Ratings are assigned by specialized organizations—credit rating agencies. There exist many of them worldwide (roughly 130 to 150 as of 2000), and they vary in terms of size, geographical and industry focus, and the methodology that they employ. However, most of these agencies are rather small, and the field is dominated by two major players: Moody's Investors Service Inc. (Moody's) and Standard & Poor's (S&P). The large credit agencies play an important role in capital markets. First, they provide valuation by disseminating timely and supposedly valuable information to the market participants. Second, they indirectly participate in financial regulation: In some countries letter ratings are viewed as useful credit quality benchmarks, and capital requirements are directly linked to credit ratings. For example, the quasi-regulatory role of the major credit agencies has been increased by the Basel II Framework.

There are two main types of ratings: solicited and unsolicited. A solicited rating means that a company itself expressed a wish to be rated and asked an agency to issue it a rating, usually for a fee. An unsolicited rating implies that it was an agency's own decision to rate a company. In the case of unsolicited ratings, an agency usually has to rely on publicly available information only to come up with an assessment. The rationale for the practice of assigning unsolicited ratings is that it discourages a self-selection process in which only low-risk issuers are rated and all others avoid obtaining a credit rating by not requesting it. Rating agencies also use unsolicited ratings to establish their reputation or expand their business into new markets. When a rating is solicited, an agency relies not only on public information, but also makes extensive use of internal data such as company documents, interviews with the company's executives, etc.

There are several reasons why issuers are interested in acquiring a credit rating. The main one is the access to capital markets—in some countries, having a rating is a de-facto prerequisite. Other reasons include building up market reputation, lowering the cost of funding (an unrated entity usually has to pay a larger risk premium), and distinguishing oneself from competitors.

The rating processes used by different agencies can vary significantly. Large agencies use both quantitative and qualitative criteria to assess an issuer, whereas smaller agencies tend to focus on quantitative criteria only. The rating process consists of the assessment of various factors. One of them is the environment, which can vary considerably depending on the nature of the entity under assessment. Meetings with the issuer constitute an important part of the rating process. During these meetings, comprehensive in-depth information is collected and any questions that came up in previous phases are clarified. The rating process also often includes the analysis of a peer group (a group of comparable entities).

Several points of criticism have been expressed about the credit-rating agencies. They have apparently failed to predict large-scale crises such as the 1997 Asian crisis or notorious corporate scandals such as Enron and WorldCom. Another source of criticism is the secretive nature of the rating process—rating agencies disclose their rating methodologies only partially. Some have expressed concerns about the fact that rating agencies have conflicting incentives connected with their two functions of information dissemination and facilitation of contracts. Another point of criticism has to do with the so-called rating triggers. A rating trigger is a contractual provision that gives lenders certain rights in case a borrower's rating falls below a predefined level. Rating triggers can lead to the loss of investor confidence and the bankruptcy of an issuer.

Credit Suisse

The Credit Suisse Group is a Zurich-based financial services corporation offering investment banking, private banking, and asset management through its three divisions. The Credit Suisse Shared Services division provides services in support of the other three divisions, principally legal and IT service.

Alfred Escher (1819–82) founded the company, then called Schweizerische Kreditanstalt, in 1856. An adept politician from Zurich, Escher had made a nationwide name for himself with his support of railways as the solution to Switzerland's malaise following the brief civil war of the 1840s, a solution that would end the country's economic and geographic isolation. In particular, Escher was instrumental in keeping the railroads in the private sector—benefiting Zurich, since state-supported railroads would centralize the industry and its earnings in Bern, the capital of the new federal government (established in 1848). While continuing his political service, Escher also acted as the Managing Director of the Northeastern Railway Company, and founded the Kreditanstalt to finance transalpine railway lines. He helped develop Swiss Life, now Switzerland's largest insurance company, the following year.

The Credit Suisse offices in Hong Kong. In 2007 the company employed 50,000 people worldwide.

Three million francs of Kreditanstalt stock were issued, valued at over 200 million francs within days. The Swiss Confederation, at risk of falling behind western Europe and its Industrial Revolution, was hungry for industrialization and the railways helped make that possible while the Kreditanstalt helped finance it—and helped Zurich become and remain Switzerland's financial center. As Switzerland industrialized, it entered—until World War I—a golden age that helped it become the banking capital of the world. The first foreign office of Credit Suisse was opened in 1870 (in New York City), and by the end of the 19th century the company had become the principal player in the Swiss underwriting business. Branch offices outside of Zurich began opening in 1905 (the first in Basel), and its underwriting business expanded overseas.

The impact of the Great Depression increased tensions and nationalist sentiment across Europe, and Credit Suisse looked overseas for safer sources of capital. The Swiss American Corporation was founded in 1939 in New York City, as a subsidiary of Credit Suisse's underwriting business and investment consultancy. Years later, it would be discovered that during the war years, Credit Suisse was one of several banks guilty of improper dealings with Nazi Germany, and mishandling of the "dormant accounts issue" (accounts opened before the end of the war by account holders who became victims of the Holocaust). Like the other banks, Credit Suisse eventually settled by paying money into a pool for reparations as well as to establish a humanitarian fund. In 1964 Credit Suisse was granted a license as a full-service bank in the United States, and in 1982 the bank became the first Swiss bank with a listing on the New York Stock Exchange (via its subsidiary Swiss American Securities).

The American bank First Boston was taken over by Credit Suisse in 1990, becoming Credit Suisse First Boston—now the bank's investment banking division. The acquisition came in fits and starts. Credit Suisse First Boston had been the name of a joint CS/FB venture in 1978, and unhappiness with the terms of the venture along with an unsuccessful stretch of a few years led to the departure of several CSFB executives, some of them leaving for Merrill Lynch.

Credit Suisse's acquisition of First Boston, folding it into CSFB, was part of its response to the change in investment banking in the 80s as Goldman Sachs and Salomon Brothers began to compete with them in the Eurobond market, along with the perception that CSFB and Credit Suisse were in competition with one another for certain services. The 1987 stock market crash and mid-1980s allegations that the bank participated in laundering eastern European drug money had hit Credit Suisse hard, while First Boston suffered from bad loans made for mergers and acquisitions. The acquisition and restructuring was meant to strengthen and redefine both companies.

The 1990s saw more acquisitions and alliances, and the array of banks and services were reorganized in 2002 as the Credit Suisse Group. Several restructurings followed in rapid succession as the company maneuvered to recover from the record losses it had posted in 2002. The current form of the bank, with its three main divisions and shared services division, originated in 2006, in commemoration of the original bank's 150th anniversary. Credit Suisse First Boston provides debt and equity underwriting, securities services, and mergers and acquisitions management. The group is the second largest financial services firm in Switzerland, behind UBS, and operates in 60 countries, with over 200 retail branches in its homeland.

Croatia

At the beginning of the 20th century, Croatia was part of the Austro-Hungarian Empire. Following the empire's demise in 1918, a kingdom of Slovenes, Croats, and Serbs was established. Croat opposition to the new structure gradually increased, but any attempts to promote democratic change were stifled, and Yugoslavia was established in 1929. An independence movement, led by the Ustase Croatian Liberation Movement, gradually grew. Force was used in an attempt to establish an independent state. However, it was not until the German invasion of Yugoslavia on April 6, 1941, that Ustase leader Ante Pavelic was installed as the leader of an independent state of Croatia. However, by 1943 partisan opposition forces, under Josip Broz (Tito), controlled much of Croatia. On October 20, 1944, Tito became prime minister of Yugoslavia; Croatia became one of six constituent republics of a federal, independent communist state.

The further concentration of power in Belgrade produced further unrest in Croatia, culminating in the Croatian Spring of 1971—a call for greater autonomy and constitutional reform. When Tito died in 1980, Croatia was still a long way from independence. However, 1989 saw political change sweeping across Eastern Europe. Following elections, constitutional changes, and a referendum, Croatia declared independence on June 25, 1991. Fighting broke out. Amid ethnic rivalries thousands were killed and hundreds of thousands were forced to leave their homes. In January 1992 the United Nations negotiated a cease-fire and Croatia was recognized by the European Union (EU), and in April by the United States.

January 1993 saw further fighting in the Krajina region. In June 1993, the Krajinian Serbs voted to join Greater Serbia. Fighting continued, with widespread atrocities on both sides, until the Dayton Accord, recognizing Croatia's traditional boundaries, was signed in Paris in December 1995, establishing the Republic of Croatia as a presidential/parliamentary democracy, with Zagreb as its capital. The last Serb-held enclave in eastern Slavonia was returned to Croatia in 1998. Croatia's bid for membership of the EU received a boost in March 2008 when the European Commission said that it should be possible to complete accession negotiations by the end of 2009.

Croatia is now divided into 20 counties, and in 2008 the population is estimated to be approximately 4.5 million. The president is the head of state, elected to a five-year term. The leader of the majority party or the leader of the majority coalition is usually appointed prime minister by the president and then approved by the unicameral Assembly or Sabor. The Assembly comprises 153 seats; members are elected from party lists, by popular vote, to serve a four-year term. In the elections of November 25, 2007, the center-right Croatian Democratic Union or HDZ was the biggest party, with 66 seats; although not a majority, they were able to hold power through deals with smaller coalition partners that gave them an 83-seat total.

Croatia's economy suffered badly during the 1991–95 war as output collapsed. Since 2000, however, economic fortunes have improved steadily. gross domestic product (GDP) growth has been between 4 and 6 percent (5.6 percent in 2007). This has largely been on the back of a rebound in tourism and credit-driven consumer spending. Croatia registered 53 million tourist nights in 2006, up 36 percent from 2000. Total annual visitors could top 12 million by 2012. Inflation over the same period has remained low, 2.2 percent in 2007, and the currency has been generally stable. The government has also reduced the budget deficit to 2.6 percent of GDP in 2007. On the downside, the unemployment rate remains high at 11.8 percent in 2007, though economic growth should bring this down. There is also a growing trade deficit and uneven regional development.

Incremental reforms have helped the investment climate, as reflected in improved ratings in 2007 from Transparency International, the World Bank, and the World Economic Forum (WEF). The WEF's Global Competitiveness Index for 2006–07, published at the end of October 2007, ranks Croatia 57th out of 122 countries, with strong scores for education and technological readiness, along with weak scores for state administration and corruption.

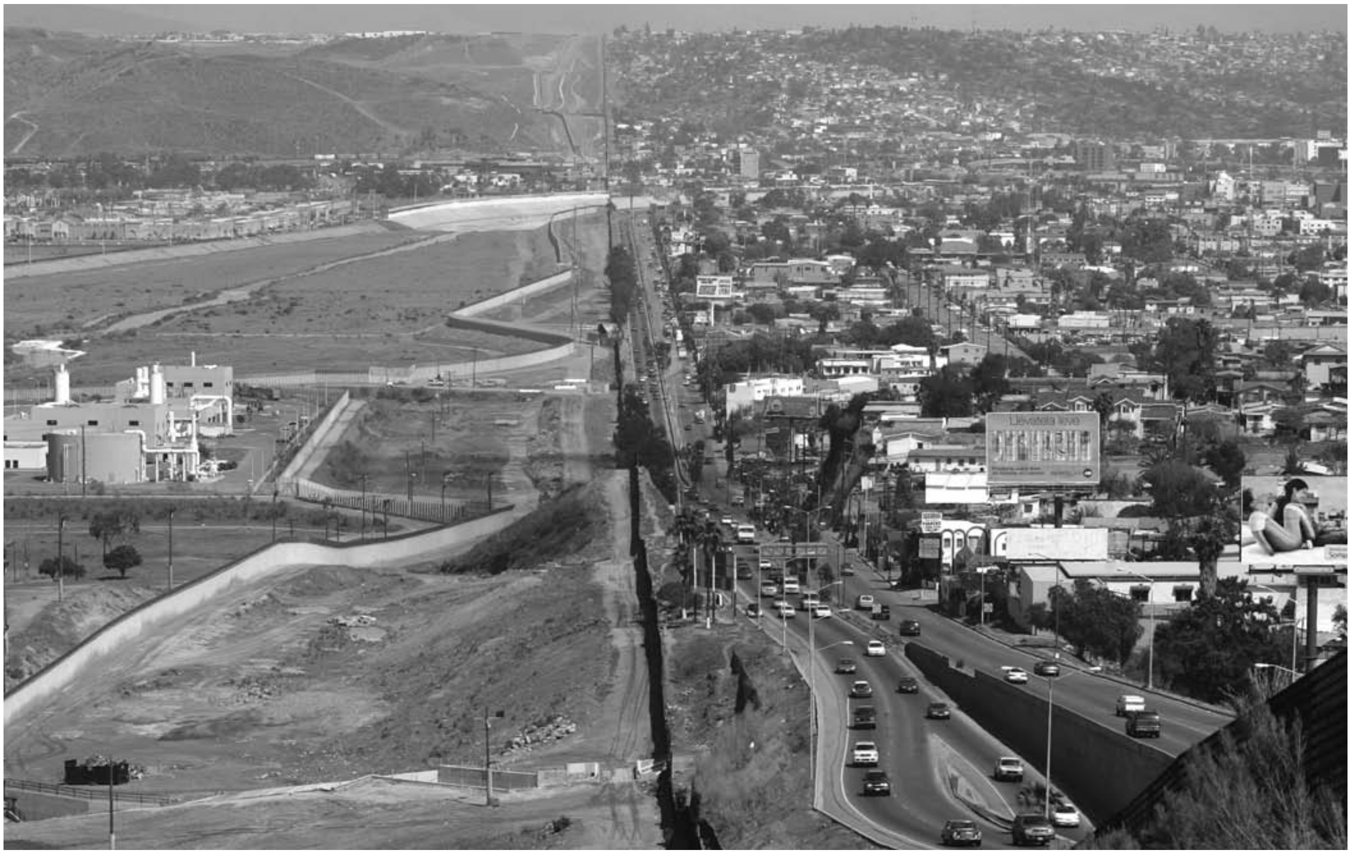
Cross-Border Migrations

The human species has a long nomadic history. The more recent concept of "cross-border migration" emerged from the formation of powerful territorially-based states in Europe. It gained practical importance after developments in transportation, communication, and industrialization enabled Europeans to colonize large parts of the rest of the world, and to relocate both within Europe and overseas in large numbers. By the early 20th century, with the general adoption of passports and border controls, cross-border migration had become a widespread political concern, and foreign workers a major source of labor used by businesses large and small.

In 2007 about 200 million people, or 3 percent of the world's population, lived outside the country of their birth. Likewise, the roughly 100 million migrant workers globally amounted to about 3 percent of the world's workforce. In certain regions, especially Western Europe and North America, and in certain occupations, such as computer programming, nursing, restaurants, and crop harvesting, these percentages have been much higher. International migrant remittances to developing countries totaled about $250 billion in 2005.

Most modern cross-border migration is associated with economic differences between countries. In 1975 per capita gross domestic product was about 40 times greater in high-income countries than in low-income countries; by 2000 this ratio had risen to over 60. Other "pushes" and "pulls" motivating international migration are noneconomic, notably family reunification and mass flight from disaster. Refugees with a "well-founded fear of persecution" have protected status under international conventions and within many national jurisdictions. In practice, however,



A densely populated Mexican city, at right, juts up against the heavily fortified border with the United States. In 2000 per capita gross domestic product was over 60 times greater in high-income countries than in low-income countries.

"economic migrants" and "political refugees" are overlapping categories. Similarly, although a cross-border migrant is generally one who moves internationally and stays at least a year in the new "host" country, it is often difficult to distinguish between "temporary" and "permanent" migrants. A more recent concern is the potential for cross-border refugee flows provoked by natural disasters, particularly catastrophic floods and droughts associated with global climate change.

A considerable fraction of cross-border migration moves without documentation and illegally into receiving countries. This causes practical problems along migratory routes and political problems for governments of sending countries (whose people want to leave) and of receiving countries (which cannot "control" their borders). Undocumented migrants also face the risk of exploitation by smugglers and difficulties of social integration while working "underground." How to deal with illegal immigration has recently been a major political issue in the United States.

Government Policies

Government policies on cross-border migration have been inconsistent. There are far fewer border restrictions on leaving than on entering. Official policies also partly reflect popular ambivalence. Voters in receiving countries are often apprehensive about large numbers of foreigners in their midst, but not opposed to readily available low-cost labor. Migrant workers are usually more productive than they would be at home, but the resulting net benefits of cross-border migration are unevenly distributed. At times, low-skilled workers in richer countries may suffer wage declines due to migration. Movements of migrants, however, are significantly influenced by economic cycles, not just by public policies or popular attitudes.

A "guest worker" program bringing foreigners temporarily to the United States was a key component of the comprehensive "compromise" immigration bill rejected by the U.S. Congress in 2006. Past guest worker programs, such as the "bracero program" of the 1940s and 1950s in North America, and the imports of labor to Western Europe during the 1960s boom, did provide economic benefits. "Temporary" guest workers, however, have often become permanent residents, bringing in relatives through the family network links that have long been central to self-replicating migration. Such networks are also prevalent within the growing migration between developing countries.

Large corporate employers in developed countries have been particularly interested in hiring more high-skilled foreigners. With cross-border flows of goods and finance much less restricted in recent decades than movements of workers, it has been more cost effective to tap the low-skilled labor of poorer countries by "outsourcing" production, assembly, and clerical functions there. Movements of professional workers, especially in science, engineering, and higher education, are a smaller but important form of cross-border migration. The extent and incidence of benefits and costs resulting from this "brain drain" are a matter of considerable interest to scholars and policy makers on which no general consensus has yet emerged.

Cross-Border Trading

The role and importance of international financial markets and the traders who work in the industry has grown during the past decades. Professional traders are highly visible, especially in the media. They tend to be in a position to exploit market imperfections and have access to privileged information, critical mass, or proprietary knowledge and models.

Financial markets can be defined in two ways. The term can refer to organizations that facilitate the trade of financial products or it can refer to the interaction between buyers and sellers to trade financial products. Many who study the field of finance use both definitions, but economics scholars tend to use the second meaning. Financial markets can be both domestic and international.

Financial markets can be seen as an economics term because it highlights how individuals buy and sell financial securities, commodities, and other items at low transaction costs and prices that reflect efficient markets. The overall objective of the process is to gather all of the sellers and put them in one place so that they can meet and interact with potential buyers. The goal is to create a process that will make it easy for the two groups to conduct business.

When looking at the concept of "financial markets" from a finance perspective, one could view financial markets as a way to facilitate the process of raising capital, transferring risk, and conducting international trade. The overall objective is to provide an opportunity for those who want capital to interact with those who have capital. In most cases, a borrower will issue a receipt to the lender promising to pay back the capital. These receipts are called securities and can be bought or sold. Lenders expect to be compensated for lending the money. Their compensation tends to be in the form of interest or dividends.

Traders

Trader activities can be divided into three categories, which are trading on behalf of the customer, market making, and propriety trading. Traders with the least amount of risk are the ones who act on behalf of the customer. At the other end of the spectrum are proprietary traders, who take on the greatest risk. Regardless of the category, traders must utilize a set of strategies and approaches in order to make a profit. Four of the main strategies include the following:

1. Insider strategy: The trader achieves the advantage by exploiting privileged access to information. However, the trader must be cautious because some techniques may be illegal. For example, information about company earnings

and potential takeovers could be considered illegally obtained information. Insider strategies give the trader an opportunity to anticipate market movements.

2. Technical strategy: Some traders attempt to exploit market imperfections by analyzing past price information. One form of technical strategy involves the use of patterns in price data in order to identify potential turning points in price trends. This is referred to as charting. Traders attempt to identify trends early, buy into those trends, and exit before the trend breaks. There are a number of traders who use the technical strategy to complement other techniques.
3. Fundamental strategy: Fundamental strategies focus on the fundamental relationship between the economic value of the underlying asset and the market price. Traders use this strategy to seek expertise and information in order to obtain an accurate valuation of securities. There is an assumption that market values will converge to theoretical values.
4. Flow strategy: This strategy predicts prices as a function of demand and supply for securities in the market.

Swaps

In the world of finance, a swap can be defined as an agreement between two parties, who are referred to as counterparties. The counterparties exchange cash flows over a period of time in the future. The cash flows are calculated based on a notional principal amount, which is not exchanged between the counterparties. As a result, the swaps can be used to create unfunded exposures to an underlying asset. The value of a swap is the net present value (NPV) of all the future cash flows. Most swaps are traded over the counter (OTC) for the counterparties. There are five basic types of swaps: interest rate swaps, currency swaps, credit swaps, commodity swaps, and equity swaps.

An interest rate swap is one in which the counterparties exchange cash flows of a floating rate for cash flows of a fixed rate or vice versa. Although notional principal does not change hands, it is based on a referenced amount against which interest is calculated. Interest rate swaps can be international or domestic. Counterparties may participate in an interest rate swap if (1) there are changes in financial markets that may cause interest rates to change, (2) borrowers have different credit ratings in different countries, or (3) borrowers have different preferences for debt service payment schedules. Interest rate swaps tend to be organized by international banks acting as swap brokers. These transactions allow borrowers to receive a lower cost of debt service payments and lenders can obtain profit guarantees.

A currency swap is one in which one party provides a certain principal in one currency to its counterparty in exchange for an equivalent amount in a different currency. Principal exchange is not redundant with currency swaps. The exchange of principal on the notional amounts is done at market rates, and tends to use the same rate for the transfer at inception as is used at maturity. Currency swaps allow organizations to have extra flexibility in order to take advantage of their comparative advantage in their respective borrowing markets. These swaps start with a net present value of zero. However, over the life of the instrument, the currency swap can go in-the-money, out-of-the-money, or stay at-the-money.

A credit swap occurs when two parties enter into an agreement and one counterparty pays the other a fixed periodic coupon for the specified life of the agreement. The other party does not make any payments unless a specified credit event occurs. Examples of credit events include a material default, bankruptcy, or debt restructuring for a specified reference asset. If one of these types of credit events occurs, the counterparty is required to make a payment to the first party, and the swap is terminated. As a rule, the size of the payment tends to be linked to the decline in the reference asset's market value following the credit event.

A commodity swap is where exchanged cash flows are dependent on the price of an underlying commodity. This is usually used to hedge against the price of the commodity. There are two types of commodity swaps, which are fixed-floating swaps and commodity for interest swaps. Fixed-floating swaps are similar to the fixed-floating swaps in the interest rate swap market. However, both indices are commodity based indices. Two popular market indices in the commodities market are the Goldman Sachs Commodities Index and the Commodities Research Board Index. These two indices place different emphasis on the various commodities in order to meet the swap agent's requirements.

Commodity for interest swaps are similar to equity swaps in which a total return on the commodity in question is exchanged for a designated money market rate. Swap agents using this type of swap must take into consideration (1) the cost of hedging, (2) the institutional structure of the particular commodity market in question, (3) the liquidity of the underlying commodity market, (4) seasonality and its effects on the underlying commodity market, (5) the variability of the futures bid/offer spread, (6) brokerage fees, and (7) credit risk, as well as capital costs and administrative costs.

The last type is the equity swap, exchanges of cash flows in which at least one of the indices is an equity index. An equity index is a measure of the performance of an individual stock or a basket of stocks. Common equity indices include Standard & Poor's 500 Index, the Dow Jones Industrial Average, and the Toronto Stock Exchange Index. Equity swaps makes the index trading strategy easy, especially for the passive investment manager and emerging markets fund managers.

Cross-Cultural Research

Culture shapes the values, attitudes, and behavior of human beings. In a managerial context cultural differences lead to diverse management activities and processes, which may present barriers to effective decision making and profit orientation in international management. Information and knowledge on cultural differences and their effects on modern management can help overcome these differences and improve and ease business processes.

Cross-cultural research therefore investigates managerial research questions in two or more cultural settings. Cross-cultural management research focuses on comparing management processes in corporations located in different cultures. Its overall aim is to make these differences understandable and allow managers to develop solutions to overcome and bridge cultural differences and challenges in an international business environment.

Cross-cultural research methods can be divided into qualitative and quantitative research methods. Data can either be gathered by getting hold of secondary data sources, which is information that has been collected before, or by collecting primary data, which refers to the researcher conducting his or her own cross-cultural research project to receive the necessary information to answer a specific research question. The main challenges when conducting research in a cross-cultural context are conceptual and functional equivalences of data collected in different cultures.

Culture in International Management Research

Culture is a critical factor in a global economy. While internationalizing, multinational corporations enter markets that differ in economic, legal, political, social, and cultural levels. But whereas economic, legal, and political differences between countries and their citizens can be observed easily, cultural differences between countries are often not so obvious.

Culture can be defined as a set of common values within a certain group or system, which is communicated from older members of the group to younger ones. According to Nancy Adler, culture becomes evident through common values, attitudes, and actions within a group or system. Cultural differences present challenges to perform management processes effectively. In a corporate context, they lead to different managerial actions, different consumer attitudes and buying behavior as well as particular expectations of international negotiation partners, all of which subsequently may lead to misunderstandings or conflict between employees of multinational corporations.

From an international manager's perspective, culture and differences between cultures therefore play an increasingly important role. To avoid mistakes and promote goal-oriented decision making, gaining information on cultural differences and their effect on international management is vital. Cross-cultural research provides this information and refers to any kind of research in which a research question is investigated in two or more different cultures.

The idea of investigating exotic cultures is not new and was originally a research topic of cultural anthropology, a research field that concentrates on culture and involves the investigation of different societies, their cultures and norms. Management studies, on the other hand, has so far not developed a research stream investigating cultures and their particularities from within, but focuses on comparisons between cultures or groups of cultures. This is done through a number of theoretical frameworks on cultural diversity that have been developed.

The most prominent classifications are Hall and Hall's, Kluckhohn and Strodtbeck's, Hofstede's, and Trompenaar's cultural dimensions. All of these authors distinguish culture across several dimensions. E. T. Hall and M. R. Hall identify cultural differences among the following dimensions: structure of space, structure of time, speed of messages, and context orientation (low-context or high-context). F. Kluckhohn and F. L. Strodtbeck defined six different dimensions and classify cultural differences along time orientation, relation to nature, relations with other people, mode of human activity, space, and belief about basic human nature. The most cited author in this area is Geert Hofstede, who developed the following categories to classify cultures: individualism versus collectivism, power distance, masculinity versus feminity, and uncertainty avoidance.

The final classification presented here was developed by Fons Trompenaars and Charles Hampden-Turner. In this classification, cultures are grouped along these dimensions: universalism versus particularism, individualism versus communitarism, neutral culture versus affective culture, specific culture versus diffuse culture, achievement culture versus ascription culture, sequential time orientation versus synchronic time orientation, and inner-directed culture versus outer-directed culture. All these frameworks present the base of cross-cultural research and aim to provide an overview on the complex topic of culture. They also allow cultural comparisons that support managers in understanding differences in managerial practices.

Aims

Cross-cultural research is important at every stage of a corporation's internationalization process. The first stage of entering a foreign market is dominated by the question of which market is the most suitable for the corporation. Researchers need to compare economic, legal, and political information on different countries to assess the business opportunities of each market. Once the host market is decided upon, the conditions of this particular market need to be investigated in greater detail. In this area, cross-cultural research often focuses on the examination of international consumers, their attitudes, behavior, and preferences. Information on consumers helps multinational corporations to adapt their marketing activities and improve profits in international markets.

Cross-cultural management research further examines processes inside the firm. Cultural differences among employees may lead to complications in reaching company goals or to manage efficiently. The overall goal of cross-cultural management research is to compare management processes in different national cultures. Areas investigated include differences in corporate culture, attitudes, values, and behavior of organizational members, as well as culture-related management processes, such as differences in leadership styles, human resources management styles, decision making, and process development. Based on cross-cultural research results, managers can develop effective solutions to overcome these differences and to create effective management processes for multinational corporations.

Cross-Cultural Research Methods

Cross-cultural research can be conducted via collecting secondary or primary data. Secondary sources refer to data that was collected beforehand and is readily available. Primary sources, on the other hand, are data that are collected by the researchers personally to answer a specific research question. Cross-cultural secondary sources can be found at governmental or government-related organizations, trade associations, universities, or market research institutes. Primary sources are collected by the researcher himself and find answers to specific questions that have not been previously investigated. Primary cross-cultural research can be conducted via qualitative and quantitative research methods. Qualitative cross-cultural research methods include observations, experiments, focus groups, and qualitative interviews. Quantitative cross-cultural research methods refer to standardized surveys conducted in two or more countries.

Challenges

The differences in national cultures between corporations, managers, and employees also create challenges for researchers of international management. Researchers engaged in cross-cultural research face problems and research conditions that differ from their traditional research setting. Not only is the research project conducted on more than one market, it is also conducted in environments that have very unique characteristics.

Using secondary sources in cross-cultural research can save on cost and effort. However, secondary data sources may not always be reliable, and may lack in accuracy, comparability, and timeliness. Secondary data must be carefully selected and examined for its usability in a cross-cultural research project.

When conducting primary research in a cross-cultural setting, researchers need to think about how to avoid inequivalence between data collected in different countries or in different cultural settings. Information and data may not be available or comparable to data from other cultures. Jean-Claude Usunier divides equivalence into conceptual and functional equivalence. The researcher must first assure that concepts investigated have an equivalent meaning in each country's setting. Survey translation must be carefully conducted to confirm that all respondents are not only asked the same questions, but also understand these questions in the same way. Sample equivalence, which refers to finding a comparable sample in every culture investigated, is another aspect that ensures that data collected is comparable.

Functional equivalence, on the other hand, refers to similar standards applied when developing measurement and collecting data. Respondents of cross-cultural surveys may show biases and may answer according to their national culture. Accuracy, reliability, precision of measurement, and survey supervision may differ from one country to another and need to be constantly administered and supervised by cross-cultural researchers in order to gain data that can be compared across cultures.

Cross-Hauling

Generically speaking, cross-hauling is the concurrent trade of the same product or service in reverse directions over the same route. For instance, the import and export of an identical product or service by a specific country at the same time is a type of cross-hauling. However, it should be noted that there are different sorts of cross-hauling. There may be cross-hauling of foreign direct investment (FDI) or capital, normally resulting from technological differences or differences in governments' tax and tariff policies; suburb-to-suburb cross-hauling, when residents of the suburbs cross the city in the opposite direction every morning on their way to work; duty-free cross-hauling, when duty-free goods purchased on the outbound journey are brought back for consumption at home; and even cross-hauling of polluting factors. Here we will discuss cross-hauling from a trade perspective.

Cross-hauling of goods can occur for a variety of reasons. For instance, some goods, such as vegetables and fruit, are both imported and exported. Some of this cross-hauling can be explained easily by proximity to a border. For example, it may be cheaper for retailers in the south of France to obtain their vegetables and fruit from Spain, at the same time that producers in the north are sending some of their output to Belgian consumers.

Product differentiation is another reason. While some consumers may prefer Gala apples, others may have a preference for Fuji apples, and because these two varieties have different geographic origins, cross-hauling will occur. If each product were completely homogeneous there would be no reason for cross-hauling to exist. For example, if automobiles were homogeneous, consumers in the United States would buy only Ford and GM cars and consumers in Germany would buy only Mercedes and BMW. In reality, however, automobiles are quite heterogeneous. Mercedes are shipped into the United States and Fords are shipped in the other direction.

In countries where vertical differentiation greatly exceeds horizontal, such as India, China, and Brazil, it is not surprising that these countries are likely to export low-quality apparel and import high quality, for example, or to be part of globally or regionally integrated supply chains. Products with strong brand image and consumer loyalty are implausible candidates for substitution, explaining much of the existing cross-hauling.

Where there are a large number of competing manufacturers serving a small geographic area, each one using a different carrier operating less than truckloads, on a single road segment containing several stops, the possibility of cross-hauling increases. In the case of a retailer, poor sales forecast per store may imply the removal of surplus stock back to the distribution center. Finally, there are industries in which the range of products is so large that an individual manufacturer or even a cluster of local producers cannot compete effectively in all segments of the industry.

If we accept that cross-hauling is the act of shipping the same good in opposite directions at the same time, then it seems clear that much of it is stimulated by low trade barriers, public policy to promote competition, consumer acceptance, and the interest of transport companies (railroads, haulers) to boost their traffic. Trade between different regions and countries is generally beneficial because it allows for scale economies and makes markets more competitive. An increase in trade of similar products, driven by profit margins perceived by each firm in external markets, is hence expected and cross-hauling is therefore unavoidable in facilitating the permanent adjustment of supply and demand.

On the other hand, the effect of the present-day fight among large manufacturers for the conquest of the global market is no more than a mere exchange of accounts, leading to the increase of unnecessary marketing and transportation costs, as they work farther and farther away from their home territory where they can market their product most economically. Yet we are so amazed by the impressive economies of mass production that we refuse to face the fact that marketing and transportation cross-hauling is eating up all that mass production saves and may also be socially costly because it makes use of real resources, for two-way trade of similar goods and marketing campaigns, and no longer transfers revenues to society.

With computers and centralized buying, it appears the cross-hauling problem should have been reduced. Yet trains today meet other trains loaded with the same products, and empty trucks meet other matching empties. These motorway encounters might be acceptable for perfumes and designer clothes, but it is hardly justified for more commoditized goods. The most unnecessary and wasteful elements of cross-hauling should therefore be discouraged.

Cross-Licensing

A cross-licensing agreement is a contractual arrangement that allows a group of companies to make use of one another's patents. All firms involved agree to refrain from suing one another for patent infringement, usually for both currently held and future patents. These agreements are sometimes referred to as "patent pools."

Cross-licensing allows the participating firms to design and manufacture new products without fear of being sued for patent infringement. Certain complexities, such as excluding specific patents from the pooled arrangement, are often part of the contract. The concept of cross-licensing has deep roots in certain industries, such as high technology, that rely heavily on patents. While there is some debate, on balance cross-licensing agreements are usually thought to be good for competition and good for the economy.

The key benefit of a cross-licensing agreement is "freedom to design." Consider the situation of an established firm in a rapidly evolving industry where much of the competition is based upon the use of patented technology. Examples would include pharmaceuticals, consumer electronics, and almost any aspect of high technology. Such a firm may hold thousands of patents, and annually apply for hundreds more. Each of its major competitors also holds thousands of patents. Any one of these patents may apply to dozens or even hundreds of individual products, thousands in the case of a particularly important patent.

Thus, each firm in the industry faces enormous risk. With so many patents outstanding, it is not possible to be completely certain that a newly designed product will not infringe on any patent held by any competitor. Even if this new product avoids infringing on an existing patent, it could still infringe upon an applied-for, but not-yet-issued patent. Any patent—currently held or pending—held by any direct competitor represents a potential disaster for the new product. A patent infringement suit could delay the new product, drain the profits out of it, or kill it completely.

This situation makes any research and development (R&D) investment quite risky—unless competitors develop cross-licensing agreements. The arrangement reduces the risk of lawsuits for any participating firm. Thus, the participating firms have greater freedom to design; there is less need to filter each new design element to ensure that it will not violate someone else's patent.

Concept Development

The concept of cross-licensing is not new. Early in the 20th century, new competitors moving into the rapidly evolving field of radio quickly realized that they were at constant risk of infringing on one or another of their competitor's patents. The key competitors in the field formed a company to hold all major patents and license the use of those patents to all founding companies. This newly formed company, the Radio Corporation of America, or RCA, is still a major force in the field of entertainment today.

In the 1950s an antitrust ruling affecting IBM helped create a cross-licensing culture in the computer industry. Under the ruling, IBM was required to enter into a cross-licensing agreement with any firm wishing to enter such an arrangement. As part of the arrangement, the applicant agreed to allow IBM reciprocal patent access and agreed to pay reasonable royalties, similar to a modern cross-licensing contract. This open approach characterizes behavior in much of the computer industry to this day: IBM recently announced that it will allow free access to some 500 software patents considered key to software interoperability. Similar traditions in the communications industry may be traced to a 1950s antitrust ruling concerning AT&T/Bell Labs that mandated behaviors parallel to those required of IBM.

More recently, some firms have taken the entire concept of cross-licensing a step further and made patent licensing their core business. For example, Acacia Technologies Group is in the business of acquiring and licensing pools of patents. They design no products and manufacture no products. They are one of a new wave of patent clearing houses building an entire business on intellectual property (IP) alone. The largest of these firms is Intellectual Ventures (IV), founded by several Microsoft alumni. Some reports indicate that IV garners hundreds of millions in royalties and is seeking an additional investment of $2 billion to continue expansion of its patent portfolio.

Not all cross-licensing agreements are as straightforward as two firms agreeing to refrain from suing one another. First, the agreement would normally be limited to specific portions of either firm's patent portfolio. For example, a diversified firm operating in both the chemical industry and in aviation may not wish to include all patents in any single agreement. If this hypothetical firm made an agreement involving chemical patents only, it might wish to further limit the agreement based on field of application. Such a limitation might allow a partner firm to make use of the patents for fertilizers but not for paints or other industrial applications.

Most important, the agreement will probably recognize that all patent portfolios are not of equal value. A firm with a more valuable portfolio will likely receive royalty payments from a firm with a less valuable portfolio. A valuable portfolio will include patents that enjoy broad application and are not yet nearing the end of their legal viability.

Is cross-licensing good or bad for the economy? While this is a hotly debated topic, there is little doubt that cross-licensing agreements, properly implemented, can facilitate the health of an industry and benefit consumers. By lowering the risk of investing in R&D and providing freedom to design, cross-licensing speeds innovation, accelerates the release of new products, and lowers operating costs.

Cross Rate

A cross rate reflects the exchange rate between a foreign currency and another foreign currency. It shows the relationship between two foreign currencies with neither currency being the domestic currency. If the exchange rate between U.S. currency and country X's currency is known, and the exchange rate between U.S. currency and currency of county Y is also known, it is possible to determine the implied exchange rate between the currencies of countries X and Y. The implied exchange rate is what is referred to as a cross rate.

Foreign exchange rates can be quoted in two ways: direct quote and indirect quote. A direct quote is stated in the form of domestic currency per foreign currency. An indirect quote is expressed as the number of foreign currency units needed to acquire one unit of domestic currency. A direct quote is also referred to as a normal quote, while an indirect quote is called a reciprocal quote. An example of a direct quote between the U.S. dollar (USD) and the British pound (GBP) is USD/GBP = 1.90. This means that \$1.90 of U.S. currency is needed to purchase a unit (£1) of British currency. The direct quote can be converted into an indirect quote of the form, GBP/USD = 0.53. Again, this means that £0.53 British currency is needed to purchase a unit (\$1.00) of U.S. currency.

The cross rate is usually calculated from two other foreign exchange rates. Let the exchange rate between U.S. dollar (USD) and South African rand (ZAR) be stated as USD/ZAR = 7.5. Again, let the exchange rate between U.S. dollar (USD) and Mexican peso (MXP) be stated as USD/MXP = 10.5. From these two quotes, it is easy to determine the implied cross rate between ZAR and MXP. The cross rate is MXP/ZAR = 0.71 (calculated as 7.5/10.5).

In order to understand the rationale for its use, it is important to examine the concept of vehicle currencies. Vehicle currencies are currencies that are actively traded in the foreign exchange market. Examples of vehicle currencies are U.S. dollar (USD), euro (EUR), Japanese yen (JPY), and the British pound (GBP). International transactions are conducted in a few vehicle currencies. The logic for using a few currencies for international transactions is to promote efficiency. If the number of currencies used in international transactions is denoted as N, then there are N(N-1)/2 possible exchange rates. The larger the value of N, the larger is the number of exchange rates to be determined. Therefore, it makes sense to use a few currencies for international transactions and then infer the cross rates from existing relationships among trading currencies of the world. The *Wall Street Journal* publishes a table of cross rates daily.

The foreign exchange market is an integrated market that is made up of a network of large commercial banks in the major financial centers of the world. The existence of modern communication technology means that information is quickly transmitted in the market. Thus, all the markets are linked together. This is the reason why quoted exchange rates are consistent. For example, the USD/GBP rate quoted in New York is not significantly different from the USD/GBP rate quoted by a London bank.

Cultural Norms and Scripts

Cultural norms are sometimes defined as "the way we do things around here," but that merely describes the custom and practice processes or interactions within a particular environment. It does not explain *why* things are done in that way, how those norms gain authority, or what mechanisms ensure that relative compliance occurs. Cultural norms are important because they are the generally accepted way that a society or culture guides and regulates the behaviors of its members. Without them, a societal group would be wholly subject to the self-interest of each individual member.

Many societies share commonalities in respect of the types of behavior that are subject to governance by social standards, but this is by no means universal. Cultural norms are often divided into four main categories with differing degrees of importance: "conventions" or "folkways" are codes of social conduct or a standard of etiquette that is expected but is not morally significant, for example, not taking food from another person's plate; "mores" are more strongly held and breaches carry greater sanctions, for example, one does not walk down the street naked; "taboos" are behaviors that are actually forbidden by a culture, like murder or incest in many societies, and are often enshrined in legislation; "laws" are formalized norms backed by the power of government, containing virtually all taboos, but only the more significant mores. What falls into each category and the prescribed penalties for breaches varies between countries or even within the same country, an example being state variance in U.S. legislation.

For a society or group to function, the majority of participant members must agree upon what is "normal" and desire to conform to the rules. These are invariably internalized through the socialization processes taught to children and reinforced through the educational system. Where an individual or group fails to conform, social control mechanisms are utilized in order to encourage conformity, enforce adherence to rules, and in extreme cases, exclude or segregate those who have broken laws or serious taboos. Social control ranges from disapproval at one end of the spectrum to imprisonment or even execution at the other.

Interestingly, there often tends to be more social acceptance of certain infringements than others: While theft and exceeding the driving speed limit are both illegal in many countries, the former usually carries significantly more disapproval than the latter, in the same way that imbibing too much alcohol (an addictive substance) or smoking cigarettes is often deemed by many people to be more acceptable than using certain drugs.

Within a culture may exist "countercultures," wherein the norms of a group or subgroup differ or run counter to those of the prevailing social group. These often, but not always, manifest themselves in the espoused values, behaviors, dress, and musical preferences of younger members of society, or the norms of those with orientations "other" than those of the societal majority. Examples in Western society from the 1960s onward include Beatniks, hippies, and punks. Norms exist within these groups, but they may not be aligned with recognized and ratified societal norms. This is different from an absence of norms, sometimes referred to as "anomie." It is suggested that a state of anomie is categorized by societal breakdown and psychological dissonance.

Cultural norms are by no means universally similar within the global context. Variance is evidenced not only in external manifestations such as art and music, but in behaviors, nonverbal communication, and eye contact. This is also said to influence how individuals from different countries interact with others and with their environment. Theories exist that explore national cultural dimensions. Some suggest that people may have a "national" tendency, possibly embedded through socializing processes, toward certain orientations and preferences; for example, adherence to rules, respect for authority, assigning of power, emotionality, collectivism, and individuality. These dimensions may be seen in folkways, mores, taboos, and laws, in varying degrees.

Organizations can be deemed to have cultures, influenced by factors including age, type, leaders, demographics, sector, and size. Although few would attempt to change or merge all aspects of national cultures, this is frequently attempted at the organizational level. Culture change strategies should focus upon creating norms that support desired behaviors and allow for individual choice; therefore, culture change efforts should be directed at making those behaviors norms.

Cultural Scripts

It is generally accepted that speech communities have different ways of speaking, not just in respect to the specifics of language, but also in the form of the interactions. These differences reflect the assumptions that people have about social interaction in that particular environment or the contextual "nuancing" that people bring with them to the interaction. These assumptions influence the form but not the content of the interaction, for example, the degree of formality, directness, and cooperation. While most languages have "universal" words in common, including words for *I*, *there*, and *and*, other aspects of the language are context-specific or culturally nuanced conventions, which may reflect the cultural norms of a country. "Cultural scripts" can be viewed as rules of interpretation and evaluation that indicate more than just the semantic meaning of the actual words. Cultural scripts are not intended to provide an account of real-life social interactions, but are descriptions of commonly held, societal assumptions regarding how members of a particular group think about social interaction, the "norm," and how this transfers into communication.

Changes in speech patterns can often reflect shifts in cultural values or norms. An example of this would be where a country has a language with an informal and formal address: *tu* and *vous* in French; *du* and *Sie* in German. Should there be a decline in the use of the formal address and an increase in the use of the informal, this may indicate within that particular society, a change in how individuals interact with each other, reflecting a move toward a more classless informality.

Culture Shock

The term *culture shock* was first introduced in the 1950s to describe the anxiety a person can frequently experience when moving to a different environment, and encompasses feelings of disorientation and not knowing what to do or quite how to do it and, ultimately, what is acceptable or appropriate within the new culture. The discomfort experienced can be physical as well as emotional, and while the term might be used in different contexts (and where it might then have different meanings) *culture shock* is generally interpreted as the process of coming to terms with differences in culture, as these occur through daily interaction in the new context.

The term may be traced to two sources. First of these is Schumann's Theory of Acculturation, which attempts to explain the various stages that an immigrant will go through from initial arrival in the foreign country to eventual assimilation. Schumann envisages a continuum of adaptation along which the immigrant will travel, even accepting that many people will not stay in a foreign country long enough for total "conversion" to occur. The second source is represented by the work of the pioneering and world-renowned anthropologist Kalervo Oberg. Born to Finnish parents in British Columbia, Oberg had an early academic career in universities in the United States (Missouri and Montana), the United Kingdom (London School of Economics), and Brazil (São Paulo). He then worked for various U.S. government agencies as an applied anthropologist with postings to South America, before late in his career returning to academe (then at the universities of Cornell, Southern California, and Oregon State).

The basis of Oberg's developed theory of culture shock was his now famous address to the Women's Club of Rio de Janeiro on August 3, 1954, which outlined the feelings common to people when face-to-face with a cross-cultural situation. The model he developed was a four-stage one, although more recently this appears to have been expanded to five elements; nor is there total acceptance of the relevant nomenclature.

It is important to recognize that while psychology is the study of individual personality, it is the alternative discipline of sociology that is the study of groups and the behaviors they exhibit. Thus the study of culture is not about the study of individuals per se since the development of a particular culture is not something to which the individual can contribute. Culture is developed within a nation over a period of many years and through processes that are largely beyond the awareness of the individual. Culture imbues a country with national characteristics: The concept of "living the American dream" (anything is possible) familiar to a U.S. citizen or the British obsession with the weather are obvious examples. Other frequently cited aspects of culture are the acceptability (or otherwise) of smoking, semi-nudity, drinking or kissing in public (perhaps particularly by women). More specific examples might be, for example, not showing the soles of one's feet in public, or demonstrating appreciation of a meal by belching, or leaving one's shoes outside one's host's house.

Oberg considered that culture shock is precipitated by the anxiety that results from losing all familiar signs of social intercourse. This leads to feelings of frustration and anxiety; the home environment suddenly assumes enhanced significance; and ridicule may be poked at everything that is now encountered that is found strange or unfamiliar. The stages of culture shock that have been identified are as follows:

1. The first stage is generally known as the "honeymoon" stage (although also variously as "incubation" or "stimulation"). The recent arrival is full of hope and excited by everything new that is encountered and this positive (even euphoric) outlook keeps negative feelings at bay.

2. The second stage is the culture shock (or "hostile") stage, when the need to settle into the new culture (probably through now starting work as either a businessperson or student) means coping with day-to-day situations that are different from "back home." Dislike and/or criticism of the host culture surfaces, to be frequently accompanied by homesickness, lethargy, irritability, and even outright hostility to the host culture.
3. The third or "acceptance" stage is when a period of adjustment is gone through, during which the individual begins to perceive value in their new environment. A favorable comparison of "new" and "old" environments may even occur as the new arrival gains understanding. Pleasure and good humor return as empathy with the new environment develops.
4. In the fourth or "enthusiasm" stage, the host country begins to appear more and more like "home" and certain aspects of the adopted culture may well be perceived to be preferable to the native culture. Integration is accompanied by an enhanced sense of belonging.
5. The fifth (and final) stage occurs following return to the native culture (hence "re-entry" or "reverse culture" shock). Things may not be the same as they were upon leaving, so a readjustment process must be gone through all over again.

It is important to recognize that not everyone will be affected to the same extent by culture shock. The state of an individual's physical and mental health, their personality, language familiarity, level of education, and previous travel experience can make the necessary adjustment process easier or more difficult.

Culture-Specific Values

For American companies to conduct successful business globally, cultural values must not be ignored. The attitude of "if it works in America, it will work anywhere" should not prevail. If cultural values are ignored, a businessperson's effort to forge a relationship will be met with resistance, for even though some cultural values are elective and are not deal-killers, some are cultural exclusives and must be honored. Americans conducting business in other countries must be aware of all cultural values, for any disrespect could be a deal-breaker. Singapore and India present two contrasting examples of the role of culture-specific values in business.

Singapore is the smallest country in southeast Asia. The ethnic makeup of Singapore is diverse, with Chinese as the majority, followed by Malay and Indian. When conducting business, English is the preferred language. Singapore is a group-oriented culture; therefore, a businessperson must form personal relationships. Just like in the United States, in Singapore, businesspeople can take their time and work their way into cliques or get in through being introduced.

In comparison to the United States, conducting business in Singapore is more formal; therefore, protocol is valued. Appointments must be made in advance, with writing a letter the number one preferred choice. Punctuality is essential, for being late for appointments is viewed negatively.

Conducting business in Singapore is also more slowly paced than in the United States. Singaporeans frown upon being rushed; therefore, a businessperson must allot adequate time to conduct business. Business is not discussed immediately; small talk always comes prior to the business discussion. Therefore, businesspeople eagerly wanting to make a connection must be cognizant of being too aggressive. In Singapore, upon entering a business meeting, one must never take a seat immediately. One must wait until being told where to sit. This is in sharp contrast to the United States, for in many cases upon entering a business meeting, the businessperson will sit in any available seat.

Singapore, dubbed one of the safest countries in the world, deals with crime differently from the United States. A businessperson must be cognizant of the differences, for Singapore's laws are as applicable to noncitizens as to citizens. For example, crimes such as first-degree murder carry an automatic death sentence; minor offenses are dealt with harshly. A violator on public transit can be fined up to $500 for eating or drinking. Chewing gum is prohibited unless for medical or dental reasons, as is spitting in public.

In contrast, the U.S. legal atmosphere is more lenient than in Singapore. Even though penalized in Singapore, Americans can eat and drink on public transit, chew gum, and spit virtually anywhere. A businessperson must be aware that commercial disputes that may be handled as civil suits in the United States can escalate to criminal cases in Singapore and result in heavy fines and prison sentences.

India, a country in south Asia, has more than 1 billion people. Even though India has a large population of English-speaking people, at times, confusion can arise over words' meanings. Unlike Singaporeans, Indians value punctuality, yet may not be punctual themselves. Even though it is advisable for appointments to be made at least one month in advance, a businessperson should confirm the appointment upon arrival. Business appointments should ideally be made for late morning or early afternoon, between the hours of 11 and four.

Like Singaporeans, Indians do not like to be rushed when making decisions; therefore, a mild, relaxed demeanor is valued, whereas impatience is frowned upon and viewed as being rude and disrespectful to their culture. Unlike the United States, where the purpose of the meeting is stated almost immediately, in India a meeting usually begins with friendly small talk. The talk normally involves questions about the family unit, for in India, the family is highly valued; therefore, discussing the family unit shows respect.

American businesspeople must be aware that even though in the United States disagreements are usually directly expressed, in India disagreements are rarely expressed directly due to the value placed on well-established honest business relationships. Therefore, to avoid hurt feelings, Indians use indirect communication and nonverbal cues. Because of the value placed on structure and hierarchy in Indian companies, senior colleagues are highly respected and obeyed. Therefore, Americans must be sensitive by showing the needed respect.

Even though it may be a company's dream to expand overseas, it is important that cultural values not be ignored. Familiarity with business customs specific to a culture can determine the success or demise of a venture.

Currency

The term *currency* generally refers to the official means and regulations of payment of a country or region, which have been legally introduced and which are accepted (by law) as a compensation for goods and services. Currency includes banknotes and coins and represents a sub-category of money. Money refers to all means of exchange, also gold, whiskey, tobacco, and other commodities. Currencies, however, are means of payment that are produced and regulated by the government and do not represent goods on their own. Their intrinsic value (i.e., the physical value of a currency) does not coincide with its traded value.

The production and issuance of currencies is, in most cases, incumbent on national central banks or a single central bank for a certain currency zone, such as the European Central Bank, which is responsible for the European Monetary Union. Such institutions regulate the money supply in order to guarantee price stability and, thus, avoid inflation.

Today, about 160 different currencies exist which have, according to their name, an ISO 4217 currency code consisting of three alphabetical letters. They are used in international trade, e.g., EUR for the euro or USD for U.S. dollar. In order to buy goods from any other society it may be necessary to have foreign currency. Therefore, currencies can also be subject to trade and the value of one currency in terms of another currency is expressed by the exchange rate. For international trade, very often leading currencies (i.e., currencies that are preferably used in cross-border transactions) are chosen. They can be easily traded internationally and are often chosen to lock out the exchange rate risk, because they are considered more stable than other currencies. Such leading currencies include, among others, the U.S. dollar, the euro, the yen, the pound sterling and the Swiss franc.

Functions and Characteristics

A currency fulfills three main functions: medium of exchange, unit of account, and store of value. As a medium of exchange, a currency allows its holder to exchange it for any good or service that he or she requires. That is, the seller of a product is not confined by the products of his clients, as would be the case in barter transactions, where goods and services are exchanged without money. Therefore, currencies give their owners more flexibility. It is necessary that people trust in a currency as a medium of exchange, i.e., that they can reliably exchange it for other goods or services. This is of special importance if the traded value of the currency does not reflect the real value of the material that the currency is made of; for example, banknotes may indicate a higher value (printed on the surface) than their real, physical value (i.e., the value of the paper) represents. In order to guarantee that the nominal value of a banknote equals the real value of goods and services, its issuer has to hold reserves of commodities (such as gold) that guarantee the nominal value. In case of inflation (i.e., a decrease in the value of a currency), market agents may lose their trust in a certain currency and shift to barter transactions to exclude the risk of a devaluing currency.

Currencies, as a unit of account, also facilitate the comparison of unequal goods or services. It may seem difficult to compare a haircut (a service) with a new notebook (a commodity) without having a value of reference. By indicating how much of a currency is needed to buy a haircut and a notebook, it is possible to easily compare these commodities with each other. In addition, this also allows the comparison between countries by using the exchange rate, e.g., how much does a certain notebook cost in country A and how much in country B. Currencies as a unit of account also facilitate the comparison of productivity and success of companies across industries and countries.

Finally, currencies allow their owner to store value for future consumption. In comparison to goods, such as fish or vegetables, currencies are more durable and therefore save value. Historically speaking, however, periods of inflation and deflation have shown that the real value of a currency can considerably be altered, which relativizes this function. Still, the advantages of currencies outweigh other media of exchange or units of account. Currencies also allow the establishment of more complex credit systems, where those who need value to buy certain assets can borrow money from those who have stored it for future consumption. This again improves the efficiency of an economy as money can more optimally be allocated by its participants, in line with their wants and needs.

In order to fulfill all these functions, a currency has to have certain characteristics. A good currency is easy to recognize and can be easily distinguished from other assets. This is definitely true for gold, due to its unique luster, color, and weight. Regarding banknotes and coins, they are unique, because they have special imprints and embossments. Apart from that, they also include several copy protections. It is also important that a currency is divisible and portable. On the one hand, if gold is used as a currency, it can be simply cut into pieces without destroying the value of the broken parts as they reflect their implicit value. As far as banknotes and coins are concerned, there are several subunits of them, indicating different values printed on their surfaces, which do not represent their real

Some of these traditional paper currencies and coins have been supplanted by the euro.

value (see above). On the other hand, the transportation of a currency should be easy, thus increasing the its flexibility and circulation. Finally, it is crucial that a currency is durable. This is necessary to fulfill the function of storage of value as explained above. Today, the use of electronic transactions and electronic credit cards, instead of a physical exchange of currencies for goods or services, makes these characteristics nearly obsolete. Also, bank accounts are denominated in currencies and not in goods or services.

Currency and the Economy

The introduction of a currency facilitates intranational and international trade considerably. David Ricardo's theory of comparative advantage postulates that countries, companies, and individuals should specialize in the production of certain goods or services in order to realize gains from trade. However, this indicates that agents have to buy several other goods or services in order to survive, as they specialize in producing only one particular product and not everything they may need. In simple economies, barter may be eligible, but costs of trade will increase due to higher transportation costs, thus making products more expensive. In more complex economies, trade that is solely based on barter transactions is almost impossible.

Due to the three functions of currencies (see above) it is not necessary to triangulate transactions, i.e., individual A wants to buy goods from individual B, who is only prepared to exchange products for those of individual C, who him/herself needs products from individual A. As a consequence, currencies even speed up trade and reduce the number of transports as the purchase and sale of goods or services can be separated from each other. This increases efficiency in trade and transaction costs can be cut severely.

Currency Crises

The pressure on global financial markets in the 1990s caused several currency crises. Examples include the Czech Republic crisis in 1997 and the Russian crisis in 1998, which harmed their economy severely. It is worth mentioning that both crises had been triggered by different economic variables. On the one hand, the Czech currency crisis was characterized by a deterioration of macroeconomic fundamentals and political instability, appearance of a speculative attack, an effort to defend the koruna, and finally a depreciation and change in the exchange rate regime from a fixed to a floating one. On the other hand, the crisis in Russia can be seen as the consequence of its fragile and vulnerable economic and political fundamentals and massive capital flight.

So far, three different prevailing models aim at explaining how currency crises come into existence and which variables best describe or even predict them. Krugman's model, developed in 1979, is generally known as the traditional approach concerning currency crises. It is based on balance of payments problems, reflected by a steady but slow reduction in international reserves, in a country with a pegged currency. According to this model, the expansion of domestic credits to finance fiscal deficits or improve a weakening banking system and the increase of money demand reduce international reserves and consequently results in a speculative attack that would force authorities to abandon their fixed exchange rate regime. In following years, Krugman's model was extended by other studies and showed that a real appreciation of a currency often precedes a speculative attack. In addition, domestic interest rates increase if a currency crash is at hand. To sum up, the first-generation models focus on expansionary macroeconomic measures undertaken by a country with a fixed exchange rate regime and therefore are said to be predictable.

Second-generation models refer to countercyclical government policies and take into account uncertainties and features of speculative attacks. Currency crises are also defined as changes from one monetary policy equilibrium to another, caused by self-fulfilling speculative attacks. For example, agents believe that currency A will lose its value in the near future and therefore exchange it for a more stable one. Therefore, the demand for currency A decreases and, as a consequence, its value does as well. The interaction of economic policies and economic agents could allow jumps between multiple equilibria without having an impact on fundamentals. Thus, an economy with a fixed exchange rate regime could find itself in equilibrium, but a turn in expectations of economic agents could trigger policy measures, which cause a breakdown of the exchange rate regime. In other words, speculative attacks are independent of the consistency between the currency policy and an exchange rate fixing. In short, second-generation models imply that currency crashes are far more difficult to predict, but economic fundamentals are still of importance, although there is no strong relation between these indicators and a possible crisis.

While second-generation models assume that all speculators know about each others' intentions, third-generation models eliminate this unlikely assumption in arguing that fundamentals can only be monitored with noise. Moreover, the amount of noise in a signal may vary between speculators, but at the same time results in a new equilibrium. Furthermore it is concluded that economic fundamentals might not signal an upcoming crisis, like in second-generation models, but speculators would still attack the currency, due to the uncertainty of expectations of other economic agents. Apart from that, third-generation models are based on structural weaknesses, e.g., foreign currency debt exposure in the corporate and financial sector. Finally, these models are characterized by moral hazard, imperfect information, and the exorbitant up- and downturns in international lending and asset pricing.

In view of the above, currency crises can be considered to be diverse in their nature and, as a consequence, in their origination. Very often currency crises accompany or are accompanied by banking crises.

Currency Exposure

Firms doing business in more than one currency (i.e., U.S. dollar, euro, yen, etc.) face currency exposure. This exposure arises from the fact that, in the current global environment of floating exchange rates, the value of a currency relative to other currencies (its exchange rate) is constantly changing—rising or falling based on forces of supply and demand, government activity, even currency speculators. There are three main types of currency exposure—transaction, translation, and economic.

Transaction exposure reflects the exposure of the firm to changes in the value of a foreign-currency-denominated transaction (sale or purchase) between when the price is set and when payment is made. For example, say a U.S. aircraft manufacturer contracts to produce and sell 10 airplanes to a German airline for 100 million euros, to be paid upon delivery in six months. Although the dollar/euro exchange rate when the deal is signed is $1.50/euro, the U.S. manufacturer does not know whether the value of the 100 million euros it will receive in six months will be higher or lower than the current value of $150 million (dollars), and is thus faced with transaction exposure. If the dollar/euro exchange rate drops to $1.25/euro in six months, the 100 million euros will be worth only $125 million, whereas a rise to $1.75/euro would result in a better-than-expected $175 million. If the U.S. firm wishes to eliminate variability in the dollar amount, they may enter into a contract on the forward market, which allows them to lock in a future exchange rate. Alternatively, they may purchase a foreign currency option, insuring them against the downside risk of a decline in the value of the euros they will be receiving, while still allowing them to benefit from potential increase in the euro's value.

Translation exposure arises within the firm's accounting function. The financial statements of the firm's foreign units must be translated into the parent currency, then consolidated into the financial statements of the parent. If there has been a shift in the exchange rate between the subsidiary's and parent's currencies since the last consolidation was performed, unrealized "paper" gains/losses may affect the company's books. If the U.S. aircraft manufacturer had purchased a German factory for 10 million euros when the exchange rate was $1.50/euro, it would appear as an asset on the parent's books, valued at $15 million. If the exchange rate were $1.75/euro the following year, that same factory, with a value of 10 million euros (not accounting for depreciation), would translate into the parent's books valued at $17.5 million, a $2.5 million gain based not on increasing real value, but merely driven by rising exchange rates (alternatively, a drop in the exchange rate to $1.25/euro would create a $2.5 million "paper" loss).

It can be risky for firms to make strategic decisions based on "paper" gains/losses; one technique for minimizing translation exposure is to balance foreign currency assets and liabilities. The aircraft manufacturer could borrow 10 million euros to purchase the German factory, resulting in a 10 million euro asset (the factory) and a 10 million euro liability (the loan), which would effectively cancel each other out—whenever the euro rose/fell against the dollar, asset and liability would rise/fall simultaneously.

Economic exposure reflects the degree to which exchange rate shifts affect a firm's future foreign profitability. This exposure has the greatest potential for long-term impact on firm performance, and thus requires greater strategic planning and decision making on the part of the firm. Once the U.S. aircraft manufacturer owns a factory in Germany, economic exposure could be triggered by a large rise in the value of the euro, say from $1.50/euro to $2.00/euro. Such a shift may hurt the firm (reduced export performance from Germany, as their products will now look pricier on international markets) and/or may have a positive impact on the firm (profits made in euros will translate into more dollars than before). One way firms can manage economic exposure is to diversify production locations internationally, so that large shifts in one currency will not affect their entire business.

Currency Speculators

A currency speculator is an individual who trades in the foreign exchange market with the sole purpose of making a profit. For example, if the British pound is falling relative to the U.S. dollar, currency speculators will sell pounds, expecting to buy them back again sometime in the near future at a lower price.

This implies that speculators will have an uncovered "open position," which can be difficult to cover if the pound does not fall relative to the U.S. dollar. Currency speculators are willing to take this exchange rate risk when they believe that exchange rates will move to their benefit.

In general, currency speculators trade either on the spot market and/or on the derivatives market. In the first case, a speculator will sell on the spot price if he believes that the asset is overvalued and then wait to buy back the asset in the future when he thinks that the price has fallen by so much that it will generate him a profit after all transaction costs have been paid. In the second case, currency speculators will sell the overvalued currency at the spot market and at the same time they will buy the future price of the same currency. The future price of currencies is traded in the derivatives markets and can be in the form of a forward, a future, or an option contract. In most cases, the currency speculator will "short sell" the asset, that is, she will sell an asset that she does not own hoping to buy it back in the future at a lower value.

The advantage of selling and buying the asset simultaneously is that the potential profit that can be derived from this strategy is secured. However, the downside is that by buying the asset for future delivery the trader binds himself to the future price of the asset. In such a case, the trader discards the opportunity to get an extra profit if the spot price of the currency in the future is much lower than its price of the future contract. Also, speculators, using the purchasing power parity (PPP) rules between two or more currencies, speculate by trading on the price of one currency compared with the value with all the currencies that can be exchanged for one unit of this currency.

Currency speculators predict the future exchange rate prices by analyzing changes in value or by just bluffing about the future price of assets. When speculators analyze changes in the value of assets they do so by estimating the change in the value of assets that is caused by news about their value. For example, if the American interest rate is set at a point higher than the European Union interest rate, speculators will short sell euros as they will expect that investors will start selling euros as well in order to buy U.S. dollars that offer a greater return. The downward pressure will destabilize the euro/U.S. dollar exchange rate and speculators will earn their profits by buying back euros at a lower price. On numerous occasions speculators have been accused of deliberately selling the currency of one country in order to create downward pressure; thus their prediction of a devaluated currency becomes a self-fulfilling prophecy.

The most famous example of a currency speculator is George Soros. Soros is said to be responsible for the "Black Wednesday" when the United Kingdom was forced to withdraw the British pound from the Exchange Rate Mechanism that was designed to keep a number of currencies floating within very small margins. On September, 16, 1992, Soros sold short more than £10 million, putting enormous downward pressure the Bank of England (BoE) either to raise interest rates, so that investors will start buying pounds, or to devaluate the currency. Eventually, the BoE decided to let the currency float freely, leaving the Exchange Rate Mechanism. It is said that, on that day, Soros made more than £1 million from this speculative trade.

However, currency speculators claim that it is on their actions that markets become fully efficient. Their argument is the following; when prices are not fully efficient, i.e., prices do not reflect the true fundamental values of assets, currency speculators trade on those assets, making the prices more informative and as a result the trading prices converge with the fundamental value of assets. Had the currency speculators not traded, the asset prices would have continued to trade in prices different from their optimal. In other words, speculators argue that they help prices to trade at their true value and the absence of speculative trading will have devastating results in the long term. Nevertheless, as with any profit-motivated trader, speculators ask for greater returns in order to accept the exchange rate risk that is associated with trading currencies.

Currency Zone

A currency zone or optimum currency area is defined as a geographical region in which there is a single currency or several currencies that are pegged to each other so that the currencies can fluctuate only against the rest of the world. Currency zones eliminate exchange rate uncertainties and maximize economic stability within that area. The most prominent example of a currency zone is the Eurozone in which the European Union member states have decided to abandon their domestic currencies and adopt the euro as their single currency.

The optimum currency zone theory, first published by R. Mundell (1961), along with the theory of comparative advantage of David Ricardo, are the most cited theories in international economics that have also seen widespread applications in recent decades.

The benefits associated with the adoption of a single currency are twofold: First, the elimination of transaction costs and, second, the minimization of risk originating from exchange rate uncertainties. In particular, it is argued that the most visible gain of a monetary union is the removal of costs associated with exchanging one currency into another. Yet, even though this benefit is relatively small, less than half of 1 percent of the Eurozone GDP, it should be added to the overall benefits of a single currency. These benefits mainly refer to the increased usefulness of money. That is, a currency zone increases price transparency, decreases price discrimination within the zone, and in general fosters competition. So, a currency zone promotes trade between the member-states of the zone, increases efficiency in the allocation of resources, and endorses cross-area foreign direct investment.

The second major advantage of a currency zone is that it reduces the exchange rate uncertainty risk. Even when two or more currencies are narrow-banded to each other, like in the case of the Exchange Rate Mechanism, there is still some exchange rate risk associated with the individual currencies. This risk is eliminated when a single currency is introduced to replace the old monetary system. The indirect welfare gains that come from a currency zone are said to help firms increase their efficiency by eliminating the uncertainty about the future prices of good and services. This, in turn, should increase economic growth within that area. At the same time, a single currency removes from single countries their ability to print money; thus, inflationary pressures to single countries are eliminated.

However, skeptics of currency zones argue that the loss of the ability of individual countries to conduct a national monetary policy is more important than the benefits of a single currency. That is, a nation joining a single currency loses its ability to change interest rates, to determine the quantity of money, and to change the price of its currency. The key point is that, within a currency zone, the member countries may face the one-size-fits-all problem, which refers to the application of policies that are inappropriate for individual countries. So, for example, combating inflation within the Eurozone might have disturbing consequences for individual member states that have no inflation problems. Further, it has been argued that member states lose their ability to react to asymmetric shocks, that is, shocks that affect one economy differently from others.

The costs and benefits of a currency zone are strongly linked with the assumptions that determine its effectiveness. These assumptions refer to the degree of labor and capital mobility within the currency zone and to price and wage flexibilities that apply across the different member states. In the case of the Eurozone, strong doubts have been raised about the mobility of labor and about the wage and price rigidities that seem to persist for some countries. However, as convergence progresses, these problems are likely to decrease.

In general, the effectiveness of a currency zone relies on the pre-conditions that must be met before the application of a single currency and on the time horizon and the law enforcement tools that are available when the single currency is introduced. The Eurozone has still a long way before it is an optimal currency area in terms of reacting to asymmetric shocks and eliminating the structural differences between the member states.

Current Account

The current account measures transactions in goods, services, and income, as well as current transfers between residents and nonresidents of a country. As such, the current account records the value of real resource transactions (i.e., exchanges involving goods, services, and income) and current transfers (i.e., unilateral transfers such as food donations) in a specific time period between a country and the rest of the world. The balance on the current account and the size of the current account relative to gross domestic product are important indicators of a country's integration and openness to the rest of the world.

The value of transactions recorded in the current account of a country is estimated through periodic surveys of economic exchanges between its residents and nonresidents. In the current account, each transaction is recorded either as a credit or debit entry. A transaction that is a source of foreign exchange leads to a credit entry; a transaction that is a use of foreign exchange generates a debit entry. Thus, exports of merchandise goods are recorded as credit whereas imports are recorded as debit.

The current account is said to be in deficit when the value of real resources and current transfers acquired from the rest of the world exceeds the value of real resources and current transfers provided to the rest of the world. A surplus in the current account indicates that the opposite is true: real resources and current transfers to the rest of the world have a greater economic value than those from the rest of the world. Furthermore, the balance on the current account shows the relationship of national expenditure to national income. A current account deficit indicates that a country spends more than it produces (its income); the difference between what it spends and produces is imported from the rest of the world.

The current account is a primary component of a country's balance of payments. The other major component is the capital and financial account, which records capital flows and transfers. The balance of payments is organized on the basis of the double-entry accounting principle; it records economic transactions between residents and nonresidents of a country in the form of two offsetting entries, a credit and a debit. A credit entry in the current account is a source of foreign exchange, which implies an increase in the financial assets acquired from the rest of the world. It is thus recorded as a debit entry in the capital and financial account. For this reason, a surplus or deficit in the current account is offset by a deficit or surplus in the capital and financial account. In other words, a country running a deficit in the current account is a net debtor from the rest of the world whereas a country running a surplus is a net creditor to the rest of the world. It should be observed that the relationship between the current account and the capital and financial account holds true through accounting identity.

The balance on the current account can be seen as being constituted by the balance on goods trade, the balance on services trade, the balance on income, and the balance on current transfers. While the current account is conceptually different from the balance on goods and services trade, a deficit or surplus in the current account is often driven by a trade deficit and surplus. This is because exports and imports of goods and services are often the biggest—in terms of value—components of the current account.

Custodians

The global custody business is the safekeeping of clients' assets. It includes processing cross-border securities trades, keeping financial assets safe, and servicing the associated portfolios. Institutional investors, money managers, and broker/dealers are among those who rely on custodians and other market participants for the efficient handling of their worldwide securities portfolios. The kinds of assets involved include 1) equities, 2) government bonds, 3) corporate bonds, 4) debt instruments, 5) mutual fund investments, 6) warrants, and 7) derivatives.

Custodians effect settlement of trades (that is, completion of a transaction, wherein the seller transfers securities or financial instruments to the buyer and the buyer transfers money to the seller) and provide safekeeping of the assets on behalf of clients. The services also include (1) collection of income arising from the portfolios (dividends and interest payable), (2) application of entitlements to reduced rates of withholding tax at source and reclaiming withheld taxes after-the-fact, and (3) notification and dealing with corporate actions (such as bonus issues, rights issues, and takeovers).

In terms of service offering, custodians have moved far beyond the core services on which the business was founded—safekeeping and settlement, income collection, proxy voting—as companies have sought to add value for an increasingly sophisticated globalizing client base. Securities lending, benchmarking services such as performance measurement and risk analysis, compliance monitoring, fund accounting, and retail transfer agency are today variously or all part of the deal, as custodians seek to recast themselves as information enhancers and global market facilitators.

Many custodians outsource safekeeping of assets in foreign markets to sub-custodians. Sub-custodians use their knowledge and expertise for that particular market and charge a fee for their services. This helps custodians extend their network over a wider region and provides better service irrespective of region of operation.

While much of the work is administrative and repetitive, the role of the custodian has widened to a range of other services. Custodians typically specialize in a particular area. Custodians also have client-focused and technical personnel. Relationship managers, for example, work with clients to reassure them that their assets are safely maintained.

The global custody product was conceived out of changes to U.S. pension laws. In 1974 the Employee Retirement Income Security Act (ERISA) became law, requiring U.S. pension plan sponsors to segregate investment management and custody of the underlying assets. Prior to this, banks had provided settlement and safekeeping services on an international basis. However, these activities were typically provided free of charge—and the functions therefore starved of resources—as part of investment management or other activities. The term *global custody* was coined in 1974. Global custody services include the following:

- Safekeeping activities: Ensure that assets are protected.
- Clearing: Operate in a highly automated environment to ensure accurate records are kept of mutual positions in the exchange of cash and securities between counterparties or among a group of participants and to effect orderly settlement of their obligations on a net basis.
- Settlement activities: Ensure timely, accurate, and secure transmission of trade instructions and timely completion of settlement Straight-through processing (STP); an automated passage of a securities trade from execution to settlement is used for faster turnaround time.
- Derivatives: Ensure timely and accurate accounting for derivatives and associated margin payments.
- Network of markets: Ensure strength and reliability in supporting all required markets.
- Other services such as reporting and record-keeping, cash management, securities servicing, and income collection.

Today technology is also enabling an unprecedented democratization of business. It is now feasible for mid-size and even smaller companies to go global. In the future, global custody is going to be more concentrated, more comprehensive, and more competitive. Relationship management will be crucial: Custody will become commoditized. There will be more products and more consolidation. Only those who extend their product through joint ventures, acquisitions, alliances, and consortiums will survive. Stratification and specialization will continue, and processes will be more transparent. There will be more players, but technology will allow custodians to become more specialized. Their clients will choose the best products from a large group of specialists. Technology is a major driving force. Clients will want the ease of access that already exists on the retail side. Key players are the Bank of New York, Citibank, HSBC, EFG Eurobank, and Mellon group, to name a few.

Customer Relationship Management

Customer relationship management (CRM) is a customer-centric business philosophy, policy, and strategy that focuses on processes and systems that organizations undertake to enhance their relationships with customers. Customer relationship management is based on the premise that a stable customer base is a core business asset, and further, that knowledge of customer behavior and attitudes coupled with effective service delivery at every point of interaction with customers enhances business performance. CRM takes a long-term perspective, focused on customer retention, and the building of multiple levels of relationships between buyer and seller, in pursuit of enhanced levels of customer commitment. Goals of CRM typically include providing better customer service; making call centers more efficient; cross-selling products more effectively; helping staff close deals faster; simplification of marketing and sales processes; discovery of new customers; and increasing customer revenues.

Successful CRM is dependent on the coordination of different players within the organization responsible for delivering customer value (in accordance with Porter's value chain). These include (1) customer facing operations: the people and technologies that interact directly with and deliver service to the customer; (2) internal functional operations: the people and technologies in the back office that support the activities of the customer facing operations; (3) supplier and partner organizations: the people and technologies that support organizational processes; (4) impression management operations: the people and technologies that have responsibility for managing the impression of the brand, brand reputation, and brand experience.

Types of Relationships

Businesses can seek to create different types of customer relationships. These might include (1) basic: where the organization sells the product; (2) reactive: where the organization sells the product and encourages the customer to call with questions or problems; (3) accountable: where the organization contacts the customer a short time after the sale, to check on product performance; (4) proactive: where the organization contacts the customer with suggestions for use improvements, and with details of new products; and (5) partnership: where the organization works continuously with the customer to drive innovation and improved customer value.

The appropriateness of CRM, and more specifically, the choice of relationship type depends upon the product (e.g., level of complexity and uncertainty in purchase, margins); the customers (e.g., tendency to shop around, consumers or businesses); and, the marketing organization (e.g., structure, business process, and core values). In addition, relationships may vary on another dimension—the stage of the life cycle that they have reached with a specific business. The customer development process is concerned with moving customers through this life cycle: suspects (consumers and businesses with a profile that suggests they might become customers); prospects (consumers and businesses who have indicated potential interest in the organization's products); first time customers; repeat customers; clients (who are in a dialogue with the business); members (who have signed up to a contractual membership engagement); advocates (who actively promote the organization); and, partners (who work with the organization to enhance its products and services to the mutual benefit of both parties).

CRM is designed to reduce customer turnover, or churn. Customer switching is determined by relationship strength (the nature and depth of the bond with the organization), perceived alternatives (e.g., competitors offerings), and critical episodes (such as an unsatisfactory experience). Relationships may terminate if the customer no longer has need for the organization's products or services; more suitable providers enter the marketplace; the relationship strength has weakened; the organization handles a critical episode poorly; and/or there are changes in the organization's offering (such as changes in brand reputation or price) that cause the customer to reconsider their behavior.

Types of CRM

There are two main types of CRM. The first is operational CRM, which supports customer facing operations, including sales, marketing, and customer service. Service agents record details of each interaction into a customer contact history, so that staff can retrieve information on customers from the database to support subsequent interactions. Such data is useful in call centers, but also for managing campaigns, and marketing and sales automation. The second type is analytical CRM, which includes applications that analyze customer data generated by CRM applications to provide information to improve business performance. Analytical CRM applications are based on data warehouses that consolidate data from operational CRM systems and mine the data, to, for example, identify buying patterns, create segments for marketing, and identify profitable and less profitable customers.

Businesses need to be able to identify more profitable customers and focus relationship building on those customers. In seeking to optimize their customer portfolio, businesses seek measures of customer worth. A key measure is customer lifetime value, based on consideration of customer interactions in terms of recency x frequency x value. Other measures may be based on estimates of "relationship costs" versus "relationship revenue" for specific customers, or on the balance between the value of a customer and the risk associated with their likelihood of switching. Such analysis complements the effect of the segmenting and targeting undertaken by the organization on the customer portfolio.

Customer Responsiveness

Organizations compete in their markets basically in two ways: By offering products and services at lower prices than competitors do and by offering better products and services than competitors do. In the first case, an organization relies on cost leadership business strategy and in the second case on differentiation business strategy. An organization that can outdo its competitors in terms of lower price or differentiation stands to gain competitive advantage.

Charles Hill and Gareth Jones, in their text on strategic management, describe customer responsiveness as giving customers what they want, when they want it, and at a price they are willing to pay so long as the organization's long-term profitability is not compromised in the process. Customer responsiveness can thus be understood as the ability of an organization to take action to identify their customers and react to their needs and wants in a way that will satisfy them. Consequently, customers learn to attribute more utility to the products and services. For example, an automobile company trying to develop customer responsiveness can build cars to order for individual customers, letting them choose from a wide range of colors and options. In doing so, it strives to be better than its competitors and aims to gain competitive advantage.

The purpose of customer responsiveness is to develop customer loyalty—preference of customers for an organization's products and services so that they continue using them. When an organization is successful at creating customer loyalty it can charge a premium price that the customers are willing to pay for that something extra they get and that they do not get elsewhere.

Organizations that provide superior customer responsiveness pay attention to several aspects such as customer response time, superior design, superior service, and superior after-sales support. Customer response time is the time it takes for the product to be delivered to the customer. An organization that takes less time to respond to its customers reaches them earlier than its competitors. In this manner, that organization gains on time beating its competitors and gaining competitive advantage. Superior design and service backed by superior after-sales support is another way organizations try to serve their customers better than their competitors do. For example, mobile phones have evolved from being simple communication device to becoming sophisticated, multiple-feature gadgets, responding to customers' needs as time went by. Those mobile phone companies that have succeeded in offering better mobile phones with more features have consistently outrivaled their competitors. As they did so, they were able to charge a premium price that their customers are happy to pay.

An organization striving to develop customer responsiveness has to start by identifying what its customer needs are. This calls for keeping customers at the forefront when designing products and services. The top management of an organization plays a critical role in creating commitment to customers within the organization. They may design the mission statement of an organization that puts customers first. This gives a clear signal to the employees inside and the customers outside of the priorities of an organization.

When an organization tries to provide customer responsiveness outside it has to take several steps inside. For instance, a company trying to develop customer responsiveness may design newer products with new features that it thinks will serve customers' needs better. It will have to manage its internal processes in such a way that they are attuned to serving customers' needs better. This will require added emphasis to quality and innovation.

When an organization builds products and services around customer needs and wants, the process is called customization. In the example of the automobile company that builds cars keeping in view their individual customer needs, it is trying to customize its cars to satisfy the unique requirements of its customers. Customization usually results in increasing the costs of production, forcing the company to raise the prices. So long as customers are willing to pay those higher prices, customization works. When the costs become prohibitive, companies have to find other ways. This may involve better and faster production methods that save on costs.

Organizations that operate internationally may choose to consider each of their country markets as separate market segments, adapting their products and services to suit the local preferences of customers in those market segments. This approach, often referred to as the polycentric approach, involves customizing the marketing mix in each market segment in order to meet the unique needs and wants of customers in those market segments.

Customization

Customization refers to the efforts of companies to offer goods and services specifically designed or customized according to the needs of a particular customer, a group of customers, or an entire market (country). The core of customization or customization strategy is the focus on specific customer needs. The opposite of customization is standardization, which refers to the efforts of companies to offer a common product or common marketing programs throughout a particular market, region, or the whole world. Therefore, with respect to global business, companies pursuing the customization strategy or view treat each country as having unique features and customize their offerings accordingly instead of offering standardized products. That means that companies will modify their offerings according to differences in market characteristics, culture, industry conditions, legal environment, and marketing infrastructure (distribution channels, advertising agencies, and media) to better serve foreign consumers. Some terms used in the same or similar meaning with customization are *adaptation, personalization, personalized marketing*, and *one-to-one marketing*.

There are two broad strategies regarding international operations of companies: the global and the multidomestic strategy. In companies implementing the global strategy, products are the same across all countries in which the company operates and there is a centralized decision-making and control system. This strategy is appropriate when there are small differences across foreign markets with respect to the product the company offers; this strategy provides cost advantage and flexibility. However, companies pursuing the multidomestic strategy customize their offerings for each market and give these markets autonomy in decision making. This strategy is appropriate when there are significant differences across foreign markets and companies may better serve local customers if local needs and preferences affect buying behavior. Compared to the global strategy, the multidomestic strategy is harder to design and implement due to the existence of different factors to be considered in each foreign market.

From the marketing point of view, companies are expected to serve consumers better through customization than standardization since the ideal market segment size is one for which 100 percent customer satisfaction is needed. Therefore, customization at the individual level is the highest level of customization and assumes that each individual is different from others and thus has unique needs. Therefore, companies need to know the specific needs of each customer to be able to individually customize their offerings. For example, many computer producers now do not offer computers with only standardized configurations; instead, they give consumers the opportunity to configure computers according to their needs. Similarly, companies in many industries such as automobile, clothing, real estate, and tourism offer customization opportunities to best meet the needs of their customers.

However, it may not be possible for some companies to customize products at the individual level since such a high level of customization increases costs and requires additional resources. As a result, some companies implement customization at the consumer group or segment level as well. For example, the needs of children, teenagers, and adults may be different, and thus companies customize their offerings according to the group's needs; in addition to age, customers can also be segmented in many other ways, for example, climate, language group, media habits, education, and income.

In addition to customization at the individual and group level, customization can be done at the country level as well; laws and regulations, traditions, and religion may necessitate such a country level customization. For example, cars with the steering wheel on the right in the United Kingdom and meatless hamburgers in India are examples of customization of products at the country level, resulting from differences in law, regulations, and religion across markets.

Customization is sometimes referred to as mass-customization, which means production and marketing of good and services according to customers' needs at normal or low prices that are close to prices of products produced in large quantities, which is called mass-production. When companies engage in mass-production, they are able to decrease their unit cost, capitalizing on the scale economies; however, with respect to customized production, this is not always the case since companies need to have additional resources to produce customized or somewhat different products. So, how are products not so high priced in mass-customized production? In the past, companies could offer low-priced but similar products through mass-production (having taken advantage of low unit cost), but they used to offer customized or differentiated products at generally higher prices. However, technological developments nowadays have allowed companies to interact with customers easily and effectively and also enabled quick and flexible production that together allow decreases in costs of customized products as well. Therefore, mass-customized products are not priced as high as they once were.

Types

There are four types of customization: collaborative, adaptive, transparent, and cosmetic. In collaborative customization, companies listen to their customers and find out their exact needs. According to this information, companies then produce the product. Customized computers, clothes, and cars are all this type of customization. In adaptive customization, companies produce a standard product but the consumer or the end user can change the product according to his/her needs. For example, think of two chairs. One is not adjustable, whereas the other is adjustable. The latter gives opportunity to the end user to adjust the chair and is an example of a product for adaptive customization. In transparent customization, companies offer individual customers unique products without telling them directly. This kind of customization occurs when companies can foresee customers' specific needs. Companies implementing transparent customization observe consumers without interaction and based on this observation and further analyses, companies forecast the needs of customers and produce accordingly. In cosmetic customization, consumers use a product in a similar way, but they do change the way the product is marketed. For example, through different packaging, advertisement, marketing materials, promotion, placement, terms and conditions, and brand names, a particular product is highly customized psychologically or emotionally but not functionally.

There are several patterns and various degrees of customization that firms can adopt to do business in international markets. The most common of these are obligatory and discretionary product customization. An obligatory or minimal product customization indicates that a company is urged to introduce minor changes or modifications in the product design for either of two reasons. First, customization may be obligatory to enter and operate in a particular foreign market. Second, customization may be forced by external environmental factors, including the special needs of the foreign market. In brief, obligatory customization is related to safety regulations, trademark registration, quality, and media standards. An obligatory customization requires mostly physical changes in a product. Discretionary, or voluntary, product customization reflects a sort of self-imposed discipline and a deliberate move on the part of an international company to build stable foreign markets through a better alignment of product with market needs and/or cultural preferences.

Many factors necessitate customization, and customization may require significant changes in the design, manufacturing system, distribution, and marketing of the product in foreign markets. These changes will no doubt bring additional costs, and if the company has operations in many foreign markets, then the costs will further increase due to the increased number of adaptations. Therefore, if possible, companies usually prefer standardization because it is easier and less costly than adaptation. Others implement customization to meet local customer needs and mandated regulations. In most cases, companies implement standardization and customization simultaneously at varying degrees since it is rarely feasible or practical to follow a one offering–one world strategy across all different markets. Convergence of regional preferences, regional economic integration, harmonization of product standards, and growth of regional media and distribution channels all make regional customization more feasible than pursuing global standardization.

In conclusion, customization offers opportunities to companies to better serve their customers since companies can create greater variety in their products to be sold at competitive prices because products are produced according to customers' specific needs. When companies are able to find opportunities for mass-customization by identifying unique needs of consumer groups, they can gain benefits from offering both unique and relatively low-priced products. Companies may also have to customize their offerings for a foreign country since laws, traditions, life styles, and religion necessitate customization.

Customs Broker

A customs broker is a company or individual licensed by the host country to act on behalf of importers and exporters. The broker handles the formal paperwork to assure legal compliance and speed in the importing process. While brokers are involved in expediting imports, they are often hired by the exporter to assure that all work is done in compliance with local law and to speedily meet the conditions needed to receive payment for their products. The broker prepares import documents and calculates client payments for duties, tariffs, excise taxes, and any other special fees. The broker performs this work at the local customhouse—the government specified location where customs duties and import transactions are managed. In the United States, customs brokers are a licensed profession.

When goods reach a foreign destination, the customhouse performs a series of steps before allowing them to enter the country. These steps typically include checking to see if entry documents are properly completed, verifying any necessary markings related to the country of origin, making sure the goods are not on a prohibited item list, checking the goods against the tariff schedule (a price list of tariffs organized according the Harmonized System), checking the inventory of goods, and determining the value of goods in terms of customs duties and tariffs. When all of these steps are completed, the government customs agent clears the goods for entry into the country and posts the results to a public space (typically an electronic space). Because of the sheer volume of goods that pass through a port of entry, shipments without an expediter move more slowly. The slower the goods move through the entry process, the more cost is accrued for warehousing and storage.

The customs broker expedites the customs clearing process, assisting the customhouse to clear goods for entry. The broker, for example, reviews the tariff schedule and prepares a customs invoice for the client. The customhouse need only verify that the broker selected properly. In some ports, the broker certifies that the client has met the obligations for country of origin markings. If markings are incorrect, the customs broker will act as an intermediary, securing the correct documentation and markings and affixing them to the goods while in customs. To accelerate the customs clearing process, clients often provide their customs broker with power of attorney, a legal document that empowers the broker to act on behalf of the client in all customs clearing issues. The customs broker is a valuable source of knowledge for the exporter, staying current on all issues related to import documentation and duty and tariff changes.

Certain customs clearing tasks require notification and/or approval by government agencies other than the customhouse. For example, aquaculture importers into the United States need approval of the Fish and Wildlife Service of the U.S. Department of Agriculture to ensure that imported fish are not on the invasive species list. Because of these unique requirements, many customs brokers specialize in particular industries. Because of the relationship of customs clearing to overall delivery efficiency, many freight forwarders employ their own customs brokers.

Importing firms often bring in goods that they transform for export. In most cases, the local government allows a refunding of the duties when the goods leave the country after transformation. We call the refunding of duties a "duty drawback." Customs brokers who maintain contractual relations with clients often manage their duty drawback programs to ensure the client receives full refunds for duties paid.

In the earliest days of customs clearing, brokers and customs officials would post their findings on bulletin boards in the local customhouse. Brokers would read the bulletin board and telex their findings to the client. The current state of the art is to have sophisticated electronic data interchange systems (EDI). With each change in status, the broker instantaneously transfers information to the client's account. Brokers also provide document imaging services, scanning processed documents for immediate retrieval by their clients. Similarly, modern brokerage services interlink with freight forwarders to provide documentation that the exporter has met transportation security standards. Often, this includes the sophisticated integration of global position (GPS) data with accounting information.

To become a licensed customs broker in the United States, candidates must meet experience requirements and pass a proctored standardized examination. In developed countries, the preponderance of all import transactions are managed by customs brokers.

Customs Union

A customs union is a treaty signed between two or more countries to promote trade between participants. The countries in the customs union establish a common free trade market with each other while simultaneously maintaining a common trade barrier for foreign goods. This agreement is the third step in complete trade integration between participating nations, occurring after the "free trade" zone step and before the "common market" step. Trade with outside participants is regulated through a common external tariffs rate and the application of a common trade policy. Some custom unions will be negotiated to allow different import quotas from one country to the next. Current custom unions include the Southern African Customs Union and the East African Community.

Customs unions provide three main advantages for participating countries. They promote the trade of goods between participants; protect industries operating within the protected region; and serve as a source of revenue for participating countries that are less likely to generate trade activities.

Customs unions promote the trade of goods in participating countries due to lower tariffs. Hence, the union increases local competition and lowers costs of goods for consumers while imposing a common barrier for the same goods from nonparticipating countries. This is used to effectively promote intracountry trades. A recent study examined the impact of Turkey's integration in the European Custom Union. It found a positive effect in importations from European Union (EU) countries without overly impacting local industries.

Simultaneously, external tariffs protect regional industries operating inside the protected zone. This is important, as it protects a strategic sector of activity (such as agriculture and fishing). Hence, products that are produced inside the tariff zone have an immediate advantage over products that are from the external zone.

Finally, custom unions can serve as a source of revenue for the participating members, since revenue generated by the external tariff is pooled in a common revenue pool and shared among participants. This allows sharing of import revenues between participants. This is especially beneficial for countries that are insular and are less likely to trade with nonperipheral countries.

There are also have a number of disadvantages that countries must contend with when participating in a customs union. These include some loss of control over fiscal policy, increased competition to local industries, and the inherent advantages customs unions confer to larger participating countries.

One disadvantage a country faces when joining a custom union is that participants have to give up some level of control on fiscal matters. Hence, when a country is unable to unilaterally control tariffs, excise duties, and sales taxes, it loses some level of ability to use these instruments to control internal economic policy and strategy formulation.

Another disadvantage is that while custom unions favor the emergence of some regional industries, they can produce adversity for national companies as they find themselves competing directly with neighboring countries (without the benefit of tariffs to protect them). This often leads to the disappearance of local inefficient industries in favor of more regional competitors.

Finally, customs unions often favor larger countries because they are able to take advantage of economies of scale to produce goods more cheaply than their smaller counterparts. As such, bigger participants usually have the upper hand in these arrangements. While smaller countries get access to cheaper goods, they often find that their local industries are slowly eroding, leaving them unable to compete in their national markets.

Hence, smaller countries have to increasingly depend on market specialization, focusing their local economies on some natural resources or local expertise in favor of a broader diversified industry.

Customs unions are present throughout the world. Examples include the Southern African Customs Union (SACU), which is the oldest customs union in operation. Established in 1910, SACU permits the free movement of goods among five member countries (South Africa, Botswana, Lesotho, Swaziland, and Namibia), and a uniform external tariff regime on goods from outside the region. The East African Community (EAC) is another customs union in Africa, comprised of five east African countries—Kenya, Tanzania, Uganda, Burundi, and Rwanda.

Other examples around the world include the European Union. While not itself a customs union, the EU establishes customs unions with other countries when they are evaluated for membership (like Turkey in 1996). Mercosur is a free trade area that is considering evolving into a full-fledged customs union. Negotiations in the region are ongoing.

CVS Caremark

Woonsocket, Rhode Island–based CVS Caremark (NYSE:CVS) is the largest U.S.-based integrated pharmacy service provider, combining one of the leading American pharmaceutical benefit management companies (Caremark) with the country's largest pharmacy chain (CVS). The U.S. healthcare system is struggling to manage growing costs as employers shift responsibility for managing costs to employees. In response, CVS acquired Caremark for $26.5 billion in order to become more consumer-centric and responsive to rapid changes in the healthcare delivery system. This 2007 merger of the two entities was expected to permit more fully integrated pharmacy services, including pharmacy benefit management, mail order, specialty pharmaceuticals, an online pharmacy (CVS.com), and the retail-based health clinic subsidiary, MinuteClinic.

CVS Caremark has been making investments in new stores and technology in order to drive future growth both through in-house start-up and acquisitions. Several of their larger recent acquisitions include the 2004 purchase of over 1,200 Eckerd drugstores, primarily in high-growth markets in Florida and Texas, and in 2006 Southern California–based Sav-on and Osco drugstores (700 stores total) that were integrated into CVS/pharmacy. Altogether, CVS Caremark offers end-to-end services from plan design to prescription fulfillment. The company feels that the combination of CVS Caremark helps payers control costs more effectively, improves patient access (through phone, mail, the internet, or face-to-face), and promotes better customer health outcomes.

The lineage of CVS Caremark can be traced back to the Melville Corporation, a large retail holding company incorporated in 1922 as the Melville Shoe Company, and renamed in 1996 as CVS Corporation. (The CVS stands for Consumer Value Stores.)

Caremark was established in 1979 as Home Health Care of America, changing its name to Caremark in 1985. In 1987 Caremark was acquired by Baxter International, but then spun off as a public company, Caremark, in 1992. In 1996 Caremark merged with MedPartners/Mullikin, Inc., and they became MedPartners. In 1998 MedPartners changed its name to Caremark Rx.

CVS Caremark currently employs 136,000 people in two operating segments: CVS/pharmacy and Caremark Pharmacy Services. CVS/pharmacy fills more than one of every seven retail prescriptions in America, amounting to more than 1 billion prescriptions per year, which is more than any other pharmacy service provider. CVS/pharmacy generates over 68 percent of its revenues from its pharmacy business. Their ExtraCare program has enrolled over 50 million cardholders. Caremark Pharmacy Services is one of the nation's leading pharmacy benefit management companies, providing comprehensive prescription benefit management services to over 2,000 organizations' health plans, including corporations, managed care organizations, insurance companies, and government agencies. Caremark also operates a national retail pharmacy network of over 60,000 participating pharmacies, 11 mail service pharmacies, and 70 specialty pharmacies.

Among their initiatives in community involvement are the CVS Caremark Charitable Trust (education and community involvement in cities where the company operates pharmacies), the CVS Samaritan Vans providing free roadside (medical and on-site auto repair) assistance to motorists and communities in numerous cities, and the annual CVS Caremark Charity Golf Classic.

According to CVS Caremark, the average revenue per employee is close to $200,000. Strong future demand is anticipated in response to an aging population, increasing incidence of chronic diseases, and increasing utilization of the Medicare drug benefit.

Cyprus

Cyprus is an island in the Mediterranean Sea whose political status is dominated by the division of the country into the Greek-Cypriot southern area (Republic of Cyprus) controlled by the Cyprus government and the northern area that is administered by Turkish-Cypriots. The Greek-Cypriot part of the island enjoys a prosperous economy—it is one of the advanced economies of the world according to the International Monetary Fund.

A large part of the southern part's prosperity is attributed to Cyprus's strategic location at the crossroads of three continents and in close proximity to the Middle East. This position has played a significant role as Cyprus has been a country with a platform of political turbulence for many years. Characteristics like a developed infrastructure, a stable legal framework, and the highly skilled workforce also contribute to the wealth that Greek Cypriots enjoy, and have made Cyprus a popular business center. Moreover, tourism plays a dominant role in growth and wealth generation, which is, however, susceptible to external influences such as fluctuations in the financial conditions of major tourism-producing countries (primarily western European countries such as Germany and the United Kingdom).

The Turkish Cypriot area of the island has about 20 percent of the population and its gross domestic product (GDP) is one-third of the GDP of the southern part of the island. The de facto Turkish-Cypriot administration is recognized only by Turkey, so attracting foreign investment has been a difficult task to accomplish. As a result, the economy of the northern part still relies on agriculture and on the government.

The Republic of Cyprus has been a member of the European Union since May 2004. The beginning of 2008 marked the entry of the country to the Eurozone and thus, Cyprus has adopted the euro at a fixed exchange rate of CYP 0.585274 per EUR 1.00. The introduction to the Eurozone was accompanied by accelerated growth at a rate that is above the European Union average. This growth is largely a result of the activity of traditional, family-owned enterprises with a strong entrepreneurial flair supported by a liberal economy whose backbone is the private sector. In this respect, the public sector has a supervising role monitoring the smooth operation of the economy and providing public utilities. The main economic indicators manifest the country's economic "health," with the inflation rate being less than 3 percent and registered unemployment less than 4 percent.

The services sector is an increasingly important part of the economy, as indicated by its 70–73 percent contribution to GDP and its share in employment. At the same time, the importance of agriculture and manufacturing showcase a steady decline over the years. Key services sectors include banking and financial services, insurance, advertising, legal, architecture and civil engineering, accounting and auditing, consultancy, design, electrical and mechanical engineering, market research, medical, printing and publishing, public relations, education, software development, tourism, and related services. In terms of social life, Cypriots enjoy a high standard of living with no or extremely low levels of homelessness or criminality.

In terms of international trade, the country relies on the importation of energy resources such as oil from the Middle East because of the lack of raw materials and heavy industry. Export-wise, many Cypriot products and services go international, primarily to several European and neighboring Middle Eastern countries. A prime feature of the Cypriot economy is its attractiveness for foreign investment. The strategic location of the country, favorable tax incentives, and a free zone area located near Larnaca airport provide an ideal location for many investing enterprises. Some restrictions on foreign investors are, however, applied in some economic sectors such as broadcasting, land development, education, the press, travel agencies, commercial shipping, and fisheries, since relevant licenses must be obtained.

Czech Republic

The Czech Republic, capital Prague, is a small landlocked central Eastern European state with a population of 10.2 million. The lands of Bohemia and Moravia were an advanced part of the Austro-Hungarian Empire. When the empire collapsed in 1918, a new Czechoslovak state was formed. This lasted until Nazi expansion in World War II. Liberation led to the recreation of the state and a short-lived coalition government before integration into the Soviet bloc in still-controversial circumstances in 1948–49. The communist regime was shaken in 1968 by the Prague Spring. Soviet invasion halted this, but in 1989 the communist regime collapsed in the face of popular demonstrations and the peaceful Velvet Revolution. The current Czech state emerged in January 1993 from a Velvet Divorce with Slovakia—hitherto the eastern part of the country.

When the communist regime failed, the Czech Republic was seen as something of a model transition country and its leaders sought to obtain recognition for its strategic location in central Europe. (Czechs were often offended at being considered "east," as Prague is farther "west" than Vienna). The Czech Republic joined NATO in 1999 and the EU in 2004.

Czech leaders, and especially Vaclav Klaus as prime minister from 1992 to 1997 (elected president in 2003 and 2008), were careful to echo the appropriate free market rhetoric, although some skeptics suggested that reality often deviated. Czech privatization was distinguished by the use of vouchers to create popular share ownership. This aim was not achieved but the management quality of Czech privatized firms tends to be relatively high. Early on, a high international credit rating was gained. Czech politics and society were viewed positively despite undercurrents of corruption, crime, racism, and minority oppression. The tourist boom reflects these contradictions, with some attracted to the glories of the past and others by cheap alcohol and prostitution.

Czech industrialization began early, and the country today is 75 percent urban. Agriculture plays a small role (3 percent output). Industry provides around 38 percent, and services the remainder. The Czech arms industry was famous for many decades. Engineering, machinery, and iron and steel along with consumer goods, including the famous Czech beers, are an important part of industrial output. But parts of Czech industry are still in the central European economic "rust belt." There is significant inequality between the 13 different regions of the Czech Republic, with a strong polarization around the capital Prague.

Economic growth has enabled a sustained rise in output per capita. Inflation has been held down and unemployment has been contained. The government has tried to make the Czech economy more market friendly. Staged reductions in corporate taxes are in place, as is the replacement of the progressive income tax with a flat rate. But there is a strong tradition of welfare support and opposition to elements of a neo-liberal agenda. This makes consensus difficult to maintain.

Trade is focused on the West, with Germany having a third share. Trade with Slovakia is relatively small given the history of unity. Manufactured goods make up an important part of commodity trade. The Czech Republic early on attracted significant foreign investment and is one of the more successful cases in the transition states. Brands like Skoda and the Czech beers were still seen to be valuable by Western multinationals.

The Czech population offered a more qualified support for joining the European Union, with a 77 percent yes vote on only a 55 percent turnout. Both as prime minister and president, Vaclav Klaus has been notorious for his skepticism about aspects of the European Union. This has often found him favor in Washington and among those who see the possibility of a more pro-American "new Europe" to set against the "old" western Europe.

Dai-ichi Mutual Life Insurance

Dai-ichi Mutual Life Insurance (Dai-ichi Seimei Hoken Sōgo-gaisha) was founded on September 15, 1902, by Tsuneta Yano, and it is the oldest mutual insurance company in Japan. It took its name from the Dai-ichi Bank Ltd. that had been established in June 1873, the first banking institution established in Japan (when it was called the First National Bank). In 1896 it became a joint-stock commercial bank as the Dai-ichi Bank; the insurance company was established six years later when Tsuneta Yano published a small booklet entitled *Characteristics of My Company*. The company prospered and in 1938 moved its headquarters to its current location in Chiyoda, the business district of Tokyo. In 1945, its headquarters became the General Headquarters of the Allied Powers under General Douglas MacArthur. Later Dai-ichi built a new 20-story building for the company's policy service department and computer systems section.

During the 1960s, Dai-ichi Mutual Life Insurance Company started to expand into other parts of Asia, but faced problems in some areas owing to the lingering resentment toward the Japanese in parts of the region they had occupied during World War II. This led Dai-ichi to join the Foundation for the Advancement of Life Insurance Around the World (FALIA) in 1970. Five years later, the company established its first overseas office in New York City, initially to help staff study how the U.S. insurance market works, and later to help with the promotion of business in the United States. Seven years later it opened an office in London. The company continued to prosper and in 1990 invested in the Lincoln National Life Insurance Company, the first time a Japanese company had provided capital for a leading U.S. insurance company. Three years later, in 1993, the company finished its DN Tower 21 as its new head office.

The Great Hanshin (or Kobe) earthquake on January 17, 1995, listed in the Guinness Book of Records as the "costliest natural disaster to befall any one country," resulted in such a vast number of claims that this led to the simplification of the entire claims settlement procedures, and in the following year the company set up a subsidiary, the Dai-ichi Property and Casualty Insurance Co. Ltd., and in 1997 the Dai-ichi Life Research Institute, Inc. After years of competition, in 1999 the company agreed on business cooperation with the Industrial Bank of Japan (now the Mizuho Financial Group), and in 2000, there was an agreement to form a business alliance with the Sompo Japan Insurance and with Aflac.

This building was damaged in the Kobe 1995 earthquake, a costly disaster that led Dai-ichi to change its procedures.

In 2001 Dai-ichi won the Japan Quality Award, being the first company from the financial and insurance industry to get this award. In recent years the company has continued to expand, and in 2007 it bought Bao Minh CMG and started trading in Vietnam as Dai-ichi Life Insurance Company of Vietnam, Ltd. The Dai-ichi Mutual Life Insurance Company employs about 54,400 people (2005), with total capital of $21,425 million (2006) and total assets of $276,552 million (2006). It now has about 8.65 million policy holders.

DaimlerChrysler

DaimlerChrysler was the name of the entity created by the 1998 merger of two of the most storied names in automotive history, the Chrysler Corporation of the United States and the Daimler-Benz AG of Germany. This was the first major merger of an American and a German auto firm, and was valued at the time at $36 billion. The companies had co-headquarters, one in Auburn Hills, Michigan, and the other in Stuttgart. During its existence, it was the fifth-largest automobile company, by vehicle production, in the world.

Chrysler, a company created by auto industry legend Walter Chrysler in 1925, had, since the 1960s, been the third of America's Big Three auto makers, continually lagging behind General Motors and the Ford Motor Company. After a near-bankruptcy in the late 1970s, the company bounced back spectacularly under the leadership of president Lee Iacocca. Iacocca introduced new products such as the K-Car and the minivan and secured government-backed loans during the company's darkest period. By the 1990s, Chrysler's successes in the marketplace, particularly with its minivans, large trucks, and Jeep brand, had made the company a lucrative proposition.

Daimler-Benz AG, Germany's most famous brand, had been created in 1926 by the merger of the Daimler and Benz companies, two of the most important and innovative firms in the worldwide motor industry. After World War II, Daimler Benz reclaimed its place among the leading German firms by focusing upon quality and luxury vehicles, such as its flagship nameplate, the Mercedes Benz. While it remained among the most popular brands in Europe, by the 1980s and 1990s, the company was keen to expand its market share, particularly in the largest car market in the world, the United States.

In 1998, following a series of highly secret meetings, the two companies announced what they called a merger of equals. There were to be co-CEOs, German Jürgen Schrempp and American Robert Eaton, equally sharing decision making. The announcement of the merger was met with skepticism in many quarters, as some observers saw the coupling as ill-fitting, given Daimler Benz's focus on luxury, while Chrysler was known for its big trucks. Some saw this as a strength, and believed the two companies would present a synergy for the new company. Others saw it as another example of America's corporations being taken over by foreigners. Still others felt that the $36 billion that Daimler-Benz paid for Chrysler was far too high.

Initially, there was some success. The two companies shared some technology, and Chrysler's quality improved through its association with Daimler. However, within a few years, it was clear that the decisions for the company were all being made in Germany, even for the Chrysler unit. Eaton stepped down in 2000, leaving Schrempp as the sole executive. The Chrysler unit's chief executive was a German, Dieter Zetsche, and only a few products emerged from direct cooperation between the two entities, such as the sporty Chrysler Crossfire.

Soon, many in Germany, especially in the automotive press, were unhappy about the erosion of the Daimler brand and valuation. Many Americans were also unhappy, feeling that instead of a merger of equals, the transaction was actually a takeover. There were court cases over the merger by some of Chrysler's main investors, which further drove down the value of the company. After 1998 a general downturn in the American market, coupled with high gas prices, meant that the success that Chrysler had experienced in selling large trucks and sport-utility vehicles was coming to an end. Its market share, which reached nearly 14 percent in the mid-1990s, declined to under 10 percent by the mid-2000s. The company's stock slowly declined.

Given these difficulties, in 2007 Daimler announced that it was selling 80 percent of Chrysler to an American private equity firm, Cerebrus, for $7.4 billion. Daimler would maintain a 19.9 percent share of the company and also assume one-fifth of the company's outstanding pension obligations to workers. Daimler also promised to invest $1.7 billion in Chrysler. In the end, the merger of these two companies was a failure. With the de-merger of the two companies, Daimler-Benz was renamed Daimler AG, while Chrysler took the name Chrysler LLC. Chrysler is a privately held company, while Daimler AG is a public company traded extensively in Europe and the United States.

DAX Index (Germany)

The Deutsche Aktien Index (DAX) is a blue-chip index tracking 30 major stocks on the Frankfurt Stock Exchange (FSE), with prices taken from the Xetra electronic trading system that has been in use since 1997. One of the biggest stock exchanges in the world, FSE is also considered the most efficient. Business is conducted from 9 A.M. to 5:35 P.M.; in order to coincide with U.S. trading hours, the Late DAX Index tracks prices from 5:45 P.M. to 8 P.M.

The following 30 companies are tracked by the DAX 30: Adidas AG, the sports apparel manufacturer; Allianz, a financial services and insurance provider; BASF, the largest chemical company in the world; Bayer AG, a chemical and pharmaceutical company; BMW (Bavarian Motor Works), the automobile company; Commerzbank, the second-largest bank in Germany; Continental AG, a manufacturer of tires and auto parts; Daimler AG, the German motor company (no relation to the British Daimler Motors); Deutsche Bank, the largest bank in Germany; Deutsche Börse, a marketplace organizer and transaction services provider; Deutsche Lufthansa, Europe's largest airline; Deutsche Post, a German postal services company; Deutsche Postbank, a retail bank; Deutsche Telekom, Germany's largest telecommunications company; E.ON, an energy corporation and the largest company on the DAX 30; Fresenius Medical Care, a medical supplies producer; Henkel, a company manufacturing home and personal care supplies; Hypo Real Estate, a holding company for real estate financing banks; Infineon Technologies, a semiconductor manufacturer spun off from Siemens; Linde AG, a gas and engineering company; MAN AG, an engineering company; Merck KGaA, a chemical and pharmaceutical company; METRO AG, a wholesale and retail company; Munich Re, the world's largest reinsurance company; RWE, a power company; SAP AG, the largest European software company; Siemens AG, Europe's largest engineering company; ThyssenKrupp, an industrial conglomerate; TUI AG, a tourism and shipping company; and Volkswagen AG, the automobile manufacturer.

Debt

Debt is the state of owing something to another party. It is generally assumed to involve the transfer of financial assets, but in the barter economy the payment is executed in kind. It is important for both lender and borrower to reach an agreement about a deferred payment, and the lender is rewarded with an appropriate interest payment for forgoing current consumption. In the contemporary Islamic world, which has strong similarities with the stance of the medieval Catholic Church that condemned usury, debt repayment is replaced by profit sharing of co-investing parties. The orthodox religious thinking in certain parts of the world thus indicates that interest payment associated with debt leads to profit making without commensurate work effort and simultaneously causes the exploitation of those expected to pay it.

Nevertheless, debt has been an important market phenomenon throughout history. Expensive and prolonged wars had to be financed by extensive borrowing and this could eventually lead to bankruptcy. Private investors, such as the Rothschilds, supported the British government in war against Napoleon I, and one of the major roles of early central banks in the world was to provide public financing for the state. In contemporary economic flows it is evident that leverage, i.e., increased debt levels, lead to higher risk, but also to higher returns because of the difference between the (higher) investment return and (lower) cost of debt. The cost of debt financing is even lower because it is paid before tax, which implies lower after-tax cost of financing.

The notion of debt is not only essential at the microeconomic level. Governments issue so-called sovereign debt instruments (bonds) or accumulate various sorts of international loans for investment and consumption-related purposes and like companies are prone to default on debt if overexposed to the same. The best examples are Mexico and Brazil in 1982, the Russian Federation in 1998, and Argentina in 2001.

Small- and Medium-Scale Enterprises

At the micro level, companies borrow funds directly from financial markets or indirectly from financial intermediaries, such as commercial banks, savings institutions, credit unions, and finance companies. The scale and scope of lending instruments is different among lending institutions and are suited for particular market niches that occasionally include individual consumers (car financing provided by finance companies or personal loans from commercial banks). The involvement of a financial intermediary increases borrowing costs by a charged fee, which is potentially more disadvantageous with comparison to direct financing. However, small- and medium-scale enterprises (SMEs) would pay a significant premium to obtain funding from non-bank investors who do not have full insight in its business/credit rating. Accordingly, bank lending can be more attractive for SMEs, due to financial intermediaries' customer knowledge base and especially if debt is collateralized, i.e., supported by tangible assets that can be resold in the case of bankruptcy to retrieve extended funds.

Two-thirds of bank loans have maturities shorter than one year, and the modes of loan extension are diverse. Banks ask companies to sign promissory notes that may be secured with tangible assets. A series of promissory notes are issued as part of an informal line of credit indicating the maximum credit a bank will provide for the borrower during the year. When formalized, the line of credit becomes "revolving," the committed sums are larger, lending periods turn generally longer than a year and loans are provided by a single bank or a syndicate of banks.

Large Enterprises

By contrast, "blue chip" companies with high credit rating receive comparatively low-cost funding by issuing debt instruments directly to public or even private placements. Securities issued in debt markets are called bonds, denoting certificates issued by the borrower, which promise regular annual/semi-annual interest payments and on maturity date, the return of the principal amount stated on them. Zero-coupon bonds are issued at a heavy discount, do not provide interest payments (no interest coupons to be cashed in), and the principal is returned at the end of the contracted period.

