markets**

SIMON P. ANDERSON AND JEAN J. GABSZEWICZ

*Chapter 19*

**The Movies**

ARTHUR DE VANY

*Chapter 20*

**Rockonomics: The Economics of Popular Music**

MARIE CONNOLLY AND ALAN B. KRUEGER

*Chapter 21*

**The Economics of Books**

MARCEL CANOY, JAN C. VAN OURS AND FREDERICK VAN DER PLOEG

**PART 8: LABOR MARKETS**

*Chapter 22*

**Artistic Labor Markets: Contingent Work, Excess Supply and Occupational Risk Management**

PIERRE-MICHEL MENGER

*Chapter 23*

**Artists' Careers and Their Labor Markets**

NEIL O. ALPER AND GREGORY H. WASSALL

*Chapter 24*

**Human Capital and Artists' Labor Markets**

RUTH TOWSE

*Chapter 25*

**Stardom and Talent**

MOSHE ADLER

**PART 9: AUCTIONS AND PRICES**

*Chapter 26*

**Art Auctions**

ORLEY ASHENFELTER AND KATHRYN GRADDY

*Chapter 27*

**The Computation of Prices Indices**

VICTOR GINSBURGH, JIANPING MEI AND MICHAEL MOSES

**PART 10: HERITAGE***Chapter 28***Cultural Heritage: Economic Analysis and Public Policy**

ILDE RIZZO AND DAVID THROSBY

*Chapter 29***The Economics of Museums**

BRUNO S. FREY AND STEPHAN MEIER

**PART 11: LOCATION***Chapter 30***Culture in Urban and Regional Development**

TRINE BILLE AND GÜNTHER G. SCHULZE

*Chapter 31***Cultural Districts and Their Role in Developed and Developing Countries**

WALTER SANTAGATA

**PART 12: POLICY***Chapter 32***The Arts and Economic Policy**

ALAN PEACOCK

*Chapter 33***Culture in International Trade**

KEITH ACHESON AND CHRISTOPHER MAULE

*Chapter 34***The Making of Cultural Policy: A European Perspective**

FREDERICK VAN DER PLOEG

*Chapter 35***Cultural Policy: An American View**

DICK NETZER

*Chapter 36***Tax Incentives in Cultural Policy**

J. MARK SCHUSTER

*Chapter 37***Philanthropy**

STANLEY N. KATZ