From the maturity point-of-view, short- and medium-term debt instruments are called notes, while issues with longer maturities are called bonds or debentures. For periods shorter than one year, companies brandishing high credit standing issue unsecured commercial papers, i.e., promissory notes assuring that the principal payment will be made after the expiration of the prescribed period, which can be anything from one day to nine months. Funds raised are used to finance daily operations and as a bridge until long-term funds have been received. If a company does not have a good credit rating, banks provide acceptances to increase the quality of the issue called the bill of exchange. Alternatively, the sale of a security accompanied by a promise to repurchase the same at a future point in time is an additional vehicle for secured near-cash investments and is called a repurchase agreement.

Debentures are long-term bonds that are not collateralized by any property (tangible asset) as a reassurance that the debt will be paid. Not surprisingly, blue-chip companies routinely issue debentures. If called "subordinated," debentures are inferior to all senior debt positions on the liabilities side of the balance sheet. This indicates that no payments will be made until after all senior obligations have been honored, which is an important rule in liquidating the company.

A company can accrue liabilities due to the nature of its business or taxation policies. Salaries are paid on fortnightly or monthly basis and some of these liabilities will accrue in the balance sheet. In addition, sales taxes are paid on a weekly, monthly, and quarterly basis, which leads to further accruals. These liabilities are interest free, but the creation of this type of debt is not controlled by the company. Another type of debt financing is provided by trading partners. If a firm purchases goods with a payment expected after an extended period of time (30 or 60 days), there will be a significant amount of accounts payable (trade credit) on the liabilities side of the balance sheet. If the market player acts as a monopsonist, i.e., a business entity with overwhelming purchasing power in the market, it is possible to extract longer payment periods from suppliers.

On the other side, an aggressive market growth policy would most likely include an increase in the amount of trade credits extended to new customers in order to drive them away from competitors. Nevertheless, in order to improve cash flow positions, companies offer discounts for early payments. For instance, if a payment been made by a purchaser after 10 instead of 30 days, a 2 percent discount is offered. The debtor will make early payments if this 2 percent return is sufficient to offset any other profitable short-term investments over the 20-day period (from the 10th until the 30th day).

In a more complex multinational corporation, the parent provides loans to subsidiaries in which case notes and interest payable appear as additional balance sheet positions of a subsidiary. The parent company combines intracompany debt issues with other types of financing such as equity infusion or loans extended by local banks in the country where the subsidiary is located.

The last source of financing is politically desirable, because it strengthens ties with the local banking community and reduces the incidence of expropriation by rogue regimes. It is essential that the capital structure reflect an appropriate level of the subsidiary's (debt) leverage and that it acts as an independent entity from the parent, which leads to an increase in efficiency in the face of potential default not guaranteed by the parent company.

Sovereign Borrowing

Sovereign countries borrow from domestic and international markets and like companies are expected to provide good record in repaying debts. Financial institutions request collateral in order to secure placements, but this feature is sometimes unfeasible in extending sovereign loans. Therefore, lenders must conduct the meticulous analysis of trade policy, government intervention, political stability, fiscal and monetary austerity, foreign direct investment flows, inflation, and financial system structure in order to obtain adequate risk assessment. Thereafter, risk levels are converted into premiums for each country above or below U.S. Treasury bond rates, which is a good estimate of debt costs associated with the foreign project. Even though U.S. Treasury issues are assumed to be risk-free in financial evaluations, the incidence of sovereign countries' defaulting on international debt is not unheard of.

Moratoriums, i.e., unilateral decisions to postpone repayments of sovereign debt, can lead to significant financial losses. In 1982, Mexico and Brazil announced their inability to service debt, which prompted many U.S. banks to increase reserves in the expectation of an increase in unserviceable loan positions. Citicorp in 1987 boosted reserves by US$3 billion to cover losses. In 1998 the Russian Federation defaulted on a US$40 billion short-term debt, and the subsequent year some banks accepted 5 cents for each dollar owed to creditors. The abandonment of the Argentine peso peg to the dollar in 2001 caused financial turmoil and the default on a US$130 billion in sovereign debt. However, a settlement with international creditors was not reached until 2005, when 30 cents was offered on the dollar of debt defaulted in 2001. In this manner, Argentina has topped the list with the most unfavorable, nonnegotiable dollar-denominated debt settlement ever reached.

Commercial lenders and creditor countries have always tried to create countervailing forces against irresponsible debtors. The Paris Club of creditor countries in 1956 and the ad hoc London Club of commercial lenders were created as a result of this tendency. The Paris Club comprises 19 creditor countries from North America and Western Europe along with the Commonwealth of Australia, Japan, and Russian Federation. Another 13, mainly newly industrialized or resource-rich countries, have been invited to attend meetings on a case-by-case basis, but any final agreement is made between permanent members and debtor countries. It was created in 1956 as a result of negotiations between Argentina and various creditor nations; over the period of 50 years, the Club negotiated 402 debt restructurings worth US$532 billion across 81 countries.

Since 1996, significant concessions have been granted to the Highly Indebted Poor Countries (HIPC), following the joint recommendation of the International Monetary Fund (IMF) and the International Bank for Reconstruction and Development (IBRD) to reduce debt burdens for most disadvantaged countries. This action should allow them to service debt through trade, financial aid, and capital inflows. To become eligible for this scheme, a country must (a) be the exclusive recipient of international development assistance from the IMF and World Bank; (b) reach unsustainable debt levels where extant debt-relief mechanisms such as Naples terms are insufficient (a potential reduction of eligible external debt of 67 percent in net present value (NPV) terms); and (c) demonstrate a track record of reforms advocated by IMF and World Bank. By 2008, 21 countries had reached the completion point at which Paris Club members reduced their debt burden by 90 percent or more in net present value terms. An additional 18 countries are still at various stages of negotiation leading to the final completion point.

The major criticism of the Club's policy is directed toward decisions that are allegedly politically tainted, such as the 80 percent write-off of Iraq's debt in 2004. In addition, the growing concern voiced by Club officials is related to the aggressive lending of nonmember countries such as Brazil and China. The extending of loans under less strict terms prompts borrowing countries to request the Paris Club to renegotiate previous debt agreements under more acceptable conditions.

The London Club is an informal group of commercial investors temporarily created for negotiations with the sovereign debtor. Following the acceptance of the debtor's request, the Advisory Committee of the London Club is created, which is usually chaired by a leading financial institution. When the restructuring agreement is signed, the Advisory Committee is dissolved.

In the contemporary financial markets, investors purchase developed and emerging countries' bond issues by visiting local debt markets. While in developed countries most of the bond issues have investment grade, in developing economies potential borrowers can seldom demonstrate high investment grade, which is Baa or above if rated by Moody's or BBB or above if rated by Standard & Poor's. In addition to political risk, impediments to this type of cross-border investments are the exchange risk and occasional inability to transfer funds outside the country. By contrast, governments rarely default on bonds denominated in domestic currency, because they can always print money to fully repay debt.

Alternatively, foreign bonds can be issued on major national bond markets and are denominated in the currency of the trading place. Dollar-denominated foreign bonds traded in the United States are called Yankee bonds, while foreign bonds denominated in yen and traded in Tokyo are called Samurai bonds. Third, investors buy Eurobonds, which are bonds placed by a syndicate of international banks in countries that are different from the one in which currency the issue is denominated. Among emerging economies, major Eurobond issuers are the representatives of largest Central and South American countries.

Finally, as part of the Brady plan in 1990, heavily indebted emerging countries decided to issue Brady bonds that are traded in the international capital market and mainly supported by various principal and interest payment guarantees. In addition, Mexico and Venezuela issued securities linked to the price of oil, which means that extra payments are made to investors if the value of oil exports increases over time.

Islamic Finance

If someone is using someone's money, he or she is expected to pay interest, and depending on the maturity of the obligation, the interest rate will be fixed. In other words the price of using money is interest that one party has to pay to another. However, in early Christian times, as now in Islamic finance, usury or charging interest was forbidden and *haram*. Therefore, Islamic finance offers a series of instruments which have interesting complexity in order to offer free-interest banking for those who observe religious rules closely. In Islamic finance, the modalities are such that a person lends money via a financial intermediary and becomes an indirect business partner, and shares to some extent the (business) risk to which the borrower may be exposed when utilizing borrowed money. The non-interest (or not-for-profit) options offer a richer variety of instruments and give a different perspective on debt and borrowing and how the risk may be pooled or shared, depending on a situation.

Debt-for-Equity Swap

A debt-for-equity swap is a financial transaction in which creditors who have debt in a company (such as loans or bonds) agree to have these debts canceled in exchange for equity in the business. Hence, this transaction alters the capital structure of the firm. It does not generate any new cash flow for the business (although there are some considerable administrative costs related to the transaction), but it does improve the profitability of the business by lowering debt service payments and restructuring the current debt/assets ratio. Companies do these swaps when in a favorable or difficult financial situation, depending on its strategic implications, but consequences on the company's stock are usually negative, given the negative market perspective on this type of operation.

Typically, a company that wishes to initiate a debt-for-equity swap will offer its investors to exchange their debt for a predetermined amount of equity (or stock). The amount of equity given in a transaction is usually determined by current market rates, but in some cases, the company's management may offer higher exchange values to convince debt holders to participate in the swap. If the investors agree to cancel their existing debt, they are given equity equivalent to the negotiated amount.

Motivations

Companies that are in a positive financial situation rarely use a debt-for-equity swap, as the cost of servicing bonds or loans is usually less than the long-term costs related to stocks. Nonetheless, some companies will do this type of transaction to take advantage of specific tax provisions or if there is favorable internal information about the Net Present Value of existing and future projects. A company might also proceed with this type of operation to take advantage of current stock valuation. As for lenders, doing a debt-for-equity swap results in trading a fixed-rate debt for an asset whose return is tied to company performance; if the firm is doing very well, the lender might be enticed by the higher return potential. In all cases, swaps under positive financial circumstances are rather rare.

Most of the time, debt-for-equity deals take place when a company has run into severe financial troubles, and the cost to service the debt is crippling the short-term functionality of the company, or the company feels it might be unable to make face value payments in the near future. Other reasons for swaps include a contractual obligation to maintain a specific debt/equity ratio or pressure from existing lenders to reimburse some amount that is currently due. Hence, facing bankruptcy, the company will try to arrange for a private reorganization of its capital structure.

Lenders habitually accept these swaps because the current debt is very large and the company's remaining assets are worth significantly less than current assets and there is no advantage in driving the company into bankruptcy. Also, faced with a choice of writing off the debt and getting nothing or writing off the debt and getting equity, lenders often prefer to get equity in the hope of recouping their investment. Hence, debtors participate in these transactions to get an increased level of control over the company, so they are better positioned to recover some amount of capital.

During a favorable financial situation, a debt-for-equity transaction might increase stock values, but only to a small extent. Even if the firm is restructuring its capital structure to take advantage of external events (such as higher stock prices or corporate tax shields), market reactions are usually negative to this type of transaction, perceiving it as masking an unfavorable internal financial situation.

When used in a downturn situation, this type of transaction benefits the company by relieving some of the pressures linked to servicing the debt. It can also be used in a defensive manner. For example, if a company has low market valuation, it could be worried about being a target of a hostile takeover; by converting debt into shares, it could reduce the risk of hostile acquisition by increasing the total number of shares outstanding.

Responses

Existing shareholders are usually displeased with the announcement of a swap. First, they may find their shares severely diluted as substantial amounts of new stock are issued, and significant debts are restructured into a deteriorating stock. Furthermore, several studies have demonstrated that the value of the stock declines at the announcement of a swap.

This is most often attributed to an information effect, whereas stockholders find (or believe) that a company's financial condition is worse than expected. Sometimes, it is possible for shareholders to block these transactions if the value of the shares being issued exceeds the value of the debt being written off, but in the case where the company has a net negative value, shareholder consent is usually not necessary to proceed.

By the same token, debt holders, seeing the risk related to their investment increase, may prevent the swap from occurring without their consent. As such, management will often deploy extra incentives (such as a higher valuation of debt capital) as a necessary step to increase the likelihood of this transaction occurring.

Debt Rescheduling

Debt rescheduling is the reorganization of an outstanding debt amount (stock) and/or its terms. Debt rescheduling is undertaken in situations where the debtor faces serious obstacles in repaying the debt, either on time or at all. Often this procedure is referred to as debt reprogramming. In most instances when debt rescheduling is undertaken it eases the position of the debtor, addressing the issues of his/her liquidity and the potential of insolvency. The rescheduling of the debt may address the amount that is borrowed, where the creditor may reduce the principal in order to facilitate the debt service, but all the other conditions of the original contract remain in force. Or, the creditor may focus more on the servicing of the debt and facilitation of the repayment process, allowing the deferral of payments due, reducing the interest rate, extending the maturity, etc. In critical situations, the rescheduling may target both the outstanding debt stock and the conditions of contract. The creditor is interested in saving as much as possible of his/her own money and also ensuring the economic viability of the debtor, as a potential future client as well.

Debt rescheduling is a contract that alters the previous debt contract and requires the full consent of both contractual parties. Both creditor and debtor have to agree on new terms and conditions in order to have this contract concluded. Often it is assumed that unilateral actions are debt rescheduling modes, but this is not the case. Unilateral actions are usually undertaken by the creditor in situations where it is difficult, if not impossible, to gain consent of the debtor, and where the debtor's situation is virtually hopeless and it is necessary to undertake measures that would ease its position, even without consent. This on a few occasions has been the case with the least developed countries (LDCs), where their inability to service loans has been endemic and the only way forward was to write off part of the loan, or arrears, or sometimes both. Even if a new credit follows unilateral action of the creditor, these two consequent contracts should be regarded separately. Debt rescheduling is just one of the modalities of debt restructuring (reprogramming). Rescheduling entails the changes in terms for repayment of the principal and/or interest of the signed contract, or deferment of some or all payments until some mutually agreed future date. In the case of deferment, one can focus on flow rescheduling or stock rescheduling. If debt rescheduling is entertained, the debtor may find it a temporary relief, but if the structural problems are not addressed, the eventual capitalization of interest and future possible successive rescheduling agreements may prove far too costly to be done in the future. Rescheduling of debt in a narrow sense of the term means changing the conditions of the contract and not really addressing the underlying problems of inability to meet payments either on time or in general.

Debt refinancing is another modality of debt rescheduling in a wider sense, and in the case of refinancing, the debtor is getting a new loan that would consolidate all existing debts, and/or will provide full accounting support for the activities. In the case of refinancing the client would look for favorable (lower) interest rates and/or longer maturities. In the case of increased competition in the banking sectors worldwide, it is likely that some new entrants in the market would attempt to penetrate the market with underpricing, and therefore these refinanced credits can prove to be a time bomb. Refinancing options can be either voluntary or involuntary. In the former case the country is short of cash, foreign reserves, etc. and simply cannot meet the payments; while in the latter case the country is just following the market conditions, and if a country can raise the money in the financial markets cheaper, it will be prone to repaying the costly debt and looking for another, cheaper one.

One of the possibilities for rescheduling is the debt buyback. In this case the debtor may purchase its own debt at a discount. The creditor would agree to this transaction, in order to salvage at least some of the costs invested. Most recently Nigeria has repurchased a significant amount of public debt due to the unexpected revenues from oil. The debt buyback model is promoted by the International Development Association (IDA), which targets the world's poorest nations; IDA provides support if requested. IDA has created a special debt reduction facility that gives grant funding either alone or in partnership with some of the players.

Another instrument for debt restructuring is debt conversion and swaps. Swaps offer a possibility of exchanging the loan in foreign currency for a loan in domestic currency and in this way reduces the risks of foreign exchange rates. A number of conversions/swaps can take place: debt-for-equity swaps, debt-for-nature swaps, debt-for-development swaps, debt-for-education, and debt-for-debt swaps. Although debt swaps may be attractive, they may have a series of disadvantages, such as the fiscal impact of prepayment, associated inflationary risk, and high transaction costs in the case of a bespoke service.

Although debt rescheduling is a two-way process, either of the contractual parties may initiate the process. Often the debtor is the one who initiates the change in terms and proposes the amendments to the existing contract. Usually both sides begin with negotiations as to how to change the current contract to reflect the current situation and immediate future (in economic terms) of the debtor. The debtor can also put forward a finalized proposal and ask creditors to adhere to it. In the case of Dominica in 2003, the preemptive restructuring was intended to head off the default on public debt. The government of Dominica had approached all creditors (multilateral, bilateral, private, and so on) and offered the exchange of the bonds that were in default for three new classes of bonds. Because the situation was rather serious, almost three-quarters of all creditors have endorsed the proposal.

In the end, debt restructuring may have several outcomes. Debt rescheduling is usually seen as short-term relief, as is refinancing, while write-off (although a unilateral action) and various swaps are perceived to have contributed to the permanent reduction in debt exposure. Both the London (a group of creditors representing commercial banks) and the Paris Clubs (a group of creditors consisting of national governments, official bilateral creditors) have endorsed the policy of debt restructuring (rescheduling) from the late 1980s, when the problem of high international indebtedness emerged. In a number of instances, without the well-designed model, many countries would have defaulted on their credits, and it would have led to a serious systemic shake-up of the international financial system. Debt rescheduling (restructuring) is now accepted as a common practice.

Debt (Securities)

Debt, in general can be understood as an amount (of money) owed to a person or organization for financial resources (funds) that have been borrowed. Debt can appear in several ways: In the form of a banking credit, in the form of securities, or in any other form that confirms that an entity (physical or a legal person) owes something to someone (specified either as a bearer or by name).

In terms of size, businesses borrow the most from banks, including the financial systems where financial markets are very propulsive. The reason for that lies in the fact that it is comparatively more difficult to raise finance in financial markets, and that the price of borrowed funds is usually higher than the interest that is under normal circumstances paid to the (commercial) banks. There are a series of securities that can be used for providing debt finance to an enterprise and they are primarily classified based on the term conditions. Companies can issue bills and/or bonds. In the former case one is looking at the term of less than a year, and in the latter case the security will mature in more than a year. There are also many varieties of these financial instruments, but the basic principles remain largely the same. Debt instruments are associated with a number of risks. Creditors are often able to claim some or all of the assets of the enterprise in the even of noncompliance with the conditions of the loan, which sometimes can result, ultimately, in liquidation. Some of the instruments can have additional conditions attached to them and there may be a requirement to keep certain financial ratios at the preferred level.

Instruments

Debt securities are bonds, commercial papers, treasury bills and treasury notes, certificates of deposit, and mortgage-backed bonds or mortgage bonds. Not all these instruments are equally and readily available. Bonds are long-term contracts in which the bondholder agrees to lend the money to the firm and in turn the firm promises to pay the bondholder interest until the bond matures. Depending on the type of bond, the borrower will pay both principal and interest, or will just pay interest in the predefined intervals, usually semi-annually or annually. The principal that is returned when the bond matures is often called the par, face, or nominal value of the bond. Bonds may be regarded as somewhat more complex "I owe you" (IOU) instruments, which are traded in secondary financial markets. The trading is usually done in an organized manner, through the Exchange and via the authorized broker. Therefore, although bonds have specified maturity, they may be sold in the market and the proceeds received would be immediately available to the bond holder, without waiting for redemption concepts.

Because bonds are fixed income instruments, they are highly dependent on the movements of interest rates. Negotiability of the bond, that is, their marketability in the secondary market, is an important feature for the investors, especially those who cannot easily plan their liquidity needs. A classical form of bond will pay out interest semi-annually and will have a specified redemption date; these bonds are known as straight, vanilla, or bullet bonds. Some bonds can be commodity indexed, or even linked with some events, and depending on the outcome of the event, the condition would come into force.

There are also different levels of security, and debentures are the most secured bonds. Debentures are usually secured by either a fixed or a floating charge against the company's assets. A fixed charge means that specific assets are sued as security which, in the event of default, can be sold at the insistence of debenture bondholder. There are also possibilities to include some trust deeds and covenants (like the limits on further debt issuance, dividend level, limits on the disposal of assets, and keeping financial ratios at a desired level).

Investors also have an opportunity to invest in financial debt instruments that are retailed in the international financial market. The international bond market, as a subset of the international financial market, trades foreign bonds and Eurobonds. Foreign bonds are denominated in the currency of the country where they are issued, when the issuer is a nonresident. Eurobonds are those bonds that are sold outside the jurisdiction of the country of the currency in which the bond is denominated.

A security that enables short-term financing is a bill of exchange. The bill of exchange is a document that sets out a commitment to pay a sum of money at a specified point in time. Historically, bills of exchange have been used to finance international trade and as such have played an important role in providing short-term liquidity to the system.

Use

When it comes to analyzing financing of debt by securities, one must take into account the term for which the debt finance is requested. If the case is with long-term finance, one opts primarily for bonds, especially debentures (fixed-charge, floating-charge debenture, zero-coupons). There are also floating-rate notes (FRNs), which are used as both long-term and medium-term instruments. Medium-term notes (MTNs) are a promise to pay a certain sum on a named date in the future. Short-term debt finance can be based on the commercial paper, mentioned bill of exchange, acceptance of credit (bank bills), or revolving underwriting facility (RUF). In either case, a borrower will issue a security of some kind or a written document. Sometimes there are limitations imposed on trading in some instruments, but not all securities are to be traded in the financial markets. In fact, some trading gives better results if a usual national blueprint is followed. In deciding how to finance its needs, a company follows the pecking order, where raising money through the issue of securities comes only after financing with retained profit and bank credit becomes the form that can be endorsed.

Debt security is a financial instrument representing the borrower's obligation to the lender from whom he/she has received funds. In this particular contract the contracting parties will agree on terms of repayment (most notably, the maturity) and lender's remuneration, expressed usually as interest. Interest is in fact a price of using other people's money. The obligation to pay provides a schedule of financial flows defining the terms of repayment of the funds and lenders' remuneration within the time framework. As already mentioned, the comparative advantage of debt securities to the bank credits is that the former can be traded, even in very limitedly developed financial markets. In trading in the financial markets, it is important to ensure the soundness of the financial instruments traded in them, in order to ensure that stability has not been affected adversely. To have a debt security work without much trouble, it is necessary to stipulate in the contract the nominal or face value, issue price, redemption, issue date, interest rate, and periodic coupon repayment.

Redemption may have interesting variations, as the particular contract may stipulate a deferred redemption period. In this case the issuer enjoys a grace period and may focus on the activities that will secure the market position of the company, rather than wasting talent on routine operations. As the securities are (as a rule) traded on the financial market, the market price of securities is important and to a large extent the offer prices are not of much importance for future developments. Trading in the secondary market is very important for proper understanding of costs of capital. Namely, the change in the yield on the secondary market suggests clearly how much the company will have to commit in costs before even considering rising funds and services. Debt securities are generally the second, or even third, option in the pecking order, as they will always be more expensive to arrange and service than drawing financial resources from the retained profit position and securing a bank credit. Often, only after these two options are given careful consideration, a borrower will begin looking at the securities option.

Similarly, the attractiveness of the option and marketability of the instruments have led to the practice of securitization, where immobile assets are bundled together and, based on the future guaranteed or estimated cash flows, one issues securities that are large in size and have some guaranteed income (or at least easily definable future revenues).

The very practice of securitization requires as a precondition a stable financial system, a robust regulatory environment, and a high level of legal, regulatory enforcement.

Decision Making

Decision making is a complex process that can be seen to involve many different stages or events before an actual decision is made. Essentially, decision making is concerned with the processing of generating options and then choosing among them. Decisions in organizations can be divided into various groups, and each decision has various phases. For instance: operational decisions, usually with short-term effects and of a routine nature; tactical decisions, usually with medium-term effects and of a nonroutine nature; strategic decisions, usually with long-term effects concerning the organization's goals.

Moreover, decisions can be classified into various types. Many are routine, with considerable guidance available on how and what to do, given company policy and prior history. These may be considered well structured and they are called programmed in the sense that organizations have a program to deal with them. Other decisions have to be more creative because they are made about phenomena that are new or where there is a limited amount of data or experience to go on. These may be considered ill structured or unique and they are called nonprogrammed.

There is strong evidence among traditional theories of a polarization between unitary and pluralist approaches to decision making. Unitary approaches to decision making posit a general agreement about goals and the best means to achieve them. Pluralist approaches to decision making emphasize conflict and power struggles between individual coalitions in organizations in circumstances in which participants have substantial knowledge and information. The basis of most of the traditional models of decision making is choice. Decision making in this approach can be defined as a response to a situation requiring a choice.

Models

There are various models of decision making with different assumptions about aspects of decision making, such as the preference and goals of participants; the types of conditions with which different styles and processes of decision making are associated; the nature of power and authority implicit in them; expected results and outcomes; and the underlying values, beliefs, and dominant rationale. Under the rational model of decision making, the assumption is made that participants have agreed in advance that making a decision is the right process to follow and that the rules and language of decision making are understood by all. The rational model aims at making optimal decisions on the basis of a careful evaluation of alternative courses of action. The model views the decision-making process as a sequential series of activities leading from an initial recognition of a problem, through the delineation and evaluation of alternative courses of action, and the selection of the preferred alternative to the implementation of action.

The administrative model of decision making is based on the actual behavior of decision makers, proposing that organizational decision making is a product of bounded rationality. This model recognizes the influence of nonrational, emotional, and unconscious elements in human thinking and behavior on suboptimal efforts to reach decisions and the existence of group pressures that limit the appearance of optimizing behaviors as well as the limited availability of perfect information and time and cost considerations attached to information gathering and evaluation. Thus, decision making leads to a satisfying rather than a rational decision, which broadly satisfies the parameters of a problem rather than searching for an ideal or optimal solution.

Incrementalism introduces the notion of mutual adjustment and gradual change, reflecting the troublesome character of decision-making processes arising from the competing interests and values that are brought into play in complex decision-making processes. It proposes that the decision maker does not attempt to roll out all possible alternatives before tackling a problem, but rather places limits on the alternatives to be considered, based on the current state of knowledge, and solves the problem through making small and gradual changes.

The garbage can model of decision making assumes that some organizations display characteristics of organized anarchy, for instance, problematic goals, unclear methods, and fluid participation. Under such conditions, where clear criteria of choice are absent, extraneous matters tend to get lumped into the decision making process, and solutions often bear little relation to problems. According to this model, the factors that influence decision making in organizations are the range of issues-cum-solutions-cum-problems that happen to be in the garbage can at a particular time and the total demands upon the decision makers at that time. In this sense, it could be argued that the model is based on circumstantial rationality.

The political model is pluralistic in nature, recognizing the role of various stakeholders as well as of conflict and conflict resolution in the decision-making process. According to this model, organizations are portrayed as consisting of shifting coalitions, and decision making is about reconciling the interests of different stakeholders.

Group Behavior

Many decisions may also be affected by the effectiveness of group behavior. In the case of successful groups, a phenomenon that can lead to the escalation of bad decisions is referred to as *groupthink*, which is defined by Irving Janis as the “deterioration of mental efficiency, reality testing and moral judgment that results from in-group pressures.” The primary condition of groupthink is group cohesion, underwritten by a history of individual and group success. Groupthink has the following symptoms: (a) an illusion of invulnerability, with excessive optimism and risk taking; (b) pressures on individual members to conform and reach consensus, meaning that unpopular ideas may be suppressed; (c) the continuing search for group consensus can result in collective rationalization by members, which leads them to discount warnings and negative information; and (d) an unquestioned belief in the morality of the group that leads members to be convinced of the logical correctness of what they are doing and ignore the ethical or moral consequences of decisions. With groupthink, members’ striving for unanimity—their need for consensus—overrides their motivation to realistically appraise alternative courses of action.

To prevent or reduce the effects of groupthink, managers can encourage each member of the group to evaluate their own and others’ ideas openly and critically; ask influential members to adopt an initial external stance on solutions; discuss plans with disinterested outsiders to obtain reactions; use expert advisers to redesign the decision-making process; assign a devil’s advocate role to one or more group members to challenge ideas; explore alternative scenarios for possible external reactions; use subgroups to develop alternative solutions; and meet to reconsider decisions prior to implementation.

Finally, there have been recent developments that recognize some of the limitations of traditional decision-making literature and have led to a shift away from decisions to other concerns such as action; from choice to that of change in the context of decision

Decision making among close-knit teams can lead to “groupthink”—ways to combat it include designating a member to play a devil’s advocate role, seeking input from outsiders, or creating subgroups to develop alternative solutions.

making or to the interpretation of action. These revisions acknowledge that the concept of a decision is problematic and individuals in organizations are not often faced with clear-cut rational choices. In fact, decision makers often value ambiguity and they can see how events unfold and influence interpretations of them so that they can look good and avoid blame.

Dell

An international computer manufacturing and sales company of the United States, Dell, Inc., was founded by Michael Dell (1965–) in 1984. With capital of $1,000, Dell set up PC's Limited while a student at the University of Texas, Austin. He left the university to work full time in his business enterprise, helped by $300,000 from his family. The "Turbo PC" with an Intel 8088-compatible processor with a speed of 8 MHz was the first computer manufactured by the company in 1985. It netted about $73 million in the same year.

After four years PC's Limited founded the first on-site service program. It began outside the United States with a branch in Great Britain, followed by 11 outlets throughout the world. With a new name, Dell Computer Corporation, from 1988, the company's market capitalization increased from $30 million to $80 million with an initial public offering (IPO) of 3.5 million shares. Selling directly to consumers was one of the reasons for the phenomenal growth of the company. By 1992 it became one of the world's 500 largest companies named by the *Fortune* magazine.

After four years, Dell adopted the innovative method of selling computers from its Web site. The strategy of adopting online commerce resulted in market valuation of Dell growing at an incredible rate of 7,600 percent. The introduction of dell.com was advantageous for both consumers and the company and reduced the cost of taking orders by telephone. The inventory turnover of the company also became much faster.

By the end of the 20th century, Dell Computer Corporation had become number one in sales of personal computers, and its revenue was $25 billion in January 2000. The company expanded from personal computers into multimedia and printers. It changed its name to Dell, Inc., by which it is known today. Apart from its headquarters at Round Rock, Texas, Dell, Inc., set up an assembly plant in Winston-Salem, North Carolina, in 2004. In February 2005, *Fortune* magazine placed Dell first among its "Most Admired Companies."

Not everything went smoothly for Dell. It incurred losses of $300 million because of defective capacitors for Optiplex GX270 and GX280 motherboards. Its first forays into using the Linux operating system as an alternative to the dominant Microsoft Windows stalled. A second attempt in 2007 resulted in selling computers with pre-installed Ubuntu Linux 7.04 in France, Germany, and Great Britain only. Dell was also losing to its competitor Hewlett-Packard by the end of 2006; the latter's market share was 17.4 percent in comparison to Dell's 13.9 percent. Its sales and net income went down 5 percent and 33 percent, respectively, by March 2007 versus the previous year. Dell also faced innumerable lawsuits over alleged claims in advertising, exaggerated financial reports, backdating, and delayed service to consumers.

Despite its problems, Dell has become a pioneer of the information technology industry in recycling programs. It has also strived to reduce carbon emissions and to manufacture the "greenest personal computer." The company has also not lagged in philanthropic activities. The University of Texas, Austin received a grant from the Michael and Susan Dell Foundation of $50 million for a pediatric research institute, computer science building, and a center for healthy childhood development.

The international operations of Dell have made it a truly global concern. Apart from centers in Europe, it has assembly plants, production units, and customer contact centers in Asian countries including China, Japan, India, Malaysia, Singapore, and the Philippines. However, recession in the United States, decline of the American dollar, and increasing strength of local currencies have decreased profits in early 2008, impacting Dell call centers in India to an extent.

With a net worth of $15.8 billion, Michael Dell became the 30th richest person in the world in 2007 as estimated by *Forbes*. In the age of fierce competition in the computer market, Dell has not fared badly. Its growth has been the result of an innovative marketing strategy, avoidance of overproduction, and willingness to provide service to customers around the clock.

Deming Model

A method for ensuring that quality is incorporated into every stage of every task carried out by an organization is known as the Deming Model or Deming Cycle. The model is named for Dr. William Edwards Deming (1900–93), who is widely credited with exerting a lasting influence on the study of quality. Deming's model is a feedback loop with four parts: (1) Plan: identify customer needs and expectations, set strategic objectives; (2) Do: implement and operate processes; (3) Check: collect business results, monitor and measure the processes, review and analyze; and (4) Act: continually improve process performance.

Deming argued that managers must continuously improve their production and service processes. He believed that improvement was not just a one-time effort, but that managers are obligated to continuously search for and implement ways to reduce waste and improve quality. Continuous quality improvement is driven by two imperatives: (1) To maintain and increase sales income, companies must continually evolve new product features and new processes to produce these features; and (2) to keep costs competitive, companies must continually reduce the level of product and process deficiencies. Continuous improvement is embodied in a structured approach—the Plan, Do, Check, and Act model (PDCA)—that emphasizes organizational commitment to the systematic, continual improvement of the capability, reliability, and efficiency of business processes.

Deming was one of the leading figures in the quality movement of the 1950s to 1970s. His early work involved the development of statistical quality control (SQC) on production lines. While his work was largely ignored in his home country, in the early 1950s in postwar reconstruction Japan, Deming, and another quality control expert, Joseph Juran, emerged as major influences on the Japanese drive for quality, most notably in the Toyota Production System. In the late 1970s, as American firms found themselves under increasingly fierce competition from Japanese firms producing low-cost, high-quality goods, Deming and Juran were rediscovered by their home country as quality issues became integrated into management thinking and practice. Today, Deming-influenced practices can be seen in firms of every size all around the world, his name forever associated with the concept of total quality management (TQM).

While pursuing his Ph.D. in mathematical physics at Yale University, Deming spent his summers working at the Hawthorne-based telephone assembly plant of Western Electric, a subsidiary of AT&T. During Deming's time at Hawthorne the company was part of a research project, led by two Harvard University investigators, Elton Mayo and Fritz Roethlisberger, focusing on the effects of environmental conditions on productivity. Deming's Hawthorne experience taught him about factory management and the mistakes being made in terms of both machine and human efficiency. While at Hawthorne, Deming came across the pioneering work in statistical quality control being undertaken by Walter Shewhart, then employed in doing research for AT&T. Shewhart developed statistical sampling methods that could identify defects or variations in quality during the production process. In Shewhart's view, the root causes of defects need to be detected as soon as possible, and then those causes should be eliminated.

During the 1980s Deming was for a time the best-known management guru in the world. To Deming, quality was more than just a set of techniques for quality control and standardization. Quality had to become a mindset, embraced by the entire company. His book *Out of the Crisis* (1986) describes how a quality system can be introduced, while his last work, *The New Economics for Industry, Government, Education* (1993), urges the importance of quality thinking for national competitiveness and prosperity.

Deming believed that the primary responsibility for quality lay with management; he was opposed to the misconception that poor quality was due solely to low skills and/or poor performance by workers. From Shewhart, Deming adopted the PDCA cycle in which actions and events are constantly monitored and defects or problems noticed quickly and eradicated. This became famous in Japan as the Deming cycle or Deming model.

Revisionists think that Japan (as well as Shewhart) had a profound influence on Deming's thinking, rather than the reverse. Statistical quality control was already known in Japan and several organizations were actively involved in its development and implementation. Japanese ideas on total quality management influenced Deming's later thinking. Other revisionists credit Joseph Juran with even greater influence in Japan than Deming. Working independently, Juran argued that to achieve quality, management needs to move away from statistical targets and toward a culture of continuous improvement, backed up by training and motivation. Another quality guru, Philip Crosby, an engineer with ITT for many years, developed his own 14 points, which likewise include training, motivation, and the commitment by top management to improving quality, focusing on zero defects to avoid repairs, replacement of defective products, and lost customers.

Democratic Globalization

Democratic globalization is the idea that all humans share a common interest and should have a common say in the future development of humanity. Its supporters counterpose democratic globalization to existing globalization, which they claim reflects the interests of state, corporate, and financial elites. These groups control policy in existing global institutions and the world's 200 or so states. Instead, supporters of democratic globalization insist on globalization "from below" rather than "from above."

Few human communities in history have ever grown up in isolation from one another. In this sense globalization is not new. But the paradox of capitalism's political economy is that as it has developed in the last five centuries the world has been brought closer together in some ways but become more divided in others. The end of the Cold War in 1989–91 seemed to suggest that this had changed. Market capitalism had triumphed. The next years saw a huge wave of globalization talk and claims of a qualitative shift in global relations. Critics saw the euphoria of this "globo-babble" as the equivalent in ideas of the "irrational exuberance" that seemed to characterize markets at this time. It served to allow corporate and financial interests to try to remold the economy more in their favor.

"Free Market Fundamentalism"

Free market and neoliberal economists argue that markets are welfare enhancing and work best when they are free. They deny that there are serious trade-offs or choices and argue that if some gain more this is of little consequence. Everyone can hope to gain something through the trickle-down effects of the integration of global markets. These ideas were embodied in the politics of the Washington Consensus and the policies of the U.S. government abroad, the International Monetary Fund (IMF), the World Bank and, from 1995, the World Trade Organization (WTO). "Free market fundamentalism," as its critics call it, has been invested with a moral character, part of the struggle between good and evil. These ideas are propagandized, advised, and even imposed on many parts of the world as part of the conditionality of Western aid.

Such ideas always had their critics but it was not until November 1999 when a meeting of the WTO in Seattle met with huge protests that this opposition found its real voice. Described variously as the anti-globalization movement, the alter-globalization movement, or the anti-capitalist movement, it developed into an alliance of groups with varied (and sometimes competing) perspectives. They shared a common skepticism about the claims made for globalization and the trustworthiness of the forces behind it. This informal alliance is often chaotic. Nevertheless it has sustained campaigns around the globe and regular meetings of a World Social Forum, initially at Porte Allegre in Brazil but later at changing locations. The movement also began to develop into an anti-war movement opposing U.S.-led intervention in Afghanistan and Iraq and threats elsewhere.

This movement for democratic globalization was immediately attacked as naïve, utopian, and even irresponsible. But it was able to mobilize considerable pressure and arguments in its favor. It was helped by internal critiques of earlier globalization talk and not least by the work of the leading economist Joseph Stiglitz. It also found support from the International Labour Organization's World Commission on the Social Dimensions of Globalization (2001–04), which concluded that "seen through the eyes of the vast majority of women and men, globalization has not met their simple and legitimate aspirations for decent jobs and a better future for their children."

Supporters of democratic globalization challenge the way in which existing globalization is shaped by the interests of powerful states (the United States, United Kingdom, European Union, Japan) and the major multinational corporate interests. Some even suggest these interests now form the basis of an unaccountable transnational ruling class. They argue that there can be no truly democratic globalization without there being a local democratic base. This democracy must extend to the democratic control of the economic and social structures of the world. Even where formal democracy exists there is a large democratic deficit, and at the global level there are no structures that allow the proper relationship to the interest of the mass of humanity.

Institutions

Current global governance reflects the interests of powerful states. The United States plays a decisive role followed by the other members of the G8 (Canada, France, Germany, Italy, Japan, Russia, and the United Kingdom [UK]). The United Nations (UN) is dominated by its five veto-holding permanent members (the United States, UK, France, Russia, and China). Leadership of the IMF and the World Bank is shared by Europe and the United States, but with the United States having a de facto veto. The WTO is formally more equal at the level of state participation but actually operates on a two-tier system of the same powerful insider states and supplicants outside.

These and similar institutions are characterized by a lack of transparency and accountability. Key decisions, especially in trade and finance, are even negotiated by ministers with limited input from their government colleagues, let alone their parties and their electorates. This is sometimes justified as putting control into the hands of experts and so "depoliticizing decision making." What it actually does is enable global policy making to be subject to the influence (if not be determined by) big companies and their lobbyists who have direct access to the decision-making process. This accounts for the narrow and self-interested priorities of existing globalization, which conflict with the interests and priorities of those on the outside. The global arena remains a lawless one. There is no legality independent of the interests of the powerful. Such "global law" as exists tends to codify the interests of the strong, since they determine and enforce it. Its use is highly politicized and it is used effectively when it is in the interests of the powerful states and their clients.

Arguments

Supporters of democratic globalization challenge this global democratic deficit. At the level of theory, the more radical supporters of democratic globalization question the role of markets themselves. Less radical supporters accept a role for markets but argue that market failure is endemic because, as Stiglitz puts it, markets are always incomplete and information always imperfect. Far from being competitive, the global economy can only be understood through an analysis of the imperfect competition of global corporations and financial institutions which have the power to ignore externalities and exploit informational and other asymmetries.

Contrary to textbook simplicities, comparative advantage does not always produce a win-win situation. Resources do not flow easily from the rich to the poor but often in the opposition direction. Knowledge is not treated as a public good but protected by patents whose reach is being extended by corporate campaigns for trade-related intellectual property rights (TRIPS). Knowledge is also being trapped by attempts at "corporate bio-piracy" through the patenting of naturally occurring forms, including the processes of the human body. Powerful states, too, that advise deregulation and state minimization for others regularly protect their own through regulation, subsidy, and protection.

Controversy also exists over the claimed successes of globalization. At the level of individuals there is no dispute that deregulation has allowed a growing concentration of personal wealth in the hands of global elite as wealth and income inequality has increased. At the turn of the new century it was estimated that the 225 largest personal fortunes were equivalent to the income of nearly half the world's population. The top 15 fortunes equalled the income of the whole of sub-Saharan Africa. If absolute global poverty has decreased, and this is contested, it is because tens of millions now survive just above the $1-a-day poverty marker than below it. No less, "the great divergence" between the worlds's richest and poorest countries is continuing to grow. Whereas in 1960 the top 20 percent of the world's population had an income 30 times the poorest 20 percent, by 2000 their income was 80 times that of the poorest.

But not all countries have remained poor. In recent decades rapid progress has been made in East Asia, including more recently China. The problem is knowing whether this is explained by these states following the prescriptions of the neoliberal globalizers or ignoring and violating them as their critics argue. This dispute becomes especially sharp at times of crisis when supporters of democratic globalization argue that global institutions use their power to enforce neoliberal measures as part of a "shock doctrine" that risks undermining economic and political gains in the world at large.

The use of "shock" to enforce "economic globalization" over democratic globalization is seen as an expression of the way in which the "invisible hand" of the market often depends on a very visible fist of power. War and intervention have always been a part of globalization from above. In the 19th century when gunboat diplomacy was used to open markets, it was commonly supported by a moral rhetoric. "Barbarians" were thought to fail to appreciate the benign nature of Western power (even as that power was being used to enforce the payment of odious debt or to force the opium trade to the Far East).

Latter-day Western states have proven equally adept at supporting, even bankrolling, undemocratic states when it is in their interests. When it is not, they use the rhetoric of "humanitarian imperialism" to justify overthrowing those who are now seen to stand in their way. Globalization from above and imperialism are therefore two sides of the same coin. This is even reflected in the "revolving door" effect as individuals move from one job to another. Robert McNamara (1916–), for example, rose from being the first non-family president of the Ford motor company to prosecuting the Vietnam War as U.S. secretary of defense (1961–68) to becoming president of the World Bank

(1968–81). A generation on, the career of the neoconservative Paul Wolfowitz (1943–) took him through various positions in the U.S. defense establishment including deputy secretary of defense (2001–05) (in which role he advocated the invasion of Iraq and then oversaw the first years of its occupation) to president of the World Bank (2005–07) until he was forced to resign amid accusations of abuse of his position.

Many supporters of democratic globalization argue that the 2003 invasion of Iraq and its subsequent bloody occupation seemed as much about oil and the seizure of Iraqi assets under the guise of liberal deregulation as it was about rescuing the Iraqi people. The reduction, for example, of odious debt accumulated by Saddam Hussein was made conditional on the opening of the Iraqi economy and making its resources available to Western multinationals.

Achievements

The potential breadth of the movement for democratic globalization can be seen in a number of its achievements. One strand is built on single-issue politics and has often proven creative in mobilizing youth through its association with youth culture and music. The 1980s popular campaigns against debt and South African apartheid can be seen as forerunners of later developments. Nongovernmental organizations (NGOs) successfully led a campaign against land mines in 1997 against the opposition not least of the U.S. government. As the 1990s neared their end, Jubilee 2000, drawing on the churches, mobilized a huge campaign for debt relief of the poor countries, which chimed with a new wave of youth campaigns, concerts, and the like.

Seattle then saw the birth of a more openly political and broader movement for democratic globalization. It became difficult for international organizations that had previously met in comfort to come together save in heavily guarded and remote locations for fear of provoking major demonstrations, countermeetings, and festivals of resistance. As opposition to the war in Iraq mounted, an estimated 35 million demonstrated globally in January–April 2003, including some 20 million on February 15. These are the biggest demonstrations ever held and led the *New York Times* to talk of a new "world second superpower."

Three political tendencies have played a major role here. One has been the French-based organization ATTAC—the Association for the Taxation of Financial Transactions to Aid Citizens. This was founded in 1998 with a focus initially on campaigning against global financial speculation, but its interests soon widened to pressuring nation states toward reform. A second strand is a more radical socialist one looking for more fundamental change. A third is the autonomist strand that contests traditional concepts of political power.

Strategy and Tactics

There are four overlapping areas of debate about strategy and tactics. One is whether we can imagine a world in theory, and achieve it in practice, where those who hold power will relinquish their domination in favor of more democratic decision making and whether this democratization is compatible with capitalism or needs systematic change from it. Those who suggest that it is compatible point to the fact that two centuries ago national democracy seemed a dream and was frequently said to threaten the survival of capitalism. Yet it developed in many countries and some now argue that capitalism and democracy can be mutually supportive. Advocates of the need for systemic change argue that earlier democratic advance still involved major upheavals and even then it produced an attenuated democracy. Economic power remains protected from democratic control. It is just this economic power that needs to be challenged to achieve democratic globalization.

The second debate is over organization. But in part because of the negative experiences associated with supposedly left-wing dictatorships, some sections of the movement are deeply suspicious of the dangers of overorganization and thought control. Others insist that a degree of centralization and movement democracy is both possible and necessary if the campaign for democratic globalization is to be a success. Spontaneous organization is limited, especially when your opponent is well organized as is existing globalization with its formal state-based meetings, summits, and forums and its informal but real structures of power.

The third area of debate is over alliances within and outside the movement. The role of NGOs is a special problem. Some see them as the basis for a new global civil society. But while the movement for democratic globalization could not exist without them, they are nevertheless often seduced (or forced) to work with the existing system rather than challenge it. Some see the dangers of this reflected in the career of Bernard Kouchner (1939–), who courageously cofounded and led the medical humanitarian NGO Médecins sans Frontières (Doctors without Borders) only to become a supporter of "humanitarian intervention" and a French government minister, UN High Representative in Kosovo (1999–2001), and French foreign minister. No less a cause of debate is how far alliances would be made with establishment politicians and political forces. The self-appointed rock and film stars who meet presidents one day and popes the next, while pausing to announce the success of a major initiative to a group of reporters on the way, also have a contradictory effect. They bring enormous publicity but also disorientation and confusion and misplaced optimism about where power lies and who is an ally and who is not.

The fourth area of debate is over priorities. The roots of the movement for democratic globalization lie in concerns over economic and social injustices, poverty, unfair trade practices, sweatshops, debt, and so on. Necessarily, though, concern reaches out to other issues like the environment, climate change, and war. Should the movement for democratic globalization embrace all of these or is there some virtue in separating them and emphasizing a narrower rather than a broader agenda? Western interventionism in the new century has provoked tensions as some argued that the movement for democratic globalization had also to be a movement against war while others criticized the danger of having too broad a set of goals. While the strength of antiwar sentiment and criticism of U.S. policy worked in favor of the first view, these tensions were evident within different groups' countries and between them.

Democratic globalization remains therefore an idea and a movement in motion and development. To its critics it is an unwelcome diversion. To its supporters it is the basis of a new and better world that needs to be built.

Demonstration Effect

The meaning of demonstration effect (DE) depends on the context in which it is used. Regardless of the context, DE entails some form of imitative behavior. This entry focuses on DE as widely used in the consumption, international trade/investment, and international tourism literature.

With globalization and improvements in transportation and communications, the movement of people, businesses, or products across international borders has intensified. As a result, societies are more likely to be exposed to other societies' lifestyles and consumption habits (e.g., food, transportation, dress, and entertainment). The perception that the new lifestyles are superior may incite their imitation, which may be more expensive. For example, a multinational corporation with headquarters in a more developed country (MDC) may set up production or sales facilities in a less developed country (LDC) and advertise extensively to promote the consumption of its new and more expensive products in the LDC. Also, the arrival of foreign tourists from more affluent countries may expose the populations of the host countries to the tourists' lifestyles, which may be deemed superior, albeit more expensive. The worldwide proliferation of the internet has also facilitated the accessibility of information pertaining to the superior standards of living enjoyed by other societies, triggering imitation of such living standards.

DE entails the transfer of new and more expensive consumption habits and lifestyles/tastes to other societies. Two aspects of DE are noteworthy. First, DE may affect different countries differently depending on information and transportation costs, sociocultural factors, and effectiveness of advertising or communication networks, among others. Second, since the adoption of expensive tastes is of greater concern to LDCs, whose resources are more limited, DE is widely used in the development literature to mean the adoption of expensive Western standards of living by LDCs. Examples of DE in LDCs include the substitution of expensive infant formula for breast milk and the substitution of cheaper staple foods by more expensive imported foods. Contributory factors to DE include tourism, foreign trade, and the operations of multinational corporations.

The DE concept appeared in the trade literature in the 1940s and 1950s when Milton Friedman and Franco Modigliani, winners of the 1976 and 1985 Nobel Prize in Economics, respectively, and James Duesenberry promoted the idea of "interdependent consumption functions" for which the consumption of one individual/group might influence that of another individual/group. In that literature, DE is labeled the "relative income hypothesis." Economist Ragnar Nurske popularized the concept in the economic development literature by arguing that the exposure of the LDC populations to information pertaining to the (higher) consumption standards in MDCs incites imitation of these habits with negative impacts on savings and, hence, economic growth in LDCs. In light of this argument, some have ascribed the underdevelopment of LDCs to DE.

How does DE impact economic growth in LDCs? The literature on this issue is convoluted, rendering it difficult to generalize the impact. This difficulty arises because the impact could be positive or negative. For example, as noted above, DE impacts economic growth negatively by reducing savings incentives. However, DE may cause an increase in work incentives to support the expensive lifestyles, with positive effects on growth. Also, DE may have adverse effects on the balance of payments, a statistical summary of the transactions between a country's residents and its nonresidents during a given period, if the new products are imported from abroad. However, the balance of payments problem may rectify itself over time if local firms imitate investments in the production of the imported goods, thereby reducing the need to import. Thus, the net impact of DE on a particular country depends on the extent to which the positive and negative impacts do cancel out.

As noted above, DE is also used in other contexts. For example, in politics and sociology, DE describes situations in which successful protests/revolutions by political or social activist groups in one place led to their imitation by similar groups in other places. In economics, DE is also used to explain the motives for intergenerational income/wealth transfers. For example, economists Donald Cox and Oded Stark use the concept to convey the ideas that when parents transfer income/wealth to their own parents, they are motivated by the desire that their own children will imitate this behavior in future.

Denmark

This northern European country has a population of around 5.5 million (2007), and has a land border with Germany, but has always had close contact with Sweden. Historically, Denmark was one of the major powers in Scandinavia, where it controlled, at times, modern-day Norway (until 1814, then ruled by Sweden until 1905) and Iceland (until 1944). It still controls the Faeroe Islands and Greenland making it, technically, the second largest country in Europe.

In the Middle Ages, Denmark was the center of a large trading network. Copenhagen, on the island of Jutland, emerged as a major port, and there was a great concentration of traders and wealth. As a result, with the start of European colonial expansion to Africa and the Americas, Danes started taking part in the slave trade, establishing forts in West Africa, in modern-day Ghana, and also taking over three Caribbean islands, which became known as the Danish West Indies (modern-day U.S. Virgin Islands). There was also extensive trade with India, and the Danish East India Company was founded in 1614 (dissolved in 1729). Denmark was to lose its possessions in West Africa with the rise of British maritime power, but held onto the Danish West Indies—major producers of sugar—until 1917, when it sold the islands—St. Thomas, St. Croix, and St. John—to the United States for $25 million.

Denmark has become a leader in wind power technology. The photo shows a turbine in Copenhagen.

Denmark remained neutral in the Crimean War and in World War I, emerging as a major producer and exporter of dairy products, biscuits, chocolates, and fish products. Its neutral status in most European conflicts allowed it to establish contacts with some countries anxious not to get entangled in European politics, with Danes training the Siamese (Thai) police force. The East Asiatic Company, founded in 1897, also developed into becoming agents for many European products in east Asia and southeast Asia, taking its lead from the business Andersen & Co., which had been operating in Bangkok, Siam (Thailand) from 1884.

The Nazi Occupation of Denmark from 1940 until 1945 left the economy of the country badly damaged, although because there was little fighting in Denmark, the infrastructure was not damaged as much as in most other European countries. With high rates of literacy in Denmark, the country emerged from the war as a small but significant economic power, but one which was fiercely independent. Denmark joined the European Economic Community, the precursor to the European Union (EU), in 1973, and in a referendum held in September 2000 rejected a closer monetary union. In spite of this, and occasional opinion polls published showing dislike of some EU policies, the Danish governments have committed themselves to remaining in the EU, especially since its expansion into the Baltic.

Some 76 percent of the workforce are in the services sector, and produce 74 percent of the country's gross domestic product (GDP), with 21 percent working in industry contributing 24 percent to the nation's GDP. Only 3 percent work in agriculture, and in spite of the continued reputation of Danish dairy products and bacon, this provides only 2 percent of Denmark's GDP. In terms of its balance of payments, Denmark generally runs a surplus, with exports being mainly machinery and instruments, meat, meat products, dairy products, fish, chemicals, furniture, and ships and shipping equipment. In addition, Denmark has harnessed wind power and exports wind technology, including windmills. Lego has been a major Danish export, as have been other toys and playground equipment. Major imports include machinery, raw materials, and semi-manufactures for Denmark's industry, chemicals, grain and foodstuffs, and consumer products. Some 17 percent of exports go to Germany, which makes up 23 percent of its imports. Sweden also contributes much to bilateral trade, with many exports to the United Kingdom, and imports from the Netherlands.

Department of Commerce

The purpose of the U.S. Department of Commerce is "to foster, promote, and develop the foreign and domestic commerce" of the United States to ensure that "the United States continues to play a lead role in the world economy." The current mission statement of the Department of Commerce states that it "creates the conditions for economic growth and opportunity by promoting innovation, entrepreneurship, competitiveness, and stewardship." The Department of Commerce seeks to promote job creation and improve living standards for all Americans.

The Department of Commerce and Labor (32 Stat, 826; 5 U.S.C. 591) was created by the U.S. Congress on February 14, 1903. On March 4, 1913, President William Howard Taft authorized renaming it the U.S. Department on Commerce following the creation of the U.S. Department of Labor (37 Stat. 737; 5 U.S.C. 616). The Department of Commerce is headquartered in Washington, D.C., and normally employs over 35,000 persons. Temporary staffing during the Decennial Census increases the number of employees to over 500,000 persons.

The Office of the Secretary of the Department provides general management for its operating units, supports the formulation of policy, and provides advice to the president of the United States. The Departmental Management (DM) supports the Office of the Secretary, and develops and implements policy for the Department of Commerce affecting U.S. and international activities.

Operationally, the Department of Commerce is composed of 12 bureaus or administrations: the Bureau of Industry and Security (BIS), the Economics and Statistics Administration (ESA) with its Bureau of the Census (Census) and its Bureau of Economic Analysis (BEA), the Economic Development Administration (EDA), the International Trade Administration (ITA), the Minority Business Development Agency (MBDA), the National Institute of Standards and Technology (NIST), the National Oceanic & Atmospheric Administration (NOAA), the National Technical Information Service (NTIS), the National Telecommunications and Information Administration (NTIA), and the Patent and Trademark Office (USPTO).

The Bureau of Industry and Security (BIS) enforces effective export control and treaty compliance and promotes strategic technology leadership. The Economics and Statistics Administration (ESA) provides economic research and policy analysis in support of the secretary of commerce and the president.

The Bureau of the Census maintains the U.S. Census, which serves as an important source of economic and demographic data about and for the American people in support of effective decision making by policy makers, businesses, and individuals. The Bureau of Economic Analysis (BEA) also produces timely, relevant, and accurate economic statistics that are used by policy makers, business leaders, households, and individuals for financial decision making.

The Economic Development Administration (EDA) promotes favorable business environments across the country through its Economic Development Assistance Program, which enhances economic capacity by planning and building infrastructure investments and making grants to regions, states, and communities. The International Trade Administration (ITA) supports the development, negotiation, promotion, and implementation trade laws and agreements and also ensures compliance with them and the enforcement of them. The Minority Business Development Agency (MBDA) promotes the ability of minority-owned businesses to grow and participate in the global economy through a network of centers that provide business assistance services.

The National Institute of Standards and Technology (NIST) develops, promotes, and disseminates measurement science to create standards and technology needed by industry to compete successfully through quality enhancement and by innovation.

The National Oceanic & Atmospheric Administration (NOAA) maintains and improves coastal and ocean resources, supports sound environmental practices in commercial navigation, studies climate variability and change, and provides weather information. The National Technical Information Service (NTIS) collects, preserves, and disseminates scientific, technical, engineering, and business-related information for the industrial research community and American business.

The National Telecommunications and Information Administration (NTIA) develops telecommunications and information policy for the executive branch and ensures the effective and efficient use of the federal radio spectrum. The Patent and Trademark Office (USPTO) administers U.S. patent and trademark laws and provides technical advice and information on intellectual property to other executive branch agencies.

The fiscal year 2009 budget request for the Department of Commerce was for $8.18 billion in discretionary funds. This appropriation, less one percent for its administration, is designed to serve three strategic goals. The first strategic goal is to maximize U.S. competitiveness and enable growth. The bureaus charged to support strategic goal one are the ITA, the EDA, the ESA, the BEA, the Census, the BIS, and the MBDA. The second strategic goal is to promote innovation and industrial competitiveness in the United States. The bureaus charged to support strategic goal two are the NIST, the NTIS, the USPTO, and the NTIA. The third strategic goal is to promote stewardship of the environment, and the bureau charged to support it is the NOAA.

The Department of Commerce has a "Management Integration Goal" which is about achieving organizational and managerial excellence by effectively implementing a performance-based budget process. This goal is the responsibility of the Departmental Management and the Office of the Inspector General.

Dependency Theory

Defined as an explanation of the economic development of a state in terms of the external influences—political, economic, and social—on national development policies, dependency theory argues that history shapes economic structure, favoring some countries to the detriment of others and limiting their development possibilities. Dependency theory sees the world economy as comprising of two sets of states, those that are dominant and those that are dependent. The dominant states are the advanced industrial nations in the Organization of Economic Co-operation and Development (OECD). The dependent states are those states of Latin America, Asia, and Africa that have low per capita gross national products (GNPs) and which rely heavily on the export of a single commodity.

Most dependency theorists regard international capitalism as the motive force behind dependency relationships, which are caused by a rigid international division of labor that is responsible for the underdevelopment of many areas of the world. The dependent states supply natural resources, in which they might be said to have an absolute advantage, and cheap labor, but depend on the industrialized nations for manufactured goods. Foreign direct investment flows into the dependent states, but the allocation of investment is determined by the economic interests and efficiency requirements of the dominant states, and not by the economic interests of the dependent state.

Theories

While not all dependency theorists are Marxists, many have been, including Paul Baran, whose critically acclaimed book, *The Political Economy of Growth*, is regarded as a pioneering study of the problems of underdevelopment. Writing in the mid-1950s, Baran tried to relate underdevelopment in the Third World to the global operations of capitalism. He held monopoly capitalism responsible for underutilization of human and material resources, inefficient organization of the productive facilities, and an insufficiency of effective demand. To overcome these weaknesses, Baran advocated a form of centralized planning. Following Baran was Andre Gunder Frank, who wrote extensively on underdevelopment from the mid-1960s to the mid-1970s. A recurrent theme in his works concerns commercial monopoly as the particular economic form with which metropolitan countries have exploited their satellites.

A new theory of dependency was introduced by Theotônio Dos Santos in the 1970s. This new theory of dependency understands industrial development to be dependent on exports, tied to the traditional sectors of an economy that are controlled by the landed bourgeoisie. Exports generate foreign currency with which that bourgeoisie buys imported capital goods. Despite the efforts of the dependent countries to impose policies of exchange restrictions and taxes on foreign exports and to lean toward the nationalization of production, industrial development is conditioned by fluctuations in the balance of payments, which in dependent countries often lead to deficits caused by trading in a highly monopolized international market, the repatriation of foreign profits, and the need to rely on foreign capital aid, leading to deepening dependency that cannot be altered without a change in internal structure and external relations.

Latin American dependency theory and its African and other Third World variants were introduced in the late 1960s and early 1970s. Director of the United Nations Economic Commission for Latin America (ECLA) Raul Prebisch argued that the international division of labor was outdated, imposing on Latin America, as part of the periphery of the world economic system, the role of producing food and raw materials for the great industrial countries. There was no place within this scheme for the industrialization of Latin American countries.

Yet world events—two world wars and a great economic crisis—were forcing industrialization on the Latin American countries, showing them where their opportunities lay. To eliminate dependence, ECLA advocated planning as a means of rationally allocating scarce resources; a program of export diversification and import substitution; accelerated industrialization; use of the state apparatus to bring about institutional reforms; and the formation of regional entities to integrate the economies of the countries in the region. These policy recommendations evolved into what became known as "state capitalism."

Critiques

Dependency theory has had numerous critics. Stephan Haggard argues that dependency theory underestimates the growth potential of underdeveloped nations, as evidenced by the emergence of East Asian economies; that it overestimates the importance of external factors and ignores the fact that many of the most powerful obstacles to development lie in the domestic system and in the histories of individual states and societies; that it places too much emphasis on the role of foreign direct investment, downplaying the importance of the international trading and financial system; and that there is no necessary link between dependence in the international economy and political systems, whether democratic or authoritarian.

Citing the rapid development of some southeast Asian countries, which dependency theory failed to predict or to explain, Ted Lewellen calls the theory's prescriptive solutions, which called socialism or delinking from the capitalist system self-destructive or impractical, and its classification of core and periphery nations, simplistic. This classification has been replaced by a much more complex, multidimensional system of interaction based not on raw material production versus manufacture, but on low-tech manufacture versus high-tech manufacture and factory production versus information processing, combined with attention to international finance, media technology, and local culture. Ngaire Woods notes that in Central America it was not global capitalism and exploitation but Cold War geopolitics and security issues that prompted aspirations of nationalism, independence, and autonomy.

Deregulation

The erosion or abandonment of formal regulations by legislative means is known as deregulation. Formerly regulated industries—transportation, electric utilities, gas utilities, telecommunications, and financial markets—share certain characteristics that made them candidates for regulation, and in transitioning to deregulation they share a common set of problems.

Wherever they have appeared around the world, regulatory systems were not the result of strategic planning, but represented a reaction to financial, economic, and political crises. The airline industry, the steel industry, and every other industry have been subject to direct and indirect regulation. Indirect regulation dealing with the environment, work safety, product quality, truth in advertising, and similar issues affects all firms. The fundamental reasons for regulating the banking industry lie in the key role banks play in the efficient functioning of the economic system and in the conduct of an effective monetary policy, as well as protection for depositors and monetary stability.

In a Brookings Institution study, Martha Derthick and Paul Quirk acknowledge that government regulation had long been rationalized as a way of guaranteeing service to the public by industries having the character of public utilities and as a means of protecting the public from monopoly pricing practices, including the destructive competition that was said to lead to the creation of monopolies. However, the regulatory agencies had instead sheltered the regulated industries from competition and fostered very costly inefficiencies. Long a target of experts in administrative law, public administration, and political science, who found much fault with their structure and procedures, by the 1960s the regulatory commissions had become a target also of economists, who attacked their purposes by undertaking to show that the social costs of regulation far outweigh the benefits.

The notion of government regulation as a profit-seeking enterprise in which self-interested groups and individuals seek to gain competitive advantage and in which the regulator is captured by the regulated is the basic argument of Chicago School economists George Stigler and Sam Peltzman. Deregulation suddenly changes the game of market competition, threatening the long-held advantage of dominant large firms and opening the way for new entrants.

The United States

Deregulation has been the global trend since the late 1970s and early 1980s. In the United States, the energy, airline, trucking, and telephone industries were deregulated in 1978, 1980, and 1982. Under strict federal regulation since 1954, the natural-gas industry began to exhibit shortages in the late 1960s. By the 1970s, producers were unable or unwilling to supply as much gas as customers wanted to buy at the regulated price. In 1978 Congress set a timetable for deregulation of most natural-gas prices. By 1985, when all gas discovered after 1976 was freed from federal price regulations, gas prices began a steep plunge. After that, federal regulators began to transform natural-gas pipelines into "open access" transporters of gas from various producers. Deregulation not only lowered prices for consumers, but also improved the quality of service by removing the threat of artificially created shortages.

Before 1978, both the maximum and minimum fares for air travel were set by the Civil Aeronautics Board (CAB). The CAB began to loosen its regulations in the mid-1970s. In 1978, Congress passed legislation to abolish the CAB within six years, open up the industry to new competitors, and eliminate government-set fares. Under regulation, intercity airline routes were served by one, two, or three carriers, all charging the same fare; after deregulation both the number of carriers and their prices became highly competitive, including such practices as restricted discounts, promotional fares, reduced off-peak fares, and premium services.

Federal regulation of interstate trucking began in 1935. Throughout the 1960s and early 1970s, economic research showed that trucking rates would be far lower in a competitive marketplace. In response to the growing opposition to interstate regulation, Congress passed legislation in 1980 that virtually deregulated the trucking industry. Deregulation meant shipping rates could be negotiated by individual shippers and carriers, with prices and services tailored to the shippers' needs. While big shippers were in the strongest bargaining position, smaller shippers often needed to consolidate shipments to get a good rate.

The collapse of the merged Penn Central rail line in the mid-1970s prompted a major push to deregulate and transform the railroad sector. Congress passed a bill in 1976 that allowed railroads to merge and to abandon unprofitable routes; in 1980, Congress deregulated rates for some commodities. Gradually, rate deregulation extended to about 90 percent of rail traffic. Rail deregulation led to improved service, improving delivery time by 30 percent.

The first movement toward competitive long-distance telephone service came not from Washington policymakers but from the entrepreneurial efforts of Microwave Communications, Inc. (MCI). In 1969 MCI won federal permission to begin competing with the AT&T monopoly to provide "private-line" long-distance to companies, but did not receive the go-ahead to enter the ordinary long-distance market for businesses or residences. MCI clandestinely began to offer standard long-distance to businesses in 1974 without authorization by the Federal Communications Commission (FCC). The FCC tried to stop MCI, but lost in federal court. The FCC did authorize competition in telephone equipment, a move ratified by the courts in 1977.

As the pressure for competition in the long-distance and telephone-equipment industries began to heat up, the federal government challenged AT&T's use of its monopoly on local telephone service to compete unfairly. Its legal actions finally led to a consent decree in 1982 that split "Ma Bell" into seven local telephone companies and a separate long-distance and equipment business that retained the AT&T name. Equipment prices fell by 6 to 7 percent a year between 1972 and 1987. Competition has also improved quality dramatically and led to the introduction of many new devices and services. Deregulation meant telephone users found that they could shop for bargains in long distance service. Whereas American Telephone and Telegraph (AT&T) and the affiliates and "independents" in its network were at one time the sole suppliers of long distance service, competitors now offered service at rates substantially below AT&T's.

While the history of U.S. financial deregulation began in 1973, the period 1982–90 saw the disintegration of the savings and loan insurance fund and a sizable portion of the thrift industry and regulator-sponsored deregulation that provided increased earning opportunities, and risk, for surviving thrifts and commercial banks.

Japan, Russia, and China

By the early 1980s many capitalist governments reduced government interference in the marketplace, prompting increased competition. Japan's telecommunications monopoly, NT&T, was deregulated in 1985, and European deregulation followed in the mid-1990s.

Before the collapse of communism, governments in most command economies exercised tight control over prices and output through state planning, prohibiting private enterprises from operating in most sectors of the economy, severely restricting foreign direct investment, and limiting international trade. Deregulation involved removing price controls, thereby allowing market forces to set prices. Laws regulating the establishment and operation of private enterprises were abolished, and restrictions on foreign direct investment and trade were relaxed or removed.

In Russia deregulation of prices was imposed through a presidential decree of December 3, 1991, "Measures to Liberalize Prices," which solemnly declared that "on January 2, 1992, [the Russian Federation would undertake] the basic transition to free (market) prices and tariffs, formed under the influence of demand and supply" on producer goods, consumer goods, services, and labor. By the end of 1993, only two sectors, energy and agriculture, were regulated. The state monopoly on foreign trade had effectively been abolished in late 1986, when various branch ministries were given the right to pursue foreign trade independently.

Deregulation in China went through two phases. From 1980 until 1993, government began the partial or total deregulation of public sector enterprises, increasing the autonomy of state-owned enterprises under the "contract responsibility system," under which state-owned assets were leased out. By 1987 over 27,000 state-owned enterprises had been leased out.

The second stage in China's deregulation began in 1993 when the Central Committee of the Chinese Communist Party issued the so-called Resolution on Several Issues Concerning the Establishment of a Socialist Market Economy, which established a 50-point agenda for bold economic reform, including placing the assets of 1,000 large state-owned enterprises under the supervision of new asset management companies; transferring control of 100 large and medium-sized state-owned enterprises to shareholding companies, among other reforms. The plan was stalled by the 1997 East Asia financial crisis, but has resumed.

India

In mixed economies, the role of the state was more limited, but in certain sectors the state set prices, owned businesses, limited private enterprise, restricted investment by foreigners and restricted international trade—alongside an active, growing private sector. India is a good example of a mixed economy that is currently deregulating a large portion of its economy. Deregulation in India has involved reforming the industrial licensing system that made it difficult to establish private enterprises, opening areas that were once closed to the private sector, removing limits on foreign ownership of Indian assets, and lowering barriers to international trade.

Like China, India has also followed a sequenced deregulation pattern since the mid-1970s, when the central government proposed a reduction in the number of industries reserved exclusively for the public sector. India's public sector undertakings are the equivalent of state-owned enterprises, often state monopolies in core or strategic industries, which are the sole suppliers of steel, coal, and oil to industry. A significant percentage (over 70 percent) of the total employment in the industrial sector is in these enterprises; other public sector undertakings exist in noncore or nonstrategic areas, such as hotels and tourism.

Major institutional reforms in the public sector were announced in July 1991 with the passage of the New Industrial Policy, which gradually reduced India's extensive industrial licensing regime. The New Industrial Policy also encouraged reforms of public enterprises in order to make them better performers and more competitive. Beginning August 7, 1996, the Ministry of Industry moved quickly and aggressively to select public sector enterprises for disinvestment. India's economic reforms have continued despite an apparent trend in minority governing coalitions at the center.

Latin America

During the 1980s, many developing countries entered upon a process of deregulation in which government controls over market operations, resource allocation, and capital flows were removed or loosened, a consequence of the oil price shock and the ensuing economic crisis, which forced fundamental reorientation of development strategies across countries and thrust the issue of financial reform onto the policy agenda. Coupled with the economic crisis was a cross-national ideological crusade against state interventionism supported by the World Bank, the International Monetary Fund (IMF), and major industrial powers to expand the role of market forces. In Argentina, Chile, and Uruguay, deregulation included steps to privatize state-owned banks, free interest rates, and eliminate restrictions on capital flows. Contrary to what had been expected by proponents of financial liberalization, reform efforts in the Southern Cone ended in chaotic financial markets, massive inflation, and worsening external imbalances, leading to the reversal of the liberalization process.

The disastrous outcomes raised the question about the appropriate economic and institutional conditions under which financial reform strategies should be designed and implemented.

Unlike their Latin American counterparts, however, the East Asian newly industrializing economies (NIEs) took a cautious and gradual line of action, until the second half of 1997, when many of the East Asian NIEs were struck by the worst-ever financial crisis in the postwar economic history of the region.

Indonesia, Korea, and Thailand

Farrukh Iqbal and William James note that until the mid-1980s, Indonesia lagged behind its East Asian neighbors in deregulating or liberalizing trade and investment policy, due in part to reliable primary sector (mostly oil) revenues. During the latter half of the 1980s, Indonesia made substantial reforms in its trade, investment, and financial regimes: Tariffs were cut, nontariff barriers were reduced, a duty-drawback system was introduced for export activities, a complex investment licensing system was replaced by a much simpler and relatively short "negative list," foreign investment regulations were significantly eased, credit ceilings and interest rate controls were abolished, and entry into the banking system was made substantially easier.

Like many of their neighboring economies, Korea and Thailand opted for a gradual pattern of policy responses, particularly in the initial stages of financial reform. Korea adopted a gradual and piecemeal approach to the liberalization of interest rates and credit controls, but gave greater freedom to nonbank financial institutions, such as finance companies, merchant banking corporations, and securities firms, to mobilize savings and develop the financial system.

In Thailand, the authorities placed more emphasis on expanding the role of the banking system in service diversification and financial development. Thailand, which had maintained relatively relaxed controls over its external financial transactions, further deregulated the remaining controls while liberalizing the domestic financial market.

Effects

Sarkis Khoury sees the deregulated international financial environment as having been developed partially by design, but largely as a result of the dynamic market forces that produced more competitive markets all over the world and "leaner and meaner" financial institutions, with consolidation through mergers and acquisitions reducing the number of firms and increasing competition among the larger, remaining institutions. Khoury predicts that competition will only continue to increase as markets become more global and as new, aggressive entities come into the market. The Japanese firms which were once nowhere on the list of prominent financial institutions are now dominant in the world of finance. The Koreans and the Chinese have become major players. European financial institutions have streamlined their operations, and improved their product mix and their resource base in order to better compete more successfully in a united Europe.

While governments have taken a proactive strategy to deregulate their industries and financial markets, to open trade and foreign direct investment in order to stimulate sluggish economies, the permanency of the changes is still in doubt. A severe worldwide economic setback could prove a real test. Again, it must be emphasized that regulation is cyclical and potentially reversible. As Barbara Emadi-Coffin argues in her study of deregulation and governance, while deregulation implies the roll-back of the state, in fact, deregulation and the establishment of free trade zones have necessitated extensive government regulation and subsidy.

A financial crisis in 2008 had its roots in the Gramm-Leach-Bliley Act (1999), a bank deregulation bill, that swept away a Depression-era law known as Glass-Steagall. Gramm-Leach-Bliley tore down the separation of banks doing risky investments from those doing basic lending. In addition, some investment banking houses make risky bets that went awry in 2008. American policy makers and regulators let Wall Street recklessly invest in the context of extremely inflated housing prices (a bubble). Also to blame was the Commodity Futures Modernization Act, which freed the derivatives market and enabled banks to become more aggressive in their mortgage investments.

Deutsche Bahn

The German National Railway Company, Deutsche Bahn AG, was founded on January 1, 1994, taking over from the state railways of Germany, the Deutsche Bundesbahn ("German Federal Railways") in West Germany, and the Deutsche Reichsbahn ("German State Railways") in East Germany. Its origins lie in the establishment of the railway network in Germany that started with a steam locomotive in Bavaria running between Nürnberg and Fürth in 1835 and the first long-distance railroad from Leipzig to Dresden in 1839.

When the German Empire was founded in 1871, there were a number of state railways operating in various parts of the new country. To make this easier to maintain, the Deutscher Staatsbahnwagenverband ("German State Railway Wagon Association," or DSV) was created to standardize the wagons used. German railway expertise was outside Germany, with German engineers working in the Ottoman Empire before World War I, especially on plans to build the Baghdad Railway and the railway to Mecca (which was bombed by T. E. Lawrence). In 1920 standardization of the network continued with the formation of the Deutsche Reichsbahn; in 1924 it became the Deutsche Reichsbahn-Gesselschaft ("German State Railway Company"—DRG), which continued until 1945.

By the end of World War II, the network had been seriously damaged, and Germany had been divided into four zones. Each of the occupying powers established their own network with West Germany, from 1949, forming the Deutsche Bundesbahn, and East Germany retaining the old name, Deutsche Reichsbahn. Technically, the Deutsche Bundesbahn also had access to the railway that went from the West German–East German border to West Berlin, although the line was owned by the East Germans. It was the closing of this line in 1948 that contributed to the Berlin Blockade and the subsequent Berlin Airlift.

With the reunification of Germany on October 3, 1990, there was a need to unify the network that operated with different locomotives and rolling stock, but had the same gauge. This was the reason for the establishment of Deutsche Bahn AG in 1994 as a public limited company, although all the shares were owned by the government of the Federal Republic of Germany that had long planned a privatization of the company. However, before that could be achieved, an extensive administrative railway reform, or *Bahnreform*, took place. Initially this saw the structure changed to that of a private company, and then in 1999, the track, personnel, and assets were divided into five subsidiary organizations.

The Deutsche Bahn Reise & Touristik AG (later renamed the Deutsche Bahn Fernverkehr AG) handles long-distance passenger services, with the Deutsche Bahn Regio AG covering regional passenger services. Deutsche Bahn Cargo AG (now Railion AG) provides freight services, Deutsche Bahn Netz AG runs the railway system, and Deutsche Bahn Station & Service AB controls the stations. Hartmut Mehdom, a German who was born in Warsaw in 1942, has been the chairman since December 16, 1999.

There is much controversy over the plans to privatize the railway network, with the government arguing that it will make the company more efficient and raise fresh capital for an upgrade of the system. However, there are economic and political concerns—

first about Deutsche Bahn maintaining an effective monopoly over rail transport, and politically about worries that a privatized company might reduce its labor force. This led to a strike by rail engineers, the first on the railways since the 1992 nationwide strike. With the company worth an estimated €200 billion, it seems likely that the government might sell the shares in several tranches, initially retaining a 51 percent stake, and then gradually lowering this.

Deutsche Bank

Deutsche Bank was founded in 1870 by Adelbert Delbrück (a private banker) and Ludwig Bamberger (a politician and currency expert). In the beginning it focused on foreign trade and was involved in the development of Germany's electrical, engineering, iron, and steel industries.

Soon after its establishment, a period of rapid expansion followed, with branches opening outside Germany. Shanghai and Yokohama in 1872 were the first branches to be established, followed by the London branch the next year. Deutsche Bank expanded in the United States, too. In the beginning, this was accomplished via partnerships, but in 1979 it established its first branch under its own name in New York. The solid base generated in Germany was a major support for the bank's ability to finance its foreign businesses. Deutsche Bank started buying other major banks as early as 1876. In the 1890s, the bank formed alliances with banks in various locations in Germany, strengthening its presence in various industrial regions of the country.

Continuing domestic investments, Deutsche Bank merged with Disconto-Gesellschaft in 1929, the largest merger in German banking industry. In the 1930s, the bank became a tool of the Nazi state. That period was almost catastrophic for the bank. In 1947 it was divided into 10 smaller banks, which merged in 1957, reestablishing Deutsche Bank. In the 1980s and 1990s, Deutsche Bank managed to build a worldwide network of branches. It was also involved in acquisitions, and at the same time established subsidiaries around the world.

Deutsche Bank continued its worldwide expansion strategy in the new millennium. In 2001 it was listed on the New York Stock Exchange (NYSE). In Europe, it acquired Rued Blass & Cie (2002) and Russian investment bank United Financial Group (2006) in order to support its private banking business. However, it did not neglect domestic investments—it acquired Noris Bank and Berliner Bank. This move strengthened its retail business in Germany, but its investments were not limited to that—there was also expansion into the markets of China, India, and Russia.

Deutsche Bank offers its services not only to corporate and institutional customers, but also to private and business clients. Grouping the services offered, the bank can be divided into two divisions. First, the Corporate and Investment Bank Group Division deals with capital markets. It involves the origination, sales, and trading of capital markets products including debt, equity, and other securities, together with its corporate advisory, corporate lending, and transaction banking businesses. This division is further subdivided into (1) Corporate Banking and Securities, whose main services are the origination, sales, and trading of capital market products, corporate advisory and corporate financing businesses, asset finance and leasing, and commercial real estate; and (2) Global Transaction Banking, whose main services are trade finance, cash management, trust, and security.

On the other hand, the Private Clients and Asset Management Division offers investment management services to both private and institutional clients. It services private individuals and small and medium-sized business with traditional banking activities. It is further subdivided into (1) Asset and Wealth Management, which offers traditional asset management, alternative assets, real estate asset management, and mutual funds to retail clients across the globe as well as wealth management, portfolio management, tax advisory, inheritance planning and philanthropic advisory services; and (2) Private and Business Clients, which offers banking services (loans, current accounts, deposits and payment services, securities and mutual funds, and portfolio investment advisory) to private customers as well as small and medium-sized business clients in Germany and seven other countries across Europe and Asia.

The bank has a presence in 75 nations worldwide through its 1,922 branches, 986 of which are in Germany (as of 2008). More than half of its 80,253 employees work outside Germany. Its mission is to be the leading global provider of financial solutions for demanding clients, creating exceptional value for its shareholders and people. In fulfilling the above, Deutsche Bank's strategy aims at accelerating global growth, maintaining strict cost, risk, and capital discipline. It also aims at taking advantage of synergies across complementary business lines. Future investment options will include not only organic growth, but also acquisitions of other organizations, which will contribute to the successful global presence of the bank.

Deutsche Post

The German postal company that now is also involved in logistics and courier services, Deutsche Post AG was refounded in 1995, taking over from a company of the same name that had a mail monopoly in Germany. Although the word *Reichspost* was used by Franz von Taxis as early as 1495, the German postal service in its current form was the Deutsche Reichspost, which was established in 1871 with the unification of Germany, and operated until the end of World War II.

Initially after the war, the various Allied-controlled postal authorities issued their own postage stamps and ran their own services. Subsequently four entities took over, the major ones being the Deutsche Bundespost (German Federal Post Office) that operated in West Germany and the Deutsche Post DDR in East Germany. Because of its different status, there was also a Deutsche Bundespost Berlin for West Berlin, and a separate postal authority for the Saar until 1956. In 1990 the Deutsche Bundespost took over having a monopoly on postal services until 1995 when it became Deutsche Post AG.

Prior to 1871, the various states in Germany operated their own postal services, with the people in Prussia and nearby places using those of the North German Confederation. King Wilhelm I of Prussia had, on January 18, 1871, been proclaimed emperor of Germany, and he started unifying the various agencies of the German states. The first German Imperial Parliament met in March 1871, and on May 4, 1871, the German Reichspost officially came into being. Wurttemberg was allowed to use its own stamps for a period, with stamps for official state business until 1923; and Bavaria was also allowed to issue its own postage stamps until 1920.

To show the unity of Germany, the first postage stamps issued by the Reichspost in 1872, "inscribed Deutsche Reichspost," had the Imperial Eagle, and ranged in value from ¼ Groschen to 18 Kreuzers. Demand was such that some were reprinted by the Prussian State Printing Office in July 1872. In 1875 the old currency was replaced by the Pfennings and the Marks, and new stamps were issued. From 1900, stamps started showing "Germania," a figure embodying the German spirit. In that year some larger stamps were also issued by the post office, featuring the General Post Office in Berlin, the unveiling of the Kaiser Wilhelm I Memorial in Berlin, and Wilhelm II speaking at the 25th anniversary of the founding of Germany in 1896.

In 1902 the stamps were designated "Deutsches Reich" and this continued until 1944, when a stamp showing Hitler had the caption "Gross Deutsches Reich." From 1945, the Allied occupying powers issued their own stamps with "Deutsche Post," and from 1951, the stamps of West Germany were designated "Deutsche Bundespost." Those of West Berlin were inscribed "Deutsche Bundespost Berlin," and those of East Germany had "Deutsche Demokratische Republik" or "DDR" on them. After the reunification of Germany, the stamps continued to have "Deutsche Bundespost" on them until May 1995, from when they were designated as "Deutschland."

This change signified the creation of Deutsche Post AG, which maintains its headquarters in Bonn and has divided its operations into four sectors. One is in charge of mail delivery and handles about 70 million letters, with deliveries on every day except Sunday. It also has direct connections with most countries in the world for delivery of mail overseas and receipt of mail from these countries. The second sector of Deutsche Post, under the DHL brand, covers courier services, express, and parcel shipment around the world. The logistics section, also operating under DHL, handles long-term contracts with major companies; and the last sector of the business is financial services, with a retail banking network in Germany for about 14.5 million customers. Privatized in 2000, Deutsche Post claims to be the leading logistics provider in the world. It employs about 520,000 employees in almost every country in the world. It has revenue of $80.65 billion (2006).

Deutsche Telekom

Formed in 1996 from the Deutsche Bundespost (German Federal Post Office), Deutsche Telekom is the largest telecommunications company in Germany and also in the European Union. When it was controlled by Deutsche Bundespost, the telephone service in Germany had been part of the state-owned monopoly that also controlled the postal services.

After the establishment of the first telephone services in the United States, it was not long before the first telephone network was established in Germany. In 1880 the first telephone exchange in Germany was built in Mulhouse, in Alsace, then a part of Germany but now a part of France. The builders wanted to get a government permit to start operations, but the authorities in Berlin did not want a telephone service in Mulhouse before there was one in the German capital, so Berlin quickly opened its exchange in January 1881, initially with eight subscribers. The exchange had capacity for 99 people, and they were dubbed by the press the "99 fools." However, by May 1882, there were 699 subscribers, and the service grew rapidly after that, with the Berlin Boerse (stock exchange) having a large number of lines for its brokers to use.

The Reichspost—which also ran postal services—also continued with the telephone service, and by 1888 the Berlin Telephone Exchange was able to claim that it had more telephone connections than any city outside the United States. Two years later, a public "pay

The headquarters of Deutsche Telekom in Bonn displays the logos of T-Mobile International, a wholly owned subsidiary.

phone" was established in each of the 10,000 local post offices. The service became better during World War I with the increased use of military engineers, and was also adapted and improved after the war by the Inter-Allied Control Commission.

During the 1920s and 1930s, the telephone system continued to grow, with international calls possible, some by radio. It was even possible—at a cost—to telephone zeppelins such as the *Hindenburg*. During World War II, the Germans connected conquered territories in eastern Europe to their telephone network. However, much of the phone system in eastern Germany was destroyed in late 1944 and 1945, although many lines survived—a Soviet soldier was able to telephone the Berlin Bunker where an astonished Josef Goebbels answered the telephone.

After the war, the system was repaired and much of the network in Berlin and in many other cities were working reasonably well by the end of 1945. There were then two systems in operation, one covering West Germany and West Berlin, and the other for East Germany. There were also separate networks established by the Americans and the British, but these were quickly merged with the West German system. In spite of the Cold War, it remained possible to telephone from West Germany to East Germany and vice versa, but there were occasional technical difficulties. Nevertheless, the system did work well and with the unification of Germany on October 3, 1990, the two systems were both held under Deutsche Bundespost, although moves were already afoot to split the postal and telephone services of the company, as had happened in so many other countries in the world.

In 1996 Deutsche Telekom was privatized, but the German government has continued to hold a stake in it. The expectation was that the new company would be able to raise capital more easily and be more efficient. Instead, with privatization, the government was forced to break the telephone carrier's monopoly; this led to some 1.5 million customers leaving them for rival companies in 2005 and 2006. As a result, Deutsche Telekom shed 30,000 workers as its stock price fell dramatically. At the height of the speculative fever, shares went as high as €100, but later fell to €12, and in August 2008 they were trading at €10.97.

Devaluation

Devaluation occurs when a government or its central bank reduces the official price at which its currency can be bought on the foreign exchange (Forex) market. For example, suppose that the current $/£ exchange rate was 2:1, meaning that two USD had to be given up for each 1GBP or, equivalently, that 1GBP was worth 2 USD. If the GBP were devalued, this would mean that fewer USD had to be exchanged for each GBP, meaning that GBP had become cheaper in dollar terms.

Devaluation occurs under a fixed exchange rate regime. Under such a regime the government is committed to a particular exchange rate and manages its foreign exchange reserves (holdings of foreign currencies and gold) to ensure that this rate is maintained. Because a country's holdings of foreign exchange reserves are closely related to its balance of payments, the extent to which a government is able to maintain a fixed exchange rate is also affected by the balance of payments. For example, a country that has a deficit on its external account would face a positive net supply of its currency as domestic residents seek to pay for their net imports. This, in turn, would place downward pressure on the exchange rate and the government would intervene to defend it by buying its domestic currency on the Forex markets. This mechanism works in the opposite direction in the case of a revaluation.

The operation of this balance of payments mechanism can impose severe macroeconomic costs on the country effecting devaluation. Often, devaluation occurs because of persistent trade deficits caused by a country experiencing higher rates of inflation (or lower levels of productivity growth) compared to its trading partners. To overcome this problem, one solution is to impose contractionary fiscal and monetary policies to reduce inflation in an effort to restore international competitiveness. Such policies can result in significant reductions in the standard of living for domestic residents in the following ways: Reduction in government expenditure on education, health, social, and welfare programs. In certain cases, the International Monetary Fund (IMF) requires the imposition of such policies as a pre-condition for international borrowing. In more serious cases, and to avoid a conflict between external policy objectives (deficit on external account) and internal policy objectives (low levels of unemployment), countries can devalue their currency. The advantage of devaluation in this case is that by making the currency less expensive, deflationary pressures are subdued.

Historically, countries that have devalued their currencies have suffered relatively lower rates of growth in productivity and this, in turn, has resulted in significant deficits on the external account. A classic example of this situation was Britain in 1967. It is often the case that heavy international speculation precedes devaluation. This is because speculators hope to benefit from purchasing a currency at a lower price and selling it after revaluation. In the preceding example, the Bank of England spent £200 million on November 19, 1967, trying to defend sterling against speculative attack. Similarly, in a more recent British example—the decision to take sterling out of the European Exchange Rate Mechanism in 1992—the chancellor of the exchequer authorized the Bank of England to spend billions of pounds trying to defend sterling from speculative attack.

Devaluation can be beneficial for a number of reasons, especially in the short term. For example, it makes exports relatively cheaper with consequent benefits for the trade balance. In the short run, it is possible that a devaluation will worsen the external account. This is because contracts agreed before devaluation have to be honored after devaluation, but using a cheaper currency. Only in the longer term, when contracts are renegotiated and when the full impact of the devaluation on exports has occurred, will the external account improve. Additionally, there are two other factors that can undermine the long-run benefits from devaluation. The first is that if a country continues to have relatively high rates of inflation (or relatively low rates of productivity growth) after devaluation, any costs advantage will quickly be eroded and eventually reversed; this may require another devaluation. Second, and particularly in times of a global recession (for example, during the 1930s), devaluation by one country can trigger a series of competitive devaluations by other countries.

Devaluation can also generate disadvantages. Devaluation increases the costs of imported goods and can result in imported inflation. This imported inflation can generate a wage-price spiral as workers demand higher wages to compensate for the higher costs of imported products. These disadvantages are exacerbated the more dependent a country is on imported foodstuffs and energy. A further problem is that devaluation can reduce efforts to improve competitiveness. This is because in the short term devaluation removes the need to lower costs to increase exports; in the long-run, if the "breathing space" offered by devaluation is not used to improve productivity, the country will end up with the same problems it had prior to devaluation.

Development Assistance

Development assistance, (or synonyms such as technical assistance, international aid, overseas aid, foreign aid, development aid, or development cooperation) is aid given by bilateral and multilateral agencies to support the socioeconomic and governance development of developing countries. It is provided by governments through their bilateral aid agencies such as the Canadian International Development Agency (CIDA), the U.S. Agency for International Development (USAID), the United Kingdom Department for International Development (DFID), or through multilateral institutions such as the World Bank, regional development banks, or through international development nongovernmental organizations. Development assistance focuses on poverty alleviation and governance as opposed to emergency relief or humanitarian aid, which aims at alleviating suffering following crises such as war or natural disasters.

Official development assistance has three main characteristics: (1) it is undertaken by government bilateral and multilateral organizations; (2) promotion of socioeconomic development and governance is the main objective; and (3) it has favorable terms, including donations and concessional loans, which have low interest rates on a longer repayment period including a grace period for repayment. Development assistance, as a flow of resources between developed and developing countries, differs from remittances—financial transfers sent home by foreign workers—or foreign direct investments made by multinational corporations. Most recently, some have included in the definition a security-related spending component, which is debated by several nongovernmental organizations, which argue that any military expenses, for example, cannot be accounted as development assistance.

Evolution

Development assistance emerged in the post–World War II, Cold War period. Development assistance began with a "modernist" paradigm involving the transmission of technical knowledge and technology in large infrastructure projects and in "universal" programs, such as programs in public health, most often funded and led by governmental and multilateral agencies. The focus of development assistance over the decades shifted from mainly large physical capital- and technology-intensive infrastructure to human education, population control, and after the 1980s, to policy reforms in the form of the structural adjustment plans, and decentralization in the 1980s and 1990s. Overall, although large infrastructure projects have remained central in development assistance, there has been an increased recognition of the importance of smaller scale, local capacity-building projects led or managed jointly by governments and nongovernmental organizations. Different forms of partnerships, in the form of collaborations, cross-sectoral partnerships, and cooperation have emerged.

The domain of international assistance changed in the 1990s due to several factors. The first one concerns the emergence of national and international NGOs (nongovernmental organizations) also labeled "civil society" or "third sector organizations" or associations. This has been referred to as "the rise of global civil society." The second factor has dealt with the emergence of new conceptions of "development" and "poverty," especially under the influence of Martha Nussbaum and Amartya Sen.

Sen's definition of development goes beyond the economics-based definition of poverty, which often tends to misrepresent the level of well-being of an individual or of a community. Sen argued that the most important factor to human beings does not concern income or consumption per se, but rather the capacity to realize their potential as individuals and groups and to achieve what they truly value. Sen views the removal of structural "un-freedoms," or obstacles to human beings to achieving what they truly value, as a central element of poverty alleviation strategies and as a way to achieve individual and collective development. This new conception of development has been translated into measures of development including, among others, the Human Development Index.

The third factor concerns a major policy change toward aid effectiveness, which questioned the practice of international development assistance. Aid effectiveness has questioned the notions, the policies, and practice of international development, arguing that there was limited evidence of the effectiveness of its programs. It has led to rethinking the evaluation of processes and outcomes of development assistance. The fourth factor has aimed to connect aid—often operated and led by international cooperation agencies such as CIDA, Agence Française au Développement, USAID, and others—to development through trade, often led by trade departments, especially for Africa under the Clinton and Bush administrations in the United States. The fifth factor concerns the emergence of global private foundations such as the Bill and Melinda Gates Foundation.

In September 2000 the Millennium Summit was concluded by a common declaration of 191 heads of states to eight objectives on global poverty reduction for 2015 through concerted actions, which includes a reporting system to assess progress each year. The Millennium Development Goals create a template with objectives for coordinated activities to prevent duplication of efforts, which existed in parallel bilateral aid relations, and promote collaboration between sectors along commonly-defined objectives.

Quantitatively, the levels of aid funding promised by donor countries have most often not been translated into actual funding. Resolution 2626 adopted at the United Nations (UN) General Assembly on October, 24, 1970, assessed for each economically advanced country the objective of giving 0.7 percent of its gross domestic product (GDP) by 1975 in development assistance. Resolution 35/36 at the UN General Assembly on December 5, 1980, reassessed this objective. Two decades later, the 2000 Millennium Summit recognized that this objective for all the economically advanced countries to give 0.7 percent of GDP to the official public assistance had not been achieved. As of 2003, only five OECD countries were giving 0.7 percent of their GDP in foreign aid. The United States was providing 0.14 percent of its GDP to official assistance. In all, it is estimated that official development assistance has amounted to between $50 billion and $60 billion per year.

Structural and Contextual Limitations

Development assistance needs to be understood and evaluated in the broader context of North-South/international relations and country-level structural constraints. On the global level, agricultural subsidies in the United States and in Europe penalize developing countries' exports and create conditions of unfair trade, as poorer countries face high barriers to access to international markets in products such as cotton. Second, it has been argued that the effectiveness of development assistance needs to be taken into account within changes in economic policies. Third, it has been argued that international/multinational corporations in oligopolistic positions control large areas of trade and severely restrict conditions for international trade. International assistance has been criticized for not addressing structural conditions to countries such as unequal access to means of production, including land.

Development assistance has been criticized on several accounts. The first critique concerns more particularly bilateral aid. It has been argued that large amounts of funding were dedicated to supporting strategically important leaders and regimes, especially in sensitive regions and during the Cold War. A second critique concerns the form of aid; several anthropologists have contended that developed countries were projecting their own needs, values, and solutions onto other societies through development assistance, regardless of local needs. Such projections have led to increased inequalities and disruption.

A third critique has proposed that development assistance creates dependency and corruption as funding flows into developing countries. This inflow of funds may discourage local production and distort local markets. Last but not least, the final critique concerns "red tape," or the "bureaucratization" of international development assistance. It has been argued that developed countries have put so many conditions on aid that it has reduced aid effectiveness and distracted the focus from development outcomes in the countries per se to managing relations with donor countries.

New Business and Development Assistance

New forms of development assistance that connect the business sector with the aid and governmental sectors have emerged over the last few years. Several have proposed that globalization of business activities could have the potential to successfully address development issues. These new business–development assistance approaches include, among others, new market solutions, microcredit and microfinance, the UN Development Programme's Growing Inclusive Market approach, the Bottom of Pyramid, and several initiatives related to information technologies and communication in order to reduce the digital divide between technologically advanced and poor countries. In all, there is an increasing trend toward more partnerships across sectors related to development assistance.

Diffusion of Innovation

The sociological theory of diffusion of innovation analyzes the development, adoption, and success of inventions, new ideas, processes, and technologies. With globalization and worldwide interconnectedness of business, cultures, and communications steadily increasing, the spread of innovation is more often accelerated as diffusion patterns change. As the adoption or rejection of new abstract ideas depends significantly on the attitudes of individuals, groups, organizations, or nation-states, the communication and persuasion means employed to influence potential adopters are of the highest significance for the diffusion of innovation. Ultimately the adoption or rejection of innovations may initiate or accelerate structural change.

Diffusion refers to "the process in which an innovation is communicated through certain channels over time among the members of a social system." Innovations are new ideas, the new application of innovations, or an idea perceived as new. When it comes to the adoption of innovations and ideas, one of the central questions surrounding diffusion research is the identification of differences between early and late adopters.

Innovativeness refers to the willingness and ability to adopt new ideas earlier than other people or groups. Are some actors more open to innovation than others? The literature identifies six factors that characterize adopters: (1) societal entity of innovators, (2) familiarity with the innovation, (3) status characteristics, (4) socioeconomic characteristics, (5) relative position in social networks, and (6) personal characteristics. Apart from these actor-specific characteristics, the nature of the environment is also important in terms of adoption and diffusion.

Although the focus of many diffusion studies is more upon the individual and group attitudes toward innovation or the environmental context, the adoption of innovation also has consequences for the actor(s): these consequences can be differentiated into private and public consequences. The adoption of innovation that results in private consequences includes innovation that directly shapes the well-being and structures of individuals, small organizations, and communities. Public consequences tend more to involve and influence macro-structures, and societal and historical issues. In more recent years, the role of the media in the diffusion of innovation and the persuasion of actors has been recognized.

A further area of interest is the role of the perceived attribute of an innovation in the rate of adoption. Individuals may understand innovation based on (1) the relative advantage of the innovation in comparison to existing solutions and practices, (2) its compatibility with existing and potential needs and experiences, (3) its complexity in terms of the degree of understanding, (4) the trialability, that is, to experience the innovation to a certain degree and time period, and (5) the observability or degree to which an innovation or its results are observable. The thesis is that if individuals see the success of an innovation they are more likely to adopt it.

Time is a critical element in the diffusion of new ideas as it involves (a) the innovation-decision process, (b) innovativeness, and (c) the innovation's rate of adoption. The innovation-decision process is a process of learning about the innovation, the building of an attitude toward the innovation that results in the decision to either adopt or reject the innovation, the modes and extents of the implications of the innovation, and confirmation of the decision. An S-shaped diffusion curve distinguishes earlier adopters from late adopters. The curve starts slowly in line with the few early adopters, followed by an overproportional growth, followed by a stagnation phase. The five adopter categories include innovators, early adopters, early majority, late majority, and laggards.

In 1903 French sociologist Gabriel Tarde identified the "laws of imitation," that is, the diffusion of the innovation process that explains the rate of adoption or the diffusion rate. Tarde recognized that the rate of adoption follows the S-shaped diffusion curve. Years later, a number of European anthropologists in England and Germany-Austria used diffusion research to explain the consequences of innovation as they pertain social change in a society. One of the early explicit diffusion studies was conducted by Ryan and Cross in their examination of the spread of hybrid-corn use in 1943. In his seminal 1962 book *Diffusion of Innovation*, Everett Rogers identified major diffusion research traditions ranging from anthropology, sociology, education, communication, marketing and management, and geography. From then on, various disciplines used diffusion research to analyze the sequence and consequences of innovations.

Everett Rogers identified eight main types of diffusion research: Earliness of knowing about innovation, rate of adoption of different forms of innovation in a social system, innovativeness, opinion leadership, diffusion networks, rate of adoption in different social systems, communication channel usage, and consequences of innovation. The study of the diffusion of innovation is relevant for areas such as information system research, knowledge management, marketing, change management research, and social change research.

Direct Export

Direct exporting involves personally handling every aspect of the exporting process from market research and planning to foreign distribution and collections. Therefore, a significant commitment of management time and attention is required to achieve superior results, making this the most ambitious form of exporting. Nevertheless, this approach is probably the best way to maximize profits, obtain the most control over the process, develop closer relationships to the overseas market, and achieve long-term growth.

A company usually begins exporting by treating its export sales no differently than its domestic sales, using existing personnel and organizational structures. A small firm is likely to have just a single export manager who has the responsibility for the full gamut of international activities. As international sales increase, it is likely to separate the administration of exports from that of domestic sales. Larger firms or those at advanced stages of exporting may decide to retain an international division or organize along product or geographic lines. A firm with distinct product lines is more likely to create an international department in each product division, while those that have products that have common end users are more likely to organize geographically.

Irrespective of how the firm organizes its exporting efforts, its success in foreign markets depends less on the unique attributes of its products and more on sound marketing methods. Proper channels to handle direct exporting include sales representatives, distributors, foreign retailers, and direct sales to end users.

Sales representatives are also called manufacturer's representatives or a sales agents. They use the firm's product literature and samples and present them to potential buyers. A sales representative typically handles many complementary lines that do not conflict and works on a commission basis, essentially as a broker assuming neither risk nor responsibility for servicing the product after the sale. They are usually under a contract that clearly defines the period of the agreement, their territorial jurisdiction, whether or not they will operate on either an exclusive or a nonexclusive basis, the method of compensation, and limits on legal authority of the representative to obligate the company.

Foreign distributors are merchants who purchase goods from an exporter at a substantial discount and subsequently resell it for a profit. They also generally provide support and service for the product and carry an inventory of sufficient supply of spare parts. Distributors maintain adequate facilities and personnel for normal servicing operations, and normally sell a nonconflicting but complementary range of products. They may resell the product to local dealers and retailers.

Selling through foreign retailers usually involves consumer products, and is effective in countries that have large retail chains such as the United States, Canada, the United Kingdom, and Japan. The technique relies on traveling sales representatives contacting foreign retailers or mailing them catalogs, brochures, and other literature. This approach has benefits of eliminating commissions, reducing travel expenses, and reaching a broader audience. To maximize results, companies using direct mail to reach retailers should integrate it with other marketing activities.

Companies may sell their products directly to end users in foreign countries—entities such as foreign governments, banks, hospitals, schools, or businesses. The buyers can be contacted either through trade shows, international publications, or through the Commerce Department's Export Contact List Services. Selling to end users overseas may incur additional costs such as shipping, payment collection, and product support and service.

Dirty Float

"Dirty" float, also called managed float, is the result of intervention by a nation's government or central bank in the behavior of its currency on the foreign exchange market. Not a fixed exchange rate, in which the value of a currency is pegged in a static relationship to some other value (like gold or a specific foreign currency), dirty float refers to an otherwise floating exchange rate governed principally by market forces but occasionally guided—the waters dirtied—by corrective intervention.

When the international economy becomes uncertain and the exchange rate of a currency on the foreign exchange market fluctuates too wildly or in response to artificial influences like the actions of currency speculators, the consequences can be dire: the depreciation of the country's currency, rising inflation, reduced economic efficiency and growth, and the necessity for greater taxes on trade and foreign investment.

Currency fluctuations can curtail the benefits of globalization by forcing a country to shutter some of the doors between it and the outside world, in order to keep the financial weather at bay. In such a volatile environment, it becomes necessary to smooth out exchange rate fluctuations through the intervention of the central bank (or some other government authority).

Central bank intervention to manage the exchange rate can be accomplished through a variety of means. To influence daily fluctuations, the central bank can buy or sell its own currency, just as central banks have bought or sold government-issued securities to affect the supply and demand of their currencies. Short and medium-term fluctuations can be dealt with by delaying the exchange receipts and payments in exports and imports, and the movement of a currency's exchange rate can be resisted or slowed by putting restrictions on the market, like the cash reserve ratio or statutory liquidity ratio.

Furthermore, the central bank can put a ceiling on the credit extended to foreign firms, restricting the flow of currency from the country. Direct foreign investment can be limited too, restricting the flow of foreign currencies into the country, as well as domestic firms' dependence on those currencies and thus vulnerability to foreign economic mishaps. In some cases, the central bank can limit the amount of money that domestic investors can put in overseas investments, to a similar end. Borrowing and lending operations can be managed to maintain an equilibrium in balance of payments.

The exposure and outflow of the country's currency can also be limited by limiting the repatriation of dividends, interest, and royalty payments. Interest rates can be adjusted in order to impact the health of the currency, as they often are for other economic matters as well.

The sense and effectiveness of such manipulations is sometimes called into question. In the case of real calamities like the Asian financial crisis of the late 1990s, such intervention seemed limited in its positive impact; in the economic uncertainty of 2007 to the present, it is difficult to tell how much trouble central banks have saved their respective countries. The power of speculating hedge funds is vast and takes effect swiftly.

Disclosure Requirements

Disclosure requirements relate to the data collection, analysis, and dissemination relevant to specific transactions that is required by law. Disclosure is part of many legal regimes around the world that protect business from the indisputable temptation of corporate insiders to loot business treasuries, a phenomenon that often goes undetected. Disclosure is a way to protect investors and shareholders against self-dealing—the use of corporate assets for personal gain. It is a prerequisite for robust equity markets to develop.

To be efficient and growth-oriented, entrepreneurs require regulatory regimes that give investors such as stock markets, private shareholders, and other financial institutions the confidence they need to provide finance without the need to exercise daily control of the business. They need laws that prevent expropriation and expose it when it happens. This requires protection of shareholders and enforcement of defaults and irregularities. It means that a well-governed business should disclose ownership and financial performance information. Information on financial transactions, on board directors, and on voting agreements among the shareholders must be freely available to current and potential investors. It also means that a director should face legal liability for self-dealing, and that shareholders should be able to sue officers and directors for misconduct.

In a comparative analysis of disclosure requirements, the World Bank's *Doing Business* (DB) survey comparatively examines national disclosure requirements. For an example using a hypothetical case, say that a Mr. Singh owns 60 percent of Buyer Ltd., a commercial delivery firm, and he owns 90 percent of Seller Ltd., a retailer. Seller Ltd. is facing financial problems, recently shut a large number of its stores, and has trucks for sale. Mr. Singh proposes to Buyer Ltd. that it purchase Seller's unused trucks to expand Buyer's capability. Shareholders then sue Mr. Singh and the parties who approved the transaction. In such a case, one must ask (1) whether and in what detail Mr. Singh must make mandatory disclosures regarding his interest to Buyer's board of directors; (2) whether and in what detail disclosures regarding the Buyer-Seller transaction are legally required to be made immediately to the public, the regulator, or the stock exchange; and (3) whether and in what detail disclosures regarding the Buyer-Seller transaction are legally required in Buyer's annual report.

The World Bank's index ranges from zero to 10, with higher values indicating greater disclosure. Taking the Asia-Pacific region as an example, New Zealand and Singapore have the highest rankings in the disclosure index. In 2007 the United States ranked at seven on this index, and the lowest rating went to Laos, at zero.

Another example of disclosure requirements is often seen in an initial public offering (IPO). In this case, detailed disclosures of the company's affairs must be made public. New-venture firms often prefer to keep such information private. In an IPO, the firm usually must issue a prospectus, which is a formal written offer to sell securities that provides an investor with the necessary information to make an informed decision. If a company is raising capital by offering its shares or other securities to the public for the first time (usually called a "float" or IPO), it will issue a disclosure document called a prospectus.

In Australia, for example, a prospectus must be lodged with the Australian Securities and Investments Commission (ASIC). The prospectus will then be made available in an electronic format, called e-prospectuses, via the internet. The prospectus must fully disclose all pertinent information about a company and must present a fair representation of the firm's true prospects. All negative information must be clearly highlighted and explained. Some of the specific detailed information that must be presented includes the history and nature of the company; capital structure; description of any material contracts; description of securities being registered; salaries and security holdings of major officers and directors and the price they paid for them; holdings; underwriting arrangements; estimate and use of net proceeds; audited financial statements; and information about the competition with an estimation of the chances of the company's survival.

Disclosure (or its absence) is connected to a country's level of transparency (or corruption). The knowledge of amounts in financial transactions must be reasonably exact before they can be controlled, curtailed, or reformed. Disclosure fulfills two very important functions: Accounting and accountability, which serve as both preventive measures and monitoring tools in combating corruption. The accounting function allows for the construction of itemized reports of funds received and spent. The accountability function is the presentation of these reports so that shareholders, investors, and regulators can make more informed choices about business performance.

Benefits and Pitfalls

There are three major benefits of disclosure requirements. The first is the ability to "follow the money." Without it there is no way to keep track of—and thereby enforce—regulations. The ability to "follow the money," or construct an "audit trail," is the first defense against system irregularities and can have an impact on good governance.

The second benefit of disclosure is that it acts as a preventive measure. Disclosure serves to monitor and reveal information that can prevent conflicts of interest. It provides watchdog groups and the media with informed analysis of business finance and creates more educated shareholders. Through "name and shame" exercises, it also serves to warn corporate officials that they must act in the shareholders' interest, not for private gain.

Another benefit to disclosure is that it builds confidence in the business process. On a level business playing field, the underlying principle behind disclosure is that the more transparent and open a company's finances, the more its shareholders and investors will trust the business.

In the absence of any international standards, pitfalls that mar the disclosure process include: (1) Deceptive interpretations. Few words in finance are as overused and poorly defined as *disclosure.* (2) Limited access to data. Opening records to the public is the ideal, but some legal regimes make accessing them difficult. (3) Poor quality of data. A more subtle form of deception is the low quality of data that many disclosure laws produce. (4) Low quantity of data. Many countries claim disclosure, but fulfill only some of the variables required for full disclosure.

Full disclosure, or the maximum extent of openness in reporting political contributions, requires information on how much money a business has received; how much free or in-kind support was given to the business (e.g., goods, services, or loans); the names (and sometimes addresses) of the "givers"; how much money the business has spent and on what; and names (and sometimes addresses) of companies or persons who received the money spent on goods and services provided to the campaign. Full disclosure also requires businesses to file financial assets (ownership and debts).

Discount Rate

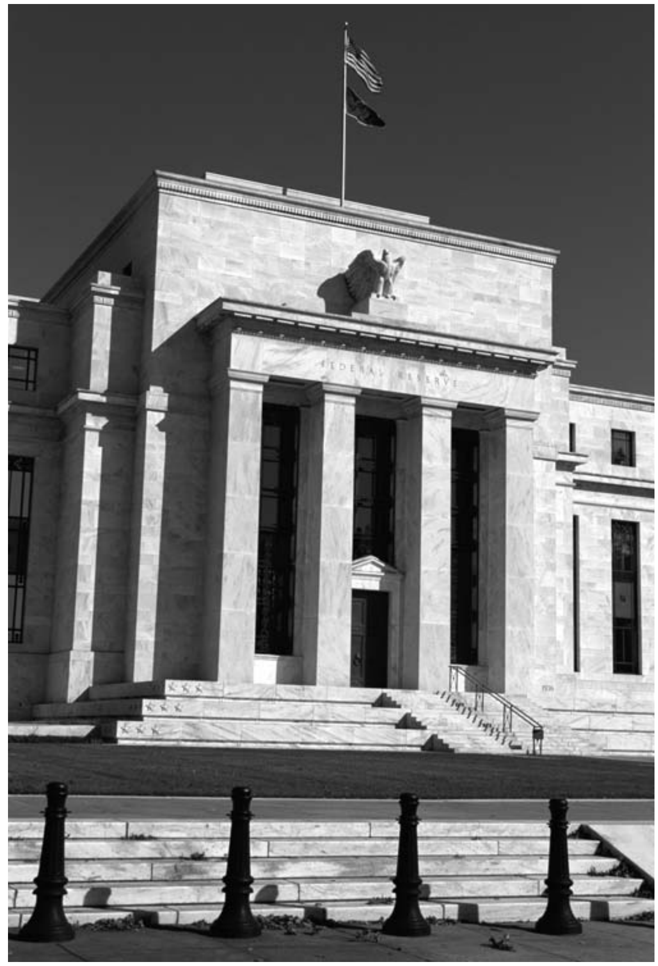
One definition of a discount rate is the interest rate the U.S. Federal Reserve (or another central bank) charges on loans to banks through the discount window. The establishment of the U.S. Federal Reserve System in 1914 was to provide a source of funds (reserves) from which commercial and depository institutions can borrow in case of a temporary shortage. The discount window is the mechanism through which each of the 12 regional U.S. Federal Reserve banks lends to commercial and depository institutions. Another definition of a discount rate is as an investor's opportunity cost of funds. It is the best return an investor can earn on investments given the risk of such investments. The borrowing rate is also referred to as a discount rate. In the money market for securities, where securities are issued at a discount from par (face) value, discount rate refers to the rate of return on a security.

The U.S. Federal Reserve (Fed) serves as the lender of last resort. When banks and depository institutions face temporary shortage of funds they can borrow from the Fed through the latter's discount window.

The Federal Reserve originally limits discount window loans to discount or rediscount activities for members of the Federal Reserve System. Thus, a borrower sells "eligible paper," such as agricultural loan documents supporting a loan to a customer to a Federal Reserve Bank. The Federal Reserve Bank in turn provides credit in the amount of the discount in the borrowing bank's account. Once the loan is paid, the Fed returns the "eligible paper" and makes a debit entry in the reserve account of the bank. Over the years, discount window loans were dominated by advances, which are loans secured by approved collateral. Such loans are paid back with interest at maturity.

In 1980, after the passage of the Depository Institutions Deregulation and Monetary Control Act (DIDMCA), discount window loans were extended to all depository institutions including banks that are nonmembers of the Federal Reserve System. In "unusual and exigent circumstances," individuals, partnerships, and corporations that are not depository institutions can take advantage of the discount window opportunities subject to approval of the Board of Governors of the Federal Reserve System.

Traditionally, the Fed extends discount loans to depository institutions through three programs: (1) adjustment credit, (2) seasonal credit, and (3) extended credit. Adjustment credit loans are the most common and they are given to cover temporary needs for funds arising from deposit outflow. These loans can be obtained with telephone calls to a regional Fed. Repayment of such loans is made fairly quickly, from a day to a few days for large depository institutions. Seasonal credit is extended to small institutions that depend on seasonal activities such as farming and tourism. The borrowing institutions also have limited access to national money markets. An extended credit can be granted to a depository institution facing special liquidity difficulties. A group of institutions can be given extended credit if they face deposit outflows because of changes in the financial system, such as natural disasters or other difficulties that are common to the borrowing institutions. The repayment of extended credit takes time. A borrowing institution needs to provide a proposal that outlines a call for credit and how and when the liquidity position of the institution will be restored. A good example involves Franklin National Bank, which borrowed about $1.75 billion from the Fed in 1974.



The Washington, D.C., headquarters of the U.S. Federal Reserve, which decides the discount rate in the United States.

In January 2003 the Board of Governors of the Fed authorized the Federal Reserve Banks to operate the following revised discount window programs: (1) Primary Credit, (2) Secondary Credit, and (3) Extended Credit. The new primary credit program involves loans that are extended for a very short term (generally on overnight basis) to depository institutions that are adjudged to be financially sound. The discount rate on primary credit is set above short-term market interest rates that include the federal funds rate. Borrowing institutions of short-term primary credit are not required to have exhausted other sources of funds before participation in the discount window activities. Each borrowing institution must meet the collateral policies as specified in the Federal Reserve Act. Those depository institutions that are not eligible for primary credit can apply for secondary credit to meet short-term liquidity needs or to resolve severe financial difficulties. Participation in the secondary credit program is contingent on a timely return to reliance on private funding sources. In the case of a severe difficulty, the Federal Reserve Bank in cooperation with the Federal Deposit Insurance Corporation must agree that granting secondary credit is a least-cost resolution of the problem. Seasonal credit is available to small and medium-sized depository institutions that experience significant seasonal swings in their loans and deposits. Seasonal credit should help to address recurring intrayear fluctuations in funding needs of small banks in agricultural or seasonal tourism communities.

In general, changes in the discount window loan rate occur infrequently. The lowest discount rate in history was 0.5 percent from 1942 through 1946. The highest rate was 14 percent in 1981. The primary credit discount rate has varied from 2 percent to 6.25 percent from 2003 through mid-2008. In order to stem the growing problems within the U.S. financial system, the Fed began a spate of cuts in the discount rate since August 2007.

Discount Rate Policy

As a part of its monetary policy mandate, the Fed controls the volume of discount loans in two ways: By controlling the price of the loan (discount rate) and by controlling the quantity of the discount window activities. Through its power over discount window activities, the Fed can influence the money supply in the economy. For example, an increase in discount loans leads to an increase in bank reserves and consequently an expansion of money supply. Conversely, a decrease in the volume of discount loans leads to reduction in money supply.

Based on the foregoing, the discount window can be used to influence the reserves of depository institutions. Another important function of the discount policy is its implied announcement effect. A change in the discount rate is perceived as a signal of the Fed's future direction in terms of monetary policy. Unlike some other monetary policy instruments, the discount rate is used irregularly. When a change is made in the direction of the movement of the discount rate, the public often interprets this as a signal of the thinking of the Fed's Board of Directors concerning the future course of monetary policy.

An increase in the discount rate after a series of reductions may indicate that the board foresees impending inflationary pressure. In order to control this, the Fed makes it harder to get credit in the near future. There may be a problem with the interpretation by the public of Fed's intentions. For example, when market interest rates are increasing relative to the discount rate, the volume of discount loans tends to rise as well. The Fed may increase the discount rate just to keep it in line with market interest rates without necessarily changing its policy to be less expansionary. Bankers may see this development as an indicator of a potential shortage of reserves and react by slowing down loan commitments.

A significant advantage of the discount policy is that it allows the Fed to perform its function as the lender of last resort. Historically, the performance of this function has provided some stability to the financial sector. The notable cases of the use of the discount window include the rescue of Franklin National Bank in 1974, Continental Illinois National Bank in 1984, and in September 2007, the Fed announced a huge cut in both the federal funds rate and the discount rate in order to facilitate borrowing by America's largest banks. This was considered necessary to facilitate the bailout of their affiliates and other operators, such as hedge funds, caught in the subprime loans crisis.

There are arguments against the use of the discount window as a tool of monetary policy. The misinterpretation of the announcement effect of a change in the discount rate can exacerbate the economic problem being addressed by the Fed. Since the use of the discount rate is rather infrequent, by setting the discount rate at a level, the spread between market interest rates and the discount rate may fluctuate widely as market interest rates change. These fluctuations may lead to unintended fluctuations in the volume of discount loans and consequently in the money supply. The use of the discount window to bail out financial institutions exerts some financial burden on the public, thereby creating negative long-run consequences on the economy. The action of bailing out large financial institutions under the guise of "too big to fail" impeded the functioning of a competitive market system.

Interest and Inflation Rates

The other concept of discount rate is as a function of both interest rate and inflation rate. There are four fundamental factors affecting the cost of money and they are production opportunities, time preferences for consumption, risk, and inflation. The production opportunities define the returns available in an economy from productive assets. The time preferences for consumption reveal consumer preferences between current consumption and saving toward future consumption. Moreover, the market interest rate accounts of risks as well. Risk represents the likelihood that investors do not realize their expected rate of return on an investment. In other words, risk consists of a possibility that an unfavorable state of nature appears to determine the variability of future financial flows, thereby making them unpredictable. The inflation rate is the rate of general increase in the prices of goods and services, making it an index of change in the purchasing power of money. A discount rate accounts for the competing forces of interest and inflation. In general, the market interest rate is associated with the cost of borrowing money and thus represents the earning power of money.

The concept of time value of money in finance and accounting is also based on the use of a discount rate. Time value of money is based on the idea that a dollar today is worth more than a dollar expected next year with all things being equal. Consider a major proposal by a business enterprise that is expected to generate $161,000 in one year. Assume that the present value of this future amount is $140,000. The present value is the amount of cash that makes the owner of the firm be indifferent between receiving $140,000 today or receiving $161,000 next year. This means that the business owner expects to receive a 15 percent rate of return from the project. Therefore, $140,000 invested at the rate of 15 percent for a year will yield $161,000. In this case, 15 percent is referred to as the discount rate.

Distribution

In business, distribution is the process by which a good or service is made available to the consumer. Distribution is one of four elements of the marketing mix, along with pricing, product, and promotion—"the four Ps," as they are called when distribution is bent over backwards and called "place."

The idea of the marketing mix comes from the 1950s and early 1960s, the heyday of the Mad Men and marketing firms whose professions were seeing a new level of professionalism and inter-industry discussion to match the new revenue streams provided by television. Marketer Jerome McCarthy, author of the influential textbook *Basic Marketing*, was the first to propose the four Ps as a solution to the suggestion that there should be something recipe-like underlying marketing decisions. In their brevity and alliteration, the four Ps are themselves a very marketable idea, a catchy notion. Naturally the notion lends itself to expansion, and some marketing texts or gurus may add to the Ps—packaging, personnel, premium, et cetera.

The best way to define the marketing mix is by reverse engineering: that is, the primary end of marketing is the optimization of the marketing mix, and so therefore that which must be optimized is the marketing mix. The product, of course, is the good or service, and may be improved or optimized in all sorts of ways depending on its nature; the price must fit the product's place in the market, while occupying a comfortable position relative to the customer's ability and the supplier's necessity; promotion encompasses advertising, public relations, word of mouth, and point of sale. The use of the term *mix* here does not mean that these elements change in relation to each other, nor do they have a mathematical relationship to each other as in a "recipe"—that is, there is no

Forces that affect a business's distribution channels, such as a jump in fuel costs, can mean higher prices for consumers.

element that scales, the way flour does to sugar when doubling a cookie recipe. Changing the price in the marketing mix does not necessarily impact the other elements, and certainly does not represent a quantity to remove from other elements.

Channels

There are different possible channels of distribution, and a product very often (but not always) has more than one. Beginning with the channel with the fewest intermediaries, there are direct sales made by the producer—which encompasses everything from farmers selling goods on their farm to a home business selling goods on eBay or through an online store. There are agents selling goods on the producer's behalf, such as in a consignment shop or literary agents brokering deals with publishers. Wholesalers buy from the producer and resell to retail locations. Retailers sell to consumers (and may deal with a wholesaler, an agent, or directly with the producer).

Franchising impacts the distribution channels, as when a franchise restaurant prepares food at some central location, selling it to the individual franchises to be cooked or reheated for sale to the customer. Even when all food is prepared from scratch on site, if the recipes originate with the franchising company there is some sense in which the product has been distributed to the franchisee before being resold to the customer; this is true too of service franchises, like gyms, salons, and other businesses where a process, concept, or even just a brand name originates with the franchiser and is sold to the franchisee.

The question of how many intermediaries to use in distribution is an important one for every business, and is decided according to the nature and scale of the business. Although profits are shared with more parties when more intermediaries are involved, the costs of distribution are also shared. Marketing and advertising costs can be located at any level of distribution; while in most cases the producer is expected to be principally responsible for advertising, the producer may expect wholesalers or retailers to do their part to support the product as well, and this may include exclusivity agreements.

The comic book industry in the 1990s was subject to a great deal of change and shifting fortunes as the typical retail location shifted from the neighborhood newsstand to the comics specialty shop, increasing the importance of the comics distributors who worked with those shops (often referred to as the "direct market" in the industry, even though direct sales were not being made to customers). Marvel Comics, one of the two big publishers, acquired the comics distributor Heroes World to use as its exclusive distributor, resulting in similar moves throughout the industry, amidst a tulip-bulb-like collectors' mentality that encouraged the creation of distributor-exclusive editions of comics with metallic-ink covers and other gimmicks. Eventually, though, sales faltered to such a degree that the temporary bumps caused by such gimmicks—whether in packaging, like those special-ink covers, or in the form of stories about Superman's death—were necessary to keep revenues healthy.

The principles of distribution and its optimization apply to the transfer of goods and services within a company's "internal market," among its myriad departments or locations, as much as it does to the transfer of those products to customers. An apparently seamless system can sometimes become problematic when a factor changes unexpectedly. When agriculture shifted from small or medium-sized farms to multi-state businesses, for instance, the new business model tended to call for feed to be produced in one location, sometimes stored in another, and then transported to the livestock at still another location—as opposed to the zero-intermediary system previously employed, wherein a farmer would graze the livestock or raise their feed himself. This system originated when fuel was cheap enough to justify the increased cost invoked by transport, because economies of scale allowed agricultural businesses to save money in other areas and to profit from lower profit margins due to volume sales. One reason for the rise of food commodity costs in 2007–08 was the spike in fuel costs, which suddenly doubled the cost of an aspect of this distribution channel.

Diversifying Investment

Diversifying investment is a risk management technique that is used to minimize the risk of individual securities by investing in a portfolio of securities. That is, if investors reduce their reliance on particular assets, they can more easily bear a downturn on an individual security. Diversification is the cornerstone of modern portfolio theory that has seen wide applications in financial decision making. Both firms and individuals diversify investments. The former diversify by investing in individual activities, while the latter diversify by investing in portfolios rather than in individual assets.

In portfolio theory, investors are assumed to be risk averse, that is, they prefer lower to higher risk for a given return and will accept a higher risk only if they are compensated with a higher return. This creates indifference curves, lines on which risk and return combinations are offered to investors and as long as investors are on this line, they are indifferent on where to invest. Namely, as risk increases, return increases as well, so that investors are compensated for the increased risk they take on. The expected return of an investment in a single asset is the sum of the returns on that investment conditional on the probability of every return occurring. For example, if there is 60 percent probability that an investment earns a 5 percent return and 40 percent probability that it will earn 15 percent, the expected return on this investment is 9 percent, which is the weighted average of the probability of each event occurring. Furthermore, the expected return on an investment portfolio, i.e., on a combination of investments, is the sum of the weighted average of the returns of the individual holdings of the portfolio.

On the other hand, variance measures the variability of returns and is used as a benchmark for the risk of individual assets. In a single asset, the variance is the square root of the difference between the realized and the expected return on the asset. However, the variance of a portfolio of assets is proportional to the weights that are invested on each asset, to the variance of individual assets, and also to the degree of correlation between the individual assets.

Correlation

Correlation is a measure of interrelationship between assets and measures the extent to which the returns from two investments move together. If the correlation coefficient is +1 this means that the returns of the two investments always change proportionately in the same direction (perfect positive correlation). A correlation coefficient of –1 means that the returns always move proportionately in the opposite directions (perfect negative correlation). When the correlation coefficient is zero, this means that the returns have no correlation whatsoever and their returns are independent from one another.

The essence of diversification lies on the correlation coefficient of securities. Since the variance of a portfolio has two components, the individual securities' variance component and the correlation coefficient component, when two assets are negatively correlated, i.e., when the second component is negative, the portfolio variance is greater than portfolio variance. In other words, by investing in securities with negative correlation, the overall risk of the portfolio is reduced. If the correlation is zero, the second term of the portfolio variance is zero, so the variance of the portfolio is simply the sum of the individual variances of each stock included in the portfolio. The benefit of diversification is eliminated when the correlation coefficient is +1. Thus, other things equal, the smaller the correlation between two assets, the smaller the variance (risk) of the portfolio of the two assets. One can create the same risk level and higher expected returns by diversifying one's investments across a wide range of stocks. The only assumption is that as long as the individual stocks are not perfectly correlated, the risk-return combination of the portfolio will be better than the risk-return combinations of all individual stocks. The benefit of diversification increases as the degree of correlation decreases. This creates the efficient frontier, which represents the set of portfolios that give the highest return at each level of risk, or alternatively, the lowest risk at each level of return.

The above is also extended to portfolios of assets of more than two individual securities. Even though the computation of the correlation of more than two securities becomes very complex, the principle of diversification applies to complex portfolios providing that none of the securities are perfectly positively correlated. Also, as the number of securities that are included in a portfolio increases, the benefit that is derived from diversification of adding one more asset to the portfolio decreases. In other words, the benefit that is derived from the reduction in risk by increasing the number of holdings in a portfolio is outweighed by the additional costs (transaction and monitoring costs) that are associated with increasing the number of securities. For that reason, it has been studied that individual investors do not need to hold more than 1–15 assets in order to capture 90 percent of the benefits from diversification, while for individual investors the number of shares should not exceed 50.

Limits

However, there are limits to diversification. These limits are set by the two types of risk that are embedded in asset prices. The first type of risk is called unique or unsystematic risk that refers to the effect that random events may have on individual firms. These events are unique and can be diversified away. The second type of risk is called systematic or market risk and it refers to the risk that is embedded in all securities of a single market, a single industry, or even a single country. For example, the interest rate risk is a type of systematic risk that affects all securities of one country. Thus, as long as portfolios are constructed of assets that include securities from one country, the interest rate risk is nondiversifiable and will only be embedded in the total variability of the constructed portfolios.

The way to minimize the systematic risk is to create portfolios of securities that share very few common elements. For example, one can eliminate the country-specific risk by investing in assets in a wide range of countries. Also, the stock-specific risk is diversified away by maintaining a portfolio of assets that is a combination between different types of securities, i.e., bonds, deposits, works of art, real estate. As a rule of thumb, a well-diversified portfolio should not contain more than 40 percent of its value in individual stocks and the remainder should be invested in other forms according to the investor's liquidity and risk-return preferences.

In practice the portfolio theory of diversification has found computational difficulties, since, for example, for a portfolio of 300 securities more than 45,000 need to be calculated. In addition, diversifying investment theory is difficult to apply in physical investment decisions as, in contrast with financial assets, the calculation of correlation coefficients in physical investments is not always accurate. Further, some difficulties become apparent when applying the diversification theory to a multiperiod model. Also, should firms that diversify their individual activities be rewarded for their actions? In other words, should firms evaluate the correlation of each project with its portfolio of existing projects? If so, then the value of a firm's portfolio of individual projects should be greater than the value of the sum of the parts, thus the present value principle is no longer applicable.

Fortunately, diversification is very difficult to apply in firms in such a manner. This stems from the fact that individual investors are able to diversify their investments more easily. So, investors can invest in a firm this week and pull out next week, whereas a firm would find it extremely difficult to do the same with an investment project.

Applications

The theory of investment diversification has found wide applications in the construction of indexes that are designed to track the performance of individual securities. Such specific indices are the index funds that contain all stocks that are traded in an index and can be sold as a ready-made investment portfolio to individual investors. The fund's objectives are to offer simple, diversified solutions at a low cost, yet the main disadvantages of such funds are the tracking error that results from failing to replicate the index accurately and the fact that index funds can only produce the return of the index and not outperform it.

Diversity

In contrast to the equal opportunities stance, there is a growing body of work related to the need to manage what has become known as diversity in the workplace—to be responsible for and sensitive to the different types of individuals who make up an organization. Gender is an important topic in diversity, as are race, ethnicity, class, disability, and HIV status, as well as other issues less prominent in the equal opportunities literature, such as personality, value systems, working style, religion, lifestyle, education level, and so on. As Patricia Arredondo points out, the idea of managing diversity refers to a strategic organizational approach to workforce diversity development, organizational culture change, and empowerment of the workforce. It represents a shift away from the activities and assumptions defined by affirmative action (an equal opportunities tactic involving positive discrimination) to management practices that are inclusive, reflecting the workforce diversity and it potential. Ideally it is a pragmatic approach in which participants anticipate and plan for change, do not fear human differences or perceive them as a threat, and view the workforce as a forum for individuals' growth and change in skills and performance with direct cost benefits to the organization.

Managing diversity means establishing a heterogeneous workforce to perform to its potential in an equitable work environment where no member or group of members have an advantage or a disadvantage. Managing diversity includes a process of creating and maintaining an environment that naturally allows all individuals to reach their full potential in pursuit of organizational objectives. Diversity management emphasises building specific skills, creating policies and drafting practices that get the best from every employee. It assumes a coherent environment in organizations and aims for effectiveness, productivity, and ultimately competitive advantage targeting everyone within an organization, as opposed to focusing simply on less-represented groups such as women or people of color. Through effective integration of diversity management principles in the key human resource functions of recruitment and selection, training and development, performance appraisal, and remuneration, an organization can effectively manage workforce diversity.

However, traditional organizational imperatives may drive decision makers away from an affinity toward or an awareness of diversity training initiatives. Highly bureaucratic and mechanistic organizations have traditionally thrived on sameness. The principles of management in the past were generally seen as being based on the concepts of standardization and homogeneity. According to R. M. Kanter, the desire for social certainty causes decision makers to prefer to work with individuals that they perceive to be similar, revealing an unspoken, and perhaps even unconscious, drive to maintain traditional demographics in the workplace and to accept diversity only in the shallowest of terms. Moreover, the need for control and the ways in which managers achieve control in the workplace are still seen as being based on standardization of work outcomes, work processes, or skills. However, while managers may experience a need for control, this is also accompanied by a need to perform and achieve results. Building a business case for diversity is likely to be one of the most persuasive ways of promoting and encouraging diversity across occupations and hierarchical levels.

Training

Although organizations are using a broad range of initiatives in their efforts to manage diversity, training is one of the most widely used strategies in effectively managing diversity in the workplace. Diversity training has been categorized in different ways. One perspective, according to P. Nemetz and S. Christensen, looks at four different classifications: (1) sensitivity training, (2) dissonance creation, (3) cultural awareness, and (4) legal awareness.

Several types of diversity training programs can help improve both workplace culture and customer interactions.

Sensitivity training is designed to sensitize individuals to feelings provoked by discrimination. Content tactics include separating individuals by characteristics like eye color and then arbitrarily discriminating against a group to illustrate the underlying belief that all individuals are hurt by discrimination. For example, men are separated from women, and women are empowered through role-playing to sexually harass men. This strategy is used to illustrate the belief that men victimize women.

The dissonance creation approach is based on purposely creating cognitive dissonance with the hope that the target audience will resolve inconsistencies by changing attitudes and ultimately behaviors. Tactics range from requiring an individual who exhibits initial prejudice to write an essay showing the absurdities of stereotyping to requiring an individual who shows initial prejudice to debate in favor of the idea that the dominant group is oppressive.

Cultural awareness training provides an exploration of cultural differences. Tactics range from discussing stereotypes and unintentional slights to building consensus on ways to avoid stereotyping. Cultural awareness training also separates the oppressed from the oppressive while encouraging the former to express their feelings to the latter.

Finally, legal awareness training is based on explaining discrimination laws. Content includes describing various activities that violate the law with an explanation of the consequences of the violation. Content also includes discussing unfairness and bias in laws and the injustice present in white-male dominated justice systems.

A second perspective, according to M. Gentile, identifies five categories of diversity training. These include: (1) introduction to diversity, (2) focused awareness, (3) skill building, (4) sexual or other forms of harassment, and (5) integrated diversity training.

The first category, introductory training, usually includes the presentation of demographic statistics, a brief overview of historical approaches to diversity in organizations, descriptions of distinctions between affirmative action and valuing diversity, provision for basic self-awareness building, and exercises to help individuals see ways in which they may unconsciously harbor and act upon various stereotypes. The purpose of this type of program is to begin to develop a shared definition and vocabulary around diversity, to share the organization's rationale and goals, and to create a sense of positive interest in further individual training.

The second type of training is in-depth, focused awareness development. These programs feature more individual and small group interactions. They pursue an understanding of the nature, functions, and prevalence of various stereotypes in the organizational setting. Sometimes they focus on race, gender, or particular ethnic groups. The purpose of these programs is to expand individual understanding as a means to changing behavior in relation to other employees and those in the business environment.

A third type of training is the skill building workshop. It is increasingly recognized that specific competencies and skills are necessary in order to work successfully as members of a diverse group. People who are not equipped with these skills will be less able to develop the integrating group processes that are characteristic of highly effective diverse groups. This type of training workshop is designed to teach specific communication skills such as listening across differences, conflict resolution, interviewing, and mentoring with an emphasis on the ways gender, race, culture, or other differences may affect the process.

These skills could in turn be based on the existence of some key preconditions: A shared social reality between group members; ability to "decenter" or to consider viewpoints that may differ from one's own; motivation to communicate; ability to negotiate and endorse contracts of behavior and ability to attribute difficulties appropriately. Developing people's abilities to create such preconditions might form the basis of a competence and skills based training program.

Another training technique in this category targets the workshop for specific minority groups within an organization. For example, some companies have developed programs for middle-management-level women who are trying to counteract the effects of the perceived "glass ceiling." This type of program can have a negative impact if members of the targeted group are perceived as being less prepared than others to advance within the organization or if the targeted group is perceived as getting special assistance or attention. Some organizations have avoided these problems by having members of the targeted group develop these workshops for other members as a function of a special support network.

A fourth type of training is the workshop on sexual or other forms of harassment. Such programs usually focus on communicating the legal definition of harassment and the organization's policies and practices for dealing with such occurrences. Sometimes these efforts provide discussion where conflicting feelings and concerns about the definition of harassment can be aired.

Diversity training can also be provided in the form of integrated diversity training. Such programs integrate appropriate diversity issues into the course of pre-existing and new training efforts that target specific functional skills or business goals. For example, in customer service training programs the particular challenges and opportunities of serving a diverse customer base can be introduced.

Finally, some of the goals frequently mentioned by the experts related to increasing organizational effectiveness include connecting the diversity training to the organization's strategic goals; and improving organizational culture. According to diversity experts, an organizational climate that emphasises fairness and equity and promotes trust, respect, and understanding among all employees motivates individuals to maximize their individual performance and contributions to an organization's profitability and competitive edge.

Doha Round

The Doha Round is the latest series of trade negotiations taking place within the World Trade Organization (WTO). The objective of the "round" is to further the liberalization of trade in goods and services between the 152 members of the WTO. Begun in 2001, the round has so far failed to reach agreement on controversial issues of liberalization of agricultural and manufactured goods. There are fears that failure to liberalize on a multilateral level will lead to a further regionalization of trading blocs, undermining globalization.

The Doha Round was launched at the WTO Ministerial Conference in Doha, Qatar, in December 2001. The conference came after a disastrous WTO ministerial conference in Seattle in 1999, where antiglobalization protestors disrupted the talks. There was thus a clear need to show unity and dynamism in the world trading system. Launched against the background of growing skepticism on the merits of that system for developing countries, the round was presented from the beginning as a development-oriented round. It was christened the "Doha Development Agenda" (DDA) in reference to these objectives. Fulfilling the hopes of developing countries in a manner acceptable to industrialized countries has been a constant theme in the round.

Progress on the round has been slow. This is partly a result of a wide and complex agenda that went much further than that of the preceding round—the Uruguay Round. It originally covered not only services liberalization, agricultural market access (AMA), and nonagricultural market access (NAMA), but also several "nontrade issues" including the so-called Singapore issues of investment, competition, public procurement, and trade facilitation. This heavy agenda proved difficult for developing countries to manage and, in a tense ministerial conference in Cancun in 2003, the former three themes were removed from the main agenda of negotiations, leaving only trade facilitation—an uncontroversial topic.

With the removal of the Singapore issues, the most contentious negotiating topics in the Doha Agenda are AMA and NAMA. The controversies around these issues reflect the political economy of the members of the WTO. The highest tariffs in the world trading system tend to be in agriculture in industrialized countries and in manufactured goods in the developing world, particularly in emerging markets. The key negotiating point is therefore the extent to which both will agree to reduce their tariffs in these key areas.

Within the round, developing and developed countries do not always split exactly along the lines described above. In NAMA, developing countries who wish to protect their manufacturing sectors are grouped around the G20, a group of mainly emerging nations with relatively high tariffs such as India and Brazil. In AMA, developing countries are not universally in favor of full liberalization, as some still see the need to protect their own agricultural sectors. These countries are grouped into the G33, which includes India and Indonesia. Their main objective is to secure the right to maintain their market protection through the definition of "special products" where liberalization would be limited.

Another key concern for developing countries is the issue of preference erosion. Some are concerned that extensive tariff cuts could actually work to their disadvantage. These countries, such as the Africa Caribbean and Pacific (ACP) group and the Least Developed Countries (LDCs), have extensive preferential access, with little or no tariffs for their exports to several or all industrialized markets. Their concern is that a general reduction of tariffs will erode the cost advantages that their preferences assure them. These countries are grouped together in the G90. Key products of importance in this discussion are bananas, sugar, processed fish, and clothing.

Discussions between these groups have been long and torturous. Several deadlines have already been missed. The ministerial conference in Geneva in 2008 made progress on several key points leading to optimism that the round could be concluded. However agreement was not secured on the key issue of developing countries' capacity to protect against import surges in agriculture—a major concern of the G33.

The broad lines of the agreement seem to be in place, but discussions on the numbers are the most difficult. In agriculture , there is agreement that levels of tariff cuts should vary between countries, with the EU making the highest cuts; however, the exact extent of the cuts is still at issue. The latest EU offer was for a 60 percent cut. In NAMA, there is agreement that cuts will be based on the so-called Swiss formula, an approach that results in greater cuts in higher tariff rates. The negotiations focus on the figures that decide the extent of the cuts. The latest EU offer, for example, would have left no tariff over 6 percent.

Dollar Hegemony

The U.S. dollar is the anchor currency in the international system. The dollar's hegemony depends not just on the economics of its being the major reserve currency, but also on the political condition that it is the currency of the hegemon in the international system—the United States. An economic system depends for stability on the structural/positional power of the hegemon as the leader. The hegemon has the power and capability to define the rules of the game, provide for the anchor currency, and act as the lender of last resort. It undertakes the tasks of supervision and management of the system, as this control provides it with significant economic benefits and political influence. The system continues to be stable so long as a majority of other states perceive it to be mutually beneficial. However, stability is not synonymous with equitable distribution of welfare among the states.

After World War II, the United States instituted the Bretton Woods regime as the framework for an international economy. According to the rules of this regime, a pegged exchange rate of $35 for an ounce of gold was established. This dollar-gold exchange standard collapsed in 1971 due to several reasons. First, as the United States lost its advantage in trade due to international competition, its current account deficits started to rise. The United States, however, was not interested in curbing its growth or social welfare through austerity measures.

Second, given the U.S. desire to maintain policy autonomy of expansion by exercising its privilege to print money, the peg was no longer viable. The consequence of this was that the available liquidity of currency in the system surpassed the gold reserves. Finally, with deficits on the rise in the United States, domestic inflationary pressures increased. This brought the dollar under speculative attack of investors who had lost confidence in the U.S. ability to maintain the peg, resulting in the dollar's devaluation. This galvanized countries like France to convert their dollar reserves into gold. Facing these kinds of pressures, the Nixon government found it politically expedient to rescind the U.S. commitment to the peg. The international monetary system then experienced the rise of the floating exchange rate with market exchanges determining the value of a currency.

However, even though the dollar was no longer the de jure hegemonic currency, it became the de facto hegemonic currency for several reasons. First, with the development of deep financial markets in the West, particularly the Euromarket in 1960s, the dollar had become the most traded currency. Second, the American economy provided enormous investment opportunities to the rest of the world because of its excellent regulatory institutional environment. This capital inflow from the developed and the developing world enabled the United States to finance its trade and fiscal deficits by borrowing heavily from the capital markets. It did this by selling government bonds at cheap interest rates.

Third, many countries in southeast Asia, Latin America, and the Gulf had their currencies pegged to the dollar to provide for exchange rate stability. Fourth, whenever there were windfall profits in the primary commodity market of oil, petrodollars accumulated. This provided for additional sources of liquidity in the system and countries without high rates of domestic savings, like Latin America, borrowed in hard currency at cheaper interest rates to propel growth. Since these countries had their currencies pegged to the dollar, their fortunes were tied to changes in the fortunes of the dollar. This created potential sources of financial crises as changes in U.S. interest rates and the value of the dollar created unpredictable swings in these countries' currencies and consequent capital flight. Fifth, with increasing financial crises across the world, the major emerging economies like China and India were invested in building up huge dollar reserves as a buffer against crises.

Finally, the American economy is the largest consumer economy in the world. This means that the majority of the world is dependent on exports to the United States. Consequently, major exporting economies like China are invested in keeping their currencies depreciated against the dollar to boost exports. This enables the dollar's value to be propped up by artificial measures of sterilization (buying up hard currency inflows with local currency) undertaken by these economies.

Alternatives

Over the years, two alternative currencies have emerged as contenders to the dollar—the euro and the yen. However, despite the shift in portfolio allocation by investors with changing shifts in market expectations about currency values, the dollar continues to rule for several reasons. First, Japan is dependent on the United States for strategic reasons of protection from its neighbor China. It also has huge investments in assets in the United States. Consequently, it is not in Japan's interest to allow the dollar's value to precipitate drastically (a phenomenon called "hard landing"). Second, both Japan and the EU are major trading partners of the United States, and hence, cannot afford to allow the dollar and the U.S. economy to collapse. Consequently, throughout post-1970s period, the G-7 countries' central banks have coordinated to ensure that the dollar's hegemony is maintained by propping up its value every time there is a threat of serious dollar depreciation. Third, given that the dollar represents a liquidity that cannot be parked elsewhere, most countries cannot dump their dollar reserves without significant loss of value. Finally, despite growing attempts to create currency pegs to a basket of currencies, as China has sought to do with the yuan, most countries believe that besides the dollar there is really no good alternative.

Impact

What are the consequences of dollar hegemony in terms of world welfare? Due to global interdependence of economies, other countries dependent on the U.S. economy have to bear the burden of adjustment of the spillovers of economic outcomes in the United States. Dollar hegemony enables the United States to maintain its policy autonomy, pursue inflationary policies, and externalize the burden of inflation onto others. This has often forced other countries to pursue policy austerity of high interest rates and stringent fiscal cutbacks to ensure that they can draw in capital. The curtailing of fiscal expenditure impacts distributive issues of consumption within a country. Countries have also been forced to build dollar reserves to ensure that capital flight does not affect them. This means that their gains from trade cannot be used for distributive purposes inside their countries.

A current example of the impact of dollar hegemony is the effect of an emerging recession in the U.S. economy on the rest of the world. The securitization crises, the depreciation of the dollar, and growing recession in the United States have forced countries to lower their interest rates to prevent speculative capital inflows from overwhelming the stability of their economies. This has added to the growing inflationary spiral around the world as consumers borrow and spend heavily due to the sudden increase in domestic credit. This has added to the current crises of rising food prices and emerging famines in vulnerable economies.

Dollarization

Official dollarization refers to the practice by some countries of using the U.S. dollar as their official currency. In such a system, there is no central bank, no independent monetary policy, and no independent exchange rate. By adopting the U.S. dollar, a country enjoys price stability because the job of currency production is implicitly outsourced to the United States. Moreover, the practice makes it possible for international commerce and trade to be conducted with fewer currencies.

Unofficial dollarization involves the unofficial use of a foreign currency, usually the U.S. dollar, by the residents of a country while the domestic currency still circulates alongside the foreign currency. Unofficial dollarization includes cases where holding foreign assets is legal as well as illegal. The motivation for holding foreign assets by residents is to hedge against spiraling inflation.

Proponents of dollarization argue that there are too many currencies circulating in the world today and that this can become dangerous and inefficient. All of these currencies are backed by the confidence that investors have in them. When there is too much pressure on these currencies, the monetary authorities yield to devaluation. Devaluation brings hardship to the people as a result of attendant inflation. On the other hand, dollarization results in low inflation and relatively stable interest rates.

When the focus is on the individual as a decision maker, an economic choice becomes logical. Economists argue in favor of "consumers' sovereignty" rather than a national monetary sovereignty. The question then becomes: Who should possess the power to choose what currency to use? Proponents of dollarization argue that the choice should reside with individual consumers.

The recent financial crisis in several developing countries of the world (for example, the Asian financial crisis) is an indicator of the failure of monetary management in these countries. The failure of the Argentinean currency board system is a case in point. These crises can be avoided if dollarization is adopted because the national government is removed as an issuer of currency. In most countries of the world, the central banks have performed poorly in terms of promoting low inflation, foreign exchange management, and general monetary stability.

Dollarization is not a mechanism for replacing the monopoly of a domestic monetary institution with a monopoly of a foreign monetary authority. Some scholars argue that it is an evolutionary process for selecting an appropriate currency in terms of economic strength. It gives a country the opportunity to examine several currencies from which it could abandon an inferior one for a strong one.

Another legitimate argument in favor of dollarization is based on the concept of impossible trinity. This concept is the foundation of macroeconomics of open economy. It is premised on the idea that a country cannot achieve a fixed exchange rate, free movement of capital, and an independent monetary policy at the same time. At best, a country can achieve two. A country that pursues dollarization can overcome exchange rate volatility relative to the U.S. dollar and, consequently, can avoid future currency crisis. Moreover, such a country will benefit from an increased economic integration with the U.S. economy.

There are several key arguments against dollarization. The currency of a nation is a source of national pride and sovereignty that should not be transferred to another entity. The second argument is premised on the role of a central bank in an economy. In a dollarized economy, a central bank cannot create money. Therefore, it cannot serve as a lender of last resort. Critics of dollarization argue that the banking system in any country needs a lender of last resort to guard against panics. It is also important to have a central bank with power over monetary policy. This is because a central bank is the only institution that can restrain politicians through monetary policy instruments by neutralizing negative consequences of fiscal policy.

With dollarization, a country loses the benefit of seignorage. It is a gain associated with issuing money in an economy. For example, issuing new money may reduce the value of old money as a result of inflation and consequently reduce the liability associated with old money, thus creating implicit benefits for a money-issuing government. Finally, critics argue that Panama's economic prospects, for example, have not been outstanding even though it dollarized in the early 1900s. Other nations that recently adopted dollarization include El Salvador, Ecuador, and East Timor.

Dominican Republic

The Dominican Republic is an island located at the core of the Antilles Archipelago in the Caribbean and it is the second in extension within the Greater Antilles. The Dominican economy is generally considered to be lower middle income with the majority of business being small and middle-sized enterprises (SMEs).

Sugarcane farmers in the Dominican Republic, where GNP grew 7.7 percent per year from 1996 to 2000.

About half of Dominicans live in rural areas and many are small landholders. More than three-quarters of the population have low educational attainment levels, reaching only a secondary level of education.

The country has a representative democratic system of government, yet antidemocratic and exclusivist processes take place at all levels within the government, which result in a political system that promotes corruption and irresponsibility and encourages a lack of governance. This affects the role of regulatory institutions and organizational dynamics in both the public and private sector, as well as the way business is generally conducted, as there is evidence of a lack of business ethics that affects both social and political life.

In terms of economic development, after processes of economic and political transformation in the 1970s and 1980s, the 1990s were a period of accelerated social transformation. Following a global and regional trend, the country moved toward the readaptation of its productive apparatus and commercial openness aimed at regional integration and global insertion. After an initial recession in 1990–91, the country adopted sound macroeconomic policies oriented at attracting and creating a new environment for direct foreign investment, which resulted in a decade of continual growth in the economy. For instance, the gross national product (GNP) grew speedily from 1993 to 2000, reaching 7.7 percent per year from 1996 to 2000. As a result, the rate of expansion of Dominican production sustained the highest levels in the Latin American region, widely surpassing the regional average. Similar rates have been maintained to the present. However, though there has been a notable economic growth, this was not balanced with the development of institutional reforms and policies needed to increase distributive equality, create long term sustainability, protect macroeconomic stability, and achieve consolidation of the state of law.

The primary bases of revenue are tourism and free trade zones. The main economic sectors are services (tourism and transportation), industrial production (sugar refining, pharmaceuticals, cement, light manufacturing, construction, and non-fuel minerals such as nickel, gold, and silver), and agriculture (sugarcane, coffee, cocoa, bananas, tobacco, rice, plantains, and beef). In addition, the economy relies heavily on transfers from Dominicans living abroad (US$1.6 billion).

In terms of trade, the Dominican economy is very active both with exports and imports. The exports are mainly from processing and free trade zones (FTZ) and include textiles, sugar, coffee, ferronickel, cacao, tobacco, meats, and medical supplies exported to the United States, Canada, western Europe, and South Korea. The country imports foodstuffs, petroleum, industrial raw materials, and capital goods from the United States, Japan, Germany, Venezuela, Mexico, and Colombia.

Economic activity has increased; for example, total imports in 2004 amounted to US$7.84 billion, and in 2007 they amounted to US$8.797 billion. This has been strengthened by the country's 2005 ratification and 2007 implementation of the Dominican Republic–Central America Free Trade Agreement (DR-CAFTA), which was signed by the Dominican Republic, Costa Rica, El Salvador, Guatemala, Honduras, and Nicaragua with the United States and is expected to promote substantial economic growth, especially in the FTZ industry.

As shown, the Dominican Republic maintains business and trade relationships with a variety of countries throughout the world. Regionally, though the country has not been successful in its attempt to become part of the Caribbean Community (Caricom), it signed the CARICOM–Dominican Republic Free Trade Agreement, which came into effect in 2001 and helps the country expand its commercial markets, especially encouraging special trading arrangements in agricultural products. In addition, the country is a member of the Association of Caribbean States (ACS), benefiting from the Association's special committees that focus on reinforcing regional policies in trade, transport, sustainable tourism, and natural disasters for the Caribbean Basin.

Dow Chemical

The Dow Chemical Company is an American chemical company with headquarters located in Midland, Michigan. Dow Chemical is a multinational firm that has a presence in over 175 countries. As of December 2007, the company was the second largest in the world in terms of chemical sales. From 2003 to 2007, net sales grew from nearly $33 billion to approximately $54 billion. The company employs 46,000 people worldwide. Dow Chemical operates in four major product categories: engineering and basic plastics, industrial chemicals, agricultural products, and hydrocarbons and energy. Dow subdivides the global market into five regions. These are, in order of importance (2007 sales): North America, Europe, Asia Pacific, Latin America, and India/Middle East/Africa.

Dow Chemical was founded in 1897 by Herbert H. Dow, a Canadian chemist. The company began as a start-up enterprise that commercially exploited Herbert Dow's invention of extracting bromine and chlorine from Midland's natural supply of underground brine. By 1902 Dow Chemical was producing mass quantities of bleach and potassium bromide. Facing stiff predatory pricing strategies by the British (in the bleach markets) and the Germans (in the bromide business), Dow Chemical early on established the tradition of diversifying its product line based on common process technology. By the early 1940s Dow had expanded well beyond bleach, chlorine, and the bromides and was a major producer of phenol and related products (e.g., dyestuffs), magnesium metal (extracted from seawater), agricultural chemicals, and resins and plastics (most notably, ethylcellulose and polystyrene), which were becoming one of the company's most important business areas.

World War II

Dow Chemical played an important role during World War II. And, conversely, the war established for Dow a foundation for its postwar expansion. First, the war demonstrated the strategic and commercial importance of the company's magnesium process. Most notably, its magnesium metal proved critical to the war efforts as it was needed for making strong yet lightweight parts for transportation equipment and for aircraft. Second, the war compelled the formation of Dow's important joint venture with Corning Glass (Dow Corning) to produce silicone and related products for military use. As with magnesium, the silicones would prove of important commercial importance in the postwar period. Third, the requirements of the war effort led Dow to establish its position in the great petrochemical complex of the Southwest.

By 1942 Dow had constructed and was operating its Freeport, Texas, complex to turn out products—heavy chemicals and ethylene-based synthetics—for the military. Over the next 60 years, Freeport would become Dow's largest site and "one of the largest integrated chemical manufacturing sites in the world." In 2003 this site alone produced nearly 30 billion tons of chemical products representing nearly a quarter of Dow's total output worldwide.

Fourth, because of Dow's ability to mass-produce styrene, a critical ingredient in styrene-butadiene synthetic rubber, the war introduced Dow as a major player in the synthetic rubber industry and, at the same time, gave Dow its first experience constructing and operating a plant in another country (i.e., a styrene plant in Sarnia, Ontario, Canada).

The Postwar Years

The postwar period has been one of great opportunities to expand upon the advances made during the war, but it also brought great challenges. In the 1960s and 1970s, Dow confronted a series of legal and public relations problems unprecedented for a U.S. chemical company. The issues surrounding such Dow products as Napalm and Agent Orange (both developed for the military during the Vietnam War), the Dow-Corning breast implant controversy, and the DBDC soil fumigant case have continued to plague the company through drawn-out lawsuits and a continued residue of taint to its image right up to the present day.

There were also challenges facing the U.S. chemical industry in general, and Dow in particular. In the 1980s, Dow, as other chemical companies, faced stiff competition from the major oil companies—Exxon, Shell, and British Petroleum (BP), who had integrated backwards into petrochemicals. The large refiners had access to cheap raw materials, deep pockets, and economies of scale that even the chemical companies could not easily match. In the 1990s, the U.S. chemical industry went through a general decline in profits. (except for a peak in 1995–96) due to high feedstock costs, "recession-induced low pricing," and increasing competition from both chemical and backward-integrated oil companies in different product markets.

Despite these issues and challenges, Dow has grown and expanded as a company over the last few decades. It has done so by retaining a growth strategy for most of the period, and up to the present day. Indeed, the company was willing to go heavily into debt in order to support this focus on growth. As a result, Dow is one of the larger chemical companies that has remained in the field as a competitor to the oil companies in the petrochemicals field. Dow's growth strategy hinged upon four major interrelated components.

First there was its commitment to an aggressive research and development (R&D) program. Dow of course looked for new products, as it did in its discovery of a commercial process for styrene. However, Dow Chemical concentrates mostly in the business of making basic chemical and intermediate commodities. This focus on improving economies of production (and finding cheap raw materials and feedstock) meant that Dow could successfully use a low-price strategy to gain markets and thus help to expand old markets, and find new ones for existing products.

Second, Dow has proven itself very flexible in changing its organizational structure as it outgrew older structures, and especially to facilitate internal communications and access expanding external markets. Restructuring in the 1960s and 1970s centralized the marketing function and linked R&D more closely with other departments in order to motivate employees to innovate solutions as they came across problems in their areas of expertise. By the 1980s Dow reorganized geographically to take optimal advantage of its growing international network.

Third, Dow Chemical has expanded and diversified through an increasingly robust program of strategic merger/acquisition and joint venture and partnering arrangements. Its first important joint partnership with Corning Glass brought Dow into silicone and its products. In 1960 Dow entered into the pharmaceutical industry by acquiring the drug company Allied Labs. Dow expanded its pharmaceutical business in 1981 with the purchase of Merrell Drug. Dow's 2001 acquisition of Union Carbide, while highly controversial, has propelled the company into a leading petrochemicals company. Dow's recent joint venture with Cargill to make polymers from renewable (agricultural) resources has introduced Dow into advanced materials and biorefinery products.

Dow has also been successful in forming outsourcing relationships to further optimize efficiencies. Regarding suppliers, by the 1990s Dow had contracts with 50 qualified suppliers to assure quantity and quality; this helped to improve the quality and cost structure of the company. Dow also has outsourced a large portion of its IT requirements to Accenture, which has helped the company reduce operating costs by $70 million annually while improving time to market by 10 percent.

Fourth, Dow has been successful in taking advantage of the post–World War II globalization movement. Dow established its first overseas subsidiary in Japan in 1952. But it was in Europe that Dow made its first major incursion. Dow was one of the first U.S. chemical firms "to establish a strong European manufacturing presence." Following the war, at the request of the German government, Dow took over, refurbished, and operated some of Germany's largest pre-war plants. Dow completely integrated these plants to form one, large complex. By 2000 Dow had a world-sized plant built at relatively low cost to itself and strategically located to the markets of both western and eastern Europe. In the 1960s, Dow built a large chemical complex in Terneuzen, Switzerland, and under the threat of an aggressive pricing strategy, Dow expanded its European presence as a supplier of chlorinated solvents including carbon tetrachloride and chloroform.

In the 1980s, taking advantage of the free trade and privatization policies of the Mercosur countries, Dow entered South America, and made important gains in Argentina. Here, in the late 1990s, Dow acquired the Bahia Blanca petrochemical complex and entered into a joint venture with Petrobas, Repsol, building a 450,000-ton-per-year petroleum cracker. These actions meant that Dow had strengthened its role as a leading player in Mercosur's petrochemical sector. The latter demonstrates that Dow exploited the advantages of joint ventures with local firms. These benefits included closer availability of raw materials and markets, the sharing of costs and risks, and access to expertise and contacts critical in doing business in a foreign market. For example, Dow (as did BASF) formed a strategic joint venture with Petronas in Malaysia and so expanded the company's presence in Asia.

Dow plans to continue its four-tiered growth strategy over the foreseeable future, including further acquisitions and joint ventures in its search for new technology and a growing market presence in Europe, Asia, and Latin America. The company is also incorporating into its strategy local environmental, social, and economic needs of the developing countries that it enters.

Dow Jones Index

Dow Jones Index, also known as the Dow Jones Industrial Average (DJIA), or often simply the Dow 30 Industrials, is a price-weighted average of 30 U.S. blue-chip stocks. These are shares of some of the largest and most financially strong and stable companies in the United States. As the second-oldest continuing U.S. stock market index, it remains one of the most widely reported indicators of the price performance of U.S. equities.

The index was originated by Charles Dow (1851–1902), one of the founders of Dow Jones and Company, who began publishing the daily average prices of 12 "industrial" stocks in *The Wall Street Journal* in 1896. In 1916 the index sample was increased to 20 stocks, and then in 1928 to 30 stocks, where it has remained to the current day. In 1956 the DJIA became the first stock index to be made available in real time during trading hours.

In 1884 Dow began publishing an earlier index of 11 primarily railroad stocks that was published in *Customer's Afternoon Letter,* a precursor to *The Wall Street Journal*. In 1896 the last non-railroad stock was removed from this index, which became a 20-stock average of railroad stocks. As a result of the change in its composition over the years, this index was renamed the Dow Jones Transportation Average (DJTA) in 1970. The DJTA has the distinction of being the U.S. oldest continuing stock market index. Also among the most commonly referenced Dow stock indices is the Dow Jones Utility Index (DJUA), which was established in 1929 and includes 15 large natural gas and electricity utilities. Together these three indices and their combined 65 stocks comprise the Dow Jones Composite Average. Reportedly, Dow's goal in publishing stock indices was to provide market participants measures of longer-term trends in stock prices that minimized the import of daily, random price fluctuations.

Composition

The composition of the Dow 30 is determined by the editors of *The Wall Street Journal*. Changes are infrequent and are usually driven by a change to one of the component companies, such as its acquisition or a significant change in its business. Whenever a change is required, all component stocks are reviewed. Historically, the DJIA index's composition has been less "industrial" than its name suggests. Reportedly, the editors look to include large successful companies whose shares are widely held and are not represented in the separate indices for both transportation and utility companies. In general, the composition of the DJIA index has changed to reflect the changing American economy as it has developed over the past century from the dominance of agricultural and commodity production to leadership from such sectors as technology, retail, and financial. These changes are reflected in the original and recent lists of companies included in the index.

In 1896 the DJIA originally consisted of the following 12 companies: American Cotton Oil; American Sugar; American Tobacco; Chicago Gas; Distilling & Cattle Feeding; General Electric; Laclede Gas; National Lead; North American; Tennessee Coal & Iron; U.S. Leather (preferred); and U.S. Rubber. Among these companies in the original index, only General Electric remains on the current DJIA. (However, General Electric has not been in the index continuously; it was not included from 1898 to 1899 or from 1901 to 1907.)

Currently in 2008 the Dow 30 includes the following companies: 3M Company; Alcoa Incorporated; American Express Company; American International Group, Inc.; AT&T Incorporated; Bank of America Corporation; Boeing Company; Caterpillar Incorporated; Chevron Corporation; Citigroup Incorporated; Coca-Cola Company; DuPont; ExxonMobil Corporation; General Electric Company; General Motors Corporation; Hewlett-Packard Company; The Home Depot Incorporated; Intel Corporation; International Business Machines; Johnson & Johnson; JPMorgan Chase & Company; McDonald's Corporation; Merck & Company, Incorporated; Microsoft Corporation; Pfizer Incorporated; Procter & Gamble Company; United Technologies Corporation; Verizon Communications, Inc.; Wal-Mart Stores Incorporated; and Walt Disney Company. All but two of these 30 companies are listed on the New York Stock Exchange. The two exceptions are Microsoft and Intel, which are traded on NASDAQ. Both companies, the first technology stocks in the index, were added in 1999.

Calculation

In the original calculation of the index, the 30 stock prices were summed and that sum was divided by 30. The first DJIA reported on May 26, 1896, was 40.94. The divisor of 30 has had to be adjusted frequently over the years to reflect stock splits, in which the number of shares outstanding is increased by issuing additional shares to existing shareholders, spin-offs, rights issues, and large or special cash dividends. The divisor is also adjusted when the component stocks are changed so that the average is unaffected by the change. In June 2008 the prices of the 30 stocks in the index were added and divided by a divisor of 0.122834016. The resulting number is expressed in terms of "points."

As a result of its methodology, the index gives greater weight to higher-priced stocks. For any given percentage change to a stock's price, the price change to the higher-price stock will result in a larger change to the DJIA than will the same percentage change to a lower-priced stock in the index. To determine the impact of any one stock's price change on the index, the price change is divided by the Dow divisor. For example, a $5 increase in any one stock's price would increase the DJIA by 40.7 points (5/0.122834016 = 40.70534). In the years before the financial crisis of 2008, the index had risen higher than 14,000 points. In the previous decade the index rose from 2,588 in January 1991 to 11,302 in January 2000, topping 10,000 in 1999, 10 times its 1972 level.

A computer display showing the Dow Jones Industrial Average, the second-oldest continuing U.S. stock market index.

Criticisms and Theories

Although the Dow 30 is criticized as being too small a sample to be representative of the movement of the larger market, it continues to be the most closely watched and reported U.S. stock market index, even exceeding the coverage given to the S&P 500 Index and the even larger NASDAQ Composite, which includes over 3000 stocks. As an indicator of the price movement of large cap stocks, the Dow 30 has been found to be highly correlated with the much broader S&P 500. Other criticisms of the Dow include the imprecision of the selection criteria for inclusion in the index and the regular necessity of the recalculation of the divisor. Regardless, with its long history and regular publication and promotion in *The Wall Street Journal*, the Dow has stood the test of time across generations of market participants as the principal barometer of the broad price performance of U.S. equities for over 100 years.

As a broad index of common stock price trends, the Dow Index has been the basis for a number of stock market trading strategies. The most famous is the Dow Theory, a form of technical analysis developed by Charles Dow's successor as editor of *The Wall Street Journal*, William Peter Hamilton. Formally named in Charles

Rhea's 1932 *Dow Theory*, this market timing strategy seeks to offer buy or sell signals based on primary trends in the market as represented by the Dow Jones Industrial and Transportation Averages. This market timing strategy attempts to differentiate primary trends, so-called bull or bear markets that are believed to alternate regularly, from both secondary market corrections that may persist for a few months and tertiary daily random price fluctuations that can be ignored.

Another trading strategy based on the Dow Index is the so-called Dow 10 or Dogs of the Dow that involves investing equal amounts in the 10 stocks in the Dow 30 that have the highest dividend yields (the ratio of the annual dividends paid on a stock to the current market price of the stock) in any given year and then repeating the process each year as the composition of the Dow 10 changes. Debate continues on the ability of such trading strategies based on movements in the Dow Index to generate consistently high returns.

Downstream

The term *downstream* has historically been used in the natural resources and chemicals industries, and specifically in the oil and gas industry, to refer to activities that relate to the processing of crude oil and natural gas or related petroleum products to the point where the feedstock is broken down and purified into a series of products such as aviation gas (avgas) or bitumen for roads, or petrol/gasoline for cars and trucks, or even when natural gas is used as a source material for electricity generation.

The origins are in the sense of location of the deposition of minerals in a streambed, e.g., gold-panning activities (so even older than petroleum exploration and production) where heavy minerals were deposited "down stream," i.e., away from the water's source but originated "upstream." It is, however, also used today to refer to bioprocesses where it refers to the purification and quality control processes for new biological materials, data transfer speeds between host servers and clients analogous to downloading, and as a term for later activities or later elements of sequencing in manufacturing and production processes.

Petrochemical products, for example bitumen, were found to have been used in Roman camps such as Uttoxeter in the United Kingdom, but until the late 19th century, interest in downstream products was based around their roles as lubricants. Much of industrial development was coal based with interest growing in petroleum, though gas was almost an inconvenience. With the dwindling of black-coal mining, which is associated with high health and safety risks, in many countries, oil and gas-based chemical production has taken over and many downstream products are in everyday use.

While upstream companies may just concentrate on the exploration and production of oil and gas, an activity still possible on a small scale of a single oil well and with limited capital, downstream activities are large scale and hugely capital intensive. Plant design, scale, and scope (integration) are all important drivers for firms to capture as much of the added value chain for bulk low-margin products such as olefin precursors used in polymers and plastics. Many of the larger companies adopted an integrated strategy from upstream to downstream activities, a strategy still in use by national oil companies such as Petrobras and

Petronas. Indeed, ExxonMobil began life as Standard Oil of Ohio in the oil refining business—the Standard Oil companies were a cartel controlling 85 percent of the United States' oil industry and were then split into a number of companies that form the precursors of today's Western supermajors.

Downstream petrochemical activities are often split into self-explanatory areas such as bulk chemicals, fine chemicals, or fertilizers, many categories of which are traded as commodities on world markets. Key success determinants are access to cheap feedstock (upstream-generated oil and gas of the optimal quality and chemical constitution for the plants in question); other allied input costs include cheap energy and skilled labor. Plant set-up costs are high, technology is heavily protected, and there are limited numbers of world-class suppliers. However, it is the opportunity to capture added value within resource-owning host government countries that is attractive, with the result that many major downstream activities are now located closer to production sites or to major users. An example of this trend would be Saudi Arabia's development plans for further petrochemical processing and product delivery.

This drift away from Western Europe and the United States has also been affected by the consequences of plant closures in the former Soviet Union and Eastern bloc as a result of failure to meet European Community safety and health standards and also environmental pressures in the West for better emissions management and enhanced ecological expectations. This trend is also affected by events that became international incidents when systems failed and serious accidents occurred. One such event—the explosion at the Bhopal plant in India in 1984 with serious loss of life, injury, and ongoing contamination issues—focused international opinion on foreign company investments in this sector. Older plants are much more expensive to adapt to modern standards, and secondhand plants from country to country are not always as attractive a cost option as they initially appear, leaving many firms with expensive and sometimes technically challenging issues around decommissioning old plants but also facing increasingly urgent claims from a wider universe of stakeholders than in the days when the plant was the major employer and stakeholder groups felt less able to speak out about problems.

Dumping

Dumping is a predatory price practice generally used only in the context of international trade law as international price discrimination, where a company exports a product at a lower price than the price it normally charges on its domestic market or at a price that is below its own costs of production. In this case, the product is considered to be a dumped product.

In general, one can define dumping as the act of selling products in a foreign market at prices below the normal value in the country of the exporter (i.e., the comparable price for the like product consumed in the exporting country or in third countries as the case may be, in the ordinary course of trade), for the purpose of injuring competitors of the importing country, thus gaining market share and securing a monopoly in this market.

Under World Trade Organization (WTO) rules (Agreement on the Implementation of Article

VI—Anti-Dumping Agreement—of the General Agreement on Tariffs and Trade 1994 [GATT 1994]), dumping is discouraged and countries are authorized to adopt anti-dumping measures, when dumping and material injury resulting from it has occurred to the domestic industry producing the like product or one product that has mainly the same characteristics of the imported dumped product. All WTO Members have been required to bring their laws into conformity with the Anti-Dumping Agreement. In fact, one can argue that one of the major achievements of the Anti-Dumping Agreement has been the establishment of relevant rules, at the international level, governing the determination of dumping, the initiation and conduct of dumping investigations, the imposition of anti-dumping and provisional measures, and the duration and review of these measures.

Looking at dumping practices, a number of questions may arise, such as: Why do companies practice dumping? What are the effects of dumping? How can you identify dumping? When can anti-dumping measures be taken? The answer to the first question is simple. In a competitive global market where import duties are reduced, companies may intend to increase their market share, driving producers from other countries out of the market and thus securing a monopoly. Regarding the effects of dumping practice, the most relevant one is that it disturbs the market that receives dumped products and may drive local producers out of business. There is a large body of literature discussing the conditions that facilitate the practice of dumping by companies.

One identifies dumping by comparing prices in the export and the import markets. As simple as this fair comparison of prices may be at first glance, this procedure is very complex and requires an investigation conducted by the importing country to determine the normal value price at the exporting market and the appropriate price in the domestic market. For this purpose, prices are compared to those transactions that are at the same level, in general at factory level, and as close as possible to the same time of the sales transaction at stake.

Also, discriminatory price by itself is not sufficient to authorize anti-dumping measures, according to the Anti-Dumping Agreement. These measures can only be applied when dumped exported products cause or threaten damage to the domestic industry of the importing, like-product country and a material injury results therefrom. The basic requirements for determination of injury are the volume and price effects of dumped imports and the impact of dumped imports on the domestic industry.

Anti-dumping measures may take two different forms: Anti-dumping duties or price undertakings offered to exporters to avoid anti-dumping duties. Anti-dumping measures are based on a detailed investigation conducted by the import country. The investigation has to evaluate all relevant facts, not limited to economic aspects, that may prove that dumped price and material injury occurred therefrom, such as: Significant increase in dumped import products, price undercutting by dumped imports compared to the price of like product of the importing country, significant increase of volume and price effects of dumped products, actual or potential declines in sales of like products in the importing country, increase of market share by dumping producer, actual or potential effects on cash flow, inventories, employment, and wages of importing country, significant margins of dumping and other factors that may be deemed relevant. Thus, anti-dumping measures can be imposed by the importing country only after the investigation has determined that the dumping is occurring, the domestic industry is suffering material injury and, last but not least, there is a causal link between the two: Dumping price and injury.

Factors other than dumped products that may be causing injury to the domestic industry have to be excluded by the investigation in order to establish the causal link between dumping products and material injury. Provisional anti-dumping measures may be determined by the importing country as long as a preliminary determination of dumping, injury, and causality has been duly established and after initiation of the investigation.

A country's failure to respect the requirements of the Anti-Dumping Agreement can be taken to the WTO Dispute Settlement Body and may be the basis for invalidation of such anti-dumping measures. Hence, with the WTO rules, dumping has been successfully discouraged, yet dumping practices still remain.

Dutch East India Company

In the mid-to-late 16th century, European enterprises began to reassert a time-honored interest in the potential rewards offered by long-distance trade. Among them was the United East India Company, or Verenigde Oost-Indische Compagnie. The VOC, as it is often referred to, developed over the next two centuries into an organization so large and powerful that it is considered to be the world's first-ever multinational corporation.

The VOC was established as a charter company in 1602 by the Dutch parliament, the States-General of the Netherlands, from a collection of smaller companies. At the time, European economy and society, especially in England and Holland, were undergoing rapid change through the growth of the merchant middle class that preferred trade rather than land as the method of income. Within that was another economic transformation: Bills of exchange emerged as a favored currency for business transactions, which, combined with the opening of banks in large cities and the first waves of colonialism, led businessmen to new concepts of investing their capital.

The Dutch had been one of the leaders in creating a structure of modern colonialism that involved merchant businessmen joining with their home states on the formation of monopolistic, imperialistic companies. One manner of effectively accomplishing such an outcome, they discovered, was to raise capital for ongoing ventures by pooling individual assets into a single company. In return, the individual investor would receive transferable shares of stock in the company. Then, at the point in time at which the venture turned a profit, the company would divide and disburse the profit based on the proportion of shares held by the investor. It was the VOC that became the first-ever company to begin—and benefit from—this practice of limited liability.

From the outset, the VOC turned a profit from its ventures and did so largely by buying low, selling high, and trading favorably in all manner of commodities across the Asian continent. The capacity to do so systematically began with the company directors, the Seventeen Gentlemen, dispatching a few VOC fleets each year to the hub outpost in Batavia (present-day Jakarta, Indonesia). These voyages had a tendency to last anywhere from seven to nine months in each direction, as the fleet sailed to Batavia and back via the Cape of Good Hope. When the fleet reached Batavia and unloaded its cargo of tradable goods and precious metals, servants, and instructions to the colonial High Indies Government, agents of the colonial government would in turn oversee the distribution of cargo throughout the commercial hierarchy and local geography.

From there, VOC merchants transported the imported goods, metals, and people to regions including India, Persia, Japan, and, later, China. The effectiveness of the land-based operation—and the monopoly itself—was settled as much in various collection posts along the trading routes as in maintaining coercive or inequitable relationships with local populations. Through whatever means, the commodities, once acquired, would be delivered to Batavia for shipment to the Netherlands on a returning fleet. Upon arrival, the cargo would be brought to a VOC warehouse until the company saw fit to release the goods to the European market through auction. The resultant profit was then used to provide dividends to shareholders and fees to directors, and to fund existing and future company operations.

As an additional part of their business, the VOC financed voyages such as those on which Henry Hudson was sent in the early 1600s to explore and discover a more efficient route to India via Greenland. In any case, the sheer magnitude and force of the overall operation—geographically, economically, organizationally, politically, and militarily—was at once the basic element in the company's early ability to reduce its risk and also precisely what led to a considerable amount of uncertainty at even the minutest step in their business processes. As time went on, for instance, the Seventeen Gentlemen experienced difficulty in obtaining accurate information about goings-on in Batavia while also mismanaging the balance of better incentives and harsher sanctions to their many agents. But these relatively internal hindrances began to emerge in larger numbers around the same time as fiercely increasing external competition, most notably from the British East India Company that had gained its footing by the mid-to-late 17th century.

By the end of the 17th century and the beginning of the next one, the centralized authority within the VOC began to seriously break down. Some conveniently-situated VOC agents found power in their positions, for these agents were situated in manners that would have allowed them to direct VOC resources through any channels they perceived to be beneficial. That is, the agents eventually recognized that they were effectively positioned to act as principals, which meant they could selectively become direct competitors of VOC principals should they so choose. Many acted on the opportunity in the interest of greater personal gain and, though the formal hierarchy remained in place, the authority of VOC principals withered away until the company was dissolved on December 31, 1795.

Duty

A duty is a tax on goods imported into a country, levied by the government and paid by the purchaser. Duties are commonly called tariffs. Duties vary by country of origin, country of import, and product type. Duties are usually levied as a fixed rate per unit of good (called "specific tariffs") or as a percentage of the value of the good (called "ad valorem tariffs"). If the duty is calculated as both a rate per unit and a percentage of the good's value, it is called a "compound duty."

Duties can be distinguished by where they are levied. Most duties are "import tariffs," which are those levied as a good enters the destination country. If the duty is levied by the country of origin as it is exported, it is called an "export tariff." For example, in 2004, China imposed an export tariff on 74 textile products to promote the use of these textiles within the country. Duties can also be levied by countries through which a good passes; these are called "transit tariffs." Governments also levy duties on goods manufactured and sold within their country. For example, excise duties are commonly applied to alcoholic beverages, tobacco products, and fuel products such as gasoline, electricity, and coal.

Governments have several reasons to impose duties on products. First, duties act as indirect taxes on the consumption or the use of certain products. Duties raise the prices of imported goods, making them less competitive within the market of the importing country. As the price of these products increases, the demand decreases. By controlling price and demand, governments use duties to achieve the correct balance between supply and demand. Second, governments use duties to increase the cost of the good in an attempt to reduce consumption and importation of that good. In turn, these duties protect domestic industries producing the product by making imported goods more expensive than local. Also, by controlling the market for certain products, duties protect the cultural identity of the domestic country.

Third, duties raise revenues for the governments. Often, this revenue is used to pay for the enforcement of government regulations controlling the product and related industries. A government can also gain an economic advantage by collecting revenue from a good controlled by that country or in abundance in the country. Fourth, governments often have political motives for imposing duties. In the past, duties have been used to penalize the county of origin by effectively reducing their exports.

Lastly, duties can also be a tax to reduce the consumption of luxury (high-priced goods such as a boat) or socially forbidden goods (such as alcohol and tobacco). The efficacy of these duties is limited and some argue that they increase the likelihood of smuggling and the use of black markets. In response, some governments provide limited provisions for personal use, which has spawned the creation and growth of duty-free shops, and ports allowed personal purchase of a limited number of goods in the late 20th century.

Information about the duty amount each country levies is available from the U.S. Department of Commerce's International Trade Administration. The agency manages a Web site, www.export.gov, in collaboration with the 19 federal government agencies that provide export services. Duties are assessed using the Harmonized Commodity Description and Coding System (or Harmonized System), which is an internationally standardized system of commodity nomenclature and categorization.

DZ Bank

The DZ Bank, or to give its full name, the Deutsche Zentralgenossenschaftbank (or German Central Cooperative Bank), is based in Frankfurt, Germany, with headquarters in the DZ Bank Tower; as a major commercial bank, it is one of the largest in Germany. In addition to having its own customers, the DZ Bank AG works alongside WGZ-Bank, which controls the administration for some 1,400 cooperative banks. This represents about 75 percent of all the Volksbanks and the Raiffeisenbanks in Germany and also in neighboring Austria. In some ways the history of the bank is not dissimilar to the Trustee Savings Bank in Britain, which brought together a loose "federation" of savings institutions and is now a part of Lloyds TSB Group.

The origins of the bank lie in the establishment of a range of loan institutions known as the Volksbanken, which were founded and promoted by Hermann Schulze-Delitzsch (1808–83), a politician and the founder of the commercial cooperative system in an effort to encourage thrift and saving among the urban lower middle class and also the working class. Soon after this, Friedrich Wilhelm Raiffeisen (1818–88) became heavily involved in the expansion of the rural cooperative loan associations that led to the establishment of what became known as the Raiffeisenbanks after the man most associated with the promotion of them. However, it was Wilhelm Haas (1839–1913) who, in 1883, established the Landwirtschaftliche Genossenschaftsbank AG in Darmstadt, in the state of Hesse, in the west of Germany, and the Preußische Zentralgenossenschaftskasse, which operated in Berlin to help encourage savings in the German capital.

This myriad of structures led to the creation of a three-tier banking system that was to lead to many problems in the 1920s, but also allowed the various tiers to help the others at times of major crisis. The cooperative movement managed to survive the Great Inflation of 1923; to strengthen the system, the Frankfurt Cooperative Pact of 1929 resulted in the Preußenkasse becoming the central credit institution for the entire rural cooperative system in Germany. By the outbreak of World War II in 1939, the bank had been renamed the Deutsche Zentralgenossenschaftskasse and helped provide stability for the entire Volksbanken system.

The system of tiers of banks continued, but in 1972 the Federal Association of German Cooperative Banks was established and there was a merger between the Volksbanken and the Raiffeisenbanken. Three years later the DG Bank was established to bring these cooperative banks together in a state-owned corporation. In 1975 the bank was restructured, and in 1985 it slowly eroded the three-tier system. In 2000, the DG Bank was eager to expand after a bad banking year in which its risky loans quadrupled, with problems arising from rural credit over mad cow disease and foot-and-mouth disease. Finally on June 24, 2001, the DG Bank and the GZ Bank merged to form the DZ Bank, which was at that time the sixth-largest bank in Germany; the merger was completed in September 2001.

The structure of the DZ Bank remains complicated, as it controls some 1,250 local cooperative banks and services some 30 million customers. The DZ Bank includes Bausparkasse Schwäbisch Hall, DG HYP, DZ Bank International, DZ Privatbank Schweiz, R+V Versicherung, TeamBank, Union Investment Group, and VR Leasing. As with other banking institutions, the DZ Bank Group also is involved in insurance, arranging reinsurance, and the provision of various levels of financial services to individuals and businesses. The DZ Bank also has established branches outside Germany with offices in the Cayman Islands, Hong Kong, London, Mexico City, Milan, New York, Sao Paulo, and Singapore, as well as operating subsidiaries in Hungary, the Irish Republic, Luxembourg, and Poland; and the DZ Bank International SA in Spain and the DZ Privatbank Schweiz in Switzerland. Its representatives have branches in Beijing and Shanghai, Istanbul, Moscow, Mumbai, and Tokyo. It also operates through other parts of western Europe through alliances and arrangements with banks in Belgium, France, the Netherlands, and other countries.

EADS

The European Aeronautic Defence and Space Company (EADS N.V.) is the leading European company for aeronautic, defense, and aerospace services. EADS was set up in 2000 as a public limited-liability company under Dutch law, and it came from the merger of DaimlerChrysler Aerospace (Germany), Aerospatiale Matra (France), and CASA (Spain). EADS is the owner of Airbus, an aircraft manufacturer, which represents the core business of the company. EADS is also a world leader in the production of helicopters, space launch vehicles, missiles, military aircraft, satellite, defense systems, and electronics.

EADS is legally seated in Amsterdam (Netherlands), with the company's head offices located in Germany (Ottobrunn and Munich) and France (Paris), and locations and offices distributed around five continents. On December 31, 2007, the number of employees was 116,493.

Its shareholding structure as of June 30, 2008, is as follows: Sogeade (French company formed by Lagardère and the French state) owns 25 percent of the shares, German Daimler controls 23 percent of the shares, and the Spanish state company SEPI is the owner of 5.5 percent of the capital of the company. These companies together control 53 percent of EADS, and they have established a contractual partnership in order to run the company. The 47 percent of the remaining shares represent the free float of the company. EADS is listed in the stock exchanges of the countries of origin of the main shareholders: the Paris, Frankfurt, and Madrid Stock Exchanges.

The company is structured in five divisions, each of them responsible for one business unit: Airbus, Military Transport Aircraft, Eurocopter, Defence & Security, and Astrium. The aircraft manufacturer Airbus is a fully owned subsidiary of EADS, in charge of the production of aircraft. The headquarters of the company are located in the French city of Toulouse. The history of Airbus, from its origins to today, parallels that of European economic and political integration, with moves forward, periods of stagnation, and slight backward steps.

In 1967, the United Kingdom, France, and Germany signed a memorandum of understanding to launch a new European aircraft that was due to reduce the dependence of European airlines on American aircraft and which could eventually compete worldwide with American Boeing, who was at that time the major manufacturer able to produce commercial aircraft on a profitable and sustainable basis. The final agreement

French, German, and Spanish companies control 53 percent of EADS, whose Airbus division competes directly with Boeing.

(1969) was ratified only by the French and German ministers, though it also involved the British and the Dutch. Other countries, such as Spain, entered the consortium in subsequent years.

From its early stages Airbus has striven to seize the leadership of aircraft manufacturing from American Boeing. This commercial battle has been one of the most interesting business issues in the aviation industry of last quarter of the 20th century, with success for the Europeans in the last years, although this situation could be reversed.

At present Airbus manufactures five families of aircraft: A300/A310, A320, A330/A340, A350, and the largest passenger aircraft in the world, the Airbus A380. The final launch of Airbus A380 was preceded by several delays with regard to scheduled delivery dates, which caused an increase in costs due to compensations to clients, and gave rise to a financial scandal involving top management and shareholders. These were suspicious of executing trades before the delay of the Airbus A380 was announced to the market in June 2006.

The Military Transport Aircraft division is in charge of the production of the A400M, a military air transport developed at the request of eight European NATO members. First delivery of the plane is due in 2010. Eurocopter is the world's largest helicopter producer of both civil and military aircrafts. The Defence & Security division provides military aircraft, airborne weapons and defense systems, and electronics. Its most renowned product is the combat aircraft Eurofighter.

Astrium is the company providing space services and products, among which are the Ariane launchers, used in space transport, and the satellite navigation system, Galileo, which is destined to compete with American GPS.

According to company financial statements, the EADS group reported in 2007 a total revenue of 39,123 million euros (US$58,685 million, approximately), which was allocated among its divisions as follows: Airbus, 64 percent; Military Transport Aircraft, 3 percent; Eurocopter, 11 percent; Defence & Security, 14 percent; Astrium, 9 percent. The company in 2007 lost 33 million euros mainly due to the unfavorable euro/dollar movements, the negative impact of the revised delivery schedule for the A400M, and the costs of the new A350.

Earnings Management

Earnings management is an accounting process whereby managers manipulate reported earnings to obtain some private gain. As an indicator of opportunistic managerial behavior, investors and regulators are both concerned with the deliberate use of generally accepted accounting procedures to arrive at a desired level of reported earnings. However, the term *earnings management* now has a wider connotation and embraces every kind of striving in earnings manipulation. The purpose may be to increase management's compensation, or to meet earnings forecasts, but employment practices such as "revolving door," where a company hires senior finance executives such as a chief financial officer (CFO) or controller from its current external audit firm are also studied under the canopy of earnings management. The practice is also associated with managers using their discretion in financial reporting to smooth earnings, to reduce the likelihood of violating lending agreements, and to window-dress financial statements prior to initial public offerings (IPOs).

While earnings management is used to provide private benefits to managers, it is the firm that bears the cost of conducting it. Traditional literature has thus focused on investigating the nature and significance of unexpected accruals. More recent work has instead looked at the distribution of reported earnings for abnormal discontinuities such as declines in earnings. There are many interesting examples of how earnings are manipulated upward by changes in current asset and liability items such as accounts receivable and payable. These include bringing forward credit sales or deferring recognition of expenses. Managers may report accruals that defer income when the earnings target in their bonus plan is not met. When firms cap bonuses, managers may also defer income when that cap is reached. Other accrual options or accounting method choices that are susceptible to abuses of management's reporting judgment include banks' use of loan loss provisions, insurers' use of claim loss reserves to meet regulatory requirements, and IPO firms' use of bad debt provisions or income-increasing depreciation policies to increase the offer price.

Managers are compensated on the basis that they will act in the interest of firm owners. There are a large number of studies that find that managers use incentive pay plans to increase their payouts. One particular example is earnings-based bonus awards. Managers maximize the value of their bonus award by increasing (or decreasing) reported earnings. In some situations, payouts from a bonus pay plan are made only when earnings exceed a specified threshold or "hurdle" rate. Depending upon the total cash flows from operations and nondiscretionary accruals, managers then have the incentive to select the level of discretionary accruals that maximizes the expected value of their bonus award.

Weak corporate governance practices are also associated with managers' incentives to use discretionary accruals to maximize their compensation. This is the case when manager compensation is tied to stock price performance through options. Chief executive officers (CEOs) and top executives can then profitably exercise their stock options by exaggerating firm earnings that support higher stock prices. When job security is a paramount concern, managers could engage in smoothing earnings, thereby reducing the likelihood of dismissal. Managers may also attempt to develop a favorable reputation of their competence by managing earnings that show a steady growth in firm performance.

Capital market environments are particularly ripe settings for earnings management. Managers may be tempted to avoid reporting losses or reporting an earnings decline in the midst of a business downturn. To reduce earnings fluctuations, they will add or remove cash from reserve accounts. Consequently, they will keep the figures that match a predetermined target and that also meet market expectations. Market expectations are generated when investors and financial analysts use accounting and market signals of performance. If there is a gap between firm performance and investors' or analysts' forecasts, managers may try to smooth earnings to meet their expectations.

Changes in corporate control such as management buyouts and IPOs are also the likely settings in which managers exercise accounting discretion to paint a favorable picture. Valuations in management buyouts involve earnings information and managers of buyout firms may have an incentive to "understate" them. Managers may "overstate" or inflate earnings using income, increasing abnormal accruals in periods prior to equity offers or merger proposals. However, empirical research has frequently noted that firms with such unusually high accruals perform relatively poorly after their flotation.

There is some evidence to suggest that at least in some situations investors see through earnings management. Construction of reputational rankings on the basis of the extent of earnings management and the higher numbers of class action suits seen in recent years against individual company managers and directors of fraudulent corporations suggest that investors and other stakeholders are aware of suspected incidences of earnings management. Investor activism on these lines inevitably increases the cost of earnings management. Moreover, any suspicion of earnings management is likely to result in significant stock price declines, as when earnings management prior to equity issues impacts share prices, which may ultimately put the future of the firm in jeopardy.

Earnings Quality

Generally, earnings quality is the degree to which earnings (also known as net income) accurately reflect the economic performance of an enterprise for the particular period of time to which the earnings apply. Earnings quality (also known as quality of earnings*)* is also a measure of the usefulness of the earnings number. It is reasonable to assume that a more accurate report of a firm's performance would be more useful than a less accurate report. Earnings that can be sustained—expected in the future—are more useful, and hence of higher quality, than those that appear transitory. The real debate is about the specific factors that influence earnings quality and how we can measure earnings quality.

Measures of earnings quality may include (1) the number of estimates embedded in the earnings calculation, (2) the choices in accounting methods, (3) significant changes in discretionary expenditures, (4) the relationship between cash from operations and earnings, and (5) the adequacy of disclosure and degree of transparency in the financial statements.

The calculation of earnings is fraught with estimates. For example, the useful lives of assets and the assets' salvage values must be estimated to calculate depreciation expense. All else equal, a firm with more long-term assets would have lower earnings quality than a firm with few long-term assets because the former would have many opportunities to influence the level of depreciation expense with these estimates. Management judgments create opportunities for errors. In general, more estimates involved in the calculation of earnings suggest lower earnings quality.

Firms must choose the appropriate method of accounting for certain transactions, and these choices can influence the quality of earnings. For example, under U.S. generally accepted accounting principles, a firm may use FIFO (first-in, first-out) or LIFO (last-in, first-out) for the calculation of cost of sales. If the cost of the inventory has been rising, LIFO may result in higher earnings quality because the more recent costs will be matched with the period's sales. That means the resulting earnings amount may be more useful in predicting the future than earnings calculated using FIFO costs, which match old inventory costs with the period's sales. On the other hand, a firm's earnings quality could be reduced if the firm liquidated old LIFO layers, which would result in the inclusion of illusory profits in the earnings calculation. This example shows how difficult it is to measure the quality of a firm's earnings, even on a single dimension like the cost of sales.

A reduction in expenditures on research and development (R&D) or on maintenance could have a positive effect on the size of earnings, but in some cases it could mean a reduction in earnings quality. Any reduction in discretionary expenditures should be investigated to see whether the firm is increasing its efficiency (which would increase earnings quality) or simply trying to keep earnings high while sacrificing maintenance and R&D.

Because earnings are calculated using accrual-basis accounting, we know that earnings are not the same as cash. However, even with accruals and deferrals for such items as credit sales or credit purchases, eventually firms are interested in generating cash from the operations of the firm. Some people view earnings as higher quality when there is a strong relationship over time between elements in the calculation of earnings and elements in the calculation of cash from operations. Suppose, for example, that a firm's net sales revenue was always larger than its cash collected from customers. This may signal a pattern of underestimating uncollectible accounts, which reduces earnings quality. Overall, a positive correlation between earnings and cash from operations is often seen as an indication of higher earnings quality.

The more the users of financial statements know about the financial transactions and accounting choices made by a firm, the more useful the information is. When it is difficult to understand a firm's financial statements (as in the case of Enron, for example), the quality of the earnings may be called into question. In general, disclosure and transparency in the financial reports are positively associated with earnings quality.

There is no universally accepted definition of earnings quality. Conceptually, there is some agreement that earnings quality is associated with accurate representation of economic events and also associated with usefulness. However, measuring the quality of any specific earnings number is complicated and difficult.

Eastern Europe

Economic conditions in eastern Europe have varied considerably since early modern times, and the region has been devastated by a number of wars: the War of Polish Succession, the Napoleonic Wars, World War I, and World War II. During these conflicts, the boundaries of many countries changed, altering the nature of inter-country trade.

Historically, the vast majority of the people in eastern Europe—as elsewhere in the world—were involved in agriculture, although traders did operate along land routes of commerce and along rivers. A considerable part of eastern Europe was never occupied by the Romans, but archaeologists have discovered evidence of extensive trade with parts of the Roman Empire. In medieval times, traders along the Baltic Sea started to establish what became known as the Hanseatic League. Its origin goes back to 1159, when Duke Henry the Lion of Saxony rebuilt the town of Lübeck. Other ports soon became associated with Lübeck, and it was not long before a trading agreement tied the various ports together. In an account of a storm in the Baltic Sea in 1351, it was recorded that there were 61 English ships taking refuge in the port of Danzig alone, giving some idea of the trade even at that early stage.

With the start of the Agricultural Revolution, and later the Industrial Revolution, there was great interest in the minerals in eastern Europe, with Frederick the Great annexing Silesia in 1740 in order to get control of the iron ore there. However, developments in eastern Europe during the Industrial Revolution badly lagged behind western Europe, as can be seen by the mission of the Swedish businessman and industrial spy Reinhold Rücker Angerstein (1718–60), who took little interest in eastern Europe. And it was to western Europe that Peter the Great had looked when he sought to build up the Russian economy.

Trade between countries in eastern Europe continued to increase during the 18th and 19th centuries. By the start of the 20th century, Russian businesses tended to dominate eastern Europe—indeed, the Russian Empire then covered more of eastern Europe than at any stage other stage in history. The other eastern European countries, as they became independent—Greece in 1821, Romania in 1859 (as Wallachia and Moldavia), Serbia in 1867, Bulgaria in 1878, Albania in 1912—became heavily reliant on German and Russian business expertise and technology as they sought to erode the previously heavy Turkish economic influence. The railway network helped tie the economies of these countries closer together.

World War I and II

The fighting in World War I left the region devastated, but also led to the creation of new countries. Poland was re-created and was given access to the sea along the Polish Corridor, in the hope of making the country more viable and less susceptible to attack from Germany. The formerly German city of Danzig (now Gdansk) was turned into a free port. The Austro-Hungarian Empire was split to form Austria, Czechoslovakia, Hungary, and parts were given to Poland; other parts of Serbia became the Kingdom of the Serbs, Croats, and Slovenes (and from 1929, the Kingdom of Yugoslavia).

During the 1920s and the 1930s, the countries of eastern Europe started improving their trade, with telegraph and then telephone lines connecting the various capitals. To connect Istanbul (formerly Constantinople) with Berlin, lines ran through Sofia, Bucharest, and Budapest. However, during this interwar period, the isolation of the Soviet Union meant that many of the countries of eastern Europe started closer economic interactions with each other, and the newly independent Baltic States of Lithuania, Latvia, Estonia, and Finland started trading with each other, with Sweden, and with Germany. German companies were also involved in investing in these countries, and in the Soviet Union. There were German and British capitalists who used Latvia as a point of entry into the Soviet Union as some trade links were expanded in the mid-1930s. Romania managed to develop its economy through its oil, with the Ploesti Oilfields being important in the German war effort.

During World War II, the whole of eastern Europe was, once again, devastated by war, and after the war, Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Romania, and Yugoslavia all had communist governments with centrally planned economies dominated by state corporations. They were all part of COMECON, as was the Soviet Union, which meant that trade between all these countries increased, but at the expense of any trade links that had been established with western Europe. Some foreign companies did operate in eastern Europe during the Cold War, but these were heavily restricted in their scope and largely involved in selling or buying products to and from eastern Europe, rather than any significant investment in either country's economies. There were exceptions in Yugoslavia, especially when Australian industrialist Lang Hancock managed to establish a barter deal with Romanian communist leader Nicolai Ceaucescu. There was also the controversial gas pipeline that took gas from the Soviet Union to Poland, East Germany, and Czechoslovakia, and from there to western Europe, enabling the Soviet Union to earn desperately needed hard currency.

The Fall of Communism

The fall of communism in 1989 and the collapse of the Soviet Union transformed eastern Europe considerably. All the countries had had their economies dominated by large state corporations, many of which were inefficient and wasteful. Some, like the Gdansk shipyards, had to be phased out, in spite of their role in ending communist rule in Poland. The coal miners from the Jiu Valley in Romania flexed their muscle in ensuring that former communist Ion Iliescu managed to keep in power in 1990. The industrial workers of Ukraine were able to exert their political power from time to time.

The end of communism usually is associated with non-communist governments coming to power in eastern Europe. Some managed to rule well, but many others were stymied by their own inexperience and by the communist bureaucrats, many of whom remained in their old positions. Others were involved in fraud or allowed fraudulent operators to operate schemes that would not have been allowed in western Europe. Taking advantage of the now unregulated economic climate in eastern Europe, and the large savings that many people had accumulated during the period of communist rule, inflation devalued the savings of many people, and some "pyramid" investment institutions managed to defraud people out of what was left of their money. Albania was the worst hit, and in the economic crisis of 1996, large numbers of people lost their life savings in a matter of months, causing rioting in parts of the country. There have also been problems over restitution for property seized by the Nazis during World War II from the Dutch and from those in other countries.

Gradually the economic situation in many of the eastern European countries settled down, and respected western companies started to invest heavily in infrastructure. The telephone system in most countries was overhauled and modernized. Public transport systems were often updated and made more efficient. The nature of power generation was also changed for greater efficiency, and safer environmental standards were enforced. Some countries started to return to having former communists running the country, and others ended up with technocrats.

During the communist period, tourism in eastern Europe had been heavily restricted, but after 1989 many tourists visited many parts of eastern Europe, encouraged by cheaper package holidays, and the opportunity to travel to new countries, both of which coincided with the introduction of cheaper air fares. Independence for the former Baltic States of Estonia, Latvia, and Lithuania, as well as independence for Belarus, Moldova, and Ukraine, and the "velvet divorce" between the two parts of Czechoslovakia to form the Czech Republic and Slovakia, all led to the creation of a number of "new" countries. Travel has become much easier with some eastern European countries joining the European Union: the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, the Slovak Republic, and Slovenia in 2004; and Bulgaria and Romania in 2007.

War in the former Yugoslavia also led to Slovenia, Croatia, Macedonia, and Bosnia-Herzegovina all becoming independent countries, and Montenegro split from Serbia in 2006. The war also saw the wrecking of the economy and much of the infrastructure of former Yugoslavia, a situation partially ameliorated by the availability of foreign aid.

Although the Russian Federation no longer dominates eastern Europe in the way it had, it still has a major influence. This can be seen in threats over the use and cost of Russian gas. When countries elect pro-Moscow governments, the Russians often permit gas to be sold at cheap rates to that country. However, if a leader is elected who wants to move away from Russian influence, such as Viktor Yushchenko in Ukraine, Russia threatens to force that country to pay the market rate for the gas or to reduce the gas output. Part of this has been because of the expansion of the European Union and NATO and resurgent nationalism in Russia. However, in spite of occasional political problems, the amount of international trade between all the countries of eastern Europe has continued to increase.

Economic Development

The meaning of economic development (ED) has broadened over time with the progress of the study of ED. One can claim that the study of ED may have originated in the writings of Adam Smith or the Classical School of Economics, but the subject as it is known today began only in the 1930s. There is a general agreement that the systematic study of ED focusing on a large number of developing countries (in Africa, Asia, and Latin America) emerged only after World War II. As the understanding of ED as a phenomenon broadened over time, the meaning of ED also changed, gaining in breadth, clarity, and precision. As a result, there have been many views and definitions for ED in the related literature. Researchers have used the term in three different senses. Most of them seem to have used it to refer to a desirable state of a society such as a modern industrial society, while others have used the term to refer to processes of transformation by which such a state is reached over time or to actions undertaken by various local, national, and international actors to improve quality of life in societies at various levels.

Traditionally, prior to the 1970s, the term ED referred to the capacity of an economy to increase and sustain total output or income. This essentially meant what is defined as economic growth today and improvements in such factors affecting economic growth as technology, productivity, and structural changes. Economic growth can be defined as an increase in total real output or real income measured by real gross domestic product (GDP) or real gross national product (GNP). Some references are found in the literature that define economic growth as increases in real GDP per capita or real GNP per capita, rather than real GDP or real GNP. The terms GDP, GNP, GDP per capita, and GNP per capita are described in the next section. However, prior to the 1970s, ED was seen as an economic phenomenon in which economic growth was at the center.

The experience of many developing countries in the 1950s and 1960s clearly indicated that economic growth did not necessarily improve the overall standard of living and general well-being of people in those societies. This led to the understanding that ED is not merely an economic phenomenon and it encompasses a much broader spectrum of factors that represent both economic and noneconomic dimensions. Dudley Seers, for example, argued that ED goes beyond economic factors and includes noneconomic factors such as basic human needs and equity. Further, he argued that economic growth does not necessarily guarantee decreases in poverty, unemployment, or inequality in income distribution. Contributions of Seers and others who emphasized the importance of noneconomic factors gave rise to the much broader view of development that came to be known as Human Needs–Centered Development as opposed to Growth-Centered Development. According to this view, ED implies such noneconomic aspects as equality, democracy, true national independence, high levels of literacy, and education, equal status for women, human security, and sustainable ability to meet future needs, in addition to low levels of poverty and unemployment.

Sen's Capabilities Approach

In the 1980s and 1990s, dismal growth performance combined with serious problems of poverty and fiscal and external deficits in many developing countries highlighted the fact that ED must be thought of as a multidimensional phenomenon requiring fundamental changes in entire social systems. At present, many believe that Amartya Sen, the Nobel laureate in economics in 1998, is the leading thinker on the meaning of ED. His views on economic development are sometimes referred to as Sen's capabilities approach. According to this approach, ED has to be about enhancing basic human capabilities and freedoms of people to live the lives they choose to lead. Income is only one factor that affects human capabilities and freedoms, and therefore, ED goes far beyond reducing income poverty. He argued that economic growth is not an end in itself, and that development has to do more with enhancing the lives people lead and the freedoms they enjoy. He further argued that poverty cannot be properly measured by income. In his view, the well-being of people depends on what people can and do make of commodities and not on the characteristics of commodities they consume.

Sen has identified five broad factors apart from income that affect capabilities of people to live the lives they choose to lead. They include (1) personal heterogeneities in such terms as age, gender, and disabilities; (2) environmental diversities such as differences in climate and clothing requirements; (3) variations in social climate in such terms as the crime rates and rates of violence; (4) differences in relational perspectives (i.e., differences in relative deprivation); and (5) distribution within the family (distribution of family resources among family members by gender, age, etc.). In his view, the goal of ED is to enhance capabilities and freedoms enabling people to live the lives they desire.

Other Definitions

As stated earlier, there are many definitions for the term ED in the related literature. There has been no consensus on any particular one of them except for the broad agreement that ED must mean something much broader than economic growth or mere improvements in favorable economic conditions. Many argue that economic growth is necessary but not sufficient for development. Some argue that the emphasis placed on growth is too much and there is no evidence to support that growth increases happiness. And therefore, ED is possible even without economic growth in certain contexts. However, many others (for example Lewis) argue that economic growth is essential for developing countries as a means of increasing choices and advancing human freedoms.

Michael P. Todaro's definition of development is a good example for the broad view of development that exists today. He defines development in very broad terms as "the sustained elevation of an entire society and social system toward a 'better' or more humane life." He identifies three core values of development: sustenance (being able to meet basic needs), self-esteem (being able to live a life with a sense of worth and self-respect), and freedom from servitude (being able to choose). He also identifies three broad objectives of development: to increase the availability and widen the distribution of basic life-sustaining goods, to raise levels of living, and to expand the range of economic and social choices available to individuals and nations.

A set of internationally committed development goals for the early decades of the new millennium has been developed in the United Nations (UN) Millennium Declaration adopted in September 2000. This set, widely known as the Millennium Development Goals (MDGs), includes the following eight goals: (1) eradicate extreme poverty and hunger; (2) achieve universal primary education; (3) promote gender equality and empower women; (4) reduce child mortality; (5) improve material health; (6) combat HIV/AIDS, malaria, and other diseases; (7) ensure environmental sustainability; and (8) develop a global partnership for development. A comprehensive set of targets to achieve each these goals and indicators by which progress can be judged have also been developed. In total, there are 18 such targets and 48 indicators.

Measuring Economic Development

Traditional measures are the national income measures derived from GDP and GNP, which can be considered broadly as measures of economic growth rather than ED. GDP is the total value of all final goods and services produced within the borders of a country during a specified period of time, in general a year. GNP is the value of final goods and services produced by resources belonging to the nation (citizens and permanent residents), both in and out of the country. GNP is the sum of GDP and the net factor income from abroad. Net factor income from abroad is the difference between factor incomes, such as dividends, earned from abroad and factor payments made to foreigners. It can be positive when incomes exceed payments or negative when payments exceed income during the given period. As a result, GNP can be smaller than GDP when the net factor income from abroad is negative. In such cases, GNP may be a better measure of national income than GDP. However, GDP and GNP are measures of both the level of output and the level of income. International organization like the World Bank (International Bank for Reconstruction and Development, [IBRD]) refer to GNP as the Gross National Income (GNI).

The national income measures include real GNP per capita, real GDP per capita, and their annual growth rates (annual percentage changes). Real GDP and real GNP are the GDP and GNP measured at constant prices (prices in a year selected as the base year), respectively. They can be computed by deflating nominal GDP (GDP measured at current prices) and nominal GNP (GNP measured at current prices) by an appropriate price index, such as GDP deflator or Consumer Price Index (CPI). Thus, real GDP and real GNP are the values of GNP adjusted for inflation, respectively. Real GDP per capita and real GNP per capita values are computed by dividing real GDP and real GNP by total population, respectively. These GDP-based per capita measures have been used for measuring national levels of ED and criteria for their comparison over time and across nations.

International Comparisons

For international comparisons, GDP or GNP per capita measured in national currencies of different countries must be expressed in a common currency. Earlier, the standard practice was to convert the national values into U.S. dollar values using official exchange rates. The use of official exchange rates in conversion has been criticized for the fact that official exchange rates in developing countries are not competitive market exchange rates and are thus unrealistic. They are distorted by direct and indirect trade and exchange controls and the existence of multiple exchange rates, including illegal black market exchange rates.

In addition, the rankings of GDP per capita converted using official exchange rates do not necessarily portray the true rankings of per capita incomes in terms of their purchasing power among the countries ranked, because the purchasing power of one dollar differs in different countries due to differences in the prices of goods and services. The method of using Purchasing Power Parity (PPP) exchange rates in conversion takes these differences into account and produces better rankings of international per capita incomes as measures of ED. Estimates of GDP and GNP in terms of PPP are reported in the publications of various agencies of the United Nations, the World Bank, and the International Monetary Fund (IMF), among others. However, one can argue that GNP per capita values thus calculated are still not comparable for reasons such as practical difficulties of measurement and the inclusion of certain goods and services in GDP by some countries but not by others.

Measurement Shortcomings

GDP is considered as the best measure of total output and economic growth, yet it suffers from many shortcomings as a measure of total output. GDP may underestimate total output for various reasons. It includes only the values of market activity (goods and services that are traded in markets) and the values of such nonmarket activity as subsistence farming, and unpaid household production activities are excluded. Developing countries have significantly large informal or subsistence sectors in which a substantial proportion of production is not directed toward markets or traded through barter. The values of some goods and services traded in markets, particularly in rural areas, are also excluded as they are not formally recorded. Some values of market activities such as illegal activities (underground economy) are unreported or underreported to avoid taxes. The value of excluded activities can be estimated, but finding accurate prices for goods and services untraded or traded through barter may be difficult for many reasons. Based on the above mentioned shortcomings, it has been argued that GDP is not an accurate measure of economic growth.

As measures of ED, real GDP per capita and real GNP per capita have also been widely considered as indicators of the standard of living and general well-being of people in a country. Standard of living and general well-being depend not only on the availability of goods and services brought about by economic growth but also on their quality and many other economic and noneconomic factors such as the composition and distribution of total output, changes in the rates of crime and violence, environmental quality, and changes in the number of hours of leisure, etc. GDP ignores the negative effects of economic growth such as environmental degradation, pollution, and congestion. It also ignores the qualitative changes in produced goods and services over time. Any changes in the quantity and quality of leisure enjoyed by people are also not incorporated into GDP. As a result, real GDP per capita and real GNP per capita cannot be considered as accurate indicators of standard of living or general well-being of the people.

Recently, attempts have been made to refine GDP statistics to eliminate some of these shortcomings. For example, measures called Green GDP and Net Economic Welfare (NEW) have been developed to take into account the negative effects of economic growth such as environmental degradation and crime. Notwithstanding their shortcomings, real GDP per capita and real GNP per capita have been found to be correlated with many other economic and noneconomic indicators, such as rates of literacy, mortality rates, and rates of educational attainment. And therefore, they are still widely regarded as important comprehensive measures of standard of living, general well-being, and ED.

Alternative Measurements

Realization of many shortcomings of national income measures, and the understanding that ED is a much broader phenomenon than economic growth, led to the search for alternative and complementary indictors such as social indicators of development identified by the United Nations Research Institute on Social Development in 1970. In the mid-1970s, Morris David Morris developed the Physical Quality of Life Index (PQLI), which summarizes infant mortality, life expectancy at age one, and basic literacy on a zero to 100 scale. International rankings based on PQLI differed from the rankings based on GNP per capita as some high income countries (for example, Middle East oil-producing countries) ranked low in terms PQLI and some low-income countries (for example, Sri Lanka) ranked high in terms of PQLI. However, the practice of assigning equal weights to the three indicators included in PQLI in calculations has been cited as a shortcoming of the measure.

Many believe that the Human Development Index (HDI) developed by the UN Development Program (UNDP) to be the most comprehensive measure of ED developed so far. HDI is a composite index that combines three important dimensions of human development: living a long and healthy life (measured by life expectancy), knowledge (measured by adult literacy and enrollment at the primary, secondary, and tertiary level), and standard of living (measured by per capita income adjusted for purchasing power differences). The index, which was developed in 1990 and subsequently refined, taking criticisms into account, ranks countries on a scale of 0 (lowest human development) to 1 (highest human development). Rankings of different countries have been reported by UNDP in its annual Human Development Reports since 1990.

At present, the countries with an HDI below 0.5 are included in the category of "low human development" and the countries with an HDI of 0.8 or greater are included in the category of "high human development." The rest of the countries ranked belonged to the category of "medium human development." UNDP itself acknowledges that HDI is not in any sense a comprehensive measure of human development, because it does not include, for example, such important indicators as gender or income inequality, human rights, and political freedoms. Yet, it provides a broadened prism for viewing human progress and the complex relationship between income and well-being. However, recently UNDP has developed other indexes such as the Human Poverty Index for Developing Countries (HPI-1), the Human Poverty Index for Selected OECD Countries (HPI-2), the Gender-Related Development Index (GDI), and the Gender Empowerment Measure (GEM).

The fact that ED is a complex multidimensional phenomenon makes it impossible to develop a single comprehensive measure that can fully capture both quantitative and qualitative changes in all of the economic and noneconomic dimensions of ED. All of the measures that have been developed so far have their strengths and shortcomings as well. Therefore, measurement of ED does necessarily require use of many complementary indictors representing all of the economic, social, political, cultural, and other dimensions of social welfare. Information about such indicators can be found in annual reports of several international organizations such as the United Nations, World Bank, and the IMF.

Models of Linear Stages of Growth

As mentioned earlier, there are disagreements among researchers about the origin of ED thought. For some, it dates back to Adam Smith's *The Wealth of Nations* (1776). For others, it began in the 1930s. Many agree, however, that the systematic study of ED began only after World War II. During this period, many models and theories have been developed to explain the process of ED and factors affecting the process. These theories can be categorized in many ways. Broadly, four major views dominate the post–World War II literature on ED. They are the models of linear stages of growth, models of structural change, models of international dependence, and neoclassical models of market fundamentalism.

Models of linear stages of growth viewed faster economic growth as ED, and the process of development as a series of successive stages of economic growth. Savings and capital formation are the crucial determinants of economic growth. For example, according to Rostow's stages of growth theory, a country passes through five stages of ED:

1. Traditional society: Subsistence activity dominates the economy. Production of output is mainly for producers' consumption and not for sale. Direct exchange (barter) is the most widely practiced form of trade. Traditional agriculture that depends on labor-intensive technology is the most important sector.
2. Pre-conditions for take-off: A stage of transition characterized by increased specialization that generates surpluses for trading, emergence of economic infrastructure such as transport in support of trade, emergence of entrepreneurs, considerable growth of income, savings, and investment. External trade also occurs, concentrating on primary products.
3. Take-off: A stage of increased industrialization that is characterized by rising industrial employment as workers switch from the agricultural sector to the manufacturing sector. Growth, however, is not widespread and concentrated in a few regions and a few (one or two) manufacturing industries. The rate of investment exceeds 10 percent of total income. New political and social institutions evolve in support of the industrialization and economic transition taking place. Higher levels of investment lead to increased incomes which, in turn, generate higher levels of savings for further investment required for self-sustaining growth.
4. Drive to maturity: A stage of increased diversification of economy in terms of the structures of output and employment, technological innovations, and investment opportunities. The dependence on imports decreases as a result of output growth.
5. Age of high mass consumption: The highest stage of development in which the economy is geared toward mass consumption. As a result, the industries producing consumer durable goods flourish and the tertiary (service sector) becomes increasingly dominant.

Walt Rostow's model emphasizes the importance of preconditions and substantial increases in investment (domestic or foreign) in capital for achieving a successful stage of take-off. However, many development economists argue that Rostow's model has only limited applicability to developing countries for various reasons. The fact that the model was developed by generalizing the experience of the developed West limits the model's applicability to a large number of developing countries which are diverse in many ways and different from the comparable historical stages of the developed countries. Some argue that the model does not explain in sufficient detail the nature of the preconditions for growth. It has also been pointed out that in practice policy makers are unable to clearly identify various stages as they merge together. The fact that the model is clearly a model of growth rather than a model of development also limits its applicability.

Roy Harrod (1939) and Evsey Domar (1946) developed the Harrod-Domar Model in the 1940s mainly to explain the relationship between growth and unemployment in developed countries. It has been extensively used to investigate the relationship between growth and capital requirements in developing countries. Also known as the AK model, the Harrod-Domar model uses a simple production function, with constant returns to scale, in which output linearly depends on capital (i.e., the level of output is always a constant times the capital stock). According to the model, economic growth rate (g) depends on the national savings ratio (s) and the capital-output ratio (k) or the productivity of capita (i.e., $g=s/k$).

This model highlights the necessity of generating more savings and investments for faster economic growth. One can argue that higher savings and productive investments are necessary but not sufficient for economic growth or development in developing countries. The model ignores the role of technology and other social, political, and institutional factors. The assumptions of fixed capital-to-output, capital-to-labor, and labor-to-output limit the applicability of the model to only very short periods of time.

Influenced by the Marshall Plan and the Cold War, the model fails to recognize the crucial differences between developing countries and the developed countries.

Models of Structural Change

Models of structural change gained popularity in the 1960s and 1970s. These models viewed ED essentially as a process of structural transformation from a traditional subsistence economy to a more diverse modern industrial economy. The surplus labor theory developed by Sir Arthur Lewis and later extended by John Fei and Gustav Ranis, and the empirical studies that focused on the patterns of structural changes in developing countries, are among the best known examples for models of structural changes.

The Lewis model (1954) assumes a dual economy with a traditional agriculture sector and a modern industrial sector. The traditional sector is characterized by low levels of productivity, savings, income, and a surplus of labor. The modern offers relatively higher wages that help attract surplus labor from the traditional sector without causing any loss of output in that sector. The progress of the modern sector depends directly on investment and capital formation in that sector. The growth in the modern sector generates demand and also provides funds for investment. Higher incomes generated by the modern sector trickle down throughout the economy. Based on the empirical experiences of developing countries, the model has been criticized mainly for its assumptions such as the existence of surplus labor in agriculture while there is full employment in the industrial sector, the existence of constant demand for labor from the industrial sector, the existence of constant real wages in the industrial sector until the surplus labor is completely exhausted, and the existence of diminishing returns in the industrial sector.

Models of International Dependence

Models of international dependence became very popular in the 1970s. Some of them have their origins in developing countries. The names of Raul Prebisch, Paul Baran, Andre Gunder Frank, Samir Amin, and Arghiri Emmanuel are closely associated with this class of theories. These models viewed a set of international and domestic institutional, political, and economic rigidities and the dependence on developed countries which dominate international power relations as responsible for underdevelopment in developing countries. The emphasis was placed on the need for terminating political, economic, and cultural dependence of developing countries for their development.

Broadly, this class of models includes three different models: neocolonial dependence model (exploitation of developing countries (the periphery) by developed countries (the center) is largely responsible for underdevelopment in the periphery, false-paradigm model (faulty and inappropriate advice from the experts representing the interests of the developed countries is responsible for underdevelopment), and dualistic-dependence model (existence of dual societies and persistence of widening gap between the rich and the poor at national and international levels are responsible for underdevelopment). Models of international dependence have been criticized for failing to offer clear insights into how countries initiate and sustain development. The experience of some developing countries shows that their policy prescriptions such as import substitution have not produced expected favorable outcomes for development.

The Neoclassical Models

The neoclassical models of market fundamentalism gained popularity as models of ED during the 1980s and 1990s. Their emergence has been identified closely with the neoclassical (or neoliberal) counterrevolution in economic theory. The economists like I. M. D. Little, Harry G. Johnson, Bela Balassa, and Deepak Lal are among the leading thinkers in this class of models. According to these models, market imperfections and distortions created largely by excessive government involvement and regulations that result in inefficient allocation of resources are responsible for underdevelopment in developing countries. Economic liberalization, privatization and downsizing the government, deregulation of markets, and promoting free trade and foreign direct investment are seen as crucial for efficient allocation of resources and economic development.

Three different variants can be found among the neoclassical models: free-market analysis (which assumes that markets in developing countries are efficient and effective in resource allocation and the effect of existing imperfections are negligible), new political economy approach (or public-choice theory which argue that the actions of politicians, governments, bureaucrats, and citizens driven solely by self-interest result in misallocation of resources), and market-friendly approach (which recognizes the existence of certain market imperfections in developing countries and that governments have a responsibility to play certain roles in a market-friendly manner).

The traditional neoclassical growth models grew out of the Harrod-Domar model and the Solow neoclassical growth model. Robert Solow uses an aggregate production function model in which the level of output depends on the capital stock, labor, and technology. The Solow model assumes diminishing returns for both capital and labor inputs. Technology is assumed to be exogenously determined. According to the traditional neoclassical growth models, economic growth depends on the quantity and quality of labor, capital, and technology. They argue that capital inflows from developed countries make it possible for open economies to grow faster than regulated closed economies. Therefore, economic liberalization and deregulation are favorable for ED.

These policy prescriptions were widely adopted by a large number of developing countries during the 1980s and the 1990s, paving the way for an increased international integration of their economies. However, there has been strong opposition to the adoption of neoclassical policy prescriptions both in national and international levels. Neoclassical models have been criticized for using assumptions that are unrealistic in the context of developing countries, such as the existence of competitive markets. They are also criticized for failing to recognize social, economic, institutional, and cultural differences between developing countries and developed countries on the one hand and the differences among developing countries themselves on the other.

Many influential models, which are considered as modern models of development and underdevelopment, have been developed since the late 1980s. Among them are the models of endogenous growth, such as Paul Romer's model of endogenous growth, Michael Kremer's O-ring model, and many other models which differ from classical models to offer better explanations for the current states of ED in developing countries. For some of these models, the reader is referred to Todaro's popular text book on ED.

Economic Indicators

An economic indicator is a relatively simple or straightforward variable that, on the basis of past experience, can act as a signal for changes in a set of other, often more complex variables in the economy. To some extent a single economic indicator can act as a "proxy" for a combination of other variables. New business start-ups, for instance, can indicate a whole set of interconnected changes in the business sector and the wider economy. In the United States in the 1920s and 1930s, "freight car loadings" were reported on the business pages of newspapers, and these were avidly read by investors, business managers, politicians, and others, as the movements of raw materials and finished goods around the American railway system was, at that time, believed to be a reliable indicator of the general health of the economy.

In business terms, an economic indicator can be used as a piece of information that assists in managerial decision making. Indicators can also be used by governments in order to guide future policy, such as plans for raising revenue and the setting of priorities for the allocation of government expenditure.

Leading and Lagging Indicators

A "leading" indicator is a variable or a series of statistical data that can be expected to anticipate changes in some related areas of the economy, and which usually precedes the changes by a fairly consistent time period. A leading indicator can therefore be used to make predictions and forecasts. For example, if demographic trends show that there is likely to be a significant expansion in the relative size of the 16–25 age group among the male population in a few years' time, then it is reasonable to predict that the country in question is going to experience a "crime wave." This is because, in many countries, most crime is committed by young men. Such information would be of interest to, among others, government departments concerned with crime and justice, companies supplying private sector prison facilities, and the insurance industry that can expect to be called upon to underwrite and compensate for the financial costs of crime to individuals and businesses.

Leading indicators such as investment plans, orders for machine tools, and new house-building starts can be combined to construct a measure of "business confidence," which in turn can help predict cyclical changes in gross national product. Similarly, "consumer confidence" is linked to variables such as future spending, output, and incomes, through economic mechanisms such as the multiplier principle.

A "lagging" indicator is a variable or a series of statistical data that can be expected to reflect earlier changes in some related areas of the economy, and which usually follow the changes by a fairly consistent time period. A lagging indicator can therefore be used to make an analysis of previous trends in the economy, or a diagnosis of previous problems with a view to avoiding similar problems next time around. The inflation rate, for example, is calculated using recent historic data concerning price movements within a statistically constructed "basket" of typical goods and services. If an analysis of the inflation rate shows that its causes are demand led, then an appropriate policy response (such as an adjustment of the interest rate) can be prescribed as a solution.

If, on the other hand, the diagnosis is that inflation is imported due to higher world commodity process (a cost factor rather than a demand actor), then the interest rate approach might be inappropriate or even damaging to the wider economy. Since government policy makers are not noted for their infallibility, knowledge of lagging indicators is as important as leading indicators as a piece of managerial intelligence, because this knowledge can help business people to be prepared in advance for changes in the wider business environment, some of which will come from government policy adjustments, whether appropriate or inappropriate.

It is quite possible for a particular indicator to be interpreted as being both leading and lagging simultaneously. A country's unemployment rate, for example, tells us something about the performance of the economy in recent history, and shows the end result of many contributing factors including the efficiency of the business sector, the state of the labor market, and the efficacy or otherwise of government policies concerning both the "hard" economy of variables such as interest rates and taxation, and the "soft" economy of education, training, and investment in human capital. However, the unemployment rate can also be used to make forecasts of likely future trends in directly affected variables such as saving and consumer spending, together with more indirect knock-on effects on other variables such as investment, output, and national income.

When economists analyze "leads and lags" they are referring to the timing differences that exist between, on the one hand, the peaks and troughs of leading indicators and lagging indicators and, on the other hand, peaks and troughs in the general business cycle. If, for example an 11-year cycle can be discerned in the level of economic activity, with a peak in the growth rate of gross national product in year four and a trough in year eight, it could be that manufacturing investment acts as a leading indicator that peaks in year two and troughs in year six, while house-building acts as a lagging indicator that peaks in year six and troughs in year ten. It should be noted that indicators of this sort can work quite differently in different countries.

The state of the manufacturing and house-building sectors can have quite different significance in Germany, say, compared with the United Kingdom (UK) and United States, depending on factors such as the structure of their business sectors, and the role played by different types of industry in contributing to national output and employment.

Variables

When using economic variables as indicators, it is worth distinguishing between independent and dependent variables. Economic theory is largely built upon hypotheses about and observations of functional relationships between variables. If, for example, we suggest that "consumption is a function of income," then we are saying that income is an independent variable, while consumption is a dependent variable. We are saying that what people spend depends on their income, rather than vice versa.

Economists use the following equation (1) to show a basic relationship between a large set of variables:

$$Y = C + I + G + (X - M) \tag{1}$$

Here, Y stands for "national income," which in economic theory is equal to the value of planned national output, which in turn is equal to planned total national expenditure on goods and services. Income, output, and expenditure are also obviously linked to employment, since higher levels of employment will tend to coexist with higher levels of income, spending, and output, whereas a fall in these three variables can be expected to reduce employment and hence increase unemployment. If it is believed that inflation is demand led, then higher levels of economic activity can be expected to coexist with higher levels of inflation, if it is the case that there is any difficulty in utilizing spare productive capacity, due to such problems as inadequate infrastructure, or the existence of skills gaps.

C stands for "consumption," or consumer spending on goods and services. I signifies "investment," or spending on capital goods (as opposed to consumer goods). Capital, or investment goods, such as factory buildings and manufacturing infrastructure, is used in order to produce consumer goods and services.

G stands for government spending, and (X – M) signifies the net effect of export earnings and import spending—in other words, it indicates the net effect of international trade, or the balance of trade surplus or deficit. Economists use a model known as the circular flow of income to show how the variables linked in the above equation relate to each other, and also to show that injections into the circular flow (investment, government spending, and export earnings) tend to increase the level of economic activity, while withdrawals or leakages from the circular flow (saving, taxation, and import spending) tend to reduce the level of economic activity. This also follows from the alternative way of expressing the macroeconomic equilibrium condition (equation 2):

$$I + G + X = S + T + M \tag{2}$$

This tells us that if the sum of planned investment, government spending, and export earnings (i.e., total planned injections) equals planned saving, taxation, and import spending (i.e., total planned withdrawals), then there is no reason for economic activity either to increase or decrease.

Implications

In business, the uses to which economic indicators such as these are put can be complex and sophisticated, or they can be relatively straightforward but no less valuable for their simplicity. For example a sudden change in interest rates will have implications for many business enterprises. Those implications can be predicted by making reasonable deductions from the basic models outlined above. In equation 1, interest rates can be assumed to have a direct effect on consumption (C), since many major individual spending decisions (for example, the decision to buy a car or another major household item) are influenced by interest rates, if they tend to be bought using borrowed money. Households repaying a mortgage can also be assumed to adjust their consumption expenditure, at least to some extent, in response to changed interest rates, since a change in their monthly mortgage repayments will, in effect, alter their disposable income. Interest rates will also affect investment (I) in the equation, since it is reasonable to assume that investment decisions are sensitive to interest rate changes, depending in part on the extent to which investments are financed by borrowing, as opposed to sources of finance such as shareholding or ploughed-back profits.

The same principles can be applied to equation 2, where a change in interest rates will have direct effects on saving (S) and investment (I). Similarly, changes in other indicators, such as the exchange rate, can be applied to these equations and predictions made about their likely effects on variables such as export earnings (X) and import spending (M). The effects of variables under direct government control, government spending (G) and taxation (T), can also be predicted. From experience, businesses should be able to extrapolate the knock-on effects of changes in the level of economic activity. There are, of course, differential effects on different types of business, with sectors such as tourism, house-building, and car manufacturing often acting as weather vanes, and in turn being used as indicators for the likely future level of activity in the rest of the economy.

Use and Interpretation

Companies that offer economic forecasting services will, of course, use models of the economy that are highly sophisticated and complex, and some will attempt to replicate the high-powered computer models used by government departments and agencies such as the Federal Reserve and the Bank of England; but the basic models on which these programs are based will be similar in their fundamentals to the relationships shown in the equations above. The "average" business person should not fall into the trap of believing that the implications of changes in economic indicators are too complicated to be understood and interpreted by the everyday practitioner.

If business people are to use economic indicators to help in managerial decision making, however, it is important that they take care not to react to changes that might be one-off "blips." Some indicators are more volatile than others, and in general terms the more volatile ones reflect what might be called the "virtual" economy rather than the "real" economy.

Medium to long-term trends in share prices are more reliable indicators of economic trends than day-to-day prices of monetary instruments such as "futures" and "options" for the simple reason that these variables are not indicating the fundamental activities of wealth creation; rather, they are reflecting short-term profit making based on the hopes and fears of speculators. During the oil price hike of 2008, for example, some experts estimated that the activities of speculative traders added as much as 25 percent to the price of a barrel of oil and the vast majority of these traders were, in effect, gambling on a rise or fall in future oil prices, rather than having any intention of ever possessing an actual barrel of oil. Similarly, it is possible that well over 90 percent of the transactions that take place on the currency exchanges of the world are led by speculation, rather than being connected to the desire to actually exchange a sum of money in one currency for real notes and coins in another denomination.

In the mid-1990s, British unemployment statistics underwent an interesting and relatively sudden change. The main reason given for individuals being long-term unemployed due to chronic health problems and claiming welfare benefits changed from "muscular-skeletal" to "mental health" problems, or to put it more simply, from "back pain" to "stress." This could have been ignored by employers and policy makers as a statistical blip, but in fact it turned out to signal a sustained trend, which is likely to continue to be a feature of the UK labor market for some time to come, as well as being reflected in many other economies, especially those adopting the Anglo-Saxon model of "flexible labor markets." As a long-run trend rather than a blip, it requires a policy response, in terms of occupational health and welfare benefit strategies. This particular indicator reflects wide-ranging changes in industry and the economy, including the trend in employment from secondary (manufacturing) toward tertiary (service) industries, and employment conditions leading toward a more "flexible" and inherently more insecure workforce.

Economic indicators extracted from time-series data can show four basic types of variation that can be used for the purposes of forecasting:

1. Secular trends, which show relatively smooth development over the long term, e.g., the growth of gross national product in established economies, and the tendency for economic development to result in a decline in the proportion of national income and employment accounted for by the primary sector, initially to be replaced by an expanding secondary sector, with the tertiary sector ultimately becoming the major source of economic activity.
2. Cyclical patterns, e.g., the short-term variations in actual growth around the long-term trend rate of economic growth, with "output gaps" (overstretched capacity) occurring during an "upturn" phase and "negative output gaps" during a "downturn." This is the classic "sine-wave" pattern that is associated with the trade cycle or business cycle. Output gaps are used as a major indicator in the anti-inflation regime that has been adopted in various forms in the UK and the Eurozone, for example, where interest rate setting has been delegated to a quasi-independent central bank.
3. Seasonal variations, which are short term but regular and reasonably predictable, e.g., the low-season activity in large parts of the tourist industry in winter; retail sales in Western economies prior to Christmas.
4. Exogenous shocks, which tend to be unpredictable, wrongly predicted, or unexpected, and which result in irregular changes to established trends. An example would be the ramifications of the collapse of the U.S. subprime market in 2008 and the resulting global credit crunch; or rapid increases in food prices arising partly as an unintended consequence of the use of land for biofuels, which in turn was a response to faster-than-expected increases in energy prices and commodity costs, especially the price of oil.

Economic Integration

The agreement among countries or regions to establish links through the movement of goods, services, capital, and labor across borders is known as economic integration. Economic integration includes at the far end a truly global economy in which all countries share a common currency and agree to a free flow of goods, services, and factors of production. At the other extreme would be a number of closed economies, each independent and self-sufficient. Each of the various integrative agreements in effect today involves some sacrifice of national independence and autonomy to enjoy the benefits of free trade and stable exchange rates. Levels of economic integration include the free trade area, the customs union, the common market, and the economic union.

Free trade agreements account for about 90 percent of the economic integration across groups of countries or regions (REI). While the primary function of REIs is to eliminate tariff and non-tariff barriers, open border controls to increase capital, increase resources, increase spending power by citizens, generate more jobs and profit between the countries engaged in the agreement, countries outside the agreement are subject to high tariffs, which may be set by the group as a whole (customs union, common market, and economic union) or set by the individual country (free trade area).

The free trade area is the least restrictive and loosest form of economic integration among countries. In a free trade area, all barriers to trade among member countries are removed. No discriminatory taxes, quotas, tariffs, or other trade barriers on free trade area members are permitted. The most notable feature of a free trade area is that each country continues to set its own policies in relation to nonmembers, including tariffs, quotas, or other restrictions that it chooses. The most notable free trade area is the North American Free Trade Agreement (NAFTA). Sometimes a free trade area is formed only for certain classes of goods and services; For example, an agricultural free trade area is restricted to agricultural goods only.

The customs union is one step further along the spectrum of economic integration. Like the members of a free trade area, members of a customs union dismantle barriers to trade in goods and services among themselves. In addition, however, the customs union establishes a common trade policy with respect to nonmembers. Typically this takes the form of a common external tariff, where imports from nonmembers are subject to the same tariff when sold to any member country. Tariff revenues are then shared among members according to a prescribed formula. The Southern African Customs Union and Andean Community (Comunidad Andina de Naciones or "CAN") are examples of this model of economic integration.

Further still along the spectrum of economic integration is the common market. Like the customs union, a common market has no barriers to trade among members and has a common external trade policy. In addition, however, factors of production are also mobile among members. Factors of production include labor, capital, and technology. Thus restrictions of immigration, emigration, and cross-border investment are abolished. The importance of factor mobility for economic growth is very important. Mercosur, or the "Common Market of the South," is an example of this form of economic integration.

Despite the obvious benefits, members of a common market must be prepared to cooperate closely in monetary, fiscal, and employment policies. While a common market will enhance the productivity of members in the aggregate, it is by no means clear that individual member countries will always benefit.

Economic union requires integration of economic policies in the addition to the free movement of goods, services, and factors of production across borders. Under an economic union, members would harmonize monetary policies, taxation, and government spending. In addition, a common currency would be used by all members. This could be accomplished de facto or in effect by a system of fixed exchange rates. The formation of an economic union requires nations to surrender a large measure of their national sovereignty to supranational authorities in community-wide institutions.

The Americas

The North American Free Trade Agreement (NAFTA), the free trade bloc of the United States, Canada, and Mexico, removed export tariffs in several industries, reduced tariff barriers on agricultural products, put in place intellectual property protections, created mechanisms to resolve commercial disputes, and facilitated the trade in illegal drugs. The economies of all three countries have grown since the agreement was signed in 1994, with Canada growing the fastest and Mexico the slowest. Most economists see a favorable impact of NAFTA, but this may be influenced by the general "theoretical" disposition, which typically favors free trade and views the adverse consequences as outweighed by long-term benefits. Under NAFTA, Canada, Mexico, and the United States are permitted to set and apply their own labor and environmental standards as these standards pertain to trading among member nations.

The Central American Free Trade Agreement (CAFTA) represents a trade pact to promote free trade among the United States, Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua, and the Dominican Republic. CAFTA proports to eliminate barriers to trade among the member nations, eliminate barriers to foreign investment, and protect intellectual property, in addition to increasing transparency in corporate governance, legal systems, and due process for member nations. CAFTA is a trade agreement that is patterned after the North American Free Trade Agreement between Canada, Mexico, and the United States.

The Mexico–Northern Triangle Trade Agreement represents a trade agreement governing regional economic integration among Mexico and the Central American countries of Costa Rica, El Salvador, Guatemala, Honduras, and Nicaragua. The objective of the Mexico–Northern Triangle Agreement is to create a free trade zone among its member countries.

A train being inspected on the Canadian border in Montana. The Canadian economy has grown the fastest with NAFTA.

The Group of Three (G-3) Trade Agreement represents a multilateral trade agreement formed originally among the countries of Colombia, Mexico, and Venezuela. The principal goal of the G-3 agreement is to eliminate tariffs in trades among its member countries. Since the signing of the G-3 agreement in June 1994, Panama joined the G-3 as a signatory in 2004, and Venezuela announced its intension to withdraw from the G-3 in 2006.

Asia Pacific and Europe

The Association of Southeast Asian Nations (ASEAN) was established on August 8, 1967, in Bangkok by the five original member countries, namely, Indonesia, Malaysia, Philippines, Singapore, and Thailand. Brunei Darussalam joined on January 8, 1984; Vietnam on July 28, 1995; Lao PDR and Myanmar on July 23, 1997; and Cambodia on April 30, 1999. China joined these 10 Southeast Asian countries in November 2004.

ASEAN is intended to lay the groundwork for the world's biggest free trade zone by 2010—the group would cover a total population of nearly 2 billion people. The agreement includes a promise to liberalize tariff and non-tariff barriers on traded goods and to establish a trade dispute mechanism. Importantly, the agreement includes full liberalization of the services sector, which for developing countries is a more significant force for growth than traditional agricultural and light industrial goods. In addition to its economic impact, the agreement will increase China's role as the growth engine for ASEAN's export-led economies, because of China's huge need for raw materials, finished goods, and components.

The European Free Trade Agreement (EFTA) currently unites Iceland, Norway, Switzerland, and Liechtenstein in a free trade agreement. There are now several EFTA and other countries, such as Mexico, Korea, Israel, and Singapore. Emphasis has been placed on the free trade of industrial goods. Agriculture was left out to allow member countries the flexibility to determine what they needed. Member countries also determine the trade barriers applied to goods coming from outside EFTA.

Customs Unions

The Southern African Customs Union (SACU) consists of Botswana, Lesotho, Namibia, South Africa, and Swaziland. The SACU secretariat is located in Windhoek, Namibia. SACU was established in 1910, making it the world's oldest customs union. The economic structure of the union links the member states by a single tariff and no customs duties between them. The member states form a single customs territory in which tariffs and other barriers are eliminated on substantially all the trade between the member states for products originating in these countries; there is a common external tariff that applies to nonmembers of SACU.

The Andean Community (CAN), composed of Bolivia, Colombia, Ecuador, and Peru, joined together for the purpose of achieving more rapid, better balanced, and more autonomous development through Andean, South American, and Latin American integration in order to contribute effectively to sustainable and equitable human development, to live well, with respect for the diversity and asymmetries that agglutinate the different visions, models, and approaches and that will converge in the formation of the Union of South American Nations (Unasur).

Common Markets

Mercosur, also known as the Southern Common Market, comprises Argentina, Paraguay, Uruguay, and Brazil, and represents a total population of nearly 200 million individuals. It objectives include the free transit of production goods, services, and factors between the member states, the elimination of customs rights and lifting of non-tariff restrictions on the transit of goods or any other measures with similar effects; the fixing of a common external tariff (TEC) and adopting of a common trade policy with regard to nonmember states or groups of states, and the coordination of positions in regional and international commercial and economic meetings; the coordination of macroeconomic and sectorial policies of member states relating to foreign trade, agriculture, industry, taxes, monetary system, exchange and capital, services, customs, transport, and communications, and any others they may agree on, in order to ensure free competition between member states; and the commitment by the member states to make the necessary adjustments to their laws to allow for the strengthening of the integration process.

Economic Unions

The European Union (EU) is the most highly integrated regional entity, and if you add up its members' gross national incomes, the EU is probably also the regional entity with the greatest wealth and intra-system trade. The EU's intended function is to create a uniform system, including currency, that facilitates the most frictionless and efficient transfer of goods, services, people, and factors of production while limiting the risks of currency conversion and fluctuation arising from vastly different country situations with respect to debt as a percentage of gross domestic product, unemployment levels, tax rates, industrial policy, etc. The point is not to have a uniform standard but to narrow the range of differences. As of 2008, there were 27 members, including Austria, Belgium, Bulgaria, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, the Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, and the United Kingdom. Croatia, Macedonia, and Turkey were still candidate countries in June 2008.

Economic Statistics

Economic statistics is composed of two interrelated fields, those related to data collection and those to data analysis. In fact, economic statistics is differentiated from other fields of applied statistics due to its unique data collection methods, and because of the scope/scale of analysis.

Most economic data is collected by governmental or large-scale pseudogovernmental agencies. These include the United Nations, the World Bank, and International Monetary Fund (IMF), and the various regional development banks. These are often compilations of data provided by the various countries' central banks. By its nature, macrolevel data is nearly impossible for individual researchers to collect. However, the governmental provision of economic data is increasingly extended to microeconomic data. In the United States, for example, the most comprehensive individual, or microlevel, data is compiled by the Census Bureau and the Bureau of Labor Statistics.

Economic statistics have traditionally been centered upon directly measurable concepts, or to concepts that are potentially well defined. For example, there is less ambiguity in the definition or proper measurement of "income" than there is in defining the concept of "happiness." For this reason, the statistical problems implied by large measurement errors require less attention in economics than in fields such as marketing or psychology.

Many economic phenomena can be measured in different ways; in fact, they are often defined in different ways as well. Some countries, for example, compute the inflation rate by adjusting each good's price by a quality improvement factor; others do not. For this reason, several agencies and companies have specialized in producing datasets that are internationally comparable. These include the Penn World Tables, the International Financial Statistics database compiled by the IMF, much of the data reported by the Organisation for Economic Co-operation and Development, and several databases compiled by the United Nations.

Methods

Econometrics is the application of statistical techniques to the analysis of economic data and their interrelationships. Physical scientists, and some social scientists, can often rely upon carefully crafted, controlled experiments with which to collect data and test competing theories. Because large-scale controlled experiments are not feasible on a national level, econometrics required a unique set of tools.

In earlier statistical research using the regression methodology, the role of regression was to estimate the correlation between an exogenous variable X on an endogenous variable Y, while holding the other exogenous variables constant. This is accomplished in a statistical sense, since controlled experiments are rare in economics. This is done simultaneously for many endogenous variables within a single equation: Y is a function of Xs.

The concept of General Equilibrium, however, required that the economic variables of interest are jointly determined. That is, X causes Y, but Y also causes X. This phenomenon is often termed the "endogeneity problem." Since all economic data in the United States, for example, are determined within the same national economy, the analysis is significantly complicated. Such endogeneity is, in fact, the cornerstone of economics, as embodied in the Supply and Demand graphs, a system of two, not one, equations. Market prices and quantities are determined by the interaction (indeed, intersection) of supply and demand. Thus, one cannot hold price constant in order to isolate the effects of X on quantity.

Econometrics, as a unique field of study, arguably began with the formation in the early 1930s of the Cowles Commission, the Econometric Society and their journal *Econometrica*, and in the 1940s with the Department of Applied Economics at Cambridge. As fitting the world's preoccupation with the global macroeconomic problems of the time, economic theory and economic statistics became understandably macro-oriented. Especially at Cowles, the aim was to study systems of equations much larger than the simple two-equation supply-and-demand system. Rather, dozens of such systems were incorporated into large-scale models of economies, with each sub-market influencing and being influenced by all other markets. During this time, the mainstream economic school of thought was Keynesianism, according to which there is a large role for government in controlling the economy. Thus, measurement and analysis were prerequisites to control. The Keynesian macroeconometricians sought to estimate the parameters of their many economic equations. These parameters were thought to be constants just as there are physical constants in the hard sciences. Once all of the economies' parameters were estimated, fine-tuned economic prediction and control could be exercised.

Governmental institutions became engaged in developing truly massive systems of hundreds of equations with which to model their home economies; this, in an attempt to predict the likely outcome of proposed economic policies. This method of analysis remained the dominant technique until the 1970s, when very simple time-series models were found to outperform their large-scale brethren. These simple models, developed largely by George Box and Gwilym Jenkins, were usually univariate time-series models which leveraged the inertia in economies by putting lagged dependent variables as the key terms used for prediction.

In 1976, an influential paper by Nobel Prize–winning economist Robert Lucas introduced what is now known as the "Lucas Critique." This critique, in effect, pulled the theoretical rug out from under large-scale econometric modeling. Lucas argued that even the estimated parameters were the results of the economic process; the parameters were not unchanging and structural, they were also endogenous. From that point onward the systems approach has been largely abandoned in favor of a return to single-equation models, though these are considerably more complex than the univariate time-series models of Box and Jenkins. (Interestingly, this occurred at largely the same time that other social sciences turned from single-equation models to multiple "structural equations" models.)

Econometrics is at the intersection of economic theory and economic data, where the priority of one over the other remains in dispute. For some economists, the primary role of econometrics is to test the validity of economic theories. In the physical sciences, where theory is well established, the functional forms of the equations to be estimated are well defined. These well-defined forms have not been found in the social sciences. For many econometricians, proper practice requires developing a formal model with microfoundations (utility functions, production functions, etc.) as a necessary step prior to estimation. If one theory, for example, maintains that there is a positive relationship between X and Y, but it is estimated that the relationship is negative, then it can be argued that the theory has been falsified. On the other hand, a completely different conclusion can be drawn.

There is often little testing that can be done regarding whether the equation that is estimated is properly specified in the first place. Thus, many researchers advocate using economic theory as a guide to model selection. In this vein, if an equation is estimated and it is found that there is a negative relationship between X and Y, this has not falsified the theory, but rather, it has called into question the equation that was said to represent the theory. Thus, a competing use of econometrics is the illustration, not testing, of economic theory. These researchers adopt a more intuitive approach to model selection. Finally, adherents to Chris Sims' theory-free approach eschew theory altogether, preferring the "data to speak for themselves." Sims' approach recognizes the endogeneity of all economic variables, and estimates all of their interrelationships, without placing restrictions on what these relationships would be (regardless of what economic theory may imply).

While much of this entry has been devoted to macroeconometrics, this is not to say that micro-level econometrics was not practiced throughout this time. However, most of this data was at the industry level, and so the data were necessarily aggregated to some extent. Increasingly, truly microlevel data—that is, data collected at the individual level—are being examined. In the United States, for example, popular microlevel datasets are collected by the Bureau of Labor Statistics and the Census Bureau. Moreover, under the guidance of Vernon Smith, experimental economics has established controlled experiments as a valid means of collecting microeconomic data. Increasingly, economists have become freed of the governmental macrolevel databases, and have begun generating their own microlevel data, tailored to their own research needs.

From the 1930s to the present, econometrics has been shedding its macroeconomic roots, and is largely indistinguishable from the other branches of applied statistics that use the regression approach. The differences lie in the questions that are asked, not in the techniques they use to answer these questions.

Economic Union

An economic union is the deepest form of economic integration between two or more countries that allows the free movement of capital, labor, and all goods and services. It also involves the harmonization and unification of social, fiscal, and monetary policies as well as labor market, regional development, transportation, and industrial policies. An economic union is also a common market with provisions for the harmonization of certain economic policies, most notably macroeconomic and regulatory policies. Since all countries would essentially share the same economic space, it would be counterproductive to operate divergent policies in those areas. The Latin Monetary Union in the 1800s, the Benelux Custom Union in 1944, and the European Union in 1957 can be given as examples for the existing economic unions. International institutions would be required to regulate economic, political, and social interaction within the union to ensure uniform application of the rules. These laws would still be administered at the national level, but countries would abdicate individual control in this area.

Any established economic union frequently includes the use of a common currency and a unified monetary policy. According to Paul De Grauwe, eliminating the national currencies and moving to a common currency is expected to lead to gains in economic efficiency for two main reasons. One of the reasons is to eliminate transaction costs associated with the exchanging of national money and to allow businesses to choose their locations freely. The other reason, for Ali El-Agra, is to eliminate the risk of uncertain future movements of the exchange rates. Eliminating exchange rate uncertainty improves the functioning of an economic union by allowing trade to follow economically efficient paths without being disproportionately affected by exchange rate considerations.

European Economic Union

Jorgen Hansen stated the ultimate goal for the European Economic Union was to create a European identity based on common values and a common desire to develop a Europe free of wars and to organize economic, political, and social relationships between the European member states and their peoples in a coherent manner. In order to create a dynamic framework for the European economies and to foster economic growth in that zone, a kind of economic interdependency among member states had to be created.

To be able to create the economic interdependence between countries, the first key goal was security. To be able to avoid the excesses of nationalism and of the nation-state system, in particular after two devastating world wars, establishing economic union in Europe was considered the best strategy. To protect countries from each other's destructive attacks, having similar goals was the best policy for common security. The second key goal was economic. Because of World War I (1914–18), economic depression in the 1930s, and World War II (1939–45), countries adopted protectionist trade policies to protect their economies and to stand on their feet. Nevertheless, after their initial recovery, they later examined the benefits of establishing a single market to minimize the damages of wartime destruction and to keep alive their economic ideology. Therefore, it was commonly believed that building the economic union would benefit all member states in Europe once all trade barriers were lifted gradually. The third and the final goal was political. To protect Europe from the Soviet threat and its political ideology was the main deterministic goal in establishing an economic union.

The first six member states—Belgium, Germany, France, Italy, Luxembourg, and the Netherlands—came together in 1951 with the intent to establish the economic union. Then, in 1973, Denmark, Ireland, and the United Kingdom joined, although not as full members. In 1981 Greece, in 1986 Spain and Portugal, and in 1995 Austria, Finland, and Sweden joined the European Economic Union club. Since then the enlargement has continued and other nations have applied for membership.

The GATT (the General Agreement on Tariffs and Trade), the OEEC (the Organization for European Economic Cooperation), and the EPU (the European Payments Union) were also established to increase trade liberalization and economic integration. The GATT was established in 1947 to reduce tariffs between countries and later in 1995 was transformed into the World Trade Organization (WTO). The OEEC was established in 1948 to coordinate financial assistance to rebuild European countries after World War II. The third organization, EPU, was established in 1950 to secure convertibility of currencies when countries engage in trade. Initializing the Single Market in 1986 was the next step toward influencing the economic structure of the countries involved.

Economies of Scale

Economies of scale refers to reduction in unit costs associated with producing large volumes of a product. Reductions in cost in this manner arise in a number of ways. First, by producing in volume, more of the fixed costs involved can be distributed over a larger number of final products. Then, too, large-scale producers can take advantage of specialized equipment and manpower that are highly productive due to increasing returns of specialization. Economies of scale play a critical role in global business today, with respect to government policy, regional integration, and business strategy. It is a central component of strategic trade policy (otherwise known as the new trade theory) and in the strategic profiles of multinational firms. A growing concern for multinationals is the increasing difficulties implementing economies of scale strategies in the 21st century.

The origins of economies-of-scale production can be traced to the early phases of the industrial revolution in the United States, and particularly in the second half of the 19th century. The ability to efficiently turn out products in large volumes was in part due to the growing pool of labor-saving machines designed and built by American inventors and machinists. A turning point in this progression was the shift from batch and semi-continuous production to fully continuous operations. The moving assembly line and the division of labor into specialized tasks carried out at specific workstations along that line to produce standardized products was a culmination point in this effort to place production on an economies-of-scale basis. The automotive industry—and Ford Motor Co. in particular—spearheaded this mass production revolution. Other industries soon adopted the technology in its various incarnations suitable to the particularities of their production processes.

Achieving economies of scale in production depended also on seamlessly integrating these machines and systems into the organizational fabric of the factory and ultimately the corporate structure as a whole. The close structural interlinkages formed between corporate divisions through managerial and organizational innovations by the third decade of the 20th century assured a smooth and timely flow of materials and components upstream into the plant and the readiness of the distribution network and market demand at the appropriate time downstream. All this contributed to a steady high-volume output of final product and the essential economies that attended large-scale production.

Since the 1980s, economies-of-scale production has diffused into many industries, including electronics and information technology. Economies of scale are also an important force in the evolution of the European Union and the rise of the "Single Market." The fact that much of Western Europe is a monetary union, for example, leads to economies of scale in financial markets and, in turn, greater availability of cheaper capital for multinationals.

Global Strategies

Economies of scale play an important role in global business strategy. Supporters of neomercantilist policies stress that governments that support certain industries, especially those burdened by high capital costs—which can include high research and development (R&D) costs—to achieve first-mover advantage in global markets actually produce a net positive impact for all countries. Such strategic trade policy is relevant in high–fixed cost industries, such as aircraft production, in which total market demand globally is limited and can support only one or two multinational companies (MNCs) efficiently. Government subsidies to these companies, including tax incentives, R&D support, and so forth, allow them to take early control of global markets. This assures them that they serve sufficiently large demand to produce in volume and, through economies of scale, at reduced costs. In turn, the market receives a greater variety of products at low prices. But government support is by no means a sine qua non of achieving such first-mover advantage.

An MNC that, through its own resources, attains economies-of-scale production can take control of global markets through appropriate pricing strategies. From the 1930s through the 1960s, the U.S. petrochemical industry proved particularly adept in this sort of strategy. They rapidly scaled up production of new products discovered in their R&D departments, thereby quickly securing a lock on markets within the United States and internationally. When competition eventually filters in—as it did in petrochemicals in the 1970s and aircraft production in the 1980s—the market becomes segmented and the minimum output required for the benefits of economies of scale to kick in cannot be achieved within any competing company. Inefficiencies then infect the industry as a whole, profits erode, and economic activity in the industry as a whole contracts.

The appropriate strategy to be taken by a multinational firm in increasingly globalized markets depends to a large extent on the degree of cost pressures it faces relative to pressures to be locally responsive. A specific type of strategy that is most effective in negotiating cost pressures is often referred to as a "global" strategy. These pressures can arise from companies having to bear high costs of production (fixed costs, R&D, etc.), face stiff competition in strategic markets, or both. At the same time, such MNCs make, sell, or distribute standardized, commodity products—e.g., bulk chemicals, petroleum, steel, sugar, and many industrial and consumer products—or services that have a universal need, and therefore are not concerned with redesigning products for different local markets. In these situations, MNCs can take full advantage of economies of scale by building and operating of a few large plants designed along mass production lines and located in strategically sensitive positions—near critical raw materials, central to its markets, optimal access to suppliers and subcontractors, and so on—around the world. Further, global industries that rely extensively on economies-of-scale strategies tend to be more difficult for outside firms to enter due to the high capital costs involved.

Transnational Strategies

In fact, most MNCs must realistically consider both cost and local pressures when devising and carrying out their business strategies. Differences in customer tastes and preferences, traditions and beliefs, infrastructure and distribution channels, and laws, regulations, and standards between countries compel MNCs to adjust—or customize—products and services to the specific requirements of local demand and conditions; at the same time, they must compete in both quality and price. The type of business strategy that must balance and coordinate these two types of pressures is called a "transnational" strategy.

Since an "economies of scale" or "global" strategy depends on the mass production of standardized products and services, and since a "localization" (otherwise known as "multidomestic") strategy functions by custom-designing products and services for smaller than mass production markets, a transnational strategy appears to require the balancing of competing and highly inconsistent demands. Nevertheless, recent organizational, logistical, and technological innovations have introduced crucial flexibilities in production and distribution functions that facilitate the effective implementation of transnational—or "mass customization"—strategies. Organizationally, the innovative global matrix structure differs from traditional architectures in that the control of a product or service is the shared responsibility of two managers, one specializing in geographical regions ("localization" expert) and the other in the global production and distribution of the product or service ("economies of scale" expert). These managers work together to simultaneously handle localization and cost pressures.

Logistically, transnational firms handle cost pressures by designing its products to use standardized components that are then assembled into a basic machine in a few large, strategically placed plants (thus meeting the "economies of scale" requirement). The MNCs then deal with local pressures by sending the mass-produced product to smaller finishing facilities for modification to regional demand and distribution requirements. Technologically, the incorporation of information technology and computer-aided design into mass production plants allow rapid model changeovers (to meet local demands) at low economies-of-scale costs. Industries that employ transnational strategies include pharmaceuticals, agricultural equipment, textiles and apparel, and automotive.

In general, business strategies that require consideration of economies of scale—whether global or transnational—are more difficult to implement than multidomestic strategies in terms of need for coordination of information and resources, integration of functions and skills, and cultural controls.

Economies of Scope

Economies of scope refers to the cost savings and efficiencies generated by the joint production or distribution of final goods and services. Rather than specializing in a single product, a firm can promote its profitability as well as control some of its market risks by diversifying its product line to take advantage of inherent and acquired economic, technical, and organizational advantages. In the late 19th and early 20th centuries, large firms noticeably began to develop into multibusiness firms; but less conspicuously and often on a much smaller scale, other individual manufacturers with comparable incentives became multiproduct firms. Profit maximizing remains a core assumption in standard business models and firms that produce related products can often do so at lower average production costs.

The basis for the joint production of goods, or economies of scope, can vary in the particular but generally it occurs when a manufacturer utilizes common material inputs (including specialized labor skills) within existing production and managerial facilities to fabricate related final goods. Consequently, a particular firm can become more efficient and more profitable in production without necessarily altering the size or scale of its operations.

Since multiproduct firms have the capability to start and stop production relatively quickly, it also suggests that even in situations where there are a limited number of firms, a market may nevertheless be fairly competitive in practice. However there are situations where there are trade-offs between economies of scale and scope, so the relative mix and number of specialized and integrated establishments and/or firms can be influenced by relative market conditions. Efficiency is ultimately promoted by improved coordination and managerial advances, but given that technological variances persist across various sectors of the economy, there will likely not be a standardized model of firm specialization and integration.

The ability of a particular operating unit to engage in joint production will be inhibited by any inadequate and undependable flows in the inputs needed in the production process, but given sufficient resources and market conditions, a firm could reliably use its assets to manufacture, market, and distribute different but related goods. There are technical and market benefits for producing different yet related goods, since the manufacturer's advantages are centered in its abilities to employ its existing and often specialized resources at full capacity and thus cost efficiency as well as to diversify its product offerings enough so the firm might avoid or at least delay market saturation. A manufacturer operating below capacity can reduce its variable or operating costs somewhat but its fixed or overhead costs remain even with idle production facilities. The firm's relative efficiency (its average cost of production) can be measured by summing its fixed and variable costs relative to its level of output.

Firms with sizable fixed costs cannot realistically afford to underutilize production capacity. For instance, consider the example of an electronics manufacturer that develops an integrated circuit to be used in a line of high-quality and long-lasting handheld electronic calculators. The technical expertise needed to design and build their integrated circuitry may well have required significant overhead (fixed) costs, but if the firm intends to manufacture only electronic calculators, it faces higher average costs once they have saturated the existing calculator market. On the other hand, the manufacturer's available workforce, production facilities, and technical innovations may find application in any number of related products (such as electronic watches, musical instruments, cameras, and other digital devices) that could be efficiently and profitably manufactured, marketed, and distributed by the firm within its existing resources and organization.

Economies of scale and scope played a significant role in the years from around 1880 until the start of World War I as big business began to dominate several industries including oil, steel, chemicals, electricity, machinery, automobiles, and tobacco. Several of these industries had been transformed not only by the adoption of continuous-process production techniques and more functional interchangeable parts but also by the implementation of more sophisticated and professional forms of business organization. Economies of scale, cost savings, and efficiencies related to the same activity, often get more widespread notice than do economies of scope, but this may be due more to the sensationalism of bigness rather than the realization that it is more practical for many firms to consider scope ahead of scale as a means to reduce costs.

Ecuador

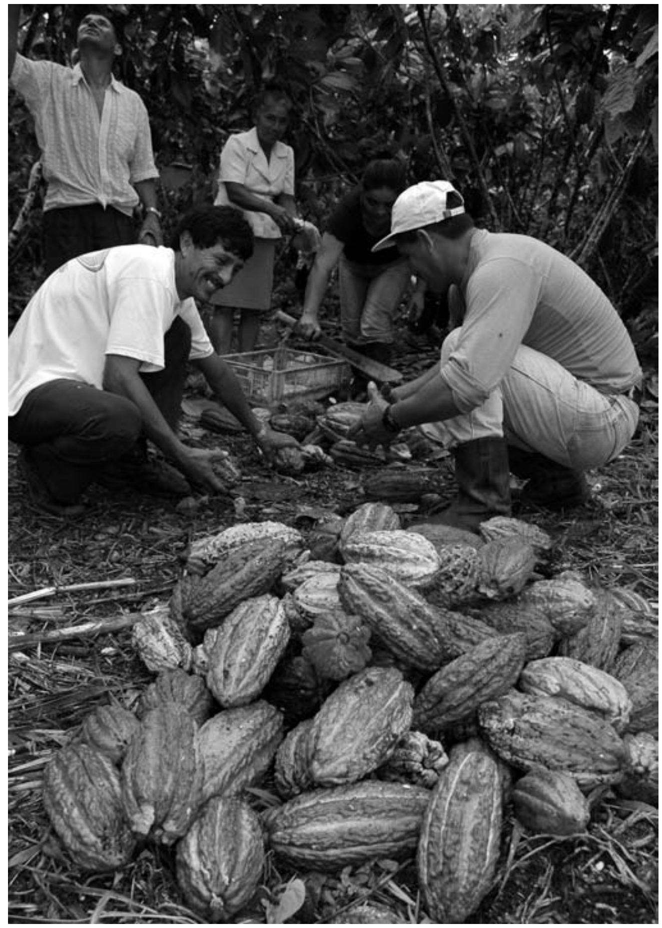
Located on the west coast of South America, sharing borders with Colombia and Peru, Ecuador has a population of 13.7 million. It was a part of the Inca Empire until the arrival of the Spanish in the 16th century. Ecuador gained its independence as a part of Gran Colombia in 1822, and as an independent country in 1830. Historically, the economy of the country has relied heavily on agriculture with the export of primary products including bananas, flowers, and shrimp. However, for many years the major export was cacao, used to make cocoa. There was also a substantial export economy in sugarcane, tobacco, and cotton. Some of the latter was turned into clothes in workshops known as *obrajes*, where many locals, in poor working conditions, would make woolen and cotton clothes. Sugarcane was often used to make pure sugar, and also molasses and rum. Most of this came from "Costa," the coastal region of the country that developed at the expense of the "Sierra," the Andean highlands. The Spanish also established a large shipyard at the main port, Guayaquil, and it soon became one of the biggest in Spanish America.

With independence in 1830, much of Ecuador's population of about 500,000 was working in agriculture as sharecroppers. Labor was cheap and the country's cash crops, which were grown for export, were able to be produced more cheaply than in most other countries. As a result, Ecuador's economy was very much linked into the world economy by the middle of the 19th century. This meant that at times of economic slump overseas, the Ecuadorian economy would suffer. To increase the amount of foreign income, in the second part of the 19th century, the production from cacao was tripled—it became the mainstay of the economy and also Ecuador's principal source of foreign currency—and the total exports of the country increased 1,000 percent. Although Quito remained the capital, Guayaquil came to be the commercial center of the country, and for imports and exports.

During the 1930s and the 1940s, pestilence caused a major diminution of cacao production throughout the country, and the government sought to revitalize the economy by promoting the growing of bananas. This started in 1948, but there was a sudden increase in demand for cacao, and although bananas had started to replace cacao as the major export crop by the mid-1950s, Ecuador remained the sixth largest exporter of cacao in the world in 1958. The banana industry, however, was successful with help from the United Fruit Company, although demand began to fall in the late 1960s, and by 1972 the country had to, once again, restructure itself.

By the 1980s, agriculture and fishing were still the largest employers in the country, and made up nearly half the country's foreign currency earnings. In 1986, bananas, coffee, and cocoa combined made up only 2.4 percent of the country's total gross domestic product. By this time Ecuador also started to benefit from the tourist industry, with many people visiting the Galapagos Islands, and there was coastal fishing from Guayaquil, the country's largest city and a major port. Guayaquil now has a population of over 2 million, compared to just less than 1.5 million for Quito.

The discovery of petroleum in the early 1970s and its exploitation have transformed the country. This coincided with a major increase in the world demand for petroleum, and with the oil crises of 1973–74 and 1979, petroleum rapidly became one of the major sectors of the Ecuadorian economy. This helped finance increasing government expenditure and in May 1992 about 1.1 million hectares were handed back to indigenous communities. To ensure that the economy continued to remain strong, in 1992, Argentina had pegged the local currency, the Sucre, to the U.S. dollar, and Ecuadorian president Jamil Mahuad decided in 2000 to adopt the U.S. dollar as the official currency of his country. Although there were initial political problems, the U.S. dollar was adopted in 2001.



Farmers sorting cacao pods as part of a USAID project in Ecuador, where oil has overtaken cocoa production.

In 2008, Ecuador was decried for attempting to wrongly get billions of dollars from Chevron through legal maneuvers over what some saw as bogus pollution charges against Chevron.

Education Allowance

An education allowance is broadly understood as a stipend or other payment made by public funds or from an employer to an employee undergoing training for a certain period, usually outside the normal place of work. More narrowly understood and as used here, it is a stipend or other payment program where the target employees are mid-career or late-career, and the practice thus not part of initial education and training.

In general, an education or training allowance (EA and TA, respectively) may be regarded as attempting the implementation of knowledge society–oriented policies at corporate, national, and international levels. This means that the extent and contents of the practice, including terminology, varies greatly. Overall the practice tends to follow the philosophy inherent in the conventional International Labor Organization (ILO) definitions of lifelong learning used as encompassing all learning activities undertaken throughout life for the development of competencies and qualifications, and by the European Commission (EC) as encompassing all purposeful learning activity, whether formal or informal, undertaken on an ongoing basis with the aim of improving knowledge, skills, and competence.

Prominent examples of public EA and TA implementation include Denmark's financial support systems within the Adult Education Reform Act of 2001 and Sweden's new adult education recruitment grant scheme introduced in 2003. The latter is aimed at people aged 25–50 with relatively little initial education. In Finland an adult education subsidy is available to employees and self-employed persons who have a work history of at least 10 years and wish to go on a study leave. Ireland's expenditures for adult literacy programs increased approximately nineteenfold during 1998–2003.

In theory EA may benefit both employers and employees by securing continuous learning for the individual employees and the corporation. From the perspective of the employers, there is a certain risk that employees receiving continued education might leave the corporation in spite of or because of newly attained education levels. It is, in addition, a challenge to determine what kinds of education and training should be deemed as relevant and eligible. A narrow and focused approach could be perceived by employees as too instrumental and hence lack the motivating factor, whereas too-broad approaches may lead to distractions from the necessities of operations. For managers operating in multiple countries an additional challenge is to familiarize oneself with the legal requirements and possibilities regarding the practice. For employees the benefits of continued education may on the one hand be self-evident, whereas the implementation may be seen as coming at the expense of executing day-to-day responsibilities.

One should be aware of the lack of consensus regarding vocabulary within this field. Some countries (e.g., Australia, Finland, Norway, and Sweden) usually refer to EA or TA broadly, much in accordance with the definition and examples rendered here, whereas other countries may use the EA and TA concepts mostly for specific situations or target groups, such as the U.S. public programs targeted specifically at military veterans, United Kingdom programs for young persons, Irish programs for disabled persons, and several countries using the concept with reference to continued education programs for unemployed persons. Individual sectors sometimes operate with specific concepts, e.g., the health sector and its concept of postgraduate EA (PGEA).

Effective Rate of Protection

Protection of domestic industries from international competition is a common policy of many countries. Tariffs on imported goods (and services) are just one form, albeit the most common one, of such protection. A tariff of 10 percent (for example) allows domestic industry an "inefficiency cushion," that is, it allows the domestic firms to be about 10 percent less efficient in their production costs and still be able to compete with imported products. If, however, domestic firms have to obtain their inputs at higher prices than their international competitors, their "inefficiency cushion," more precisely their effective rate of protection, is reduced. Government's efforts to protect the input producing industries, in this case, reduce (or even negate) the protection that the government wishes to provide the downstream industries. Generally the effective rate of protection for an industry will be higher than the nominal tariff rate when its input producing industries are not protected, and lower when its input producing industries are protected even more.

Effective rate of protection can be calculated by isolating the value added of an industry. Consider the case of the barbed wire industry. Assume that the international price for barbed wire is $1,200/ton and, for the sake of simplicity, that the only input required to produce barbed wire is steel. Further assume that the international firms can purchase steel at $1,000/ton and need one ton of steel to produce one ton of barbed wire. Given this price structure, international firms add a value of $200/ton to steel to produce barbed wire. Now consider the domestic industry in a country where the government wishes to protect its barbed wire industry and imposes a tariff of 10 percent on imports. If there were no tariffs on steel, domestic firms would import steel at $1,000/ton and could compete with imports as long as they could produce and sell barbed wire at $1,320/ton. This allows them a margin of $320/ton compared to a margin of $200/ton for international producers. Their effective rate of protection is, therefore, 60 percent, much higher than the nominal protection rate of 10 percent.

Suppose now that the government also wishes to protect the steel industry and imposes a tariff of 20 percent on steel imports. Domestic producers of barbed wire now have to pay $1,200/ton for their raw material and have to convert steel into barbed wire at a maximum cost of $120/ton. They have to be more efficient than their international competitors. Their effective rate of protection is minus 40 percent.

In a situation where the only protection is provided in the form of tariffs, the effective rate of protection (ERF) can be calculated as follows:

$$\mathrm{ERP} = (t_f - i \,.\, t_i) \,/\, (1 - i)$$

Where t_f is the tariff on the finished products, t_i is the tariff on inputs and "x" is the proportion of the value of the finished product accounted for by the inputs in the international (tariff-free) environment.

The difference between nominal and effective rates of protection helps in understanding the arguments behind imposition and lifting of tariffs on steel by the U.S. Government. The steel industry in the United States used to have significant political clout and since the early 1970s, it had successfully lobbied for protection. The last round of tariffs on steel was approved by President George W. Bush in March 2002 and all tariffs were finally removed in December 2003. The removal of these tariffs was cheered by steel importing firms that needed steel as an input. Higher cost of one of their imports had required them to be more efficient than their international competitors.

Effective rates of protection are notoriously difficult to calculate. Last known estimates were quoted by Giancarlo Gandolfo (1994). In the United States, the soft drink industry had a nominal tariff rate of 1 percent but an effective rate of minus 9.5 percent. Similar numbers for the soybean oil industry were 22.5 percent and 253 percent. In the European Economic Community the median tariff rate of 12.1 percent resulted in an effective rate of 33.1 percent. Similar numbers for Japan were 16.5 percent and 45.4 percent. These examples merely highlight the importance of examining effective rates of protection rather than making policy based solely on the nominal rates.

Egypt

Egypt is situated in the northern region of Africa, bordering the international frontiers of the Mediterranean Sea to the north, Libya to the west, Sudan to the south, and the Red Sea to the east. It encompasses the Asian Sinai Peninsula and enjoys the rich flow of the Nile River. Egypt is a major player in Middle Eastern geopolitics, stemming from its strategic position as a transcontinental nation. Arabic is the official language, and English and French are widely understood by educated classes and used in business activities.

Egypt has a total area of 1.01 million sq. km. Since 1953 and after independence from British control, it became a republic and currently encompasses 26 governorates, with Cairo as the capital. The population was estimated at 81.714 million in August 2008; the great majority live near the banks of the Nile River, an area of about 40,000 sq. km making up only 5.5 percent of the total land and constituting Egypt's only arable agricultural land. Egypt's currency, the Egyptian pound (L.E.), is 5.331 to the U.S. dollar in August 2008. In terms of religion, Islam is practiced by 90 percent of the population; the remainder are Coptic/Christians.

Over time Egypt has embraced the Pharaonic, Greco-Roman, and Coptic civilizations, in addition to its historic role as a satellite for the Islamic civilization. It contains some of the world's most famous monuments, including the Pyramid complex and Sphinx. The southern city of Luxor possesses numerous ancient relics, such as the Karnak Temple and the Valley of the Kings. Egypt was the first country in ancient times to introduce writing with the creation of the hieroglyphic signs and letters used in recording historical episodes and activities.

It is endowed with rich natural resources such as iron ores, phosphates, manganese, limestone, lead, and zinc, in addition to petroleum and natural gas. Its main industries include textiles, food processing, tourism, chemicals, pharmaceuticals, hydrocarbons, construction, and cement. The economy depends mainly on income from agriculture—key agricultural products include cotton, rice, corn, wheat, beans, fruits, and vegetables. Egypt controls the Suez Canal, a navigable waterway that presents a sea link between the Indian Ocean and Mediterranean Sea.

After a harsh period of stagnation, Egypt's economy began considerable development in recent years after the adoption of more liberal economic policies by the government. The stock market boomed and gross domestic product (GDP) grew by about 6.9 percent per year in 2005–06, and topped 7 percent in 2007. Foreign direct investment (FDI) into Egypt also has increased considerably in the past few years due to recent economic liberalization measures. With favorable costs of land and labor as well as competitive prices of electricity and gas, the government offers generous incentives to invest in Egypt's private sector, including investment laws revolving around tax incentives, customs exemptions, and many new investor protections and guarantees.

FDI reached US$6.1 billion in 2005/2006, increasing 50 percent from 2004, and with a significant boost in 2006/2007, it set the stage to reach about US$10 billion in 2007. Egypt also takes part in a number of trade and investment agreements with different countries, such as COMESA and GAFTA

A factory in Egypt that was funded in part by a line of credit from the African Development Bank to the National Bank of Egypt in 2005 in an attempt to improve employment opportunities in over 200 small and medium-sized enterprises in the country.

with Libya and Sudan, QIZ with Israel, AGADIR with Jordan, Tunisia, and Morocco, and TIFA with the United States. It has a market capitalization amounting to 65 percent of GDP and recently had a 30 percent increase in non-oil exports; net foreign reserves recorded US$28.6 billion in May 2007, up from just US$14 billion in 2003/2004. Export sectors, especially natural gas, represent a promising potential for the economy.

However, the internal economic situation for citizens has recently been rather dismal. This is because, despite its achievements, the government has failed to raise living standards for the average Egyptian, and has had to continue providing subsidies for basic necessities. Such subsidies have contributed to a sizable budget deficit of approximately 7.5 percent of GDP in 2007, which represents a significant drain on the economy. Therefore, the government needs to continue its aggressive pursuit of reforms in order to sustain the spike in investment and growth and begin to improve internal economic conditions for the greater population.

Egyptian companies are successfully competitive overseas and have expanded regionally and internationally; a particularly productive example is the information technology (IT) sector that has witnessed rapid growth in recent years with 30 billion Egyptian pounds invested in information and communication technology companies. Illustrating a favorable economic climate, many of those companies conduct business with giant corporations in North America and Europe. Such moves aim to increase exports from US$250 million in 2005 to US$1.1 billion in 2010.

Eléctricité de France

Eléctricité de France (EDF) is an energy operator involved in the generation, distribution, and transmission of electrical energy. It operates globally to provide energy and services to 38.5 million customers. EDF mainly operates power plants (hydro, thermal, nuclear, and other renewable) and distribution systems. For the fiscal year ended December 2007 the company recorded revenues of $81,702.7 million. The company controls about 84 percent of France's electricity market. Top direct competitors of EDF include E.ON, RWE, and Enel.

EDF was established in 1946 and nationalized by the French government. As a public undertaking of an industrial and commercial nature, EDF replaced more than 1,000 private companies that up until then had been responsible for generating, transmitting, and distributing electricity. By 1950, the rationing of electricity had stopped and distribution networks had been completed or rehabilitated. EDF remained a national company focusing only on the French market until 1992. In 1992, EDF created the holding company Eléctricité de France International and expanded into many global markets, gaining presence in Africa, Asia, North America, and the Middle East. Further strategic developments included the acquisition of London Electricity by EDF's United Kingdom subsidiary.

Since the creation of EDF International, EDF has increased their presence in the global energy arena. In 2003, through a French-Japanese consortium, EDF began construction of a power plant in Vietnam. In the same year, EDF was involved in the first gas pipeline constructed in Mexico, providing experience in gas transport. Simultaneously, through increased investment in research and development (R&D), EDF inaugurated a farm of eight wind generators in France. EDF continued their rapid global expansion through joint ventures, alliances, and acquisitions of local providers of electricity and energy. In 2005 they acquired 100 percent stake of the generation company Laibin Electric Power in China. EDF expanded in Europe as well, acquiring organizations in Poland, Italy, Greece, and Switzerland.

EDF demonstrates capacity for innovation, offering customers services through energy savings, renovation advice, and decentralized renewable energy generation solutions. One of the main strengths of EDF is their R&D capabilities. The group's R&D aims at developing tools and methods to improve operations and optimize the life span of facilities without compromising safety. The dedication of EDF to product and system innovation is reinforced by the strong portfolio of patented products, which consists of 375 patented inventions.

Another strength of EDF is their strong financial position. Through expansion in the global energy arena, EDF has managed to accumulate strong financial growth. There has been a steady increased in profits since the establishment of EDF International. The company's margins are also higher than its main competitors' in 2007. The operating profit margin of EDF was 17 percent as opposed to 15.2 percent of E.ON, 13.7 percent of RWE, and 16 percent of Enel. This increase in margin reflects the efficient cost structure of the company. It also shows the success of EDF's management in controlling costs despite fierce competition and pricing pressures in the energy sector. This cost control is also associated with the heavy investment in R&D that lies at the heart of EDF's organizational culture.

Moreover, EDF is a vertically integrated company with a diversified presence. This diversity of businesses offers a competitive advantage for EDF as it provides cross-selling opportunities to the company and enables it to spread its revenue base.

However, EDF has experienced problems in recent years. The company was charged with involvement in market manipulation in 2007. The European Commission charged that its long-term supply contracts with industrial users have blocked other electricity providers from offering their services. EDF has also been criticized about the condition of their hydroelectric dams. In 2006, 450 dams showed signs of decay and posed a risk to the environment. EDF announced that they will invest $685 million in improving the conditions of the hydroelectric dams.

Overall, EDF has shown a steady increase in their profits, continuous improvement of their operations, and efficient management of their dynamic capabilities. EDF has managed to establish themselves as key players in the global energy industry through extensive organic growth as well as strategic acquisitions and alliances.

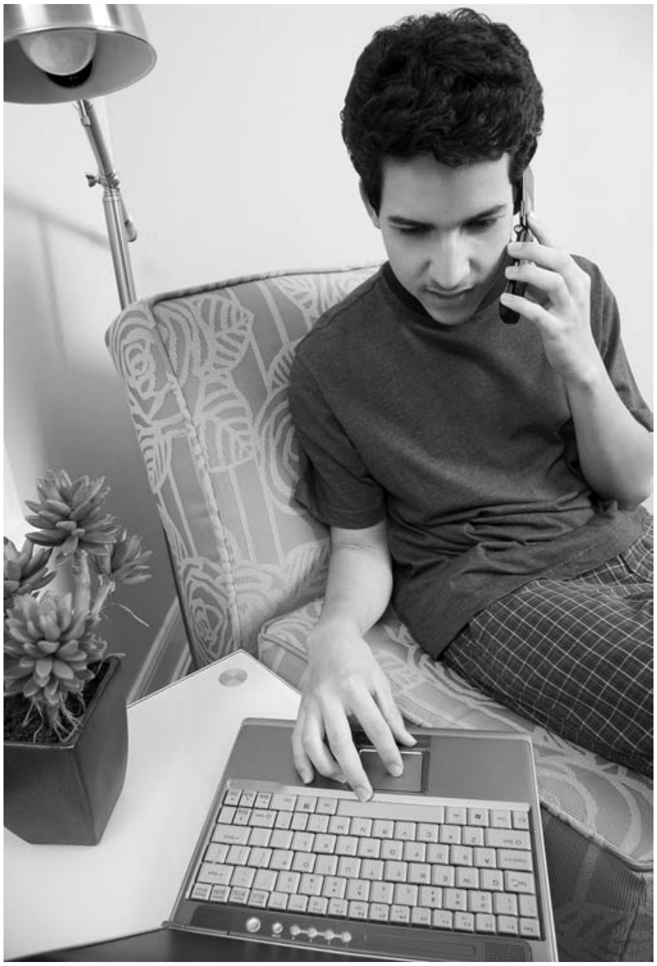
Electronic Commerce

Electronic commerce, or ecommerce (sometimes conducted by online "etailers"), is the selling of products and services online and through other electronic services. Since the 1990s, it has been a growing sector of the American economy, with significant impact both on the economy in general and on specific industries. It is especially associated with online stores located on the World Wide Web, which for many people is metonymous with the internet itself.

The earliest electronic commerce was enabled by the development of electronic funds transfer—the shifting of money electronically from one account to another, whether in the form of online banking, direct deposit and debit, or the use of credit and debit cards at ATMs and points of sale. In that sense, the first ecommerce consumers were aware of was the use of electronic systems to facilitate credit card purchases, in the 1970s and early 1980s. ATMs and telephone banking spread throughout the 1980s, allowing more and more access to one's money without needing to go to the bank; by the end of the decade, debit cards were in use at many supermarkets and gas stations, and through the 1990s debit cards became more universally useful as Visa and MasterCard branding was attached to them and regional interbank networks such as MAC and Pulse adopted mutual agreements.

Visa- and MasterCard-branded debit cards soon assisted online ecommerce as well, by enabling online purchases without the use of a credit card and without the delays or security concerns of an electronic checking balance transfer. Early online marketplaces were bulletin board system (BBS) based, predating the arrival of internet access in most homes. The Boston Computer Exchange—BCE or BoCoEx—was the first of these, enabling the buying and selling of used computers and computer parts in 1983, arriving at the same time as the IBM XT (the successor to IBM's original PC).

A precursor to eBay, BCE allowed home users to browse inventories uploaded by sellers; but in these early marketplaces, only the shopping was done online, and purchases were conducted over the telephone. BCE realized an early side benefit to running its marketplace, issuing each week the BoCoEx Index, listing the high, low, and closing prices for the most popular items in its marketplace. The Index quickly became the "blue book" for used computers, used in asset valuation and court cases, and was published by the major industry magazines. Within a few years, BCE was licensing its software and technology to computer exchanges in other cities—and in Chile and the Soviet Union.



As home internet access spread, online shopping grew rapidly, becoming a $200 billion business in the United States by 2008.

1994 was the big year for home internet. Though available through dial-up internet service providers for years in many cities, the popularity of the internet was slim compared to online services like America Online and Prodigy—in no small part because those services offered graphics and a single program interface, while internet access was spread out among multiple protocols like telnet, email, and FTP, with limited or no graphics. But in 1994, Netscape's browser for the World Wide Web was introduced; through the use of hypertext, the Web (as proposed by Tim Berners-Lee at CERN) unified multimedia content in an experience much like using America Online, with far more content. Commerce arrived quickly: Pizza Hut instituted online ordering in some markets, online banking began, and online pornography and flower delivery were introduced within months of each other. Netscape soon upgraded its browser to provide encrypted communications, making credit card transactions more secure. The following year, Amazon and eBay—still the two giants of ecommerce—launched.

The dotcom boom shortly followed, even before DSL and cable internet access made highspeed home internet access commonplace. Companies like Amazon, eBay, PayPal, Google, Yahoo, and YouTube became household names, introduced by and associated with a technology adopted as fast as radio and television had been. The bubble burst in 2000, in part because of exuberant overspeculation, venture capitalists who didn't understand the marketplace well enough because it was too new to be known, and too many big ideas that didn't clearly lead to profit; but the internet quickly showed that it would become more and more integrated into everyday life rather than fading like a fad, and ecommerce was no less integral a part of the economy when the boom died off. In 2003, Amazon posted its first profits. By 2008, American ecommerce accounted for over $200 billion in sales.

Newer, robust protocols and systems have been developed to process online transactions, for the protection of privacy and financial data, in an environment of increasing concerns over identity theft and other fraud. Whole industries have emerged around or developed in response to ecommerce. Even more than catalogue mail order, ecommerce has enabled the success of niche direct-to-consumer companies, from barbecue shacks selling their sauce online to independent record labels making their albums available for purchase. The mp3 has become the common commercial unit of music, and billions of dollars of ringtones are purchased each year, directly from cellular phones. Amazon has introduced its Kindle, an ebook reader revolutionary not in its design—competing models are similar—but in its integration with Amazon's inventory and the ability to purchase ebooks wirelessly without need of a home internet connection.

Companies like Netflix, which rents a flexible number of DVDs a month for a flat fee, have successfully competed with their "brick and mortar" counterparts. Blockbuster soon found it necessary to offer a DVD-by-mail subscription service as well, while Movie Gallery, the second-largest American movie rental chain, filed for bankruptcy in 2007.

Electronic Data Interchange

Electronic Data Interchange (EDI) refers to the linking together of channel member information systems to provide real-time responses to communication between channel members. For example, a retailer's computerized inventory management system is connected with and monitored by a wholesaler's computerized inventory management system. Ordering of merchandise can then take place automatically when the retailer's inventory level of that wholesaler's products reaches certain minimum re-order points. Thus, the retailer's computer orders the products from the wholesaler's computers without human intervention or paperwork of any kind. The more sophisticated EDI systems can also forecast demand based on sales history. In the case of the wholesaler-retailer relationship the wholesaler's computers will initiate the order for the retailer by predicting what quantity of the product the retailer will need during a specific accounting period. EDI systems can also be linked to production scheduling, allowing production to be determined by sales patterns in the different retail outlets. That is, merchandise that is being sold on a given day in retail outlets around the country will provide the necessary information to guide a manufacturer's production process taking place on the same day.

The emergence of the internet has enhanced the potential of EDI because the internet enables firms to be connected and communicate in a similar manner to EDI but with less investment in computer hardware and software. As such, firms linked via the internet will be able to enjoy the benefits of EDI at a significantly reduced price.

EDI technology enhances distribution efficiency, resulting in substantial benefits to all channel members, including the final customer and consumer. The manufacturer benefits through more accurate production scheduling, while wholesalers and retailers benefit via savings on order processing and inventory carrying costs. The final customer benefits from the reduced distribution costs made possible by EDI and by the higher probability of finding the items they are seeking on retailers' shelves. The obvious primary barrier of EDI is that all channel members must share information openly for the EDI system to work. For those channel members who feel they need control of what they believe to be sensitive or confidential information about the sales of their products, EDI does not have a great deal of appeal.

There are also other barriers to adopting EDI. One of the most significant of these is the necessary change in business processes. Existing business processes built around slow paper handling may not be suited for EDI and would require substantial changes to accommodate automated processing of business documents. For example, a business may receive the bulk of their goods by one- or two-day shipping and all of their invoices by mail. The existing process may, therefore, assume that goods are typically received before the invoice. With EDI, the invoice will typically be sent when the goods ship and will therefore require a process that handles large numbers of invoices whose corresponding goods have not yet been received.

Another significant barrier is the cost in time and money in the initial set-up. The preliminary expenses and time that arise from implementation, customization, and training can be costly and therefore may discourage some businesses from adopting EDI. The key is to determine what method of integration is right for the particular company, which will in turn determine the cost of implementing EDI. For a business that only receives a small number of orders on a per annum basis from a client, fully integrated EDI may not make economic sense. In such a case, a business may use outsourced EDI solutions provided by EDI "service bureaus." For other businesses that have relatively large volumes of orders from a particular client, the implementation of an integrated EDI solution may be necessary as increases in trading volumes brought on by EDI force them to re-implement their order processing business processes.

The key disadvantage to successfully implementing a fully integrated EDI system is the perception of the nature and format of EDI. Many view EDI from the technical perspective that EDI is in a data format. It would seem to be more beneficial and accurate to adopt the perspective that EDI is a system for exchanging business documents with external entities, and integrating the relevant data from those documents into the company's internal systems and records. Successful implementation of EDI takes into account the effect that externally generated information will have on their internal systems and validates and verifies the information and data received. For example, enabling a wholesaler to reorder product for a retailer without appropriate checks and balances would be a recipe for disaster leading to overstocking in certain product lines and possibly stock outs in others. Businesses new to the implementation of EDI should take pains to avoid such pitfalls.

Increased efficiency and cost savings drive the adoption of EDI for most trading partners. EDI has revolutionized traditional ordering practices and has dramatically reduced the occurrence of stock outs among retailers and wholesalers. Instead of having to write an order, phone it in and wait for confirmation, a channel member simply inputs the order on a computer terminal and it is electronically transferred to the manufacturer's computer system almost instantaneously. Once the order is received by the manufacturer, products are picked from inventory, delivery documents are prepared, a carrier is notified to pick up the order and a proforma invoice is issued. Most systems also make adjustments to invoices, confirm orders, provide shipping advice, and present information on new products, price changes and promotional programs.

In the most sophisticated EDI systems, the wholesaler's computer does not wait for orders to come in from retailers but takes the initiative by interrogating the retailer's computer to check inventory levels. If the retailer is low on any items, the wholesaler's computer automatically places an order for the retailer.

El Salvador

El Salvador is the smallest country in Central America, bordering the north Pacific Ocean between Guatemala and Honduras. The total land area is approximately 20,720 sq. km (about the size of the U.S. state of Massachusetts). According to estimates in June 2008, over 7 million people inhabit the country; the population growth rate is 1.68 percent and the median age is 22.2 years. The country achieved independence from Spain in 1821 and from the Central American Federation in 1839. A civil war between 1979 and 1992 ended with the government and the leftist rebels signing a treaty that provided for political and military reforms.

Almost 90 percent of the population belong to the mestizo ethnic group, 9 percent are white, and the remaining 1 percent are classified as Amerindians. Approximately 83 percent are Roman Catholic, but there is no official religion. Spanish is the official language, although some Amerindians speak Nahua and other native languages. Culturally, according to Geert Hofstede's analysis, El Salvador scores very high on "uncertainty avoidance," indicating a high concern for rules, regulations, controls, and issues of career security and risk averseness. On the other hand, they rank fairly low on "individualism," indicating a propensity toward collectivist tendencies, i.e., manifesting in close long-term commitments to family, extended family, or extended relationships, and everyone taking responsibilities for fellow members of their group.

El Salvador has the third-largest economy in Central America, yet growth has been modest in recent years. The country's gross domestic product (GDP) was $41.65 billion in 2007 and was growing at the rate of 4.7 percent a year. It exported $3.85 billion worth of commodities to the United States (50 percent), Guatemala (14 percent), Honduras (9 percent), and Nicaragua (5 percent), primarily in the form of offshore assembly, coffee, sugar, shrimp, textiles, chemicals, and electricity. The commodities imported were valued at approximately $8.2 billion (2007) in the form of raw materials, consumer and capital goods, fuels, foodstuffs, petroleum, and electricity, primarily from the United States (32 percent), Guatemala (9 percent), Mexico (7 percent), Germany (6 percent), and China (5 percent).

Approximately 2.5 million legal and illegal Salvadorans, equivalent to more than a third of the population of El Salvador, live in the United States and remit an estimated $2.5 billion annually, or 17.1 percent of the GDP, back to their family members. The remittances have grown at the rate of over 6 percent per year over the last decade and currently almost one in four households receives money from relatives in the United States, the most of any Latin American country. Three-quarters of the money goes to paying for household expenditures—with a 13 percent sales tax, the remittances in many ways subsidize the government budget.

The country lost control over its monetary policy with the adoption of the U.S. dollar as the currency in 2001, and is now focused on maintaining a disciplined fiscal policy. It was the first to ratify the Central America–Dominican Republic Free Trade Agreement (CAFTA-DR) in 2006, thus strengthening an already positive export trend. The current focus has been on economic diversification in the form of promoting textile production, international port services, and tourism through tax incentives. Another trend is the growth of privatization, including industries such as telecom, electricity, distribution, banking, and pension funds. In 2007, the government signed a five-year $461 million agreement with the Millennium Challenge Corporation to alleviate poverty and stimulate economic growth in the country's less-developed areas, particularly in the northern region, through investments in education, public services, enterprise development, and transportation infrastructure.

Embargoes

A nation or group of nations can make trade with a particular country or countries difficult or impossible. The main types of trade restrictions are tariffs, quotas, embargoes, licensing requirements, standards, and subsidies. A trade embargo is a ban on trade with another country (called target country) or group of countries. This restriction can be on exports and/or imports, and it can be a total ban on trade or be limited to specific products. An embargo can restrict exports of certain products to the target country (i.e., a ban on export of defense articles or services, as in U.S. economic sanctions against China imposed as a U.S. response to the Chinese government's crackdown against a fledgling democracy movement in the spring of 1989).

Usually, embargoes are declared against a specific country to isolate it, pressure its government, and cause it to reverse a specific policy. Embargoes, and other economic sanctions, are widely seen as a less violent alternative to war and as a tool for coercive foreign policy. U.S. president Woodrow Wilson called sanctions a "peaceful, silent, and deadly remedy" that no nation can resist. Embargoes are a tool of economic warfare—the use of economic means against a country in order to weaken its economy and thereby reduce its political and military power.

Embargoes can take shape as either unilateral or multilateral. In the first case, sanctions are imposed by only one country against a target country. In the second case, sanctions are imposed by more than one country. The United States is the country that has most frequently applied unilateral economic sanctions after World War II. Well-known examples include those meted out to punish Cuba (1962), the Iraqi dictatorship, Chinese antidemocratic actions, and the Yugoslavian government in the 1990s. In a parallel way, several measures imposed by the United Nations (UN) Security Council have taken place in recent years. The UN Charter grants the Security Council powers to decide the sanctions that have to be taken in order to maintain or restore international peace and security. These powers are made in the form of Security Council Resolutions under Chapter VII (*Action with Respect to Threats to the Peace, Breaches of the Peace, and Acts of Aggression*) of the UN Charter. The EU also imposes embargoes consistent with its Common Foreign and Security Policy objectives.

The type of UN sanction most widely used is the arms embargo, such as those imposed on Angola, Ethiopia, Iraq, Liberia, Rwanda, Sierra Leone, Somalia, Côte d'Ivoire, and Sudan. There have also been commodity embargoes, for example, on diamond exports from Angola, Sierra Leone, Liberia, and Côte d'Ivoire; travel bans and asset freezes on individuals in Angola, Sierra Leone, Liberia, Côte d'Ivoire, and Sudan; and a ban on the sale of petroleum products to the Angolan rebel movement UNITA.

Embargoes and Negative-Sum Games

In an increasingly integrated global economy, it is important to have a clear understanding of the costs and benefits of embargoes. The focus of the literature on economic sanctions has been twofold: their effectiveness and their economic impacts on the sender (the sanction-imposing) country, the target country, and the neighbors.

As to the question of effectiveness, most studies conclude that economic sanctions have limited utility for changing the behavior of governments in target countries. Moreover, for these countries, the effects of banning economic exchanges can cause isolation, reduction in trade and investment flows, and deterioration in their overall economic welfare.

As to economic impacts, several studies have focused on the strategic interaction between targets and senders of sanctions, and on quantifying the costs to both parties. The main findings suggest a relatively high cost of economic sanctions to the economies of both parties while sanctions are in place. The evidence that comprehensive sanctions affect bilateral trade flows between the sender and the target countries is strong. Allegedly, sanctions also hurt third countries, neighbors or major trading partners. Research suggests that UN sanctions cut off trading routes, increase transportation and other transaction costs, and disrupt established trading ties with clients and suppliers. This reduces trade flows between land neighbors and the rest of the world.

As embargoes can also lead to serious economic recession, macroeconomic effects in the target country cannot be underestimated. Restrictions on imports and exports reduce overall gross national product and per capita income, employment falls, the decline in state revenue leads to reduced capital investment, and to lower levels and quality of social services. On August 6, 1990, the Security Council imposed economic sanctions on Iraq. Seven years later, the UN Committee on Economic, Social and Cultural Rights noted that the living standard of a large section of the Iraqi population had been reduced to subsistence level since the imposition of the embargo. Per capita income was estimated to have declined by about three-quarters from 1990–93, increasing social inequality.

As we can see, economic sanctions often hurt those people in the target country who are least responsible for the policies that prompted the imposition of sanctions, and who are also least likely to be able to change these policies. The impact of trade sanctions on the citizens of some countries raises the question of the relationship between civil and political, and social and economic rights. This is why, in recent years, the international community has become increasingly concerned about the humanitarian impact of embargoes and other economic sanctions. For example, in the case of worldwide sanctions against South Africa (1977–94), critics argued that the sanctions harmed the group the sanctions were supposed to help. Several researchers have also pointed out the evidence of the impact of sanctions against Cuba, Haiti, and Iraq, specifically on health and health services. Since 1991, international agencies have documented Iraq's explosion in child mortality rates, waterborne diseases from untreated water supplies, and malnutrition in large sectors of the population.

To mitigate the humanitarian implications, three important international initiatives—the Interlaken, the Bonn-Berlin, and the Stockholm Processes—were launched between 1998 and 2002, with the objective of making UN sanctions more effective by targeting them more precisely on political objectives. The efficacy of embargoes as an instrument of foreign policy is in great doubt. Now the goal is to influence decision makers in the target country while avoiding negative humanitarian effects.

Emerging Economies

Emerging economies are generally known as the largest, wealthiest, and fastest-growing of the developing countries. Emerging economies are typically economies in transition, moving from a closed to an open economy, undergoing far-reaching economic reforms as they seek to integrate into the world economy. This transition, however, can be tenuous as political or economic turmoil threatens to impede movement toward open markets. These economies may grow rapidly, but they can make for risky economic investments because of political instability, inequality, social unrest, and the potential for financial crises. Often, these countries present sharp contrasts of cutting-edge technology and relative prosperity coexisting beside stark poverty and poor infrastructure.

Their growth is due primarily to the use of new energy, telecommunications, and information technologies as well as rapid industrialization. China, for example, is already moving away from low-skilled manufacturing as it ships those jobs offshore to Vietnam, Bangladesh, and the Philippines. It is expected that by 2020, the five biggest emerging markets' share of world output will be 16 percent, up from 7.8 percent in 1992. They will also become more significant consumers than industrialized countries due to their fast-growing populations and rise in the countries' middle-class. While industrialized countries will add about 100 million more middle-income consumers by 2020, the developing world will add over 900 million, and China alone will add 500 million.

In the past five years, China, India, and Russia, together with other fast-growing economies mostly in Asia and Latin America, have averaged almost 7 percent growth compared with the industrialized countries' 2.3 percent. It is expected that by the middle of the new century, Russia, India, China, and Brazil together could be larger than the combined economies of the United States, Japan, the United Kingdom, Germany, France, and Italy. China alone could be the world's second-largest economy by the end of the second decade of 2000 and could surpass the United States by 2050, with India predicted to follow.

In the 1980s, the emerging economies were mainly the "Asian Tigers" and some Latin American countries. In recent years, the largest developing countries of Brazil, Russia, India, Mexico, and China, known as BRIC or BRIMC, are viewed as the primary emerging economies. Other countries considered emerging economies include Mexico, Argentina, South Africa, Poland, Turkey, Indonesia, Chile, and South Korea. Due to their rapid growth, the United Arab Emirates, Chile, Malaysia, Vietnam, Bangladesh, and the Philippines form the next wave of emerging markets.

Emerging economies are expected to change the face of global economics and politics, as they gain increased stature in the world political arena and as the world increasingly relies on them to drive future growth. Their growth has resulted in calls for the largest of them to conform to greenhouse gas emissions limits, something they were exempt from doing in the first phase of the Kyoto Protocol (2008–12) in order to give them a chance to catch up with the economic development of the industrialized world.

Competition from the emerging economies will force developed countries to find areas of comparative advantage to ensure their own economic growth, whether it be specialized technologies of high value or commodities, requiring the retraining of their workforce to meet these specializations, something the developed countries do well. Whether the potential of emerging economies can be realized depends in large part on their ability to invest in their growing populations, government stability, and commitment to open markets, none of which are certain.

Emerging Markets

Emerging market is a loose term, one often used by people who are not entirely comfortable with it but have not found a useful substitute. What substitutes do exist tend to be highly specific and have criticisms of their own, like BRICs or Asian Tigers (or the various other Tigers). The term was originally coined by Antoine van Agtmael in 1981, as a shift away from the *third world* tag, a replacement term that emphasized forward motion. In general, an emerging market is one transitioning from a developing nation to a developed nation. Obviously this is problematic since every "developing" country is, by implication of the term, transitioning, and for that reason, the *emerging* term is sometimes used to imply a liminal stage at the end of that transition, a position on the cusp just before becoming "developed." Emerging markets are sometimes considered to be developing more rapidly than other developing nations, too, particularly since the *developing* label is sometimes attached to countries engaged in no obvious motion toward the received standard of developedness.

Emerging markets are not necessarily bound by common interest, and may in some cases be competitors, or perceive each other as such. There is no official list, or criteria, of emerging markets, and although there are indices that track groups of emerging markets, those indices should not be considered exclusive.

Emerging markets do not always consider themselves emerging. Russian economists and politicians, for instance, have taken offense at Russia's economy being called "emerging," even in light of its recent financial troubles.

Emerging Market Lists

The FTSE maintains two lists of emerging markets. The Advanced Emerging Markets have higher income and more developed infrastructure than the Secondary Emerging Markets. The Advanced Emerging Markets are Brazil, Hungary, Mexico, Poland, South Africa, and Taiwan. While this is clearly a disparate group of countries, with little in common, what they share is some abundance of natural resources (especially Brazil and Mexico) or extensive political and economic history with more developed allies, which gives them an edge, at least a perceived one, over the secondary markets. The Secondary Emerging Markets include Argentina, Chile, China, Colombia, Egypt, India, Indonesia, Malaysia, Morocco, Pakistan, Peru, the Philippines, Russia, Thailand, and Turkey.

The FTSE further describes Frontier Markets, which are sometimes called "pre-emerging markets." A tier down from the secondary markets, Frontier Markets are those developing economies that for one reason or another are considered to have a similar risk and return profile as that of the emerging markets. While the infrastructure and economic environment are not as developed as in developed nations nor, generally, in the emerging markets, Frontier Markets are marked by their general economic and political stability relative to other groups of developing nations. The FTSE Frontier Market list includes Albania, Bahrain, Bangladesh, Bosnia and Herzegovina, Botswana, Bulgaria, Croatia, Cyprus, Estonia, the Ivory Coast, Jordan, Kenya, Lithuania, Macedonia, Mauritania, Nigeria, Oman, Qatar, Romania, Serbia, Slovakia, Slovenia, Sri Lanka, Tunisia, and Vietnam.

Financial services and rating company Standard and Poor's (S&P's) coined the *Frontier Market* term in 1996, and launched two Frontier Market indices in 2007. The Select Frontier Index tracks 30 companies from 11 countries on the list; the Extended Frontier Index tracks 150 companies from all 27 countries on the list. The S&P's Frontier Market list includes Bahrain, Bangladesh, Bulgaria, Cambodia, Croatia, Cyprus, Estonia, the Ivory Coast, Jordan, Kazakhstan, Kenya, Kuwait, Lebanon, Lithuania, Nigeria, Oman, Pakistan, Qatar, Romania, Slovenia, Sri Lanka, Tunisia, the Ukraine, the United Arab Emirates, and Vietnam.

Since S&P's launch of the Frontier Market indices, Deutsche Bank and Morgan Stanley have adopted their own such indices using largely the same list. Morgan Stanley also maintains an Emerging Market list: Argentina, Brazil, Chile, China, Colombia, the Czech Republic, Egypt, Hungary, India, Indonesia, Iran, Israel, Jordan, Malaysia, Mexico, Morocco, Pakistan, Peru, the Philippines, Poland, Russia, South Africa, South Korea, Taiwan, Thailand, Tunisia, Turkey, and Vietnam. *The Economist* maintains a list virtually identical to Morgan Stanley's, adding Hong Kong and two countries Morgan Stanley considers developed rather than emerging: Singapore and Saudi Arabia. (Many would argue that South Korea is a developed nation, and its inclusion in so many Emerging Markets lists is one reason the term is falling out of favor.)

The Emerging Economy Report maintained by the Center for Knowledge Societies (a consulting firm in India) defines emerging markets as those that "are experiencing rapid Informationalization under conditions of limited or partial Industrialization." Their list emphasizes markets that lagged behind the developed world throughout a significant part of the 20th century, but which are able to take advantage of 21st-century technological opportunities. The Center for Knowledge Societies list includes Brazil, China, Egypt, India, Indonesia, Kenya, and South Africa.

Emerging Market Debt

External debt incurred by the governments of Emerging Market countries is called Emerging Market Debt (EMD) and is a potential source of investment, such as in the funds promoted by van Agtmael when he coined the *Emerging Markets* term. Specifically, EMD refers to the bonds issued by such governments, or any securities derived from other debts of those governments. Such bonds are usually low rated: bonds are rated by groups like S&P from (in increasing order of quality) D (debts that are in default), CC, CCC, B, BB, BBB, A, AA, AAA, with +s and –s for further distinction. Anything below BBB– is considered "below investment grade,"

An agricultural research program staffer working on methods to improve crop production in Mexico in 2004. Mexico is considered an advanced emerging market because of its relatively developed infrastructure and abundance of natural resources.

sometimes called "speculative grade" since such bonds are traditionally the province of more aggressive investors. Because of the high risk indicated by low ratings, bonds with a speculative grade rating at the time of issuing are popularly known as junk bonds. Most EMD bonds are rated as junk bonds; some may reach BBB, or in rare cases A. As with other bonds, the ratings of EMD bonds fluctuate after issuance.

EMD bonds have become more common since 1989, when in the wake of widespread Latin American debt crises, U.S. Secretary of the Treasury Nicholas Brady proposed a plan to convert bonds issued by friendly developing nations into dollar-denominated bonds, i.e. bonds redeemable in American dollars instead of the currencies of these fragile economies. Commercial banks holding debts from developing countries were allowed to exchange those debts for such bonds. In the process, the nominal outstanding debt obligation could be reduced, in exchange for the original creditor being protected from exposure to risk. The Treasury Department helped to oversee this process, which essentially renegotiated debts between debtor governments and creditor banks, ostensibly to the benefit of both. Restructuring was highly flexible, and generally involved collateralizing the restructured principal with special 30-year dollar-denominated bonds issued by Treasury for this purpose. These so-called Brady bonds were more highly-rated than most EMD bonds are today, with their interest payments sometimes guaranteed by high-rated securities held by the Federal Reserve.

Types of Brady bonds included discount bonds, which were guaranteed and issued with market-rate coupons, but which had been discounted from the original value of the debt; this was especially common as many commercial banks wanted out of investment in developing/emerging markets altogether, and were willing to reduce the amount of the original debt out of the belief that if they did not take advantage of the opportunities of the Brady plan, they might never recoup that debt at all. Par bonds were issued at the original value of the loan, but with a below-market-rate coupon. There were also front-loaded interest-reduction and debt-conversion bonds.

The original Brady bonds were issued to collateralize debt obligations from the governments of Argentina, Brazil, Bulgaria, Costa Rica, the Dominican

Republic, Ecuador, Mexico, Morocco, Nigeria, the Philippines, Poland, and Uruguay. Though the program ended in the 1990s after dealing with the fallout of those initial Latin American crises, the creation of the Brady bonds standardized and facilitated the secondary market for EMD bonds. Notably, several of these emerging markets have since paid off the debts the Brady bonds represented. Mexico was the first to do so, in 2003; Brazil, the Philippines, Colombia, and Venezuela have all done likewise (the latter two having joined the Brady program later in the process). Many EMD bonds are available as part of mutual funds.

Newly Industrialized Countries

There is a fair bit of overlap, conceptually and geographically, between "emerging" or "frontier" markets, and the classification of "newly industrialized countries." Both share a liminal, or threshold, quality: they describe something going on right now more than something that has been achieved. Like emerging markets, newly industrialized countries have pulled ahead of other developing nations. Specifically, they have done so because of their advances in industrialization, which generally leads to rapid economic growth, an improvement in the balance of trade, and a significant increase in exports and export incomes. Newly industrialized countries do not always enjoy the political and social stability necessary to be considered emerging markets, however: the rapid industrialization can disrupt rural, agrarian societies, which in turn can lead to political uncertainty during a period of adjustment.

Generally speaking, the newly industrialized countries are considered to be Brazil, China, India, Malaysia, Mexico, the Philippines, South Africa, Thailand, and Turkey. Egypt and Indonesia are often included, and advocates of the usefulness of the BRICs designation include Russia by implication. The newly industrialized nations have such diverse histories and heritages that, like emerging markets, they should no longer be considered a homogeneous group. China and Russia, for instance, have a history of communism to contend with—still in force but modified in China's case, and in the recent past in Russia's. India and Mexico, on the other hand, have long histories of democracy and struggles with imperialist powers.

Emotion

Emotion has various definitions. Some characteristics of emotions that are generally accepted are that they involve thought, appraisal, and judgments, a physical reaction, and an experience that is intentional. These characteristics indicate that emotions are both physical and cognitive. They help create meaning and action, and they are intrinsic to social order, conflict, politics, influence, etc. Emotions are affected by intellect, language, culture, and experience.

Emotions, with the exception of stress and satisfaction, were missing from the organizational context as they were perceived as incompatible with reason or rationality and were therefore viewed as a human limitation, something that needed to be controlled or eradicated. Organizations were understood as rational entities that aimed to eliminate irrational behavior of people as it was likely to interfere with the accomplishment of their goals, and emotions were perceived as synonymous with irrationality. Interest in emotion in business and emotional work has increased since the 1970s as the realization that emotion cannot be excluded from human interaction increased and the shift away from the pure rationalist perspective of organizations took place. More recently, emotions are perceived as not only compatible with reason but as something that can complement reason or even as something necessary for reasoning and decision making.

In organizational studies, *affect* is sometimes used as the umbrella term that contains emotions and moods. Emotions are of increased interest in organizations because they affect work motivation and job satisfaction. In the organizational literature, an emphasis on positive emotions such as happiness, love, joy, and enthusiasm is identified because they enable individuals to feel good and have positive consequences by creating a harmonious, strong, fair organization. In contrast, negative emotions like anxiety, fear, and hate are seen as destructive and disruptive, and therefore, based on the assumption that they can be separated from positive emotions, the prescriptions relating to them focus on their elimination. This view is questioned, however, since positive and negative emotions cannot be separated, as they inform and develop each other.

Mapping the journey of emotions in the organizational arena, first a reluctance to allow emotions in organizations developed, followed by a more recent reluctance to accept negative emotions. Other views see selected emotions as inherently part of organizations as long as they relate to aggression, confidence, and competition, which define organizational life, while other emotions that relate to weakness, submission, and caring are inherently not organizational.

In the organizational context, the effect of emotion in relation to performance, decision making, turnover, prosocial behavior, negotiation, group dynamics, and leadership has been researched with evidence that suggests that positive emotions improve performance at the individual, group, and organizational levels. Some negative emotions have been found to have positive consequences in relation to concerns about fairness, power, and negotiation. Further, current research in emotions suggests that they are not necessarily only attributed to individuals but they are also attributed to organizations.

Perceptions of the place of negative emotions in the workplace have been changing in recent years.

The interest in emotions in organizations increased with the development of emotional intelligence (EI) and emotional labor. EI is the ability to monitor and control one's own and others' emotions and to be able to use them effectively in one's thinking and action. Emotions are used and controlled to improve intelligence. EI is perceived as a competency and capability that enables people in organizations and in particular leaders to achieve outstanding levels of performance. Debates about EI, despite its popularity, concern its nature and measurement. Some argue that EI is based on abilities that help people understand and use emotional information while others argue that EI is a set of characteristics that can be applied in interpersonal settings.

Emotional regulation and emotional labor relate to how employees exhibit their emotions at work. Emotional regulation provides the link between feeling and consciousness and it is argued that all emotion is regulated, thus understanding emotion regulation as relative is more appropriate than regulated or unregulated emotion. When, however, this regulation is imposed by the organization this difficulty disappears, as the employee has to comply with emotion display rules that result in emotional labor. Emotional labor is the commercialization of emotions for organizational ends. It includes the management of emotions at work, as well as the organizational controls on emotional displays through roles, tasks, social interaction, and culture. It is labor because employees have to regulate their emotions so that they can produce appropriate emotional states in others.

Employer–Employee Relations

Employer–employee relations or employment relations replaced industrial relations as the study of the relationship between employers and employees, a relationship that may be affected by government and unions. The employer–employee relations field is comprised of industrial relations and human resource management (HRM). Recently more importance is given to the legal characteristics of the employment relationship and to HRM than during the traditional industrial relations era, which emphasized collective bargaining. This is a consequence of the weakening influence of trade unions that enabled employers to redefine employment contracts and job content. Increased employment protection legislation, however, provides regulation and protection to employees, but it does so at the individual rather than the collective level. Management thinking about the relationship also changed with more emphasis on a personal relationship between employers and employees based on commitment rather than control in an increasingly competitive business context.

Despite differences in perspectives, there is agreement that the employment relationship is changing in most parts of the world. This change is the consequence of a number of factors including economic, technological, and structural developments; organizational downsizing and restructuring, the composition of the labor force which has changed from male, blue collar, and manufacturing to female, white collar, and service. Globalization also affects the employment relationship as it leads to the deregulation of labor markets to improve flexibility and facilitates convergence of employment relations systems around the world.

In addition, the employment relationship has been affected by the rise of nonstandard contracts of employment that became more prominent as organizations sought to improve flexibility and more women entered the labor force, the individualization of the workplace that led to the reduction in union membership, and the shift away from the unitarist and toward a pluralistic perspective of organizations. Traditionally the relationship was fundamentally one of conflict represented by industrial relations, but more recently issues of trust, fairness, employee voice, involvement and participation, and dignity and respect are increasingly important in the relationship with more emphasis on moral as well as economic issues and concerns.

The two main models of the employment relationship are the unitarist and pluralist. In addition to these, the egoist and the critical models also examine the employment relationship. John Budd provides an overview of the four models and explains that the unitarist perspective assumes that employers and employees have shared interests and any conflict is a consequence of inadequate management practices. This perspective emphasizes the individual and views government and trade unions as unnecessary. This is the model adopted by applied human resource management.

The pluralist perspective views employers and employees in a bargaining relationship within imperfect labor markets and with the presence of conflicts of interest in organizations. This model accepts that employees and employers may have shared or conflicting interests. A fundamental principle of this view is that labor is not a mere commodity and therefore it is entitled to voice and equity. Government and unions are important in this perspective because they assist in leveling the inequalities that exist due to market imperfections.

The egoist model subscribes to the view that freedom and individual self-interest result in optimal outcomes through the free market transactions. The employment-at-will doctrine (the right of employers to hire and fire for any reason or no reason at all and the right of the employee to accept a job and resign at will) is based on the egoist model adopted in the United States. Finally, the critical perspective sees the employment relationship as a struggle for power and control, a struggle that is not confined to this relationship but is found throughout society.

An increasingly important aspect of the employment relationship is the psychological contract, which represents the relationship between an employer and an employee and the perceptions of their duties and obligations in that relationship. The psychological contract is based on social exchange theory, and it has been used extensively to research and understand the employment relationship despite the debate about its conceptualization, because it develops the relationship beyond the employment contract and highlights the mutual expectations that exist.

Denise Rousseau's work on psychological contracts, which she defines as an individual's beliefs about the terms and conditions of a reciprocal exchange agreement, further developed the concept focusing on the individual rather than the relationship and on the more powerful mutual obligations in the relationship rather than the expectations. The psychological contract between employees and employers has changed from exchange of life-long employment for loyalty and mutual commitment to an exchange of opportunities. This development, it is argued, led to the extinction of "the organization man," the employee who would obediently discount all other interests for the benefit of the organization. Others, however, argue that the new employment relationship that relies on the base of "no long term," i.e., on free agents and not life-long employees, is a relationship that corrodes trust, loyalty, and commitment, thus having a negative impact on people's quality of life.

The focus of the employment relationship is now on individual employees rather than on the employees as a collective, a relationship that is focusing on cooperation rather than antagonism. Discussion of the new employment relationship in the literature focuses on the changes in the employment contract as well as the psychological contract. It identifies training and development, employee involvement and participation, and two-way communication as the elements that characterize the new relationship.

Empowerment

Empowerment is the process of conferring decision-making capacity upon those who previously had been unable to decide matters for themselves or had limited ability to do so. In management, employee empowerment refers to the practice of giving employees more responsibility and autonomy in decision making. Empowerment allows decisions to be made at lower levels in the organization and is expected to improve the responsiveness of the organization, increasing productivity and employee commitment to company goals.

Tracing the historical development of the notion of empowerment across disciplines, Jean Bartunek and Gretchen Spreitzer have showed that the meanings of empowerment may be subsumed within three broad categories: sharing real power, fostering human welfare, and fostering productivity. Empowerment meaning sharing real power appeared in the 1960s and 1970s, focusing on giving power to those who have little. Empowerment as enabling and fostering human welfare emerged in the 1970s and 1980s, focusing on improving the life of people through increasing self-worth, increasing knowledge, dignity, and respect. The last meaning of empowerment, which emerged in the 1980s and 1990s, focuses primarily on empowerment as a factor in fostering productivity. This category includes participation in decision making, taking responsibility, sense of ownership, and working in teams. All these three different meanings of empowerment have contributed to the development of the notion of employee empowerment.

In management, *empowerment* is a term that may cover many different types of management initiatives and an overall common definition has not evolved. A simple definition of employee empowerment is the involvement of employees in the decision-making process regarding their work-related tasks. In this perspective empowerment can be seen as a one-dimensional phenomenon concerned with delegation of management power to subordinates. Alternatively it has been argued that empowerment is a multidimensional phenomenon, an element of broader management strategies to mobilize the multiple skills of employees in order to enhance operational and economic effectiveness. In this perspective empowerment is a management practice that is concerned with a variety of issues, for example, how leaders lead, how employees react, how employees interact with each other, and how work-related processes are structured.

Employee involvement initiatives had been proposed earlier under other labels such as job enrichment, employee participation, and profit sharing. The modern form of employee empowerment emerged in the particular business context of the late 1980s together with notions of enterprise culture giving greater room for individual initiative and new management approaches such as total quality management (TQM) and human resources management (HRM). By the late 1980s, businesses had adopted the basic idea of the need for new modes of managing in turbulent markets, constantly changing technology, and the need to satisfy even more demanding customers in terms of choice, quality, design, and service. Empowerment then became one important element in the management models introduced as an alternative to the traditional hierarchical model of management.

Socio-Structural Empowerment

Three different perspectives have been used to study and understand empowerment: the socio-structural perspective, the psychological, and the critical perspective. Socio-structural empowerment refers to organizational policies, practices, and structures that grant employees power, authority, and influence regarding their work. The focus of the socio-structural perspective is on sharing power throughout the organization. Having power is seen as having formal authority or control over organizational resources. The emphasis is on employee participation through increased delegation of responsibility. The socio-structural perspective emphasizes the importance of changing organizational policies, practices, and structures away from top-down control systems toward high-involvement practices. Specific management practices that indicate a high involvement organization include participative decision making, skill- and knowledge-related pay, open flow of information, flat organization structures, and training of employees. Each of these practices may contribute to employee empowerment.

From a socio-structural perspective, empowerment represents a moral hazard for managers, in the sense that the success or failure of employee empowerment depends on the ability of managers to reconcile the potential loss of control inherent in empowerment practices with the organizational need for goal congruence. Setting clear limits for empowerment and building trusting relationships have been found to be effective mechanisms for reducing the risk of this kind of moral hazard.

Psychological Empowerment

In contrast to the socio-structural perspective which defined empowerment in terms of delegation of authority and sharing of resources, the psychological perspective views empowerment as enabling and enhancing personal efficacy. According to the psychological perspective, empowerment is achieved when psychological states produce a perception of empowerment within the employee. Several models of empowerment have been developed to describe different dimensions of this psychological state of the employee, for example the employee's sense of meaning, competence, self-determination, and impact.

Meaning involves a fit between the needs of one's work role and one's beliefs, values, and behaviors. Competence refers to self-efficacy specific to one's work, a belief in one's capability to perform work activities with skill. Self-determination is a sense of choice in initiating and regulating one's actions. Self-determination reflects autonomy over the initiation and continuation of work behavior and processes. Impact is the degree to which one can influence strategic, administrative, or operating outcomes.

Research on the antecedents of psychological empowerment suggests that leaders have a wide variety of levers for enabling psychological empowerment of employees. Many of these antecedents could be developed within the socio-structural perspective on empowerment above. What is different in the psychological perspective is that rather than assuming that the socio-structural antecedents are an indication of empowerment, they are viewed as enabling mechanisms that can facilitate the individual experience of empowerment. For example, a system may provide employees with access to important information, but unless they realize they have value having this information and know how to use it, it will not contribute to their experiencing empowerment. The two perspectives on empowerment are then linked, but have different viewpoints on what empowerment means.

The Critical Perspective

The critical perspective questions the notion of power in empowerment, arguing that typical empowerment interventions are in fact disempowering. According to this perspective, empowerment interventions sometimes create more controls over employees through less obvious means. For example, interventions focused on empowering employees by putting them into work teams may result in extensive peer pressure that leaves employees feeling ever more controlled and disempowered.

These three perspectives on empowerment—the socio-structural, the psychological, and the critical—may be seen as complementary to one another, each providing a different lens for understanding empowerment in the workplace. The socio-structural perspective focuses on the organization. The psychological perspective focuses on the individual and their experience. And the critical perspective focuses on the political nature of empowerment and the potential for new forms of domination.

Empowerment Programs

Employee empowerment initiatives may involve a variety of management policies, for example, information sharing, upward problem solving, task autonomy, attitudinal shaping, and self-management. Information sharing between management and employees is a central element in three different areas. Downward communication from management to employees is important to raise employees' understanding of the reasons for business decisions. It is also seen as important that employees have the opportunity to express their views openly through upward communication, as well as through horizontal communication channels in teams or in work groups. Upward problem solving involves various practices that make it possible for employees to inform on or to act directly on production problems observed to stimulate continuous improvements of products or processes.

Task autonomy involves organizational restructuring toward more or less self-managing teams. The teams may have autonomy concerning most production-related issues but are normally still working within a structure determined by management. Attitudinal shaping concerns psychological aspects of empowerment and my involve training and education. A further core element in empowerment programs is a limited form of self-management in projects, teams or work groups. Empowerment programs may incorporate some or all of these dimensions.

It is generally assumed that empowerment is connected with high levels of commitment and organizational performance. From a relational perspective, empowerment involves power redistribution that is expected to produce interpersonal trust and collaboration among employees. Empowerment allows decisions to be made at lower levels in the organization, thereby improving the responsiveness of the organization. Research shows that employee empowerment can lead to better decision making as well as to higher levels of training, motivation, and productivity.

Enculturation

Enculturation is the process whereby an established culture influences and teaches an individual, group, or organization to the extent that the target adopts the particular culture's values, norms, and behaviors and the target finds an accepted role within the established culture. The concept is distinct from acculturation, cultural adjustment, and cultural adaptation. The individual process of enculturation also applies to enculturation within organizations. An awareness of the processes of enculturation is important in effective intercultural training. The process of enculturation is not entirely passive or unconscious, as the cultural transmission (or transmutation) involves processes of teaching and learning that are reflective, deliberate, incidental, and functional.

The term *enculturation* was first coined by cultural anthropologist Melville Herskovits in 1948. Anthropologist Margaret Mead clearly defined enculturation in 1963 as a process distinct from socialization in that enculturation refers to the actual process of cultural learning with a specific culture whereas socialization refers to the universal developmental process of social learning. Enculturation is the process of learning a culture in all its uniqueness and particularity whereas socialization is a process common to all human societies. The process of enculturation establishes a context of boundaries and correctness that dictates what is and is not permissible within a society's framework.

The concept of enculturation is also distinct from acculturation. Acculturation is the modification of the culture of a group or individual as a result of contact with a different culture. Enculturation is the original process whereby the learner acquires a primary cultural identity within their ethnic or organizational group apart from engagement with another culture. For example, consider the case of Company "A" and Company "B" merging. In this merger, enculturation refers to the initial process whereby the employees of Company A adopt Company A's culture, whereas acculturation refers to the process whereby a Company A employee adopts some of the cultural values of Company B.

The process of enculturation includes learning about the material aspects of one's own culture such as identifying symbols, ceremonial artefacts, and cultural icons. Acquiring the nonmaterial aspects of culture includes cultural values, attitudes, beliefs, and corresponding behavior patterns. For example, a child from an individualistic culture such as the United States may learn to place greater value on making personal goal-oriented independent decisions over collective decisions, whereas a child from a collectivist culture such as Japan may learn to primarily value consensus-based group decisions rather than group-oriented collectivist decisions. This enculturation process in developing ethnic identity may be mirrored in adopting an organizational identity, where a new employee will learn to primarily value making either individual goal-oriented or group consensus–oriented decisions through supervisory feedback and performance management processes.

An understanding of enculturation is an important part of training global staff in developing intercultural skills. Intercultural training often begins with activities that make the trainees aware of their own ethnocentrism, and their enculturation into their own culture. The individual must come to realize that as they developed and acquired competence within their culture, they also acquired cognitive maps that continue to guide their behavior, whether they are living in that cultural context or not. Related to this enculturation awareness training is training to develop an understanding of how others have been enculturated into very different cultures.

In the global business context, successful organizations develop an enculturation process to orient and align the values of a new employee to the values of the organization. Communicating organizational culture may involve initiation rituals, learning stories of the organization's founding, reference to symbols, heroes, slogans, and ceremonies. Membership in the Boy Scout movement, for example, usually involves learning stories of the founding of the organization, initiation ceremonies, familiarization with symbols, and reciting the Scout promise. The processes of enculturation within an organization may include utilizing systems of employee participation that rely on systems of incremental commitment, utilization of groups for control of members, and utilization of reward systems involving recognition and approval.

Enculturation has sometimes been confused with cultural adjustment and cultural adaptation. Cultural adjustment has been defined as the social and psychological adjustment of individuals or cultural groups to the new cultural environment in which they now reside. Cultural adaptation involves a process of mutual change and accommodation between newcomer and relevant environmental factors. Cultural adjustment and adaptation, therefore, are more related to acculturation rather than an individual or group initially acquiring a cultural identity and role through enculturation.

Enel

Enel is engaged in the production, distribution, and sale of electricity and gas across Europe and North and Latin America, managing a range of hydroelectric, thermoelectric, nuclear, geothermal, wind, and photovoltaic power stations. It currently operates in 21 countries with 75,500 MW of generating capacity and serves more than 50 million power and gas customers. It is the largest power company in Italy and the second in Europe by installed capacity. It is also the second-largest Italian operator in the natural gas market, with approximately 2.5 million customers and a 10 percent market share in terms of volumes. Headquartered in Rome, Italy, in fiscal year 2007 Enel recorded revenues of 43.7 billion euros and net income of 4 billion euros. Its main global competitors are Centrica, EDP, Électricité de France, Electrabel, Eni; E.ON, Iberdrola, National Grid, RWE, Suez, and U. Fenosa.

Enel (Ente Nazionale per l'Energia Elettrica) was founded in 1962 with the nationalization of the power industry by the Italian government. The realization of the Italian transmission network and the building of new power plants was the first objective of the company, which had to face a difficult period in the 1970s with the increasing of construction costs and the Arab oil embargoes. Enel's monopoly was disassembled in 1992 when the Italian government decided to open power generation to outside producers and Enel was converted into a joint-stock company. The actual shareholder's structure is represented by the Economy and Finance Ministry (21.1 percent), the Cassa Depositi e Prestiti (10.1 percent), retail investors (34.5 percent), and institutional investors (34.3 percent).

Today Enel operates through eight different divisions. The Sales Division is responsible for sales and quality of commercial services targeted to the end-user market for electrical power and gas. The Generation and Energy Management Division operates power generation and environment safeguarding. The Infrastructure and Networks Division is in charge of distributing electricity and gas in Italy. Engineering and Innovation is a new organizational division that manages and controls the engineering processes related to the construction of generation facilities, coordinates research activities, and promotes and supports the development of innovation opportunities across the various business areas. The International Division consolidates and promotes the internationalization strategies of the company in all foreign countries of interest with the exception of Spain, Portugal, and Latin America, which are the responsibility the new Iberia and Latin America Division. Finally, the Parent Company and Services and Other Activities area has the purpose to leverage group synergies and provide transversal services to Enel's core activities.

Especially in recent years, innovation, infrastructure development, excellence in customer service, and internationalization through alliances and direct investments have represented the key success factors of Enel's growth strategies. Innovation has constantly sustained company growth and profitability. Enel has been the first utility company in the world to replace its customers' traditional electromechanical meters with modern electronic devices. The ability to take meter readings in real time and manage contractual relationships remotely has enabled Enel to implement time-of-use electricity charges, offering customer savings for evening and weekend electricity use, globally improving the efficiency of its electricity network. Innovation investment is now focused on the development of renewable energy sources, for research and development of new environment-friendly technologies, and for modernization of old power plants.

The consolidation of international activities has recently been driven by the necessity to reduce dependence on Italy. Enel has a relevant presence in Europe (Bulgaria, France, Greece, Italy, Romania, Russia, Slovakia, and Spain), North America (Canada and the United States), and Latin America (Brazil, Chile, Costa Rica, El Salvador, Guatemala, Mexico,

Enel, the largest power company in Italy, has expanded to serve 50 million power and gas customers in 21 countries.

and Panama). Recent acquisitions and alliances have been numerous. The acquisition of Endesa, the leading electricity company in Spain and Latin America, was completed through the partner Acciona, one of the leading Spanish groups operating in the development and management of infrastructure, services, and energy from renewables. Also of relevance is the completion of the public tender offer for OGK-5, one of the largest Russian generating companies. Both acquisitions have given Enel the size to play a leading role, reduce regulatory and business risks, and expand its growth potential, creating the basis for future efficiency.

Eni

Eni is one of the leading integrated energy companies in the world, and its success is mainly based on continuous innovation and growth strategies. The primary businesses managed by the company through different operating divisions and subsidiaries are Exploration & Production, Gas & Power, Refining & Marketing, Engineering & Construction, Petrochemicals, Oilfield Services and Engineering. From exploration and production (upstream segment) to the supply, transport, distribution, and sale of natural hydrocarbons (midstream segment), to the processing and marketing of refined products (downstream segment), Eni has a presence in all phases of the energy value chain. BASF, BP, Chevron, ConocoPhillips, E.ON, Enel, ExxonMobil, Marathon Oil, Pemex, Petrobras, Repsol YPF, Royal Dutch Shell, Sunoco, and Total are among its main global competitors.

The company, headquartered in Rome, Italy, has reached a strong international position operating in around 70 countries with a staff of about 76,000 employees. During fiscal year 2007 the group recorded revenues of €87,256 millions, and a net profit of €10,011 millions.

Eni (Ente Nazionale Idrocarburi) was established by the Italian government in 1953 with the mission to promote and develop national energy-related operations. It became a joint stock company in 1992. Today the main shareholders are the government (20.31 percent), the Cassa Depositi e Prestiti (CDP SpA, whose capital is held 70 percent by the Italian Ministry of the Economy and Finance and 30 percent by some Italian banking foundations) with a share of 9.99 percent, the Intesa San Paolo Group (2.27 percent) and the Monte dei Paschi di Siena Group (2.11 percent).

Since the beginning, under the leadership of its chairman Enrico Mattei, the company was focused on developing international key business alliances with many producer countries. Furthermore, relevant investments into research and technologically advanced structures of excellence had been always considered a key success factor for satisfying customers' needs and protecting the environment. Technological, business-model, and new-to-the world product innovations are continuously developed in Eni, resulting in the creation of maximum value and generating a strong and durable competitive advantage.

In Eni the continuous growth of its upstream and downstream activities has been always considered a strategic priority. The growth strategy, supported by a strong pipeline of projects and strongly coordinated with an increasing operational efficiency and relevant technological investments, is differently implemented depending on the business lines.

Exploration & Production Division growth has been based since its historical origins on a continuous increase of production, thanks to some foreign direct investments carried out through development projects, acquisitions of assets, and new exploration licenses. Partnerships and strategic agreements have enabled the company to accelerate the achievement of its growth strategies. Today organic production growth is relevant in some strategic regions such as the Caspian Sea area, Gulf of Mexico, North and West Africa, where Eni is part of some important projects. Nowadays, one of the company's targets is to replace in the medium term more than 100 percent of produced reserves.

Also in the Gas & Power business Eni occupies a strong and integrated position in Europe. The company's value drivers can be summarized in the following: a strong capacity to dialogue with oil and gas producing countries such as Russia and Algeria; a competitive advantage in capturing full value from the gas value chain; business development with an integrated approach between Gas & Power and Exploration & Production.

Eni's profitability in the Refining and Marketing Division is also a priority. In Refining, profitability is reached through focused investments that enable the company to obtain a continuous increasing of the refining conversion index. This results in higher value and quality products, lower operating costs, and increasing refinery flexibility in processing low-quality crude oils. In Marketing, with its retail business focused in Italy where the company is the leader with the brand Agip, Eni is involved in focused marketing initiatives and effective segmented pricing strategies. Nevertheless the company is strengthening its position in other international growing markets through the acquisition of local service stations.

Finally, among the numerous differentiating strategies that determine the competitive advantage in the other company's business lines and subsidiaries, is the continuous geographical expansion and innovation, the constant business integration, and the creation of plants which enable the company to generate significant economies of scale.

Enron Corporation

When Enron Corporation filed for bankruptcy under Chapter 11 protection on December 2, 2001, it was valued at over $60 billion, thus achieving the notoriety of being the largest U.S. corporate failure at that time. The exemplar of American commercial enterprise became a byword for corporate malfeasance.

Enron was brought into being by Chief Executive Officer Kenneth Lay in 1985 from an amalgamation of Houston Natural Gas (HNG), of which he was previously CEO, and InterNorth of Nebraska. The new corporation's business was centered on some 37,000 miles of natural gas pipelines and supply contracts. Until the late 1980s, gas pipeline operators were required to be buyers and resellers of natural gas as well as transporters of the product. Deregulation motivated Enron to remove the constraints of entering into purchase contracts and reduce their involvement to transportation and tolling. In 1988, a meeting of top executives was told by Lay and his vice chairman Richard Kinder that far from harming their business, deregulation should provide the impetus for reengineering their business.

By 1990, a review of their corporate business strategy led to a reprofiling of the corporation. Some noncore businesses were sold off and the business was relabeled as an energy provider. In reality, this was a move from their previous conservative strategy of developing trading opportunities from a capital asset base to becoming an energy trading entity with capital assets.

This business transformation was led by Jeffrey Skilling, who joined Enron in 1990 from the consultancy business of McKinsey and Co., where he had been senior partner of their energy business. He came with his strategy to turn Enron into an "asset-light"

Enron, based in this complex in Houston, Texas, was the largest U.S. corporate failure ever when it went bankrupt in late 2001.

organization, fueling expansion through financial trading. From using their "Gas Bank" to fulfill contractual obligations, their trading from 1992 might be better considered as derivative trading, since Enron was more involved in creating energy and financial markets than selling either products or services.

From its foundation, Enron was saddled with substantial debt inherited from HNG and InterNorth. This was increased in 1988 to buy out some 16 percent of the shareholding held by Irwin Jacobs, a major investor in InterNorth, and later investors, who had threatened to mount a takeover bid for the young Enron. This raised their debt-to-capital ratio to some 75 percent, making the corporation a poor investment risk. Through refinancing, this ratio was reduced, but keeping debt and losses off their consolidated balance sheet eventually led to Enron's collapse. This was not helped by some of Enron's less successful ventures, such as Azurix (water/utilities) and Elektro Eletricidade e Servicios (Brazilian electricity utility).

Enron also invested in the internet, buying into RhythmsNetConnections, an independent internet service provider (ISP). While developing a means of hedging following their initial public offering (IPO), Andrew Fastow, who was promoted to chief financial officer (CFO) in 1998, set up the first LJM entity. This was an investment vehicle formed by his family (their initials) that became an integral part of Enron's SPEs (special purpose entities). Earlier SPEs, such as the Cactus Fund, were legitimately used to create trading liquidity in gas markets. The later SPEs, such as the Raptors and Talon partnerships, became vehicles for "off balance sheet" accounting, avoiding the consolidation of debt, risk, and losses.

Two other Enron ventures also need to be mentioned, since they contributed to a shift in Enron's reputation with the public and investors. First was the trade in electricity supplies in California. By using their expertise to play the deregulated markets in 1997–98, as the largest power trader, Enron was able to make substantial profits during a crisis period, mostly at the expense of consumers. It was reported that they generated profits of $1.5 billion before suddenly leaving the market.

The other venture was EnronOnline, which was launched in 2000 and where using their strong technical expertise, Enron was able to take advantage of the boom in dotcom technology. The online market created was primarily a tool for their own business rather than as an open or third-party online marketplace. They were able to increase their trading capacity through the immediacy of this internet trading. However, the growth in liquidity of their trading, with the reduction in timescale, now meant that deals were smaller and standardized for simplicity and thus subject to a much decreased profit margin. Whether this influenced the change in trading practice or was a product of practices that were already undergoing change is open to debate.

In February 2001 Jeffrey Skilling became chairman of Enron, a post he held for only six months before resigning on August 14 and returning the responsibility to Ken Lay. The following day, Lay received an anonymous letter that later transpired to have originated from Sherron Watkins, who worked in Enron as an accountant for their SPEs. She expressed her concerns for their insubstantial collateral and their tax implications. Lay met with Watkins and subsequently took legal advice from Enron's lawyers, Vinson and Elkins.

Enron's stock value continued to fall, so Lay made efforts to appease the financial community by explaining Enron's income and disengaging Fastow from their SPEs. However, he and several other Enron executives had been selling their stock since 1999 and continued to do so while aware of the corporation's serious financial problems.

On October 19, the *Wall Street Journal* revealed that Fastow had made a profit of over $7 million from his SPE activities. This prompted the Securities and Exchange Commission (SEC) to announce an investigation into these activities. Enron immediately replaced Fastow as CFO and appointed Jeffrey McMahon to replace him. Shortly thereafter, Enron restated its earnings downward by $0.5 billion and increased its debt by $2.6 billion.

Dynergy opened a bid to buy Enron on November 9, supported by Chevron Texaco, though they pulled out of the deal three weeks later following an announcement of a further $700 million loss. Enron's credit rating crashed to the extent that on December 2 they filed for bankruptcy under Chapter 11 protection. On January 23, 2002, Lay resigned. A report by William Powers following an inquiry by Enron's Special Investigation Committee blamed Lay, Skilling, and accounting firm Arthur Andersen for the collapse. A subsequent hearing found Arthur Andersen, Enron's auditors, to be guilty of obstruction of justice for shredding documents while aware of a pending investigation by the SEC.

In May 2006, Lay and Skilling were found guilty of fraud and conspiracy, although Lay died of a heart attack six weeks later and his conviction was quashed. Skilling was sentenced to 24 years in prison and Fastow to seven years, with lesser sentences handed out to others. Enron stockholders are still working to minimize their losses.

Entrepreneurship

Entrepreneurship can be defined as the practice of starting a business or "breathing life" into an existing business. One can do so by exploring and pursuing new business initiatives that have the potential to make the organization grow.

Basic Categories

Although many do not attempt to distinguish the different types of entrepreneurs, Webster (1977) classified the title into five different categories. He believed that the distinctions between the different categories allowed one to understand the different terminology in the field and practice. His five different categories of entrepreneur included the following:

- The Cantillon Entrepreneur. Richard Cantillon introduced the term *entrepreneur* in the early 18th century to denote a person who is treated as one of the four factors of production (i.e., land, labor, capital, and the entrepreneur). The entrepreneur is considered the catalyst in the role of innovator, and is responsible for fueling growth in a capitalist economy. Entrepreneurs can be successful and make a profit when they have the ability to create an opportunity where they have a temporary monopoly to change market products and processes before the competition has an opportunity to dilute industry profits. Many economists do not view the entrepreneur as a real person. Rather, the entrepreneur is seen as a "silent theoretical entity that makes rational decisions, strives for profit maximization as defined by the economists, and assumes managerial and other uninsurable risks in exchange for profits."

- The Industry Maker. Traditional management research views the entrepreneur as an industry maker, or someone who builds the nation's economic system, is hard-working and willing to take risks, and invests personal assets. According to this school of thought, the entrepreneur establishes the foundation for an organization, and then builds it into an industry leader.
- The Administrative Entrepreneur. The entrepreneur role is viewed as an executive who establishes a new company, or a reorganization of an existing corporation, and becomes a permanent leader of the management team. Although there are similarities, there is a distinct difference between an industry maker and an administrative entrepreneur. Administrative entrepreneurs are usually associated with an individual organization (e.g., Henry Ford); whereas industry makers are usually considered as manipulators (e.g., Jack Welch) of an entire industry or of a large segment of an industry.
- The Small Business Owner/Operator. During Webster's time, small business owners were perceived to be the local merchants, and tied predominantly to the retail and wholesale industry. Many scholars believed that these vendors were limited in scope in regard to sales, geographical outreach, and profit potential. However, technology, such as the internet, has allowed service businesses as well as retail businesses to reach an international market.
- The Independent Entrepreneur. An individual who creates ventures from scratch, and does not generally commit to long-term managerial responsibilities to one venture. These individuals tend to be very creative and get a thrill with developing the business, and they tend to be loners.

Current Categories

All five types can be seen in the system, but they have different roles. Webster's work was written in the 1970s and times have changed. As noted with the small business owner category, the increase in technology and globalization have changed the way that business is conducted as well as how entrepreneurs are categorized. Allen's categories (2006) are reflective of how business is conducted in the 21st century, and the new categories include:

- The Home-Based Entrepreneur. According to the American Association of Home Based Businesses, more than 24 million people operate home based businesses. Although many of these businesses start out as sole proprietors, many have grown to the point that they can compete against large, well-known businesses. Technology has made it possible for businesses to operate from any location, and home-based businesses are able to tap into resources via the internet. Home-based businesses are usually the starting point for many businesses.
- The Cyber Entrepreneur. This type of entrepreneur enjoys the fact that he or she is able to run a full fledged business without a brick-and-mortar location. Cyber entrepreneurs are able to process all of their business transactions with customers, suppliers, and strategic partners over the internet. In addition, their businesses tend to be digital products and services that do not require a physical infrastructure such as a warehouse.
- The Serial Entrepreneur. These entrepreneurs enjoy creating businesses, but have a desire to move on when the business is up and running. They are motivated by the hype of the pre-launch and start-up phases of the business, but do not have a desire to handle management responsibilities.
- The Traditional Entrepreneur. Traditional entrepreneurs are classic entrepreneurs. They start brick-and-mortar businesses and stick with them as they begin to prosper. Traditional entrepreneurs will be around as long as there is a need to build sustainable businesses, especially in industries such as food services, manufacturing, and retail.
- The Nonprofit Entrepreneur. Nonprofit entrepreneurs have a passion for work that involves socially responsible themes such as education, religious, and charitable initiatives. Many seek their 501(c) status so that they can solicit fund-

ing and donations from organizations and individuals who believe in the mission. Their businesses are allowed to make a profit as long as the profits are used for business purposes and not distributed to the owners of the company.

- The Corporate Venturer. Corporate venturers are individuals who seek out new ventures while working within established large organizations. Organizations create skunk works so that they have a unit to explore potential opportunities. Skunk works are autonomous groups that are given the mandate to find and develop new products for a company that may be outside of the organization's core competencies. However, many have found this a difficult task due to the bureaucratic structure of many large organizations. In order to be a successful corporate venturer, it is important that the following factors are present: senior management commitment; corporate interoperability, meaning that the work environment must support collaboration and provide resources; clearly defined stages and metrics so that the organization can decide whether or not to continue to pursue the initiatives; a high-performance work team; and finally, a spirit of entrepreneurship. Although success is the goal, failures may occur. Organizations must support the team as they explore the opportunities, even when efforts are failures.

Financing

One of the greatest challenges for new ventures is the ability to secure capital for investments that will allow the company to grow. All projects will reach a crossroad where sufficient cash flow is necessary in order to go to the next level. It could be after a period of time or it could be because the venture was so popular and the company is growing at a rapid rate due to demand. Regardless of the situation, the company's management team will need to determine when and how they will invest in items such as purchasing new equipment, hiring new staff, and putting more money into marketing initiatives. Raising money can be a difficult task if the company has not established a reputation or is still new.

When determining the amount of capital needed, the decision makers must analyze the situation and decide how much and what type of capital is required. Since the situation is not the same for all businesses, there is no magical formula. Some businesses may only need short-term financing for items such as salaries and inventory; whereas, other businesses may need long-term financing for major items such as office space and equipment. Each business must develop a customized plan that will meet its unique needs.

Securing capital is a choice made after weighing the pros and cons of various options. There are three popular sources for obtaining funding for new ventures: borrowing from financial institutions, partnering with venture capitalists, and selling equity/ownership in exchange for a share of the revenue. All financing options can be classified into two categories—debt financing and equity capital.

Debt financing includes bank loans, personal and family contributions, and financing from agencies such as the Small Business Administration. Loans are often secured by some type of collateral in the company and are paid off over a period of time with interest. On the other hand, venture capitalists and angel investors provide funding in the form of equity capital. Both are given ownership in the company in exchange for money. Pierce (2005) offers some advice which may be of assistance when assessing which option may be best for the company. Some of the tips include:

- A Small Business Administration program may not be the best option if the company needs less than $50,000.
- Debt financing is usually cheaper and easier to find than equity capital. Financing the venture via debt leads to the responsibility of making monthly payments whether or not the business has a positive cash flow.
- Equity investors expect little or no return in the early stages of the business, but require more reporting about the company's progress. In addition, they expect the company to meet the established goals and milestones.
- Debt financing is usually available to all types of businesses. However, equity capital tends to be reserved for businesses with fast and high growth potential.
- Angel investors tend to invest money in companies that are within a 50-mile radius, and the amounts of funding tend to be in the range of $25,000 and $250,000. Angel investors may be

friends, family, customers, suppliers, brokers, and competitors.
- It is difficult to secure venture capital funding, even in a good economy.

Debt financing and equity capital options both require the business owner to complete detailed documentation prior to the award of financing. The owner should be prepared to produce quarterly balance sheets, background information on the company, and projections.

Debt Financing

If a company cannot finance its expansion through personal investments, the management team will need to develop a business plan that meets the criteria for potential lenders. Commercial banks may be the first choice, especially if the owner has a relationship with a specific lender. Since traditional lenders tend to be conservative, good rapport and an established relationship will be beneficial when applying for a loan. According to the University of Maine's Cooperative Extension, a 1980 Wisconsin study of small businesses found that 25 percent of the businesses interviewed were initially denied, but 75 percent of these groups were approved when they submitted their proposal to another group.

If a commercial bank is not an alternative and the entity is a small business, the Small Business Administration may be another option. The business must satisfy the agency's criteria and not be able to secure financing from other sources. The Small Business Administration (SBA) is an independent agency of the Executive Branch of the federal government, and it is responsible for assistance to small businesses in the United States. There are four types of assistance this agency can offer: advocacy, management, procurement, and financial assistance. Financial assistance can be granted through the agency's investment programs, business loan programs, disaster loan programs, and bonding for contractors.

There are three loan programs, and the Small Business Administration sets the guidelines and other entities such as lenders, community development organizations, and micro-lending institutions make the loans to small businesses. In order to reduce the risk to these entities, the SBA will guarantee the loans. When a business applies for an SBA Loan, they are actually applying for a commercial loan with SBA requirements and guaranty.

In 1958 Congress created The Small Business Investment Company (SBIC) program. SBICs, licensed by the Small Business Administration, are privately owned and managed investment firms. SBICs partner with the government and use their own capital with funds borrowed at reduced rates to provide venture capital to small businesses.

The Surety Bond Guarantee (SBG) Program was developed to provide small and minority contractors with contracting opportunities for which they would not otherwise bid. The Small Business Administration (SBA) can guarantee bonds for contracts up to $2 million, covering bid, performance, and payment bonds for small and emerging contractors who cannot obtain surety bonds through regular commercial channels.

Equity Capital

The first venture capitalist firm was established in the 1940s with the purpose of providing financial and business support to entrepreneurs in exchange for repayment in capital gains. They tend to gravitate toward technology initiatives because of the potential for high returns. In addition, these organizations were interested in promoting their services nationally and internationally. During the last two decades, venture capitalism has expanded to the global marketplace.

Venture capital is usually available for start-up companies with a product or idea that may risky, but has a high potential of yielding above average profits. Funds are invested in ventures that have not been discovered. The money may come from wealthy individuals, government-sponsored Small Business Investment Corporations (SBICs), insurance companies, and corporations. It is more difficult to obtain financing from venture capitalists. A company must provide a formal proposal such as a business plan so that the venture capitalist may conduct a thorough evaluation of the company's records. Venture capitalists only approve a small percentage of the proposals that they receive, and they tend to favor innovative technical ventures.

Funding may be invested throughout the company's life cycle with funding being provided at both the beginning and later stages of growth. Venture capitalists may invest at different stages. Some firms may invest before the idea has been fully developed while others may provide funding during the early stages of the company's life. However, there is a group of venture capitalists who specialize in assisting companies when they have reached the point when the company needs financing in order to expand the business.

Many firms receive some type of funding prior to seeking capital from venture capitalists. Angel investors have been identified as one source that entrepreneurs may reach out to for assistance. As Edelhauser (2007) puts it:

> In a nationwide survey of more than 3,000 individual angel investors conducted by the Angel Capital Association, more than 96 percent predict they'll invest in at least one new company in 2007. Also, 77 percent expect to invest in three to nine start-ups, and five percent think they'll fund 10 or more new companies.

Including angel investors in the early stages of financing could improve the chances of receiving venture capital financing. A 2005 study of small businesses found that 57 percent of the firms that had received angel investor financing had also received financing from venture capitalists. Firms that did not receive angel investing in the early stages (approximately 10 percent of the firms in the study) did not obtain venture capital funding. It appears that angel investor financing is a significant factor in obtaining venture capital funding. Since obtaining venture capital tends to be difficult, businesses can benefit from the contacts and experience of angel investors in order to prepare for a venture capital application and evaluation. The intervention of an angel investor may make the company appear more attractive to the venture capitalists.

Regardless of how a company decides to finance the venture, it often has to make an agreement that is beneficial to the investors since investors are providing the capital. Therefore, it is important to select a choice that benefits the business in the long run. Initial decisions may set the tone for future deals. Advani (2006) has provided some recommendations to consider when determining what will work best. These suggestions include the following:

- Don't give pro-rata rights to your first investors. If your first investor is given pro-rata rights, chances are your future investors will want the same agreement. It would be wise to balance the needs of your early investors to protect their stake in the company with how attractive the company will be to future investors.
- Avoid giving too many people the right to be overly involved. If too many people are involved, it could create a bureaucracy and make it difficult for decisions to be made in a timely manner. In addition, the daily tasks of a business may be prolonged due to the need for multiple authorization signatures.
- Beware of any limits placed on management compensation. Some investors may place a cap on the earning potential of senior management personnel. This type of action could create a problem with human resource needs such as attracting and hiring quality talent to run and grow the business.
- Request a cure period. Many investors will request representation for every legal agreement to protect themselves if the management of a company is not in compliance with laws, licenses, and regulations that govern the operation of the business. Although all parties may have good intentions, errors do occur. If a "cure period" is added to the financing agreement, the entrepreneur will have the opportunity to find a solution to the problem within a given period of time (e.g., two to four weeks).
- Restrict your share restrictions. Having unrestricted shares is often a good negotiating factor with future investors. Therefore, it would be wise to evaluate any requests to restrict the sale of shares owned by the founders and/or management team.

Entry Mode

An entry mode is the manner in which a company decides to enter into foreign markets. International market efforts take many forms. There are various strategies an organization may implement once it has decided to enter the global market. Ways to enter a foreign market include licensing, franchising, joint ventures, exporting, and direct investment.

Licensing occurs when a target country grants the right to manufacture and distribute a product under the licenser's trade name in a target country. The licensee pays a fee in exchange for the rights. Small and medium-sized companies tend to grant licenses more often than large companies. Since there is little investment required, licensing has the potential to provide a large return on investment. However, it is seen as the least profitable way to enter the market because most companies use licensing to supplement manufacturing and exporting. Licensing tends to be a viable option to enter a the market when (1) the exporter does not have sufficient capital, (2) when foreign government import restrictions forbid other ways to enter the market, or (3) when a host country is not comfortable with foreign ownership.

Advantages of this method to a multinational corporation (MNC) are (1) there is no capital expenditure requirement, (2) it is not risky, and (3) payment is a fixed percentage of sales. Disadvantages are (1) the multinational does not have any managerial control over the licensee because it is independent, and (2) the licensee can give the multinational's trade secrets to a potential competitor.

Exporting is the marketing and direct sale of domestically produced goods in another country. It is a traditional and established method of reaching foreign markets. New companies tend to enter international markets through exporting. One reason may be because this type of entry does not require the organization to produce the goods in the targeted country, which means that the organization would not have to invest in foreign production facilities. Marketing expense is the biggest cost with exporting. There are two ways an organization can make sales in exporting—directly or indirectly. Direct sales can be made via mail order or through offices set up abroad. Indirect sales are made via intermediaries who locate the specific markets for the organization's products. The four players in the exporting business are the exporter, importer, transport provider, and the government. Many organizations are able to successfully establish themselves abroad and do not have to expand beyond exporting.

Direct investment occurs when there is direct ownership of facilities in the target country, and it requires a high level of resources and a high degree of commitment. This type of market entry may be made via the acquisition of an existing entity or the establishment of a new enterprise. It requires the transfer of resources such as capital, technology, and personnel. Direct ownership can provide a high level of control in the operations as well as provide the opportunity to better know the potential customers and competitive environment. MNCs may select this method when they want to (1) grow: the organization reaches a point where it realizes that it is not growing; therefore, there in an initiative to identify new markets so that it can continue to make profit; (2) bypass protective instruments in the target country. American MNCs avoid set-up subsidiaries in order to avoid the common external tariff imposed by the European market; (3) prevent competition: MNCs may buy a foreign company so that it will not become a competitor; and (4) reduce costs: labor costs tend to be different in countries. Many MNCs will attempt to identify countries that have qualified workers that will work for lower wages. For example, many American MNCs have outsourced their customer service and technology functions to India.

There are a number of reasons why a franchise may consider going global, and some of these reasons include opportunities to (1) build more brand and shareholder value, (2) add revenue sources and growth markets, (3) reduce dependence on the company's home market, (4) leverage existing corporate technology, supply chains, know-how, and intellectual property, and (5) grow more franchises in the home country by being global.

Joint ventures occur when an organization enters a foreign market via a partnership with one or more companies already established in the host country. In most cases, the local company provides the expertise on the target market while the exporting company manages and markets the product. A joint venture arrangement allows organizations with limited capital to expand into international markets, and provides the marketers with access to its partner's distribution channels. Key issues in a joint venture are ownership, control, length of agreement, pricing, technology transfer, local firm capabilities and resources, and government intentions. Potential problems include (1) conflict over new investments, (2) mistrust over proprietary knowledge, (3) how to split the pie, (4) lack of parent company support, (5) cultural clashes, and (6) when and how to terminate the relationship if it is necessary to take such action.

Environmental Standards

Environmental standards are recommended or compulsory policy specifications designed to regulate human, generally business, effects on the environment, the surroundings in which an organization operates. Compliance means conforming to a policy specification that has been clearly defined. The International Organization for Standardization (ISO) is the confederation for environmental, health, and safety and quality standards, consisting of a network of the national standards institutes of 157 countries. Each member country has one member representative on the ISO and decisions are made via consensus. The ISO headquarters are located in Geneva, Switzerland. The ISO is internationally recognized as the hallmark for an audited Quality Management Control System.

Specific environmental standards become law through international treaties or national standards. Many countries have specific departments that regulate the impact of businesses on the environment. Also, trained, accredited environmental auditors can relate company environmental impacts against ISO or other international or national environmental standards while operating under an ethical professional code of practice. The introduction of an accredited environmental management system within a company demonstrates legal and regulatory environmental requirements and should result in sustained improved management of environmental risks as internal processes are constantly reviewed; however, it requires resources. Nevertheless, there are a number of reasons from a strategy perspective why companies might voluntarily set environmental standards that are stricter than those set by law or recommended.

An organization's environment is the surroundings in which it operates and extends from within the company to the global system. Businesses impact on the environment by using raw materials and energy in production processes and by producing wastes and emitting pollutants onto the land or into waterways and the atmosphere. For example, the combustion of fossil fuels such as coal and petroleum oil in power plants and many other industrial processes has contributed to the substantial increase in atmospheric carbon dioxide concentration over the past 50 years. There is considerable evidence that this increase in carbon dioxide concentration is a factor contributing to global warming. The combustion of fossil fuels in power plants and other industries can also result in the production of other gaseous pollutants such as sulphur dioxide and nitrous oxide. These gases can have adverse effects on human health as well as on the environment. Nitrous oxides are also emitted in the production of nylon and nitrogen-based fertilizers while use of nitrogen fertilizers has had negative environmental effects on land, water, and the atmosphere, contributing to the eutrophication of nutrient-poor land habitats, fresh waters, estuaries, and coastal water; a decrease in biodiversity inside and outside the agricultural systems; and emissions of greenhouse gases to the atmosphere. Utilization of raw materials and energy, and production of pollutants, is not related only to large industries. With few exceptions, all businesses require electricity or gas for lighting, heating, and running of appliances and also produce waste.

Different countries can have different environmental standards and environmental standards can vary between different parts of a country. For example, in the United Kingdom, environmental standards can be different in Scotland than in England or Wales. In the United States, environmental standards can be different in different states. The ISO has developed international environmental standards addressing a broad array of subjects and new standards are published annually. These standards are generic in nature and are periodically updated. Initially such standards were quite inflexible to diverse business operations. In response to growing credible criticisms, the ISO responded by modifying standards to accommodate different organizational operations, while maintaining its fundamental principles.

The ISO 14000 Series

The ISO publishes the ISO 14000 Series Environmental Management systems, which is a series of international standards on environmental management. The fundamental principle of the ISO 14000 Environmental Management Standard is to provide a framework of reference for organizations to reduce/minimize their commercial processes that negatively affect their internal and external environment; adhere to relevant legislation; add further environmental requirements as necessary; and demonstrate continuous improvement of environmental procedures. The ISO 14000 series specifies the actual requirements for the development of an environmental management system and its supporting audit program to be carried out by a company. It applies to those environmental aspects over which a company has control.

The major parts of the ISO 14000 series are ISO 14001 and ISO 14004. ISO 14001 is the international specification for an environmental management system; it provides details of the requirements of a company in establishing an environmental policy. ISO 14001 identifies the activities of an organization that impact the environment, sets measurable targets for improvement, and details a management program to achieve these targets. The process involves continual checking and management review with the implementation of corrective action if required. ISO 14004 is a guidance document for ISO 14001 giving more detail on the establishment of an environmental management system, the setting of measurable environmental targets for improvement, and the implementation of checks and controls. It also provides details on the coordination of an environmental management system with other management systems such as those related to health and safety, and quality.

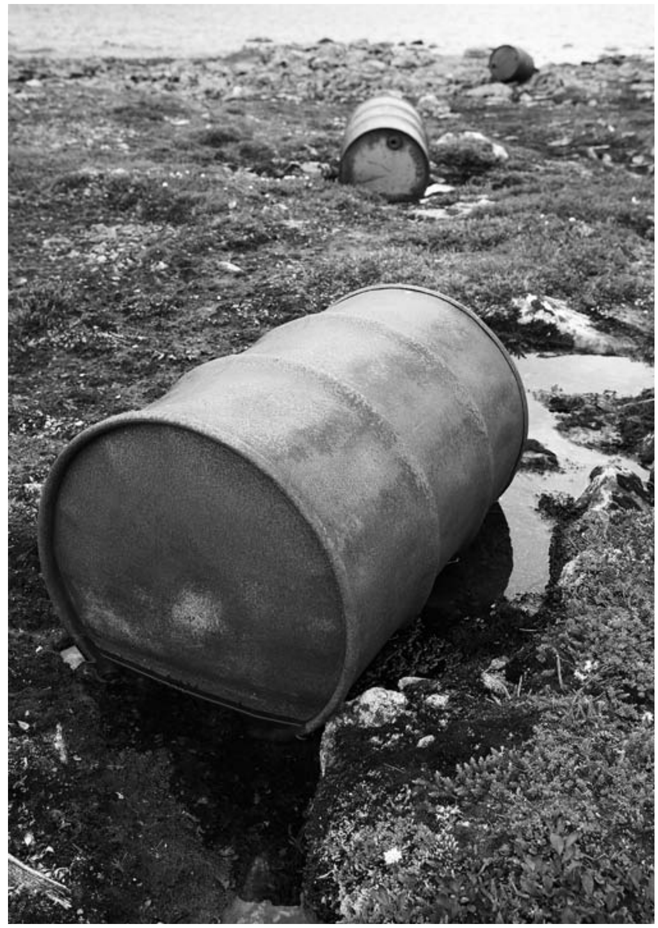
Environmental management standards are akin to quality management standards. They focus on the outcome of the production process as opposed to the product/item, utilizing the concept of "cleaner production." Their fundamental aim is to design and control an auditable procedure aimed at minimizing adverse environmental "aspects," for example, production of waste, spillage of chemicals, and carbon dioxide emissions. An "aspect" is an element of an organization's activities or products or services that can interact with the environment. ISO 14001 identifies suitable methodologies/tools to interpret such aspects and to assess their impact. ISO 14001 is a set of standards against which all organizations can be assessed. As of 2008, over 100,000 companies worldwide have been certified to ISO 14001 standard.

Assessment

Environmental impacts fall broadly into two classifications, direct and indirect impacts. Direct impacts are effects that are the immediate result of the actions or operations of an organization, for example, waste production and carbon dioxide emissions. Indirect impacts are the effects that occur upstream or downstream of the organizational activities, for example, extraction of raw materials that are transported to, then utilized by, a company. The ultimate aim is to formulate realistic proactive remedies for sustainable continuous improvement.

Tried and tested aspect assessment approaches that can be utilized within a company can fall under three methodologies: the risk-based scoring methodology, environmental and commercial qualitative methodology, and criteria-based methodology. The risk-based scoring methodology adopts a numerical cut-off value. The likelihood of breaches in organizational systems (A) are multiplied by severity of environmental impact (C). Both A and C are allocated criteria and ranking such that the significance figures fall between 1 and 50. Those risk-based activities that are allocated above 20 points are deemed "significant" and need to be addressed. The environmental and commercial qualitative methodology adopts a traffic-light scheme. Color codes are allocated to specific aspects that are benchmarked against predetermined criteria, for example, legal requirements, cost savings, and customer views. The criteria based methodology identifies key yes/no answerable questions. The largest number of yes responses represents the highest significance.

Many countries have specific governmental, publicly-funded departments/agencies that regulate the impact of businesses on the environment. For example, the United States has the U.S. Environmental Protection Agency; Australia has the Department of the Environment, Water Heritage and the Arts; and England and Wales, the Department for Environment, Food and Rural Affairs (DEFRA). These organizations provide guidance to businesses in relation to meeting environmental standards. Also, in some cases, they have the power to issue improvement or prohibition notices which may lead to the prosecution of businesses that breach environmental regulations. Convicted organizations are fined and listed on governmental Web sites and, as a result, can suffer long-term difficulties in retaining or sourcing supply chain clients. This is one of the primary reasons to ensure environmental conformance.



Many environmental standards aim to control industrial waste, including requiring records to make waste traceable to its origin.

Trained, accredited environmental first-, second-, and third-party auditors can assess company environmental impacts against environmental standards, for example, ISO 14001 or other international or national standards while operating under an ethical/professional code of practice. First-party auditors carry out audits within their own department. Second-party auditors can be from within the company but are outside the department being assessed or are independent consultants. It is considered best practice for internal auditors to audit outside their formal management line, in order to maintain a neutral assessment. Third-party auditors come from an accrediting body that carries out official audits. The role of the third-party auditor is to identify nonconformance, and the organization must identify corrective action.

EMAS

Within the European Union, the Eco-Management and Audit Scheme (EMAS) is a voluntary initiative designed to improve companies' environmental performance. EMAS is more rigorous than ISO 14001. It aims to recognize and reward those organizations that go beyond minimum legal compliance and continuously improve their environmental performance. For example, EMAS requires the completion of an initial environmental review that is an assessable part of the environmental management system. ISO 14001 recommends an initial environmental review if an organization does not have an existing environmental management system but it is not a requirement. Also, EMAS requires a maximum three-year audit cycle and the publication of an environmental statement by the company that reports on their environmental performance, while ISO 14001 requires "periodic" environmental management system audits and that an organization should "consider" external communication.

EMAS has very specific requirements in the type of environmental aspects that should be addressed within the environmental management system and it is possible that ISO 14001 does not cover some of these areas. The European Union has formally recognized that ISO 14001 satisfies many of the requirements of EMAS and has set out steps on how to implement EMAS if a company is already ISO 14001 certified. Auditors require additional competencies to award EMAS in comparison with ISO 14001 accreditation.

The Institute of Environmental Management and Assessment (IEMA) is a not-for-profit professional membership body that supports environmental auditors internationally and provides training courses for them. As of 2008, the IEMA had over 12,500 members in 87 countries.

Certification

Organizations wishing to apply for accreditation from an official environmental standards body are assessed against the standards and, if successful, are awarded certification. Certification is not indefinite; organizations must undergo reaccreditation periodically. Successful organizations maintain accreditation, while those who exhibit noncompliance are issued a report that addresses the audit findings. Such findings may include "observations," "action requests," "noncompliances," and specify a period to correct those highlighted issues. If significant noncompliances are discovered or the previous audit report recommendations were not addressed, accreditation may be suspended or, in extreme cases, withdrawn.

Generally, a company is responsible for environmental aspects over which it has control and this can encompass procedures outside the company site. For example, in relation to waste management, in England and Wales, the producers of waste are responsible for its correct disposal. Here, a company must develop and maintain a waste inventory, listing the date the waste was produced, the source, type and amount of waste produced, the medium (land, air, or water) affected by the waste, and how the waste was dealt with, for example, by controlled disposal via skip to landfill or special disposal such as incineration. Also, the person responsible for the waste disposal must be stated. Then, in relation to the transfer of waste offsite, the company must ensure that carriers and waste sites have the proper licenses to deal with the waste produced. In relation to the transfer of hazardous waste, the company must pre-notify the Environment Agency, a nondepartmental public body of DEFRA, when it intends to transfer this offsite and complete consignment notes that must be kept for three years.

As a further check, there are waste acceptance procedures that must be carried out by waste disposal companies. For example, a waste disposal company operator must inspect the waste at the entrance to the landfill and at the point of deposit in order to verify that it matches the description given on the relevant documentation from the company that produced it and from the company that transported it. The operator must keep a register of the date the waste was delivered, the origin of the waste (company that produced it and company that transported it), and type and quantity of waste. With respect to hazardous waste, the precise location of the site in which it was deposited must be recorded. Thus all waste deposited should be traceable to the activity that resulted in its production.

Accredited environmental management systems within companies require commitment and can be costly. Time and funding must be allocated to the development and maintenance of the system. This would involve staff training to develop a company-wide culture of environmental awareness. Nevertheless, some companies have made a commitment to operate policies that are more rigorous than the environmental standards set. There are a number of reasons from a strategy perspective as to why companies might voluntarily set environmental standards that are stricter than those set by law or recommended. For example, every organization has complex involvement with stakeholders, all groups or individuals that are affected by or can affect an organization's objectives. Stakeholders are a critical factor in determining the success or failure of a business. By matching and concentrating on the interests of various stakeholder groups, managers can increase the efficiency of their organizations' adaptation to external demands. Setting environmental standards that are more rigorous than required could lead to greater stakeholder satisfaction. If this satisfaction were felt by customers, this could lead to increased sales. Thus from a cost-benefit framework perspective, commitment of a company to more rigorous environmental standards than required could increase consumer demands for its products. Also, it could improve corporate reputation in the market and enhance relations with regulating agencies, community, nongovernmental organizations, and media.

In marketing terms, implementation of environmental standards more rigorous than recommended or required by law could give a company a competitive advantage over rival companies, assuming the environmental standards set by these other companies is less rigorous. Also, this advantage could be sustained if a company continuously analyzes and responds to changes in the environment.

E.ON

E.ON describes itself as the world's largest investor-owned power and natural gas company. E.ON is involved in every step of the power supply chain from development, through transportation, to final delivery to customers. The company describes its wide range of activities as not only allowing it to minimize risk but to also claim that its supply of both gas and power allows its customers the benefit by needing only one supplier. The antitrust offices in the European Commission have taken issue with that assertion.

In 2007 E.ON reported €67 billion in sales and €7.7 billion in profits. It employs approximately 88,000 employees. It is based in Dusseldorf, Germany, and operates throughout Europe but also has electric, gas, and renewable energy operations in North America.

E.ON came into existence in 2000 when the companies of VIAG in Germany and VEBA AG (which had existed since 1929) were merged. Since the merger E.ON has made several important acquisitions including companies in Britain, Russia (where is also has an arrangement with Gazprom), and Sweden. It has also extended its reach throughout Europe, including eastern Europe as a result of its acquisition of the natural gas provider Rurhgas in 2003.

E.ON has not been in successful in all cases where it has tried to expand. In April 2007 E.ON stopped its efforts of over a year and a half to acquire the Spanish utility company Endesa for €42.4 billion. Competing against a Spanish utility corporation and the Italian energy company Enel, which had acquired 46 percent of Endesa, E.ON dropped its bid. In return, it received a promise that it could buy part of Endesa's assets worth approximately €10 billion.

E.ON has also drawn the attention of the European Union's antitrust offices. In June 2008, E.ON and another energy company, GDF, were accused by the European Commission of agreeing not to sell energy to each other's countries. E.ON has denied all accusations and has stated that it will collaborate with the European Commission to resolve the charges. Further, the company stated that it had invested several billion euros in projects to improve infrastructure that will carry gas throughout Europe. Additionally, E.ON has been under a great deal of pressure from the Commission to sell part of its infrastructure, the supply grids, to facilitate cross-border competition and in 2008 the company announced that it would sell some of its assets. Other charges against the company include accusations that it has withheld electricity in an effort to drive the price up.

The European Commission is not the only organization that has taken issue with E.ON. E.ON has been investigated by the German Government's Cartel Office. As a result of the initial investigations, E.ON agreed that it would pay €55 million as refunds to its customers served by six of its regional companies. In addition, E.ON promised it would not initiate its planned 10 percent price increases in gas until the end of 2008. In return the Cartel Office stated that it would stop further investigations into E.ON. E.ON's rationale was not that it had done anything wrong but that it wished to present legal proceedings that might go on for a long time and that it preferred to refund money to its customers than pay fines to the government. In November 2008 Germany's Federal Supreme Court issued an order prohibiting E.ON from increasing the holdings it currently has in municipal services of German towns. For 10 years utility companies such as E.ON and RWE had been buying shares in these corporations in response to a loosening of regulations in 1998.

E.ON has also drawn the opposition of environmental groups. As wind farming has not been as successful in Europe as planned, E.ON has commenced the construction of coal-fired electrical generation plants, an action that has resulted in protests.

Equities

The term *equity* means different things in different contexts. In the business world, equity usually refers to stocks or other securities that represent ownership rights (to a company or some other business entity). A person possessing any amount of equity in a company owns the corresponding portion of that company. If a legal person (a person or a business entity) owns more than 50 percent of the outstanding shares of a company, then the person possesses a controlling share of that company. A company owning a controlling share of another company is called the parent company while the latter is called the subsidiary company. Equity can also mean the difference between the value of an asset (for example, a house) and the debt (mortgage) amount the owner still owes.

In the context of margin trading, equity is the value of the margin account less the amount borrowed from the brokerage firm. Margin trading is trading of securities using a margin account with a brokerage firm. Margin trading allows the investor to invest in securities with borrowed money from the brokerage house and thereby leverage their investment (magnify both the gains and losses from the investment).

In the context of global business, however, equity primarily refers to the stocks or other securities representing ownership rights to companies across the nations. The trading of global equity has created global capital flow across countries, and has created a single world financial market that truly spans all the economies. The economic impact of a single global financial market has been enormous. The growing businesses of the world now can raise capital faster than ever and the investors have the widest range of investment pool available to them. But it has also given rise to problems like capital flight, which has devastated different economies from time to time.

In a globalized world, a person can own equities in multiple foreign business entities. Foreign stocks are traded in all the major stock exchanges in the world. Global equity trading increased sharply beginning in the 1980s. Equity trading across borders has allowed companies to be cross-listed and dual-listed, has enabled the formation of parent subsidiary relationships between foreign companies, and has given rise to unique business structures like that of Renault-Nissan Alliance.

Cross-Listing or Co-Listing Companies

Shares of many large companies are traded in multiple stock exchanges, so that investors from different countries can have easy access to their securities. For example, Fortis, a banking, insurance, and investment management company that has a presence in Europe and North America, is listed on three stock exchanges: Euronext Brussels (Ticker symbol FORB), Euronext Amsterdam (FORA), and Luxembourg stock exchanges (FOR). Getting listed on a stock exchange in a country other than the country of incorporation has certain business advantages. Many large Canadian companies are listed both on the Toronto Stock Exchange and the New York Stock Exchange (NYSE). Getting listed on the NYSE has helped these Canadian companies to expand in the large U.S. market. The disadvantage of cross-listing is, of course, the extra work necessary to adhere to the regulations (financial reporting) of different countries.

It is important to note at this point, however, that a foreign company's security can be traded between investors through other channels. For example, in the United States, investors can buy and sell foreign companies' stocks in over-the-counter trading (process of directly trading equities as opposed to trading through a stock exchange). Many banks like JP Morgan Chase issue instruments like ADR (American Depositary Receipt) and GDR (Global Depositary Receipt) that enable investors to buy foreign securities while bypassing the hassle of international transactions. Buying ADR, GDR, or similar other instruments essentially means buying the ownership rights to the underlying (foreign) securities; investors can buy them and receive their dividends in U.S. dollars.

Dual-Listed Companies

While cross-listed companies are those that are listed on more than one stock exchange, a dual-listed company (DLC) is a special corporate structure consisting of two listed companies, with separate bodies of shareholders sharing the ownership of the corporate entity. DLC works like a merger (a process of forming a new company by merging two existing companies) in some ways, but both the original companies continue to exist. The companies in a DLC have separate bodies of shareholders, but they share all the risks and rewards of the entire corporate structure in a fixed proportion. Dual-listing allows companies from different countries to collectively do business without having to undergo any merger or acquisition process. In this way, dual-listing facilitates integration of business operations of two companies where business environmental forces (national pride, commitment to corporate identity, etc.) do not support mergers or acquisitions between the two companies.

Unilever, the giant multinational corporation that owns many of the world's consumer product brands, is a dual-listed company. Unilever consists of Unilever NV in Rotterdam (Netherlands) and Unilever PLC in

London (United Kingdom). Both Unilever companies have the same directors and effectively operate as a single business. Similarly, Thomson Reuters, a leading media company of the world, is also a dual-listed company consisting of Thomson Reuters Corporation, a Canadian company, and Thomson Reuters PLC, a United Kingdom company.

Cross-Border Corporate Alliances

Global equity flows have allowed parent-subsidiary relationships between foreign companies, facilitating vertical integration of business operations across the border. For example, the U.S. soft drink giant Coca-Cola has assumed control over various Chinese bottlers and distillers over the course of its several-decade business presence in China. Besides conventional parent-subsidiary relationships, global equity trading has enabled unique corporate alliance structures like Renault-Nissan Alliance Group.

Renault-Nissan Alliance is a group of two global carmakers (Renault and Nissan) that are linked by cross-shareholding. Renault S.A., a French company, owns 44.4 percent shares of Nissan, a Japanese company, which in turn owns a 15 percent share of Renault. Both the companies, especially Nissan, which was in deep financial crisis before the formation of the alliance, have benefited from the alliance. In some aspects the Renault-Nissan Alliance works much like a merger since it has allowed integration in operations and management of the two companies (Carlos Ghosn is the CEO of both the companies). But the alliance does not face the legal and corporate challenges associated with a merger.

Capital flight has been a problem in various countries' capital markets. Aggressive foreign investors often initially flood a given country's capital market with fresh investment capital for the time being. However, when in the presence of some triggering phenomena (e.g., political turmoil, economic worries, etc.), these investors often pull back their investment in droves and the capital market of that specific country faces cataclysmic crisis. This is commonly referred to as capital flight. It is hoped that better international regulations will alleviate such problems.

Estonia

The country of Estonia is the northernmost of the three Baltic States, having been a part of the Russian Empire from 1721 until independence in 1918. In 1940, it was invaded by the Soviet Union, and in 1941 it was invaded again, this time by Nazi Germany. The Red Army retook Estonia in 1944 and occupied it until independence in 1991. On May 1, 2004, Estonia joined the European Union. The country now has one of the fastest-growing economies in the world.

Estonia is known for involvement in multiple industries, but has especially extensive timber, with forests still covering some 47 percent of the land, and there are also limestone deposits. The Estonians have a regional reputation for canniness in financial matters, and before World War I, although some 90 percent of the population were ethnic Estonians, there was a substantial German business class. There were also several thousand Swedes who had an important role in local commerce that was out of proportion to their small number.

During the period when Estonia was part of the Russian Empire, the city of Tallinn became relatively wealthy. One of the merchants of the city, Robert von Glehn (1801–85), moved to London, and his son, Alfred George de Glehn (1848–1936) made a major contribution to the development of the steam locomotive. After independence, Estonia started to develop many of its own industries to prevent reliance on other former parts of the Russian Empire. It exported timber and timber products, dairy products, cotton, and wool. Many imports came from Germany and also Austria, with Steyr automobiles being popular. There was also a substantial trade with Britain involving companies such as Ilford Limited for photography.

While Estonia was a part of the Soviet Union, the economy was centrally controlled, and many Russians settled in Estonia; Russians now make up 25.6 percent of the population of the country, while 68.7 percent are Estonians. The Estonian capital, Tallinn, remained a prosperous city, not having been as badly damaged during World War II as many others in the region. With independence, the new Estonian government decided that as an economic policy, they would allow the free market to operate, and as a guarantee against future invasion, the country would seek close ties with the West. These objectives saw Estonia welcome investment, tourism, and joining the European Union.

The transformation of the Estonian economy after independence has seen a move from a period when it is believed that up to 90 percent of the economy was controlled from Moscow, and all the major economic decisions were made there, and when some 95 percent of the labor force worked in government-owned enterprises or on collective farms, to a major embracing of the free-market economy, engagement with the International Monetary Fund, and trade with northern and western Europe. The selling off of state property to allow private property ownership was a major plank in the policy of the Estonian government and property was returned, when possible, to the pre-1940 owners, or compensation paid.

The new Estonian currency, the kroon, was pegged to the U.S. dollar to ensure confidence in it and also stability, and this reduced any threat of inflation that had badly affected nearby Lithuania after it achieved independence. Foreign trade has grown massively, as has foreign investment in Estonia, and it has become a popular holiday destination for many Europeans. The major exports from the country are machinery and equipment (24 percent), wood products, textiles, food and food products, metals, and chemicals. Machinery and equipment make up 31 percent of the country's imports, with food, metals, and textiles also being imported. Some 23 percent of exports go to Finland, and 15 percent of imports come from Finland. There is also considerable bilateral trade with Germany, Russia, and Sweden.

Ethnocentric Human Resource Policy

The term *ethnocentric* is derived from the Hellenic (Greek) word *εθνοκεντρισμός*, a composite word that consists of the term *έθνος*, which means nation, and the term *κέντρο*, which means center. The meaning of the term is identical in both the Hellenic and the English language, and signifies that policies and systems in the countries in which the multinational corporation operates (the host countries) revolve around the policies and systems of the country from which the multinational organization originates (the home country).

In ethnocentric orientation, human resource systems in the host countries mirror those that are utilized in the home country. The idea is that if these systems have worked well in the home country, they should work well everywhere, with little or no adaptation to the local conditions and culture. Hence, the ethnocentric human resource approach pays minimal attention to local factors. However, evidence suggests that direct transferability of human resource systems across national boundaries without taking into account cultural factors is risky.

A trademark characteristic of the ethnocentric human resource approach is the employment of home country nationals to fill key positions in the host country. Reasons for adopting an ethnocentric approach in the staffing of operations include:

- Starting up operations in host countries. This is a critical stage, and there is a need to place individuals in host countries who are fully aware of the needs of the multinational and any specifications, as these have been set by the headquarters. Normally individuals who are most familiar with the goals and demands of the multinational as these have been set by the headquarters are home-country nationals who have been with the corporation for some time.
- Technical expertise. Many times multinational corporations need to transfer scientific and technological knowledge, professional expertise, and managerial skills into new operations. In many cases the knowledge and skills do not exist in the local workforce, especially if the product is highly specialized and utilizes cutting-edge technology. Therefore, it is necessary to deploy home-country nationals in host-country operations.
- Maintenance of financial control and facilitation of coordination. A major need for the headquarters is effective and efficient communication as well as trust with key employees in host countries. It is natural to consider that this is more feasible when key positions in host-country operations are filled with home-country nationals.
- Provision of international experience for promising managers and professionals. An assignment abroad normally requires ability to work independently and to show initiative in an unfamiliar environment. This serves as a test and as an opportunity for development for home-country managers and professionals who are groomed for senior positions.
- Need to maintain the foreign image of the multinational corporation. Sometimes the headquarters consider that it is in the best interests of the corporation that operations in particular countries are associated with the home country. This, for example, can be the case when products from a particular home country in a particular market have a very good reputation; or when a particular home country is viewed positively by host-country nationals.
- The multiracial or multireligious population of the host country. In some cases the host country has a population that belongs to two or more races or religions that have a history of rivalry. In such cases it may be risky for the multinational corporation to appoint a local national, because nationals from the other races or religions may perceive it as bias against them.

Ethnocentrism in human resource policy has been the norm in the past, but it is a phenomenon that is dissipating. There are a number of reasons for this, including the realization of the importance of cultural factors in the appropriate functioning of human resource systems, the improving level of education around the globe that has increased the availability of qualified managerial and professional workers in host countries, and the high cost of expatriates.

Ethnocentrism

Ethnocentrism refers to the human tendency to view the world through the lens of one's own culture. An ethnocentric individual considers their race or ethnic group and aspects of their culture—behavior, customs, language, and religion—as superior to others and judges them in relation to their own. This affinity for one's culture is explained in psychology as an individual's preference for people that share similar values, beliefs, and behavior (in-group). Furthermore, it can be difficult for individuals to understand different cultures from perspectives other than their own since they are socialized in their birth culture for which they may develop an intrinsic bias. Consequently, an ethnocentric person will view these other cultures as not only different but may resist or reject another culture and its patterns of thought and behavior as they are considered less desirable or inferior to their birth culture. This predisposition may lead to a range of discriminatory behaviors, most commonly in-group favoritism ("ethnocentrism") and out-group hostility ("xenophobia"). Ethnocentrism has been associated with ethnic conflict, war, voting, the instability of democratic institutions, and consumer choice.

Ethnocentrism has also been related to genetic similarity among ethnic groups that can produce an alignment of interests among members. In this way, ethnocentrism has been linked to the concept of nationalism in political science and use of the term *ethnocentric* to describe national and ethnic groups as selfish and culturally biased. There are many instances where citizens and nations have demonstrated ethnocentric behavior. For example, an Anglo-centric world view was created through the measurement of longitude in degrees east or west of Greenwich, England. Eurocentrism refers to the tendency to view the world from a European (or Western) perspective with an implied belief about the superiority of European culture and to interpret the histories and cultures of non-European societies from this point of view.

Despite increasing access to foreign-made products, often of superior quality and lower price, socio-psychological motivations such as ethnocentrism still drive consumers to purchase domestically made products, even against their economic self-interest. Consumer ethnocentrism may be defined as the beliefs held by consumers about the appropriateness, indeed morality, of purchasing foreign-made products. This concept may be described in terms of a continuum. On one extreme is nationalism, characterized by the willingness to sacrifice individual interests for the nation, coupled with hostility toward external groups. This attitude is based on the belief of one's own country's superiority, right to dominate, and an uncritical attachment to national values. Nationalists blindly overemphasize the virtues of domestically made products while downplaying, even boycotting, those of foreign origin in order to weaken other countries economically.

On the other extreme of the continuum one finds internationalism, characterized by positive feelings toward other nations and their people, thus fostering a sense of global community. Internationalism shows concern about other nations' welfare and empathy for problems abroad. Internationalists find it morally acceptable to purchase imports and to actively support the struggle and welfare of other nations. It is possible for consumers to have a moderate attitude, what can be described as healthy patriotism, or love of country. Patriots also consider it their duty to protect their country's economy, even at personal expense, through the purchase of domestic products but without aggressive bias against out-groups. Research indicates that the level of consumer ethnocentrism varies according to demographic variables. Less-educated, lower-income, older, and female consumers tend to be more conservative, patriotic, and even nationalistic in their consumption. As incomes and education increase, so does the likelihood of international travel, exposure to foreign products, and openness toward imports.

Consumer nationalism and patriotism can be from the bottom up, in the form of spontaneous popular movements. This sentiment can also be from the top down—a product of deliberate government policies. In its more benign form this can result in "buy national" campaigns which encourage consumers to purchase domestic products, helping local manufacturers but not necessarily consumers and the overall economy. In its more extreme manifestations, consumer ethnocentrism can move consumers to boycott products, conduct demonstrations, and even engage in violent acts against foreign brands and corporations. Unlike ethnocentrism, which applies to what consumers perceive to be foreign, animosity is a more specific phenomenon that generates negative feelings toward particular countries affecting consumer purchases. This, in turn, is more politically and culturally determined, with mass media playing a critical role. An example of animosity would be the boycott by some New Zealand consumers of French products and brands in response to France's South Pacific nuclear testing program in the mid-1990s.

Ethnocentrism may also affect decision making in international business through staffing policy. Companies that fill key managerial roles exclusively with staff of parent-country origin are implementing an ethnocentric staffing policy. This approach is not as widespread today, but has been previously adopted by companies including Philips NV, Procter & Gamble, Matsushita, and Samsung.

An ethnocentric human resource policy may be favored for three main reasons: (1) means to achieve a unified corporate culture, (2) perceived lack of suitably qualified candidates from the host country to fill senior management positions, and (3) means to transfer core competencies to foreign operations. However, this approach can create "cultural myopia," whereby the firm may fail to appreciate cultural differences in the host country and expatriate managers may take considerable time to adapt to the new host culture. In particular, ethnocentric expatriates may be hesitant to learn from host-country nationals, less likely to socialize with them, or to establish local networks. Thus, in-group–out-group distinctions become more noticeable within the organization.

Conversely, expatriates who are open to different perspectives and new experiences are more likely to interact with host-country staff and adapt to the culture more quickly. On the other hand, highly ethnocentric host-country nationals may resist or disassociate themselves from expatriates who are viewed and treated as out-group.

Euro

The euro is the currency of those member states of the European Union (EU) that (1) want to use a common currency with other members of the Union, and

(2) meet the criteria for joining the "eurozone." As of July 2008, 15 countries within the EU use the euro as their currency: Belgium, Germany, Ireland, Greece, Spain, France, Italy, Cyprus, Luxembourg, Malta, the Netherlands, Austria, Portugal, Slovenia, and Finland. Other countries (Bulgaria, Czech Republic, Denmark, Estonia, Latvia, Lithuania, Hungary, Poland, Romania, Slovakia, Sweden, and the United Kingdom) are members of the EU but do not use the euro as their currency. Of these, Denmark and the United Kingdom have decided to "opt out" from participation, while the remainder (many of the newest EU members plus Sweden) have yet to meet the "convergence criteria" for adopting the single currency.

The euro is an artificial or a synthetic currency that was launched on January 1, 1999. It first became the new official currency of 11 countries, replacing the old national currencies—such as the Deutsche mark and the French franc—in two stages. For the first three years of its existence, the euro was a virtual currency used by financial institutions for cashless payments and accounting purposes. Old currencies continued to be used for cash payments. The euro then appeared as banknotes and coins on January 1, 2002, for all transactions and the older national currencies were phased out of use within three months. In addition to the original 11, Greece adopted the euro in 2001, Slovenia in 2007, and Cyprus and Malta in 2008.

National currencies were converted into euros at fixed rates. One euro, for example, was worth 1.95583 Deutsche marks, 0.787564 Irish pounds, and 239.640 Slovenian tolars. These fixed rates are now only of historical interest. Euro's value in all other currencies of the world is free to fluctuate according to the dictates of market forces. In early July 2008, one euro was worth 1.57 U.S. dollars and 0.79 UK pounds.

The launching of the euro was the culmination of the process of integration of European economies that had begun in 1957 with the Treaty of Rome. The first step in this integration process was the formation of a common market, followed after many other steps by the establishment in 1979 of the European Monetary System, whose main objective was to reduce the volatility of exchange rates between the currencies of the European Economic Community.

The final step in the establishment of one currency, the euro, was the 1992 Maastricht Treaty (Treaty on European Union), which committed the EU members to have a common currency and set out the ground rules for the establishment of the common currency. These conditions came to be known as "convergence criteria" (or "Maastricht criteria"). The objective of stipulating these criteria was to ensure that the countries that adopt a common currency have comparable monetary conditions before forming a monetary union. These criteria were applied quite flexibly in 1998 to allow the first 11 countries to launch the euro in 1999. When the euro came into being, monetary policy became the responsibility of the independent and newly created European Central Bank (ECB). National central banks of the member states adopting the euro then became arms of the ECB for overseeing the implementation of the monetary policy within their jurisdictions.

Benefits and Drawbacks

The euro, as a single currency, confers a number of benefits on the countries that use it. Elimination of national currencies reduces the risk inherent in changing exchange rates between these currencies. Elimination of exchange rate risks stimulates trade between the countries and encourages integration of financial markets. Use of one currency also permits transparency of prices. People traveling between countries can make price comparisons more easily than if they have to convert prices from one currency to another. Research indicates that prices of goods between member countries have converged since the introduction of the euro. One currency also eliminates some transaction costs for financial transactions.

There are also some drawbacks for countries that give up their national currencies. Most important of these is the loss of monetary independence. Countries using the euro have surrendered an important tool—their monetary policy—for managing economic fluctuations to a central authority—the European Central Bank. There is now one monetary policy within the whole of the eurozone. Each country has only a limited voice in setting this policy. Should there be higher inflation or a recession in one region of the eurozone compared to other regions, monetary policy cannot be adjusted to accommodate the needs of one region. A country with its own currency can change its interest rates to manage the economic shock. Introduction of the euro also resulted in an initial bout of inflation as traders took advantage of confusion surrounding

The euro was launched in 1999, and by 2007 its use had surpassed that of the U.S. dollar by some measures.

the conversion of prices from local currencies into euros and raised their prices.

Soon after its introduction, the euro fulfilled the expectations of many by becoming an important international currency. Of all international reserves, 26.5 percent were held in euros at the end of 2007 compared to only about 15.4 percent at the end of 1995 (in currencies that now constitute the euro). By early 2008, the volume of international bonds raised in euros exceeded the volume of such bonds raised in the U.S. dollar—a currency that used to dominate transactions in international financial markets. By early 2007, the value of outstanding banknotes in euros exceeded those in dollars. Some of these numbers, however, may represent a slightly distorted picture due to a significant decline in the value of the U.S. dollar compared to the euro since 2002.

Usage of the euro is expected to continue its growth. It is expected that Slovakia will join the eurozone in 2009, Bulgaria, Estonia, Lithuania and perhaps Hungary in 2010, the Czech Republic in 2012, and Poland in 2015 or later.

European Bank for Reconstruction and Development

The European Bank for Reconstruction and Development (EBRD) was founded in May 1990, and inaugurated in April 1991, and works in the economies of 27 countries in central and eastern Europe and central Asia with a view to ensuring them a stronger economic outlook and strengthening democracy. Its stated objectives are

> to contribute to the progress and the economic reconstruction of the countries of central and eastern Europe which undertake to respect and put into practice the principles of multi-party democracy, pluralism, the rule of law, respect for human rights and a market economy.

The EBRD draws financial support from some of the members of the European Union and the European Free Trade Area, and also other countries, specifically Australia, Austria, Belgium, Canada, Cyprus, Czech Republic, Denmark, Egypt, Finland, France, Germany, Greece, Iceland, Ireland, Israel, Italy, Japan, Luxembourg, Malta, Mexico, Morocco, the Netherlands, New Zealand, Norway, Portugal, South Korea, Spain, Sweden, Switzerland, Turkey, the United Kingdom, and the United States. In addition, the European Community and the European Investment Bank were also shareholders in their own right. The funds and resources are used to help 26 countries: Albania, Armenia, Azerbaijan, Belarus, Bosnia and Herzegovina, Bulgaria, Croatia, Estonia, Georgia, Hungary, Kazakhstan, Kyrgyzstan, the Former Yugoslav Republic of Macedonia, Moldova, Mongolia, Montenegro, Poland, Romania, Russia, Serbia, Slovakia, Slovenia, Tajikistan, Turkmenistan, Ukraine, and Uzbekistan.

The foundation of the EBRD was intended to help the former communist countries of eastern Europe and the Soviet Union adapt their economies and political systems and to integrate them into the world economy. To do this, projects were raised with the EBRD, which has its headquarters in London. All projects had to be located in one of the target countries, have "strong commercial prospects," involve the host country's government or other agencies also contributing, and benefit the economy of the host country with a view to developing the private sector. In addition, accountancy and banking standards had to be maintained and the overall project had to abide by strict environmental standards. Initially all payments were made in ECUs, the European Currency Unit used for denoting European Union transactions. However these were later denoted in euros.

The projects that were supported by the EBRD included those in agribusiness, manufacturing, natural resources, power and energy, property and tourism, telecommunications, information technology and media, transport, and also in dealing with the establishment of financial institutions, introducing energy efficiency standards, and projects to deal with governmental, municipal, and environmental infrastructure.

The initial problems facing many of the host countries were large, and there were many complications that followed the collapse of Yugoslavia and the subsequent fighting in the region. International politics proved to be important in the allocation of funds, and there were some early notable successes including the Czech Republic moving from being a recipient to a donor. It is expected that Bulgaria, Estonia, Hungary, Poland, Romania, Slovakia, and Slovenia—all now members of the European Union—will also see an end to operations, and possibly become donor countries by 2010. The problems faced by the EBRD were further exacerbated in August 1998 when Russia faced a major economic crisis. However, in the calendar year 1999, the EBRD was able to approve 88 operations for which funds totaling €2,162 million were involved.

The first president of the EBRD was the Algerian-born French economist Jacques Attali (b. 1943) who held the position from April 1991 until June 1993. After Attali had to resign in the wake of several scandals, he was succeeded by Jacques de Larosière (b. 1929), the French civil servant who had been managing director of the International Monetary Fund from 1978–87. He was EBRD president from September 1993 until January 1998, and restored confidence in the bank. The third president, Horst Kohler (b. 1943), a German economist, held the position from September 1998 until April 2000, and on July 1, 2004, became the president of Germany. He was succeeded by a French economist, Jean Lemierre (b. 1950), who had been director of the French Treasury from 1995 and a member of the European Monetary Committee from 1995 until 1998. He was the EBRD's president from July 3, 2000, until July 2008, and then the German politician Thomas Mirow (b. 1953) was appointed in July 2008. He had been the chef de cabinet of Willy Brandt, and then held senior positions in the Hamburg government.

European Coal and Steel Community

The European Coal and Steel Community (ECSC) was a supranational organization instituted under the 1951 Treaty of Paris, which provided a framework for the pooling of coal and steel resources across member countries. The ECSC was designed to make future military conflict between France and Germany materially impossible through the integration of heavy industry, while contributing to the economic development and political stability of postwar Europe. A new range of political institutions were established under the treaty to oversee the operation of the organization, and the ECSC can be regarded as both the first attempt at a supranational organization and the forerunner to the European Union. The organization had considerable success in the modernization of production, advancement of commercial policy, and management of industrial dislocation before the expiration of the Treaty in 2002.

The formation of the ECSC was spurred by the efforts of the French foreign minister Robert Schuman, who believed that a unified Franco-German coal and steel industry would stand at the heart of a peaceful and prosperous Europe. The treaty establishing the ECSC was signed in Paris by France, Germany, Italy, Belgium, the Netherlands, and Luxembourg on April 18, 1951, with the common market for coal, iron ore, and scrap metals coming into force on February 10, 1953, and the common market for steel on May 1, 1953. The mission statement of the ECSC was set out in Article 2 of the treaty: to contribute to economic expansion, higher employment, and an improvement in living standards while ensuring rational distribution, high productivity, and the avoidance of economic disturbances in member states. In order to fulfill these objectives, a new range of supranational institutions were established: the High Authority, the Assembly, a Council of Ministers, and a Court of Justice.

The High Authority was the independent executive committee, composed of nine members from the six participating countries, whose ultimate responsibility was to ensure treaty obligations were fulfilled. The High Authority obtained funding for the ECSC's administrative costs and schemes from a levy placed on coal and steel production, while it had powers to gather information pertinent to the execution of its duty from member states and enforce sanctions against those states remiss in their obligations. The Assembly, composed of 78 representatives of the national parliaments, held supervisory power over the operation of the ECSC while the Council, including a representative from each participating country, acted as the harmonizing agent between the actions of the High Authority and the national economic policies of member states. The Court of Justice, composed of seven judges appointed for six-year terms, ensured that the law was observed with regard to the implementation of the treaty while protecting individuals and enterprises against any administrative malpractices by the ECSC.

The High Authority acted upon the information ascertained from undertakings and market data to decide commercial policy, and the necessity of any intervention through the establishment of production quotas, fixed prices, or customs duties. The ECSC also tried to prevent collusion between member firms, while removing restrictions upon the free movement of labor between member states. From the levy imposed upon production, the ECSC was able to provide financing for research and development (R&D), technical modernization, and investment loans. The organization also provided significant funding for the construction of employee housing and the compensation and retraining of workers displaced from the sector due to general industrial decline.

The ECSC enjoyed considerable success in the main areas of policy despite operating in a period of relative industrial decline in western Europe. Although certain failures were apparent in the organization's inability to prevent economic concentration between member firms and equalize wage rates between countries, these are juxtaposed against significant social benefits accrued from the retraining and redeployment of displaced labor. The ECSC treaty expired on July 23, 2002, with provision being made for the transfer of the activities of the organization to the European Community. The 2001 Treaty of Nice provided for the transfer of all remaining funds to the European Community for the purpose of R&D in the coal and steel industries.

European Monetary Union

The European Monetary Union (EMU) represents countries within the European Union that have agreed to have a common currency, the euro, and a common monetary policy. As of July 2008, 15 of the 27 countries that form the European Union were part of the EMU.

The EMU is the culmination of the process that began in 1971. Just before what was to be the advent of the floating exchange rate regime in 1973 after the collapse of the Smithsonian agreement of 1971, European Common Market (later to be known as European Union) countries had agreed to stabilize the values of their currencies against each other within a narrow band. A new set of parities had been agreed to in 1971, but the central banks were still responsible for maintaining the exchange rates of their currencies within bands of ± 2.25 percent agreed at the Smithsonian Institution.

In 1972 Common Market countries agreed to maintain parities of their currencies within a narrower band of ± 1.25 percent (called a snake) than the band within which the same currencies could float against the dollar (called a tunnel) set by the Smithsonian agreement. The system came to be known for a while as the "snake within the tunnel." After the collapse of the Smithsonian agreement in 1973, it was agreed that the "snake" would be retained but the "tunnel" would be abandoned. Other industrialized countries had by that time adopted the fluctuating exchange rate system in which the markets determined the values of the currencies.

The turbulence that followed the advent of the floating rate regime proved incompatible with the goal of promoting intra-union trade and integration of the Common Market economies. To counter the effects of the volatility of exchange rates, a European Monetary System was established in March 1979. The centerpieces of this system were (1) the Exchange Rate Mechanism that limited the exchange rate movements between the currencies of the member countries to within ±2.25 percent (± 6 percent for Italian lira) of the established parity rates, and (2) a basket currency called European Currency Unit (ECU). The exchange rates were to be maintained within their defined bands through a European Monetary Cooperation Fund. One of the unique aspects of this Exchange Rate Mechanism was that when an exchange rate between two currencies moved close to one of the limits defined by the 2.25 percent bands, both the countries whose currencies constituted that exchange rate were required to intervene in the foreign exchange market. The usual practice in the international financial markets had been that the country whose currency depreciated with respect to others was required to intervene and protect the value of the currency.

The Cooperation Fund was also used to coordinate the monetary policies of member countries. The basket currency ECU was an artificial concept that consisted of fixed amounts of national currencies. There were nine national currencies in the basket in 1979 and 12 by 1989 (addition of more currencies was barred by the Maastricht Treaty). ECU was to be used only for settling accounts between countries and in financial markets. Actual notes and bills denominated in ECU were never issued, although individuals could open bank accounts denominated in ECUs. Over time, the currency became a popular unit for issuance of financial instruments such as bonds.

The foundations of the European Monetary Union were laid in December 1991 when the Maastricht Treaty was put forward for approval by member countries. In spite of the currency crisis of 1992–93, and initial rejections by voters in some countries, the treaty was adopted in November 1992.

The essence of the treaty was the formation of a monetary union and adoption of one currency. The common currency would be issued by the European Central Bank (ECB) and ECB would conduct the monetary policy for the countries using the common currency. These countries would give up their control over the monetary policy in their economy. Countries' existing central banks would become instruments of ECB.

Following the recommendations of the original report, countries were allowed to join the monetary union if they met all four of the following convergence criteria—known as Maastricht criteria—established in 1998. Countries have the option of "opting out" of the union.

1. Fiscal deficits: The government deficit must not exceed 3 percent of the country's gross domestic product and the total government debt must not exceed 60 percent of the gross domestic product—declining debt level is, however, acceptable.
2. Price stability: The inflation rate of the country over the previous year must not exceed by more than one and a half percentage points the average inflation rates of the three member states with the lowest inflation rates.
3. Interest rates: The long-term nominal interest rate must not exceed by more than two percentage points the average of the long-term interest rates of the three member states with the lowest interest rates.
4. Exchange rate: The exchange rate of the country must have remained within the fluctuation margins (± 15 percent since the 1992–93 exchange rate crises) provided for by the exchange-rate mechanism and must not have faced severe tensions for at least the last two years before entry.

In addition, it is required that there be legal compatibility for the central bank to join the monetary union in the form of freedom from political interference. The treaty also requires compatibility on factors like balance of payments, integration of markets, and unit labor cost without setting specific numerical goals. These criteria are not applied very rigidly—the final decision as to whether a country will be allowed to join or not is political.

The European Monetary Union was formally launched on January 1, 1999, with 11 countries (Belgium, Germany, Ireland, Spain, France, Italy, Luxembourg, the Netherlands, Austria, Portugal, and Finland). *Euro* was the name chosen for the common currency and its value was fixed in terms of the national currencies. Greece joined two years later. Three other countries have since joined the EMU (Cyprus, Malta, and Slovenia). Other countries (Bulgaria, Czech Republic, Denmark, Estonia, Latvia, Lithuania, Hungary, Poland, Romania, Slovakia, Sweden, and the United Kingdom) are members of the EU but do not use the euro as their currency. Of these, Denmark and the United Kingdom have decided to "opt out" from participation, while the remainder (many of the newest EU members plus Sweden) have yet to meet the "convergence criteria" for adopting the single currency.

For the first three years, the euro was used simultaneously with the national currencies for financial statements and public accounts. Bank notes and coins were introduced on January 1, 2002, and by July 1 of that year old national currencies were no longer legal tender in their countries.

Effects

The European Monetary Union has not been an unqualified success. It has improved economic efficiency because introduction of one currency has eliminated risks associated with exchange rate changes within the euro area as well as transaction costs associated with conversions of currencies. After an initial bout of inflation resulting from the tendency of retailers to take advantage of conversion of prices from national currencies into euro, prices in member countries have shown a tendency to convergence. Use of one currency has encouraged development of integrated financial markets. Early in 2008, the volume of bonds denominated in euros exceed that of dollar bonds for the first time ever. The share of euro in international reserves held by countries has increased over the past decade.

On the down side, countries are feeling the effects of loss of independence of monetary policy. When the euro rises in value against other currencies, as it has done since 2002, member countries feel the effects differently. Lacking ability to implement different monetary policies in the absence of full factor mobility may lead to loss of a country's international competitiveness. This is indeed the case for Greece, Spain, Italy, and Portugal in 2008.

Introduction of a common currency in Europe has been one of the landmark events in European history. There is very strong will in large parts of Europe for this experiment to succeed. Chances are the euro will be around for a while.

European Union

An international organization comprised of independent nations that share their sovereignty to be stronger and have a greater global influence, the European Union (EU) was created by the Maastricht Treaty (1992), and put into operation by 12 countries (Belgium, Denmark, France, the Federal Republic of Germany, Greece, Ireland, Italy, Luxembourg, the Netherlands, Portugal, Spain, and the United Kingdom) on November 1, 1993. The purpose was to form a continent united by common institutions, progressively harmonize national economies, establish a greater common market, and gradually coordinate social policy.

Since its emergence, Austria, Finland, and Sweden (1995); Cyprus, Slovakia, Slovenia, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, and the Czech Republic (2004); and Bulgaria and Romania (2007) have been incorporated into the EU. The 27 members have a total population of 495 million people and a land extension of 4.2 million sq. km.

European Institutions

Institutions are essential in the assumption of decision making in the European Union: These are the European Council, the Council of the European Union (CEU), the European Commission, the European Parliament (EP), the European Court of Justice (ECJ), and the European Court of Auditors (ECA).

The European Council was created to make official the meetings of heads of state that had previously been convoked irregularly. It convened for the first time in 1975 in Dublin. Meeting at least twice a year, it is formed by the heads of government of member countries, and attended by foreign affairs ministers. The state that currently holds the presidency of the CEU presides over the function.

The Maastricht Treaty was the initiator of the Union's first policies, which granted arbitration power in questions of conflict between ministers who cannot reach an agreement in the CEU. It also addresses pressing international problems through the Common Foreign and Security Policy (CFSP), which is designed to allow the EU to speak with one voice on diplomatic issues.

The Council of the European Union (CEU), the Ministers Council, pertains to the defense of the interests of member states. Council presidency is held by one of the member states for six-month terms, which grants an essential role in the organization of work in the institution and is a driving force in the legislative and political decision process. The assemblies are held in the CEU and attended by the member states' ministers responsible for issues to be addressed (for example, foreign affairs, finance, social issues, transportation, agriculture). It executes a legislative power, generally in codecision with the European Parliament to assure economic policy coordination of member states; define and put common foreign and security policy into practice; observe international accords in the name of the Union; coordinate state movement and adopt measures in the scope of police cooperation and penal matters; and constitute the authority that passes the Community budget.

The most customary procedure to approve decisions is by a qualified majority of the 27 member states, whereby each country, depending on its population, has a portion of the 345 total votes (2007). Any adopted decisions must be passed by a majority of the member states, and any state may solicit confirmation that the votes in favor represent at least 62 percent of the total population of the EU.

The European Commission represents and defends the interests of the EU, proposes legislation, policies, and proceedings programming, and is responsible for applying the decisions of the EP and the CEU. Since 2007 it has comprised of 27 members and 24,000 functionaries. The president is elected for five years by the governments of member states and he or she thereby elects his or her commissioner, who must be accepted as a whole by the Parliament. The Commission, with headquarters in Brussels and Luxembourg, is supported by an administration made up of 36 General Directorates. The president is in charge of delegating work to each commissioner. The Commission meets once a week to pass proposals.

The European Parliament

Since 1979, members of the European Parliament (EP) have been directly elected by the citizens of the EU. There are currently 785 members due to the entry of Bulgaria and Romania (2007), but this will be reduced to 732 in the 2009–14 legislature. The two most significant political groups are the European People's Party (Christian Democrats) and the Party of European Socialists. The Parliament's headquarters are in Strasbourg.

The EP has legislative, budgetary, and democratic checking powers. With respect to the legislative, it employs three procedures: "codecision" with the Council, which allows it to influence the orientation of European politics like the free circulation of workers, the interior market, research and development, culture, and health; "consultation" that submits international accords negotiated by the Commission to parliamentary approval, as well as future expansions of the EU; modification of functions and statutes of the European Central Bank (ECB), which implements objectives and organization of structural and cohesion funds; and "cooperation" for which the Parliament participates in community directives, essentially deciding what to propose in the Commission.

Since 1970 the EP has shared budgetary power with the Council. The European Commission prepares a preliminary budget that is elaborated by the Council and sent to the Parliament. In December, the Parliament either approves or rejects the Union budget. It also guards against public funds fraud. Finally, the EP exercises checks on the performance of the Commission, the Council of the European Union, and the European Council. Furthermore, it can create commissions to investigate possible infractions of community rights or cases of administration deficiencies of the institutions of the Union. Monthly plenary sessions take place in Strasbourg. The Parliament also functions in Belgium and Luxembourg, where the secretariat of the European Parliament has its installations.

The European Court of Justice

The European Court of Justice (ECJ), based in Luxembourg, was established by the Treaty of Paris in 1952. In early 2007 it was comprised of 27 judges, one for each member state, and eight attorneys general. This judicial body is in charge of guaranteeing community rights, interpreting treaties, and avoiding legal discrepancies from one state to the next. Created in 1989, the Court of First Instance oversees matters intervened by physical persons and cases of unfair competition practices between businesses. The decisions of the Court of First Instance (CFI) are appealable before the European Court of Justice.

The European Court of Auditors (ECA) was created in 1975. After the Treaty of Maastricht was put into effect, it was recognized as an institution. Its function consists of controlling the correct execution of the community budget, as well as being accountable to European citizens for the management of public funds of community authorities and member states.

This court is made up of members from each country of the EU who are designated by a qualified majority in the Council after consulting the EP. A member's term is six years and can be repeated.

Origins

After World War I (1914–18), Count R. Coudenhove-Kalergi (1894–1972) pushed the idea of a federation of the people of Europe (1924). Even before World War I, others had found commonalities among European countries and proposed systems designed to maintain peace and establish institutions that assured cooperation between them. But the most spectacular initiative was that of French minister Aristides Briand (1862–1932), who presented in 1929 a project for the League of Nations to create "a common market to maximally raise human well-being throughout the entire territory of the European Community." However, the economic crisis, Briand's death, and the victory of national-socialism in Germany ended the project.

At the conclusion of World War II (1939–45), the end of European hegemony was visible. The Yalta Conference (1945) had divided the continent into two blocs under the direction of the United States and the Soviet Union, which led to a new conflict: the Cold War. It was necessary to recover lost ground and impede future confrontations. That is why Europeans looked again to the ideas proposed by Winston Churchill (1874–1965) at the University of Zurich to advance the construction of "a type of United States of Europe" (1946).

Meanwhile, steps were being taking to reconstruct Europe. The United States launched the Marshall Plan (1947) as economic aid. To administer that aid, the Organization for European Economic Cooperation (OEEC) was created to liberalize trade, develop economic cooperation, and introduce ideas about monetary agreements (1948). The Marshall Plan resulted in being a great economic success as it enabled restoration of productive infrastructures in war-torn western Europe.

The Rome Treaty

France, the Federal Republic of Germany, Italy, Belgium, Luxembourg, and the Netherlands signed the Treaty of Paris in 1951, through which the European Coal and Steel Community (ECSC) was born in 1952. The initiative, shared by French politicians Jean Monnet (1888–1979) and Robert Schuman (1886–1963), tried to coordinate the production of coal and steel, fundamental instruments of war, by suppressing the restrictions on its entry and exit. New room for confidence was born for "a future European federation that assures peace keeping" that would put an end to Franco-German disputes over the resources of the Saar and Ruhr coalfields.

In parallel, in 1956, a report sent to the Council of Ministers of the ECSC proposed to complement itself with two new communities: one, for a common market and the other, for atomic energy. Signed by the six members of the ECSC in the Rome Treaty on March 25, 1957, the European Economic Community (EEC) and the European Atomic Energy Community (EURATOM) came to be. When the Rome Treaty was put into effect on January 1, 1958, it proposed as objectives the principles to

> promote, by means of the establishment of a common market and the progressive rapprochement of politics among member states, a harmonious development of economic activities in the whole of the Community, a continuous expansion and equilibrium, a growing stability, an accelerated rise in the standard of living and closer relations between the States that form the Community.

As each institution functioned with distinct components, the next step was to unify them through the Merger Treaty. On July 1, 1967, the EEC joined the ECSC and EURATOM with the Council of Ministers (CEU) and the European Commission. One of its fundamental contributions was the launching of the Common Agricultural Policy (CAP) in 1960, which was greatly needed since a fifth of the active population of the Community worked in agriculture. Prices were maintained by means of purchasing production surpluses, placing protective tariffs on importations from other countries and establishing a system of subsidies to improve agrarian structures and input costs. The European Agricultural Guarantee Fund (EAGF, 1962) executes these policies and absorbs a greater part of the Community budget (60 percent until 1989). As financial solidarity had been set out in the CAP, its cost has become a center of permanent dispute between member states.

The Rome Treaty achieved its objective. In 1968, it established a customs union that eliminated any type of restrictive duty and instituted the Common External Tariff (CET) for nonmember countries. This customs union facilitated economies of scale and improvements in competitiveness of businesses in the global market. Trade grew and converted the EEC into one of the first economic powers in the world.

The European Twelve

Meanwhile, Great Britain had founded the European Free Trade Association (EFTA) in 1959 as an alternative organization, which eventually failed. That is why, soon after, Great Britain requested entry into the EEC. However, the request was denied by General Charles De Gaulle (1963 and 1967), alleging it would put the French leadership in danger. The arrival to the presidency of the Republic of France by Georges Pompidou (1911–74) allowed the entry of Great Britain, Ireland, and Denmark in 1973. Thus began the journey of the "European Nine."

In 1981 Greece entered, resulting in the "European Ten." Shortly after in 1986, Spain and Portugal joined to make the "European Twelve." This enlargement generated difficulties, especially in terms of the CAP, since the new members brought such an agricultural weight. It was also necessary to adopt policies geared toward alleviating significant structural deficiencies and to reduce economic differences between the new members and countries of the north.

In February 1986, the "European Twelve" signed the Single European Act (SEA). After achieving the goal of a Common Market at the end of the 1960s, aspirations of a political union emerged. These were outlined over the following decade and during the presidency of Jacques Delors were materialized with the "White Paper" (1985). In 1987 all the member states ratified the SEA that guaranteed the free circulation of goods, services, capital, and people, and permitted the constitution of an authentic economic and monetary union. On December 31, 1992, free circulation was put into effect, and later the single market on January 1, 1993.

The SEA meant important advances in social policies, especially those referring to health and safety in the workplace, dialogue with social partners, and social and economic cohesion. In addition, it created Structural Funds to stimulate development in new member states and gave a base for common foreign policy.

At the end of the 1980s, the ECC had to address the fall of the Berlin Wall (1989), which allowed it to participate in the unification of Germany. On the other hand, beginning in 1991, problems began in the former Yugoslavia. NATO in 1995 tried to put an end to the war with selective bombing, and the signing of the Dayton Accords paralyzed the conflict in November of the same year. However, fighting resumed in 1998, and only from renewed bombing by NATO was the surrender of S. Milosevic (1941–2006) obtained in the summer of 1999.

The Maastricht Treaty and Beyond

The Maastricht Treaty (Netherlands), approved February 7, 1992, came into effect November 1, 1993. From then on, the European Economic Community was to be called the European Union, bestowing a more political dimension. The treaty, which extended all the previous agreements, constituted a new phase of relations between the nations of Europe. It established a structure based on "three pillars:" the European Communities, the Common Foreign and Security Policy (CFSP), and the Justice and Home Affairs (JHA). Newly added innovations recognized European Citizenship (right of abode, to vote, and candidacy in any country of the Community), ended the single market, and established the economy of the European Union.

Attempting monetary unification was not a new concept (the Belgium-Luxembourg Economic Union in 1921 is one example). In the context of the crisis of the 1970s, the European Monetary System (EMS) was established to create a monetary area in search of financial stability in the EEC. Due to its relative success, it was not until 1989 that Delors (1925–) presented a plan to carry out the Economic and Monetary Union (EMU). Ratified in the Maastricht Treaty (1992), soon after it established criteria that states had to comply with to participate, involving, for example, inflation, interest rates, budgetary deficits, public debt, and exchange rates. The euro as currency appeared in 1999, and since 2002 has been the single currency in the eurozone (except for the United Kingdom, Denmark, Sweden, and 10 new members). The European Central Bank (ECB), created in 1998, guarantees price stability and management of the euro.

The Maastricht Treaty also hoped to achieve economic and social cohesion among diverse regions. The establishment of the Cohesion Fund allowed financial resources to be transferred to less prosperous countries to improve infrastructures. On January 1, 1995, Austria, Sweden, and Finland were incorporated into the EU, resulting in the "European Fifteen."

The Treaty of Amsterdam took effect on May 1, 1999, to try to adapt European institutions to the Community that opened the accession of central and eastern Europe. Its main accomplishment was the ratification of the Stability and Growth Pact and the agreement to promote employment policies (18 million unemployed in 1997) financed by the European Investment Bank (EIB). Furthermore, it was agreed when the EU would increase the number of member states and that there would be only one commissioner from each country in the Commission. The final draft foresaw the establishment of a common foreign and security policy, and the naming of Javier Solana, former secretary general of NATO, as Mr. CFSP, which also made him secretary general of the Council of the European Union.

The Treaty of Nice, signed in 2001 and taking effect in 2003, tried to resolve questions about future enlargements that had remained pendant in Amsterdam. The composition of the Commission, weighting of votes in the Council, and the expansion of subjects to be passed by a qualified majority were addressed. Also, the effectiveness of the jurisdictional system was increased and the recourse for "enhanced cooperation" procedure was simplified.

Negotiations for the entry of new countries from central and eastern Europe, which were presented at the beginning of the 1990s, began in 1997. In 2004, the Czech Republic, Slovakia, Slovenia, Estonia, Hungary, Latvia, Lithuania, Poland, and the islands of Malta and Cyprus were admitted to the Union, forming part of the "European Union-25." Romania and Bulgaria were added in 2007 and subsequently comprise part of the "European Union-27."

The European Convention on the future of the EU that was presided over by Valéry Giscard d'Estaing, adjourned with the conclusion in 2003 that the creation of a constitution for the EU was necessary. The idea was that after the entry of 12 new states, internal cohesion had to be strengthened and the correct functioning of the supranational institutions guaranteed. That is why the treaty that established a Constitution for Europe was signed in October 2004. However, France and Holland did not obtain its approval by referendum in 2005 as six more countries canceled its confirmation. Hence, in June of 2007, the leaders of the EU agreed to work out a new Treaty for the Institutional Reform of the European Union before the end of 2007.

The flag of the European Union flying in Spain, one of the 27 member states in 2008.

The Treaty of Lisbon was signed by member states on December 13, 2007. The new treaty declared that a president would serve a two-and-half-year term, facilitated the functioning of the institution, recognized a legally binding Charter of Fundamental Rights, and intended to display a greater personality on the international level as the CFSP became the true community ministry of foreign affairs. Furthermore, it established a new weighting of votes that will permit, beginning in 2014, the approval of matters that must be passed by double majority (55 percent of member states and 65 percent of the population).

Exchange Rate

An exchange rate is the price of one national currency expressed in terms of another national currency. Put another way, the rate of exchange between two currencies, A and B, represents the amount of foreign currency B that can be obtained with one unit of domestic currency A (provided that such transactions are permitted).

International trade necessitates the exchange of currencies since producers will eventually require payment in terms of their national currency. It is for this reason that American producers require payment in dollars, Japanese producers in yen, British producers in pounds sterling, German producers in euros, and so on. Exchange rates and exchange rate markets satisfy this need for currencies and are therefore essential elements of the international-payment system that facilitates the trade of goods and services within the global marketplace.

The international economy has experienced a number of different exchange rate regimes that fall into two broad categories: fixed exchange rates and floating exchange rates. Under a system of fixed exchange rates, the monetary authorities will maintain the value of their currency, in relation to other currencies, at a specific, predetermined rate through the purchase or sale of foreign currency in the foreign exchange market. In contrast, a floating (or flexible) exchange rate refers to a system where the rate of exchange between two national currencies is determined by supply-and-demand forces in the foreign exchange market. There has been much debate regarding the relative merits of these two systems. Since the early 1970s, the major industrialized countries have operated a managed flexible rate system. Through this system, the monetary authorities of different countries do not establish a predetermined rate, but intervene in the foreign exchange market in order offset major, potentially destabilizing, exchange rate fluctuations.

Approaches to understanding the movement of flexible exchange rates have tended to focus on fundamental variables such as national price levels and interest rates. The influence of national price levels is reflected in the notion of purchasing power parity (PPP). This suggests that the rate of exchange between two currencies is equal to the ratio of the prevailing national price levels within these two countries. In other words, exchange rate movements are taken to reflect changes in the rate of inflation in the two countries. Although the relative purchasing power of currencies does serve to explain the trend of exchange rate movements if the inflation differential is large, empirical evidence has demonstrated that it is inadequate as a general model of exchange rate determination. A number of factors—such as speculative capital movements—may cause exchange rates to deviate dramatically from their PPP.

Monetary factors such as capital movements and interest rate differentials have also been seen to play important roles in exchange rate determination. Funds will be transferred from America to Japan, for example, if the rate of interest in Japan is higher than that in America. The influence of such factors becomes complicated, however, since capital movements also reflect expectations regarding future exchange rate movements. Currency volatility therefore arises from market participants continuously adjusting their portfolios in response to evolving short-term and long-term expectations regarding future exchange rate movements. It is for this reason that economics still lacks a complete theory of the forces that determine the rate of exchange.

Significant changes in the rates of exchange are defined as either currency depreciation or currency appreciation. Currency depreciation refers to a situation where an increased number of units of one nation's currency are required to purchase one unit of a foreign nation's currency. For example, an increase in the dollar value of sterling from $1.50 to $2 reflects a depreciation of the dollar. The opposite of currency depreciation is currency appreciation. In this situation, fewer units of a nation's currency are required to purchase of unit of a foreign nation's currency. Thus, a fall in the dollar value of sterling from $2 to $1.50 reflects an appreciation of the dollar (and, by definition, a depreciation in the sterling value of the dollar).

Within the foreign exchange market, the value of the currencies may be traded on a "spot" or "forward" basis. The "spot" rate refers to the rate prevailing in the market at the time the rate is quoted. The "forward" rate, as the title suggests, refers to the rate at which contracts are established to buy or sell foreign exchange at some specified future date, i.e., in three months' or six months' time. The obvious disadvantage of a freely floating exchange system is that changes in the rate of exchange between currencies can increase the uncertainty of business decisions and significantly alter the profitability of business transactions. Without the benefits of a fixed exchange rate system, the existence of forward exchange rates reduces business uncertainties. The difference between the spot rate and the forward rate is determined, in part, by the difference between domestic and foreign interest rates, together with market expectations regarding the extent of future appreciation or depreciation of the currency. This latter point suggests that it not always possible for a business to offset exchange risk through forward exchange transactions. For example, the forward value of a currency will be pushed below its spot value if there is a significant market expectation that its future value will fall.

Exchange Rate Risk (or Currency Exposure)

Exchange rate risk refers to the risk of loss due to adverse movements in exchange rates. Currency exposure refers more broadly to the possibility that exchange rate changes will result in either a gain or a loss. These gains or losses can affect individuals, firms, or investors and reflect the impact of exchange rate changes on cash flows, on assets and liabilities, on profits, and on stock market values. Exchange rate risk is thus commonly divided into three categories, reflecting the nature of their financial impact: "transaction" (or contractual) risk, "translation" (or accounting) risk, and "economic" (or operating) risk.

Transaction (or contractual) risk arises when there is a time difference between the establishment of a transaction and its financial settlement. Any change in the exchange rate between the agreement and settlement dates will affect the value of the cash flows that are either received or paid. Many foreign exchange transactions arise from the import or export of goods or raw materials, from the payment of interest on foreign currency debt, and from the receipt of dividends on foreign investments.

Translation (or accounting) risk arises from the need to translate financial statements denominated in foreign currencies into the home currency of the reporting entity. The greater the percentage of business conducted by subsidiaries, the greater is the translation risk. In consolidating financial statements, the translation can be done using either the prevailing exchange rate or the average exchange rate over the reporting period, depending on the accounting standard applicable to the parent company. Thus, while income statements are usually translated at the average exchange rate over the period, balance sheet exposures of foreign subsidiaries are often translated at the prevailing exchange rate at the time of consolidation. Many companies apply International Accounting Standard 21, "The Effects of Changes in Foreign Exchange Rates," to translate the financial statements of foreign subsidiaries.

Economic (or operating) risk refers to the possibility that the present value of future operating cash flows, and thus the economic value of the firm, will vary in home currency terms as a result of changes in exchange rates. It measures the effect that unanticipated exchange rate changes have on firm value since expected changes should already be reflected in share prices.

Economic risk is similar to transaction risk in that both are concerned with cash flows. However, in the case of economic risk the timing and amount of the cash flows are uncertain; once a potential cash flow becomes a financial commitment, it no longer represents an economic risk but a transaction risk. The main determinants of economic risk are the structure of the markets in which a firm sells its products and sources its inputs, such as labor and raw materials, and also its ability to mitigate the effect of currency changes by adjusting its markets, its product mix, and its sourcing.

A widely used method of measuring transaction exchange risk is the calculation of value-at-risk (VaR). Broadly, VaR is defined as the maximum loss for a given currency position over a specified time horizon for a given confidence interval. For example, if a bank's U.S. dollar position has a one-day VaR of $10 million at the 99 percent confidence interval, it should expect the value of this position to decrease by no more than $10 million on 99 out of 100 trading days, if normal conditions prevail.

In theory, exchange rate risk is not a problem if purchasing power parity (PPP) exists because changes in exchange rates simply offset prior price-level changes. However, the evidence suggests that PPP only exists in the long run. Firms can mitigate exchange rate risk by entering into financial hedges using forward contracts or other derivative instruments. Such hedging may be unnecessary for shareholders holding diversified portfolios, as they may find that the negative effect of exchange rate changes on one firm is offset by gains on another. However, the exact nature of currency risk is not known to investors, so it may not be fully diversifiable. Even so, firms may actively manage currency risk to avoid the costs associated with financial distress. Although the findings of empirical studies are mixed, the bulk of the evidence suggests that exchange rate risk affects shareholder wealth, and thus that there is value in hedging.

Exchange Rate Volatility

Exchange rate volatility is a measure of the fluctuations in an exchange rate. It can be measured on an hourly, daily, or annual basis. Based on the assumption that changes in an exchange rate follow a normal distribution, volatility provides an idea of how much the exchange rate can change within a given period. Volatility of an exchange rate, just like that of other financial assets, is usually calculated from the standard deviation of movements of exchange rates.

Two measures of volatility are commonly employed in financial calculations. Historical volatility is calculated from the past values of an exchange rate. Given a series of past daily exchange rates, we can calculate the standard deviation of the daily price changes and then the annual volatility of the exchange rate. Suppose the US$/€ exchange rate was observed to have the following daily closing prices over a 10-day period: 1.562, 1.5745, 1.5615, 1.575, 1.5665, 1.5615, 1.5722, 1.5734, 1.5601, 1.5623. Standard deviation of daily price changes turns out to be 0.006774, and given that there are about 252 trading days in a year, annual volatility turns out to be 0.10754 or about 10.8 percent (volatility = standard deviation * root of number of observations). This implies that, should the historical patterns continue, chances are (about 67 percent) that the exchange rate within the next year will be between 1.5623 + 10.8 percent and 1.5623 – 10.8 percent, that is, it will be somewhere between $1.73/€ and $1.39/€ at the end of one year. Historical volatility provides a good assessment of possible future changes when the financial markets and economies have not gone through structural changes.

Implied volatility is a forward-looking measure of volatility and is calculated from the market participants' estimates of what is likely to happen in the future. More precisely, implied volatility is estimated from the quoted price of a currency option when the values of all other determinants of the price of an option are known. The basis for this calculation is the Black-Scholes option pricing model, according to which the price of an option is determined by the following: the current price of the asset (the exchange rate or a stock or a commodity), the strike price at which the option can be exercised, the remaining time for the maturity of the option, the risk-free interest rate, and the volatility of the asset (or the exchange rate.) When the market participants are able to quote the price of a foreign currency option, it can be assumed that they are using their estimate of the volatility (the implied volatility) to arrive at the price. Since all the other elements that determine an option price are easily observed, current market price of an option on a currency allows the calculation of the implied volatility. These calculations are fairly complex and require at least an advanced calculator. Many institutions provide software that can calculate the volatility when all other parameters are known.

Exchange rate volatility, like the volatility of any other financial asset, changes in response to information. Currency traders are sensitive to information that might influence the value of one currency in terms of another. The most important information is that about the macroeconomic performance of the economies behind the two currencies. Changes in the levels of uncertainty about the future of either economy will cause traders to become restless and less willing to hold a particular currency. Uncertainty about the future is the most important reason for the change in the volatility in the currency markets.

Changes in the proportions of hedgers versus speculators can also change the volatility of a currency. Central banks can also influence the volatility of their currencies with their announcements of their intentions to either intervene or otherwise in the markets for their currencies. While it is commonly believed that central banks can influence the value of their currency at most in the short run, they can certainly cause a change in the volatility. It is market belief that the volatility of the dollar/euro rate increased in early June of 2008 when the Federal Reserve Bank chairman, Ben Bernanke, expressed his opinion that the falling dollar influenced the U.S. inflation rate. Participants took the comment to mean that the Federal Reserve was going to intervene in the markets to support the dollar even though Mr. Bernanke had been strictly noncommittal on that specific point.

Ex-Factory (Ex-Works)

Ex-Factory, or Ex-Works (EXW), is an INCOTERM, one of the 13 international commercial terms used to describe the responsibilities of buyers and sellers in an international trade transaction. Standardized trade terms have a long history to which INCOTERMs are a relatively recent addition. These terms were originally deployed by the International Chamber of Commerce (ICC) in 1936, and have been frequently revised. INCOTERMs help buyers and sellers better understand their roles in terms of costs and risk assumption. As a result, they have reduced international disputes and served as a guide to arbitration of contract disputes. Customs and legal authorities worldwide recognize INCOTERMs.

The term *Ex-Works* actually appears as "Ex-Works … named place," where the named place might be the seller's factory. For this reason, many invoices still bear the term *Ex-factory*, which is a specific case of the INCOTERM Ex-Works. When the contract specifies EXW, it signifies that the delivery of merchandise occurs when the seller makes the goods available to the buyer at a named place, e.g., the seller's factory. Under EXW, the buyer bears nearly all of the responsibility and risk associated with the transportation, documentation, and customs clearing portions of the transaction.

Under Ex-Works rules, a seller has a limited set of responsibilities. The primary responsibility is to provide the goods at the specified time and location. Additionally, the seller must provide the buyer (at the buyer's cost) any required export documentation. For example, the buyer may require a certification that must be notarized or sealed in the seller's country. The seller can charge realistic expenses (for example, courier service for the documents); they do not, however, invoice for their time. The rules concerning export documentation are clear; while the expense of providing documentation falls to the buyer, the seller must take reasonable efforts to provide the buyer with documentation that is available in the seller's country (e.g., certificates of origin, pro forma invoices, etc.). It is the seller's responsibility to properly notify the buyer of the pick-up location and timing. Note that any delays in shipping due to improper notification creates liabilities to the seller. Lastly, the seller must comply with any special terms in the contract.

The buyer in an Ex-Works arrangement has significantly more responsibilities and risks than the seller. First, the buyer must arrange for payment for the goods; EXW accelerates the cash cycle as delivery occurs immediately. Further, the buyer must obtain any necessary export or import licenses. Additionally, the buyer is responsible for loading the goods for transportation abroad. From a risk perspective, the buyer takes all risks associated with the transport of the goods, assumes responsibility for clearing customs, and pays all insurance and transportation costs associated with the transaction. When purchasing with EXW terms, the buyer needs to develop estimates for transportation, insurance, documentation, and customs in order to estimate the landed-cost, the cost when the buyer finally receives the merchandise. The buyer under Ex-Works is also responsible to pay all duty and taxes. Any exceptions to the Ex-Works terms must be specified explicitly in the contract. For example, the buyer may wish the seller to load the goods onto a truck.

Beginning exporters often specify EXW for contract terms. This term does in fact reduce seller transaction complexity, transferring it and its associated risks to the buyer. Sellers who are more sophisticated recognize there are market opportunities by providing more of the services and assuming more of the risk. There are also third-party firms like freight forwarders, customs clearing houses, and insurance firms that can mitigate risk for the buyer.

Ex-Im Bank

The purpose of the Export-Import Bank of the United States (Ex-Im Bank) is "to assist in financing the export of U.S. goods and services to international markets." The Ex-Im Bank provides export financing solutions that fill gaps in trade financing arising when the private sector is unable or unwilling to assume credit and country risks. The Ex-Im Bank also provides export financing that is competitive with the official export financing support offered by other governments to support U.S. exports and the jobs they represent. The Ex-Im Bank provides pre-export financing, export credit insurance, loan guarantees, and direct buyer financing loans. Since its charter in 1945, the Ex-Im Bank has supported more than $400 billion of U.S. exports in over 150 markets, mostly going to developing markets. Congress has mandated that the Ex-Im Bank's financing is conditioned on not competing with the private sector and a reasonable assurance of repayment.

The Export-Import Bank of the United States was chartered under the Export Import Bank Act of 1945 (12 U.S.C. 635) as amended through Public Law 109-438 on December 20, 2006, and other relevant provisions updated on December 27, 2006. The Ex-Im Bank is an independent executive agency and a wholly owned U.S. government corporation. Congress periodically reauthorizes the Ex-Im Bank, as it did in 2006, extending its authority until September 30, 2011.

The Ex-Im Bank's headquarters are in Washington, D.C., supported by seven regional offices around the country. The Ex-Im Bank is structured around 12 functional areas: the Board of Directors, the Office of the President, the Credit and Risk Management Group, the Export Finance Group, the Small Business Group, the Office of the General Counsel, the Office of the Chief Financial Officer, the Office of Policy and Planning, the Office of Resource Management, the Office of Communications, the Office of Congressional Affairs, and the Office of the Inspector General.

The Ex-Im Bank reports under U.S. generally accepted accounting practices applicable to federal agencies with form and content guidance provided by the Office of Management and Budget Circular A-136. The Ex-Im Bank reports its relative efficiency and effectiveness in an annual report to the U.S. Congress on Export Credit Competition, and in the Export-Import Bank of America competitiveness report. It compares its performance to the other G-7 export credit agencies in terms of policy coverage, interest rates, exposure fee rates, and risk premiums. Additionally, the U.S. Congress established an advisory committee to help the Ex-Im Bank gain additional insight from various sectors of the economy and to review Ex-Im Bank policies and programs with respect to competitiveness. The Advisory Committee holds quarterly meetings.

The Ex-Im Bank has two strategic goals. The first strategic goal is to facilitate U.S. exports and their associated jobs, which represent over 11 percent of the U.S. gross domestic product. The second strategic goal is to facilitate U.S. exports by small businesses. The Ex-Im Bank's charter requires than no less than 20 percent of the exports it finances be direct exports by small business concerns (as defined in section 3 of the Small Business Act). In addition to its strategic goals, the Ex-Im Bank is pursuing an initiative targeting sub-Saharan Africa as a priority region for its efforts in support of the African Growth and Opportunity Act. The Ex-Im Bank has identified the top 12 African markets for U.S. exports and is establishing a foundation for credit underwriting and transactions analysis by African financial institutions, as well as promoting the Ex-Im Bank's products, methods, and standards.

In fiscal year 2007, the Ex-Im Bank approved 2,793 authorizations in the form of either guarantees or export credit insurance amounting to $12,569.4 million in support of exports with an estimated value of $16.041 billion. For fiscal year 2007, the Ex-Im Bank authorized 26.7 percent of its funding in support of direct small business exports.

The Ex-Im Bank's exposure at the end of fiscal year 2007 was approximately $57,424.5 million. The Ex-Im Bank's exposure in terms of economic sectors is as follows: the air transportation sector, 44.5 percent; oil and gas, 12.3 percent; manufacturing, 7.7 percent; power projects, 7.1 percent; and all other sectors, 28.4 percent of its total exposure. The Ex-Im Bank's exposure in terms of geographic location is as follows: Asia, 29.2 percent; Latin America, 21.9 percent; Europe/Canada, 19.3 percent; Africa/Middle East, 13.5 percent; and all other locations, 16.1 percent of its total exposure.

Although normally the Ex-Im Bank denominates its financings in U.S. dollars, it does guarantee notes in certain other foreign currencies. Its total foreign currency exposure of $8,207 million represents approximately 14.3 percent of its total exposure. The bank classifies its credits into 11 categories (1 being the least risky) and maintains an overall risk rating of 4.00 on new authorizations. Over the past five years, the Ex-Im Bank has shifted its portfolio of borrowers toward private-sector borrowers (58 percent) from sovereign or public-sector borrowers.

Expatriate

Expatriates are a distinct form of cross-cultural traveler, principally characterized by the duration and purpose of their presence in the host country. An expatriate can be defined as an individual who lives temporarily outside their home country in order to undertake a specific job, project, or assignment. This distinguishes them in particular from tourists, who generally travel for a short period of time to engage in leisure activities, and immigrants who intend to remain in a host country indefinitely. This entry focuses on expatriation in a business context, where it is evident that expatriates are used for a variety of purposes including sales, technology transfer, control of business units, and coordination and integration. The following discussion examines selected issues associated with the management of expatriate staff, including selection, cross-cultural training, and cross-cultural adjustment.

In an increasingly international environment, there are a growing number of opportunities for people to travel to other countries. Naturally, such travel is undertaken for a variety of reasons and for different durations. Consequently, it is possible to distinguish between four different types of cross-cultural traveler: tourists, sojourners, refugees, and immigrants. Tourists travel for leisure purposes, usually for a relatively short period of time. Sojourners travel for a longer, but finite, period of time in order to undertake some form of work or educational activity. Refugees' travel is involuntary, and the duration of their time in the host country can vary widely, although they typically intend to return home as soon as conditions allow. Immigrants travel in order to establish a new life, and intend to remain in the host country indefinitely.

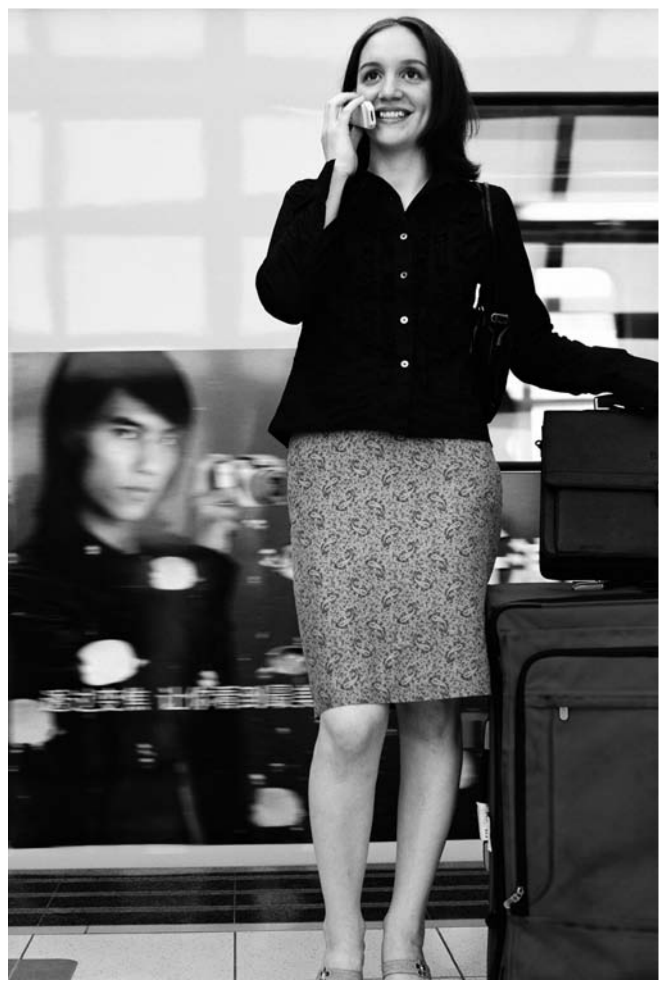
Through common usage, the term *expatriate* usually refers specifically to sojourns undertaken in an organizational context. Expatriates, then, live in a host country for an extended, but finite, period of time in order to fulfill a specific work assignment and are therefore distinguished from other categories of cross-cultural traveler by the purpose and duration of their presence in the host country.

Businesses use expatriates for a variety of reasons. The stages in a company's internationalization enable us to identify different approaches to the use of expatriate staff. With a domestic company, expatriates are used on an ad hoc basis. Visits to other countries will often be quite short, and may be used to reward staff. Individuals are unlikely to be carefully selected, although professional skills and company knowledge must be considered important attributes. It is unlikely that cross-cultural training will be provided. As a company develops its international presence, expatriate assignments begin to increase in frequency and importance. Candidates are again selected on professional competence, but adjustment and language skills are also considered. At this stage expatriates are used for sales roles, to transfer technology, or to exert control. Nevertheless, cross-cultural training is likely to be rather limited.

When a company becomes multinational, the frequency of expatriate assignments may decrease as host-country nationals are appointed to management posts as a result of their local knowledge. Allied to this, the value placed on international experience increases, and therefore expatriates are likely to undertake multiple postings. The desire to build the skills of the individual means that cross-cultural training is likely to be more comprehensive at this stage. As a company becomes global, the emphasis is on integration and coordination between business units, with expatriates being used to facilitate this. High-performing individuals are selected based on professional competence and cross-cultural capabilities. These individuals are likely to receive ongoing cross-cultural training and support in order that they can interact effectively with host nationals.

Using expatriates is expensive, some claim up to $1 million per year per expatriate, and sending organizations are therefore concerned with minimizing the risk of failure. The traditional view of expatriate failure is of premature return to the home country. However, an inability to adjust effectively to the host culture can result in poor job performance without the individual returning home early. This can be especially damaging for the sending organization, with effects including sub-optimal productivity and damage to client relations and organizational reputation. As a result, sending organizations are well advised to apply comprehensive selection and cross-cultural training processes in order to mitigate against the risk of failure.

Early approaches to expatriate selection were based on technical competence, whereby it was believed that the key to international success was an ability to perform a specific job role effectively. However, technical competence is not associated with effective cross-cultural adjustment, and is therefore best considered as a prerequisite for continuation of the selection process. Another approach has been to rely upon previous international experience, based on the argument that the individual has proven themselves capable of operating effectively overseas. This criterion continues to be widely used, and indeed there is evidence to suggest that longer overseas experience is linked to more effective cross-cultural adjustment. More recent approaches focus on personality traits on the basis that certain traits can be associated with an ability to adjust effectively to the host culture. For example, studies have linked higher levels of extroversion, agreeableness, and emotional stability with a desire to stay in post. Similarly, studies have found evidence that



While expatriate employees can be essential when a business begins expanding abroad, costs could run to $1 million each.

problem-focused coping strategies, a learning-focused goal orientation, and higher levels of self-efficacy are associated with more effective adjustment.

Regardless of the selection criteria employed, it is generally agreed that some form of cross-cultural training should be provided. Cross-cultural training aims to facilitate effective adjustment by developing the necessary skills and by creating accurate pre-departure expectations. Content-based models distinguish between information-, awareness-, and skills-based training inputs. Information-based training is the most commonly provided form of cross-cultural training. It tends to take place before departure, and principally aims to support anticipatory adjustment by creating accurate pre-departure expectations. Information is typically provided through written documents, lectures, and audio-visual materials, covering issues related to the job role and host country contexts. Awareness-based training often takes place before departure, and seeks to personalize the host culture by exposing trainees to various scenarios through the use of a cultural assimilator. Through this mechanism, trainees are able to rehearse culturally appropriate behaviors in a safe and controlled environment.

While information- and awareness-based training is specific to the host culture, skills-based training focuses on transferable adjustment skills. This training is more likely to take place in the host country during an orientation period, as it relies upon interaction with host nationals, using behavior modeling, video playback, and role play to develop the skills necessary to engage in culturally-appropriate behaviors.

Upon entering the host country, cross-cultural adjustment becomes a key issue. One model distinguishes between psychological and socio-cultural components of adjustment. Psychological adjustment has an internal focus and is rooted in the concepts of stress and coping. Socio-cultural adjustment has an external focus based on the ability to interact effectively with host nationals. In addition to personality traits, various factors have been associated with more effective adjustment including lower levels of host culture contact and limited cultural distance between home and host cultures.

Export

Export is a process in which products are shipped or sent from one country to another country for the purpose of trade or sale; it is the opposite of import. For example, Company A located in the United States sells and sends its products from the United States to Company B located in Germany; in this case, Company A is said to export its products, whereas Company B is said to import (buy from another country) the products of Company A.

Export is not restricted to only physical goods; services can also be exported. Examples of service exports are travel and tourism; transportation; architectural, construction, and engineering services; education and training services; banking, financial, and insurance services; entertainment; information services; and professional business services. Services are more difficult to communicate with consumers and require adaptation to the specific needs of customers. Export and import are important components of international business, as the two together compose international trade. Export is actually is a very popular and relatively easy way to expand into foreign markets. Therefore, it is an important element of global business.

Export has many advantages. Through export, companies can increase their sales and profit margin as the sales price can be higher in foreign countries. As production volume increases in line with export demand, companies are able to decrease their unit cost. Export also provides a kind of spreading of risk, since the exporting company will not anymore depend on only its domestic market; dependence on a single country can be risky in case of an economic or political crisis. Export also decreases the cost of foreign expansion.

However, export also has various disadvantages. As the exporting company does not have physical existence in the foreign market, its knowledge about the foreign market is limited. Therefore, it can miss potential opportunities in the foreign market. Export is also very susceptible to trade barriers and if these barriers increase, companies may have to cancel their export activities. Another fact is that companies themselves do not have power to influence these trade barriers, some of which are tariffs and quotas.

Internationalization

Companies internationalize their operations through different ways (called entry modes) such as sending their goods to other countries (export), establishing sales offices in foreign countries, giving production permission to foreign companies (licensing), partnering with foreign companies (joint venture), acquiring a foreign company, and establishing production and sales facilities from scratch in a foreign country (greenfield investment).

Export does not require much expense and knowledge of the foreign market as much as other entry modes do. Therefore, export is one of the simplest and the least risky ways of internationalization and is usually preferred by small and medium-sized enterprises. The production of the goods generally takes place in the exporter company's country (called domestic market or country); however, marketing, distribution, and customer service activities take place in the foreign country to which the goods are shipped.

Success Factors

There are various issues companies need to consider to be successful in their export activities. First of all, the management needs to have a firm and long-term commitment toward export. Export should not be thought of a daily activity because it requires long-term planning and focus. Second, not every product sold in the domestic market can be sold in other markets. Therefore, companies need to first assess whether their products have potential in foreign markets. Similarity in needs, tastes, preferences, and conditions between the domestic market and the foreign market may be an indication of sales potential in the foreign market. When the products of a company have unique features not available in foreign markets, then this may also indicate the sales potential of the product in foreign markets. Third, demand characteristics also play important roles; the demand for a particular product may be low in the domestic market but very high in a foreign market. In this situation, the product may also have sales potential in the foreign market.

Finding out the sales potential for products in foreign markets may not mean much unless the company is ready for export. As the export operations require additional resources and commitments, companies need to determine whether they are able to commit the required resources for export and whether export operations are in line with the company goals. If the company is ready for export, then a thorough export plan should be made, including the products to be exported and product modifications, if any, export pricing, target market characteristics, and resources necessary for export.

In addition, export requires shipment of products to foreign countries. Therefore, managing logistics in export is an important success factor because the competitiveness of price is also affected by the cost and effectiveness of shipping. In this regard, the parties in the whole logistics process need to be managed well under close and long-term relationship with an understanding of shared goals and mutual benefits.

Companies differ in terms of how they plan and implement their export activities. Some companies use a systematic approach to exporting whereas others do not. The more experienced managers utilize a systematic approach in order to increase the likelihood of success in their export. Such a systematic approach involves assessing global market opportunities, organizing export activities, acquiring needed skills and competencies, and implementing the export strategy.

Types of Exports

As to the organization and implementation of export activities, companies have different approaches classified as indirect and direct exporting. In indirect exporting, some companies buy products from producers in their own domestic market and then export these products. In this case, there is no risk for the producer as its buyer is also a domestic company, which then takes risks and exports the product.

In another form of indirect exporting, some companies export their product through intermediaries. In this approach, the domestic company uses another company that can construct relationships with foreign buyers; export management companies, export trading companies, international trade consultants, export agents, merchants, and remarketers are examples of such intermediary firms. Small and medium-sized enterprises with no or little knowledge about foreign markets often prefer this type of export, and as they gain more knowledge about foreign markets and construct closer relationships with foreign companies, they can switch to direct exporting.

In direct exporting, the producer directly sells or exports the products to the foreign buyer. This type of exporting is the riskiest since the exporter assumes all responsibilities; however, it is the best approach to get highest profits and long-term growth.

Export Pricing

Pricing the products to be exported is a difficult task because companies need to be price competitive and at the same time consider many factors affecting the price. Of course, the export price, like pricing of any product, should be determined so that the company gains profit. There are internal and external factors affecting the export price. The cost of the product is the major factor that is internal to the firm. Other major factors internal to the firm are market search, credit checks, travel expenses, product adaptation, different packaging, transportation, and commissions. The choice of distribution system also has impact on the price; long distribution channels increase costs, lowering profit margins. If products require adaptation or modification, this also adds costs, as the companies need to change their existing production system. However, such modified or differentiated products offer companies opportunities to increase prices.

Some factors external to companies in their export price-setting are supply and demand, location, and environment of the foreign market, such as climatic conditions, exchange rate fluctuations, and governmental interventions and regulations. If there are many factors affecting the price in a market at the same time, then adoption of a single export-pricing (called ethnocentric pricing) is difficult.

Another fact is that a particular product in a country may not be at same product life stage as in other countries. Companies generally charge high prices at the introduction and growth stages. Therefore, if the product is at the introduction or growth stage in the export destination, export price can be high. In most cases, export price is determined according to local conditions (called polycentric pricing) such as demand and supply, competition, and the market price level in the foreign market.

With respect to export pricing, there are various trade and shipping terms that explain who bears various costs associated with the transportation of export products. Ex-Works (EXW) means that the price covers only the sales price of products and the buyer assumes all the responsibility and cost of transportation when the products are ready at the seller's factory. That means that the buyer needs to come to the seller's factory and get the products.

Free carrier (FCA) means that the price covers the sales price of products and the costs associated with loading the products into a transportation means determined by the buyer; the rest belongs to the buyer. Free alongside ship (FAS) means that the price covers the sales price of products and the costs associated with carrying the products to the port and unloading and warehousing them. Free on board vessel (FOB) means that the price covers the sales price of products and costs associated with carrying products to the vessel and loading them into the vessel. Cost and freight (CF) means that the price covers the price of products and costs associated with all transportation; when the seller includes the insurance in the sales price as well, then cost and freight (CF) becomes cost, insurance, and freight (CIF).

Export Payments

There are various conventional methods of getting paid in export: Cash in advance, letter of credit, open account, consignment, and countertrade are payment methods. In the cash in advance method, the payment is received before the products are sent to buyers and in this case the exporter does not need to worry about the payment. However, buyers in this case may have worries as to their cash flow and timing of the shipment because they already paid for the products and if there are delays in the shipment, their sales or production will be delayed too. Therefore, since it creates some pressure in export, the cash in advance method is not a popular method of payment.

As the most commonly used method in export payment, the letter of credit is a kind of agreement between the banks of buyers (importers) and sellers (exporters) that guarantees the payment from the buyer to the seller when the export shipment is obtained. The open account method of payment involves payment from the buyer on account at some time in the future; in this method, the buyer needs to be credible.

In the consignment method of payment, the seller sends the products to an intermediary firm in the foreign country and this intermediary sells the products on behalf of the exporter. However, this method is not appropriate if the seller does not have a good and trustworthy intermediary. The last payment method is countertrade, in which the payment is actually made through other products instead of money.

Export Assistance Program

National governments have a vested interest in a high export quota. Not only do exports allow for the accumulation of foreign exchange reserves, exports also increase employment levels, improve productivity, and foster overall prosperity. At the same time, governments recognize the formal trade barriers and the practical challenges that companies, especially small and medium-sized ones, face in global markets. Therefore, governments, semi-government institutions, associations and other nonprofit organizations, banks, and other institutions offer support mechanisms in the form of export assistance programs or, as they are sometimes also called, export marketing programs, export promotion programs, or trade promotion programs. While the overall aim of all export assistance programs is to raise firms' competitiveness abroad, the detailed measures taken and instruments applied may vary greatly from country to country.

The support national government export assistance programs offer falls into one of five categories: (1) awareness-building and stimulation of interest, (2) acquisition and distribution of information, (3) training and capacity building, (4) consulting, advice and coaching, and (5) financial assistance. In the area of awareness-building, the basic challenge is that in most national economies, only a small fraction of all firms is actively engaged in exports. Export assistance programs try to increase the share of exporting firms through public-awareness campaigns, media reports, seminars, or conferences.

As far as acquisition and distribution of information is concerned, export assistance programs aim to help identify information needs. They fulfill them through the use of databases or through staff at their own offices abroad. The type of information needed can be very diverse. It stretches from general market information or country risk ratings to complex market data to detailed legal questions. Training and capacity building are of utmost importance to exporting companies. The services of export assistance programs in this area range from simple handbooks to seminars and workshops to whole programs on exporting.

The range of services in the consulting, advice, and coaching category includes simple and practical advice for export beginners as well as more complex tasks such as the organization of trade missions, participations in trade shows, the collection of outstanding bills, or the registration of trademarks. These services are often provided by staff at the export assistance program's head office in the home market or by foreign trade offices abroad. While such foreign trade offices are integrated into embassies in some countries, they are independent in other countries. Financial support services, e.g., in the form of export credit insurance, export loans, or export guarantees, are often provided by national governments or specialized banks affiliated with governments, e.g., export-import banks.

Export assistance programs not only have to be permissible under the anti-subsidy rules of the World Trade Organization (WTO), they also must function efficiently. Various measures have been used in order to test the effectiveness of export assistance programs. Depending on methodology, instruments, countries, and the institutional environment, the results are mixed. They show everything from clearly negative to highly positive correlations between export assistance programs and export success.

With changes in the international business environment, national export assistance programs are also being reinvented. As international trade is becoming ever more important, the future will bring export assistance programs that have been redesigned for new target groups, offering new services through new channels of information and distribution.

Most national providers of export assistance programs are members of the World Conference of Trade Promotion Organizations.

Export Financing

In today's business, competition in all export transactions takes place not only in the fields of product quality and pricing, but also in attractive payment terms offered by the exporter to the foreign buyer. Extending credit to foreign customers can be seen as a crucial means of enhancing export competitiveness. Export financing is made up of a set of different instruments and techniques to grant delayed payment for the goods or services sold to the importer. Based on the credit period, the relevant export finance tool-kit divides into short-term export financing and medium/long-term export financing.

Short-term export financing refers to payment periods or loans with a duration of up to 12 months; in some cases the period is extended to 18 months, although no generally accepted strict dividing-line exists between short-term and medium/long-term export financing. The terms of payment stipulated in the export contract are crucial for all export financing activities. For international transactions, the four primary options, ranked from (1) very secure to (4) most risky from the exporter's perspective, are (1) cash-in-advance, (2) letters of credit, (3) documentary collections, and (4) open account.

Some of these instruments, such as letters of credit, include coverage against the risk of nonpayment or default by the foreign importer. In other cases, such as the open account-option, additional export insurance or guarantees are needed to maintain a secure export transaction. The term *trade finance* is alternatively used as a blanket term for the whole range of financial instruments provided by commercial banks to facilitate international transactions in goods and services.

In the case of export sales with an open account payment condition, export factoring is a further option. Factoring firms usually buy the exporter's entire book of foreign trade receivables and pay out the relevant amount, deducting a discount. In a similar manner based on a transfer of title, forfaiting is used if the exporter sells promissory notes signed by the foreign buyer. Many forfaiters are ready to include political risks in discounting the promissory notes and to buy longer-term accounts receivable at deeper discounts.

The main purpose of medium/long-term export financing is to finance sales of capital goods with payment periods from one to five years (medium-term export financing), and even longer in the case of plant construction, infrastructure projects, and development activities. The applicable financial instruments can be differentiated into three approaches:

1. Traditional export financing is structured as a supplier credit scheme. In the export contract the supplier extends credit to the foreign customer, usually by negotiating a down-payment and a series of installments, and then asks for a supplier credit at his commercial bank. In this case, the seller is in charge of all problems caused by nonpayment of the importer because both contracts—the export contract with the importer and the loan contract with his bank—are clearly separated. Therefore the exporter is well advised to buy insurance coverage against the various potential risks of the export transaction. Often, hedging all of these risks may be a pre-condition to receiving a loan from a commercial bank.
2. In a quite different approach, the commercial bank negotiates the credit contract directly with the foreign importer, usually upon recommendation of the exporter. In a so-called buyer credit, the exporter is paid immediately by the commercial bank from the loan proceeds as soon as the exporter has duly fulfilled the export contract. From the exporter's point of view, the entire deal is transformed into a cash transaction in which the bank assumes all of the risk connected with the deal.
3. In specific cases of cash-generating projects, international project financing technique is applied. In structuring the financial flows of a large construction project, loan agreements are closed between banks and a special purpose project company that owns all project assets and controls all cash-outflows from the operating earnings of the specific project. Examples include infrastructure projects such as toll motorways, toll bridges, or power plants frequently structured as a BOT contract (i.e., build, operate, transfer). A comparable result can be achieved by including countertrade in the export financing options: in product buy-back transactions, payment for the construction of a plant is (partly) effected by delivering goods produced by this plant to the exporter.

Government assistance programs and national export credit agencies (ECAs) providing guarantee programs and loans, especially to small and medium-sized exporters, are another significant issue in the field of long-term export financing. These play a particularly important role in the case of political and economic instability in the buyer's country. If the buyer is located in a developing country, multilateral development banks provide funding to firms in the private sector for investing in private projects in developing countries.

When working with the different techniques and structures presented in this article as the typical building blocks of export financing, and when using them to finance a particular international transaction, one will see that there is only a low degree of standardization in different operations. Each individual deal is characterized by its own specific requirements stemming from the business partner or from their country, from the credit period or from the contract details. In most cases, a customized approach is required to arrive at a solution for the financial aspects of the transaction that is acceptable for all participants. This flexibility is the real challenge in successful export financing.

Export Management Company

Export management companies (EMCs) act for contracting organizations as outsourced international trade intermediaries for products or services in overseas markets, usually in lieu of an in-house export or international marketing department. Offering full-service export assistance, EMCs can vary in size, scope, geographic areas of operations, and level of specific technical or product expertise. EMCs handle all aspects and details of the export process, including documentation, regulations, distribution, and sales, and are usually paid on a commission or performance basis. Normally representing an organization's products or product line on an exclusive basis, EMCs work overseas with their own appointed networks of exclusive dealers, distributors, and export representatives in specific target markets.

EMCs operate in two forms: as exclusive distributors who take title (ownership), control, and responsibility of a good or service being exported, or as a sales representative or agent with no title, limited control, and responsibility, and subsequent minimized risk for these products. In this second approach, ownership of the good or service remains with the contracted organization or manufacturer (principal). EMCs are usually liable for all fixed costs associated with an export operation, including internal and external staff and overseas representatives, international travel, and communications. Most EMCs do not maintain their own overseas representative offices, warehousing, distribution, sales, or service subsidiaries, but many maintain strategic alliances with similar companies in selected target markets.

As distributors, EMCs normally operate under a "buy-sell" arrangement and receive specific price discounts from client organizations from which they derive their incomes from. As agents, EMCs usually work on a commission-on-sales basis. Commission rates can vary dramatically from EMC to EMC depending upon the relative competitiveness of a client organization's products in particular markets and the capabilities, capacity, and associated exports of the EMC. Historically, the commission rate has been approximately 10 percent for consumer goods and around 12–15 percent for industrial products. With the rise of services exports, and in the bio-technology, information, communications, and technology exports, commission rates can vary and are normally a function of the price of the product calculated against the relative difficulty of its marketing over time.

In addition to overseas sales and marketing, EMCs can also provide other services to organizations, including participation—on the principal's behalf—in overseas trade shows, conducting of in-market research, localization of product specifications and product adaptation, and lobbying of governmental and regulatory entities.

Technology, communications, and the globalization of trade influence the roles and function of EMCs. Most recently, developments in information and communication technology have closed the gap between domestic and international marketing by making the process of contact and communication with overseas clients easier, and "DIY" exporting more feasible and effective. This is having an effect on the number of organizations that use EMCs, some of whom are countering this trend by offering online export facilitation services and internet-based expertise services themselves.

Aside from a performance-based incentive process and associated motivations, benefits for organizations utilizing EMCs are that they can rapidly acquire a "ready made" export sales and distribution entity that has market and channel access and expertise. This translates to an immediate market presence. Organizations have, subsequently, the potential to shorten the time it takes to evaluate and access a specific target market, and can streamline the target market selection process. EMCs can often dramatically speed up export licensing and regulatory approvals and, if selected for the "distributor" role, can minimize the risk of exporting to an organization by assuming foreign credit risk and the managing of complex and diverse international credit, collections, and nonpayment.

Alternatively, by maintaining an outsourced entity for export development, an organization may not be maximizing the financial benefit of international trade, and can limit the development of internal export expertise, contacts, and sales networks. Most EMCs are smaller firms and have limited financial capacity and internal resource capabilities. Subsequently, economic imperatives can focus their efforts on products or markets that have a higher potential for near-term returns, rather than putting resources behind activities that represent a more strategic export opportunity for the principal. Finally, by using an EMC, an exporting organization can find that it has relinquished control of their product, organization name, and reputation in the export market.

Export-Oriented Development

Export-oriented development was a set of market driven prescriptions based on the policies followed by high-growth developing countries. Their adoption in developing countries was driven by a need to overcome the failures caused by inward-oriented, state-driven industrial policies. Performance of export-led development has been mixed, leading to criticism and the proposal of alternative routes to development based on the creation of sustainable societies.

Industrial policy is defined as an intervention or policy by government that attempts to alter the local sectoral structure of production toward sectors that are expected to achieve higher levels of economic growth. These interventions can be direct, in the form of grants, or indirect, in the form of tariffs, trade restriction, and exchange rate management. Historically, these policies have been used by developing countries in an attempt to move from low to high income status and have been the subject of a significant amount of research to determine successful paths to development.

Prior to World War II, world trade was determined by comparative advantage, with each country producing and exporting the items that they could create competitively. Countries such as those in Western Europe and the United States focused on the production of manufactured goods as they possessed the skills and technology, exporting these goods to developing countries. Nonindustrialized countries specialized in the production of commodities or raw materials, most of which were transformed into finished products by firms in developed countries. During World War II, however, industrialized countries shifted production to military goods, leaving developing countries with shortages of consumer goods. Immediately after World War II, prices of the commodities that the developing countries traded for manufactured goods began falling, meaning that developing countries had to spend more of the foreign exchange they earned from commodity production to import manufactured goods.

As a result of these forces, many low- and middle-income countries began ambitious programs after World War II to move from commodity producers to manufactured-goods exporters. The intent was to promote local industries to produce substitutes for goods that were imported in order to conserve foreign exchange and promote self-sufficiency. Targets were set for industrial investment and output growth, many of which attempted to change composition of industrial output from simple goods requiring little processing to complex manufactured items. Less developed countries' governments employed three major policy tools in the attempt to guide industrial development within the domestic market—direct public investment in enterprises, licensing of private industrial activities, and the establishment of development banks.

The state became the dominant actor in local markets, producing goods directly and regulating the production of other items. The intention was to overcome local limitations by providing the tools required for large-scale industry: modern facilities, the ability to create new products, and distribution capabilities. To help these industries develop, the newly formed industries or infant industries were protected and supported. Protection took the form of tariffs, import quotas, and exchange rate controls to provide a cost advantage to local producers. Industries also were supported through licensing schemes to reduce the cost of capital goods acquisition and low cost loans.

Under these policies, Latin America improved rapidly from 1950 to 1970, with the major economies experiencing sustained growth rates of over 5 percent. Growth ended with global financial liberalization in the 1970s following the breakdown of the Bretton Woods system resulting in increased debt, inflation, and stalled growth during the 1980s in Latin America. Import substitution brought several problems. Heavy protection and subsidy promoted inefficient industries, with customers in these countries forced to pay higher prices than imports for locally produced products. The expected employment benefits in terms of higher-skilled jobs did not materialize, and in many countries the employment situation deteriorated. In many cases, imports actually increased, as infant industries brought in foreign capital goods and paid out royalties to obtain licenses for foreign technology.

While import substitution was failing in Latin America and elsewhere, Japan began its phenomenal sustained growth after World War II, followed by South Korea, Taiwan, Hong Kong, and Singapore. International agencies took notice and began prescribing the practices of these countries to developing countries, encouraging them to shift from state-led to market-led development. Some of these policy lessons were summarized in the form of the "Washington Consensus," a listing of policy prescriptions created by economist John Williamson in 1989.

Generally, governments were encouraged to pursue macroeconomic stability, reduce the role of the state in the local economy and open their markets to international competition in exchange for market access from other countries. Increased international competition would force inefficient local industries to close or upgrade to improve productivity. Opening of financial and product markets would encourage foreign investment, bringing new technology. Finally, increased market access to developed countries would boost exports of locally produced items. The combination of these factors would boost domestic income and increase economic growth.

Criticism

Variations on these policy prescriptions became the dominant development ideology in the 1990s, implemented by countries in Latin America, Asia, and Africa in their pursuit of increased growth. However, many countries did not achieve the promise of high growth and the Asian financial crisis of the late 1990s opened the export-led model to criticism. As the Asian crisis demonstrated, financial liberalization can cause rapid outflows as well as inflows of capital, crippling economies.

The overwhelming focus on exports led to several additional problems. Many developing countries entered the same markets for manufactured goods, resulting in overcapacity and price competition. Income from these exports was therefore reduced as prices were lower than predicted. Some developing countries were willing to reduce the standards of worker and environmental protection to attract foreign investment, with potential long-term damage from environmental degradation. Multinational firms generally tended to make investments with mature or low-skill technology, retaining intellectual property development in developed countries. As such, the promised technological gains were never realized and local industry remained underdeveloped. Developing countries were also vulnerable to volatility in their export markets; slowdown in demand would reduce sales of their exports.

Recently, economists have used the above and other arguments to propose a broader-based view of development. In this perspective, development should take a long-term view and focus on improving the living standards of people in a sustainable manner while being sensitive to local conditions. Countries should also focus on improving the local institutional framework so that they are better able to monitor and control development. The idea is to move away from a series of rigid policy prescriptions to a range of instruments that can be selected to improve local performance in specific economic and social contexts.

Export Processing Zones

Export processing zones (EPZs) are specific geographic locations, physical sites, business premises, buildings and/or assigned localities that have special tax, tariff, or investment incentives and customs (duty) regimes in order to promote export-oriented industry and transactions. Traditionally, EPZs include locations that house special economic zones, free trade zones, free ports, custom zones, commercial free zones, and bonded facilities/warehouses. Not exclusively limited to a specified geographic area or fenced enclave, EPZs can also include single-company, single-industry, or single-commodity zones, as well as technology/science parks, logistics centers, specific areas dedicated to agriculture, aquaculture, and horticulture, and, in some instances, even tourist resorts and passenger transport vessels.

EPZs were originally established with the intention of supporting developing countries by providing enhanced employment opportunities and increased access to foreign capital. EPZs initially segregated the concentration of expertise in the higher economically developed countries to the more technical/scientific areas, while the less economically developed countries focused on more labor-intensive areas. EPZs are often found in jurisdictions where there are geographic or logistic advantages, or where production inputs are comparatively inexpensive—such as labor, raw materials, energy, or physical space—and/or where tax or tariff incentives and existing regulatory environment are favorable for investment. Activities that can take place within EPZs include the manufacture of goods and services, production, processing, assembling, trading, repair, reconditioning, reengineering, and/or packaging/re-packing/labeling of export products or services.

EPZs usually offer infrastructure of a higher standard than that available in a respective domestic economy. Electronics, textiles, clothing, and footwear were the popular industries initially established in EPZs; however, the product and service mix today can include almost any sector and can transform over time as a respective country's economic, industrial, and social development changes. With the increase in traded services export and the proliferation of technical and scientific expertise export, EPZs around the world are counting in greater numbers zones concentrating on biotechnology, financial services, information technology, and information/electronic data processing.

An EPZ, depending upon the country, legislative environment, existing free trade agreements, and relevant jurisdictions, can be established by the public, private, joint sector, or by local, state, or national governments. Initially established by governments, there is a growing trend toward the development of EPZs by private organizations, which tend to offer higher-quality facilities. Firms located in EPZs can usually access, procure, or import duty-free goods from external sources, or from other EPZs, as long as the final product or service is exported. Incentives are provided for the purpose of the eventual export of a good or service. Incentives vary country to country and zone to zone, but can range from tax holidays, duty-free export and import, staff training and employment subsidies, and free repatriation of profits to the provision of facilities, infrastructure, and exemptions from local labor laws. To qualify for incentives, there are normally criteria imposed such as level of investment, industry or industry sector, local content inputs, or levels of local employment.

EPZs are generally viewed today as a competitive method to attract both foreign investment and increase local employment opportunities. In Asia, cities like Hong Kong and Singapore have established themselves as both regional export gateways as well as significant global transshipment centers through the provision of special customs regimes for export processing and transshipment. In North America, one particular permutation of the EPZ has been seen on the Mexican side of the U.S.-Mexico border, where *maquiladoras* have emerged as a convenient method for North American firms to access the comparatively cheaper labor and energy costs of neighboring Mexico. A maquiladora or maquila is a production facility, normally bonded premises, that imports materials and equipment on a duty-free and tariff-free basis for either manufacturing or final assembly, and then reexports the finished or assembled product. A maquiladora facility is often matched by a “twin” production plant or logistics center across the border.

The history of EPZs goes back to the earliest days of cross-border trade, where special areas were often set aside for the barter and exchange of goods, and were often regulated by customs, practices, rules, and laws that were separate from the surrounding area. In more modern times, the establishment of the first export-oriented zone occurred in Spain in 1929. However, it was not until the 1970s that the EPZ concept gained true global popularity with zones established, initially, in the developing economic regions and nations of Asia, Latin America, the Caribbean, and Africa. Since the 1970s, the number and type of EPZs, and the number of hosting countries, have expanded rapidly, and are becoming increasingly popular in former Soviet bloc countries in eastern and central Europe.

EPZs can be viewed as a positive or negative outcome of globalization. On one side of the argument, the development of EPZs can be seen as a way to attract foreign investment, increase exports, support comparatively rapid economic development, and enhance a country’s strategic trading role. On the negative side, EPZs can be perceived as exclusive sites and sources of human, resource, and environmental exploitation that offer limited direct benefit to a country or its people.

Export Subsidies

Export subsidies are attempts by a government to interfere with the free flow of exports. They are payments to a firm or individual for shipping a good abroad. Similar to taxes, export subsidies can be specific (a fixed sum per unit) or ad valorem (a proportion of the value exported). Around the world, the export industry most frequently subsidized is agriculture.

The stated reasoning for export subsidies varies depending upon the product and industry, but proponents frequently invoke the notion of self-sufficiency or national security concerns. When effective, export subsidies reduce the price of goods for foreign importers and cause domestic consumers to pay relatively higher prices. They thus distort the pattern of trade away from production based on comparative advantage and, like tariffs and quotas, disrupt equilibrium trade flows and reduce world economic welfare.

In 2007, for example, the second-largest exporter of sugar was the European Union (EU), in large part because of EU sugar subsidies. Conversely, Mozambique sugar farmers have a difficult time competing in world sugar markets despite their lower production costs because the EU subsidies artificially lower the world price of sugar. In this way, export subsidies often disrupt and impede economic development in less developed countries. In addition, export subsidies can often lead individuals and countries to engage in legislative actions in order to mitigate the impact of export subsidies on them. These activities can include anti-dumping legislation, retaliatory tariffs, and non-tariff barriers to entry. While these activities can sometimes mitigate the negative impact of a subsidy on a particular group of individuals, the expenditure of resources in response to a previous intervention generally does not increase overall economic welfare as the resources employed to mitigate the subsidy's effect could have been used elsewhere in the economy.

Export subsidies have been a subject of discussion and controversy in recent years. The United States and European Community, for example, have had a number of disagreements and failed negotiations revolving around the issue of agricultural export subsidies. Europe's Common Agricultural Policy (CAP) has evolved into a large export subsidy program that harms most European consumers and taxpayers. In 2002, subsidies to European Union farmers were 36 percent of total farm output and twice as high as American farm subsidies. Together with nongovernmental organizations such as Oxfam, the United States has pushed for European agricultural reform in the interests of helping those harmed by the subsidies, but each step is met with threats of retaliatory protectionism by Europe. In addition to constant agricultural challenges, U.S. textile manufacturers often claim that export subsidies on east Asian textiles place them at an "unfair" disadvantage.

Like Europe and east Asia, the United States has used export subsidies to the advantage of some industries. For example, every U.S. citizen pays approximately $13 per year to support cotton production in the United States. These subsidies to cotton producers encourage additional production beyond the scale of the original

The United States has fought export subsidies, but each U.S. citizen still pays about $13 a year toward U.S. cotton subsidies.

market for cotton, thereby creating surpluses. To eliminate the surpluses, the government then subsidizes agribusiness and manufacturers who buy cotton from the United States. In many cases, therefore, the final result of export subsidies are large-scale interventions into an industry, where producers of both raw materials and final consumer goods are being supported. Examples similar to the U.S. cotton industry can be found in nearly every country around the world.

While export subsidies remain a controversial and unresolved issue of international trade, there have been recent calls for the elimination of subsidies. Article XVI of the General Agreement on Tariffs and Treaties (GATT), for example, states,

> If any contracting party grants or maintains any subsidy, including any form of income or price support … it shall notify the contracting parties in writing of the extent and nature of the subsidization, of the estimated effect of the subsidization on the quantity of the affected product or products imported into or exported from its territory and of the circumstances making subsidization necessary.

More recently, the Doha Round of World Trade Organization (WTO) negotiations discussed the possibility of eliminating agricultural subsidies altogether, and, at the Hong Kong Meeting in December 2005, member countries agreed to abolish all agricultural export subsidies by 2013.

While there is momentum building for reductions in export subsidies and greater integration, strong political opposition to reform remains the biggest roadblock. Farming lobbies around the world remain well organized and powerful, and politicians face strong disincentives to engage in agricultural reform. As a result, export subsidies will continue to be a challenging issue in future trade deals.

Export Trading Company

An export trading company (ETC) is a business entity engaged in export trade. It provides export-related services for industries or other economic operators aiming at selling products in foreign markets. An export trading company may warehouse, ship, and insure goods; in addition, it can supply customers with market information. An export trading company can be simply a commercial intermediary or also take title to the product and export for its own account. A special type of export trading company are those organized and operated by producers. These ETCs are structured along multiple- or single-industry lines and can represent producers of competing products. The role of ETCs in world trade is particularly relevant as in a high variety of cases the services of a specialized commercial intermediary reduce the costs of commercial transactions for both buyers and sellers.

In general, ETCs tend to specialize by products in order to better meet the needs of their domestic customers. However, there are also certain types of ETCs that organize themselves and their activities according to the needs of the host countries; in other words, they specialize in countries rather than in products. The patterns of development of the export trading companies may follow rather different trajectories, and greatly vary from country to country. Such diversity is mostly due to the origin of the export trading company as a form of commercial organization that was created and evolved as a response to the needs that each country had in organizing, and handling foreign trade, especially export trade. Conditions and needs of the domestic market, therefore, influenced the development and structure of ETCs. Different legal frameworks (company law), however, are also responsible for the diversity in the organizational structure of ETCs. In the United States, for instance, ETCs operate in accordance with the Export Trading Company Act enacted in 1982. In the same year, also, U.S. banks were permitted to own and operate export trading companies under the Bank Export Services Act.

In functioning as a provider of a wide range of export-related services, an export trading company operates as a bridgehead facilitating trading relations across countries. The origins of the export trading company can be traced back to the early modern period. The direct predecessors of present-day ETCs were the chartered trading companies of the 16th and 17th centuries, such as the British East India Company (EIC) and the Dutch East India Company (Vereenigde Oost-Indische Compagnie or VOC), just to name the most important ones. Organized as joint-stock companies, these trading companies received a royal charter that allowed them to trade in several products, usually spices, silk, and other luxury goods, between their mother countries and India and Asia as monopolies. The trading companies of the early modern period broadened the commercial horizons of European trade, and opened new areas for economic and commercial interaction in extra-European regions.

More recently Japan has offered one of the most interesting and altogether successful examples of export trading companies. The Sogo Shosha, vertically integrated trading companies, have been an efficient tool to serve the Japanese export trade. The specificity of the Japanese export trading companies lies in the close links they established with industries. Conceived as a device to favor the exportation and sale of certain categories of Japanese products, the Sogo Shosha are highly integrated with the industries they serve. In some remarkable cases they originated from the very same industry with which they were expected to cooperate. Mitsui is a case in point. The organization typical to these Japanese trading companies is usually not permitted in the United States or in Europe because of antitrust laws.

The term *export trading company* is frequently used as a synonym for *export management company* (EMC), with which it is also often confused. An export managing company, however, is a different business entity that acts as the export department for one or several producers of goods or services. It can solicit and transact business in the names of the producers it represents or in its own name for a commission, a salary, or a retainer plus commission.

Expropriation

Expropriation is a broad term. In Canada, it is analogous to the principle of eminent domain: A government or body empowered by that government expropriates property when it takes it from a private owner without consent and without consent being required; it does this as directed or allowed by an applicable law, it is not punitive, it compensates the owner, and the owner has the right to seek additional compensation if he or she feels entitled to it, which may include expenses beyond the value of the property incurred by the act of expropriation. In much of the world, however, the word is associated with communism's call for the seizure of land and industry by the socialist state, a politically motivated seizure that seeks to improve or restore social justice and the common good.

In the communist sense, expropriation is related to communist land reform, wherein there is little or no private property, and everything is owned collectively by the people and administered by the state (and those it empowers). Because communism cannot be introduced in a vacuum—that is, some other system exists wherever it is adopted—this circumstance can only be created by taking private property from its owners by one means or another, whether through purchase (as in small-scale communes) or expropriation. Sometimes this expropriation leads to redistribution—a sort of Robin Hood approach, presuming we consider the owners to be "the rich"—while in other cases the land is used for collective farms and the like. Quite often there is no compensation.

One historical example of that style of expropriation is the 1917 Decree on Land issued by the Second Congress of Soviets in the aftermath of the October Revolution. This decree, written by Vladimir Lenin, declared that the peasants had seized the lands of the nobility and the church, along with all associated livestock, buildings, et cetera, and that such lands would be put at the disposal of the volost land committees. Leon Trotsky, Lenin's second in command and the founder of the Red Army, was adamant that there would be no compensation for such expropriation; it is worth pointing out that Russia did not have a long history of private property, and so most lands were held by the nobles or the church. As the Soviets further organized in their early years, this decree and others were superseded by the 1922 Land Code, which collated and refined Soviet land law and the regulation of those land committees.

Expropriation is one of the risks involved when businesses buy or invest in land and other properties in other countries. During times of upheaval or revolution, foreign-held lands and buildings may be expropriated with only a token amount of money given as compensation; this may sometimes be politically motivated, especially in countries where the population is unhappy with foreign business activities on their soil. It may merely be politically convenient, since seizing foreign lands poses less risk of alienating a potential constituency than seizing domestic lands would, and revolutions do need to come by their funding somehow. Treaties between nations often prohibit these expropriations or require proper and fair compensation (generally without the means of appeal offered in Canadian expropriation); while revolutionaries staging a coup may not feel they are obligated to uphold older treaties, it is often in their interest to do so, to encourage foreign powers to treat the revolution as a domestic matter that does not require their intervention.

There are other times when a business or its lands may be expropriated with just cause, when a foreign business is operating without consideration for local concerns, and other attempts at redress have failed.

External Debt

External debt, in its most general sense, denotes a payment obligation in which the debtor (entity that obtained resources) and the creditor (entity that supplied the resources) are separate and in essence distinct units. The offshoot of this perspective is that creating or terminating the debt generates a corresponding change in aggregate wealth or resources on the part of both units involved in the transaction.

The entities involved can be corporations, individuals, or countries. For corporations, the debt would then be referred to as corporate debt. Debts always entail a liability that has to be eventually paid back on agreed terms. In the case of relatively small businesses, debt is usually in the form of loans or lines of credit obtained from banks.

Corporate Debt

With respect to relatively large corporations, a major portion of debt takes the form of financial instruments, usually bonds of one form or another. Bonds are borrowing arrangements whereby an issuer or borrower sells an IOU to an investor or lender. By this arrangement, the issuer is obligated to make stated payments to the bondholder on specific dates. A coupon bond obligates its issuer to make fixed nominal payments called coupon payments over the life of the bond. In addition, the issuer pays the lender the bond's face value at the time of expiration (maturity date). The coupon rate then is the coupon payment expressed as a percent of the bond's par value. The terms of the issue, including the coupon rate, par value, the maturity date, and any other legal rights and responsibilities of the issuer and the holder are spelled out in a contract, called an indenture. Sometimes coupon payments are set to zero so that the buyer pays a price below the par value to get a return equal to the price difference when principal is repaid at maturity in the amount of the bond's face value.

Usually firms issue four types of corporate debt, namely debentures, notes, mortgage bonds, and asset-backed bonds. Notes in this context are generally bond issues whereby all obligations are due less than 10 years from the date of issue. A more common maturity for corporate bonds is 20 to 30 years.

Debentures, like notes, are not secured by any specific pledge of property. They do, however, have claim to the issuer's property and earnings because they share the claim of general creditors on all assets owned by the issuer but not specifically pledged to secured debt elsewhere. They also have a claim on pledged assets whenever such assets exceed what is needed to satisfy secured lenders.

Secured debt is that whereby particular assets are pledged as collateral so that investors in bonds have direct claim to the assets given bankruptcy. This type of debt is also referred to as asset-backed bonds. Mortgage bonds are an example of asset-backed bonds secured by real property. The process of raising capital through debt financing is analogous to the initial public offering (IPO) for stocks.

Country Debt

When the entities involved include countries, external debt is defined as the outstanding amount of actual, current, and noncontingent payments of principal and interest by the debtor country that are owed to nonresidents by the residents of the borrower country. The liability has to exist and be outstanding. It is important to establish whether the creditor actually owns a claim on the debtor. The debt liabilities in this case are created through provision of economic value, i.e., financial and nonfinancial assets including goods, services, or transfers by one institutional entity, the creditor to another unit, the debtor, usually under some contractual arrangement. Liabilities can also accrue in this type of borrowing, from legal action such as when taxes, penalties, or judicial awards are imposed by force of law. Liabilities from external debt at the country level also include arrears of principal and interest charges.

Where commitments are made for provision of economic value at a future date, corresponding debt liabilities are not established unless services are rendered, items change ownership or some form of income accrues to the borrower. For example, the components of an agreed loan arrangement that have yet to be disbursed to the beneficiary or export credit commitments not utilized are not part of a country's gross external debt position.

The country-level definition of external debt makes no distinction between required principal payments and interest payments. As a result, interest-free loans are treated as debt instruments even though no interest is paid. Perpetual bonds are likewise considered debt instruments although principal is not repaid on them. The form of payment can be deposits of funds or provision of goods and services. Here future obligations to make payments, rather than the form of payments, determine whether or not a given liability is a debt instrument. Similarly, the timing of payments is irrelevant in this regard.

In order to be considered external debt, the liabilities must be owed by a resident of the borrower country to a nonresident. Residence status in this instance is based on where the debtor and creditor have their centers of economic interest. Thus, what matters is their ordinary location, not their official nationality. Also excluded from the definition of external debt are contingent liabilities. These refer to arrangements whereby one or another specific condition must be fulfilled prior to a financial transaction. This does not imply that guaranteed debt, for example, is excluded. The guaranteed debt is attributed to the debtor rather than the guarantor—until the guarantee is called.

The historical experience of developing countries with external debt highlights benefits and risks entailed in reliance on debt as a major source of capital. In the aftermath of World War II during the rapid economic expansion of the developed countries, less developed countries also enjoyed relatively fast growth rates. However, on account of their domestic savings and foreign exchange gaps, less developed countries increased their external debts to sustain their economic growth. Following the sudden oil price increases of the 1970s and the accompanying episodes of inflation, industrial countries implemented restrictive monetarist policies to stabilize their economies. This led to higher interest rates, which in turn raised costs of debt servicing.

A combination of costly debt service and easy availability of debt from oil surpluses of exporting countries contributed to a buildup of unsustainable debt among less developed countries. Most of this debt was underwritten by governments of industrial countries and multilateral institutions like the World Bank and the International Development Association (IDA). The debt problem deteriorated to a point at which more debtor defaults were likely among nations before debt forgiveness by multilaterals and governments provided bail-outs for highly indebted poor countries. The literature documents cases of default in the past with little consequence to debtors.

External Labor Market

Labor markets provide a mechanism for employers and employees to agree on terms for exchanging labor input for wages. In accepting an employment relationship, a worker agrees to receive wages (and other inducements) in exchange for submitting to the directives of the employing organization within some zone of indifference. On the labor supply side, individuals adjust their hours of work in the labor force on the basis of changes in income, career opportunities, and other conditions of employment. On the demand side, employers adjust their engagement of labor on the basis of changes in relative prices of labor, the quality of labor, and other constraints. For labor markets to operate efficiently and effectively, mechanisms must be in place to support flexibility and adaptability to changing levels of supply and demand, while conforming to social expectations regarding equity, morality, and so forth.

Labor markets exist within the firm and external to the firm. Internal labor markets are characterized by job ladders in the firm, supported by evaluation systems that reward skill development and worker commitment. Entry to the firm occurs mostly at the bottom of the ladder, and movement up the ladder follows the development of skills. Internalized work often comes with the implicit understanding that employment is permanent, or at least long term. External labor markets, by contrast, are normally more flexible, unless they are tightly regulated by governments or constrained by the behavior of labor interest organizations. External market transactions consist of contractual relationships that specify what each party to the exchange is to deliver. The simplest form of employment contract is the spot contract in which all obligations are fulfilled on the spot, as in the case of hiring day labor without any obligations for the future. To the extent that internal labor markets produce employment stability, internalization makes it expensive and politically difficult to adjust the volume of labor to changing internal organizational and external market conditions. This is the main reason why firms typically externalize labor—draw on external labor markets—when they recruit workers.

Under normal conditions, internalization increases the employer's organizational control over employees, whereas externalization enhances organizational flexibility. Externalization of labor is typically seen as a means to complement internalization and to circumvent some of the problems created by internal labor markets. In some Western countries, the external labor market is extremely dynamic, as in the United States where the proportion of new job-person matches over a five-year period has been estimated to be about 40 percent, with significant variations across age groups. General inter-country comparisons are not very revealing if they ignore differences in labor movement in terms of opportunity factors such as the size distribution of firms in a given industry and the degree of job growth over the business cycle.

Recent Developments

Recent decades have seen significant developments in labor markets in the international arena, as firms are trying to regain some of the competitiveness they have lost because of rising labor costs and the growing success of producers in newly industrializing nations. One strategy many firms use to contain labor costs is to introduce a variety of flexible working arrangements that are expected to improve the link between the level of output and the demand for labor. Some of these arrangements are based on using the external labor market as a source of employment flexibility. The most prominent of these arrangements include increased reliance on subcontracting and the increased use of temporary employment contracts. Both are considered forms of employment externalization. Externalization through the use of temporary workers has the effect of reducing the duration of employed labor in the firm, whereas externalization through subcontracting activities to independent workers is a means of increasing flexibility by reducing administrative control over labor.

Subcontracting involves the replacement of employment contracts in the firm with commercial contracts with external firms supplying specialized inputs. This approach is widely used in industries facing volatile market conditions, such as construction, where workers move from one contract to the next or are laid off until the firm obtains another order. They are also frequently used in industries that rely heavily on project work, as in the cultural sector (e.g., performing arts, film production, writing, and publishing). In these industries, many firms can meet fluctuating demand best by outsourcing activities to specialized organizations and individuals that can supply them at the time when they are needed, while retaining in-house those activities that focus on their core business.

Temporary employment refers to the use of workers hired for a fixed term. These include workers provided by temporary help service agencies, limited-duration hires, and call-ins. In many countries, temporary workers (often referred to also as contingent workers) have comprised one of the fastest growing labor force segments. It would be wrong to view contingent workers primarily as low skilled. Contingent workers include professionals such as engineers, teachers, nurses, and orchestra directors. Many of these temporary workers are highly paid, and there is some evidence that many of them view their temporary employment as voluntary rather than imposed by the state of the labor market. Temporary status may also lead to permanent employment, if the firm uses the arrangement as a recruitment device to observe the worker's qualifications and commitment until a decision is made whether to offer long-term employment.

Research typically explains the use of subcontracted and temporary labor in terms of the advantages contingent employment arrangements produce for the employer in terms of flexible staffing, cost savings, obtaining expertise, and a variety of other benefits. One may distinguish between numerical and functional staffing flexibility. Numerical flexibility refers to the ability to adjust staffing levels to changes in market conditions more easily than what is possible with permanent staff who are protected by government regulations regarding hiring and firing and who expect employment stability. Functional flexibility contributes required skills to the firm that are costly to develop in-house, especially if they are used only sporadically or are difficult to monitor by the employer because control over the use of skills lies with the worker. Drawing workers from the external labor market also provides the firm with cost flexibility to the extent that it can economize on fringe benefits and social insurance payments. And the use of independent contractors allows the firm to provide a broad range of specialized products without incurring the risks from large investments in recruitment, skill training, and labor monitoring.

When are firms most likely to externalize labor? The use of temporary workers is certainly not a new phenomenon. Employers have long organized production around fixed-term (and part-time) positions in order to cope with fluctuating market demand, as in retail and the hospitality industry. What appears to be new is the extent to which firms rely on contingent workers to hold down labor costs. It would also be too simple to argue that firms draw (more) extensively on external labor markets only because high(er) levels of uncertainty in product markets require a strong(er) concern for containing labor costs. A focus on market uncertainty and labor costs is in many cases too narrow. While the employment of contingent workers may help to contain labor costs, organizational factors and job factors may reduce these cost savings.

An important variable to consider is the nature and extent of workflow interdependence. In those cases where activities and jobs are highly interdependent, extensive use of temporary or contract workers carries the risk of disruption and insufficient control over the flow of labor resources. Research suggests that firms are more likely to externalize labor if parts of the production process can be distributed and technologies are available that enable outsourcing and adjusting the volume of output. There are also organizational factors to be considered. If, for example, employers cannot introduce bureaucratic controls—for example, because of union rules or government regulation—to ensure a sufficient level of commitment on the part of short-duration hires, they are less likely to externalize employment. Within any organization, there are a range of "hidden costs" associated with monitoring, motivating, resolving conflicts, and coordinating permanent and nonpermanent workers that limit firms' use of external labor markets.

The evidence shows that there is a clear trend toward increased labor market flexibility in many industrial countries. However, this trend builds on markedly different bases. Extensive reliance on external labor markets has existed in the United States for a long time. Employers in Europe seem to be catching up fast, although in varying degrees in different European countries. Also, the form and nature of labor externalization is different across countries. In Europe, one can observe a north/south divide, with part-time and temporary employment arrangements being more popular with employers in many southern European countries.

Variability in labor externalization is not determined by employment legislation alone. Firms in both high-regulated and low-regulated countries draw on external labor markets, and in many cases the increase in labor externalization in recent decades is similar. There is some debate concerning whether there is convergence or divergence across countries in firms' reliance on external labor markets. Those who argue that divergence is taking place suggest that, despite globalization, firms continue to be embedded in regionally or nationally distinct societal and institutional arrangements. Others who observe international convergence argue that firms' practices are increasingly disembedded of the national context, overriding more regionally or nationally specific institutions or cultural predispositions.

Some also suggest that convergence is a function of business activities becoming internationalized through exposure to customers, suppliers, or alliances with foreign firms. Even enterprises that do not participate in international markets are subject to competitive pressures and regulations. By imitating and learning from each other, firms adopt common organizational practices, including recruiting workers from the external labor market.

ExxonMobil

ExxonMobil Corp. is the world's largest publicly traded oil company, and one of the largest U.S. companies, with $404 billion in revenue in 2007 and a market valuation of $504 billion at year end. In 2007 the Irving, Texas-based company produced roughly 3 percent of the world's oil. The company was formed in 1999 when Exxon Corp., the largest U.S. oil company, acquired Mobil Oil, the country's second-largest oil concern.

When Exxon acquired Mobil in 1999, the merger was the biggest in U.S. history and the largest oil merger ever.

Nearly two-thirds of the company's net income in 2007 was generated through its production of oil and natural gas, which includes fields in the Gulf of Mexico, the Arctic, Russia, the Caspian Sea, offshore West Africa, and the Middle East. ExxonMobil has about 11 billion barrels of oil reserves as of the end of 2007, or 0.9 percent of the world's proved reserves—which ranks it behind government-owned oil companies such as those of Saudi Arabia (the largest), Iran, and Venezuela.

ExxonMobil also has a large worldwide petroleum refining and marketing operation that includes 32,000 service stations. It owns several top-selling global brands, such as Esso gasoline and Mobil 1 motor oil. Its petrochemicals operation is also large and spread around the globe, making, among other products, key building blocks of polyester and plastics.

ExxonMobil had its origins as the largest parts of Standard Oil, the massive petroleum company incorporated in 1870 by John D. Rockefeller and his partners. Standard Oil became one of the biggest and most famous companies in the world, built in part on its efficiency in transportation and refining, and in part on ruthless competitiveness. Standard controlled 90 percent of U.S. petroleum refining capacity by 1880, and dominated the petroleum and kerosene market for several decades. It eventually began acquiring oil-production companies, creating the first vertically integrated oil company. The United States sued Standard under the 1890 Sherman Antitrust Act, and in a landmark 1911 decision, the U.S. Supreme Court broke Standard up into 34 fragments. The largest fragments were Standard Oil Co. of New Jersey (which changed its name in 1972 to Exxon) and Standard Oil Co. of New York (which changed its name in 1966 to Mobil Oil). The year 1911 also marked the first time Standard's sales of gasoline surpassed those of kerosene.

The independent Standard Oil Co. of New Jersey was among the oil pioneers in international expansion, first in Iraq and later in Saudi Arabia. In the late 1920s and 1930s, Jersey Standard also led the way in expanding into petrochemicals.

The oil market changed in the 1960s and 1970s, as power shifted to national oil companies and the OPEC cartel of oil-producing nations. Oil prices rose, and many consumers blamed large U.S. oil companies such as Exxon—in part because higher oil prices pushed Exxon to the top of the *Fortune* 500 list of the biggest American corporations. Both Exxon and Mobil diversified into non-petroleum businesses, including Exxon's failed attempts to enter the computer market and Mobil's brief ownership in the 1980s of the Montgomery Ward department stores. Following these setbacks, the companies focused on their core businesses of oil, gas, and chemicals.

Exxon has long been known as an engineer's company that attracted little public affection, but its single-mindedness developed into a reputation for being environmentally unfriendly after a March 1989 accident involving one of its tankers, the Exxon *Valdez*. The *Valdez* hit a reef and spilled 240,000 barrels of oil into Alaska's Prince William Sound; the incident, which incurred a $2 billion cleanup, struck a chord with the public, bolstering environmental consciousness.

Exxon's emphasis on efficiency (sometimes at the cost of its image) has consistently made it among the industry leaders in such measures as return on capital. Exxon's publicly traded shares typically trade at a premium to those of rival integrated oil companies, which in part enabled Exxon to acquire Mobil in 1999, in what was the largest oil merger ever, to form the current company. The merger, at the time the biggest in U.S. history, took place against a backdrop of ever-larger oil projects and increased industry consolidation. It allowed for economies of scale and cemented ExxonMobil's leadership position.

Facilities Location Decision

Facility comprises the physical resources such as land, plant, machinery, and equipment that are brought together at one geographic location for the purpose of producing particular goods and/or services. Decisions on these resources are therefore of paramount importance for firms, not least because they involve large capital investments; once made, these decisions cannot be easily or cheaply undone. Overall, facilities decisions are concerned with, inter alia, where to locate the organization's production facilities, how large each should be, what goods or services should be produced at each location, and what markets each facility should serve.

Since these decisions aim to generate more profit for profit-oriented organizations or achieve a balance between costs and the level of customer service they provide for not-for-profit organizations, much time and effort needs to be put into identifying and assessing the key variables that make up these decisions because the size and binding nature of the investments make relocation hard to justify. The magnitude of these decisions is such that some organizations may be committed indefinitely to a location once it has been chosen.

The overall objective of choosing one location over alternatives is to secure the best net gains for an organization now and in the long term. In essence, such an overall objective can be achieved through establishing an appropriate balance between three related issues: (1) the spatially variable costs of the operations or costs that change with geographical location, (2) the service the firm is able to provide to its customers, and (3) the revenue potential of the firm. Of these, the last two issues are more related to for-profit organizations simply because of the assumption that the better the service the firm can provide to its customers, the better will be its potential to attract customers and therefore generate revenue. In not-for-profit organizations, however, revenue potential might not be a relevant objective and so cost and customer service are often taken as the twin objectives of the facilities location.

In order to achieve the aforementioned objectives of the facilities location, a number of factors that are believed to influence facilities location decisions need to be taken into account. These are labor factors, exchange rate and currency risk, location costs, attitudes and culture of government and worker toward location decisions, proximity to markets, proximity to suppliers, and proximity to competitors. With regard to labor factors, the primary labor considerations are the costs and availability of labor, wage rates in an area, labor productivity and attitudes toward work, and whether unions are a serious potential problem.

Although wage rates and productivity may make a country seem economical, unfavorable exchange rates may negate any savings. As a result, the values of foreign currencies and their changes need to be taken into account in location decisions. Location costs that are tangible and intangible certainly affect a location decision and therefore should be rigorously calculated. National and local government policies can also facilitate the siting of a new business by how easy or difficult they make the process involved. Cultural variations in punctuality by employees and suppliers make a marked difference in production and delivery schedules.

For many firms, it is extremely important to locate near customers. Firms also like to locate near their raw materials and suppliers, not least because of perishability, transportation costs, and bulk. Furthermore, companies like to locate, somewhat surprisingly, near competitors. This tendency (also called clustering) often occurs when a major resource is found in that region. Italy may be the true leader when it comes to clustering, with northern zones of that country holding world leadership in such specialities as ceramic tile (Modena) and gold jewelry (Vicenza). In addition to the aforementioned factors, selecting a facility location is becoming much more complex with the globalization of the workplace. That is, because of market economies, better international communications, more rapid and reliable travel and shipping, and high differences in labor costs, many firms now consider operating outside their home countries.

Having considered the critical factors influencing facilities location decisions, the question remains as to how to choose the optimal location. Although the facilities location decision is often based on opportunistic factors such as site availability and cost benefits such as government grants and favorable tax rates, a quantitative analysis brings an important perspective to the decision and helps identify the optimal location based on the key benefits an organization is seeking.

Some of the more commonly used techniques regarding the choice of optimal location are weighted-factor method, center of gravity method, location break-even analysis, and transportation model. In the weighted-factor method, a variety of relevant criteria (also called critical success factors) are included in choosing a location. Locational break-even analysis relates to the use of cost-volume analysis to make an economic comparison of location alternatives. The center of gravity method is a mathematical technique used for finding the location of a distribution center that will minimize distribution costs. Finally, the objective of the transportation model is to determine the best pattern of shipments from several points of supply (sources) to several points of demand (destinations) so as to minimize total production and transportation costs.

Factor Endowments

Factor endowments refer to the resources a country possesses. Traditionally, land, labor, capital, and natural resources were considered as important factor endowments determining the prosperity of a nation. A greater endowment of these resources and subsequent exploitation for value-adding activities is expected to lead to more wealth creation and prosperity.

Factor endowments determine the comparative advantage of nations against each other, which subsequently affects the pattern and direction of international trade. There have been several theoretical advancements based on the concept of factor endowment to explain international trade activities. Prominent among these are David Ricardo's theory of comparative advantage and the Heckscher-Ohlin (H-O) model of international trade. The theory of comparative advantage suggests that countries should specialize in products and services in which they have a comparative advantage, even though they may not have an absolute advantage. This theory does not explicitly acknowledge the role played by differential factor endowment in explaining international trade.

The H-O model builds on the theory of comparative advantage to predict that countries will export products for which they have an abundance of input factors and import those for which they lack the input factors. For example, a country with an abundance of capital will export capital-intensive products, whereas a country with an abundance of labor will export labor-intensive products. The H-O model assumes that countries differ only in terms of their factor endowments. Since countries are assumed to be similar in all other aspects, the production costs across different countries will differ depending on the relative factor endowments of a country and the factors needed for the production process. Thus a country with a superior endowment of capital will produce capital-intensive goods cheaper, while a country with a superior endowment of labor will produce labor-intensive goods cheaper.

The concept of factor endowment and the H-O model have been widely used to explain international trade between the countries of the north and the south. The countries of the north are traditionally viewed as having superior capital endowment, whereas the countries of the south have an abundance of labor. The flow of capital-intensive goods from the north and the labor-intensive goods from the south in the late 19th and early 20th century can be attributed to their relative factor endowments. The economic prosperity of the countries in Europe and North America are also attributed to their attractive endowments.

However, empirical analyses show that the flow of trade may not always be between countries with different factor endowments. In fact, a large proportion of international trade is between countries with similar factor endowments. Wessily Leontif, in trying to verify the H-O model, found that the United States, in spite of being rich in capital, exported labor-intensive products, which is contrary to the predictions of the H-O model. This observation led many economists to propose changes to the way we look at factor endowments. For example, some suggestions include looking at capital, not just in terms of financial capital but also in terms of human capital.

Labor in the United States may be more productive than other countries, providing the United States with a rich endowment of human capital. Thus, what we consider an export of labor-intensive commodities may in fact be an export of human capital–intensive commodities. Some economists also suggested that the factor endowments may be less important than the demand conditions. This hypothesis, known as the Linder hypothesis, suggests that demand conditions between different countries determine the flow of trade such that countries with similar demand conditions trade with each other.

Michael Porter proposed that a nation's competitive advantage is determined by the factor conditions, demand conditions, related and supporting industries, and strategy, structure, and rivalry in an industry. The factor conditions in Porter's model relate to the factors which are created (such as skilled labor, infrastructure, and capital), rather than inherited (such as the traditional factors of land, labor, natural resources, etc.). Thus, even though the differential factor endowments between different countries may not be able to fully explain the trade flow across all countries and in all industries, it does help in understanding the competitive advantage of nations.

Fair Trade

The modern fair trade movement evolved in Europe during the 1960s as an outgrowth of leftist student organizations protesting multinational corporations' "exploitative" trade relationships with producers in economically vulnerable developing countries. In 1968 the United Nations Conference on Trade and Development adopted "Trade not Aid" as its mantra, and focused its transnational organizational efforts on establishing a commercial fair trade framework between multinational corporations ("importers") and economically developing nations ("exporters").

Since 1994 the European Union (EU) has been on record supporting fair trade, with the European Parliament passing the Resolution on Fair Trade in 1998, and the European Commission in 1999 adopting the Communication from the Commission to the Council on Fair Trade. On July 6, 2006, the European Parliament unanimously passed "Fair Trade and Development," a resolution suggesting the development of an EU-wide policy on fair trade.

Fair trade advocates argue that there is both a market failure associated with the present international trade system and a long-term commodity crisis adversely affecting developing-country producers. Addressing the former criticism, Oxford University professor Alex Nicholls and Charlotte Opal, director of product development, Transfair USA, argue that the present international trade system results in market failure, as

> key conditions [e.g., perfect market conditions, access to markets and credit, and the ability to switch production techniques and outputs in response to market information] on which classical and neoliberal trade theories are based are notably absent in rural agricultural societies in many developing countries. … [Thus, these fundamental assumptions] are fallacious in the context of agricultural producers and workers in developing countries.

Furthermore, concerning the latter criticism, as a result of unregulated competition in global commodity markets since the 1970s, prices for many agricultural developing-country exports, including cocoa, coffee, cotton, and sugar, have fallen by 30 to 60 percent. Fair trade advocates do not believe that current market prices for many agricultural commodities reflect the actual costs of production, including environmental and social costs absorbed by producers, and therefore recommend a stable minimum price system remedy.

According to a definition developed in December 2001 by an informal group of four major international fair trade import federations, which include the Fairtrade Labelling Organizations International, International Fair Trade Association, Network of European Workshops, and the European Fair Trade Association, popularly referred to by the acronym FINE:

> Fair Trade is a trading partnership, based on dialogue, transparency and respect that seek greater equity in international trade. It contributes to sustainable development by offering better trading conditions to, and securing the rights of, marginalized producers and workers—especially in the South. Fair Trade Organizations, backed by consumers, are engaged actively in supporting producers, awareness raising and in campaigning for changes in the rules and practice of conventional international trade.

The fair trade principles referred to in the above FINE definition include the following guidelines:

Sorting fair trade coffee in Guatemala. The International Fairtrade Certification was in use in 58 developing countries by 2007.

- Fair Price. Farm and handcraft cooperatives are guaranteed a "floor" price from importers (referred to as a "Fair Trade Minimum"); in addition to this minimum guaranteed price, a premium price (referred to as a "Fair Trade Premium") is added by importers for the sale of certified organic farm products, for example.
- Fair Labor. Agricultural and handcraft workers are entitled, when they deem necessary, to the freedom to associate (i.e., the opportunity to join a labor union), equal employment opportunities, safe working conditions, and to receive living wages. Also, no forced labor or exploitative child labor is employed in the production process.
- Market Access and Sustainable Trading Relationships. Importers will make every effort to develop long-term, direct purchasing relationships with agricultural and handcraft cooperatives, thereby eliminating so-called middlemen in the supply chain; increasing profit margins for producers; and further developing farmers and crafts peoples' knowledge base and business skills, thus allowing them to effectively compete in the global marketplace.
- Democratic Cooperative Organizations and Community Development. In free association, farmers and craft workers democratically, and transparently, decide how to invest fair trade revenue in sustainable business operations and, with their Fair Trade Premium revenue, community social, economic, and environmental development projects.
- Environmental Sustainability. Farmers utilize environmentally safe and sustainable agricultural production methods that protect owner/employee health and preserve the ecosystem for future cultivation.
- Consumer Awareness. By informing consumers of the need for social justice and trade opportunities, fair trade organizations advocate for developing country producers to acquire consumer support for reform of international trade rules, leading to an equitable international trade system (as the current system of international trade is "unfair").

When discussing fair trade, there are generally two complementary approaches to trading/marketing agricultural and craft products to consumers:

- Integrated Supply Chain. Fair trade organizations, also referred to as alternative trading organizations, employ their marketing expertise (including public awareness campaigns) to import and/or distribute their clientele's products to consumers.
- Product Certification. Products complying with established fair trade international standards are formally certified, utilizing a consumer-friendly labeling "mark," to have been produced, traded, processed, and packaged according to the applicable specifications listed in the international standards.

Fair trade products are, whenever possible, verified by a credible, independent assurance system. The fair trade product certification system is designed to allow consumers to identify a product (generally, although not exclusively, agricultural in nature) by a "mark" that informs him/her that it meets certain environmental, labor, and development standards (based upon the fair trade principles described above) in all aspects of production and distribution in the supply chain.

In 1997 the Fairtrade Labelling Organization (FLO) was formed as a centralized "umbrella" organization of 12 fair trade labeling organizations (now consisting of 23 member organizations, traders, and external experts), and in 2002, FLO initiated its International Fairtrade Certification Mark (or the Fair Trade Certified Mark in the United States and Canada), which is granted for a product inspected and certified by its independent certification body, FLO-CERT (which itself follows the ISO 65 standard for product certification). FLO-CERT, created in 2004 (along with FLO International, the standard-setting entity), operates with a network of 72 independent inspectors who regularly audit producer and trade organizations to verify and report on organizational (producer and trader) fair trade practices.

As of 2007 the International Fairtrade Certification is used by 632 organizations in 58 developing countries on a range of products, including bananas, cocoa, coffee, cotton, footballs, fruit juices, herbs, honey, nuts, spices, sugar, and wine, among others. In 2007 fair trade–certified product sales were $3.62 billion globally, with the 2005 Just-Food Global Market Review forecasting fair trade–certified sales of $9 billion in 2012, and $20–25 billion by 2020.

Criticisms of Fair Trade

Opponents of fair trade argue that this concept is similar in application to a farm subsidy. As such, they posit that establishing a Fair Trade Minimum price for a product, which in many cases exceeds the market price, encourages existing producers to expand production while signaling new producers to enter the market—the result being excess supply leading to lower prices in the non–fair trade market. While the fair trade market may benefit such producers in the short-run, there are potential long-term effects on country development and economic growth. For instance, economic theory suggests that when low prices result from surplus production, in this case when artificially raising prices, it will only encourage expanded supply and the misappropriation of human capital into less productive economic activities. Other critics of fair trade argue that the present fair trade standards (as they pertain to product certification) are not strict enough or call for the establishment of a fairer, autonomous trading system not beholden to major retailers and multinational corporations.

Proponents of fair trade respond to critics, especially those employing the above mentioned market price distorting argument, by claiming that fair trade pricing does not "fix" prices, but establishes a product price floor to ensure that farmers and craft workers can meet their cost of sustainable production should market prices fall below this minimum sustainable level. They further argue that the Fair Trade Minimum price is not a "fixed" price, but only represents an initial starting point for business negotiation, as many fair trade producers who deal in differentiated products, such as coffee bean growers, routinely earn above this price floor for their higher quality, blends, packaging, and social responsibility features associated with their products. Moreover, fair trade proponents argue that, beyond the direct market benefits, there are other nonmarket benefits associated in the fair trade value chain, including increased technical assistance, democratization of markets, and crop diversification programs.

Family Leave

Family leave is a policy providing employees a job-protected leave from employment during a period of unusually demanding family responsibilities. The main reasons for family leave are the arrival of a new child or the serious illness of a child, spouse, or parent. The intergenerational structure of family leave is particular to the United States. Most other countries have maternity or parental leave policies that are separate from any policies providing leave for the care of an ill spouse or parent. Because the United States is unique in this respect, the discussion below centers on family leave policy in the United States. A more extensive international comparison of parental leave policy is found under the heading "maternity leave."

Until 1993, the United States was one of the few industrialized countries without national family leave legislation, and the United States still stands out in having particularly minimal support for employees. At the federal level, the 1993 Family Medical Leave Act (FMLA) governs family leave policy. The FMLA requires public employers and private employers with 50 or more workers to offer job-protected family or medical leave of up to 12 weeks for qualifying employees (those who worked at least 1,250 hours for the employer in the previous year) who need to be absent from work as a result of the employee's own serious illness, the serious illness of a child, spouse, or parents, or the arrival of a new child by birth, adoption, or foster care. The FMLA does not provide paid leave, although it does require employers who provide health insurance to continue coverage during the leave period. The FMLA does not apply to employees who care for in-laws, grandchildren who care for grandparents, or same-sex couples. Because of limitations on who qualifies, the FMLA covers fewer than half of the nation's private sector employees.

The historical origins of the FMLA lie in a long debate between protectionist policies for mothers and children and equal rights in the workplace for women. Beginning in the 19th century, many states passed protective legislation placing limits on women's work, excluding them from night shifts and hazardous duties, for example. The rationale for special treatment for women was their reproductive and maternal role. However, in the 1960s, the equal rights movement challenged protective legislation, arguing that it limited women's role in the workforce. Title VII of the 1964 Civil Rights Act prohibited employment discrimination on the basis of sex, and the 1978 Pregnancy Discrimination Act further established the principle that men and women were to be treated equally when they were unable to work for medical reasons.

By the 1980s, as legislators were beginning to craft federal family leave policy, the course was set toward a policy that would treat men and women workers equally. Democrat Pat Schroeder introduced the first family leave bill in Congress in 1985. The 1985 bill was voted down, as were subsequent bills in 1986 and 1987. In 1990 Congress passed a family leave bill that President George Bush vetoed. As federal initiatives foundered, many state legislatures enacted state-level family or parental leave policies, beginning with Connecticut in 1987. By the time President Bill Clinton signed the FMLA into law in 1993, 32 states had adopted state-level leave policies.

After the passage of the FMLA in 1993, the frontier in family leave policy shifted back to the states. California in 2004 was the first state to enact paid family leave. In California, all workers who pay into the system receive benefits of roughly 55 percent of wages while caring for a new child or seriously ill family member. Washington State became the second state to provide paid family leave in 2007, and New Jersey passed a paid family leave measure in 2008.

Leave policies of other nations differ from those of the United States in three major respects. First, the policies of other nations tend to provide longer periods of leave. The average leave provided in OECD nations is 10 months as compared to less than three months in the United States. Second, most countries provide some sort of wage replacement. A Harvard/

While 1993 legislation provided some relief for U.S. caregivers, average leave in some countries is still over seven months longer.

McGill study of 173 nations found that 169 guarantee paid leave to women in connection with childbirth, and 66 provide paid paternity leave to fathers. Finally, the policies of most other countries apply universally (to all mothers, fathers, or parents) rather than only to employees meeting certain qualifications.

Feng Shui

Feng shui (pronounced "fung-shway"), literally "wind and water," is a 3,500-year-old Chinese body of knowledge, the "science of placement," that advances the proposition that the buildings humans use can affect the quality of their lives. The design system is directed to allow users of an environment to benefit from *qi*, or *chi*, the flow of natural life energy. According to feng shui, every element in the physical world has its own type of energy, or "life force." The energy types correspond to elemental materials in nature, such as fire, water, earth, metal, and wood. Feng shui masters hold that chi can cause disorder and destruction unless corrected. Once chi flows properly, balance results and the obstacles and impediments in relationships, careers, family, health, and wealth-building are under control.

Feng shui is becoming popular in the West, believed to assist individuals and workers improve their quality of life. By understanding the flow of chi in an environment, feng shui practitioners claim they can learn what is lacking and make simple physical changes to improve life. In a business setting, feng shui attempts to helps owners and employees work smarter, not harder, by aligning the energy in a work space. Some Western architects incorporate feng shui techniques into their building and space designs to create a dynamic and harmonious environment to maximize productivity.

Feng shui can be used to select the location for a new facility. Paint palettes, building materials, lighting, furniture, orientation of the building and objects, and even retail product placement are designed using feng shui principles. In some cases, the beginning of construction and grand opening are decisions based on feng shui concepts. Office layout, location of work spaces (particularly desks), use of water (fish tanks, fountains), landscaping, and reflecting surfaces receive special attention from feng shui concepts.

In Asia, feng shui influences the design of most buildings and workplaces in China, including Hong Kong, Malaysia, Taiwan, and Singapore. The Coca-Cola Company, Donald Trump, Universal Studios, Virgin Atlantic, and Merrill Lynch have incorporated feng shui concepts into their buildings. At Hong Kong Disneyland, examples of feng shui design include a ballroom of 888 square meters, because eight is a number of fortune; there are no fourth-floor buttons in elevators, because pronunciation of the number four is like the Chinese word for death; cash registers are close to corners or along walls, where their placement is believed to increase prosperity; the theme park opened on September 12, told by its feng shui consultant that it was a lucky day.

Examples of using feng shui might include placing the most powerful employee farthest from the ingress door. No doorways should face each other, all corners should be rounded. Desks should be placed as far back from the entry door as possible and oriented to the door, but not directly across from the door. Plants must be healthy, water features available. The placement of mirrors is deliberate and important. For each feng shui principle, there is a corresponding rationale.

In searching for a home, some tips are that buyers should not buy if the main door is obstructed by a lamp post, a tree or an electrical pole; if the door is tilted in any way; if a beam runs across the door, inside or out; if the door is below a second floor bathroom. A kitchen should not be located in the center of the house, or where the kitchen has a stove in the center (island). Open man-made drains directly in front of a house are considered bad luck. Property where the road curves into the house, like a blade, is to be avoided, as well as alleys, narrow or wide, opposite the property. Irregularly-shaped bedrooms should be avoided; the best kind of bedroom is a square with no sloping ceilings or low ceilings.

The philosophy of feng shui has six schools of thought: the Form School, East-West School, Flying Stars School, Black Sect Tradition, Advanced Water Dragon School, and Four Pillar Astrology. The Form School concentrates on the observation of the environment inside and outside. The outside focus is on four animals (turtle, dragon, phoenix, and tiger); colors; mountains, rivers, and trees; and neighboring buildings and streets. On the inside, the School concentrates on pathways, furniture placement, color schemes, and walls and windows and their placement. East-West School determines specific locations and orientations, based on compass readings, for beds, desks, and people using a room.

The Flying Stars School is an advanced school based on compass readings, and includes consideration of the year the home or office was built. This School is the only one that takes the time factor into consideration. A Flying Stars consultant claims to be able to tell what has happened in the past and avoid similar patterns in the future. Corrections are based on five elements (water, wood, fire, earth, and metal) to restore energy balance. The Advanced Water Dragon School is more advanced, very specialized and more detailed than the Flying Star School. Four Pillar Astrology is not so much a feng shui school, but uses astrology in combination with feng shui to personalize adjustments.

Black Sect feng shui is a combination of Chinese and Tibetan Buddhist, Taoist, and folk wisdom, coupled with modern psychology and design principles. It includes individual meditation by the user, holding that the spiritual precedes the physical, and must also be adjusted for perfect harmony. It adjusts environments and the people in them.

Fiat

The history of the Italian carmaker Fiat, also FIAT (i.e., Fabbrica Italiana Automobili Torino, that is, the Italian Automobile Factory of Turin), has shaped the development of Italy’s car industry and has been considered the icon of Italian capitalism. Today, Fiat produces in 61 countries with 1,063 companies that employ over 223,000 people. The 2007 revenue was equal to €58,529 billion and the net income was equal to €2.054 billion.

The company was founded in 1899 by a group of investors including Giovanni Agnelli, who eight years later became the main shareholder. Shortly after World War I a transformation in the system of production was undertaken along the lines of Taylorism. But it was not until the end of World War II that a system of mass production could develop. Thanks to the Marshall Plan and the European Recovery Program, a reorganization of the system of production was undertaken. During the Italian golden age of economic growth, the internal market expanded. The Turin firm may also have benefited from this as a result of heavy protectionism.

Starting from the early 1990s the automobile manufacturer experienced a major financial crisis. Among the causes: A loss of market share in Italy and Europe, and the downward trends in market demand; in many of the emerging economies that Fiat entered, registrations stagnated. As a result of the enormous debts accumulated, the major Italian banks intervened for the recapitalization of the company. After an early-terminated alliance with General Motors and an additional financial intervention of the banking system, both a major restructuring of the corporate organization and a redefinition of shareholders’ prerogatives

A 2007 Fiat 500 model on display in Turin, Italy, the city in which the now international car company was founded.

were undertaken. After 2004, Fiat managed to reaffirm the brand at home and expand abroad. In 2005, under CEO Sergio Marchionne, the Italian carmaker saw its first profits after four years of significant losses.

Among the factors that contributed to the success of Fiat, four appear to have played a key role. The first factor was diversification. The company invested both in vertical integration and in other sectors. Among the current productive activities: Fiat automobiles represent the core business of FIAT; industrial vehicles (IVECO); agricultural and construction equipment (CNH Global); metallurgical products and components (Teksid, Marelli, Comau); services (Toro Assicurazioni); and publishing and communication (*La Stampa*, *Itedi*, and *Italiana Edizioni*). The second was protectionism. In the early stages the company benefited from the closed market. In the postwar period, tariffs and quotas were also high while the mass market and mass marketing were developing. After the golden age, the company gained the status of national champion, and only under the pressure of the European Union was the Italian car sector liberalized in the early 1990s. The third, internationalization. From the early stages, Fiat exhibited a marked international attitude due to an undeveloped domestic market. This affected all initial production and the choice of markets.

In recent years, Fiat continues to try to broaden its market share in Italy, in Europe, and elsewhere in the world. In 2007, Fiat's market share in Italy was 24.7 percent, and its market share in Europe was 6.2 percent. The last factor contributing to Fiat's success is management. Among the most influential people: Giovanni Agnelli, the founder; Vittorio Valletta, who played a key role in the reconstruction of the company after World War II; Gianni Agnelli, the founder's grandson and chairman between 1966 and 1996, who undertook a significant reorganization of the company management. Sergio Marchionne, who became CEO in June 2004 shortly after Umberto Agnelli's death, introduced a major change in managerial organization. In 2009, Fiat was involved in the U.S. government rescue of Chrysler Corporation, forming a partnership with the ailing U.S. auto maker.

Fiat Money

Fiat money is a form of money that has no intrinsic value. Its value as money is based on faith in the government that issues it. This faith comes from the general understanding that the government will not create too much money nor too little. Fiat money is not backed by any commodity and therefore has no value in use other than its use as money. The name comes from the Latin word *fiat*, meaning "by decree." Fiat money has value as "legal tender" simply because the government decrees it does. Most countries today have fiat-based monetary systems.

Fiat-based monetary systems traditionally begin as commodity-based monetary systems. Commodity money has both monetary and nonmonetary uses (e.g., gold, silver, beads, shells, tobacco, etc.). Commodity money serves well as money as long as the commodity is more valuable as money than it is in its nonmonetary use. In an effort to protect or store these commodities, "representative money" (e.g., coins and paper) is issued that can be traded and easily converted into this commodity. When demand and supply conditions of the commodity or of the representative money change so that it is no longer easily converted, the representative money is either devalued or it transitions to fiat money.

In order for an object with no intrinsic value to become acceptable for use as money, certain network effects must be overcome. In other words, why do people trust it as money? An individual will only accept fiat money if he or she knows that others will accept it as money as well. This acceptance can come through government decree right away, or it can arise gradually through a system of representative money and/or fractional reserve banking.

Monetary systems based on fiat money have often historically come into existence during times of war. This happens when the expense of war exceeds the available government stock of the commodity being used as money or backing representative money. Representative money fails and governments issue fiat money to pay the expenses or debt of war. Often in these instances, governments issue too much fiat money leading to periods of high inflation. During these periods, fiat money loses its ability to serve as a store of value. Examples go back in history, such as the siege of Faenza in 1241, the cases of Germany during the Thirty Years War (beginning in 1618) and later World War I, and, even more recently, in Iraq following the 1991 Gulf War. In extreme cases, the paper it is printed on becomes more valuable as a source of fuel for generating heat than as money.

Fiat money can also evolve as part of a fractional reserve banking system. Fractional reserve banking came into existence when banks (or goldsmiths) would accept deposits in gold and issue paper notes in exchange. Patrons could redeem these notes for gold at any time. Rather than conduct transactions in gold, they began conducting transactions in notes which were lighter in weight and readily accepted. Because people would occasionally exchange notes for gold, bankers would keep a fraction of the gold in the vaults to meet daily withdrawals. They would loan out the rest, thereby creating money through issuing more notes than they kept in gold to back it up. This system works as long as not everyone wants their gold at once. Modern fiat systems today work in much this same manner except that notes are no longer convertible to gold and are instead backed by trust in the government that they will always have value. To maintain this trust, governments must exercise restraint in their willingness to create and destroy money.

Much of the Western world today converted to fiat monetary systems when the United States officially severed all ties of its currency to gold with the abolishment of the Bretton Woods system in 1971. Major Western countries had tied the value of their currencies to the U.S. dollar, which was convertible to gold. When there were many more reserves held in dollars than the United States could possibly redeem in gold, it was eventually forced to abandon the gold exchange system, effectively creating a worldwide fiat system.

Financial Hedge

A financial hedge is a transaction that reduces the risk of adverse price movements in an existing investment position. It typically involves taking an offsetting position in a related derivative financial instrument. The key derivative instruments are forwards, futures, swaps, and options, and they are commonly used to protect positions in foreign currency, commodities, stocks, and bonds.

For example, the exchange rate risk associated with a foreign currency receivable or payable at a future date can be hedged by entering into a forward contract to buy (payable) or to sell (receivable) at a fixed rate on a specified future date. This locks in a guaranteed value for a future cash flow, irrespective of market fluctuations. An alternative to hedging privately with a bank using an "over-the-counter" (OTC) forward contract is to use an exchange-traded futures contract. For example, if an inflow of currency is expected in the future (an underlying "long" position), then selling futures (going "short") will ensure that any loss in the spot value of the currency is counteracted by a gain on the short futures position.

Futures contracts may not provide a perfect hedge, either because the underlying asset is different from that underlying the futures contract or because the expiration date of the futures contract does not match the delivery date of the asset or because the standardized value of the futures contracts does not match the value of the underlying exposure. As a result, the spot price of the asset and the futures price will not converge on the expiration date, giving rise to "basis risk." Although they might not provide a perfect hedge, futures contracts, in contrast to forwards, are tradable and thus allow a hedge to be unwound prior to maturity.

Whereas forwards and futures contracts oblige two parties to make an exchange in the future, and are thus useful to hedge known exposures, an "option contract" gives one party the right, but not the obligation, to buy (a call option) or sell (a put option) an asset, under specified conditions, for a fee (the option "premium"). Options are thus useful to hedge in situations where the exposure is not known with certainty. For example, a company bidding for a foreign competitor may purchase a foreign currency call option to lock in a guaranteed price, in home currency terms, for the transaction, but may let the option expire without exercising it if the deal falls through prior to maturity.

Price risk may also be hedged by means of swap contracts, which involve two parties agreeing to exchange future streams of cash flows according to a prearranged formula. Swaps can be regarded as portfolios of forward contracts, represented by the streams of cash flows, or "legs," of the swap. These are determined by reference to either interest rates, exchange rates, equity prices, or commodity prices. Although the first swap contracts were only negotiated in 1981, swaps are now the most heavily used derivative product.

Although most financial hedging involves the use of derivative products, it is also possible to construct financial hedges using the "cash" (or "spot") markets. For example, a company can hedge against the currency risk associated with future payables or receivables by constructing a "money market hedge." This involves borrowing and investing funds via the money markets and using the spot rate to lock in the amount to be received or paid. A company expecting to receive foreign currency from a client in three months may borrow the present value of the receivable now, discounted at the foreign interest rate, and immediately convert the amount into the home currency at the prevailing spot rate. This money is then invested for three months at the home interest rate. When the foreign currency is received in three months, it is used to pay off, in full, the foreign currency loan. Because no exchange of currency occurs at this point, the future spot rate has no bearing on the outcome. If "interest rate parity" holds—that is, if the difference in interest rates between two currencies is equal, but opposite, to the difference between the spot and forward exchange rates—then a money market hedge would produce the same outcome as a forward market hedge.

Although financial hedges reduce potential losses in the event of adverse price movements, they also incur an opportunity cost if the underlying investment being hedged against makes money. Investors therefore need to make a careful judgment about future market conditions before deciding whether or not to hedge.

Financial Market Regulation

Regulation of financial markets and the persons and companies involved in financial transactions is pervasive, and the goals of financial regulation are many. Governments and regulators seek to protect consumers and investors from being taken advantage of by those with more expertise or information. To this end, regulation prohibits fraud and manipulation of markets, and imposes affirmative duties to disclose important information to customers or investors and to act in their best interests. Regulation also seeks to preserve and strengthen the stability of banks and other large financial institutions. Financial regulation evolves in response to the changing circumstances brought about by financial innovation and the continual integration of global financial centers.

Banking

Perhaps the most fundamental type of financial institution is a commercial bank or other depository institution. Banks provide the essential economic function of matching up individuals and institutions desiring to save funds with those seeking capital to borrow for investment or other purposes. Regulation of commercial banking primarily involves protecting the funds of depositors, ensuring the soundness of banks, and protecting consumers from unfair lending practices. In the United States, banks are regulated by several authorities at the state and federal level.

Bank regulation stems in part from what is thought to be banks' inherent instability. Banks typically lend more capital than they have in reserves. If a significant portion of bank loans go bad, or if too many depositors withdraw their funds at once, a bank risks insolvency. To prevent collapses and runs by depositors, governments have established safety nets, such as deposit insurance and the ability of central banks to lend in times of distress. In part because the government stands ready to provide capital to banks, it also comprehensively regulates their activities by requiring banks to disclose their practices and balance sheets and to keep a minimum level of capital in their reserves.

To reduce the risks banks take, the law may prohibit the types of activities a bank may engage in. In the United States, commercial banks are prohibited from owning stock in public companies, although bank-affiliated financial holding companies may provide insurance services, deal in securities, and underwrite new issues of securities. In countries like Germany, by contrast, banks often have large shareholdings in public companies and exercise control over management. To protect consumers who borrow from banks, regulation may require disclosures of important costs and risks to consumers, place a cap on the rate of interest charged on bank loans, and prohibit excessively risky loans to unqualified borrowers.

Raising Funds With Securities

Selling (or issuing) securities to raise investment funds is an activity widely regulated by financial regulators. Two basic types of securities are stocks and bonds. Stocks give investors an ownership stake in the company and often rights to control the company through voting. Bonds, which are a form of debt and generally safer than stocks, entitle an investor to periodic interest payments and the repayment of their investment principal at a fixed time in the future. Issuing securities to the general public requires a company to register under the Securities Act of 1933 and disclose important financial information about itself. Companies are also subject to criminal and civil liability for making false disclosures. U.S. regulation is unique in the ease with which it permits investors to bring group lawsuits against companies and their executives and the high level of enforcement by federal regulators.

Furthermore, when a company's securities are traded in secondary markets such as the New York Stock Exchange (NYSE), the Securities and Exchange Act of 1934 requires the company to make continual, periodic disclosures in the form of annual and quarterly reports, and also upon the happening of certain important events such as the announcement of a merger. In connection with purchasing and selling securities in secondary markets, individuals and companies are required to disclose significant shareholdings in other companies and prohibited from trading based upon inside information not known by the public.

Derivatives Regulation

Another type of investment product is known as a derivative. A financial derivative is a security whose value is derived from the price of some other asset or metric, such as stocks or stock indices. A common type of derivative is an employee stock option that gives an employee the right to purchase stock in their own company at a predetermined price. Another type of derivative is a futures contract, which obligates one party to deliver an asset to another on a specified date. Two other types of derivatives are swaps and forwards.

In the United States, derivatives are typically regulated by a particular financial regulator based upon what underlying asset they reference. Options on stocks and currencies that trade on exchanges are regulated by the Securities and Exchange Commission (SEC). Futures and options on assets other than stocks are typically regulated by the Commodity Futures Trading Commission (CFTC). Futures on single securities or narrow-based stock are regulated by both the SEC and the CFTC.

Trading On and Off Exchanges

Regulation applies to the trading of securities and derivatives by regulating the venues on which trading takes place and manner of trading on different venues. Organized stock exchanges and derivatives exchanges are regulated in the United States as self-regulatory organizations (SROs) registered with the government. The NYSE and the NASDAQ Stock Market, as well as futures and options exchanges such as the CME Group, are SROs that have a duty to regulate and discipline the companies and brokers-dealers that utilize the exchange. Exchanges must also seek approval from the government for any changes to their internal rules. Trading of securities and derivatives that does not take place on an organized exchange takes place "over-the-counter" (OTC) and is generally subject to less governmental oversight. Derivatives are overwhelmingly traded OTC, with interest rate and foreign currency derivatives constituting most types of OTC derivatives.

Investment Funds

When a company pools together money from the public and invests their money in a group of securities, that investment fund is subject to wide-ranging regulations that are designed to protect the public investors. The most widely utilized type of investment fund is a "mutual fund." Mutual funds must disclose their holdings and investment objectives to investors, daily calculate their net asset value and stand ready to redeem investors' capital, and have a board of directors to oversee the activities of portfolio managers. Mutual funds are generally restricted in their ability to charge a performance fee to investors, or engage in short selling, derivatives trading, and borrowing money to finance investments. In contrast, the regulatory situation is much different in the case of hedge funds (private investment funds utilized by wealthy individuals and institutions). Regulation does not require hedge funds to disclose information to investors, nor does it prohibit them from charging performance fees or engaging in the aforementioned trading strategies. However, hedge funds are subject to regulations.

Investment Advisers, Brokers, and Dealers

Financial regulation also applies to intermediaries that facilitate securities trades. An investment adviser is someone who gives advice to others, including investment funds, about whether to buy or sell securities. Advisers must be registered with the government if they advise a public investment company (such as a mutual fund), or advise a sufficient number of clients or funds with significant assets under management. Regulation requires advisers to put the interests of their clients above their own. A broker is a person or company that charges a price for buying and selling securities or soliciting or negotiating such trades for others. Brokers are typically subject to more stringent regulation than advisers. Mandatory broker duties include fair dealing with clients, being licensed by the government or a private self-regulatory body, executing trades for clients with a sufficient mix of price, speed, and certainty, and making sure that the securities recommended to customers are suitable for their financial circumstances and goals. A dealer is a person or company in the business of buying and selling securities, typically because the dealer owns enough of a certain security to make a market by fulfilling the buy and sell orders of customers.

Financial Markets

Financial markets provide a way for people, companies, institutions, and even governments to get the money necessary to pay for a variety of purchases for goods, services, and large capital projects. The financial markets provide a mechanism for people to buy and sell financial instruments such as stocks, bonds, commodities, and other securities. In earlier times the financial marketplace was physical, but with the advent of computers it has become "virtual" as well.

Modern financial markets evolved from older trading markets. The modern markets are more efficient because they have been able to assemble a much larger number of investors than in earlier times; they are also able to offer a much wider array of securities for trading. Financial markets have undergone many changes in the last 300 years. Many of these changes are designed to protect capital, to increase fungibles, to increase liquidity, and to provide for trading at low transaction costs. Access to financial markets has also grown enormously with the advent of computers.

Students of financial markets have developed the efficient-market hypothesis (EMH). Developed by Eugene Fama of the University of Chicago, the hypothesis claims that financial markets are "informationally efficient." In effect this proposes that information on stocks, bonds, commodities, property, and other traded assets is well enough understood that the prices of the traded items result from full knowledge. The EMH is similar to assumptions of classical economics that said that an economy had perfect mobility of labor, capital, information, and other market affecting factors. These assumptions were rather gratuitous and not completely realistic.

Another assumption of the EMH is that it is impossible to outperform the market with knowledge that the market already has. News affects financial prices. It is unknowable and acting without it is like acting with the expectation that luck will provide the answers. The rise of news sources in the 1700s accompanied the development of the Industrial Revolution. News of ships affected insurance rates; news of weather, wars, and world problems affected prices. The individual who possessed advanced knowledge could beat the market in some instances. The case of Nathan Rothschild trading on news of the outcome of the Battle of Waterloo is a classic case of trading on knowledge before others get the news.

Markets may be general or specialized. Trading in general markets includes all manner of securities. Trading in specialized markets is limited to only one or a few commodities or securities. When markets are made they create a "space" for people to engage in exchange. The market may have only a few traders or a great many bidding for the values being traded. Free markets allow individuals to trade with few or no restrictions. Command economies seek to dictate the course of the trading or its outcome. Many of the financial markets today are the product of mixed economies. That is, they are free markets that are regulated and in many instances directed. In such cases the market, instead of being the aggregate of possible buyers and sellers who are trading something, includes government directions for political, moral, or social purposes, which, however nobly justified, distort the market.

If financial markets did not exist it would be very difficult for many projects to be financed. If the project is a school or something that is of social importance but will not directly generate income it still takes money to pay for the school or project. Financing a project on a "pay-as-you-go" basis can be seen in some countries where even short-term loans are rare, so people save, build, save some more and then build some more rather than using a financial market to pay for a project.

Banks are key institutions in the financial markets. They use the deposits of their depositors when pooled together as capital for lending. The loans, mortgages, and other financing activities performed by banks are the basis of the modern financial system. However, financing often requires more assets than a single bank has to lend. The use of a stock exchange or syndicated borrowing allows banks to participate but to not have excessive exposure to default risks because they are able to syndicate the financing.

Borrowers

There are a variety of borrowers that enter into the financial markets. They include individuals, corporations, governments, publicly traded joint-stock companies, and other private institutions. Individuals seek loans from banks for short-term financing. Sometimes the loan may be for capital consumer goods such as a refrigerator. Or it may be for much larger financing in order to buy an automobile or a mortgage for a house or a farm.

Companies are constantly seeking capital for both short term financing or for longer term projects. For instance the financing of automobiles means that the dealer has to have an inventory and then has to see that the automobile is paid for through borrowing if the purchaser does not have the cash to make the purchase. If credit is easy then financing is readily available, even at subprime rates. However, if corporations cannot finance their inventories or sales until payment arrives then it is difficult to do business except with older methods of cash on delivery. For example, college textbook stores buy millions of dollars worth of books every year. They usually pay the textbook company after the arrival of the books. Sometimes payment is made after the income is generated from the sale of the books; without financing business would be slower and at a much lower volume.

Governments are borrowers of huge sums of money. In many countries spending by the government exceeds the revenue from taxes, fees, and other sources. Budget deficit borrowing is a nearly universal practice. The collateral for the loans is in theory the entire country. However, collecting by a lender would be difficult unless another government were to become its collector. In the 19th century this was a frequent practice. Public corporations may be government-owned enterprises such as post offices, railroads, or utilities such as the Tennessee Valley Authority. These types of institutions also engage in significant financing. They often borrow through the use of international agencies that facilitate lending through the foreign exchange markets.

Organization

Financial markets are either domestic or international. With the rise of computers and global trading the world's assets have become available for lending. Consequently financial markets may be domestic but with foreign assets that are hard to distinguish. Or trading or borrowing may be international for domestic purposes by a government or for a local project. Much of the debt of the United States is owed to foreigners; on the other hand billions of dollars have been invested in foreign countries through the World Bank or foreign aid.

Markets that handle billions of dollars in exchanges have to be organized to facilitate the volume in trades and values. So "market" often refers to the exchanges where board of trade or other kinds of organizations facilitate transactions. These are stock exchanges, bond exchanges, commodity exchanges, or other exchanges for the trading of values. They may have a physical location such as the New York Stock Exchange, or the Chicago Mercantile Exchange. Or with the emergence of the internet they have an electronic system of exchange such as that of the NASDAQ. With electronic trading between institutions through computer programs the exchanges are executed in huge volumes and values. Globally the move is to electronic exchanges that can handle volume in the billions of dollars per hour or more.

Financial markets do more than provide places of exchange. Capital markets enable businesses and others to raise capital for business operations, investments, projects, or other activities. They also allow the use of derivatives for the transfer of risk. In the case of currency markets they provide a mechanism of international trade.

Capital markets may be primary markets or secondary markets. In primary markets money is raised by the issuance of new securities. Funding sought by governments, businesses, or other institutions can be raised by sale of new stock or new bonds. Capital marketing is usually done by a syndicate of securities dealers who act as underwriters. The process of underwriting a new issue of a security, called an initial public offering (IPO), usually produces cash for the borrowers, investments for the lenders, and fees for the securities dealers. The details of the IPO have to be stated clearly in the investment prospectus. In the United States a prospectus that is deceptive in some way can put those responsible into serious legal jeopardy. Many other countries also have stringent requirements for capital investment prospectuses.

Financial markets that are secondary capital markets are used for the exchange of securities that have been on the market for some time. For example, shares of General Electric that were issued 25 years ago would be in the secondary market and probably traded as part of the liquidation of an estate or for other reasons that made it practical for the investor to sell them. Secondary markets can exist in any type of good. Flea markets are a basic example of a popular secondary market. In financial markets the "aftermarket" is the market that exists just after the issuance of a new IPO. It is in effect the beginning of the trading in that market. Mutual funds are a way to invest in a basket of stocks, but with the aid of mangers who can supervise the investments.

Submarkets

There are a number of ways to array the types of financial markets as a variety of submarkets. The capital markets include the stock markets and the bond markets. Stock markets provide mechanisms for trading that finances corporations through the introduction of new public offerings of shares of a new company or of additional shares of an established company. For a new business such as a computer or stem cell company, shares purchased from it by investors offer the company a way to get capital and share with purchasers a way to invest in the growth potential of the company. Sometimes the investment may be a speculative play, but so is trying a new variety of seeds or a new crop for which a market has to be developed. In both instances the speculation is a gamble but it is based upon, or should be, much more rational calculations than games of chance at a casino.

Bond markets are mechanisms for financing all manner of projects. Borrowing from banks or other sources of capital and using the money for schools, hospitals, roads, dams, or other infrastructure projects that generate long-term cash flows of interest and the return of principal have been traditionally practiced for decades. Laws in the United States exempt interest paid to states or localities from federal taxation in order to encourage this type of financing. It lowers the cost of the borrowing for the states or localities by making the investment easier to repay at a lower cost and by allowing investors to go untaxed.

Commodity markets are centers for the exchange of livestock, grains, or other agricultural products or the exchange of metals or other non-agricultural items. Diamond exchanges in the diamond centers are commodity markets, as are local cattle sale barns. High volume sales are those through exchanges such as the Chicago exchange.

Money markets allow businesses or other institutions to engage in short-term borrowing of large sums of money. For many institutions the "petty cash" of their huge number of investors is a large sum that can be profitably loaned without concern that all investors will want all of their petty cash at one time.

The market in derivatives is relatively new. It provides a mechanism for exchanging instruments that carry a higher risk of default and loss because the underlying values may include subprime loans. Using derivatives allows for the management of risk.

Futures are contracts for the future delivery of something, usually a commodity such as sugar to a bakery, or cotton to a spinning mill. The futures contract locks in a price for the producer who is in effect a commodity consumer at the time of delivery and use. By hedging on the price, which for the industrial user is a form of cost averaging, the futures market creates futures contracts that permit speculators to maintain and stimulate the market.

Forwarding contracts are sold in forward markets. They are a form of financial market securities. Forward contracts are agreements between buyers and sellers to buy something at a future time for a set price. For a grower of the hops used in making beer the spring forwarding contract locks in a price guarantee. The brewer is also guaranteed a product at a known price at a future time that will allow for the continued brewing of the beer. However, if the brewer were to sell the forward contract in a forward market the brewer would collect the price of the hops before they were delivered. The forward price is different from the spot price, which is the price for immediate delivery.

Insurance markets are centers of exchange for distributing risks. In the days of the sailing ships the risks of sea voyages were high. As it was known that a few of those ships would be lost, the selling of shares in voyages of many ships was a way of spreading the risk. Today all manner of risks are insured against, from ships at sea to sexual misconduct by clergy. The insurance markets provide a way for engaging in risk management as a hedge against losses. The losses are contingent upon some act of nature, or in more recent times some kind of malfeasance. Without insurance markets many forms of activity would be viewed as too risky. On the other hand some critics have charged that insurance may make the insured less risk-averse than they should be.

Foreign exchange markets are centers for currency changing. Doing any kind of business other than bargaining requires some type of medium of exchange. Currencies are the most efficient media of exchange. Some currencies such as the dollar, the euro, the yen, or the Swiss franc are in much higher demand than are the currencies of countries that are war torn, economically depressed, or not heavily engaged in the global economy. Currency exchanges, through computers, now more than ever permit global trade to take place at much higher levels and at much higher rates than ever before. The retail currency trading market is global. It is called the "retail forex" meaning the retail foreign exchange (or retail FX) market. It has become the center of huge payment transfers. Retail currency trading allows currency speculations and currency exchanges to set the price of currencies based on supply and demand for those currencies as they are needed to pay for goods and services in the global market.

The foreign currency exchange rates ("forex") market is a subset of the larger foreign exchange market. Its prices are set by market forces. The participants in the markets are individuals and companies. At the present time many companies offer off-exchange foreign currency futures as well as option contracts.

The FX market had perhaps $90 trillion available around the world for investments until the credit crisis of 2008. However, it still is the center for the exchange of currencies between large banks, currency speculators, governments, and others. As goods are traded, and tourists collectively spend billions in dollars or other currencies, the daily volume in currency exchanges as currencies seek repatriation is huge. The Bank for International Settlements supervises and coordinates the regulations that promote stable international currency exchanges.

Financial Reporting

Financial reporting maintains the official records of a business's financial activity, in the form of specific financial statements. The purpose of financial reporting is to strike the right balance between a complete accounting of the relevant data, and a legible, understandable presentation. The "audience" of such reports can, and generally will, include parties within the company who need to know the business's position and progress; labor unions and parties with a similarly vested interest in the business's well-being; shareholders or prospective investors and their agents; external authorities such as lending institutions and government tax authorities; and the general public.

Financial reports provide a picture of the company's activity at a particular time or over a particular period of time. The standards to which reports are held are determined both by the Generally Accepted Accounting Principles, which adhere in the United States, and the International Financial Reporting Standards (IFRS) adopted by the International Accounting Standards Board. In the United States, adherence to IFRS is being phased in gradually, with all American companies expected to adopt them in their accounting practices by 2014. Currently, IFRS obtains in the European Union (EU), Australia, the nations making up the Cooperation Council for the Arab States of the Gulf, India, Pakistan, Hong Kong, Malaysia, Singapore, and Russia.

Most sets of accounting standards call for four basic financial statements. The balance sheet presents the company's financial situation at a specific point in time—generally the end of the fiscal year. The company's assets and liabilities are listed in full. The assets minus the liabilities are the net worth of the company—the shareholders' equity, as it is sometimes called. The balance sheet is the most basic financial statement, a product of the double-entry bookkeeping system (though individuals employing the single-entry bookkeeping system used for balancing personal checkbooks can also determine their net worth with such a balance sheet). Of course, the net worth of a company (or an individual) is not the same as its available cash, since much of what it owns will be in assets such as equipment, inventory, real estate, intellectual property, and so on. These various assets will be listed on the balance sheet. Contingent liabilities are also listed: liabilities that may or may not need to be paid at some point in the future, such as those owed from lawsuits pending, or the expense of upholding a warranty or money-back guarantee. Ideally, the balance sheet will note the likelihood of loss associated with each contingent liability (large companies issuing warranties have a general sense, as demonstrated by their past fiscal records, of how much those warranties cost them).

An income statement, profit and loss statement, or simply P&L, is narrower than the balance sheet, and accounts for the company's net income. The net income is also called the bottom line, coming as it does at the end of a sequence of subtractions (the expenses), which follow the top line: the revenue, all the money collected by the company. The net income is how much the company is "actually making," over a given period of time. The income statement will note different kinds of expenses, such as the depreciation associated with capitalized fixed assets, the administrative expenses spent on running the business, and the sales expenses incurred by the process of getting the product to the customer (including sales commissions, freight, and advertising). Irregular items are noted in a special section, such as discontinued operations, natural disasters, relevant changes in government or industry regulations that affect the business, and changes to the business's accounting practices. The income statement also reports the earnings per share.

The statement of retained earnings records the changes in a company's retained earnings over a specific period of time. It is usually presented along with a balance sheet and a P&L, and essentially expands the coverage of the changes to the company's net worth, through profits, losses, changes in assets, and so forth.

The cash flow statement is of special interest to lenders, contractors, and other parties interested in letting the company be in debt to them. It looks specifically at the company's cash inflow and outflow, which has special importance in the short term because a company that is worth a great deal but has little cash on hand will have difficulty paying its bills.

Financial reports are included as part of a company's annual report, made available to shareholders. Blue chip corporations have traditionally issued expensive, elaborate annual reports, often hardcover and filled with photographs; as the internet has provided faster ways of making information available, this has become less common.

Financial Statement Analysis

Financial statement analysis is a methodology that enables stockholders, potential investors, creditors, and managers to evaluate past, current, and future performance of a company by examining relationships among financial statement elements. It involves examining trends, making industry comparisons, and analyzing the financial health and growth prospects of a company. Financial statement analysis can be performed independently by interested parties, by companies themselves, or by financial analysts who study certain industries and provide information so that investors can make informed decisions with respect to the purchase and sale of stocks, bonds, and other financial instruments. Financial statement analysis is comprised of three types of analyses: ratio analysis, horizontal analysis, and vertical analysis.

Ratio analysis is the most popular form of financial statement analysis. It is used to express relationships among selected items on financial statements and is useful for intracompany, intercompany, and industry average comparisons. Intracompany analysis compares a company's prior year with the current year, intercompany analysis compares a company with its competition, and industry averages compare a company with industry benchmarks or norms (e.g., those provided by organizations such as Moody's, Standard and Poor's, or Dun and Bradstreet).

Ratio analysis can be expressed as a percentage, rate, or proportion and is generally classified into four categories. Liquidity ratios (e.g., current ratio, acid test ratio, inventory turnover ratio, working capital) measure a company's ability to meet it current obligations, i.e., those due within a year. These ratios are of interest to short-term creditors (e.g., bankers, suppliers). Solvency ratios (e.g., debt-to-equity ratio, times interest earned ratio) gauge a company's ability to meet long-term obligations and survive over the long term. These ratios are of interest to stockholders and long-term creditors. Profitability ratios (e.g., return on assets, asset turnover ratio, return on equity, gross profit ratio) provide an indication of a company's operating success. These ratios are of interest to creditors and investors. Finally, market indicator ratios (e.g., price earnings ratio, dividend yield ratio) relate the market price of a share of stock to what investors would be willing to pay.

Horizontal or trend analysis involves analyzing financial statement data by comparing both dollar and percentage changes for a given company over time to determine the increase or decrease that has taken place. Although this type of analysis can be used for comparison between two years, it is more informative when several years can be compared and a trend can be depicted. Horizontal analysis can be detailed (e.g., comparison of each line item on the financial statements). Alternatively, selected items may be extracted (e.g., sales, net income) to analyze trends for specific financial statement items.

Horizontal analysis requires restating financial statement items as a percentage of some selected base year. For example, if a 10-year period (e.g., 1997–2006) is being considered, each item in the analysis could be restated as a percentage of the corresponding item in 1997. Information is presented with the most recent year appearing first (e.g., 2006, 2005, ... 1997). Horizontal analysis is primarily used for intracompany comparisons.

Vertical analysis evaluates financial statement data at a given point in time by expressing each financial statement item as a percent of some base amount. This approach produces what is referred to as common-size financial statements. Balance sheet items are commonly expressed as a percentage of total assets (e.g., Cash Percentage = Cash/Total Current Assets) while income statement items are commonly expressed as a percentage of sales (e.g., Net Income Percentage = Net Profit/Sales).

Vertical analysis is particularly useful for comparisons between companies of different sizes. Comparisons that ignore size can be quite misleading. For example, if Company A has a higher net income than Company B, this is not an indication that Company A is performing better than Company B, unless both companies have the same sales revenue. To realistically assess the performance of each company, the net income of each entity would need to be expressed as a percentage of the sales revenue of each entity. This conversion to common-size financial statements reduces bias when comparisons are made between companies of differing sizes. Vertical analysis is used for both intracompany and intercompany comparisons.

Financial statement analysis that is used carefully can provide valuable information about a company's financial health and future growth prospects. However, the following caveats should be noted: (1) Financial statements are based on historical costs. Thus, they do not reflect replacement costs or inflation; (2) Companies use different accounting policies (e.g., depreciation valuation and inventory valuation). Footnotes to financial statements should therefore be carefully reviewed to ascertain the accounting policies used. When policies differ, it will be necessarily to restate the data for the companies being analyzed using a common policy in order to make a meaningful comparison; (3) Ratios can be calculated using different variations. The composition of items that are used in the calculations should therefore be investigated in order to make a valid comparison; (4) Financial statements contain many estimates (e.g., uncollectible receivables, contingent losses). Users should therefore be wary that inaccurate estimates will provide inaccurate ratios and percentages.

Finland

Finland, one of the five Nordic countries, is a small, open economy, with a population of 5.5 million people. Finland is a republic and a parliamentary democracy. It is officially bilingual, with a Finnish-speaking majority and Swedish-speaking minority (6 percent). Finland was a part of Sweden until 1809, when it was annexed to Russia as an autonomous Grand Duchy. Under Russian rule, the country experienced extensive economic autonomy. In 1917 Finland gained independence.

Finland belongs to the 20th richest countries in the world measured by gross domestic product (GDP) per capita. It is also ranked as one of the most competitive economies, renowned for some large global corporations, mainly the mobile phone producer Nokia. Also, the largest Finnish paper companies, StoraEnso and UPM, are among the largest paper corporations in the world, ranking third and sixth, respectively, in 2006.

Finland is a successful late-comer, experiencing a rapid catching up by exploiting the advantages arising from the international division of labor. The country has actually been one of the fastest-growing economies in the world over the last century, but the economy has also been highly volatile. Finnish industrialization took off in the late 19th century. The industrial development was also swift in the inter-war period, while the 1930s Depression, measured in GDP figures, was reasonably mild. The favorable development continued after World War II and by the 1980s Finland had caught up with the leading industrial nations. In the early 1990s the country was, however, hit by a deep depression called forth by a simultaneous collapse of the extensive trade with the Soviet Union and an international recession, combined with severe domestic economic and structural problems. Finland experienced negative growth during three subsequent years (1991–93), adding up to a total fall in GDP of about 10 percent, followed by debt-deflation problems, a severe banking crisis, and high unemployment. In the late 1990s, the recovery was swift. The international economic boom, Finnish membership in the European Union (EU) in 1995, the expansion of new branches and the success of some large corporations—"the Nokia phenomenon"—promoted the recovery.

By being a small, open economy, Finland has been heavily dependent on its export sectors. Historically, forest industry products (timber, sawn goods, pulp, and paper) sold in the Western market can be seen as the key to Finnish economic success. Today, exports are more varied, comprising electronics, metal and machinery products, and paper. Paper export is still significant, but the branch has suffered from structural problems, while new branches have expanded.

Trade with Russia has also been significant. Before independence, Russia formed the main export market, while in the postwar period bilateral trade with the Soviet Union was extensive, the exports amounting to 26 percent of total exports in its peak year of 1982. Finland exported primarily metal and textile products to the Soviet Union, and imported oil. This trade ended in 1991 with the collapse of the Soviet Union. Russian trade was, however, growing again by early 2000.

Finland's historical, political, and economic development shows many similarities with the other Nordic countries, but Finland's development path has also had its distinctive marks. The Finnish economy has been more crisis prone than the other Nordic economies. The country was long dependent on one single, highly cyclical branch (the forest industry), but the economic policy also aggravated the cycles. Finland has also been susceptible to outside shocks, most notably the wars.

Finland is a capitalist market economy, but its model of capitalism has undergone profound and sometimes abrupt transformations over time. The late 19th century was a period of economic liberalism, while the postwar period until the 1980s was marked by state intervention and strict regulation. In the 1980s and 1990s, a liberalization and opening up occurred and the economy went through swift structural and institutional transformations, leading to a rapid growth in the inflow and outflow of capital and foreign direct investments (FDIs), decartelization, cross-border mergers with primarily Swedish companies, and a new corporate culture. The new regime was a result of Finland becoming increasingly integrated in the global economy and a member of EU in 1995, but also of a new ideological environment more favorable toward competition and the promotion of market forces.

Also some persistent features—path dependencies—are discernable in the Finnish model. A stress on enhancing growth, by keeping the investment rate high and by promoting the export sector, has been thoroughgoing. The role of the state has been prominent, although transforming over time. During the regulative environment of the postwar decades, direct state intervention was extensive. State companies have been widespread and in spite of privatization policies since the 1990s, the state is still a significant owner in big business, Nokia being an exception.

Fixed Costs

Total fixed costs are constant over a defined time period. Examples might include certain salaries and wages, depreciation, insurance premiums, heating, rental charges, property taxes, and fixed interest charges. They are “fixed” only in the sense that they do not vary in total with the short-term planned activity levels of the organization. In the long term, all costs are variable since they can be adjusted to new levels of activity following expansion or contraction.

Many costs are partially fixed. A telephone bill may contain a fixed equipment rental element and a variable call charge. Although fixed costs do not vary with activity, they can be changed by management action. Staff can be recruited or dismissed, depreciation policies can be changed, reward systems may change, insurance can be switched to more competitive suppliers, etc. A policy decision is required by management to alter the cost structure of the business. For example, managers may change payment of the sales force from salary to a salary-plus-commission basis. The total amount paid to the sales force may increase or decrease or even stay the same, but payment will now be part fixed and part variable.

Variable costs vary in direct relationship with changes in an identified causal factor (driver). So, twice as much glass is used to produce two cars as one. Fixed costs remain unaltered despite changes in their identified causal factors. Thus, the cost of employing a pension administrator will be the same whether there are 150 or 200 on the payroll. The level of variable costs is largely a technical matter—the cost of glass will be a function of the number of cars produced. But the level of fixed costs will largely be a matter of discretion for management. There may come a point at which there are not enough people on the payroll to justify a pension administrator and managers may decide to outsource this work. In general terms, when scale or activity in the causal factors change, total fixed costs will remain unchanged but unit fixed costs will change (total fixed costs divided by total units of causal factor).

The reverse is true of variable costs. Within the range of planned activity (the relevant range) for a given configuration of land, labor, and capital, fixed costs will not vary. If the scale or arrangement of this configuration is changed, then the cost structure of the business changes and will need to be redefined for business control purposes. The operational gearing or leverage of the firm describes its cost structure as a ratio between revenue minus variable cost and its profit. The higher the proportion of fixed costs in its cost structure, the higher will be the firm’s operational gearing ratio. The higher the ratio, the more exposed is the firm to large swings in profitability as market conditions change.

The behavior of fixed costs in relation to increasing levels of output is a source of scale economies. It is also a principal feature of a number of important management accounting decision support techniques. Cost-volume-profit analysis focuses on the break-even level of output which a firm must achieve to cover its total fixed costs. Only after this level does the firm achieve profits. Contribution analysis is used to optimize the use of productive resources when in short supply. Contribution is defined as price minus unit variable cost. The residual represents a contribution to the fixed costs of the business. The purpose is to maximize the contribution these scarce resources (or limiting factors) make to the firm’s fixed costs.

This form of analysis is also used for make-or-buy decisions, or decisions whether to accept special orders on terms that do not fully recover total accounted costs. This situation might arise when the firm has idle capacity. In such situations the important point is to consider only the relevant costs. In deciding to accept a contract at a discounted price, the fixed costs are irrelevant to the decision since they will not change whatever decision transpires. Provided the discounted price covers the variable cost involved in production and distribution of the contract volume, the business will be better off accepting it and making some contribution to its fixed costs. The differentiation between fixed and variable costs provides the basis for flexible budgeting. Budgets are set with an assumed level of output. In reality this level changes and the budget will be flexed with the variable element changing in relation to the actual level of activity, the fixed level remaining unaltered.

Fixed Exchange Rate

A fixed exchange rate is a monetary regime adopted by a nation's government or its central bank in the context of its international trade and finance to maintain a fixed price of its currency in terms of the currency (or a basket of currencies) of its major trading partner(s). The fixed exchange rate is achieved through a nation's intervention (buying and selling) of the designated currencies on the foreign-exchange market, a private entity. This activity by the monetary authority of a nation compensates for the disequilibria of the demand and supply between the local and foreign currencies resulting from market fluctuations and subsequently keeps the exchange rate on the desired target.

The fixed exchange regime is also referred to as a pegged exchange system, in which case a nation's currency is pegged to a major world currency such as the U.S. dollar or euro at a particular rate. A country with a fixed exchange rate regime maintains a sufficient amount of the foreign currency that it pegs to (e.g., US$) in its foreign exchange reserves in order to keep its foreign exchange regime solvent. Suppose that China fixes its currency yuan with US$. After agreeing to purchase a number of Boeing airplanes from the United States, a large quantity of US$ is demanded (or bought) by supplying (or selling) the yuan in order for the Chinese buyer to pay Boeing. Consequently, the amount of US$ decreases while the quantity of Chinese yuan increases at the foreign-exchange market. Accordingly and to counterbalance for its fixed exchange rate, the monetary authority in China will need to demand (buy or revalue) yuan from and supply (sell or devalue) US$ to the foreign-exchange market. The reserved currency or value in this case could either be in the form of cash or U.S. Treasury bonds.

Countries with a fixed exchange rate regime also need to intervene when the interest rates of the two countries are at disparity. Using the same two-country example above, when the United States lowered its interest rate during the credit crisis to save the economy in 2008, Americans demanded more yuan for higher expected asset returns in China. The central bank in China will need to infuse more yuan and buy back US$ at the foreign-exchange market. The foreign exchange reserve increases when the country runs a balance of payments (BoP) surplus and decreases when BoP is in deficit under a fixed exchange rate regime.

In more recent years, a modified version was developed within the fixed exchange rate regime adopting a narrow band around the target rate for small adjustments. Under the European Exchange Rate Mechanism, member nations have a fixed exchange rate to the European Currency Unit (ECU). The central bank of a nation may intervene to stabilize its currency if it moves out of the 2.5 percent range, plus or minus, with the ECU.

A fixed exchange rate regime provides a higher level of certainty and control for traders in goods, services, and currencies. Because it is shielded from day-to-day fluctuations in the foreign exchange market, international trade and investment becomes less volatile and incurs limited speculation. Under a well-managed fixed exchange rate regime, where there are absences of expectations in devaluation of the local currency, inflation is contained and investments in domestic assets are protected.

Nonetheless, the fixed exchange rate regime may cause a BoP crisis when there is excessive demand in the foreign exchange reserve that ultimately brings foreign currency down to zero and when the system becomes depleted. The cause of the crisis could be due to a serious deficit in the BoP with the reserve currency country because the fixed exchange rate regime does not follow market mechanisms and the lack of transparency of the system, which may also be mismanaged by the monetary authority, could cause high expectations of devaluation of the local currency. This anticipation from investors could lead to capital flight (swapping of domestic assets for foreign assets) and cause the fixed exchange rate regime to collapse.

While they offer fewer options for monetary policy, fixed exchange rate regimes can work well for less developed nations.

Under a fixed exchange rate regime, government has less control of its monetary policy for either expansion or contraction to maneuver its economy because the local currency needs to be maintained at a certain level relative to the foreign currency to keep the fixed exchange rate valid. However, the system may be suitable for less developed nations where the benefit of running a fixed exchange regime exceeds its cost in an economy that seeks an optimal level of development and control.

Flag of Convenience

A ship flies a flag of convenience if it is registered in a country other than its country of ownership. A more formal definition is as follows:

> The flag of a country with easy or lax maritime regulations and low fees and taxes, flown by ships that register their vessels in such countries, even though their ownership and main cruising areas are elsewhere.

Maritime tradition follows "the rule of the flag"—in other words, the specific flag flown by a ship determines the country's law to be applied, regardless of which court has personal jurisdiction over the parties involved, be they owners, operators, or crew.

At the present time it appears that approximately half the world's tonnage of merchant ships is registered under flags of convenience, and while (as suggested by the above-provided definition) reduced cost is a prime motivator, be this either operating costs because of low wages or the avoidance of taxes, the circumvention of "inconvenient" environmental regulations is now emerging as a significant consideration, with fishing boats, for example, ignoring conservation agreements entered into by their home countries. This situation has caused Franz Fishler, former European Union commissioner for fisheries, to describe flags of convenience as the scourge of today's maritime world. The possibility of abuse of the system to benefit arms smugglers or human traffickers is another rampant concern.

Ships registered in the United States have to be manned by American crews. Elsewhere, problems are perceived to stem from such aspects as language differences that make communication between seafarers difficult. Poor crew conditions, inadequate training, questionable safety records, and the abandoning of crew members in distant ports—all such activities have called into question the operating of a scheme that many commentators have found reprehensible. One safeguard is the international Ship and Port Facility Security Code, which requires minimum standards for vessels entering the waters of its signatory nations. Thus the United States Coast Guard can inspect vessels entering American territorial waters and refuse entry to any exhibiting significant defects.

Panama was the first nation to become a flag of convenience country and remains, to this day, the most significant flag of convenience country as measured either by gross tonnage or number of vessels (and by a very considerable margin; the *CIA World Factbook* is a useful source of comparative data). But Panama does at least have a reputation for having adopted a "responsible" attitude toward an activity that is elsewhere considered reprehensible, since it is claimed to have given rise to the adoption of lax labor laws and low safety standards, thereby leading to a reduction in revenue for countries that apply stricter standards. Thus in the Panamanian case its own consulates deal with the necessary paperwork and collect the registration fees. Compare this with the situation of "Liberian" registration (run by a company based in Virginia), or "Cambodian" registration (operated from Singapore). In other words, registration does not even have to occur in the country where the vessel is supposedly based. Interestingly, to offer a flag of convenience facility it is not even necessary to possess a seaboard. Thus, ships may even be registered in La Paz (Bolivia is landlocked) or Mongolia (the largest landlocked country in the world).

The sinking of the oil tanker *Prestige* off the Spanish coast in 2002 heightened concern over who should pay for the damage in such a circumstance, and there is much opposition to the flag of convenience system and the abuses to which it is seen to give rise (in fact, of the absolute tonnage lost to maritime accidents in 2001, 63 percent of the total was accounted for by just 13 flag of convenience registers). Various international bodies have come down heavily on the practice, including the World Wildlife Fund, which is attempting to develop a review of the system and ensure that flag states (the country in which a vessel is registered) meet their responsibilities in applying and enforcing international shipping standards, and that the guilty party is held responsible for the consequences of poor shipping standards and practices. Additionally, the International Transport Workers' Federation, in association with the International Maritime Employers' Committee, now collectively negotiates pay scales for seafarers on flag of convenience ships.

There are, inevitably, supporters of, as well as detractors from, the flag of convenience system. The principal argument mounted here is likely to be that of arguing that the owners of a vessel engaged in international trade should be unencumbered in their choice of jurisdiction (the concept of laissez-faire taken to its logical conclusion, perhaps). Other advantages may exist in terms of a sophisticated maritime court structure and/or vessel financing possibilities. But the overriding consideration has to be that of keeping operating costs lower than would be imposed through registration with a (largely) non–flag of convenience nation such as the United States or United Kingdom.

Flexibility

Flexibility in the workforce (also known as alternative work arrangements or nonstandard work arrangements) is comprised of flexibility in working time, flexibility in work location/space, flexibility in the number of workers within a firm's workforce, and flexibility in employee skills and abilities. Such arrangements enable firms to more closely match their labor force needs with the demand for labor, and thus have become more desirable in recent times when just-in-time production, globalization of the workforce, and changing customer preferences and demands have required companies to alter how they allocate human capital. Flexibility has been associated with "work-life balance" (also called "family-friendly benefits" or "arrangements"), where employees negotiate or utilize policies for shifting work hours and location to accommodate personal commitments along with their work priorities.

The use of flexibility in work allocation has been in use for years, but this notion has been particularly prominent during the last 25 years. During and for a period after the Industrial Revolution, as work and working hours became standardized, the "nine-to-five" workday and the "40-hour" workweek became commonly expected. This was also congruent with the more typical family life, where the (male) head of household was likely to be the wage earner. However, as shifts in consumer preferences, family arrangements, globalization, new technologies, and other recent issues have impacted the dynamics of the firm and the labor force, the focus on working hours and location for employees has changed to meet these challenges. In addition, employees have had to become flexible and many have had to expand their skill bases to meet firm demands for particular competencies. Larger firms tend to develop and implement policies that enable workers to take advantage of flexible work arrangements and to allow managers to utilize discretion in their allocation. Smaller firms usually use much more informal agreements, with individuals negotiating with employers for individualized deals with respect to flexibility in work.

Work flexibility manifests itself in a variety of formats. Historically, shift work, though often entailing consistent work hours, has been considered to be an alternative work arrangement, since this can often require employees to work during the nighttime hours. The most common types of flexibility for the internal workforce involve variability of work hours. This can include the compressed work week, where workers condense a full week's worth of work hours into fewer days; and flextime, where employees can shift their work hours to any hours of the day, as long as they are present and/or available in the firm for a set of core hours each day (for example, between the hours of 10 A.M. and 2 P.M.). Part-time work can also fall into this category, with some companies utilizing job-sharing arrangements for jobs that lend themselves well to this. Job sharing can allow two part-time employees to share one position, and often there is one day of "overlap" where one partner can hand off the week's work to the other job-share partner.

Workplace location can contribute to work flexibility: Many organizations have utilized telecommuting as a way to accommodate individuals who need flexibility in their work hours or work space. Telecommuting can involve working from employees' own homes, or from satellite offices. When employees need to be in a variety of offices, employees can sometimes engage in hotelling, where employees set up a temporary office for a day in a vacant cubicle or office at a firm or client site. Contingent/contract work also falls under work flexibility, particularly in terms of using external labor. This type of precarious work (also called temporary work) often entails fixed-term contracts for workers who are contracted to the firm, but are not employed as permanent employees. In this case, employees have the ability to work at multiple firms for short periods—but companies often do not have to pay these workers healthcare and other benefits, making them a less expensive and highly flexible source of labor. A different form of flexibility, called functional flexibility, relates to employee flexibility in terms of skills (also called multiskilling).

There has been considerable discussion of the ethics of introducing flexibility in the workplace. Flexibility in the workforce has been implemented by many firms to the benefit of both employers and employees. It has proven advantageous to those who need to balance work and personal commitments, particularly skilled workers. For firms, being able to schedule work in a just-in-time manner to accommodate product supply and demand more appropriately, to account for fluctuations in production due to seasonality, nuances in the economy, changing customer tastes, etc., has helped them to become more competitive players in the global market.

While there have been numerous benefits to both parties, there have been some documented problems with overreliance on workforce flexibility. In some firms, innovation has been stifled, as there are often low levels of commitment to the employer by such workers. In addition, these employees often do not have access to training and other benefits that firms often provide to their core and permanent workforce. In effect, they have a different psychological contract than their permanent and full-time counterparts, whereby they feel less connected to their employers. In addition, there have been demonstrated occupational health problems with nonstandard workers.

Flexible Exchange Rate Regime

In contrast to the fixed exchange rate regime, the flexible exchange rate system encompasses various forms of exchange rate regimes that allow the exchange rate of two nations to be determined by the demand and supply of the currencies in the foreign-exchange market. The term *floating exchange rate* is also used to describe the general form of the flexible exchange rate in the system. In principle, the flexible exchange rate system is driven by a free market force while allowing some variations of central bank intervention. Major forms of exchange rate regimes under the flexible exchange rate system include freely floating (or clean floating) and managed floating (or dirty floating). In some cases, adjustable peg and crawling peg are also considered part of the flexible exchange rate system.

In the early 1970s, countries with major currencies, such as the United States, began to adopt a flexible rate system after the collapse of the Bretton Woods system, under which a fixed or pegged exchange rate regime prevailed. Though the majority of the developing nations still remained on the fixed exchange rate at the time, many had shifted to more flexible exchange rate systems such as the adjustable peg, crawling peg, and managed floating exchange rate systems.

What caused the movement from a fixed to a more flexible exchange rate system in this 20-year period for the emerging markets, though via a gradual process, were (1) sharp changes in value in major currencies that these nations tied their currencies to, (2) slower growth of more developed nations that launched opportunity seeking in the developing nations, (3) steep rise in the interest rate worldwide that encouraged a more flexible exchange rate system, (4) debt crisis as a result of overexpansion or huge capital inflow that put pressure on local currencies, and (5) inflation problems that called for changes in monetary policy that are more suited for a flexible exchange rate regime. In short, during these volatile times, a more flexible exchange rate regime was demanded for countries under fixed exchange rate regimes to adapt quickly and to be able to survive in the international trade and investment market. In other words, as the financial market globalized and the developing economies were more closely integrated with those of the more developed, the international exchange rate system had moved toward forms that allow nations to work more cooperatively and efficiently.

Though quite a few developing countries shifted to a more flexible exchange rate system after the mid-1990s, many still adopted the system with various degrees of control through central bank intervention or managed floating. This trend was due to the nations' smaller economies and relatively thin financial markets that were intolerant of extreme volatilities. In addition, many of these nations depend heavily on their exports or imports, and any big swings in their foreign exchange rates could cause serious imbalances in their balance of payments (e.g., a sudden depreciation in a nation's currency accompanied by a large import would cause a huge increase in its deficit in balance of payments).

However, in terms of the effect of the flexible exchange rate system on the domestic economy, and compared with that of the fixed exchange rate regime, the flexible exchange rate is more suitable when there are large inflows of capital transmitted to a developing economy. In China's case and in order to achieve stability in its economy, given the size and speed of its growth in the past 20 years, a crawling peg or managed floating exchange rate regime is more appropriate when its market is inundated with large inflows of capital. In other words, a crawling peg or managed floating exchange rate regime is more apt to alleviate the upward pressure for its currency to appreciate in a progressive manner. And in many cases, a specific form of the flexible exchange rate, e.g., managed floating, that is adopted by the central bank and is believed to be the most appropriate at the time usually work in synchronization with a nation's economy at a particular development stage. While the freely floating exchange rate may contribute to inflation at times, proper use of the monetary policy, such as interest rate increasing, will not only address the inflation problem but also encourage imports, one of the autocorrection responses from the market that further reduces inflation pressure.

Nonetheless, the flexible exchange rate system, with various degrees of government intervention, still requires a nation to be equipped with an adept regulatory establishment, a solid banking structure and supervision, and a free market that permits free information transmission to pave the way for the system to work efficiently and well.

Floating Exchange Rate

Floating exchange rate is the price of a nation's currency in terms of the price of the currency of another nation that is determined by the foreign exchange market based on the demand and supply of the currencies. For example, if the equilibrium level of US$1 is at ¥107 on a particular day, the exchange rate between U.S. dollars and Japanese yen is said to be ¥107/US$. When demand for yen increases, the value of yen appreciates and the floating exchange rate reaches ¥105/US$. In order for the floating exchange rate to work, currency systems in both the United States and Japan need to be in the floating exchange rate zone.

After the establishment of the Smithsonian Agreement in 1971 when the U.S. dollar was devalued to $38 for an ounce of gold (from $35), a wider band with 4.5 percent fluctuation was adopted in the fixed exchange rate system. When the U.S. dollar was devalued again in 1973 to $42.22 for an ounce of gold, the United States and other nations began the floating exchange rate system.

There are, however, two forms of floating exchange rate in the system, the managed floating and the freely floating; the former was adopted initially in 1973. A mirror image of the adjustable fixed exchange rate system, where government intervenes to keep the exchange around a pegged rate, the managed floating exchange rate regime follows the principle of a floating exchange rate yet with government intervention, though with reluctance, to prevent extreme movement of its currency that could interfere with its trade and investments in the international market. In the freely floating case, a country allows its currency to fluctuate based solely on the market mechanism of currency trading. Strictly speaking, a nation's exchange rate under the floating system depends on the demand and supply of the nation's currency relative to other currencies in the foreign-exchange market.

The rationale behind the floating exchange rate system is its "auto-correction" mechanism. For example, when the interest rate was reduced by the Federal Reserve Bank in the United States in 2008 during the credit crisis, the U.S. dollar depreciated initially relative to currencies of its major trading partners, a phenomenon that makes U.S. goods and services less expensive to foreign buyers. However, the U.S. dollar also appreciated from time to time during the year due to high demand for the dollar as its exports accelerated and spending increased from international tourists.

The demand and supply of a country's currency is largely influenced and counterbalanced by the movement of its balance of payments, the effect of its monetary policy, and the dynamics and expectations that global trades bring to its economy on the foreign exchange market. And when the fluctuation of the currency becomes too volatile, e.g., there is too much demand for U.S. goods that could cause higher inflation, the central bank may step in to buy dollars back, a form of managed floating exchange rate, in order to maintain the currency within a desirable boundary.

While the floating exchange rate system provides the balance power to a country's currency through the automatic correction of demand and supply in the foreign exchange market, the system also tends to be better protected from any unexpected economic or monetary movement of its trading partners. For example, under normal circumstances, when inflation in China reaches its 12-year high, its currency should depreciate to the level that U.S. importers would not pay a higher price than that before the inflation for China's exporting goods. Unlike the fixed exchange rate regime, countries under the floating exchange rate system do not need to maintain their currency at a fixed level. Subsequently, central banks are free to exert monetary policies needed for domestic economic development without interfering with its exchange rate system.

However, there are side effects under the floating exchange rate regime. In the freely floating case, because not all information that involves currency movement, such as future or forward contracts, is immediately available for investors and traders and the automatic adjustment process may take time to adjust depending on the market and economic conditions of involved nations, risk of loss due to high currency volatility can be high. In addition, a freely floating exchange rate system provides the opportunity for speculation, which could cause currency to deviate from its true equilibrium zone and therefore create greater uncertainties and losses in the international trading markets.

Focus Groups

Focus groups are a popular qualitative research methodology that engages a number of respondents who are simultaneously involved in the discussion of a topic (or number of topics). Focus groups have been used in a wide range of disciplines such as consumer research, marketing research, human resource studies, and others. They are mainly used during the exploratory phases of a research project, when usually little is known about a specific phenomenon or topic under investigation. The method could also be used to interpret quantitative data collected in the past, contributing to the better understanding of the phenomena in question. In business contexts it could be used to initiate "brainstorming" about new products/services offered and/or practices followed by a provider.

A key to the success of a focus group is the interaction among participants. Interaction is highly desirable and crucial when the researcher would like to explore the dynamics of a specific group of respondents regarding a specific issue. Hence, an important decision when setting up the groups of respondents is the selection of either homogeneous or heterogeneous groups. The decision depends on the research question. It is common, though, that researchers usually select respondents who share some characteristics such as age, lifestyle, or experiences. The advantage of a homogeneous group is that it gives participants a sense of safety expressing their views among peers with a number of similarities, a situation that generally enhances unbiased communication. On the other side, heterogeneous groups could inspire participants in a new way of thinking.

While internet surveys have become popular because they lower costs, they sacrifice some useful aspects of traditional focus groups, such as face-to-face interaction among participants.

Another key to the success of a focus group is the skill of the researcher, who is usually the moderator of the discussion. He/she is responsible for guiding the discussion so as to capture specific topic(s) of particular interest for the study. It is important that he/she should collect information by making respondents reveal their personal views and by making participants contrast them with those expressed by others in the group.

Process

The researcher first decides on the number of groups required to collect information about the topic. The appropriate selection method is purposive (and not random) since respondents are selected based on their ability to contribute to the specific topic(s) of discussion. Next is the selection of a homogeneous or heterogeneous type of group. Respondents within groups are selected based on a recruiting protocol, which describes their characteristics. Relative with the number of groups used in a study, it is generally accepted that the researcher keeps adding groups until the additional information gained is minimal (or else the researcher achieves the level of theoretical saturation as manifested by the responses from existing groups).

The literature proposes that groups should be comprised of six to 12 respondents. The rationale is that the lower the number of participants, the greater their interaction. In addition to the above, there are some practical issues to be taken into consideration. One of them is the duration of the session (a rule of thumb is around two hours so as to allow time to build rapport). Also, the researcher should carefully select the location where the group discussion will take place, taking into consideration convenience, ease of access, and lack of distractions from the environment. The internet had made this easier, allowing researchers to set up groups online.

Even though there is always the option of hiring a professional moderator, in most cases it is the researcher who plays that role. An important advantage of the latter is his/her familiarity with the topic of discussion. One drawback may be their lack of experience in playing that role. The researcher as a moderator should bear in mind his/her level of involvement. This depends on the topic of discussion. However, the logic of the method is to stimulate participants to interact and to intervene when needed. In order for the moderator to increase the effectiveness of the focus group, he/she should design the interview guide before the start of the discussion. A pre-test of the whole process would also be an advantage.

One way of analyzing information collected could be via content analysis. The advantage for a researcher being the moderator too is that he/she will have a better feel for the data collected and will perform a better quality analysis.

Advantages and Disadvantages

One major advantage of focus groups as a type of scientific inquiry is the rapid collection of desired information, since a number of respondents give their views simultaneously. This also saves money. Moreover, participants may express their views in their own words and be stimulated by the views expressed by others in the group.

One downside of the method is that the recruitment of participants may be time consuming unless the researcher has them ready at hand. Recruitment becomes even more problematic (both in terms of time and money) when the number of appropriate respondents is small, not easily accessible, and widely dispersed in a country. Another disadvantage is the usually small number of questions/topics raised. Also, participants may be influenced by the moderator's presence. Building on the above, participants may be unwilling to reveal their views in front of others. Furthermore, the researcher should be very careful with the use of findings. Due to the limitations stemming from the respondents used, the findings are not generalizable (statistically). What the researcher could try to achieve (if required) is analytical generalizability.

Variations

An interesting variation of the "traditional" focus group type of inquiry is the so-called two-way focus groups. Its difference is that instead of one person acting as the moderator, there is a whole group of moderators. There are in effect two groups; one comprises the participants and the other the moderators.

The increasing use of the internet as a viable tool for conducting social sciences and/or business research introduced an additional type of focus groups; namely online focus groups. Internet communications help researchers overcome the issue of distance among participants. Consequently, such focus groups cost less to run. There are two types: synchronous (all participants provide answers simultaneously) and asynchronous (participants receive an e-mail with other participants' responses and reflect on them). An important advantage is that they encourage participants to provide honest responses taking advantage of their anonymity. The results are also real-time. Furthermore, respondents can express their views without being distracted by others. However, they may feel demotivated due to the need to type their responses using keyboards, leading to either fewer or shorter responses. Another disadvantage is that it is restricted to participants who have internet access. Finally, the researcher cannot make notes on the participants' body language.

Follow-the-Leader Theory

Follow-the-leader theory is an investment strategy that calls for investing money in the areas where already successful investors are putting it. It is essentially a form of momentum investment strategy, and reflects economist John Maynard Keynes's comparison of the stock market to a beauty contest: Just as the most beautiful woman on the dais only wins if she's voted for, the strongest stock only rises in value if people buy it. Objective strengths are not sufficient, without the subjective perception of them.

Though there is some intuitive sense to the theory, it also swims against the current of the stream of popular consciousness, which says that in the stock market, one should buy low and sell high. Momentum investment strategy in general calls for buying high and selling higher, and follow-the-leader theory generally adheres to that in practice, even if it does not prescribe it in so many words.

The strict form of momentum investment strategy invests in securities that have had high returns in the last quarter (or year, depending on the investor) while selling those with low returns in the same period. The risk is obvious—what goes up can rarely keep going up forever—but advocates point out that using this strategy can lead to benefiting from the poor judgment of other investors in the market. It was originally principally advocated by Chicago fund manager Richard Driehaus—one of Barron's 25 most influential people of the 20th century in the mutual fund industry—and is similar to the positive feedback investing that super-investor George Soros used in the 1960s and 1970s.

To the extent that investing involves chance, that it is like and feels similar to gambling, momentum investment strategy ascribes value to the hot hand. When it is good, it will stay good; when it is bad, it will get worse. That this is significantly true a significant percentage of the time is the underlying predictive model of the strategy, and if your portfolio is diversified, it need not be true all of the time—no investment strategist would suggest all your eggs go in one basket, no matter the quality of the basket.

While "momentum investing" puts the emphasis on the movement of a stock's price, and the perceived tendency of that movement to continue, follow-the-leader theory shifts the emphasis to those early adopters who can afford to take the initial risks (or take them anyway), the trailblazers making the initial push the momentum develops from. In a sense, what follow-the-leader theory does is codify and prescribe a natural human tendency to assume that takers of action know what they are doing. If someone in a long, slow-moving line at the grocery store gets out of the line and moves to another one, someone else will often follow him even if the reason for the move is not apparent.

The mutual fund newsletter *The No-Load Fund Investor* has been putting this theory into practice since 1976, in the form of its Persistency of Performance system, which buys the top-performing diversified stock fund of the previous year, with some modifications. While the average diversified fund has a 14 percent annual return, NLFI's POP has a 21.5% percent return, a more than 50 percent increase. Others take that approach and apply it to stock sectors instead of specific stocks or funds, creating a portfolio of stocks from whichever sectors performed the best in the previous year.

There are obvious potential pitfalls. Although recent performance is often an indicator of future health, there is always an element of volatility in the market. The combination of momentum investing with the dotcom bubble would have led to enormous returns ... for a while. Depending on just what was purchased and when, the dotcom portfolio could be pretty meager today, and a Dutch tulip portfolio would have seen tremendous gains for a brief period before crashing back down to near-worthlessness.

Food and Agriculture Organization

Founded on October 16, 1945, the Food and Agriculture Organization (FAO) is the United Nations agency charged with the mission of leading and coordinating activities to eliminate global hunger. The organization's Latin motto—*fiat panis*—translated into English as "let there be bread!" reflects its primary focus on promoting global food security, especially among impoverished rural areas of the world. After its beginnings at the First Session of the FAO Conference in Quebec, Canada, its headquarters was moved to Washington, D.C., in 1948 and to Rome, Italy, in 1951. With 191 states and the European Union as members, the FAO functions as a forum for member nations to engage in policy debate and negotiate agreements relating to food production, distribution, and nutrition. In particular, the FAO serves an important function as a source of information and knowledge for developing nations to improve their food production productivity and the effectiveness of food marketing systems. In 2003 the FAO joined other international organizations, nongovernmental organizations (NGOs), and private sector organizations to form the International Alliance Against Hunger to work in partnership toward the eradication of global hunger through advocacy, accountability, resource mobilization, and coordination.

The FAO's major activities, detailed in its Program of Work, are funded through member contributions determined at the Conference of Member Nations every two years. At the biennial conference, members meet to elect a council comprised of 49 member nations, which governs for three years. Members also elect the director-general to head the agency's eight departments—agriculture and consumer protection; economic and social development; fisheries and aquaculture; forestry; knowledge and communication; natural resources management and environment; technical cooperation; and human, financial, and physical resources. Importantly, the conference reviews the FAO's key programs and policies and approves its plans and budget for the following period. Two major financial initiatives were introduced in 1994 to improve the FAO's efficiency. First, the structure of the agency has been decentralized, streamlining procedures in order to save costs. Second, the

The Food and Agriculture Organization strives to help farmers like these women who produce cowpeas in Nigeria.

organization's two-year budget was frozen at $650 million from 1996–97 to 2001 and has since gradually increased, but has not kept pace with inflation.

Programs designed to elevate hunger and promote its elimination are the core of the FAO's work. A centerpiece initiative, the Special Program for Food Security (SPFS), aims to reduce the number of people suffering from hunger by half by 2015. To achieve this goal, projects are implemented in over 100 countries, with about 30 of them developing and implementing National Food Security Programs by mid-2007. Another key FAO initiative was leading the promotion of integrated pest management for rice promotion in Asia during the 1990s. Through bilateral funding from a number of developed countries, hundreds of thousands of farmers were trained under the Farmer Field School (FFS), a group-based learning process.

Apart from the operational programs deployed in target nations, the FAO works to raise public awareness and financial support to address the problems of hunger and malnutrition facing millions of the world's people. One example of the FAO's efforts to these ends is TeleFood, a campaign of concerts and sporting events launched in 1997. This campaign has attracted donations that are used to fund projects to assist small-scale farmers to produce more food for their families and local communities. Most prominent of these efforts is the Goodwill Ambassadors Program initiated in 1999. FAO Goodwill Ambassadors are drawn from a wide field of achievements—the arts, entertainment, sports, and academia—to garner public support for the campaign against world hunger. As part of its informational role, the FAO's statistical division generates extensive time-series data on agriculture, nutrition, fisheries, forestry, food aid, land use, trade flows, and population from over 210 countries and territories. This is made accessible through the online multilingual database FAOSTAT.

Despite the progress, the FAO has also attracted much criticism, particularly since the 1970s. Over the years, critics have described the organization as increasingly inefficient, irrelevant, politicized, mediocre, and losing focus on its purpose to combat global hunger. Several high-profile summits, reports, and audits have expressed serious concerns about the FAO's effectiveness. Radical changes to its culture and management systems have been recommended to improve its efficiency and refocus its strategic priorities.

Ford Motor

Ford Motor Company started its operations in 1903 in Michigan State, led by Henry Ford and 11 of his partners. Their original capital was only $28,000, but this group of people would create one of the largest businesses in the world, one of the most popular American corporate icons, and one of the most popular brands of all time. In fact, 2008 is the year that the company's famous Ford Model T—the car that made driving available to the masses—celebrated its 100th anniversary. Since then, the company has produced more than 330 million vehicles and has grown to rank third worldwide in the production of vehicles. These performance levels create annual sales figures that are easily comparable to many countries' gross domestic product.

It is worth noting that at the time of the company's birth, there were 15 other vehicle manufacturers in Michigan State and 88 in the United States. However, up until that point a vehicle was a premium product that addressed only a niche segment of the American market, i.e., affluent consumers. It was Henry Ford who first believed the opposite and clearly stated that the car should be addressed to the masses. The premise behind this innovative thinking was that this was the only way to develop further the stagnated market for car manufacturing. His vision was to produce and sell a car at such a price that everybody would have the financial capacity to buy one.

Ford managed to reduce production costs by inventing the production line. At that time, manufacturing a car took 12 hours. Through Ford's new technique, manufacturing time was reduced to only 93 minutes. At the same time, he virtually doubled factory workers' salaries and established an 8-hour-per-day workload. The outcome of these transformations was simple: The company's employees could now afford to buy a car. In parallel with these changes, he strived to convince U.S. governmental authorities to develop a system of roads that would crisscross the states. As a result, the growth of car sales was phenomenal and by 1912, there were already 7,000 dealers of Ford vehicles in the United States. Therefore, among other achievements, Henry Ford can be also considered one of the pioneers of the franchising scheme.

Ford has been international almost since its inception, first expanding its activities to create Ford Motor Company of Canada in Ontario. Now it is represented in more than 200 countries on all continents selling vehicles of several types, employing almost 300,000 people, and having contracts with 60,000 suppliers. This globalized outlook of the firm is manifested in its expanded brand portfolio, too. After a wave of megamergers in the automobile industry, Ford Motor Company owns popular brands such as Lincoln, Mercury, Mazda, and Volvo.

Ford Motor is both a quintessential American company and a global one, with a presence in 200 countries.

Part of the explanation behind the success story of Ford Motor Company is its long-standing involvement in the electronics industry. In 1956 the company acquired Aeronutronic and thus entered the defense and aerospace industry. This strategic move would later play a major role in high-profile technological success. In the same vein, the company acquired a major producer of consumer electronics and home appliances in the early 1960s. Owning firms with resources and skills necessary for the creation of cutting-edge technologies was a great plus to Ford Motor's activities. In a synergistic fashion, the mother firm took advantage of these resources and added value to its final products by offering modern, cutting-edge vehicles. A manifestation of this successful early involvement with the electronics industry is obvious now: The firm is able to offer affordable and available on-the-road connectivity for personal electronics to its consumers.

The major legacy of the firm, though, is its contribution to the evolution of mass production and overall to managing a production-based business. The assembly line of the first Ford factory became the reference point for all mass methods of production around the world. In a sense, a new form of industrial revolution was born and the management of businesses entered a challenging era, which is still taught as an exemplar of management in many business schools around the world.

Forecasting

Business organizations compete more effectively in a global economy when they are able to use information from the past to predict future events. One of the tools is forecasting. A forecast is a statement or prediction about a future event and the act of making this prediction is called forecasting. Forecasts are used in government organizations to predict inflation rates, unemployment rates, welfare payments, gross national product, interest rates, money supplies, and various planning indicators. These forecasts are called economic forecasts. Forecasts that are concerned with rates of technological progress, like introducing new products and services that require new plants, equipment, and technology, are called technological forecasts. Projections for a company's products or services, finances, human resources, and supply chain management are called demand forecasts or microeconomic forecasts.

Forecasts can also be classified with respect to the length of future time horizon covered by the forecast. If a forecast has a time span up to one year but is generally less than three months, it is called a short-range forecast. For example, job scheduling, job assignments, planning purchases, demand planning, sales planning, and production levels planning are examples of short-range forecasts. They are usually implemented by the operations managers. If a forecast has a time span from three months to three years, it is called a medium-range forecast (or intermediate forecast). These types of forecasts are used by middle managers and are implemented in sales planning, budget planning, production, and resource planning. If a forecast has a time span of three years or more, it is called a long-range forecast. These types of forecasts are used by the top level of management or strategic managers when making decisions about locating a new facility, expanding an existing facility, investing in a new venture, introducing a new product or new service, and planning capital expenditures.

The forecasts generated within the firm must be understood and appreciated by its decision makers. It is important to understand the forecasting process and forecasting methods to make proper decisions. In general, there are two types of forecasting methods: quantitative and qualitative. If time series data are available, then quantitative methods will be used. A time series consists of data that are collected, recorded, or observed over chronological moments of time, for example, daily sales of a commodity, weekly sales of Dell computers, quarterly returns of a specific investment, and annual consumer price indices. The time series prediction is based on the assumption that the future is a function of the past. A forecaster is looking at what happened over a period of time in the past and uses past data to predict future.

Time series are analyzed by distinguishing certain patterns: trends, seasonality, cycles, and random or irregular component. Trend represents the gradual increase or decline in time series over a period of time. Seasonality is a pattern of change in the data that repeats itself after a period of weeks, months, quarters, or years. These patterns are easy to observe in sales time series that show customers' demand similarities in each season of the year or in electrical or gas consumption, which is determined by weather and temperature changes. Cycles are the fluctuations around the trend pattern and usually they occur every several years, for example, inflation, weak economy, and real estate prices. Random or irregular patterns are caused by chance or very unusual events, like hurricanes, floods, accidents in the workplace, rapid declines in the stock market, and other hard to predict issues.

Basic tools in quantitative forecasting are the naïve approach, moving average, weighted moving average, exponential smoothing, linear regression, trend analysis, and Box-Jenkins methods.

While quantitative methods use time series, qualitative forecasting methods use the opinions of experts to predict future events. Qualitative forecasting methods employ judgment, experience, intuition, and other factors. The oldest qualitative method is the Delphi method, which was developed by the RAND Corporation and is based on a panel of experts. A series of extensive questionnaires is distributed to the panel participants, who provide inputs to the decision makers before the forecast is determined. After the first round the ideas are summarized and grouped, so the number of possible forecasts is reduced. This process is continued until some consensus is reached. Consumer market survey is another example of a qualitative forecasting method. This method is based on customers' or potential customers' opinions regarding future purchasing plans. Jury of executive opinion forecast is based on a group of high-level experts who, often with the use of some other methods, arrive at the forecast of future demand.

Usually an effective forecaster is able to combine both good judgment and quantitative forecasting techniques to arrive at the best decision. In order to select an appropriate forecasting method, the forecaster must be able to define the nature of a forecasting problem, analyze the nature of the data, and describe capabilities and limitations of useful forecasting methods for given time series. The quarterly *Journal of Business Forecasting: Methods & Systems* provides articles about how to develop and utilize good forecasts. The *International Journal of Forecasting* is a main domain for research papers on forecasting methods.

Foreign Corrupt Practices Act

The Foreign Corrupt Practices Act (FCPA) of 1977, amended in 1988 and 1998, prohibits companies or their personnel and agents from paying, or arranging to pay through intermediaries, bribes to foreign officials and certain other recipients. The FCPA criminalizes such bribery. As amended, the statute applies to all businesses organized under U.S. law and to all foreign businesses issuing securities within the United States. The statute, amending the Securities Exchange Act of 1934, also subjects those businesses and even purely domestic enterprises to accounting and internal control requirements for maintaining accurate records and financial statements.

The anti-bribery provisions cover U.S. securities issuers (including foreign firms), domestic concerns, or any person acting on behalf of any of the preceding who uses any means or instrumentality of interstate commerce to offer or transfer anything of value in virtually any form to foreign officials or certain other recipients inside or outside the United States in order to influence corruptly favorable policy action. Under some circumstances, minor "facilitating" payments (i.e., "grease") to expedite otherwise required clerical action by low-level officials are exempted by the FCPA. The U.S. Department of Justice maintains an informative Web site.

The FCPA was a by-product of the Watergate scandal investigations. In an amnesty program, over 400 U.S. firms admitted to the U.S. Securities and Exchange Commission (SEC) to having made "questionable payments" abroad. Congress passed, and President Jimmy Carter signed, the FCPA. The Ford administration opposed criminalization and favored a purely disclosure approach.

Although in 1977 nearly all countries prohibited bribery of their government officials, the FCPA was the first statute to prohibit business bribery or bribery efforts (including offer or authorization) concerning another country's officials. Only Sweden, in 1978, followed the U.S. lead. A lively controversy concerned whether U.S. firms were placed at a competitive disadvantage when other firms could bribe with impunity. A number of European countries effectively permitted tax deductibility of such bribes. The empirical evidence on this issue arguably remains mixed. The controversy led to 1988 amendments relaxing some aspects of the original FCPA. These amendments permitted certain affirmative defenses concerning promotional or marketing expenses (such as entertainment), payments permitted under foreign laws such as certain political contributions, and use of agents.

The FCPA 1988 amendments instructed the U.S. president to marshal international anti-corruption cooperation in order to reduce the near uniqueness of the U.S. posture. A set of international conventions emerged in the late 1990s. The Organization of American States (OAS) adopted the first anti-bribery convention in 1996; the Organisation for Economic Co-operation and Development (OECD) acted in 1997. The FCPA 1998 amendments implemented U.S. adherence to the OECD convention and also expanded scope of coverage. The UN Convention Against Corruption was adopted in 2003. There are other regional conventions, such as those of the European Union, the Council of Europe, and the African Union. Member states of these conventions are at various stages of adopting implementing legislation and carrying out enforcement activities.

The FCPA provides severe penalties for firms and individuals violating anti-bribery and accounting provisions. The latter can receive prison sentences. U.S. enforcement has increased following the 2002 Sarbanes-Oxley Act and the UN Oil for Food Program scandal. In 2004 the Department of Justice and SEC reportedly initiated five new actions. In 2005 the number was 12; in 2006, 15. In the first half of 2007, there were about 100 active investigations. U.S. actions included Volvo and Baker Hughes. Enforcement is increasing overseas. Statoil in Norway, Siemens in Germany, and BAE in the United Kingdom have faced major corruption investigations.

Foreign Direct Investment, Horizontal and Vertical

There has been a tremendous growth in foreign or international investment since 1990s. The underlying reasons for such international flows of capital can be attributed to several factors. International investment, for example, allows capital to find the highest rate of return, helps the owner of capital to diversify his or her lending and therefore reduces the associated risk, contributes to further development and spread of best practices in corporate governance and accounting rules, and finally it prevents the government from pursuing poor policies.

The aforementioned advantages of the free flow of capital across national borders can be realised through two primary kinds of international investment: (1) Foreign Portfolio Investment (FPI) and (2) Foreign Direct Investment (FDI). While FPI is defined as investment in a portfolio of foreign securities such as stocks and bonds, it does not entail the active management of foreign assets. In other words, FPI is "foreign indirect investment" in that it represents passive holdings of foreign securities not least because the investor does not have control over the securities' issuer. Exchange rates, interest rates, and tax rates on interest or dividends are factors that directly impact on FPI.

In contrast, FDI refers to those investments that involve an equity stake of 10 percent or more in a foreign-based enterprise. FDI requires the direct and active hands-on management of foreign assets. An example of FDI is when a Japanese company takes a majority stake in a company in America, Iran, or elsewhere. In comparison to FPI, FDI requires exercising management control rights, inter alia, the rights to appoint key managers, and to establish control mechanisms. Due to the importance of management control and the need to managing foreign operations, many firms these days even invest in a large equity of up to 100 percent just to be able to exercise management control rights.

The key difference between FDI and FPI therefore is that FDI investors not only take both ownership and control positions in the domestic firms, but also are regarded as the managers of the firms under their control. In other words, while FPI investors gain ownership positions in the domestic firms, they do not exercise control over domestic firms and must therefore delegate decisions to managers, thereby limiting their freedom to make decisions because the managers' agenda may not be always consistent with that of the owners. Based on such argument or more specifically due to an agency problem between managers and owners, FPI projects are managed less efficiently than FDI projects. This in turn has resulted in a dramatic rise in FDI in recent decades and led some international business scholars to view it as an important aspect of globalization.

Overall, the basic entry choices into foreign markets can be categorized into three strategies: exporting, licensing, and FDI. As it is often the case, successful exporting can provoke protectionist responses from host countries, thereby forcing firms to choose between licensing and FDI. There are three reasons that may compel firms to prefer FDI to licensing: (1) FDI reduces dissemination risk—i.e., the risk associated with unauthorized diffusion of firm-specific know-how; (2) FDI results in more direct and tighter managerial control over foreign operations; and (3) FDI promotes the transfer of tacit knowledge through "learning by doing."

While gains to host countries—i.e., recipients of FDI—from foreign or international investments are many, in comparison to other foreign investments, the advantages of FDI can take several other forms. Given the appropriate host-country policies and existence of reliable and sufficient infrastructure, it is expected that FDI, at a micro level, contributes to the transfer of technology or even triggers technology spillovers.

This clothing factory in the Al Tajamouat Industrial City in Jordan has worked to attract foreign investment.

As FDI comes in many forms and therefore results in new varieties of capital inputs, it promotes a healthy competition in the domestic input market. The host country could also benefit from training and development of its workforce as FDI helps human capital formation across different economic sectors. Clearly, all these in turn contribute to the economic growth of the host country.

In addition to these economical benefits, FDI could also improve environmental and social conditions in the host country by, inter alia, transferring "cleaner" technologies, thereby leading to more socially responsible corporate policies. At a macro level, FDI contributes to international trade integration not least because it results in a more competitive business environment for multinational companies (MNCs). MNCs compete globally through investing their assets into domestic markets of different host countries.

Types of FDI

There are two main types of FDI: One is horizontal and the other is vertical. Horizontal FDI arises when a firm duplicates its home country–based activities at the same value chain stage in a host country through FDI. For example, Ford assembles cars in the United States. Through horizontal FDI, it does the same thing in different host countries such as the United Kingdom (UK), France, Taiwan, Saudi Arabia, and Australia. Horizontal FDI therefore refers to producing the same products or offering the same services in a host country as firms do at home.

While a horizontal pattern occurs when MNCs through FDI produce the same product or service in different host countries, vertical FDI takes place when a firm through FDI moves upstream or downstream in different value chains—i.e., when firms perform value-adding activities stage by stage in a vertical fashion—in a host country. In other words, a vertical FDI arises when a multinational firm fragments the production process internationally, thereby locating each stage of production in the country where it can be done at the least cost. For example, if Peugeot (the French automaker) only assembles cars and does not manufacture components in France, but in the UK, it can be said that Peugeot enters into components manufacturing through FDI. This pattern is called "upstream vertical FDI." In a similar vein, if Volkswagen (the German automaker) does not engage in car distribution in Germany and, instead, invests in car dealerships in Saudi Arabia (a downstream activity), it can be said that Volkswagen is engaged in "downstream vertical FDI."

While horizontal and vertical FDI serve different purposes, the bulk of FDI seems to be horizontal rather than vertical. As mentioned earlier, when a firm engages in horizontal FDI, it establishes multiplant operations that duplicate similar products and services in multiple countries. This implies that a firm's motive to adopt a horizontal pattern is mainly because it facilitates market access—as opposed to reducing production costs—and subsequent market share expansion. However, with vertical FDI firms engage in both FDI and exports. Unlike horizontal FDI in that the two countries involved are of similar size, and the nature of their operations resembles more of a pair of developed countries, in vertical FDI patterns, the home country is usually much larger and the two countries involved in FDI operations look like a developed home country and a developing host country. Put simply, in horizontal FDI patterns, the main objective to be met is how best to serve the host market (abroad), whereas in vertical FDI models, the primary objective of a firm is how best to serve the domestic (home) market.

Political Perspectives

Since FDI requires the flow of capital across national borders, it has always been intertwined with politics. Viewed in this way, three different political perspectives to FDI can be identified: radical view, free market view, and pragmatic nationalism. The radical view, which can be traced back to Marxism, treats FDI as a vehicle for exploitation of domestic resources, industries and people. Those governments who hold a radical view are hostile to FDI and therefore are in favor of nationalizing foreign firm assets or putting into place mechanisms to discourage inbound foreign firms' operations. The free market view, on the other hand, is more in favor of FDI and promotes its rationale not least because it enables countries to tap into their absolute or comparative advantages by specializing in the production of certain goods and services. According to the free market view, FDI can be regarded as a win-win situation for both home and host countries. While prior to and during the 1980s the radical-based view FDI was more common in Africa, Asia, Eastern Europe, and Latin America, the free market–based FDI is now more influential across the world and in particular in emerging economies such as Brazil, India, and China.

Finally, the third view, which reflects the current dominant perspective toward FDI and is practised by most countries around the world, is called pragmatic nationalism. Based on a pragmatic nationalism political view, FDI is only approved when its benefits outweigh its costs. For example, this view holds that FDI in the Chinese auto industry should only take the form of a joint venture (JV). By adopting such restrictive policies, the Chinese government helps the domestic auto industry learn from their foreign counterparts.

In short, FDI refers to direct investment in (10 percent or more of) business operations in a foreign country. It has benefits and costs for both the host (recipient) countries and home (source) countries. In respect to the benefits of FDI to host countries, FDI helps improve a host country's balance of payments; it can create technology spillovers; it creates advanced management know-how; and it creates jobs both directly and indirectly. However, loss of sovereignty, adverse effects on competition, and capital outflow are the primary costs of FDI to host countries. Similarly, the benefits of FDI to home countries are: Repatriated earnings from profits from FDI; increased exports of components and services to host countries; and learning via FDI from operations abroad.

In addition to all these pros and cons of FDI and its cost-benefit implications for both the host and home countries, certain issues need to be taken into account by a foreign firm before deciding to operate in cross-border markets. For example, justification of FDI in light of other foreign entry modes (e.g., outsourcing and licensing), paying enough attention to the fit between the location advantages with the firm's strategic goals, and familiarity with the institutional constraints of the host countries are all key determinants of successful FDI operations.

Foreign Exchange Market

The foreign exchange market, also referred to as the "forex" or "FX" market, is the market in which currencies are traded and exchange rates are determined. The forex market as we know it today can be dated back to 1971 when the Bretton Woods Agreement ended. This agreement had pegged the world's major currencies to the U.S. dollar from 1944 until 1971. Its demise ushered in the era of floating exchange rates and currency volatility.

The forex market is open 24 hours a day, five days a week, with currencies traded in all of the world's major financial centers. As the Asian centers close, the European centers open, and as they close the North American centers open, and eventually the Asian centers open again. The main centers for forex trading are London, New York, and Tokyo. The forex market is the largest and most liquid financial market in the world, with a daily average turnover of approximately US$3.2 trillion, according to the 2007 Triennial Central Bank Survey of Foreign Exchange and Derivative Market Activity, conducted by the Bank for International Settlements (BIS).

The forex market is classified as an "over-the-counter" (OTC) market, as most transactions are facilitated via a global network of dealers, communicating through connected computer terminals and by telephone rather than on a centralized exchange (though a segment of the foreign exchange market comprises currency futures and options, which are traded on exchanges). These dealers mostly work for the world's major banks and so the forex market is also referred to as an "interbank" market. The rates quoted in the market are visible to all banks, although each bank must have established a credit relationship with another in order to transact at the rates quoted. Some deals in the forex market are facilitated by forex brokers who match counterparties for a fee. These brokers have been adversely affected by the increased use of the internet since the mid-1990s, which has resulted in much of their business migrating to more efficient online broking systems used only by banks. Retail traders (individual investors) comprise a small part of the forex market and may only participate indirectly through brokers or banks.

Transactions in the forex market can be undertaken on a spot, forward, or swap basis. A spot transaction requires almost immediate delivery of foreign exchange (in practice, the delivery date, or "value date," is normally the second business day following the transaction). A forward transaction requires delivery at some future date. The exchange rate is determined at the time of the transaction but payment and delivery are not required until maturity. Forward exchange rates are normally quoted for value dates of one, two, three, six, and twelve months. They are often used by companies that wish to lock in an exchange rate today for future delivery of a currency in order to hedge against foreign exchange risk. A swap transaction is another way of locking in a forward rate and involves the simultaneous exchange of one foreign currency for another, with both purchase and sale conducted with the same counterparty. A common type of swap is a "spot-against-forward" swap in which a dealer buys a currency in the spot market and simultaneously sells the same amount back to the same counterparty in the forward market. According to the 2007 BIS Survey, spot transactions account for less than one-third of global forex turnover, while forwards represent 11 percent and swaps more than 50 percent of all transactions. The four most commonly traded currencies in the forex market are the U.S. dollar, the euro, the Japanese yen, and the British pound.

Banks execute trades on behalf of their clients—principally companies seeking foreign exchange to pay for goods or services, other banks, central banks, mutual funds, and hedge funds—but they also trade a large amount of currency on their own account, via "proprietary desks," in an attempt to profit from currency movements. This speculative activity, which accounts for the bulk of turnover in the forex market, involves buying currencies that are expected to appreciate in the hope of selling them at a future profit and selling currencies that are expect to depreciate in the expectation of buying them back at a cheaper price. Although sometimes controversial, many economists argue that speculators perform an important function by providing a market for hedgers and transferring risk. Banks also engage in arbitrage transactions which produce profits from temporary discrepancies between the exchange rates quoted by competing dealers.

There is virtually no forex trading based on inside information. Currency fluctuations are usually caused by actual monetary flows as well as by expectations of changes in these flows caused by macroeconomic factors such as changes in GDP growth, interest rates, inflation, and budget and trade deficits or surpluses. Major macroeconomic news is released publicly, usually on scheduled dates, so all dealers have access to this news at the same time. However, larger banks may have an advantage through knowledge of their customers' order flow, which may provide insights into likely market reaction to particular announcements.

Foreign Exchange Reserves

Foreign exchange reserves are the foreign currency denominated financial assets accumulated by the monetary authorities of a country. Foreign exchange reserves are held for various reasons. Most common uses are meeting foreign currency denominated payment obligations, management of exchange rate, control of money supply and interest rates, providing confidence to markets, and limiting external vulnerability. Because of these policy objectives, monetary authorities prefer to hold foreign exchange reserves in low-risk and liquid financial instruments; foreign exchange reserves in such instruments ensure that there is the capacity to intervene in markets at any moment.

While foreign exchange reserves provide economic benefits such as exchange rate management and reduced external vulnerability, they incur costs because foreign currencies in low-risk and liquid instruments yield less than various investment opportunities and debt and equity securities. Despite these costs, there is a secular trend—especially visible in emerging market economies—toward higher levels of foreign exchange reserves. This trend is particularly strong among East Asian economies.

A country accumulates foreign exchange reserves either because of a current account surplus or capital account surplus (in which case capital inflows exceed capital outflows). The surplus on the current account is, in general, caused by the excess of exports over imports, which leads to the receipt of payments in foreign currencies. Capital account surplus implies that a country is a net debtor, i.e., its receipt of foreign currency denominated assets surpasses the financial assets it sends to the rest of the world. In either case, monetary authorities (most often the central bank) accumulate foreign exchange through open market operations—they buy foreign exchange from private economic agents at the prevailing market prices.

Foreign currency payments oblige monetary authorities to hold foreign exchange reserves, but the magnitude of foreign currency obligations is generally small relative to the gross domestic product of a country. Especially in developing and emerging market economies, monetary authorities opt for holding foreign exchange reserves as a policy tool or for precautionary purposes rather than for meeting payment obligations. One policy example is the dirty float. Under the dirty float, the long-term level of the exchange rate is determined by markets, but monetary authorities intervene in cases where the movements deviate from fundamentals. An example of precautionary purposes is the holding of reserves in order to keep the capacity to intervene in financial markets to prevent or mitigate a currency crisis.

Foreign exchange reserves are part of a country's national wealth. Thus, like any other stock of capital, one would expect that foreign exchange reserves are put into projects or financial instruments that maximize revenue. However, this objective (maximization of revenue) is in conflict with holding foreign exchange reserves for policy or precautionary purposes. The commitment to a certain policy goal and to precautionary purposes necessitates that foreign exchange reserves are held in liquid instruments. The majority of foreign exchange reserves are held in fixed-income assets such as U.S. Treasury notes and bonds, which are considered to be safe and liquid investment instruments. However, safety and liquidity come with a price; low-risk fixed-income assets yield less compared to other financial instruments. Thus, foreign exchange reserves bear opportunity costs. While there is no consensus on the magnitude of the opportunity cost of holding large foreign exchange reserves, most scholars argue that the cost is significant.

Since the 1980s, the level of foreign exchange reserves (measured in relation to gross domestic product) remained relatively stable in advanced industrialized countries with stable financial markets and floating exchange rate regimes. In contrast, developing and emerging market economies began holding increasing levels of foreign exchange reserves by the early 1990s. This trend accelerated even further in recent years. Emerging economies in Asia—particularly China—are the leading figures in this significant reserve buildup. According to the *CIA World Factbook*, the combined value of the foreign exchange reserves in China, Japan, Russia, India, Taiwan, and South Korea stood at approximately $3.7 trillion at the end of 2007.

Foreign Portfolio Investment

Foreign portfolio investment involves transactions by residents of one country in equity and debt securities representing financial claims on and liabilities to residents of another country. The equity and debt securities include, among others, stocks, money market instruments, and private and public bonds and notes. In the case of equity securities, foreign portfolio investment is differentiated from foreign direct investment (FDI) on the basis of lasting interest and controlling position in the resident business entity by the nonresident investor.

While the dividing line between foreign portfolio investment and FDI is not always clear, in general foreign portfolio investment provides greater liquidity compared to FDI. As such, foreign portfolio investment increases the depth and liquidity of global capital markets. It enables investors to seek returns that might not be available in their home country. Furthermore, it allows entrepreneurs and businesses to tap into a greater pool of saving to finance their projects. However, foreign portfolio investment can be volatile, especially in the case where the recipient is a developing or emerging market country. Increasing amounts of foreign portfolio investment have been a defining feature of financial globalization.

Because there is a multiplicity of financial instruments bought and sold in international markets, foreign portfolio investment takes various forms. In the case of debt securities (financial instruments creating debt), foreign portfolio investment usually involves the trading of instruments such as sovereign bonds and bills, corporate bonds, commercial papers, and repos. In the case of equity securities (financial instruments representing ownership), the most common forms are stocks, shares, American depositary receipts (ADRs), and global depositary receipts (GDRs).

Foreign portfolio investment is conceptually different from foreign direct investment in the sense that the nonresident investor does not seek long-term relationship with and decision-making influence in the management of the resident business entity. In practice, foreign portfolio investment is distinguished from FDI by the 10 percent threshold rule. For example, if the nonresident investor obtains 10 percent ownership of a resident business entity, the transaction is considered to be direct rather than portfolio investment. This practice—with some variation in the threshold—is recommended by international financial institutions such as the International Monetary Fund (IMF) and Organisation for Economic Co-operation and Development (OECD) and followed by most countries in the world.

It should be noted that there are cases where the distinction between foreign portfolio investment and FDI is not clear. One example is the nonresident investor who holds more than 10 percent ownership in a resident business entity but who does not have an interest in its operations. Another example is the case where the nonresident investor acquires influence in the operation of a resident business by holding large amounts of debt securities issued by the business. The general consensus is that the cases where there is an overlap between foreign portfolio investment and FDI are of negligible magnitude.

Benefits and Risks

Foreign portfolio investment can provide significant benefits to investors and businesses across the world. For investors, the ability to invest in debt and equity securities in other countries can bring higher returns than investing in their home country. To give an example, the returns on financial instruments in developing and emerging market economies are significantly higher than what financial instruments in advanced industrialized economies yield. For businesses, foreign portfolio investment can reduce the cost of capital. The reduced cost of capital due to foreign portfolio investment is particularly important in countries where the domestic saving rate is low. Entrepreneurs and businesses in such countries can take advantage of borrowing from residents of other countries with high domestic saving rate.

Compared to other forms of cross-border investment, the advantage of foreign portfolio investment lies in reduced transaction costs. A comparison with FDI is illuminating. Acquiring a lasting and controlling interest in a business entity in another country is costly; it comprises transaction costs arising from legal procedures, bureaucratic details, and obtaining information. In contrast, debt and equity securities are traded in established markets with large numbers of buyers and sellers and with predetermined rules and procedures that incur smaller costs. As a result, foreign portfolio investment provides greater liquidity than FDI.

Reduced transaction costs and greater liquidity imply that foreign portfolio investor seeks maximum return across a spectrum of financial instruments in global markets. Because of this, foreign portfolio investment can be much more volatile than FDI, resulting in periods of systemic inflows and outflows of capital. If the size of foreign portfolio investment is large relative to gross domestic product, high volatility can have serious adverse effects. Large systemic inflows can lead to macroeconomic overheating, inflationary expansion, and exchange rate pressures; large systemic outflows of capital can cause liquidity crunch and financial depression. Foreign portfolio investment volatility increases with the frequency of various shocks to the economy, which might originate in domestic or global markets.

Foreign portfolio investment has been a central element of global financial integration. The growth of foreign portfolio investment started in the late 1970s and early 1980s, as advanced industrialized countries began deregulating their financial markets and liberalizing their capital accounts. The movement toward financial deregulation spread to developing and emerging market countries in the late 1980s and gained increasing momentum in the 1990s. As financial deregulation and capital account liberalization progressed, the opportunities for investment in international debt and equity securities expanded. The growth of foreign portfolio investment has accelerated in recent years with increasing global trade imbalances, which are reflected in current account surpluses in Asian economies and in the U.S. current account deficit. For example, the U.S. current account deficit is to a large extent financed by foreign portfolio investment (i.e., by foreign governments investing in U.S. fixed-income assets).

In general, foreign portfolio investment to developing and emerging market economies is more volatile than foreign portfolio investment to advanced industrialized economies. The volume of foreign portfolio investment to emerging market economies reached unprecedented levels in the 1990s; the combined volume of FDI and foreign portfolio investment flows has financed higher levels of domestic consumption and investment in these economies. However, high volatility of foreign portfolio investment has been a contributing factor in the financial meltdowns observed in developing and emerging market economies in the

1990s. Thus, despite its potential benefits, foreign portfolio investment induces a distinct set of risks for developing and emerging market economies.

Foreign Sales Corporation

A foreign sales corporation (FiSC) is a part of the United States Internal Revenue System tax code that allows exporting companies to shield profits from taxation. The European Union (EU) and other U.S. trading partners viewed this scheme as a subsidy, and challenged it in the World Trade Organization (WTO). The WTO found the FiSC in violation of international trade rules, and in 2002 authorized the EU to impose trade sanctions totaling $4 billion on U.S. exports to the EU. In response to this pressure, the United States in 2006 revised the tax code related to FiSCs to comply with the WTO. The FiSC issue is the largest dispute that the WTO has ruled on to date, in terms of the amount of trade involved, and underscores the impact that globalization has on a country's domestic policies.

The FiSC is a by-product of differences in tax policies among countries. The United States taxes U.S. businesses, not just on their domestic income but also on their worldwide profits. This includes both exports from the United States as well as sales of items produced at subsidiaries abroad. The United States taxes foreign corporations only on their income that derives from business conducted in the United States. Other countries apply different tax policies. For example, European governments do not tax the export revenues of European companies, exempting them from value added taxes (VAT). From the perspective of the U.S. government, U.S. companies were disadvantaged in international business because the international sales of foreign companies sometimes faced a lighter tax burden, thereby allowing foreign companies to price their goods and services more cheaply than their U.S. counterparts. The FiSC, introduced in 1984, was intended to reduce this disadvantage. The legislation permitted companies to create off-shore subsidiaries (i.e., FiSCs) outside the United States (in places like the U.S. Virgin Islands or Guam), exempting at least 15 percent but no more than 30 percent of export income from taxes. Almost all major U.S. multinational corporations (MNCs) utilized FiSCs, as did many small and medium-sized companies. It is estimated that up to one-half of all U.S. exports were made through FiSCs.

The FiSC issue created little controversy until 1997, when the EU filed a complaint with the WTO. A WTO disputes panel ruled the FiSC to be an illegal subsidy and an appellate body agreed. Attempts by the U.S. government to replace the FiSC, including the 2000 Extraterritorial Income Exclusion Act (ETI), were unsuccessful, since the revised tax regimes also violated WTO rules. Since the WTO permits member countries to impose trade sanctions against other members not abiding by the organization's decisions, the EU drew up a list of products exported from the United States to Europe that would face increased tariff levels. The WTO estimated that U.S. companies received about $4 billion in tax benefits annually from the FiSC program. Thus, the EU was permitted to collect an equivalent amount in additional tariffs from U.S. exports to Europe, and did so between March 2004 and January 2005. Finally, in May 2006 the U.S. Congress passed tax legislation that included the repeal of the FiSC and ETI, thereby ending this international trade and tax dispute.

The issue of FiSCs is important to international business for three reasons. First, it illustrates how globalization makes it increasingly difficult to separate domestic policies from international policies. In the FiSC case, domestic tax policy became an international issue once it became clear that it was being devised to enhance the economic competitiveness of U.S. MNCs. Second, the resolution of the FiSC dispute highlights the growing importance of international organizations like the WTO and EU in shaping the international business environment. Although countries create organizations such as these to facilitate international business, they sometimes find themselves constrained by the rules and procedures they put in place. Third, the United States and the EU are each other's most important trade and investment partner. Yet, despite this close relationship, disputes over FiSCs, the safety of genetically modified organisms, subsidies to the aerospace industry, and other issues often overshadow the economic links and strain political relations.

Forensic Accounting

Forensic accounting can be defined as a thorough analysis, investigation, inquiry, or examination that is collected as a result of reviewing organizational records with the main focus being to expose organizational corruption and fraud. The field combines both litigation and investigative accounting practices. Litigation support is crucial to this field given the emphasis placed on the forensic accountants having the ability to effectively present evidence in a legal system. Forensic accountants are often required to resolve disputes and present evidence in legal disputes. One goal is to resolve the dispute prior to the case reaching the court system. However, there have been occasions where a dispute could not be resolved and the forensic accountant was expected to act as an expert witness in trials. Investigation is the act of determining whether criminal activity has occurred.

Some of the duties of a forensic accountant may include

- investigating and analyzing financial data,
- using technology in the interpretation and presentation of financial information,
- communicating findings through documented hard data, and
- testifying in court as an expert witness.

Forensic accountants are required to work with more than numbers. They have to paint the big picture after data has been collected. There are many situations that can affect the future of a business. These situations can be positive or negative. Situations with negative impact may be viewed as risks, whereas situations with a positive impact can be seen as opportunities. The overall objective of most businesses is to minimize risk and seize opportunities.

Forensic accountants may be called upon to evaluate an organization's exposure to risk. Enterprise risk management addresses the risks and opportunities facing an organization by classifying objectives into four categories:

- Strategic—"big picture" goals focused on supporting an organization's mission
- Operations—effective and efficient use of the organization's resources

- Reporting—reliability of reporting
- Compliance—compliance with laws and regulations

Some of the flags that will catch a forensic accountant's attention include the following:

- Lack of an employee handbook
- Disorganized company records
- Missing documents
- Unrecorded transactions
- No bank reconciliations
- Subsidiary ledgers out of balance
- No physical inventory counts
- Checks written to cash
- Large related party loans
- Excessive other revenue
- Negative operating cash flow
- Extensive fund transfers
- Unusual transactions (inconsistent)
- Deficient hiring policies and procedures
- Employees' lifestyles inconsistent with salaries
- Employees who do not take vacations
- Special purpose entities
- Excessive insider sales of stock
- Unexplained upper management resignations
- Excessive debt/equity ratio
- CPA switching
- Strange account titles

A forensic accountant is usually asked to investigate an organization by auditing its financial and business related records. Most forensic accountants are required to have a broad skill set in areas such as accounting, auditing, and investigation. These skills will assist the individual in preparing an extensive, objective financial report that can be explained in environments such as a court of law. Many in this field have a bachelor's degree in accounting and the CPA designation. Other popular designations include Certified Fraud Examiner (CFE) and Certified Forensic Accountants (Cr.FA). When a person in this field graduates from college, the individual may have a starting salary between $30,000 and $60,000. However, seasoned forensic accountants have been projected to earn six figures.

Fortis

Fortis describes itself as providing complete banking and insurance services for individuals, businesses, and institutions. Specifically, the bank provided retail, commercial, and merchant banking services. Insurance services included life insurance, health insurance, and property coverage. Formerly based in Belgium and the Netherlands, Fortis was, at the end of 2007, the world's 20th largest corporation. Its income was reported to be €120.5 billion with a net profit of €4.35 billion. At that time it had over 62,000 employees. It is, at the end of 2008, a worldwide company with offices in 50 countries and employing over 50,000 people. Further, while several parts of the company retain the name of Fortis, they are in fact, components of this company that have now been sold.

Fortis came into being in 1990 as the result of a merger of companies, some that had originated in the early 18th century. These companies were at first, AMEV, a Dutch insurer and a Dutch banking group, VSB. Later in the same year a Belgian insurer, AG, joined the new organization. It was the first cross-border financial services deal in Europe's history. The new name, Fortis, was selected in the following year and was chosen because of the Latin meaning of the word: "strong."

In the mid-1990s, Fortis embarked on a program of acquisitions. Fortis purchased MeesPierson NV, a portion of the Dutch bank, ABN AMRO, that specialized in investment banking. Later Fortis purchased a Belgian banking and insurance company, Algemene Spaar en Lijfrentekas, Caisse General d'Epargne et de Retraite. By 2007 Fortis had also acquired the Pacific Century Insurance Holdings and a Polish Bank, Dominet. Fortis had also partnered with the Irish Postal Service to provide financial services.

Fortis then embarked on its largest deal and the one that would eventually lead to the company's demise. Fortis joined with two other banks, Royal Bank of Scotland and Banco Santander, to execute what was the largest bank acquisition in history with the partners paying €98 billion. It was also the first cross-border hostile takeover of a bank. Together, the three banks purchased the Dutch Bank ABN AMRO, with the idea that once it was acquired, the three partners would dismember the organization, each taking the parts that fit its own core business best. For its investment of €24 billion, Fortis received ABN AMRO's Dutch consumer banking as well as asset management and private banking units. Because of the long history and reputation of ABN AMRO, the name would be kept.

The acquisition was announced in October 2007 and generated a great deal of interest; from the beginning there were some doubts about the wisdom of the deal. For one thing, the partners, according to some analysts, had paid up to three times the actual book value of ABN AMRO. Some of these analysts predicted that because of the amount of the purchase price, the companies had to show good results in a fairly short period of time, 18 to 24 months.

The results did show up in a very short time but not in the way that the partners had planned. Santandar made out the best as it was able to sell its acquisitions quickly. Royal Bank of Scotland did not do so well, but Fortis, with its capital depleted by the sale, ran into trouble almost immediately. In July 2008, the CEO of Fortis, Jean Votron, resigned to be replaced for a little over two months by a member of the board of directors. The value of the company at that time was estimated to be one third of what it had been before the acquisition.

By the end of September, when a new CEO was named, Fortis was partially nationalized by the Belgian, Luxembourg, and Dutch governments, which paid over €11 billion. The parts of ABN AMRO still under Fortis control would not be integrated into Fortis but would be sold. Parts of Fortis's Belgian operations would be sold to BNP Paribas and would keep that name (hence the company Web page and communications with the Fortis name).

Forward Market

Not a formal market like the futures exchange, the "forward market" describes the informal over-the-counter trade of forward contracts. Forward contracts are similar to, and sometimes described as a type of, futures. Futures are different principally in their standardization and margining, giving them less of a credit risk; forwards, traded over-the-counter, are customized between parties.

A forward contract is an agreement to exchange an asset at a specific point in the future, with the payment exchanged in advance. That payment is called the forward price or forward rate; there are formulas that can be used to determine, based on the spot price of the asset, a forward price which entails no loss for either party. The lower limit of the price is the spot price modified by the risk-free rate of return over the period; the seller has no motive to delay selling if the price doesn't exceed what he could make by selling today and putting banking the payment. The seller, then, is at least guaranteed to be no worse off than if he or she were to sell today instead of on the forward market, and if the cost of the asset goes down or increases by less than the risk-free rate, then he or she is benefited further. The buyer takes the risk that the asset will increase in value at a rate equal to or greater than the risk-free rate.

These assets can vary considerably, and can include stocks, bonds, other securities, foreign currencies, and so on. They are principally used by speculators and hedge funds, and so are slightly more common in the foreign exchange market, especially with respect to "minor" currencies that are more subject to fluctuations—and therefore ripe for speculation—than stable, well-established currencies from major economies. Of course, because of the potential of reward beyond the risk-free rate, the forward market offers an opportunity for arbitrage.

France

Traditionally one of the most powerful countries in Europe and one of the largest economies, France, and until the 1950s, the French Empire, was a dominant force in global business. France still remains important in the global economy in many sectors, and French companies or French products can be found in every country in the world. The Celts in France certainly traded with the Britons in modern-day southern England, and there is also evidence of products from France in parts of southern Europe in this same period. During Roman times, Gaul (as France was then known) was an important center of Samian ware, reddish pottery that was exported throughout the Roman Empire, as was wine from southern Gaul, and sandals and military supplies for the Roman army.

As an entity, France has been a relatively cohesive nation since the Middle Ages, and although parts of it were occupied by the English and other nations, and Burgundy was effectively independent for most of the period, the French language served as a common bond. During the Norman and Angevin empires, when England and much of France shared a single ruler, regular commerce across the English Channel increased, with some of the stones used on Norman castles in England being sourced in France and brought over as ballast in ships.

France was devastated during the Hundred Years War, but it also saw Paris emerge as the major city in the country, and the undoubted center of business, although northern France started to become wealthy through the wool trade and its links with Flanders. This saw the emergence of wealthy port cities such as Rouen and Dunkerque (Dunkirk), and elsewhere in France at the same time, Nantes, Bordeaux, Le Havre, and Marseilles. King Henry IV of France (reigned 1589–1610) managed to help establish a major silk industry, persuading the English Elizabethan clergyman Rev. William Lee to move to France to develop his knitting frame; but the design was never taken up seriously, with the Wars of Religion in France from 1562 until 1598 having done much damage to the French economy.

With Louis XIV (reigned 1643–1715), the country went through a great period of prosperity, which he lavished on the palace at Versailles. Unfortunately, it was also a period when inventions such as the first self-propelled mechanical vehicle designed by Nicolas Cugnot (1725–1804) were not taken up, and in 1685, the Revocation of the Edict of Nantes of 1598—the law guaranteeing toleration to the Protestants—

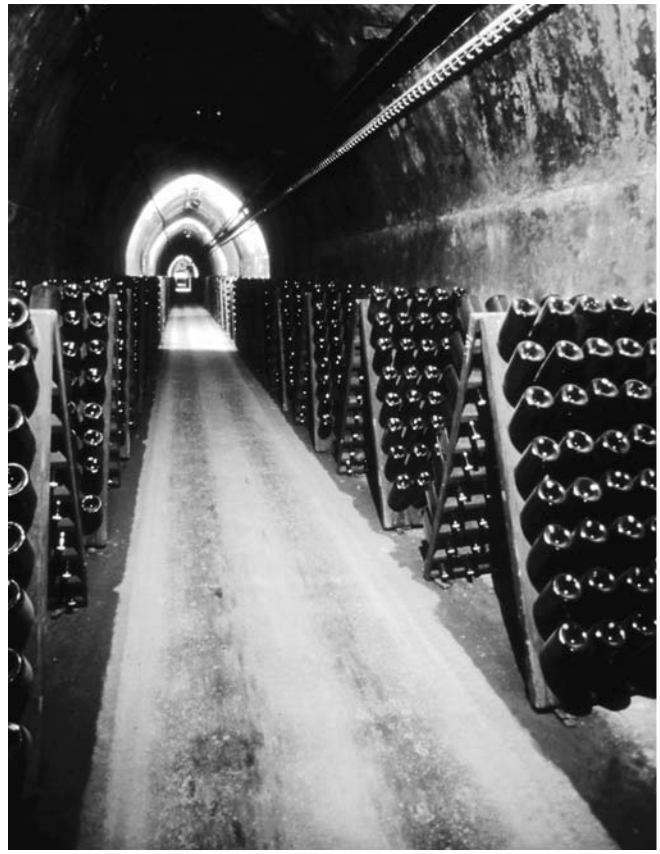
led to the flight of many Huguenots from the country. The country remained prosperous under Louis XV (reigned 1714–74) but ran into major problems under Louis XVI (reigned 1774–93), partly over the large budget deficit, the aristocratic reaction to paying higher taxes (or indeed, in some cases, any taxes), and the added cost of financing France's involvement in the American War of Independence.

The French Revolution

The French Revolution led to a transformation in French society. The system of tax farming ended and was replaced with a single and unitary state. Under Napoleon, many of the archaic systems of measurement—which had done much to hinder trade around France and with other countries—came to an end with the introduction of the metric system. Napoleon was also involved in plundering the wealth of many other countries and this in turn helped augment the finances of the French state. However, the constant wars were to drain the country, both financially and also through the loss of so many men in fighting. The French Revolution itself led to many French Royalists such as Marc Brunel (father of Isambard Kingdom Brunel) fleeing the country. Others like the chemist Antoine Lavoisier (1743–94) were executed by the revolutionaries, but some like the statistician Sébastien Bottin (1764–1853), flourished, introducing the business directory Didot-Bottin, which was heavily used in France and overseas, especially in countries in the former French Empire, until the 1960s.

The 19th Century

Napoleon tried to increase European trade, and his Continental System, which stopped trade with Britain, certainly increased the manufacturing base of some of Europe as there was no longer the danger of cheaper British imports. From the mid-19th century to the period just before World War I, France was the center of much of the creative talent in the region. Joseph Eugène Schneider (1805–75) designed the power hammer; Joseph Monier (1823–1906) invented reinforced concrete; the Michelin brothers, André-Jules Michelin (1853–1931) and Edouard Michelin (1859–1940) developed pneumatic tires; Alfred George de Glehn (1848–1936) contributed to the development of the steam locomotive; and Paul Cornu (1881–1944) devised a helicopter in 1907.



A vast wine cellar in France, where wine remains an important export, though agriculture accounts for only 3 percent of GDP.

Even though some of these designs never led to any manufacturing—such as Cornu's helicopter—it did show that France was at the forefront of design. Louis Bleriot's flying across the English Channel set the scene for French aviation. The work of Gustave Eiffel (1832–1923) and the Suez Canal of Ferdinand de Lesseps (1805–94) were examples of this on a much wider scale, although mention should be made of de Lesseps's plan for the Panama Canal, which collapsed amid major controversy in France and led to widespread criticism of the French government. The Paris Exposition of 1881 and later exhibitions showed off French produce to the world.

There was also a growth in French financial institutions that in turn led to some problems such as the Mexican Expedition, when the French intervened in Mexico where the government had tried to cancel large amounts of debts incurred by their predecessors. Alsace-Lorraine was the center of much of the industry of France, and for this reason, the area was captured by the Germans in 1870, only to be returned to France after World War I.

The creation of the French colonial empire transformed France, and French products were soon sold all around the world. The French economy expanded with the availability of cheap agricultural produce from Algeria, and later rubber from Vietnam, spices from East Asia, and nuts, palm oil, and other products from French Africa, as well as tobacco from a variety of sources. Many of the companies, now household names, originated during this period. For the automobile industry, Michelin (founded in 1888) and Renault (founded in 1899) are two examples.

The French as manufacturers were producing trains, trams, and aircraft. French foods such as chocolates, truffles, cheeses, and wines were exported to many other countries. Mineral water companies such as Perrier Water and Vichy Water became household names around the world. In banking, Crédit Foncier de France (founded 1852), Crédit Lyonnais (founded 1863), the Société Générale (founded 1864), the Banque de l'Indochine (founded 1875; now a part of the Crédit Agricole group), and other banking and insurance institutions, were institutions trusted by businesses and individuals around the world.

World Wars I and II

The fighting and the losses that France suffered in World War I had a traumatic effect on France. With the deaths of almost 1.4 million soldiers, sailors, and airmen in the war, as well as many more badly injured, it was a loss that the French population noticed greatly during the 1920s and 1930s. War production had dramatically altered the economy, but there were noticeable improvements. Prior to the war, the telephone system was antiquated. It was replaced by the Americans with a new one that served Paris and the nearby region. Factories were larger and more efficient, and women had entered the workforce in larger numbers than ever before. However, there were also many political problems with regular strikes and agitation by the newly powerful trade union movement. It was also a period when the communists, and later the socialists, started to flex their muscle.

During the 1920s and 1930s, the French colonial empire was maintained, although increasing numbers of non-French personnel had to be trained, providing opportunities for locals, some of whom were to lead the subsequent nationalist movements after World War II. During the 1920s, the United States came to epitomize mass production, but the French companies were seen as having "style." Nevertheless, owing to the jurisdictions of the various colonial empires, most goods produced in France were sold either to a home market or to parts of the French Empire. This allowed many of the French companies to expand into Africa, Indochina, and other parts of the world.

The German invasion of France in May 1940, and France's collapse less than six weeks later, led to four years of German occupation. After the war, some French wanted to return to the glory of the pre-1939 period, but colonial struggles in Indochina, and then in Algeria, ended this. Many of the French colonies in Africa became independent by the early 1960s, although most of them did retain close ties with France and continued buying goods from French companies.

Postcolonial Era

The loss of the French colonies caused a major rethink in French government policy, and combined with the absorption of many former residents of the colonies, especially from Algeria. France saw itself more and more as a leader in Europe, becoming a major force in the Common Market, which became the European Economic Community, and later still the European Union. This helped protect the agricultural sector in the country, much to the chagrin of the British, with regular disputes in the early 1980s between the British prime minister Margaret Thatcher and her French counterparts. In spite of this, agriculture accounts for only 4 percent of the French workforce and contributes 3 percent of the gross domestic product (GDP). The service sector accounts for 72 percent of the current workforce in France and makes up 76 percent of the GDP, with industry employing 24 percent of the workforce and generating 21 percent of the GDP.

During the late 1960s and from the early 1970s, France established itself as a major arms supplier in the world, and this has led to accusations about its involvement in many conflicts such as those in Africa and the Iran-Iraq War. France has continued exporting weapons and military supplies, with companies such as Aérospatiale (makers of the Exocet missile) and Dassault well known internationally. In terms of fashion, French designers such as Christian Dior (1905–57) and Yves St. Laurent (1936–2008) have led to the great interest in French style. French manufacturers of glass and plastics, and also French publishers such as Hachette, have also expanded their operations. Tourism has long drawn many people to France—some 76 million visited France in 2005, spending US$42 billion (the overall population of the country being 60.8 million)—and Air France, and through it and other companies, ownership of hotels and resorts around the world have kept most countries in the world in contact with France.

In 2005, France exported US$434.4 billion, with the major part being machinery and transportation equipment, aircraft, plastics, chemicals, pharmaceutical products, iron and steel, and beverages, especially wine. Imports included machinery and equipment, automobiles, crude oil, aircraft, plastics, and chemicals. Germany made up 15 percent of the export market, and 17 percent of the import market, with Spain and Britain being substantial recipients of French exports, and Italy and Spain being, after Germany, the main sources of imports into France.

France Télécom

The company France Télécom is the main telecommunications company in France and one of the largest in this field in the world. Until 1988 it was a part of the Ministry of Posts and Telecommunications, and was known as the Direction Générale des Télécommunications. The ministry traces its origins back to the 18th century when the French monarchs controlled the transportation system for the country. In 1794, five years after the French Revolution, the monopoly was broken and private companies were permitted to transport packages, but it was soon found that this removed a lucrative source of income from the government, and in 1804 Napoleon reintroduced the monopoly. The government also controlled the telegraph system when it was introduced but started to relax this in the 1850s.

In 1878 the first telephone was introduced to France, and three telephone networks were established; these were later merged to form the Société Générale de Téléphone (SGT), much to the joy of many people who objected to unsightly telephone lines along the streets. The Paris telephone exchange opened in 1881 and it was soon apparent that the SGT was interested in establishing a telephone network only in Paris and the major cities. It had its license renewed in 1884 for five years, but the system lagged that in many other countries, and in 1889 the French government took control of the SGT and started running the telephone service itself with the Ministry of Posts, Telegraphs and Telephones, and produced the first telephone directories in 1890.

Even under French government control, the system still lagged that in many other countries, and in 1900 there were only about 30,000 telephones in the country. By comparison, in 1909, the 100 largest hotels in New York boasted 27,000 lines. The congestion at the telephone exchange was also so bad that in 1905 it took two minutes for a connection. The government decided to improve the service and by 1912 there were 72,000 telephones in Paris, accounting for more than half of the telephones in the country.

In the years just before World War I, the French telephone service, worried about spies, removed anybody who had German ancestry or heritage. During World War I, the telephone network in northern

This France Télécom branded phone booth photographed in Wellington, New Zealand, in 2008 indicates the extent of the company's worldwide reach. It has also had a presence in such diverse locations as Kenya and El Salvador.

France was disrupted by the German invasion, but the French army tried desperately to maintain it. When the U.S. forces arrived, the American commanders were shocked by the telephone service in Paris and rebuilt the entire network.

During the 1920s and 1930s, about half of the subscribers in France were still living in Paris, and in addition to the regular telephone directory, the company Didot-Bottin produced a commercial directory listing businesses and also many private subscribers, not only in France but also overseas, especially in the French Empire. With the outbreak of World War II, the French telephone system was put under considerable strain by the military, but their commander General Maurice Gamelin was so distrustful of the telephone service that he refused to reply on telephones in his headquarters in Vincennes. German engineers were brought in to repair some of the telephone lines during the war, and the system was not that badly affected during the liberation of France in 1944.

After the end of World War II, the French telephone network in the countryside, especially in southern France, was dramatically expanded, although Paris continued to make up about a third of the subscribers in the country. The French telephone engineers were also responsible for constructing the telephone network in much of the French Empire, especially in Algeria and Morocco. In addition, French telephone engineers were employed on the telephone service in Egypt.

In 1988 the French government finally decided to sell the telephone service and it was privatized. It still continues to help with telephone networks around the world, and employs about 191,000 people, half of whom work outside France. It also has about 159 million customers around the world, and in the 12 months ending in September 2004, it had a revenue of US$60.1 billion; in 2007, its revenue was €52,959 billion. In 2005 France Télécom bought a 77 percent share in Amena, the Spanish mobile telephone company, and renamed it Orange Espana, and in November 2007 it was able to buy 51 percent of Telkom Kenya from the government of Kenya. Until 2003, it also had a large share in Telecom Argentina, selling it down to 1 percent, and also owned the telephone network in El Salvador.

Franchising

Franchising is the practice of licensing a philosophy of business—and its associated brand names—by a franchisor to a franchisee, in exchange for a share in sales and a franchise royalty fee. Chain stores and chain restaurants are the franchises best known to the public, and McDonald's is the most successful franchise network in the world. In the United States, the rise of franchises paralleled the growth of the interstate highway system and the sense of America as a nationwide culture rather than a conglomeration of regional cultures. Though not uniquely American, franchising is a distinctly American practice, at once appealing to the small business owner and representing the success of the national or international corporation.

United States

In the United States, franchising is governed by both state and federal laws. The Federal Trade Commission requires that franchisors provide a Franchise Disclosure Document (FDD) to potential franchisees, at least 14 days before the franchisee signs a contract. The FDD replaces the Uniform Franchise Offering Circular, a similar document that was required until the FTC revised its franchising-related regulations; the new regulations went into effect in July of 2008. The FDD consists of 20 items, in addition to the franchisor's financial statements, the franchise contract, and a receipt; no government agency audits a franchisor's FDD to ensure its accuracy, and a potential franchisee is expected to perform due diligence in doing so, but a franchisor misrepresenting itself is certainly liable to fraud charges.

The 20 items of the FDD are as follows:

1. The franchisor and any parents, predecessors, or affiliates.
2. Business experience. In this section, the directors, trustees, general partners, and officers of the franchisor are listed, along with any previous employment in the past five years.
3. Litigation. This section discloses any pending litigation against the parties in (1), any litigation from the previous fiscal year, and any convictions, nolo contendere pleas, or civil suit liabilities from the previous ten years.
4. Bankruptcy. Discloses whether the franchisor has filed for bankruptcy in the previous 10 years.
5. Initial fees.
6. Other fees.
7. Estimated initial investment. This includes not simply the fees paid to the franchisor, but the expenses the franchisor anticipates the franchisee will need to make, such as purchasing or leasing real estate and equipment, training employees, and purchasing inventory. One of the benefits of becoming a franchisee is that you are pursuing a business model that has been successfully pursued before, and can learn from your fellow franchisees' experience; the information disclosed in item (7) ideally reflects that collective wisdom.
8. Restrictions on sources of products and services. Some franchises require that the franchisee purchase some or all of its inventory from the franchisor, which provides the franchisor with additional revenue streams; in some cases this is true even when the inventory provided by the franchisor is not distinctly different from that which

the franchisee could purchase elsewhere (such as Heinz ketchup for a fast food franchise).

9. Franchisee's obligations. Types of obligation can include site selection and acquisition, pre-opening purchases, site development, employee training, opening, fees, standards/policies compliance, trademarks and proprietary information, product restrictions, warranties and customer service, territorial development, ongoing purchases, maintenance, insurance, advertising, indemnification, management and staffing, records and reports, inspections, transfer, renewal, post-termination obligations, non-competition convenants, and dispute resolution. The combination of post-termination and non-competition obligations are especially important to a potential franchisee, because a franchise contract is typically long term—five and 10 year contracts are common—with a penalty for early termination. A franchisee unhappy with his franchise may find that his only alternative is not simply a new business but a new industry.
10. Financing.
11. Franchisor's assistance, advertising, computer systems, and training. The complement to item (9), this section discloses the extent of the franchisor's participation.
12. Territory. Franchisees don't generally want to compete directly with fellow franchisees of the same franchise. This section discloses whether the franchise agreement grants exclusive territory, and other items related to the issue of territory.
13. Trademarks.
14. Patents, copyrights, and any proprietary information.
15. Obligation to participate in the actual operation of the franchise business. Some franchisor's require that if the franchisee is an individual, he must be on-premises for the operation of the franchise business; others let him hire a supervisor to run the business, as is common in franchises in which franchisees may own multiple locations. When supervisors are an option, there may be optional or mandatory training programs offered by the franchisor. The supervisor may also be bound by restrictions similar to those of the franchisee—such as non-competition or maintaining the integrity of trade secrets.
16. Restrictions on what the franchisee may sell. Franchisors generally want to preserve their brand identity, which may lead them to preclude a franchisee from selling anything not on a specific list of options. Or there may be some binding agreement with a third party, such as a fast food franchise's contract with Coca-Cola or PepsiCo to provide only the soft drinks from that company and not from its competitor.
17. Renewal, termination, transfer, and dispute resolution. This section lays out the franchise relationship—not only the length of the term of contract, but provisions for termination by the franchisee or franchisor, provisions for transfer of the franchise to another franchisee, provisions for death or disability, and an agreement pertaining to methods of dispute resolution should the need arise.
18. Public figures. Discloses any information about public figures' involvement with the franchise.
19. Financial performance representations.
20. Outlets and franchisee information.

The FDD offers as complete a picture as possible of the franchising experience, much like the prospectus given to potential investors in a new business. Although the FTC requires the FDD, there are no federal filing requirements; often, state laws will require franchisors to file or register at the state level, and in the 21st century there is an increasing likelihood of municipalities passing ordinances restricting franchise businesses, out of the fear that Big Business will arrive to displace mom-and-pop shops.

Several notable Supreme Court cases have dealt with conflicts between franchisees and franchisors. *Burger King v. Rudzewicz*, 471 U.S. 462 (1985) was brought before the court when Burger King (based in Florida) sued John Rudzewicz and Brian MacShara of Michigan for failing to make their monthly payments to the franchise, because of an economic downturn and lack of cash flow. The reason the case came to the Supreme Court's attention was because of the matter of jurisdiction; though the United States District Court ruled that Florida's jurisdiction extended to anyone who breached a contract in that state, the Eleventh Circuit Court of Appeals overturned that finding on the belief that the exercise of such jurisdiction violated the Fourteenth Amendment's prescription of due process. The Supreme Court upheld the District Court's decision, finding in favor of Burger King (and establishing precedent important to franchisors who might otherwise have reason to be reluctant to do business with franchisees in other states).

Franchise Validation

There are many factors to consider in entering into a franchise contract, particularly now that so many markets are filled with competing franchises, some of which seem to offer nearly identical experiences. The FDD includes a list of current franchisees, and potential franchisees typically use the list during a process called "franchise validation." During validation, potential franchisees arrange to interview current franchisees about their experience. Questions cover financial details, the relationship with the franchisor, the way marketing and promotion (typically funded by a pool into which all franchisees pay) are handled, and the availability of support and information from the franchisor after opening. Franchisees don't have to answer questions, of course, but will often be open about their experiences, and those who are unhappy with their franchisor but are stuck by the terms of their contract have no reason not to air their complaints.

But franchise validation is a time-consuming process, and potential franchisees don't always know the right questions to ask, or the right way to follow up on the answers. Franchise consulting has become a niche industry, a professional service that consults with potential franchisees and identifies a good fit for their needs, amidst the many franchise opportunities available. Franchise consulting is an industry subject to little regulation, and many franchise brokers refer to themselves as franchise consultants, which can muddy the view of the industry. Properly speaking, a franchise consultant works for a fee, paid by the franchisee. A franchise broker will advertise his services as free, but works much like a realtor does, taking a fee from the "seller" (the franchisor) in exchange for finding a "buyer" (the franchisee). Not every franchisor is willing to pay the brokerage fee, and so the options available to a franchisee working with a broker are fewer than those working with a franchise consultant. Franchise consultants, some of whom may also be franchise lawyers with a working knowledge of contract law, can also help potential franchisees understand the language of the lengthy FDD, which can be cumbersome and oblique through no fault of the franchisor. (Attorneys cannot work as franchise brokers, because state laws would find their fee from the franchisor a conflict of interest.)

History

Franchising began with the Industrial Revolution. Historian Robert Wiebe identifies the late 19th century through World War I—what is sometimes called the Progressive Era, overlapping with the Gilded Age of the post-Reconstruction years—as an organizational period in American history, when the emphasis began to shift from regional identity to national identity. This wasn't reflected simply in how people talked about themselves, or in the shift from "the United States are" to "the United States is." It was a practical change, as national professional organizations like the American Medical Association and the American Bar Organization were formed; national labor unions formed around the nuclei of local unions; magazines and newspapers began producing content that was distributed nationally; and more and more commercial products were produced not just for local consumers but for consumers across the nation. Radio, when it arrived at the tail end of this period, adopted a national mindset almost immediately, with broadcast corporations distributing their programming nationwide—a precursor to the model the television networks would follow.

Coca-Cola is one of the first early examples of franchising success; after Asa Candler bought the rights to the name and formula of the soft drink developed by Atlanta pharmacist John Pemberton, he licensed the syrup both to bottlers and to drugstore soda fountains. Rather than simply selling the syrup and allowing the retailer to do as they liked with it, Candler attached conditions to the sale and presentation of Coca-Cola; it had to be sold under that name, for instance, and he fought hard against the use of the nickname "Coke" out of fears that it would jeopardize the product's trademark. (Copycat products with names like Koke were cropping up everywhere.) He discouraged adulteration, including the addition of other flavors like cherry, lime, or coffee, despite their widespread popularity—first and foremost in his mind was the protection of the brand identity, and with a strong enough brand identity the product would outsell all in its class. It was a unique approach for the time, and must have been instrumental in the success of the company and the brand; certainly Candler's approach was aped by the soft drink companies that followed.

Coca-Cola, though, was the franchise of a single product, much simpler than the modern franchise system. It was drug store owner Louis Liggett of Boston who popularized the franchise store in 1902. He talked 40 of his fellow drug store owners into pooling money together to form a collective, which would pay for advertising and marketing, bargain with wholesalers for cheaper prices, and benefit from a unified brand name—Rexall. After World War I, the company began granting franchise rights to new stores, and it later sponsored the *Amos 'n' Andy* radio show.

The first restaurant franchise followed in 1932 with Howard Johnson's, which expanded quickly despite the ongoing Great Depression. Much of Howard Johnson's success came from bidding on the exclusive rights to build restaurants at the gas station turnoffs on major northeastern and mid-Atlantic turnpikes. The growth of the highway system would provide many opportunities for franchises throughout the next few decades, into the 1970s, as companies like McDonald's, Kentucky Fried Chicken, and Taco Bell depended on the strength of nationwide advertising and the lure of familiarity to build chains of restaurants attended by family and business travelers. As it became more common for Americans to move to different parts of the country for work or school, the existence of nationwide franchises had a somewhat homogenizing effect, providing familiarity to strangers. You may not know the local mechanic, but your past experiences provide positive associations for the Meineke brand name.

Types of Franchises

There are four broad types of franchises. Product franchises are similar to Asa Candler's handling of Coca-Cola. With a product franchise, a manufacturer enters into an agreement with a retailer to distribute his products, one that is more complicated than a simple sales transaction. The agreement may call for a minimum number of purchases per quarter or fiscal year, or may require a certain type of display; it may require that the manufacturer's competitors not be available at the same outlet.

Manufacturing franchises are like those granted to soft drink bottlers. The franchise grants the license to produce and sell a product under a particular trademark. This may also involve purchasing the equipment or materials to make the product from the owner.

Business opportunity franchises generally involve the distribution of another company's products in a particular franchised fashion—for instance, vending machine distribution is often franchised.

The most common type of franchise is the business format franchise, which includes McDonald's and other fast food restaurants, Meineke and many other auto repair business chains, Gold's Gym and Curves, and so on. The FDD is constructed with the business format franchise in mind, because this is the franchise relationship with the most potential complication.

Freddie Mac

Federal Home Loan Mortgage Corporation, or Freddie Mac, is a U.S. government–sponsored but privately owned corporation created for the purpose of increasing the supply of funds for home mortgages. The origin of Freddie Mac goes back to the Depression era when the U.S. government wanted to make it easier for potential homeowners to build and own their houses. In order to ease availability of funds to these individuals, the government created an organization that came to be known as Fannie Mae. In 1970 the U.S. Congress continued with the privatization of the mortgage market and legislated the creation of Freddie Mac.

Freddie Mac, along with other government-sponsored organizations like Fannie Mae and Ginnie Mae, increases the volume of funds available for mortgages while simultaneously lowering their cost by providing a secondary market for mortgages. In what is called the primary market, a financial institution approves a home-builder's request for a mortgage, funds the mortgage through deposits it attracts and its equity. Without a secondary market, the total volume of mortgages would be limited to the share of their total deposits that the financial institutions would be willing to commit to mortgages.

A secondary market for mortgages is created when the financial institution sells the mortgage to an institution like Freddie Mac. Freddie Mac bundles a number of these mortgages together and creates one collective asset whose cash flows are derived from the collection of mortgage payments—interest as well as the principle repayments. This collection of mortgages is called a mortgage backed security or MBS. Freddie Mac sells all or parts of this MBS to investors. Since Freddie Mac can bundle mortgages from different types of borrowers and from different regions, the MBS portfolio becomes diversified across various risk categories and has higher return and lower risk than a portfolio of mortgages held by a particular financial institution. The improved risk-return profile makes these securities attractive for individual investors. Creation of this secondary market increases the volume of funds available for mortgages and competition between various providers of funds to this market lowers the cost at which home-builders can obtain mortgages.

Freddie Mac and Fannie Mae provide similar services but compete with each other. Ginnie Mae, on the other hand, provides guarantees on loans issued by government agencies and deals with smaller sized mortgages. In contrast to Ginnie Mae, Freddie Mac deals with mortgages that are not federally insured and can be of different sizes and different interest rates. Freddie Mac mortgages tend to be of larger sizes. Together these institutions are knows as Government Sponsored Enterprises, or GSEs, because government places looser restrictions on them relative to fully private companies. Although these enterprises are not fully backed by the government, they can raise funds in the market at advantageous rates because of the common perception that the government will not allow these institutions to default. The government sponsorship became very important in the summer of 2008 when problems with the housing market exploded into a full-blown financial crisis.

Freddie Mac became a central part of the mortgage credit crisis of 2008 after a $300 billion government bailout package.

At the end of 2007, Freddie Mac held $710 billion worth of mortgage backed securities in its portfolio. The mortgage backed securities market has grown from about $200 billion in 1989 to more than $2 trillion in 2006. Till about 2001, Freddie Mac and other GSEs dominated this market, together maintaining a market share of about 80 percent. Private issuers held the remainder of the market. Since 2002, however, private issuers began offering what became known as subprime mortgages. The share of these subprime mortgages increased from about 20 percent in 2002 to about 55 percent in 2006. Private issuers resort to securitization—they hand over the administration of the mortgage contracts to suppliers of funds instead of holding the mortgages to maturity.

Crisis

Beginning in 2007, rates of defaults in the subprime sector of the mortgage market began to increase partly due to declines in house prices and partly due to the nature of the subprime borrowers. Financial institutions that had held the mortgage-backed securities based on subprime mortgages faced heavy losses resulting in bankruptcy or re-organizations of large investment banks like Lehman Brothers and Bear Stearns.

In July 2008 Freddie Mac along with Fannie Mae felt the full brunt of the emerging financial crisis. These two institutions either held or guaranteed about $5.2 billion worth of mortgages in the country—about half of the total U.S. market. Their portfolio included some mortgage-backed securities issued by other institutions ($267 billion at the end of 2007 with Freddie Mac). With their capital of $83.2 at the end of 2007, their leverage ratio of 65:1 was much higher than any other financial institution could support. Freddie Mac had lost $3.5 billion in 2007. With losses accumulating in 2008, share prices of Freddie Mac (as well as Fannie Mae) dropped from 65 in mid-2007 to less than 10 in July 2008.

The drop in share prices implied that these institutions would find it very difficult to raise new capital in the financial markets to continue supporting the housing mortgage market, which had become more important in mid-2008 due to withdrawal of private financial institutions. Their status as GSEs as well as their sizes required that the U.S. Treasury and Congress intervene to protect these institutions.

By the end of July 2008, the U.S. Senate and Congress approved a $300 billion package that would be used to guarantee mortgages issued by the two institutions—Freddie Mac and Fannie Mae. The implicit guarantee of the government thus became explicit. In turn, the government acquired preferred shares in the two organizations as well as rights to acquire some outstanding common shares, and placed a host of other minor restrictions on the activities of these two organizations. The two institutions were placed in *conservatorship*—a less offensive term than *nationalization*.

The era of unprecedented growth of these giants in the mortgage as well as the U.S. financial markets may have ended with the financial crisis that began in full earnest in 2008.

Free Markets

Free markets are economic exchanges where producers and sellers voluntarily exchange economic goods and services with no outside interference or coercion. In a free market both parties to the transaction exchange goods and services, because they expect a gain from the exchange; if there is no expectation of gain, there is no exchange. The gain from the exchange arises from the difference between the value each party gives to the goods or services received and the cost of obtaining them.

To increase efficiency in a free market, money and a market price emerge. First, money, or a standardized means of payment, is used to reduce the negotiation over the value of two different goods that are bartered by the individuals and to reduce the need to have individuals interested in the goods bartered in each transaction. Second, a market price emerges with the repetition of the exchanges to simplify the negotiation of each transaction; the market price reflects the consensus at which the particular good or service is exchanged between suppliers and buyers. Temporary changes in the price provide incentives to parties in the transaction to change their behavior. Price increases induce an increase of supply and reduction of demand, while price reductions induce a reduction in supply and increase in demand. These forces bring the market price back in line with the long-run norm. Thus, free markets and the accompanying price system are viewed as an efficient system in allocating goods and services in a cost-effective manner.

Market Imperfection and Market Failures

However, free markets are not always efficient means of exchange because of the existence of market imperfections and market failures; these prompt governments to intervene in free markets. First, market imperfection refers to a situation in which there is a deviation from the conditions of perfect competition, i.e., where there are multiple buyers, perfect information, free entry in the industry, and multiple producers with no significant market share generating a homogeneous product with the same production technology. In a perfectly competitive market, goods are exchanged at the market price, firms are price takers, and in the long run do not earn profits above the norm. However, the conditions that support perfect competition are not met in many instances. Barriers to entry in the industry, differences in production technology, or information asymmetries give rise to imperfect competition. This can take the extreme form of monopolies, i.e., when one firm controls most of the market and sets prices and quantities exchanged, or oligopolies, i.e., when a reduced number of firms dominate the market and can potentially collude to maintain a price increase. Governments are likely to intervene in the market to reduce the negative impact of such imperfection on consumers. They do so by regulating the industry, mandating specified levels of production or prices, setting limits on the power that the monopolist or oligopolists have over buyers or against new entrants, or even substituting private producers with state-owned enterprises to increase competition or to reduce prices.

Second, market failures exist when the free market is unable to provide goods and services to buyers. Market failures emerge when goods and services are subject to nonexcludability and nonrival consumption. Nonexcludability refers to the situation when an individual who does not pay for the product cannot be prevented from using or benefiting from it. In this case the free market does not work, because individuals will not pay for a product that they can obtain for free; as a result, the producer has limited incentives to generate the product. Nonrival consumption refers to the situation when the consumption of a product by an individual does not reduce the ability of others to consume the product. In this case the free market results in an undersupply of the product, because charging a price will prevent some people from benefiting from a product that could be provided at no cost. A mixed situation of part rival and part nonrival consumption gives rise to externalities, when one person does not receive the full benefits (positive externality) or does not pay the full cost (negative externality) of the impact of their action on other people.

Governments are likely to intervene in situations of market failures. They do so by subsidizing producers to serve consumers who are excluded, by imposing costs or providing incentives to producers of negative and positive externalities (respectively), or by undertaking the activities that are non-excludable and have nonrival consumption and paying for them with taxes.

Although the intellectual roots of the concept of free markets have been part of economic discussion for centuries, they tend to be associated with the work of Adam Smith. He postulates that the self-interest of individuals and their specialization resulted in a free market where the interaction of demand and supply would result in efficiency. Government intervention in free markets would only result in distortions. Competition, the so-called invisible hand, would force producers and buyers toward efficient terms of exchange and support economic growth.

Later, writers of the Austrian school of economics, like Ludwig Von Mises or Friedrich von Hayek, and the Chicago school of economics, like Milton Friedman, provided additional depth to the concept that free markets are better than governments at facilitating growth. Additionally, the authors argue that free markets would eventually lead to a free society.

Models of Development

Despite this long intellectual lineage, during most of the 20th century free markets were subject to government controls throughout the world. The controls resulted in three alternative models of development. In capitalist developed countries, which were then known as the First World, governments followed the ideas of John Maynard Keynes and established high levels of regulation and controls over the capitalist system, i.e., private ownership of means of production and a price system to allocate resources. In communist countries, which were known as the Second World, governments implemented the ideas of Karl Marx and established a communist economic system, i.e., central planning of prices and quantities and state ownership of means of production. In developing countries, which became known as the Third World, governments followed a middle road, maintaining a capitalist system, but with high levels of government regulation, state ownership, and price controls designed to promote industrialization.

Moreover, in some of these countries governments, influenced by dependency theory (which argues that developing countries were kept underdeveloped by their dependency on industrialized countries for manufactures, machinery, and technology), followed an import substitution model. Under this model governments additionally limited imports and the operations of foreign firms to protect domestic firms from international competition and enable these firms to develop.

However, the economic crisis that started with the oil embargo of 1973, which led to stagflation, i.e., inflation and economic stagnation, questioned the viability of models of high government control over free markets. As a result, governments started to relinquish control over the economy and allow free markets to operate. In 1976 Chile became one of the first countries to embark on the economic reform needed to restore free markets, resulting in its growth. However, since the economic liberalization was done by a military dictatorship, an association between an authoritarian regime and free markets was established. As a result, other developing countries did not implement economic reform until much later.

Reduced Government Control

In the early 1980s, the idea of free markets started to gain acceptance in industrialized countries when the United Kingdom, under Prime Minister Margaret Thatcher, and the United States, under President Ronald Reagan, started a process of economic liberalization, prompting imitation by other developed countries. In developing countries free markets did not gain acceptance until Bolivia, which was suffering from hyperinflation after the Latin American debt crisis of 1982, established a program of economic reform in the mid-1980s. This program of reinstating free markets and reducing government control over the economy stopped hyperinflation and brought economic growth. Since the program was implemented in a democracy, it became an example for other developing countries that a dictatorship was not needed for free markets to be implemented and deliver economic growth. Communist countries also undertook economic reforms to replace their planned economies with a capitalist system and create free markets. China started the transition to free markets in the early 1980s, while countries in Eastern Europe and the former Soviet Union started in the late 1980s.

As a result of these transformations, the idea of free markets as the more effective and efficient path toward development has taken hold in most countries in the world. The reason is not only that free markets have shown their ability to generate efficiency and growth, but also that governments, not only markets, have been shown to suffer from imperfections, particularly in planning an economic system and facilitating growth. Some of the consequences of misguided and/or misplaced government intervention are the distortion of incentives as individuals change their behavior according to what the regulations reward, the emergence of rent seeking as individuals and firms focus on extracting concessions from the government rather than achieving efficiency, or the appearance of black or informal markets as individuals and firms circumvent constraints on prices or quantities that can be sold. As a result, from a free market point of view, it tends to be accepted that it is better to leave economic relationships to markets. This does not mean that governments do not have a role to play in the economy. On the contrary, governments have an important role in providing the infrastructure that supports market transactions. This includes macroeconomic stability, the establishment of the rule of law and protection of property rights, the provision of public goods, and the protection of the weak.

Criticism

Nevertheless, although most countries have reinstated free markets as the mechanism to govern economic relationships, criticism emerged in the late 1990s and 2000s as part of the antiglobalization movement. This movement emerged in opposition to the spread of free market ideas and the consequent changes in the integration of the world and globalization of markets. The debate regarding the best way to organize economic relationships has become one of free markets versus so-called fair markets. Free markets are perceived as too focused on efficiency and wealth accumulation and not caring about the distribution of wealth. To replace this, the concept of fair markets was introduced to represent economic exchanges in which minimum levels of payment for labor and equitable distribution of wealth are included as objectives to achieve.

In some cases this has resulted in a market in its own right, such as for so-called fair trade products—products traded where producers, usually of commodities or handicrafts in developing countries, receive a higher wage or price than the prevailing market one. In other cases, the concept of fair market has been used to reassert control of the market by the government. In the extreme this has resulted in the nationalization of firms, as seen in Bolivia or Venezuela in the mid-2000s. Thus, the debate concerning which model to use to govern economic relationships is still alive.

The empirical literature analyzing the impact of free markets on countries tends to find that free markets do in fact help countries achieve economic growth and development. Recent developments in the literature argue that for free markets to operate most efficiently, complementary institutions, such as those that protect property rights and the rule of law, need to be present. The literature also finds that the benefits of free markets do take time to materialize and that some government intervention does achieve positive results.

Free Trade

Free trade is a market model in which trade in goods and services between or within countries flows freely without any restriction, such as tariffs, quotas, non-tariff barriers, or taxes. Utilizing the argument that the free market is the best "governor" to ensure increase in wealth, free trade demands that government intervention with the "free" market be eliminated and all restrictions be removed. In history, the merit of free trade was extensively discussed by Adam Smith in 1776 in his book *The Wealth of Nations,* examining the gains of free trade in the context of specialization and division of labor (absolute advantage theory).

The idea of free trade was also later formulated by David Ricardo by using one factor of production with constant productivity of labor in two goods, but with relative productivity between the goods different across countries (comparative advantage theory). David Ricardo claimed that gains from free trade will be great once a policy of free trade is adopted in an institutional setting. For Jagdish Bhagwati, the classical and neoclassical schools of economic theory constantly emphasized the advantages of free trade policies for the improvement of popular living standards and the promotion of overall rates of economic growth, and the disadvantages of protectionism. The basic conclusion of classical and contemporary neoclassical economic theory is that the advantages of free international trade represent basically only a special case of the advantages of the free market system in general.

Nevertheless, in the 20th century, "New Trade Theory" manifested itself as the economic critique of international free trade from the perspective of increasing returns to scale and the network effect. Some economists asked whether it might be effective for a nation to shield infant industries until they grow to sufficient size to compete internationally. According to this theory, the optimum-tariff and infant-industry arguments constituted some grounds for protection and protectionist policies by some countries, and more importantly were seen as a departure from free trade within the framework of the traditional theory. However, the general trend in international trade is in line with the reduction of tariffs and other trade restrictions through international negotiations.

Theories

Absolute advantage in trade theory was introduced to the literature by Adam Smith, whose view of the economic system was that nations' wealth is equal to their production capacity. In his positive-sum economy it is perfectly possible to make everybody better off and real incomes per head are able to rise indefinitely as a policy of laissez-faire promotes economic growth. In his view, as self-interest is combined with competition, which also serves public interest, division of labor increases productivity. He fortified the idea of free trade with only one production factor, which was labor. His labor theory of value states that the value of a good is determined by the amount of labor required to produce it. Nevertheless he did not consider how to deal with capital, land, and profits.

Comparative advantage was offered by David Ricardo in order to fill gaps in Adam Smith's approach on absolute advantage of nations in trade. Ricardo, like Adam Smith, was opposed to tariff and other restrictions on international trade. The Ricardian model focuses on comparative advantage of nations. It is considered perhaps the most important approach in international free trade theory today. In a Ricardian model, countries specialize in producing what they produce best, and comparative advantage is the ability to produce a good at a lower cost, relative to other goods, compared to another country. In *Principles of Economics*, Ricardo states comparative advantage is a specialization technique used to create more efficient production and describes opportunity cost between producers.

Ricardo's idea of comparative advantage suggests that unrestricted free trade brings about increased world production; that is, that trade is a positive-sum game, and also suggests that opening a country to free trade stimulates economic growth, which creates dynamic gains from trade. However, it has its own limitations as well. The most important limitations are that nations strive only to maximize production and consumption; only two countries produce and consume just two goods; no transportation costs of trading goods; labor is the only resource used to produce goods; and ignore efficiency and improvements gains from producing just one good.

The Heckscher-Ohlin factor productivity theorem was introduced by Eli Heckscher and his student Bertil Ohlin in the 1920s as an alternative to the Ricardian basic comparative advantage theory. This theorem builds its own assumptions on David Ricardo's theory of comparative advantage by predicting patterns of trade. For this theorem, relative endowments of the factors of production (labor and capital) determine a country's comparative advantage. It also suggests that the pattern of international trade is determined by differences in factor endowments. In addition, this theorem has variable factor proportions between countries, e.g., highly developed countries have a comparatively high ratio of capital to labor in relation to developing countries. This makes the developed country capital-abundant relative to the developing country and the developing nation labor-abundant in relation to the developed country. Similarly, this theorem has also its own limitations. Even so, this approach does not answer certain question. Why does a country with cost advantage not capture the whole export market? What would happen if countries have similar relative factor endowments? What would happen in the case of intra-industry trade? What would happen in the case of trade liberalization?

Arguments in Favor of Free Trade

According Anne Krueger, one of central themes of economics for the last two centuries has been the proposition that free trade between nations will be beneficial, and any nation that adopts a policy of free trade will benefit highly from free trade opportunities. Nevertheless, the protection to infant industries and pressure for it found enough support to create circumstances that support protectionism in trade. There are mainly two different opposite arguments in international free trade literature. These are arguments in favor of free trade and against of free trade.

Arguments for free trade mostly concentrate on its enhancing power of national welfare. To be able to explain the welfare impacts, these arguments focus on three aspects. These are (1) the efficiency gains from free trade; (2) the additional gains from economies of scale; and (3) the political argument.

Efficiency arguments: Although moving toward free trade may represent very real financial losses for the small minority of companies with the political influence to get themselves protected from foreign competition, these losses are normally much lower than the gains to the great majority of the population. The neoclassical school underlines the case for free trade with propositions on efficiency and aggregate welfare. For Arye Hillman, the neoclassical school defends the idea that, given sufficient information, compensating lump-sum transfers can ensure that a policy of free trade is in the self-interest of every individual of an economy. Paul Krugman and Maurice Obstfeld stated that the first case for free trade is the argument that producers and consumers allocate resources most efficiently when governments do not distort market prices through trade policy. With restricted or protected trade, consumers pay higher prices and distorted prices cause overproduction either by existing firms producing more or by more firms entering the industry.

The efficiency argument for free trade is based on the result that in the case of a small country, free trade is the best policy for the national welfare. According to this argument, a tariff causes a net loss to the economy and a move from tariff equilibrium to free trade eliminates the efficiency loss and increases national welfare.

There are two basic arguments in defense of free trade in the presence of domestic distortions: (1) domestic distortions should be corrected with domestic (as opposed to international trade) policies; for example: a domestic production subsidy is superior to a tariff in dealing with a production-related market failure; and (2) market failures are hard to diagnose and measure; for example: a tariff to protect urban industrial sectors will generate social benefits, but it will also encourage migration to these sectors that will result in higher unemployment.

Additional gains from economies of scale: Protected markets in small countries do not allow firms to exploit scale economies. For example, in the auto industry, an efficient scale assembly should make a minimum of 80,000 cars per year. In Argentina, 13 firms produced a total of 166,000 cars per year. Therefore, the presence of scale economies favors free trade that generates more varieties and results in lower prices, and free trade provides a wider range of opportunities and thus a wider scope for innovation.

Political argument for free trade: A political commitment to free trade is considered as the best strategy. Any policy that deviates from free trade would be quickly manipulated by special interests, leading to decreased national welfare. Free trade requires security and consistency in politics; therefore, it can be used as a kind of pressure on countries to sustain their political balances.

Arguments Against Free Trade

There are three theoretical arguments against the policy of free trade. Arguments against free trade focus on (1) market failure argument, (2) benefits of tariffs, and (3) infant industries argument.

The terms of trade argument for a tariff: An optimum tariff based on the application of a country's market power in the international market improves its terms of trade. For a large country (that is, a country that can affect the world price through trading), a tariff lowers the price of imports and generates a terms of trade benefit. This benefit must be compared to the costs of the tariff (production and consumption distortions). It is possible that the terms of trade benefits of a tariff outweigh its costs. Therefore, free trade might not be the best policy for a large country.

The domestic market failure argument: According to Arye Hillman, in the absence of compensatory transfers or other income adjustments, there will be no consensus how to select a trade policy that will benefit everybody in the society. Producer and consumer surplus do not properly measure social costs and benefits. Consumer and producer surplus ignore domestic market failures such as (1) unemployment or underemployment of labor, (2) technological spillovers from industries that are new or particularly innovative, and (3) environmental externalities.

A tariff may raise welfare if there is a marginal social benefit to production of a good that is not captured by producer surplus measures. The domestic market failure argument against free trade is a particular case of the theory of the second best. The theory of the second best states that a hands-off policy is desirable in any one market only if all other markets are working properly. If one market fails to work properly, a government intervention may actually increase welfare.

Infant industries argument: The infant industries argument states that developing countries have potential comparative advantages in manufacturing and they can initialize this potential through an initial period of protection. The best policy to protect domestic industries is to use tariffs or import quotas as temporary measures to get industrialization started. One of the most important reasons for this strategy is that capital markets are imperfect in most developing countries in their initial development stage. If a developing country does not have a set of financial institutions that would allow savings from traditional sectors (such as agriculture) to be used to finance investment in new sectors (such as manufacturing), then growth of new industries will be restricted. Furthermore, firms in a new industry generate social benefits for which they are not compensated (e.g., start-up costs of adapting technology). In practice, infant industries argument was supported by the import substituting industrialization policy in many developing countries during the 1960s and the 1970s, and many less developed countries pursued this strategy.

International Negotiations

International integration increased from the mid-1930s until about 1980 because advanced countries gradually removed tariffs and non-tariff barriers to trade, and the removal of tariffs became politically possible through international trade negotiations.

It is easier to lower tariffs as part of a mutual agreement as a unilateral policy because it helps mobilize exporters to support freer trade, and it can help governments avoid getting caught in destructive trade wars. Since World War II, the multilateral tariff reductions have taken place under the General Agreement on Tariffs and Trade (GATT), which was established in 1947 as a provisional international agreement, and then in 1995, it was replaced by a more formal international institution called the World Trade Organization (WTO). The GATT-WTO system is a legal organization that embodies a set of rules of conduct for international trade policy. The GATT-WTO system prohibits the imposition of (1) export subsidies (except for agricultural products), (2) import quotas (except when imports threaten "market disruption"), or (3) tariffs (any new tariff or increase in a tariff must be offset by reductions in other tariffs to compensate the affected exporting countries).

Their negotiations address trade restrictions in at least three ways: (1) reduction of tariff rates through multilateral negotiations, (2) binding: a tariff is "bound" by having the imposing country agree not to raise it in the future, and (3) prevention of non-tariff barriers: quotas and export subsidies are changed to tariffs because the costs of tariff protection are more apparent.

Preferential trading agreements are trade agreements between countries in which they lower tariffs for each other but not for the rest of the world. There are three types of preferential trading agreements in which tariff rates are set at or near zero: (1) a free trade area: an agreement that allows free trade among members, but each member can have its own trade policy towards nonmember countries: an example is the North America Free Trade Agreement (NAFTA); (2) a common market is a customs union with free factor movements (especially labor) among members; and (3) a customs union: an agreement that allows free trade among members and requires a common external trade policy towards nonmember countries: an example is the European Union.

Free trade–related negotiations can also be linked with regional integration, which is believed strengthens structural reforms, provides economic transformation, attracts foreign direct investment, emphasizes the importance of geopolitics, and helps corporations to function. Key regional blocs that pursue free trade agreements are EU (European Union), NAFTA (North American Free Trade Agreement), Mercosur/Mercosul (Southern Cone Common Market), ASEAN (Association of South-East Asian Nations), CACM (Central American Community), and FTAA (Free Trade Area of the Americas).

Compared to previous decades, the proliferation of regional trade agreements (RTAs) during the last 10 years took place at an unprecedented rate and eventually became a very prominent feature of the multilateral trading system (MTS). Some 380 RTAs have been notified to the GATT/WTO up to July 2007. Of these, 300 RTAs were notified under Article XXIV of the GATT 1947 or GATT 1994; 22 under the Enabling Clause; and 58 under Article V of the GATT. At that same date, 205 agreements were in force. If we take into account RTAs that are in force but have not been notified, those signed but not yet in force, those currently being negotiated, and those in the proposal stage, we arrive at a figure of close to 400 RTAs that are scheduled to be implemented by 2010.

Of these RTAs, free trade agreements (FTAs) and partial scope agreements account for over 90 percent, while customs unions account for less than 10 percent. While the greatest concentration of RTAs is in Europe, more than 100 RTAs are in force. The main focus of RTA activity has shifted away from Europe in the last two years toward Asia Pacific. The Asia Pacific Economic Cooperation (APEC) members, in particular, have been among the most active participants in RTAs.

In fact, RTAs are a fundamental departure from the principle of nondiscrimination of the WTO. Two broad questions raised by the formation of RTAs are (1) welfare effects: How does the creation, expansion or merger of RTAs affect the welfare of member and nonmember countries? and (2) stability: When is a trade arrangement stable? Are RTAs "stepping stones" or "stumbling blocks" toward global free trade. Welfare effects of RTAs are in particular very important because of static allocation effects (trade creation/diversion, terms of trade effects, pro-competitive, and product variety effects); accumulation effects (medium and long run growth effects), and location effects (spatial allocation of resources as economic geography studies the location of production in space). RTAs can also have growth effects. Economic integration may raise the incentive to innovate, and therefore may improve the economic growth performance of members through research and development and technological spillovers.

Free Trade Area of the Americas

The Free Trade Area of the Americas (FTAA) was an attempt to create a multilateral institution with the objective of reducing and eliminating the many trade barriers that existed between all American countries. It was also an attempt to emulate the North American Free Trade Agreement (NAFTA) that had proven quite successful for the countries that signed it. This was supposed to be the first step to creating a common market, similar to the one achieved by the European Union during the second half of the last century. It would try to harmonize all the commercial policies of each of the countries of the continent.

Initially 34 countries signed the agreement; nonetheless, controversial aspects of trade, such as intellectual property rights and agricultural subsidies, made impossible the conciliation between all parties. In fact, some countries, like Venezuela and Cuba, decided to criticize it and oppose it, trying to create their own alternatives as counterpoise. The initial talks began in 1994, with the Summit of the Americas in Miami supported by the United States, but it was in 2001 in Quebec, in the Summit of the Americas, when the discussion of the agreement became broader and the resistance of antiglobalization activists caught the attention of the public. Despite the relative advance in negotiations and the release of a draft in Buenos Aires in the same year, there were no further agreements because some member countries felt themselves at serious disadvantage, as they were producers of commodities, especially agricultural goods.

The FTAA was not the first initiative for economic integration of the American states. Since the 1960s, there were already in place many economic agreements such as the Andean Community of Nations (CAN), the Common Market of the South (Mercosur), the Caribbean Community (CARICOM), and NAFTA itself, as the main examples of the process of creating agreements of economic cooperation. One of the objectives of FTAA was to merge these agreements in one single system of trade, with the suspension of barriers, tariffs, and taxes and the homogenization of all markets, using the European Union (EU) as an conceptual model. Additionally, the Doha Development Round of the World Trade Organization (WTO) revealed many aspects that were not included in previous negotiations, with particular attention to social issues.

The United States decided not to negotiate into the FTAA these controversial topics, along with the problem of internal aid and subsidies policies in the agricultural sector, in a process called Single Undertaking, in defense of its national interests. This generated discontent in many countries, who rejected this deterioration of rights and duties. Moreover, the United States demanded strict laws in the regulation of intellectual property and copyright. With the exception of Brazil, the rest of the states were at a disadvantage if anyone decided to negotiate separately and directly an agreement with the United States, which would jeopardize the future of an FTAA.

This consequence was more evident in the Quito Ministerial Summit of 2002. Despite the release of a second draft, the differences between the United States and the rest of the countries made it inappropriate to continue with negotiations. Mercosur, with the leadership of Brazil and Argentina, decided to postpone their entrance into the FTAA. They would accept an agreement only if the United States abolished its agricultural subsidies and guaranteed free access to all of its market, with consideration of the needs, capabilities, and sensibilities of possible members; finally, there were attempts to find a solution to these controversial issues in the WTO resolutions of the Doha Round.

According to the original schedule, the approbation and launching of FTAA was supposed to be in 2005, but delays and the indisposition of the United States to change its agricultural policies and its position on intellectual property—jointly with the emergence of opposition against U.S. free trade policies of countries turned socialist, like Venezuela and Bolivia—led to the failure of the Mar del Plata Summit in Argentina in 2005, and the agreement on FTAA was far from becoming a reality. Of the total states present at the summit, 26 nations scheduled a new meeting in 2006 to resume negotiations and release the final agreement, but that meeting never took place.

In 2004 Venezuelan president Hugo Chavez along with Evo Morales from Bolivia and Fidel Castro from Cuba launched the Bolivarian Alternative for the Americas (or ALBA) as an offset of FTAA. Its main objective was the creation of energy and infrastructure agreements and the inclusion of other aspects like military and political integration. Due to the impossibility of signing the FTAA without discarding its agricultural policies, the United States decided to create bilateral trade promotion agreements (TPAs), making one with Central American countries and signing one with Peru in 2007, and negotiating similar agreements with Panama and Colombia.

Free Trade Zone

A free trade zone (FTZ), also known as an export processing zone (EPZ), is a product of globalization. An FTZ is a specially designated area for export-oriented foreign direct investment. As a result, most tariff and non-tariff barriers are eliminated through agreements of states and investments are incentivized. These incentives usually include the waiver of customs and tariffs, the suspension or curtailment of laws in areas such as environmental protection and labor rights, and the facilitation of licensing procedures for foreign companies to set up local operations. Additionally, host countries often develop infrastructural support in areas such as transportation and telecommunications to support FTZs.

FTZs can be set up solely to support a single industry if there are only certain natural resources available. An example would be the Onne Oil and Gas Free Zone in Nigeria. Furthermore, there can be other benefits to a specific free trade zone, because industry-specific and sector-specific skills are tailored to the zone. Similar to an FTZ, actual agreements between trading partners such as the North American Free Trade Agreement would be the next step to completely removing tariff and non-tariff barriers between states.

Generally, an FTZ describes foreign exporting zones in less industrialized nations, such as Bangladesh, that seek to attract multinational corporations and investment into their respective zones. In one way, FTZs demonstrate the benefits of free trade. These zones provide corporations with favorable investment conditions, while at the same time providing developing nations with vital capital, the ability to export, jobs that would otherwise not exist or would exist somewhere else, and, in some cases, the transfer of technology from multinationals to local industries in the host country. Developing nations can have somewhat of a comparative advantage that they would not normally have through the use of free trade zones.

However, there are some criticisms of FTZs. Some say that multinationals unfairly exploit the developing nations that offer the most incentives and have an unfair advantage over them. Also, these corporations exploit local communities through adverse trading relationships, unfair labor practices, environmental degradation, lack of transfer of technology, and lack of long-term commitment in the host country. Furthermore, the outsourcing that FTZs encourage has led to a drain of manufacturing capabilities in already industrialized nations such as the United States.

The strongest criticism of FTZs comes from the globalized organized response to the ill effects of exported capitalism to the rest of the world. FTZs have mobilized people across borders who are opposed to the human and environmental costs of international free trade policies. Anti–World Trade Organization (WTO) protests, socialist movements, and global social justice networks and organizations such as the "Make Trade Fair" campaign have highlighted the high price humans in developing countries have paid in these zones, as well as the long-term economic costs associated with creating, maintaining, and improving such zones.

FTZs can range from clothing assembly to electronics assembly. Traditionally, FTZs attract businesses that are labor intensive or physically intensive instead of technology based, partly because of fear of competition. However, Taiwan, Korea, and Ireland have all managed to create FTZs where high-tech companies have flocked to, and high salaries and the transfer of that high technology have followed.

FTZs are not governed by a particular body. Instead, each state provides a different package of incentives and regulations. However, multinationals continue to push host countries to increase their incentives and to deregulate. In the pursuit of offering the most attractive package, host countries will try to make their package the most attractive, thereby creating a standard among them. In turn, the working conditions of the workers in "sweatshops" become worse, and so nongovernmental organizations (NGOs) such as the International Labour Organization and others eventually push for minimum global standards for labor practices.

FTZs are complex, since they are each dynamic in their own way. They provide the benefits of globalization to both developed nations (companies that are headquartered there) and developing nations, but provide more benefits to developed nations at the expense of the developing ones.

Freight Forwarder

A freight forwarder may be defined as a consolidator that collects small shipments from shippers, consolidates them into large loads, and uses a basic mode to transport them to a consignee destination. At destination, it breaks the load down into individual shipments and delivers them to the correct consignee. Freight forwarders have been compared to wholesalers in the marketing channel or to high street travel agents, except that they arrange transportation for freight, not people.

Before describing the activity of a freight forwarder, it is important to clarify what are shippers and carriers. The shipper is the party that requires the movement of the product within the supply chain. The carrier is the organization that moves or transports the product. For example, haulers or trucking companies carry freight on trucks.

Freight forwarders can be classified as domestic or international (foreign), depending on whether they specialize in shipments within a country or externally to other countries. They purchase transport services from any of the five basic transportation modes—motor, rail, air, water, or pipeline. For instance, the domestic surface freight forwarder presents the consolidated shipments to railroads or haulers for intercity movement. Foreign freight forwarders, now designated in the United States as ocean transportation intermediaries under the U.S. Shipping Act of 1998, deal with the forwarding of an export shipment.

Advantages

Due to advances in information technology and relaxation of customs barriers (mainly in EU and NAFTA spaces), companies are outsourcing their noncore functions and freight forwarders have become a viable shipping alternative for many firms. Freight forwarders consolidate a large number of small shipments, from a number of customers or shippers, into large shipments in order to fill entire truck trailers or railcars that transport items at truckload or carload prices. Due to consolidation efficiencies, freight forwarders are able to offer shippers lower rates than the rates they could obtain directly from the carrier, because small shipments generally cost more per pound to transport than large shipments. Freight forwarders provide, for that reason, valuable services to both the shipper (lower prices and faster and more complete service) and the carrier (consolidation). The freight forwarder makes its revenue from the difference between the higher less-than-volume rate the shipper pays and the lower volume rate it obtains from the carrier. Freight forwarders procure transport services from a range of carriers, although today they may own the vehicles themselves.

International freight forwarders may have a central role in the export strategies of many firms and most companies can benefit from utilizing their services. This is mainly true for companies new to the international trade field, with small or irregular export activities, and for those located far away from the main exit or entry ports of their country. Freight forwarders have a strong knowledge of transport alternatives, can prepare and provide the required international documentation, are able to offer a lower transit time for small shipments, special freight handling, and customs clearance, and, because they are regulated carriers, are liable for cargo damage. Even global companies, with their own export department, may use the services of an international freight forwarder, which helps coordinate shipments at the port of exit and activities at the final destination.

Firms use freight forwarders for a number of reasons: to handle the movement of goods from the site of production to the customer's location, through the setting of transportation and carrier routings; to reduce transportation costs through consolidation; to speed the movement of goods and customs clearance for freight that moves internationally, as they normally receive advanced shipping notices; to provide full service logistics, including warehouse inventory, product storage, sorting, packaging, labelling and bar coding operations; to provide logistics information systems and improve customer service; to reduce staff time, as freight forwarders can obtain freight rates and make space reservation at no cost to the shipper; and to acquire outside expertise and avoid capital expenditure.

Sometimes freight forwarders and NVOCC (non-vessel operating common carriers) are considered to be the same. However, although both operate as consolidators, they differ in a number of features. A freight forwarder usually acts as an agent of the shipper and not as a carrier. It offers a groupage service using a nominated shipping line or an NVOCC. Some of its principal activities include arranging and completing export and bank documentation and negotiating freight rates on the shipper's behalf. NVOCC allows shipping companies to concentrate on ship management and the freight forwarder to utilize its expertise in marketing and consolidating cargo. Freight forwarders are often NVOCC's biggest customers.

FT Index

The FTSE (pronounced "footsie"), or the Financial Times Stock Exchange Index, is a share index of the 100 most highly capitalized companies on the London Stock Exchange, and is maintained by the FTSE Group, an independent group that originated as a joint venture between the LSE and the *Financial Times*, a United Kingdom–based newspaper. The FTSE replaces the FT 30, which measured the daily movement of 30 major stocks on the LSE, as the most used index of the British stock market.

The FT 30 (also known as the FT Ordinary or the FT Index) is now largely obsolete, more than 70 years after its establishment in 1935 in the wake of financial reorganization that followed the worldwide depression. Imperial Tobacco and Rolls Royce are the only original FT 30 companies now listed on the FTSE.

The *Financial Times* predates the FT 30, naturally, by almost 50 years. Established in 1888, when Britain's economy was still the dominant economy in the world, it declared itself "The Friend of the Honest Financier and the Respectable Broker," and was originally distributed only in the financial community of London. In contrast with the older *Financial News*, the *Times* was intended to be reliable, conservative, even printing on pink paper, which was cheaper than white. The two papers merged in 1945, keeping the FT name while the *News*'s editorial staff was cherry-picked to create a stronger paper. Beginning in the 1970s, it expanded internationally, publishing three international editions from 23 locations. It was the first British paper to sell more copies internationally than domestically. FT.com was launched in 1995, and the FT indices are updated online hourly.

The first FTSE, the FTSE All-Share Index, was created in 1962, tracking at least 98 percent of the full capital value of all qualified stocks (those that are listed on the London Stock Exchange and meet various inclusive eligibility requirements). The FTSE 100 was introduced in 1982, and in 1995, the FTSE Group became an independent company, opening several overseas offices. It also maintains the FTSE 250 and 350 (the 250 largest and 350 largest stocks on the exchange, respectively), the FTSE SmallCap (tracking the companies outside the FTSE 350), and the FTSE AIM All-Share, 100, and UK 50, which track companies in the LSE's Alternative Investment Market.

The 100 companies on the FTSE 100 are subject to change every quarter. As of summer 2008, the list is 3i, Admiral Group, Alliance Trust, AMEC, Anglo American, Antofagasta, Associated British Foods, AstraZeneca, Aviva, BAE Systems, BG Group, BHP Billiton, BP, BT Group, Barclays Bank, British Airways, British American Tobacco, British Energy Group, British Land Company, British Sky Broadcasting Group, Bunzl, Cable & Wireless, Cadbury plc, Cairn Energy, Capita Group, Carnival, Carphone Warehouse, Centrica, Cobham, Compass Group, Diageo, Drax Group, Enterprise Inns, Eurasian Natural Resources Corporation, Experian, Ferrexpo, FirstGroup, Friends Provident, G4S, GlaxoSmithKline, HBOS, HSBC, Hammerson, ICAP, ITV, Imperial Tobacco, InterContinental Hotels Group, International Power, Invensys, Johnson Matthey, Kazakhmys, Kingfisher, Land Securities Group, Legal & General, Liberty International, Lloyds TSB, London Stock Exchange Group, Lonmin, Man Group, Marks & Spencer, Wm Morrison Supermarkets, National Grid, Next, Old Mutual, Pearson, Petrofac, Prudential, RSA Insurance Group, Reckitt Benckiser, Reed Elsevier, Rexam, Rio Tinto Group, Rolls-Royce Group, Royal Bank of Scotland Group, Royal Dutch Shell, SABMiller, Sage Group, J Sainsbury, Schroders, Scottish and Southern Energy, Severn Trent, Shire Pharmaceuticals Group, Smith & Nephew, Smiths Group, Standard Chartered Bank, Standard Life, Tesco, Thomas Cook Group, Thomson Reuters, TUI Travel, Tullow Oil, Unilever, United Utilities, Vedanta Resources, Vodafone, WPP Group, Whitbread, Wolseley, Wood Group, Xstrata.

FTSE

The FTSE Group is a company that specializes in the creation and management of asset class indices. The company was created in 1982 and is jointly owned by the London Stock Exchange (LSE) and the *Financial Times* (FT). The most well-known index is the FTSE 100, which is an index of shares for 100 companies listed at the LSE with the highest market capitalization.

Market indices track the performance of the assets that are included in the index, producing a statistic that should reflect the components' aggregated performance. Indices are constructed in order to replicate a group of assets that share at least one common characteristic, which is not always based on firms' value. So, for example, the FTSE4Good Index series is designed to track companies that meet corporate responsibility standards, including also climate change criteria. In addition, each country has its own index that tracks groups of shares with common characteristics. When FTSE was first created, the letters were an abbreviation of the two owners of the company, FT for *Financial Times* and SE for Stock Exchange. However, since this firm is now an independent group, this abbreviation does not apply any more. The group has partners and clients in 77 countries worldwide, and maintains and publishes more than 100,000 equity, bond, and hedge fund indices.

The firm offers tailor-made indices to its clients, however, it is mostly known for its series of structured indices. FTSE currently classifies indices in seven broad categories. First, the Global Equity Index Series covers over 8,000 assets in 48 countries, which accounts for 98 percent of the world's market value in publicly listed companies. Apart from the Global Indices that are included in this series (e.g., FTSE All-World Index Series and FTSE Global Equity Index), the series is also divided into developed and emerging (advanced and secondary) markets' indices. These are further subdivided in regional, national, and sector-specific indices. Recently, FTSE introduced the FTSE Shariah Global Equity Index Series that tracks the performance of assets that meet the Islamic finance requirements.

The second group of FTSE Index Series is the Regional & Partner Index series that includes indices calculated at a regional or country level across the continent. The series divides the investment world in three broad regions: Asia Pacific; Europe, Middle East, and Africa; and the United States. The flagship of FTSE indices is the FTSE 100 Index that includes the top 100 companies (measured by market value) currently trading in the LSE. The FTSE/JSE Africa Index Series and the LATIBEX Index Series reflect FTSE's innovative character, replicating the performance of African firms and Latin American firms respectively.

The Fixed Income Index Series is designed to track the performance of fixed income assets. It is further divided into the FTSE Global Bond Index Series, which covers the fixed income markets globally, the FTSE MTIRS Index Series that replicates the performance of interest rate swaps, and the FTSE UK Gilts Index Series that specifically tracks the performance of all British government securities. Fourth, the real Estate Index Series is designed to provide benchmark prices either for global or local/regional real estate investments. The Alternative Investment Index Series is further divided into the FTSE Hedge Index Series, which tracks the performance of hedge funds, the FTSE Private Banking Index Series, which is specially designed for the private banking industry, and a series of indices that track the performance of publicly listed companies that are active in the infrastructure development industry.

The FTSE Responsible Investment Index Series comprises indices that include firms that meet the corporate and/or the environmental responsibilities' requirements. The socially responsible investment index series has two objectives: to stimulate investments in firms that apply the corporate governance tools and to facilitate investors who are looking to invest in firms that demonstrate environmental awareness. The FTSE Investment Strategy Index Series includes a series of indices that incorporates a different methodology in calculating each company's wealth and therefore its weight in the index. So, for example, the FTSE GWA UK Index is similar to the FTSE All-Share Index in all but the firms' individual weight in the index.

Fujitsu

Fujitsu is a publicly owned company, headquartered in Tokyo, employing approximately 160,000 employees. Calling itself "a leading provider of IT-based business solutions for the global marketplace," it is the world's third-largest provider of information technology (IT) services and products, and serves customers in 70 countries. Its main competitors are IBM, Toshiba, and NEC. Annual revenues as of March 2008 were $53 billion with profits of $868 million.

Fujitsu is currently organized into three main components: Technology Solutions, Ubiquitous Product Solutions, and Device Solutions. Technology Solutions includes system platforms (system and network products) and services including solutions and systems integration and infrastructure services). Ubiquitous Product Solutions develops and manufactures personal computers, mobile phones, hard disks, and other equipment. Device Solutions provides large-scale integrated (LSI) devices and various electronic components.

Established in 1935, Fujitsu was first known as Fuji Tsushinki Manufacturing Corporation. It began operations as a 700-employee manufacturer of telephone equipment. After World War II, Fujitsu returned to this industry. By 1950 it was making 5,000 telephones a month. The following year, the company began manufacturing calculating machines, followed by designing and manufacturing electronic communications equipment. In 1954 Fujitsu developed Japan's first computer, the FACOM-100. Additionally, the company expanded its products to include equipment for radio communications.

The number of computers and the range of the Fujitsu product line grew. Fujitsu began exporting computers in the mid-1960s. International business grew to the extent that in 1967 Fujitsu Limited, as it was now known, opened its first international branch in New York City. It established a U.S. subsidiary the following year. The company grew in the 1970s, with new subsidiaries developed or otherwise acquired, and spin-offs created. Growth also took the form of partnering agreements with companies such as Hitachi and Siemens and Amdahl.

Fujitsu was known up to this time for its large computers, including its mainframe models. It now launched another effort that would have great signifi-

FUJITSU

Fujitsu, which began by manufacturing telephones in pre–World War II Japan, is now a world leader in supercomputers.

cance: the personal computer that it first introduced in 1981. On the other end of the scale, the company announced the development of its first supercomputer the following year. In 1984 Fujitsu introduced Japan's first artificial intelligence processor. Throughout the 1980s, new computer models (mainframes, supercomputers, personal computers) were introduced at the same time that the company was developing other equipment such as digital telephone handsets that entered the inventory in the mid-1980s.

In the 1990s, Fujitsu partnered with or acquired several companies. Among the acquisitions were British International Computers Limited and Amdahl. Partnerships were established with General Magic (United States), Sun Micro Systems, Sharp, Sony, Hitachi, Toshiba, Dialog Corporation, Siemens, and Sakura Bank (to establish an online bank in 1999).

The deal with Siemens, established in 1999, created Fujitsu Siemens Computers. The new organization became one Europe's largest computer hardware suppliers and one of the world's top five providers of servers, according to Fujitsu. In August 2008, Siemens announced that it wished to end the partnership largely because of lower prices and shrinking profit margins. While Fujitsu has the first right of refusal to buy Siemens's 50 percent of the partnership, there was some doubt as to whether this would happen. Fujitsu's objectives seem to be moving away from the manufacture of computers while increasing emphasis on cell phone development and manufacture.

Fujitsu has become well known for its manufacture of consumer goods such as air conditioners and plasma televisions (Fujitsu introduced the first 21-inch full color display in 1992). Through the 1990s Fujitsu also continued its development and sales of supercomputers, sometimes on a very aggressive basis. Along with NEC, Fujitsu was named in a preliminary finding by the U.S. Commerce Department to be guilty of attempting to dump supercomputers on the U.S. market. It had bid to supply a supercomputer to the U.S. National Center for Atmospheric Research and a suit was filed by the American computer manufacturer, Cray.

At the beginning of the 21st century, Fujitsu continues the development of supercomputers and continues its alliances, most recently with Microsoft, Oki Electric, and Lucent. In 2007 it bought Infinity Solutions Ltd., a New Zealand IT hardware, services, and consultancy company. In the same year, however, Fujitsu announced that one of its subsidiaries, Fujitsu Kansai Systems Ltd., had booked nonexistent sales, an incident similar to one that occurred at NEC as well as several other Japanese companies.

Fujitsu's expansion now includes inroads in India where it is investing money with the intent of providing support for its Fujitsu Consulting India with more than 100 percent growth by 2009.

Futures Markets

One hallmark of a free market system is risk. Most producers (as well as consumers) face the risk that prices of goods (or commodities) they produce will change between the time they invest their resources to produce the goods and the time they are ready to sell their output. While in some cases long-term supply contracts at prearranged prices can be made, most prices, especially those of financial assets, commodities, and raw materials, are subject to almost constant fluctuations. Futures markets reduce the uncertainty and risk associated with these fluctuations by allowing market participants to enter into contracts, called futures contracts, which fix the price of a specified asset at a future date. Futures contracts help the real-market participants by facilitating hedging and help investors by making speculation easier.

A futures contract is an agreement between two traders to exchange an asset at a predetermined future date (called the delivery date) at the "futures price." In the case of futures markets, the "asset" has been standardized as to the quantity, quality, the delivery point, and the date of delivery. The trade may take place at a "futures exchange" or "over-the-counter" (OTC)—a service provided by many financial institutions. OTC market allows large transactions to take place at lower cost and without the risk of moving the market price. Almost all transactions now take place over the phone or electronically, replacing the close physical contact that used to characterize trading on exchanges.

A futures contract differs from a "spot" contract mainly in terms of the date of execution of the contract: A spot contract is executed immediately after the contract is made whereas a futures contract is executed at a prearranged future date. A futures contract differs from a "forward" contract in that the futures contract is for a standardized asset whereas the asset in a forward contract can be tailor-made.

The oldest futures exchange in the United States, the Chicago Board of Trade was established in 1848. Futures contracts in tulips, however, were traded in Holland in the 17th century. Commodities, raw materials, and financial assets including interest rates and currencies form the bulk of the assets traded on the futures markets. There are, however, futures contracts for many exotic assets like weather. The Chicago Mercantile Exchange offers futures contracts on snowfall, "cooling" or "heating" degree days in the United States, Canada, Europe, or Asia-Pacific, and even a future contracts on hurricanes.

Futures markets facilitate the process of "price discovery" by providing information on current and possible future prices as assessed by market participants based on available information. This process is facilitated because futures markets provide improved liquidity and reduce counterparty risk for buyers and sellers of contracts over alternative arenas where comparable contracts could be traded. Improved liquidity comes from standardization of contracts, which makes trading easier for speculators. Since all the characteristics of an asset have been standardized, a speculator can focus on the single element of the assets that is of interest to him/her—the price. Futures markets reduce the risk for traders by a practice called mark-to-market.

Futures exchanges reduce the counterparty risk for a buyer or a seller in two steps. First, the buyer (or seller) of a futures contract enters into a contract to buy (or sell) a futures contract with the futures exchange, not with the trader who may enter into the opposite side of the transaction—in this case, the entity who may sell (or buy) the futures contract. This reduces the nonperformance risk, or the counterparty risk, from that of an unknown (and sometimes a higher-risk) seller to that of an exchange. As long as the buyer believes that the futures exchange will not become illiquid, there is no counterparty risk. Second, the exchange reduces the nonperformance risk for itself by taking two related steps. First, every buyer (as well as every seller) deposits a "margin" usually equal to 10 percent of the value of the contract with the exchange when the futures contract is bought (or sold). Second, every contract is "marked-to-market" every day. At the end of every trading day, the exchange calculates the current value of the contract. If the price movement during the day has resulted in a loss of the value of the contract, the loss is deducted from the margin and the buyer is sent a "margin call." This margin call requires the buyer to add funds to the margin so that it once again equals 10 percent of the value of the contract.

Similarly, the exchange pays the day's profits to the buyer of the contract should the price movement have been in favor of the buyer. Should the buyer not respond to the margin call, the exchange can liquidate the contract on the following trading day and prevent any further losses on the contract. With this practice of marking every contract to market every day, the exchange faces no performance risk unless the price movement during the day exceeds 10 percent against the buyer and the buyer decides to default.

Regulation

Futures markets are regulated by Commodity Futures Trading Commission in the United States. The objective of the regulation is to protect public and market users from fraud, manipulation, and abusive practices. Futures markets contribute to the economic welfare of a society by increasing efficiency through centralization of services to all users of an asset. They help users of assets in reducing risks by being able to hedge future transactions. They also help the economy by allowing "synthetic securities" to be created, which allow better management of risk, especially of financial risks associated with changes in prices and interest rates. Futures markets, however, are subject to manipulation by large traders. A humorous example of such potential manipulation was illustrated in the Hollywood movie *Trading Places*, which was released in 1983.

Gannon's Cultural Metaphors

Within the field of cross-cultural organization and management studies, Martin J. Gannon uses cultural metaphors to describe, compare, and analyze national cultures worldwide. In order to explore in-depth the unique cultural characteristics of a nation, Gannon adopts an emic approach, focusing on the qualitative examination of cultural symbols, practices, and institutions within their local context.

In an increasingly globalizing world, sensitivity toward, insight into and knowledge of cultural differences has to engage the attention of business, academics and everyone interested in working and living in another culture. Notably, Gannon's work about cultural metaphors makes a significant contribution to the fields of international business and international management because not only are the target audiences, i.e., the consumers, not similar across cultures, but business managers around the world are shaped by their own individual cultures as well. Thus Gannon's metaphorical study provides an in-depth analysis of "what makes us different and unique."

Martin J. Gannon's study of cultural metaphors is about identifying, describing, and comparing cultural metaphors in their respective contextual relevance. Gannon describes cultural metaphors as "common activities, phenomena or institutions with which people of [a given nation] … cognitively or emotionally identify." He suggests that cultural metaphors can be used to describe the national culture. Furthermore, his applying of cultural dimensions to local traditions and practices enables him to scrutinize and extract some of these cultural-specific metaphors of a nation.

Dimensions or variables can include concepts of religion, educational systems, and perceptions of and attitudes toward time and space. As such, Gannon's analysis of cultural metaphors synthesizes Hofstede's dimension (e.g., power distance, uncertainty avoidance) to profile national cultures and cultural differences. His analysis of cultural dimensions of a nation encompasses both cultural-specific (emic) and cultural-general (etic) dimensions. However, Gannon's cultural metaphor approach intends in the main to explore in-depth emic dimensions; that is, the somewhat "unique" dimensions of a culture. So, while some of these dimensions can be similar or even identical across nations, other dimensions may occur or become relevant as cultural metaphor to one nation alone.

In a metaphorical journey through 17 countries (in a later edition he expands this number to

28), Gannon makes "culture" an accessible concept by identifying a number of "typical" and "unique" national metaphors. For example, he looks at cultural metaphors such as the Dance of Shiva within the dimension of cyclical Hindu philosophy, or American football, referring to the dimensions of individualism and competitive specialization. Other cultural metaphors analyzed by Gannon include the Italian opera; focus is on the voice and the implication is that messages, irrespective of whether they are private or business, should be communicated in a beautiful manner. It also implies that thoughts and ideas cannot be kept hidden: They have to be discussed with family and others.

Gannon selected French wine as the symbol for French culture, the British house to symbolize British culture, and the Chinese family altar as a unique metaphor for Chinese culture. Given the high number of overseas Chinese, certain cultural metaphors, for example emphasis on family relationships and ancestry, are transcending borders and being disseminated transnationally. While this highlights the important distinction between nation and culture, that is, that culture is not confined to one nation alone, it also points to the fact that specific cultural metaphors are not necessarily relevant to each individual in one nation.

In the second edition of *Understanding Global Cultures*, Gannon categorizes selected nations according to "authority ranking cultures" (e.g., Thai Kingdom, Japanese Garden, India Dance of Shiva, Polish Village Church), "equality matching cultures" (German symphony, Swedish *stuga*, Irish conversations), "market pricing cultures" (American football, traditional British house), "cleft national cultures" (e.g., Nigerian marketplace, Italian opera, Belgian lace) and "torn national cultures" (Mexican fiesta, Russian ballet). In another book section, Gannon looks at "same metaphor, different meanings" nations (Spanish bullfight, Portuguese bullfight). He provides further an example of a "beyond national borders" nation (the Chinese family altar).

Relevance

While globalization often pretends that cultures are becoming more homogenous, it is now more important than ever to scrutinize and analyze such statements and perceptions as they may irrevocably result in imprecise and untrue market predictions and business decisions. With the increasing globalization of business, the academic and business world has become more and more interested in analyzing the relevance of culture in organizational and management contexts. In addition to the previous research into cultural differences, Gannon's cultural analysis attempts to adopt a content-rich approach to his inquiry into the emic characteristics of national cultures. Gannon advocates the non-use of an etic questionnaire, that is, one standard set of questions for all cultures; rather, by employing the concept of cultural metaphors, i.e., culturally unique metaphors, the iniquity of cultural stereotyping can be eluded and a more culturally rich interpretation provided.

Other studies in cross-cultural management include Geert Hofstede's 1980 study, the GLOBE study, and the World Values Survey. Hofstede's landmark examination of cultural differences across nations resulted in the identification of a number of cultural dimensions such as individualism, power distance, and uncertainty avoidance. The *Global Leadership and Organizational Behavior Effectiveness* (GLOBE) cross-cultural research study examines worldwide business leadership. The World Values Survey, first conducted in 1981, investigates the nature of changing public values, especially in regard to the relevance of—and attitudes toward—democracy. However, one of the earliest studies to empirically test the validity of cultural metaphor is that of Clifford Geertz (1973), who studied Balinese cockfights as symbols of Balinese culture.

Martin J. Gannon is a professor of strategy and cross-cultural management at California State University San Marcos and a professor emeritus at the Smith School of Business, University of Maryland at College Park. In 2002 he received the University of Maryland's International Landmark Award for exceptional contributions to the global area.

Gaz de France

Gaz de France began in 1946 as a government-owned corporation that produced and delivered natural gas, founded at the same time as Électricité de France (EDF). GDF's customers were primarily consumers in France where its base, by 2000, was 11.1 million customers. It was also an international company, transporting and selling gas world wide, in Belgium, Britain, Germany, and eastern Europe with a customer base of 2.8 million outside the country. Although the main business of GDF was natural gas, its business areas included nuclear power and other forms of electricity generation.

GDF's status as a government-owned company began to change in 2005 when a limited amount of stock (20 percent) was sold on the Paris Stock Exchange for a price of approximately €2.5 billion. In the following year it was announced that GDF would merge with Suez, another French energy company. The merger was difficult to accomplish because of difficulties in several areas. Shortly after the announcement of the plan to merge, two major labor unions in France threatened to strike in protest. Italy complained to the European Union (EU) about the merger as one of its own utility companies, Enel, had been planning to acquire Suez. Finally, the European Union antitrust organization was examining the deal very closely because Suez owned Belgium's main power company and GDF owned a 25 percent share of Belgium's second-largest power company.

French national laws had to be changed because the French government was still a majority owner of GDF stock and had pledged that it would always own at least 70 percent of the company's stock. The merger would reduce the French government's holdings to around 35 percent of the new entity. There would be a new set of problems in effecting the merger when the government of Villepin was replaced by the government of Nicolas Sarkozy. Sarkozy had expressed strong opposition to the deal, although he eventually changed his mind. In September 2007 the boards of directors of both corporations and the terms of the merger were publicly disclosed. The merger, which was completed in July 2008, after two-and-a-half years of effort, resulted in a corporation with €91 billion in assets and holding the number two position among European utilities.

The interest in GDF Suez on the part of the EU has continued. In mid-May 2008 as part of a series of raids on energy companies in Belgium, Italy, Austria, and Hungary, GDF was investigated by the European Commission. The basis for the investigation was that several companies were abusing their dominant position in their own countries. One goal of the EU had been to begin to eliminate the advantages national providers of energy had exercised in their own countries, undercutting the efforts of the EU to create a single market across the EU. Less than a month later, on June 13, GDF and E.ON were accused of colluding to raise prices. The Commission charged GDF and E.ON had agreed not to sell energy to each other's countries. In addition, as both countries jointly owned and operated a gas pipeline that transported natural gas from Russia to Europe, that management of that pipeline was coming under investigation. Both companies denied the accusations which, if proven, could result in fines equal to up to 10 percent of their revenue. GDF noted that their arrangements had predated the European Commission and the EU. Both companies have in recent years been under increasing EU pressure to sell their supply grids in order to encourage competition across Europe's borders.

Finally, as 2008 came to a close, the European Commission was also investigating to determine if GDF has been purposely limiting investments in its own infrastructure in order to block competition from other companies that have access to GDF's transport infrastructure.

From the perspective of successful operations, however, the GDF Suez merger has thus far been successful. The company reported that some projects that had been started before the merger were continuing. These included acquisition of electricity generation companies in the United States and Thailand and a gas distributor in Turkey. Further increased sales of electricity in Brazil contributed to the company's success.

Gazprom

Gazprom (a contraction of the Russian for "gas industry") is a self-styled global energy company and a flagship of the Russian economy. It is the third-largest company in the world by market capitalization (after PetroChina and ExxonMobil). With 440,000 employees Gazprom's core business is energy, and especially gas. It supplies over 85 percent of Russia's domestic gas and 20 percent of global gas, controlling 16–17 percent of global gas reserves. It also controls the largest gas transmission system in the world, inside and outside Russia. But Gazprom has diversified to control part of the Russian oil industry; into finance; and has significant media holdings in Russia through GazpromMedia.

The central role of Gazprom in the Russian economy is reflected in the way that it produces just under 10 percent of Russian gross domestic product (GDP) and provides some 20 percent of state revenue through taxes. The Russian state has a 50.01 percent holding in Gazprom and its chairman is Dmitri Medvedev, the current Russian president. The vice chairman and CEO is Alexi Miller.

Gazprom controls as much as 17 percent of world reserves of gas, making some European countries dependent on its supply.

The origins of Gazprom go back to the creation of a Soviet-era main directorate for gas and synthetic fuels in 1943. In 1965 the Ministry of the Gas Industry was created from which the modern Gazprom would eventually emerge. Over time, energy and energy exports became increasingly important to the Soviet economy. With the development of perestroika and the collapse of the Soviet Union, the question arose of how these gas resources might be privatized. Those in control of the Soviet ministry managed in 1993–94 to obtain what was effectively the insider privatization of a unified and vertically integrated company, albeit with the state retaining a significant minority share.

The output of the Russian gas industry is based mainly on Soviet-era "super giant" fields controlled by Gazprom, and located in the north of the Tyumen Province in western Siberia. But further development will also depend on exploitation of the "super giant" Shtokman field in the Barents Sea. When this will come onstream is, however, debated as the obstacles to be overcome are formidable.

In the 1990s Gazprom supplied subsidized gas to domestic consumers—a policy that helped mitigate the impoverishment created by the economic transition. Its management was weak and resources were corruptly plundered and the company's assets run down. Even today the poor quality of the gas infrastructure and fixed assets is a major problem.

With the Putin presidency a degree of reconsolidation of the Russian state took place, buoyed by rising energy prices. Gazprom was central to this. The state increased its holdings, including acquisitions (notably Sibneft, an oil producer) to acquire its majority stake. Pressure was put on some foreign companies to relinquish positions obtained in the sell-offs of the 1990s. The regime also used Gazprom to help tame some so-called oligarchs—individuals who had acquired huge wealth and political power in the transition. Politically, pressure was also used to help the company clean up its management structure and reduce corruption. How much still needs to be done is hotly contested. By law, Gazprom now has its own semi-private security force that has additional powers, becoming something of a state within a state. Some critics argue that it is also destabilizing externally through its lack of transparency in global capital markets and its potential use by the Russian state as a political instrument.

Gazprom exports to 32 countries and is following state policy in "aggressively" seeking new export markets. The European Union gets a quarter of its gas from Gazprom, but many countries in central and eastern Europe depend on it for a much higher share. The growth of gas exports is necessitating a major extension of the pipeline networks—Nordstream along the floor of the Baltic to Germany; Blue Stream across the Black Sea to Turkey; and a projected South Stream to Italy.

Gazprom argues that it cannot supply gas at a loss to its external customers and especially the former Soviet republics. This has led to disputes with Belarus and the Ukraine. Unsympathetic observers have seen these as examples of the use of energy power for political ends. More sympathetic observers saw in them a straightforward expression of the logic of the market. These disputes, however, raised fears in central and western Europe that Gazprom (and, through it, the Russian state) might seek to deploy its energy power there.

Gazprom has responded by insisting that its mission is to safely implement contracted gas exports as well as to serve the interests of its Russian customers. In its presentation of itself to global and domestic markets, the company concentrates on claims of improved corporate governance, its reliability, and its positive environmental record. Cynics argue, however, that Gazprom will manage to play by the rules because its market power is becoming such that it will help to make those rules.

General Agreement on Tariffs and Trade

The General Agreement on Tariffs and Trade (GATT) is the second of three regimes governing international trade in the modern era. It has been succeeded by the World Trade Organization (WTO), and coexisted with the abortive International Trade Organization (ITO).

The International Trade Organization was intended to be a counterpart to the International Monetary Fund and the World Bank, institutions negotiated at the Bretton Woods Conference in 1944. Named for Bretton Woods, New Hampshire, site of the Mount Washington Hotel where negotiations took place, the conference—formally called the United Nations Monetary and Financial Conference, but rarely recognized by that name anymore—was attended by 730 delegates of the 44 Allied nations, already planning for the shape the world would take when World War II ended. The foundational idea of Bretton Woods was the encouraging of open markets and the lowering of barriers to trade, among member nations.

In 1946 the United Nations Economic and Social Committee called for a conference to charter the International Trade Organization. Though agreed upon fairly quickly, ITO never got off the ground; every attempt to have the United States Congress approve it failed, on the grounds that the ITO would be given too much jurisdiction over internal American matters. At the end of 1950, President Truman announced that he would stop seeking ratification of the ITO charter, and without American involvement, the organization withered on the vine.

GATT, in the meantime, had successfully been implemented but had been intended to supplement, rather than replace, the ITO. While the ITO, and the WTO that now reigns, was an organization, GATT was only a treaty, with no infrastructure, staff, or institutional existence. Negotiations over the GATT began in parallel and in cooperation with the ITO negotiations, and were originally intended to be a short-term treaty binding countries to some easily agreed-upon terms until the ITO began operations.

Twenty-three countries signed the original treaty, which in the United States was considered a congressional-executive agreement, an exercise of the president's power to negotiate trade agreements when granted such authority by Congress. In essence, it granted "most favored nation" status upon all nations signing the treaty.

A staggering total of 45,000 tariff concessions were made by the first signing of GATT, affecting half of the world's trade—an enormous initiative, despite the failure of the ITO three years later. More "rounds" of GATT followed, each addressing slightly different issues, participated in by slightly different assortments of countries:

- The Annecy Round in Annecy, France, in 1949, further reduced tariffs among 13 countries.
- The Torquay Round, 1951, England, another 8700 tariff concessions.
- The Geneva Round, 1956, further tariff concessions as well as the first participation of postwar Japan.
- The Dillon Round, 1962, Geneva, named for Secretary of the Treasury Douglas Dillon, tariff concessions and early talks about the European Economic Community.
- The Kennedy Round, 1967, Geneva, named for the late President Kennedy, involving 66 countries, the most to date.
- The Tokyo Round, 1979, 102 countries, and the first discussion of limiting non-tariff barriers and voluntary export restrictions.
- The 1993 Uruguay Round, begun in 1986, was the most ambitious. It took seven years to negotiate, involved 123 countries, and was the first to involve agricultural goods. This was the final round of GATT, as one of the reasons for negotiations lasting so long was the decision to finally create an organizational body: the WTO, which replaced GATT in 1995.

General Electric

General Electric Company, often referred to as GE, is a publicly traded, United States–based multinational corporation that designs, produces, and markets an enormous range of products and services across six divisions. Despite having recently decided to shed its venerable home appliances unit, the company boasts an extensive list of business divisions, each with its own pervasive list of business units: GE Commercial Finance offers products and services, including loans and insurance, to manufacturers and distributors; GE Money offers credit cards, loans and mortgages, and deposit and savings products to consumers and retailers; GE Healthcare designs and manufactures medical imaging equipment and information technologies, medical diagnostics, and patient monitoring and life-support systems; GE Infrastructure manufactures aircraft engines of all sizes, turbines and generators, drilling equipment, oil and gas technology, electric-diesel locomotives, and water process systems; NBC Universal develops, produces, and markets media and entertainment—such as film, television, news, sports, and special events—to a worldwide audience; GE Industrial offers lighting, factory automation systems, electrical power distribution and control systems, and security technologies. But this relatively short list of business units conceals the origins of a company that was founded in an era of transformative innovation.

GE traces part of its beginnings to the inventor Thomas Alva Edison, who established the Edison Electric Light Company in 1878. A few years before, Edison had established a laboratory in Menlo Park, New Jersey, at which he could explore work on electrical devices. From his laboratory, Edison promised to develop and sell one minor invention every 10 days and one major invention every six months. The first of many of the latter breakthroughs was the stock ticker. But it is his invention of the first commercially viable incandescent electric lamp, in 1879, that encouraged J. P. Morgan and the Vanderbilt family to partner with the inventor to take Edison Electric Light public. By 1890 Edison established the Edison General Electric Company by merging his three electric light manufacturing businesses.

But by 1892, with having to compete with other early electrical industry companies for patents and technologies, the Edison General Electric Company merged with Thomson-Houston Electric Company to create General Electric Company.

Going into the new century, Edison's varied business offerings—which had grown to include at least lighting, transportation, communication, power systems, home appliances, and medical equipment—were now folded into the new company. At the same time, Charles A. Coffin had come from the Thomson-Houston side and was building the GE strategy as its first CEO.

GE is the only original Dow Jones Industrial Index company that still holds a position on the list today.

Relatively early on, he accepted the pleas of chief consulting engineer Charles Proteus Steinmetz that the company should construct a research laboratory so as to maintain its lead in lighting and electricity and also to innovate and develop new products for its growing market. This laboratory, based in Schenectady, New York, was the first industrial laboratory in the United States.

In the following years, beyond improving its already-successful product lines and developing new ones, the company also became one of the first to consider customer values and market appeal during the product design stage. And with the exception of some ethical and legal lapses in the mid-20th century, GE built on its strengths and continued to perform as one of the leading companies in business and industry. This held true during the Great Depression, as the company's penchant for diversification tempered the difficult economic times. Later on, GE was also one of the first companies to utilize a decentralized organizational hierarchy that placed top management responsibility in an Executive Office and provided employees with considerable autonomy in their work.

Another feature of the organization is its dedication to employee development, the best evidence of which is the consistent promotion of people who have made long-standing and productive commitments to GE. This includes the list of people who have assumed the top position in the company, from the early days of Charles A. Coffin, E. W. Rice, Gerard Swope, and Owen D. Young to the eras of Charles E. Wilson, Philip D. Reed, Ralph J. Cordiner, Gerald L. Phillippe, and Fred J. Borch to the later 20th-century leadership of Reginald H. Jones and John F. (Jack) Welch.

Among this list of notable individuals, Jack Welch has achieved iconic status for having driven GE from a market value of approximately $14 billion, when he assumed leadership responsibilities in 1981, to something on the order of several hundred billion dollars when he left 20 years later. During that time, Welch also transformed GE from the United States's 10th largest company by market capitalization to the world's largest by market capitalization. Welch was succeeded by another long-term GE employee, Jeffrey R. Immelt. At present, GE is one of the world's largest companies—and the only original Dow Jones Industrial Index company to remain on the list to this day. In 2008, GE's revenue was $183 billion and earnings were $18.1 billion.

Generalized System of Preferences

In 1968, industrialized countries agreed to provide preferences for the exports of developing countries at the United Nations Conference on Trade and Development (UNCTAD conference) in New Delhi, India. Under this scheme, known as the Generalized System of Preferences (GSP), preference-giving countries would allow exports of selected products from selected less developed countries at preferential tariff rates as compared to the Most Favored Nation (MFN) rate.

Preferential treatments for some countries required special negotiations because the MFN clause of the global trading rules under the General Agreement on Tariffs and Trade (GATT) required that all members of GATT automatically became entitled to the lowest tariff rate on a product that an importing country charged any other member of GATT. Each member of GATT was entitled to be treated as a most favored nation. Without the GSP scheme an importing country that tried to give preference to a specific developing country had to offer the same low rate to all other members of GATT. This would have negated the intention of the preferential treatment, which was to give the developing country a price advantage over more experienced exporters. The GSP scheme allowed an exception to the MFN clause to be negotiated and allowed industrialized countries to give preferential treatment to developing countries' exports without having to give the same treatment to the exports coming from other industrialized countries.

The purpose of the GSP scheme was to encourage developing countries to rely upon exports rather than aid to speed up their industrialization process. The GSP scheme applied primarily to manufactured products and it was hoped that a preferential treatment for manufactures would help the poorer countries reduce their dependence on exports of primary industries like agricultural products and minerals.

Developing countries also argued that preferential treatment for their exports actually creates a fairer situation and equality of trading opportunities between them and the industrialized countries. Their argument was that the MFN treatment—which was the hallmark of GATT—results in an unfair advantage for industrialized countries due to their large size and their lead and experience in producing manufactured products.

Since the needs of each industrialized country (the country providing the preferential treatment) and those of each developing country (the country that needed preferential treatment) were very different, it became difficult to negotiate one global GSP agreement. Instead, 13 industrialized countries, including the United States, European Union, Japan, Canada, and Australia had national GSP schemes by 2008 (UNCTAD estimate). These countries granted temporary, generalized, nonreciprocal, and non-discriminatory preferential treatments to specific developing countries (of their choice) and excluded certain products from such treatment. The GSP list of the United States included 109 countries in 2008. Each preference-giving country determines the preferential rate that it will give, and the tariff structure tends to become quite complex. Only one country, Australia, has developed a very simple rule for preferences: All Australian tariffs above 5 percent will be reduced by 5 percent and those below 5 percent will be eliminated.

GSP is estimated to have had only a minor effect on the imports of the preference-granting countries. U.S. Congressional studies show that only a minor fraction of U.S. imports enter the country under the GSP scheme. Moreover, most of the goods entering under this scheme are noncritical items with little or no domestic production. U.S. importers gain due to the lower cost imports. UNCTAD studies indicate that developing countries use the GSP system to gain entry into the industrialized countries and tend to benefit from GSP schemes that offer protection at stable rates and for extended periods of time.

General Motors

One of the oldest automobile manufacturers, General Motors is also the world's second-largest, and employees over 266,000 workers, with global headquarters in Detroit and European headquarters in Zurich. Its subsidiaries are some of the best-known vehicle brands: Buick, Cadillac, Chevrolet, GM Daewoo, GMC, Holden, Hummer, Opel, Pontiac, Saab, Saturn, Vauxhall, and Wuling.

General Motors was founded in 1908 in Flint, Michigan, as a holding company for the Buick Motor Company, which had been founded five years earlier by auto designer David Dunbar Buick and had been struggling financially since. The first Buicks had rolled out in 1904–37 Model Bs, the basic design of which was not changed until 1909. William Durant was brought in to manage Buick Motors, with Buick himself selling off his stock in the company. Durant turned the company around gradually and founded GM with the intent of acquiring other small manufacturers and governing them from under a common umbrella. Between 1908 and 1910, Durant acquired Cadillac, Cartercar, Elmore, Ewing, Oakland (which became Pontiac), Rainier, Rapid, Reliance, and Welch. The acquisitions were so large and rapid that the company built up too much debt, and bankers temporarily took over the company while Durant co-founded the Chevrolet Motor Company with Louis and Gaston Chevrolet, gradually buying back enough GM stock to resume control of the company in 1916, folding Chevrolet into it in the following year. In yet another twist, industrialist Pierre Du Pont, who had backed Durant's stock purchases, demoted Durant in 1920, and for the next 30 years the company was controlled by Du Pont's companies in one form or another.

In the meantime, though, GM was a success. The Buick subsidiary introduced the first closed-body car in 1911, four years before Ford, and GM beat Ford in sales at the end of the 1920s, in part because of the management of Alfred Sloan and his willingness to finance automobile purchases, which Ford did not implement for its entire consumer product line for a full 40 years after GM introduced the General Motors Acceptance Corporation in 1919. GM was also involved in bus manufacture, buying up streetcar companies around the country and replacing them with bus services, while participating in the launch of the Greyhound bus line. From 1930 to 1948, it had various interests in aircraft design, but never seriously pursued an involvement in the industry after spinning its North American Aviation division off as a public company. By then, the automobile industry had evolved: two-car families were not long off, and the teenage and Hollywood romanticization of hot rods was only a few years away. Style and class had always been GM hallmarks more than Ford's, thanks in part to the Buick, Cadillac, and Chevrolet brands.

Since World War II, GM has (with Ford and Chrysler) been one of the Big Three, the three major automobile manufacturers that account for most American-made automobiles. In the early 1950s, after a WWII boom thanks to defense contracts (company president Charles Wilson was named as Secretary of Defense in 1953), General Motors was the largest employer in the world outside of the Soviet Union, and the largest corporation in terms of revenue. It was inevitable that success of this size would lead to some highly visible failures and vocal criticism. GM was the target of scorn, used as an example of wrongdoing to illustrate widespread cultural wrong, first for Ralph Nader (arguing for safety reforms in the auto industry in the 1960s) and later for Michael Moore (criticizing the growing tendency in the 1980s and 1990s of American corporations closing domestic plants and opening foreign ones with cheaper labor and less restrictive regulations), who saw their respective careers launched by playing David to the company's Goliath.

SUVs, which have become one symbol of the company's recent missteps, on a GM dealer's lot.

Recent Economic Crisis

The recent economic crisis severely and negatively impacted General Motors, as it also threatened the vitality of the American automobile industry as a whole. SUVs, GM's most profitable vehicle class, lost almost a third of sales in 2008 as a result of erratic gas prices, cutbacks in consumer spending, and other factors. Sales of larger trucks fell as well, and sales across the board fell by nearly half. The situation was worsened by the fact that the reduction in sales disproportionately affected the company's more profitable models. The Big Three sought a controversial bailout from the federal government at the end of 2008, supported by President Bush and President-elect Obama but opposed by the Senate. GM and Chrysler were given $13.4 billion combined directly from the executive branch, drawing from the Troubled Assets Relief Program. The final resolution to the auto industry's troubles has not yet been reached, nor are the ramifications yet clear of the effect on auto-related industries.

Geocentric

An exponentially increasing number of firms strive to engage themselves in international activities, that is, to expand their business operations internationally. This international scope of business activity helps firms target larger consumer audiences, achieve increased sales, reap benefits from economies of scale through global production, and keep pace with internationalizing competitors. However, this internationalizing outlook has also brought organizational, planning, and marketing challenges to firms, which must manage their international growth effectively.

In order to address such challenges, Howard Perlmutter has suggested the EPRG schema, which identifies four orientations/attitudes toward international activities: the ethnocentric (home country orientation), polycentric (host country orientation), regiocentric (regional orientation), and geocentric orientation (a world orientation). Each attitude is associated with successive stages in the evolution of international operations and reflects the philosophy of the corporation with regard to business strategies and managerial procedures on an international scale. Perlmutter's observations pinpoint that firms start with an ethnocentric orientation of international operations, then they gradually acquire a polycentric view, but eventually they strive to achieve a significant level of geocentrism.

A geocentric orientation reflects a globally integrated strategy where the mother firm assumes a supervising role with the purpose of reaping opportunities on a global scale through global coordination of local activities. Subsidiaries of the multinational enterprise are not distinct entities but rather cooperate with each other in order to exploit market opportunities across the world. For example, the Italian subsidiary of an American packaged food firm may act as a supplier of cheaper raw materials to a sister subsidiary in the United Kingdom whereas the latter may transfer production know-how to other subsidiaries in Asia. Thus, all subsidiaries jointly work toward a common goal: the maximization of business objectives for the global firm.

For firms that follow the geocentric orientation, national distinctiveness of markets, consumers, or employees is not relevant since the entire world is a potential market. This means that such a firm aims at the servicing of identical, inter-countries market segments through a standardized marketing offering that cuts across national boundaries. Thus, parochial considerations and, consequently, locally adapted practices are ignored in favor of a coordinated set of globally integrated activities. Additional functional implications of this orientation refer to production (e.g., centralization of global production in just one country with low labor cost) or manpower (e.g., the recruitment of the best executives wherever necessary, irrespective of their national background).

With regard to managerial and organizational procedures, geocentric multinationals usually adopt open communication channels across business units of the international firm; they empower people, and they let knowledge freely flow from one subsidiary to another. Any managerial or marketing know-how that is locally generated should serve the purpose of exploitation on a global scale and thus benefit the global structure of the firm. Such knowledge transfer processes of a collaborative, intra-firm nature are facilitated by a strong corporate culture, which surpasses the national culture of employees in terms of importance and effect.

Advantages and Disadvantages

The positive outcomes of a geocentric orientation are sources of sustainable competitive advantage, and that is why many international firms opt for achieving a globally integrated status for their operations. The pros include both cost- and sales-types of advantages. For example, large production and operational costs may be skipped through exploitation of economies of scale and scope that derive from centralized production, common sourcing policies, distributional synergies, and integrated transportation systems of raw materials and final goods. Such cost-effective solutions have desirable sales implications, too. For example, geocentric firms are able to manufacture standardized brands that are sold at convenient prices and project a consistent corporate and brand image across the world.

However, the intuitive and widespread appeal of a geocentric orientation hides the fact that it also entails several disadvantages for firms. Collecting information on a worldwide basis and disseminating such information across subsidiaries requires a sophisticated information exchange mechanism whose design and implementation are costly. Moreover, a great effort to build a cost-effective, geocentric organization may force the firm to ignore environmental conditions or local market changes that would otherwise require local responsiveness at the marketing or managerial level. Additionally, several unavoidable realities, such as the consumer idiosyncrasy of national groups or national legal imperatives, jeopardize the effectiveness of "the world as a market" perspective. Such nation-specific constraints pose a great barrier to profitable local servicing by geocentric firms that have invested a lot of money and effort in building a globally standardized and integrated organizational format.

Summarizing, we see that geocentrism seems to offer advantages at the production, research and development (R&D), and/or human resources level, but given the significant national heterogeneity that is still prevalent in world markets, it could be a risky strategy marketing-wise. As a result, there seems to be no right or wrong international orientation by firms but rather real life indicates that there is a mixture of function-specific attitudes. For example, the R&D and technical support functions may follow a geocentric approach and the advertising strategy may project a heavily ethnocentric attitude, whereas the after-sales service function may necessitate a polycentric orientation. The mixture that promises higher turnover is, in turn, dependent upon several intra- and extra-firm factors, which concurrently work toward each end. For example, the large size of the firm assists a geocentric orientation, whereas the national distinctiveness of potential foreign markets discourages firms from employing such an approach. Additional factors include the international experience of the corporations' business executives, the financial and production capabilities of the firm, the culture-bound nature of the product, and competitive pressures. Therefore, firms that ignore the holistic nature of business reality and focus only on internal organizational considerations or only on external market variables may adopt an orientation that will prove to be detrimental.

Geocentric Human Resource Policy

The geocentric approach to multinational operations reflects the attitude that the circumstances dictate the best policies and the most appropriate individuals to staff the operations. The geocentric approach could be placed somewhere in between the ethnocentric and the polycentric approaches, as it considers that the best elements of each culture should be adopted in the design of human resource systems and the most qualified individuals, irrespective of nationality, should be employed in the key positions of a multinational enterprise. The geocentric approach is allegedly the most advanced of the approaches to human resource policy, and the one that is directed by the constantly accelerating globalization that blurs borders and cultural barriers. On the other hand, it requires substantial investment and knowledge of cultural factors on the part of the multinational corporation.

The geocentric approach is more likely to characterize corporations that are found in advanced stages of internationalization. In the staffing of operations it is manifested by the utilization of home-country, host-country, and third-country nationals in key positions, both in the headquarters and in the host countries of the multinational corporation. What matters most is credentials and fit into the role rather than the country of origin. The country of origin may be taken into account when this is considered as a factor that may affect success on the job. For example, U.S. companies tended to prefer British nationals for managerial positions in their operations in former British colonies because the British were presumed to be most familiar with the culture and institutions of the host countries and also with U.S. culture (and language).

In general, third-country nationals can bring the following qualities: (1) understanding of the operation from the perspective of a foreigner, who is not biased by the cultural perspective either of the home country or of the host country; hence, these individuals can bring more unbiased and potentially novel ideas and perspectives; (2) increased likelihood of acceptance by both home country and host country employees; and (3) demonstration of the global image of the multinational corporation.

An increasing number of corporations around the globe resort to appointing third-country nationals in key positions; a major reason for this is, as already seen, the need for the most competent individual to take over important roles, and the fact that as organizations become global they gradually become dissociated with particular countries. Even Japanese corporations, which traditionally have adhered to an ethnocentric approach in staffing, are gradually abandoning this policy. This is because they have increasing proportions of their interests in countries outside Japan, and they realize that there is a need for taking into account the perspectives of these countries in their strategic planning; hence, the need to include nationals of these countries in key positions, including the boards of directors. An example of a third-country national appointment in a key position of a multinational is Jose Lopez (Ignacio Lopez de Arriortua), a Spaniard who in the 1980s and 1990s held executive positions in both General Motors (a U.S. multinational corporation) and in Volkswagen (a German multinational corporation).

The ultimate manifestation of the geocentric human resource policy is the appointment of host-country nationals in key positions in the headquarters, that is, in the home country. These individuals are labelled *inpatriates*. A prime inpatriate case has been the appointment in 2005 of Howard Stringer (British, with a corporate career in the United States) as chief executive officer of SONY, allegedly the first foreign-born CEO of a major Japanese corporation.

Geopolitics

Geopolitics concerns questions in relation to the strategic importance of geographic locations, their relationships with each other, and the changing pattern of such relationships over time. For example, the European colonial legacies and geopolitical incidents such as the two world wars, cold war, the fall of the Berlin Wall, and the 9/11 terrorist attacks have contributed to the shaping of the existing global business environment. The acts of various national and international institutions, the strategic location of a country and its relationships with other nation-states, and the military and economic powers of countries have also been identified as factors possibly affecting a country's economic and political relationships. Additionally, the demographic characteristics of the population of a specific geographic area and its cultural/historical relationship with the rest of the world are commonly thought to be other influencing factors.

Despite an ongoing and obvious link between geopolitics and international business, the study of geopolitics appears to be a relatively new addition to the international business literature. Nonetheless, examining the concept of geopolitics in the global business context is particularly critical at this time, as we are living in a world with a rapidly changing and intrinsically intricate geopolitical order.

It is widely recognized that there is no universally accepted definition of *geopolitics*, which results in the term being abused by many without fully understanding its meaning. *Geopolitics*, in general, denotes international relationships from an evolutionary, historical perspective emphasizing the role of national power and national interests in shaping the global political order. Etymologically, the word denotes location-specific factors that affect political disposition. However, since its first use by the Swedish geographer Rudolf Kjellen in 1900, the study of geopolitics has been viewed, evaluated, and contributed to from different perspectives. In 1917 Kjellen used the term to describe the geopolitical basis of national power. Karl Haushopher, a German political scientist, further expanded this idea as a relationship between political phenomena and geography. He considered geographic variables to have a direct bearing on national power.

During the inter-war period, the concept of geopolitics was used by Haushopher, Carl Schmitt, and other German geopoliticians to develop "geostrategy" as a military science. At that time, the importance of geographic location and size and their impact on the political power of a nation were at the core of the German geostrategy. This was reflected in the subsequent policy of expansionism by Nazi Germany. Later, Harold and Margaret Sprout advanced the theory of geopolitics. According to the Sprouts, geography affects all human and nonhuman, tangible and intangible phenomena. They believed that every political community had a geographic base that might affect most of the transactions among nations. They raised the issue of "transactions" as a vital ingredient of the geopolitical domain, making it easier to relate to the business and politics literature.

Geoeconomics

Geographic proximity or physical distance has always been considered as an external environmental factor affecting the political relationships among nations. Accordingly, there is a likelihood of greater communication with neighboring nations than with physically distant ones. Following the oil crisis of 1973, the emergence of a new set of geopolitical and geostrategic relationships was recognized in the international relations literature. Of special importance are the increasing scarcity of key resources globally and enhanced risk of their movements—especially of the supplies of oil and vital raw materials from producers to consumer nations. Hence, the control of resources and the resource-import relationship have added a vital dimension to the study of geopolitics.

In order to boost national business interests, countries capable of using military and/or economic power often attempt to influence other countries and regions with aims to access necessary resources, ensure market entry, and avail major public procurement contracts for their business enterprises. The Gulf War in 1990 and the Iraq invasion of 2003 provide a case of an interesting albeit obvious relationship between geopolitics and international business. Direct influence could be seen from the United States and its allies on the distribution of reconstruction projects in post-invasion Iraq. Influence of global political powers could also be witnessed in strategically important areas such as oil supplies, governance structures, and political stability in geographic regions across all continents. Such a trend emphasizes the importance of understanding the concept of "geoeconomics" from a geopolitical perspective. In this context, the relationship between geopolitics and national power needs to be further clarified.

Power plays an important role in shaping the global geopolitical landscape. As the global power base is constantly shifting from one country/region to another, it becomes difficult to ascertain the nature and strength of power exerted by any specific country or region. Both military and economic aspects of power should be taken into account when defining national power. Economic power could be defined broadly as the capacity of a country to influence other countries through the use of various economic tools that may include a country's resource base, technology, infrastructure, and gross domestic product. Military power of a country is reflected in its capacity and readiness to use military and tactical force to influence other states. Military capacity could be dependent on the country's armaments, size of the army, and the access to superior military training and technologies.

A country may use either military or economic power or both to achieve certain goals.

Hans J. Morgenthau, one of the leading political theorists, considers power as a means to an end. He considers political realism as "the concept of interest defined in terms of power." Coercive power, in this regard, has long been used to subjugate countries in order to achieve economic and political gains. These days, however, power is mostly used by countries in different and subtle ways, making the impact of such uses difficult to assess. Also known as "soft power," such an approach, compared with coercive technique, is considered more effective and relevant in the contemporary geopolitical context. As a consequence, the use of political as well as professional lobbyists has become commonplace in influencing the policies and actions of foreign governments and international institutions.

Ideological Expansion

Ideological expansion is another important element of geopolitics. It was a major concern during the Cold War period. *The Communist Manifesto* in 1848 clearly stated this concern: "a spectre is haunting Europe, the spectre of communism." The specter of communism literally haunted the Western world until the fall of the Berlin Wall. Nonetheless, an ideology-based political system is different from a liberal democratic system imposing ideological control on the country's political as well as economic activities and its relationships with other countries.

Theocracies such as the Vatican, Saudi Arabia, and Iran maintain their respective political systems primarily based on religious ideologies. The religious fanaticism demonstrated by the 9/11 terrorist attack has caused a major geopolitical concern affecting global harmony and peace. For global firms, it also has created additional costs of doing business, as they need to take extra precautions to safeguard their business operations globally.

Germany

The Federal Republic of Germany, located in the heartland of Europe, adjoins Denmark, Poland, Czech Republic, Austria, Switzerland, France, Luxembourg, Belgium, and the Netherlands, covering an area of approximately 357,000 sq. km. As Europe's largest economy and the world's 14th most populous country (2009), Germany has for centuries significantly affected this region's political, social, and economical history. This country, which saw the birth of Wolfgang von Goethe and Ludwig van Beethoven, is also the world's largest exporter.

Economic History

The political success of the reunification of Germany was not without high costs. Following the dissolution of the German Democratic Republic (1990), East Germany, which came under Soviet domination after World War II, experienced huge job losses and a rapid increase in the costs of living. Many young people left to live in the West, seeking new jobs, better education, and a new and better way of life. Unified Germany (1990) has had to provide considerable financial support to boost the flagging economy that has undermined economic growth in the eastern part of Germany.

The German Deutsche Mark was replaced in January 1999 when the European Union (EU) introduced a common European exchange currency that became known as the euro. As a result of the strict requirements imposed by the European Monetary Union, Germany's economy faltered, resulting in substantial ramifications for the nation's industrial economy. Unemployment reached a new postwar high.

While in more recent decades the economic growth rates had stagnated, in 2007 the economy showed considerable improvement with a growth rate of 2.6 percent. At approximately the same time, the long-term problem of high unemployment was steadily reduced. For a three year period beginning in 2005, unemployment rates slowly decreased. However, concomitant with layoffs, the shifting of manufacturing facilities to low-cost markets abroad and cost-cutting between 2002 to 2005, costs escalated. Notwithstanding, despite the euro trading at its highest level against the dollar, and the numerous interest rate increases perpetrated by the European Central Bank, the Germany economy recovered once more and job creation increased.

As one of the founding nations of the European Economic Community (EEC), precursor to the European Union, soon after the war Germany began to co-determine Europe's economy. In the interests of economic cooperation, Franco-German cooperation became a central factor of subsequent mutual political, cultural, and economical relationships. Since the "Economic Miracle" of the 1960s, Germany has emerged as a highly efficient and vibrant economy—not only in Europe but worldwide.

By the end of World War II, Germany's economy was in ruins. Many production facilities were either destroyed or dismantled as reparation payments. The country's successful economic recovery is often attributed to two factors of Ludwig Erhard's free market reforms: currency reforms and elimination of price controls. German industry was effectively stimulated by production investments funds from the Marshall Plan, the European Recovery Program, and the low wage scale in Germany at the time.

Germany is one of the most attractive and competitive business locations worldwide, a country in which foreign investors have increasing confidence as a destination for foreign investment. In 2006 Germany ranked third (after Great Britain and France) among the most popular European foreign investment destinations, having successfully leaped from the sixth place it occupied in 2005. The top three foreign investors were the United States, the Netherlands, and Switzerland (2006). The most popular industries that attract foreign investors are information and communication technologies, industrial machines, and the automotive industry. Today, for the first time, foreign investors own a majority of Germany's 30 largest publicly traded companies (2007).

Germany's strong economic performance is very much linked with its high number of successful companies that regularly top or are ranked high in international rankings in categories such as innovation and sophistication of the production process. "Made in Germany" signals good quality, innovative technology, reliability, and strong brands. Together with Germany's numerous multinational companies, small and medium-sized enterprises (SMEs) play an important role in the country's economy. Approximately 70 percent of all employees work in SMEs, key sectors of which include automobile manufacturing, electrical and precision engineering, chemicals, environmental technology, optics, medical technology, and logistics.

Germany is still the world's largest exporter. In 2007 it outranked China and the United States, showcasing both its influential role in the global economy and its potential as global player. Germany's major exports are motor vehicles, machinery, chemical products, and computer equipment. Export markets include France, the United States, the United Kingdom (UK), Italy, and the Netherlands. Altogether, 65 percent of exported goods went to member states of the European Union. The second largest export market was China with 11 percent, closely followed by the United States with 10 percent. According to the Federal Statistical Office, German exports increased for the fifth consecutive year.

Despite its marked export orientation, Germany lacks natural resources and is largely dependent on imports such as energy products. In 2007 imports increased by 5 percent over the previous year. The majority of imports come from Europe (predominantly France and the Netherlands), followed by Asia (China) and the United States. In 2007 Germany's exports amounted to €969 billion and imports to €772.5 billion. The record foreign trade balance of €196.5 billion is the highest ever.

With Europe having Germany's leading markets and suppliers, almost two-thirds of Germany's imports and exports either originate in or are sent to European Union member states.

Political History

In 2005 Angela Merkel became Germany's first female chancellor. An East German, Merkel succeeded Gerhard Schroeder, who was openly critical of the U.S.-led invasion of Iraq in his reelection campaign in 2002. The new government joined a coalition of the Christian Democratic Union (CDU), Christian Social Union (CSU), and the Social Democratic Party (SPD). Merkel took over as party leader of the CDU in 2000 after Helmut Kohl, the "chancellor of the unification," was caught in the middle of a party funding scandal. In 2007 *Forbes* magazine for the second time nominated Angela Merkel as the most powerful woman in the world.

Germany was involved in two world wars in the first half of the 20th century. At the end of World War II (in 1945) the Allies (United States, UK, France, and the Soviet Union) divided the country among themselves, resulting in the separation of (what would come to be known as) East Germany from West Germany and the subsequent formation of the eastern German Democratic Republic (GDR) and the western Federal Republic of Germany (FRG) in 1949. This separation was reified when the Soviet Union erected the Berlin Wall in 1961. Bonn became the provisional capital of West Germany.

The new German government was led by Chancellor Konrad Adenauer, who, by committing the country to assist Western defense systems and allowing the stationing of U.S. troops in the country, secured Germany's sovereignty in 1955. In May of the same year Germany joined the North Atlantic Treaty Organization (NATO).

During the Cold War, the communist GDR became a member of the Soviet-dominated Warsaw Pact: the FRG, being a liberal parliamentary democracy, became a member of the precursor of the European Union, the Western European Union (WEU), the European Coal and Steel Community (ECSC), and the European Economic Community (EEC). With the end of the Cold War and the political and economical weakening of the Soviet Union, the way became open for German unification. After being separated for more than 40 years, October 3, 1990, finally marked the end of divided Germany.

December 2, 1990, saw the first elections to be held in unified Germany since 1933. The CDU coalition won and Helmut Kohl became the first chancellor of the new German state: In 1991, the Bundestag voted in favor of Berlin being its capital.

Germany had been founded on January 18, 1871, concomitant with the unification of the German Empire. Prussia, one of the numerous states within the German confederation created at the Congress of Vienna (1814–15), challenged Austria, the dominating political and economic force of the time. After winning the Franco-Prussian War (1871) that resulted in the removal of the French emperor Napoleon III, on January 18, 1871, Wilhelm of Prussia was crowned emperor of Germany at the Palace of Versailles. Otto von Bismarck was appointed the first Reichskanzler. These events saw the birth of the Second German Reich, which lasted until the abdication of Wilhelm II in 1919, after Germany was defeated in World War I. (The first Reich was the Holy Roman Empire of the German Nation [800–1806].)

Before unification, Germany consisted of a collection of small states that were linked from the "Revolution of 1848" onward in their common goal of liberal reforms. In 1848, German liberals and peasants erected barricades in Berlin and other German countries, voicing their demands to be granted more rights from the German princes and aristocrats. The outcome of the revolution was the establishment of a National Assembly in Frankfurt. The German flag (a horizontal tricolor with black, red, and gold stripes), the symbol of German nationalism, has its origins here. The colors represent the colors worn by Germany's soldiers during the Napoleonic Wars, a time that marked an early upsurge of German nationalism. The flag was used until 1871, and again from 1919 to 1933, when Germany became a republic. After the war, from 1949 on, the flag represented

West Germany; after unification in 1990, it became the flag of united Germany.

Along with massive political changes that occurred in the early and mid-19th century, the Industrial Revolution generated enormous economic development in Germany. After 1850 the country underwent rapid industrialization: New factories and railway networks were built and the production and export of textiles and iron increased. The population exploded, urbanization commenced, and Germany started on the road to becoming a modern prosperous economy. With time it became Europe's dominating economic power.

Germany provides cutting-edge environmental technology. And in spite of increasing its economic output, environmental pollution has decreased in Germany over the past few years. Notwithstanding, air pollution emissions and the consumption of water and raw materials could still be sustainably reduced. Not least because of the increasing political decision making since the 1980s, German firms are among the most innovative in Europe when it comes to knowledge-intensive environmental research and environmental technologies. This is also demonstrated by the high number of environmental protection patents lodged at the European Patent Office. Germany is a world-leading exporter of potential environmental protection goods such as technologies and products designed to improve air quality, noise, and recycling, which account for 19 percent of world trade.

German Management Style

Harking back to the medieval guild and merchant traditions, German management styles have "specificness." Often cited as another crucial factor in the economic miracle of the postwar years, distinctive German management characteristics include entrepreneurism and production orientation. Furthermore, the owner attitude manifested in the German "Herr im Haus" leadership has for long characterized many traditional German enterprises. In general—and due in part to the often more technical background of German managers—management in Germany is more closely connected with the production process than in many Anglo-Saxon countries. Rather than expecting a supervisor to motivate their subordinates, it is more common to expect the superior to assign a task while the subordinate is responsible for the execution of any technical problem. Other German management traits are planning, punctuality, discipline, accuracy, and orderliness.

Education and Science

The land of ideas invests in education. In 2004 Germany spent €7,000 per student from primary to tertiary level, more than any OECD country. Most students go to public schools: Germany rates below the OECD country mean vis-à-vis students studying at private institutions. The country's unique two-track vocational training (2–3.5 years) program offers practical in-company training and specialist theoretical instruction in a vocational school. The companies pay the trainees/apprentices wages while the government finances the cost of attending vocational schools.

The high value placed on education and the applied sciences is demonstrated by the 78 German Nobel Prize winners—67 of whom received the award for their achievements in the natural sciences or medicine (e.g., Wilhelm Conrad Röntgen, Robert Koch, Max Planck, Albert Einstein, Werner Heisenberg, and Otto Hahn).

Immigration

Concomitant with the "Economic Miracle" of the postwar years, the number of immigrants to Germany has risen. From 1955 to 1973, so-called guest workers have been recruited to fill the needs of the country's fast-growing economy. These early foreign workers came primarily from Italy, Spain, Greece, Turkey, and Yugoslavia. The immigration wave in the years from 1973 to 1985 consisted mainly of family members of foreigners already living in Germany. At the end of the 1980s, there were two different forms of immigration: asylum seekers and ethnic German repatriates mainly from eastern Europe and the Soviet Union.

On January 1, 2005, a new immigration act came into force. After several years of parliamentary discussion, a single legislative framework now manages Germany's immigration policy. It constitutes a comprehensive reform of labor migration, humanitarian regulations, and integration and security aspects.

Geography

Reunified Germany is divided into 16 states: Baden-Wuerttemberg, Bayern (Bavaria), Berlin, Brandenburg, Bremen, Hamburg, Hessen, Mecklenburg-Vorpommern (Mecklenburg–Western Pomerania), Niedersachsen (Lower Saxony), Nordrhein-Westfalen (North Rhine–Westphalia), Rheinland-Pfalz (Rhineland-Palatinate), Saarland, Sachsen (Saxony), Sachsen-Anhalt (Saxony-Anhalt), Schleswig-Holstein, and Thüringen (Thuringia).

Significant mineral resources can be found in the Rhenish-Westphalian industrial area (hard coal deposits), the Rhenish Basin, the Leipzig Basin, and Lower Lusatia (large lignite fields), Rhenish Slate Mountains, east of the Franconian Alp and the northern periphery of the Harz (iron ore deposits), in Northwest Germany (oil reserves), as well as in Lower Saxony (rock salt deposits).

Germany's agriculture plays a notable role in the European Union's agricultural sector. Within the European Union, Germany is the largest producer of milk and pork and the second-largest producer of cereals, potatoes, sugar beets, and beef.

Germany is Europe's most densely populated country: Population density grew in particular along both sides of the Rhine valley, that is, in the Upper Rhine region, in the Rhine-Neckar and Rhine-Main regions, around Cologne and in the periphery of the Rhenish-Westphalian industrial area.

Germany consists of 16 federal states (*Länder*), which have the responsibility for central administrative areas such as education, law enforcements, culture, and environmental protection. The federation is mainly responsible for legislation, the Länder implement federal laws on behalf of the federation or under their own jurisdiction. The federal government is solely responsible for defense and foreign affairs. The Länder also direct regional governmental planning in a bid to ensure equal living conditions for all; that is, all citizens may avail themselves of schools, doctors, and pharmacies, for example. This is also a prerequisite for attracting business and industry. The federal states also determine environmental conservation planning, i.e., the protection of natural landscapes and economic use of natural resources.

Ghana

The country of Ghana is located on the Gulf of Guinea in western Africa and is bordered by Côte d'Ivoire on the west, Burkina Faso on the north, and Togo on the east. Ghana was established in 1957 with the passage of an independence constitution uniting the British colony of the Gold Coast and the British-controlled UN Togoland trust territory. Plagued by over two decades of coups, the country remained destabilized until former air force lieutenant Jerry Rawlings secured lasting power through a military coup in 1981.

Under the Rawlings administration, Ghana gradually implemented a constitutional democracy that has attracted and maintained international investments primarily into their gold, cocoa, and agricultural sectors. Today, Ghana enjoys a stable and growing economy, with its 2007 gross domestic product (purchasing power parity) estimated to be $31.33 billion, growing at an annual rate of 6.45 percent.

Ghana's present-day inhabitants are not believed to be the original inhabitants of the territory that now comprises Ghana, but to have descended from migrant groups that arrived via the Volta River around the 13th century. The arrival of European traders in the late 15th century brought the onset of several hundreds of years of competition (both economically and physically) between the Portuguese, French, Dutch, and English in the territory in and around Ghana. Initially these conflicts concerned trading rights to gold, ivory, and pepper and later shifted heavily to slave trading concurrent with the expansion of European plantations in the New World.

By the end of the 19th century, the British empire consolidated sole power over the entire region, quelled several uprisings by the Asante ethnic group of southern Ghana, and officially annexed the region as a protectorate under the exclusive control of the British empire.

Over the next century, the British ruled the region indirectly by administering investments and mediating intertribal disputes, while delegating most local decisions to village chiefs and elders. This period of colonial rule saw the majority of wealth exported from the country accumulated by the Europeans but also endowed the region with significant developments in transportation, sanitation, agricultural, and educational infrastructure.

By the conclusion of World War II, Africans were heavily embedded in the central government that controlled the territory of Ghana. After several failed attempts toward full self-governance, the country petitioned and successfully gained full independence from the British Commonwealth and the country of Ghana was established through the independence constitution of 1957. Ghana's first president, Kwame Nkrumah, set about to implement sweeping socialistic measures and to unify the African continent into a self-sufficient entity, breaking the pattern of neocolonialism present in much of the rest of the developing world.

Political Coups

These ambitious policies resulted in heavy financial burdens and ultimately resulted in a series of political coups, beginning in 1966 and ending with the 1981 coup led by Rawlings. After many decades of stifled political opposition and curtailed civil liberties, the Rawlings administration redrafted the country's constitution in 1992, implementing term limits and reinstating multiparty elections.

Today, Ghana's population (est. around 23.4 million) enjoys a relatively stable and growing emerging market economy, centered primarily on subsistence agriculture (56 percent of the labor force by occupation, 2005 est.). The 2006 Millennium Challenge Compact agreement between Ghana and the United States focuses an estimated half-billion dollars of investment into Ghana's agricultural sector, seeking to both grow the economy and reduce poverty.

Diamonds

In addition to agriculture, Ghana's 239,460 sq. km of land (roughly the size of the state of Oregon) is endowed with an abundance of natural resources including gold, timber, bauxite, aluminum, manganese, and diamonds that serve as the other primary source of exports for foreign exchange. Ghana continues to attempt to stabilize its currency and recently introduced the new Ghana cedi in 2007 (10,000 old cedis equals 1 new cedi). This move has contributed to the recent reduction of the county's inflation rate to single digits (9.6 percent, 2007 est.).

While Ghana continues to carry large amounts of debt, its economy is seen as one of the most promising in west Africa for international investment. Ghana's economy is now under the direction of its Growth and Poverty Reduction Strategy, which outlines the country's plans for macroeconomic stability, tax simplification, increased private sector competitiveness, human resource and agricultural development. Most recently, the discovery of large offshore oil reserves has prompted increased exploration and infrastructure development on the country's west coast.

Gift-Giving

Gift-giving is the act of transferring a present, or gift, to another. Gift-giving occurs in both social relationships and economic or business exchanges. A gift is anything of value, however large or small in value. The gift can be money or something else of value such as personal goods, services, property, or in many cases entertainment.

In principle, a gift should be a voluntary free transfer not requiring any form of compensation or reciprocity. A voluntary gift is neither a gratuity or a tip, provided as full or partial compensation for some personal service (such as restaurant tipping), or a bribe, provided or offered to an agent in expectation of some desired opportunity. Customary gift-exchange occurs mostly at specified times of the year, such as Christmas, in ritualized social relationships.

Gifts and entertainment are typical aspects of business etiquette and marketing or promotion efforts in various countries. Business practices and national laws vary with respect to such activities. Multinational enterprises typically provide guidance to employees concerning gift-giving and entertainment to customers and from suppliers. Gift-giving, gift exchange, and gratuities are also established customs or traditions in various societies to express appreciation or as a sign of thoughtfulness. In some advanced economies, tipping for personal services is expected income in lieu of full wages.

Because the boundary between bribery and gift-giving may be ambiguous, the overlapping of economic and social relationships, varying by culture, is a problematic dimension of anti-corruption efforts. The Foreign Corrupt Practices Act (FCPA) of 1977, as amended, exempts facilitating payments (i.e., "grease") under some circumstances and provides for certain affirmative defenses concerning marketing and promotion expenses including entertainment. All such expenses must be carefully reported. Some gifts, gratuities, and entertainment permissible under the FCPA may be illegal under local anti-bribery laws.

In practice, gift-giving may be a mandatory part of ritualized social and economic reciprocity. A transfer of value with the appearance of a gift might arise in a number of motives including appreciation, altruism, bribery or extortion, custom or tradition, gratuity, reciprocity, or tax incentive.

Reciprocity is an act or expectation of exchange between two parties. This reciprocity may be an established custom or tradition in some societies or communities. It may be traditional to provide some gifts, particularly entertainment and small tokens of respect or appreciation, in business settings. Corruption is bribery of or extortion by agents in which typically money, or some other item of value, is exchanged for a contract or other valuable opportunity. The key feature of corruption, demonstrated in the form of bribery, is that an agent accepts something of value from a third party to act contrary to the interest(s) of the agent's principal(s).

Public employees in democracies and private-enterprise employees are agents. Their principals are the citizens or the owners, respectively. With certain exceptions, it is not generally possible under this definition to bribe a principal. Some transactions with a hereditary sovereign, as a principal, might still be corrupt or unethical on some other basis. Gifts and entertainment expenses are important even in advanced market economies. The pharmaceutical industry is well known for company gifts to business customers, such as physicians. Reciprocal exchange relationships may be highly established in some societies, such as Japan and China. In Japan, ritual and courtesy are still very important in social and economic relationships. A classic instance of a gift economy is China. The *guanxi* networks of gifts, obligations, and reciprocity are reportedly important sources of personal influence in business and government circles. These networks are systems of trust relationships for mutual support through favors. Such networks may function in some circumstances as patron-client relationships, which were important in ancient Rome.

Multinational enterprises commonly have policies and guidelines governing gifts and entertainment expenses for customers and from suppliers. In general terms, for U.S. and European companies, some "reasonable and limited expenses" by employees may be acceptable for gifts, entertainment, and customer travel and living expenses in connection with promotion or contract execution. Employees may sometimes accept purely nominal-value gifts and entertainment expenses from suppliers. With respect to both customers and suppliers, there must be no appearance of impropriety and no improper advantage sought (a violation of the FCPA, as amended). Accurate records must be maintained and local anti-bribery laws, as well as the FCPA, must be obeyed.

Gini Index

The Gini index is a commonly used measure of inequality in the distribution of income, wealth, consumption, and other economic variables—although it can be used to calculate inequality of anything that can be measured. It was developed by the Italian statistician Corrado Gini and published in his 1912 paper "Variabilità e mutabilità" ("Variability and Mutability"). It is defined as 100 times the Gini coefficient, which is the ratio of the area inside the Lorenz curve to the area under the line of perfect equality. The Lorenz curve graphically shows the distribution by plotting the cumulative percent going to the bottom x percent of the population. The Lorenz curve for U.S. income data from 2005 shows that the poorest 20 percent of households earn 3.5 percent of the pre-tax/pre-transfer income, while the poorest 40 percent (which includes the bottom 20 percent and the next poorest 20 percent) collectively earns 12 percent of income.

Thus, a lower Gini index indicates more equality. The lowest possible value of the Gini index is 0, in which case the Lorenz curve lies on top of the line of perfect equality and everyone has exactly the same amount. The highest possible value of the Gini index is 100, in which case the Lorenz curve lies along the horizontal axis and one person has everything, while the others have none.

The Gini index is useful because it condenses the entire distribution into a single, unitless measure that can easily be compared over time, across groups and countries and across economic (and noneconomic) variables.

World Bank

The most widely cited Gini estimates are from the World Bank's *World Development Indicators.* Using data from recent years, the World Bank estimates that the most economically equal countries in the world—with income Ginis below 30—include many smaller European countries such as Austria, Bulgaria, the Czech Republic, Hungary, and all the Scandinavian countries, as well as Germany, Ukraine, and Japan. In the low to mid 30s are Australia, Bangladesh, Britain, Canada, Egypt, Ethiopia, France, Indonesia, Italy, Pakistan, Poland, South Korea, Spain, and Vietnam. In the high 30s and low 40s are India, Iran, Israel, Kenya, Morocco, Russia, and Thailand.

The average Gini coefficient in the 126 countries on the World Bank's list is 40.8—exactly the same as the rate in the United States, but almost all the countries with higher levels of inequality than the United States are much poorer. China's Gini is about 47. Other countries in the mid and upper 40s are Malaysia, Mexico, Nigeria, the Philippines, Uganda, and Venezuela. Among the highest in the world are many nations in Latin America and Africa, with Bolivia, Botswana, Brazil, Colombia, Haiti, and South Africa near 60. Topping the chart is Namibia in southwest Africa at 74.

Ironically, the Gini index for the world as a whole—estimated to be between 56 and 66—is almost higher than for any single country, since rich people tend to live with other rich people, fairly equally in rich countries, and poor people tend to live with other poor people, fairly equally in poor countries.

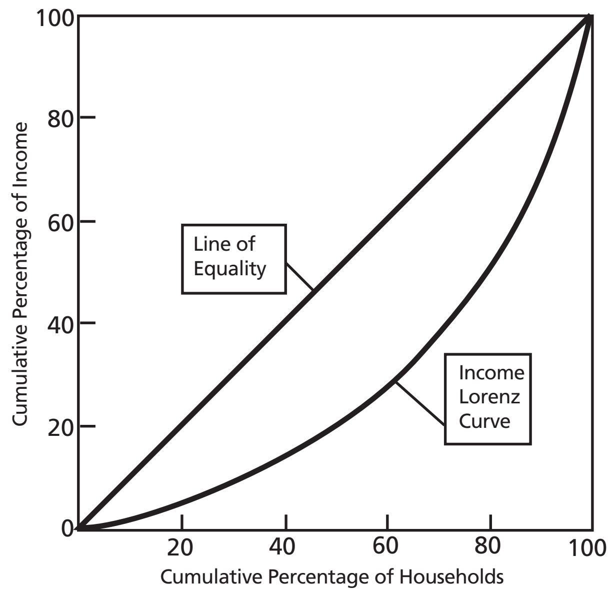
From 1970 to 2005, the Gini index for the United States rose almost 6 points. The leading explanation for this rising inequality in the United States is technological changes that have boosted the demand for skilled labor relative to unskilled labor. Gini indexes for wealth tend to be much higher than for income, but consumption Ginis are noticeably lower.

In practice there are a number of problems in calculating and interpreting Gini indexes. First, defining the units of analysis can be difficult. Does income include only monetary income or nonmonetary income such as health insurance and food stamps? A broader definition is probably better, but dollar values of nonmonetary totals are open to debate, so these are often omitted from official figures. Is the household or the individual the appropriate level of analysis? Since income is shared within households, the income Gini is usually calculated at this level, but this leads to some anomalies that skew the statistic. For example, in the United States poor households tend to be smaller than rich households. Thus, the poorest 20 percent of households contains only about 15 percent of people, while the richest 20 percent contains about 24 percent of people.

Each country collects its data differently, making comparisons difficult—although the levels and patterns reported above are generally believed to be approximately correct. Economies with similar incomes and Gini coefficients can still have very different income distributions. This is because the Lorenz curves can have different shapes and yet still yield the same Gini coefficient.

As an extreme example, an economy where half the households have no income and the other half share income equally has a Gini index of 50, but an economy with complete income equality, except for one wealthy household that has half the total income, also has a Gini index of 50.

There is no consensus on the optimal Gini index. The ideal will vary across individuals, cultures, and time. Most analysts agree that a certain degree of economic inequality is inevitable and desirable to give individuals the incentive to obtain skills, work hard, and undertake economic risks. However, if the



The Gini index equals 100 times the ratio of the area inside the Lorenz curve to the area under the line of perfect equality.

disparity gets too great, the inequality it represents can tear apart the fabric of society.

GlaxoSmithKline

GlaxoSmithKline (GSK) is one of the world's largest pharmaceutical companies. While it is based in London, in 2008 it employed around 100,000 people in over 100 countries. Close to 15 percent of its staff is assigned to research and development. Unlike some of its other pharmaceutical counterparts, GSK possesses a strong pharmaceutical pipeline and promising products, but it has also generated some controversy for some of its goods (such as its diabetes drug Avandia).

With strengths in therapeutic areas such as vaccines, oncology, cardiovascular and metabolic drugs, neurosciences and biological-based products, GSK is a key player in the pharmaceutical arena. GSK has also demonstrated increased interest in the consumer healthcare segment by commercializing products such as nutritional drinks and over-the-counter (OTC) medication.

GlaxoSmithKline is the result of the $30 billion 2001 merger of GlaxoWellcome (which itself is the result of the mergers of Burroughs Wellcome & Company and Glaxo Laboratories in 1995), and SmithKline Beecham (which is the result of the merger of Beecham Instruments, Allergan, and SmithKline in 1982).

The current company traces the bulk of its history to the 1800s in the United Kingdom and has a strong history of growth through mergers and acquisitions. It was the first company to dedicate a factory exclusively to manufacturing medicine in 1859, and has a long history of diversification in novel drugs, over-the-counter medicine, nutritional, and animal health products.

Pharmaceutical products include treatments for asthma, HIV/AIDS, malaria, depression, migraine, diabetes, heart failure, digestive conditions, and cancer. They also have an important division that manufactures and sells vaccines for diseases such as hepatitis A and B, diphtheria, tetanus, whooping cough, typhoid, and influenza. Most of the products have enjoyed modest growth in the last few years, except for Avandia, which has garnered some controversy. The drug, which was used to treat diabetes, was a blockbuster drug (which means it generated over $1 billion in annual sales) until scientific literature demonstrated that it could lead to heart attacks. The FDA required label warnings, but did not demand the withdrawal of the product. Nonetheless, sales of Avandia fell almost 22 percent in 2007.

GlaxoSmithKline has been selling its HIV drugs at cost in 64 of the world's poorest countries.

The company is different from other big pharmaceutical companies in that it has an important division dedicated to consumer healthcare, while the other big pharmaceuticals have divested their over-the-counter (OTC) divisions over the last few years. As such, GSK sells a wide array of consumer packaged goods through divisions such as consumer healthcare (with products such as NyQuil and Nicorette), dental products (with products like Aquafresh), and nutritional drinks (such as Boost). In 2007 the consumer healthcare division accounted for close to 15 percent of GSK's total business, and grew an impressive 14 percent over 2006.

GSK develops many products that target diseases that afflict populations in poorer countries, as well as developing medication for "orphan" diseases. As such, the company has traditionally adapted its price structure to accommodate poorer economies. For example, in 2007, GSK cut the price of its HIV drugs for the world's poorest countries for the fifth time since 1997, and sold those drugs at cost in 64 of the world's poorest countries. It also dedicated £282 million in 2007 for educational and community programs around the world, and is currently dedicating resources to three "priority" diseases identified by the World Health Organization: HIV/AIDS, tuberculosis, and malaria.

Through its long history, GSK has been implicated in a number of scandals. In one case, it was accused of overcharging Medicaid, to which it pleaded guilty and paid a fine of $87.6 million.

Other scandals include tax fraud, patent fraud, and antitrust behavior. Also, like all major pharmaceuticals, GSK is the subject of lawsuits relating to secondary effects in some of its drugs (such as Paroxetine and SeroXat), as well as the controversy surrounding its drug Avandia.

Global Account Management

The globalization of industries and intense competitive environments have induced some firms to undertake global account management (GAM), a systematic, firm-wide process that suppliers use to identify, develop, and retain their most important customers in global business-to-business markets.

When they expand internationally, firms often use global sourcing and expect suppliers to provide goods and services worldwide with consistent quality, efficiently, and at harmonized prices. When mergers and acquisitions reduce the number of buyers, fewer and larger customers tend to purchase higher volumes, which gives buyers purchasing power over suppliers.

Suppliers hope to protect their key business, because if they fail to supply a global buyer in one market, they may endanger their business with that buyer in other markets as well. They also tend to prefer to accelerate their organic growth by deliberately concentrating their resources on select global customers, or global accounts. Global accounts benefit from GAM, because this approach entails a value-adding sourcing and innovation partnership. Overall, GAM can help both suppliers and their global accounts strengthen their relationship and expand their global business.

A supplier's GAM program usually consists of a program director and program manager, several global account managers and their team members, and specialists who provide product-related, logistical, financial, and legal support. For example, Procter & Gamble introduced a dedicated, several-hundred-person GAM team, led by one global account manager, to cater on a worldwide basis to Wal-Mart Stores, Inc., its single largest customer. Thus, GAM programs may locate at the corporate level if they cater to firm-wide customers, as in the case of Procter & Gamble, or they may be situated within strategic business units if global customers purchase mostly from a particular business unit. The program director generally provides strategic direction for the GAM program and reports directly to the board; the program manager usually is responsible for developing and operating the processes, tools, and systems required for GAM.

Important program processes include global accounts selection and de-selection, appointment and development of global account managers, account business planning, multilevel relationship building, customer knowledge management, and relationship performance measurement.

Common criteria for selecting and deselecting global accounts encompass, for example, future business volume and profit potentials, strategic and cultural alignment between the organizations, and the degree to which the customer purchases on a centralized, global basis.

Perhaps the most important function in a GAM program is the global account manager (gam). Suppliers generally assign one full-time gam per global account, whom they locate in geographic proximity to the headquarters of the global account. Thus, the gam provides a prime contact for the buyer and orchestrates all supplier activities worldwide. The gam also leads the multifunctional global account team, which should mirror the customer's buying team to ensure optimal collaboration. The role and responsibilities of a gam thus go beyond those of an international sales manager; the gam develops and leads the implementation of a global, long-term collaboration strategy with the global account. This effort requires in-depth understanding of the global account's markets, entrepreneurial skills to identify and develop new business, and political aptitude to align the supplier's internal organization with that of the global customer. At IBM, for example, the gam's position equates with that of a managing director who leads a dedicated business team that caters to a particular global account on a full profit-and-loss basis.

The challenges of GAM primarily pertain to the organizational complexity and cultural diversity inherent to such global, inter-organizational relationships. For example, GAM programs introduce additional global structures that attempt to coordinate the supplier's activities by embracing several functions, markets, and business units, which often pursue diverging objectives. Furthermore, teamwork in a GAM team may be challenging because of the cultural diversity that results from different functional mindsets, such as research and development versus marketing, or from team members with different educational or cultural backgrounds. Consequently, suppliers implementing GAM attempt to align their go-to-market strategies and reward systems firm-wide to ensure goal congruence. Furthermore, they try to develop GAM talent and the collaborative capabilities of organizational members. Finally, suppliers need to resolve the global-local tensions that arise in response to a firm-wide program like GAM, such as product/service adaptation versus standardization.

Global Benchmarking

Global benchmarking is the process of identifying best practices in organizations anywhere in the world to seek information that can help an organization to measure and compare its performance against those best practices in order to improve its operations. A benchmark is a reference point for taking measures against. Best practices are the techniques that have worked reliably in different situations to achieve their desired purpose in the most efficient and effective way. The best practices are demonstrated to repeatedly work in different situations and can be replicated in different situations with more or less the same results. The process of benchmarking is aimed at finding the best practices within and outside the industry to which an organization belongs. The purpose of benchmarking is to find the best performers in an area so that one can match them and even surpass them. Thus, if Dell is thought to have the best supply chain management practices or Toyota the best manufacturing processes, organizations of any type, anywhere in the world, can benchmark their own practices and processes against these and make improvements in their own practices and processes.

Global benchmarking is a subset of benchmarking, which is a generic term that refers to the systematic and continuous process of measuring and comparing an organization's practices, products, or services against best practices demonstrated to be effective by industry leaders. The American Productivity and Quality Center gives an interesting interpretation of the term *benchmarking* by proposing that it is "the practice of being humble enough to admit that someone else is better at something, and being wise enough to learn how to match and even surpass them at it."

An often cited example of benchmarking is that of Xerox when it was facing trouble in the 1980s. It decided to implement benchmarking to identify ways to improve its performance. Xerox benchmarked against L. L. Bean for distribution procedures, Deere & Company for central computer operations, Procter & Gamble for marketing, and Florida Power & Light for total quality management. By the early 1990s, Xerox was benchmarking 240 functions against comparable areas in other companies. Benchmarking is credited with dramatically improving Xerox's performance.

In the United Kingdom, Lucas Industries is widely reported as a company using benchmarking, looking outside their own organization when measuring performance and generating targets. Managers at Lucas are required to prepare competitive action plans on an annual basis. These plans provide targets for performance designed to align the business unit with leading international competitors in a particular function and explain how the business unit will achieve such performance levels.

When an organization is interested in finding out what is to be compared, there are three types of benchmarking: performance, process, and strategic benchmarking. Performance benchmarking is to compare one's own performance with that of some other organization for the purpose of determining how good one's own performance is. Process benchmarking is to compare the methods and practices for performing processes. Strategic benchmarking is to compare the long-term, significant decisions and actions undertaken by other organizations to achieve their objectives.

When an organization looks to compare itself to other organizations, four other types of benchmarking may be used. Internal benchmarking is comparison between units or departments of the same organization. Competitive benchmarking is direct comparison of one's own performance against the best competitors. Functional benchmarking is comparison of processes or functions against noncompetitive organizations within the same sector or technological area. Generic benchmarking is comparison of one's own processes against the best practices anywhere in any type of organization. Global benchmarking is generic benchmarking as it involves comparisons with any type of organizations anywhere around the world.

A firm can attempt benchmarking at several levels using the different types of benchmarking. The major application of benchmarking is for performance improvement. It can also be used to find out the relative cost position of an organization in comparison with competitors. Benchmarking is a good learning experience for an organization because it helps to bring in new ideas and facilitates sharing of experiences. The main purpose of benchmarking is to find out the best practices so that one can conform to them. But before one conforms, benchmarking is enough to show where a firm excels or lags behind. This is helpful in assessing the strengths and weaknesses of an organization and finding ways to gain strategic advantage.

Benchmarking involves these steps:

- Selecting a product, service, or process to benchmark
- Identifying the key performance metrics such as efficiency of a process
- Choosing functions, business, departments, or internal areas to benchmark
- Collecting data on performance and practices
- Analyzing the data and identifying opportunities for improvement
- Adapting and implementing the best practices, setting reasonable goals, and ensuring company-wide acceptance

Despite its popularity in industry and elsewhere, benchmarking has some limitations. First, it is a tough process to use, is time consuming and expensive, and requires a high level of sustained commitment. Second, it serves little purpose if it is used sporadically, so it should be done on a continuous basis for effective results. Third, financial statements of publicly-held companies are easily and openly available and therefore organizations may be tempted to do benchmarking on the basis of these. However, it must be remembered that financial statements provide lagging indicators and may not be really useful as the basis for benchmarking. Last, it may be difficult to find comparable benchmarking candidates in all types of areas and activities, and organizations may have to rely on the second-best available choice.

Global Branding Strategy

Managers are gradually recognizing that brands are among their firm's most valuable assets. Strong global brands allow companies to increase their international revenues and growth. Global branding also helps to improve margins by driving down unit costs through economies of scale associated by winnowing agencies, ad copies, and marketing messages.

Brands also simplify decisions for consumers, who are busier, more cynical, and face a wider array of choices in an increasingly cluttered world. By maintaining a consistent brand image they reduce consumer confusion and reinforce the message in a cluttered market.

Brands can also help to mobilize and generate resources. Firms use strong brands to attract and retain talent. Obtaining external equity and debt financing becomes easier with enhanced visibility and credibility. Brands help to quickly roll out new products and protect innovations from imitation. Emphasizing a brand during market entry solidifies a firm's market position. Brands buffer firms during recessions and propel them forward when recessions end. For all these reasons, brands are intangible assets that increase the market value of firms.

Clarifying Global Branding

A brand is a collection of perceptions that may be positive or negative about a name or symbol of a product/service. It goes beyond short-lived product features to include emotional benefits and associations. At their heart, brands create trust with stakeholders.

A misconception is that global branding seeks to pursue an identical name, product, and marketing message worldwide. This practice is uncommon and often counterproductive. Most brands are not global in this sense. Procter & Gamble has over 89 brands, but only a handful are promoted identically worldwide. Its well-known laundry detergent is sold in some countries as Tide and in others as Ariel. A global branding strategy is a cross-national process to improve and harmonize a brand. The goal of a global brand strategy is to develop strong brands in all countries through a continuous improvement process using organization structure, processes, and culture to allocate brand-building resources, to create synergies, and to coordinate and leverage multiple country brand strategies.

Brands are becoming more valuable. In a globalizing world, brands can protect firms from international competition. The marketplace is confusing and cluttered with the entry of more players and the introduction of products with short lives. There is a shift, especially in industrialized countries, from manufacturing products to providing services, which are harder to evaluate and compare. Buyers lead busier lives and have less time to discern among products and sellers. So there is a need for the decision shortcuts and simplification provided by trusted brands.

The lowering of trade barriers and freer information flows make it easier for brands to cross borders and be exploited internationally. The economic center of gravity is shifting from low-growth industrialized countries to rapidly growing emerging countries. While consolidation is often emphasized in industrialized countries, enthusiasm is the theme in growing parts of the world. In industrialized countries, brands may exploit loyalty among aging consumers, while in emerging countries they may reach out to their large population of younger consumers that is climbing the economic ladder.

From emerging markets, indigenous brands (such as Tata, Lenovo, Infosys, and China Mobile) are gaining strength in international competition. Brands (such as IBM, Goldman Sachs, and Morgan Stanley) are important also in the business-to-business space because of their reputation for expertise, reliability, and security.

Other recent trends include the proliferation of media among which consumers can now choose. Environmental issues are also growing in importance. Positioning a product close to environmental issues strengthens a brand. And some trends, such as being online, have become necessary to bolster brands.

Brands can appreciate, like McDonalds, or depreciate in value, like Starbucks. The rise and fall of brands is in part tied to the popularity of their product category. Private equity groups are on the lookout to buy tarnished brands to restore their health. Managers should review their corporate practices that may tarnish their brands, such as Wal-Mart's labor relations, Microsoft's market dominance, and Nike's international contract manufacturing.

Most brands fail. Over 30,000 consumer products are launched each year, but less than a tenth have any staying power. Myopic companies reduce the quality of their products or stretch their brands unwisely, only to spend years attempting to repair the damage. Starbucks' strong brand was commoditized by overexpanding to over 13,000 coffee shops too quickly, which diminished its cachet. Brands that survive may be vulnerable to competing brands from retailers who also sell their private labels, from generic manufacturers, and from imitators where intellectual property protection is weak. They are also affected by the rise and fall of product categories, such as the Internet or unhealthy carbonated beverages.

A global branding strategy has to overcome various execution difficulties. It needs to understand the varying needs of many markets and be very creative to satisfy them. It must overcome coordination problems, varying coverage of agencies, and available media. It also needs to craft a process and design an organization to develop, strengthen, and leverage a brand.

Developing Strategy

Firms need to define various aspects of their brand. This includes a brand's personality, which is how the brand would be described if it were a person. They should develop brand associations that resonate with the public. What does the brand stands for? They should clarify user imagery: how a typical user of the brand would be described. What symbols and logos will be associated with the brand? Is the product category new, growing, and not crowded?

Key decisions must be made on the elements that should be kept constant and those that may be adapted. When going global, the following elements usually remain constant throughout the world: corporate brand, the logo, and the brand essence or values. Factors that may vary from country to country are corporate slogan, products and services, product names and features, positioning, and marketing tactics based on local differences. Abstract general values travel more easily, and can more easily be tailored to local situations than specific product features and marketing tactics.

Managers should resist pressures for short-term gains at the expense of long-term value. These pressures may overextend a brand to unrelated areas, which leads to brand dilution and public confusion. Or it may tempt managers to go down-market with the same brand, which depreciates it.

Firms can use umbrella branding to endorse innovations and, in turn, be endorsed by them. Consider the Apple iPod, the Apple iPhone, and the Apple iMac, for which consumers are willing to pay over a 20 percent price premium. They are much more than an MP3 player, a cell phone, or a PC. Otherwise standalone innovations per se will be easily imitated. Firms should consider investing in design as a way to distinguish their brand through aesthetics and ease of use. Nissan improved its brand ranking by emphasizing bold design rather than quality to differentiate itself from Toyota and Honda.

The Samsung brand, whose value has increased substantially and surpassed that of Sony, illustrates some of these brand-building principles. Less than a decade ago, it was a maker of lower-end consumer electronics sold under several little-known brand names including Wiseview, Tantus, and Yepp. It retrenched these brands and put all its resources behind the Samsung name. Then it focused on building a more upscale image through better quality, design, and innovation in mobile phones and digital TV product categories. Consumers form strong bonds with their cell phones, which they carry everywhere, and with their TV, which is at the center of their family room.

Global Brand Components

Managers should focus on building their brand leadership architecture, rather than chasing one identical global brand that may prove elusive. To implement this larger task, it should be broken down into its components. Each component should be designed to support the larger global branding goal. And the components must be consistent and dovetail with one another.

Managers need guidelines for where, how, and how much to invest in order to build global brands. Since brands have high, long-term value, firms should budget for brand building more than what would be justified with a short-term view. And broader global brands need more total investment than what would be justifiable with a narrow country view. However, this larger total budget should be allocated to conduct many pilot experiments across countries in order to discover what works. Once a successful theme is discovered, investment should be stepped up and it should be leveraged to multiple countries quickly.

Given how hard it is becoming to reach the consumer who increasingly selects his/her media, firms should not rely on one media, such as traditional advertising, to break through. They should invest in multiple campaigns using diverse media: the Web, entertainment event promotions, cell phones, handheld computers, and a retail presence. New growth media may be a particularly effective avenue. Procter & Gamble once used the emerging TV and radio soap opera to market its household products. And Google's ties to the rise of the Internet helped it become the most valuable brand in less than a decade since its founding.

Rather than restricting themselves to one marketing agency, managers should use multiple agencies to achieve broader reach while capitalizing on their relative strengths. They may have multiple agencies compete for creating new copy, then use one agency for execution, except in countries and media where that agency is weak, where they can bring in other agencies. When negotiating large contracts, firms should use their clout to insist on the best creative talent from an agency to work on their account.

Global Brand Managers

Responsibility for building a global brand should be given to an executive with branding and marketing experience. In some companies, an executive with this expertise can be found at the top management level. In other companies, this expertise is found at the middle-management level. Ideally, the appointed leader should have branding expertise, credibility, and contacts to put together a branding team. The members of the team should reflect expertise and perspectives from different countries, products, and marketing functions. The marketing functions represented should include marketing research, promotion, pricing, and advertising. Having such a diverse team reduces local bias and helps to attain synergies across units.

A global brand manager should be given more authority, especially if affiliates have been locally autonomous in the past in order to provide a counterbalance. The functions of the global brand manager are to make sure everyone knows what the brand stands for, what the guidelines are, and to approve any deviations from the guidelines when implementing it internationally. The global branding team should hold periodic meetings and conferences that bring together people from different units, marketing functions, and countries. These sessions should include a mix of formal presentations and informal idea sharing. The informal idea sharing develops contacts, transfers expertise, and leads to collaboration.

If managers are serious about building a brand, they need to develop metrics that measure its effectiveness, results, and value. These measures need to use a common vocabulary across markets and products so that performance can be compared and aggregated internationally. Brand equity may be measured by product performance in blind tests, consumer surveys of brand awareness and loyalty, and market distribution within and across markets. Brand value may be measured by the sum of all future earnings improvements that a brand is expected to generate, discounted to a present-day value. This discounted value is then capitalized to estimate the boost in the market value of the business over its tangible assets.

The International Brand Planning Process

These metrics form a common planning template and are part of a common international brand planning process. This planning process should conduct pilot experiments in different settings, evaluate performance, share insights, and leverage best practices across countries. The sharing of insights can be encouraged through meetings, conferences, and an intranet knowledge-sharing system. An example of international knowledge sharing occurred when Procter & Gamble developed a shampoo, Pantene Pro-V, whose branding was floundering in developed countries. But an experiment in Taiwan came up with a successful tagline—Hair so healthy that it shines! This tagline was then quickly rolled out to 70 other countries.

Building a global brand requires identifying and nurturing supportive values in the firm. Innovativeness is needed to try new marketing themes, messages, and product innovations. An appreciation for continuous improvement encourages brand refinements in an ongoing journey. A willingness to collaborate helps to share ideas so that insights can be leveraged internationally. And determination and a long-term view provide the discipline not to succumb to cutting corners because of short-term profit pressures.

Employees need to be rewarded for contributing to the brand-building effort. Rewards and recognition must be given for experimentation that leads to breakthrough ideas. Inventors may be recognized in company newsletters and given financial bonuses. Some companies track and reward in annual reviews the number of contributions made by employees to the knowledge-sharing system. Another possibility is to provide incentives and recognition to employees who share their insights and best practices at conferences and meetings.

A global branding strategy has the potential to create long-term value for the firm's stakeholders, but requires dispelling misconceptions and adopting a strategic process. Managers should not chase a single global brand, product, or marketing message. Instead, they need to distill and emphasize the essence of what their brand stands for. And they need to put in place a planning process to innovate, share insights, and leverage best practices internationally to continuously improve their brand in order to develop a global leadership position.

Global Capital Market

Throughout the early modern period, as communications increased in speed and effectiveness, there were attempts to make larger capital markets, with the end goal being the creation of a global capital market where money can be raised internationally, allowing for greater access by all companies to the same pool of capital regardless of where the company is located, and also free of legislative and other restrictions that apply in some parts of the world.

Historically, the raising of capital involved transactions conducted between governments and private individuals. These processes were fraught with problems for both sides, and by the late 17th century, in western Europe, there was an attempt to formalize the process. This saw the creation of the Bank of England in 1691 (incorporated in 1694), and in the early 18th century the origins of other schemes in other countries, some for city corporations, others for governments.

However with the Industrial Revolution many capitalists wanted to be able to raise capital to embark on their projects and there was no regular system of raising capital and sharing the risk. As a result with the building of the Bridgewater (or Worsley) Canal, Francis Egerton, the 2nd Duke of Bridgewater, had to take the entire risk for the venture himself, and although he did end up very wealthy, it was a move that nearly sent him bankrupt. Similarly some major capitalist ventures could come to create major crises in the countries where the vast majority of the investors lived. Two of the most extreme examples of these came from France—the attempt by the Mexican government of Benito Juarez to abrogate the debts incurred by previous Mexican governments leading to the French military intervention in the country to install Emperor Maximilian in the 1860s; and another being the Panama Canal Crisis in the 1880s when French investors lost fortunes in speculation in the shares of a company which hoped to build the Panama Canal.

20th Century

By the 20th century, there were numerous banks that were able to lend capital for industrial and other projects. This certainly helped with the needs of the vast majority of borrowers. However there were companies which invested in one country, financed by investment from another. Some of this was to do with the colonial empires, with the capital for the Malayan rubber industry in the 1900s raised in London; but there was also other examples, including the financing of the building of the Argentine railroad system, also financed in London. By the 1900s London had certainly emerged as the main capital market in the world but it was about to be challenged by New York, which started from 1919 to become the dominant center for global capital. With better communications through a regular telephone and telex service, and now with computer systems, it has been possible to link the capital markets around the world and provide, for the customer, wider options and more access to this capital, and for the lenders, a greater ability to spread the risk among capital investors, and also speculators, around the world.

As well as the global capital market which arose in the major financial centers in the world: New York, London and Paris, and later Frankfurt and Tokyo; the oil price rises of the 1970s created a new area of wealth with the availability of what came to be known as "petrodollars." This led to a number of schemes by which people claimed to have access to a more secretive "global market" with "agents" approaching governments. The most infamous was Tirath Khemlani and his dealings with the Australian government in the early 1970s. The Bank of England warned against these schemes, which profited largely through large cancellation fees which would have to be paid if the government in question wished withdraw from these—there has been no evidence of this hidden "global capital market."

The need for the global capital market became essential with increasingly larger numbers of companies having cross-listings by which their stock was quoted on a number of stock markets around the world. With the global capital market, it was possible to raise far larger sums of money than had been possible earlier, and this allowed investors and speculators to spread their risks over a wide range of capital investments all over the world.

The End of the Bretton Woods System

One of the developments that arose from this global capital market was a convergence of real interest rates around the world. This coincided with the end of the Bretton Woods system and the floating of many currencies in the 1970s, coupled with the U.S. government's suspension of the convertibility of the dollar into gold. This allowed the rates of exchange between most major currencies in the world to be set by the market, albeit with the government able to influence this through altering the exchange rates to increase or decrease demand for a currency.

As a result, if the government of a specific country sought to use macroeconomic instruments such as interest rates, and they were raised, the demand for the currency would create a rise in the value of the currency, after which the real interest rates would be comparable to those in other countries. With open markets, full and audited accounting by governments, and with the free flow of capital into and out of countries, market forces would balance the currency market forming an equilibrium. Economists defined this as the purchasing power parity theory, although similar theories had been around since the Swedish economist Gustav Cassell (1866–1945) suggested that this could become the case as early as 1916.

Speculation

If the global capital market could cope with balancing out the value of the various currencies, it was soon suggested that widespread speculation could affect the prices of the currencies allowing speculators to make (or lose) vast sums of money. This had led to the Bretton Woods system, which was a deliberate attempt by the United Kingdom, United States, and many other governments to constrain the global capital market in terms of the values of currencies, although it did not stop the two devaluations of the pound sterling to the U.S. dollar in September 1949 and November 1967.

The floating era from 1971 saw a large rise in world interest rates, largely through the rise in the price of petroleum. With the doubling of oil prices in 1978–79 after the Iranian Revolution, the effect was that the economies of North America, Western Europe, and other parts of the world went into recession. George Soros and other operators of hedge funds used the global capital market to raise large sums of money and this in turn resulted in the "Battle for Sterling" in 1992 when Soros fought the Bank of England, and later in 1997 with the Asian Economic Crisis. Since the late 1990s there has also been the increasing role of China in global capital markets, helping create a boom that led to estimates made in 2006 that the global capital market would exceed $228 trillion by 2010, although with the current crisis, this figure now seems improbable.

2008 Crisis

Thus the result of the global capital market and the spreading of risks can lead to many countries seemingly unconnected to the area at economic risk becoming affected. In 2007 with the start of serious problems in the U.S. subprime home mortgage market, the effects were felt not just by the individual lenders, and especially by Fannie Mae and Freddie Mac, but by banks and financial institutions around the world that had invested their money in Fannie Mae and Freddie Mac and suddenly found themselves exposed to the collapse of the subprime market. The crisis was triggered to a certain extent by undue offering and securitization of low-quality subprime mortgages and other lows in the United States, which were abetted by a certain extent by deregulation in the 1990s and a laxity in enforcement of regulations that continued. Stunned American legislators initiated a bailout coupled with a stream of new regulations.

Another dramatic effect in 2008 was following a crisis in the Icelandic banking system, it was revealed that vast numbers of individuals, companies, town corporations, and public organizations had invested their money in Icelandic banks because of the better returns offered, without realizing that this increased their level of risk. While there was confidence in the global capital market, there were no problems, but as soon as "panic" breaks out, there is a quick flight of capital, leaving those less able to quickly react to take potential or actual losses, and in extreme cases to lose their investments as well.

Global Competitiveness Index

The Global Competitiveness Index (GCI) is an aggregate measure of the set of critical factors that, as a group, determine the degree to which countries are expected to achieve levels of economic prosperity in the short and medium term. The GCI, introduced in 2004, was developed by Columbia University professor Xavier Sala-i-Martin for the World Economic Forum (WEF). The WEF, incorporated as a foundation in 1971, is a nonprofit, independent international organization based in Geneva, Switzerland. It publishes the annual competitiveness ranking of countries in its *Global Competitiveness Report* (GCR) based on the GCI. The report also includes comprehensive listings of the main strengths and weaknesses of countries, making it possible to identify critical areas in need of policy reform. While there are other similar reports published using their own competitiveness measures (e.g., Ease of Doing Business Index and the Indices of Economic Freedom), economists generally consider the WEF's index and rankings as representing the most competitiveness.

The GCI rankings are calculated from both publicly available data—such as that provided by the United Nations—and the Executive Opinion Survey (EOS). The EOS is a comprehensive annual survey conducted by the WEF, together with its network of "Partner Institutes" (leading research institutes and business organizations) in the countries covered by the GCR. The EOS is designed to measure a wide range of factors that impact a country's current and future business climate. For the 2007–08 EOS, approximately 11,000 business executives—deemed as representative leaders in their field—were polled in 131 countries. This represents the most comprehensive report to date in terms of number of countries included (the 2006–07 EOS covered 123 countries). Countries added to the 2007–08 EOS, and in turn the GCI, include Puerto Rico, Libya, Oman, Saudi Arabia, Senegal, Syria, and Uzbekistan. In addition, Serbia and Montenegro, previously analyzed as a single country, are now included separately. The theoretical-empirical model used to determine the GCI rankings incorporates over 90 variables that relate to a country's current and prospective economic profile. Two-thirds of these variables come from the EOS and the remaining one-third from publicly available sources.

Pillars and Stages

The GCI is based on 12 categories—referred to in the GCR as "pillars"—of competitiveness. These categories as a whole provide a comprehensive picture of the competitiveness landscape in countries around the world at all stages of development. These categories are Institutions, Infrastructure, Macroeconomic Stability, Health and Primary Education, Higher Education and Training, Goods Market Efficiency, Labor Market Efficiency, Financial Market Sophistication, Technological Readiness, Market Size, Business Sophistication, and Innovation. Certain categories are more important than others within different countries in determining their degree of competitiveness. For example, what generates productivity in Denmark significantly differs from what drives it in Cameroon. This is because the two countries are in different stages of economic development. Accordingly, the GCI separates countries into three specific economic stages according to per capita income. These stages—designated "factor-driven," "efficiency-driven," and "innovation-driven"—reflect a growing measure of complexity with regard to how a country's particular economy operates.

In the factor-driven stage, countries compete based on their factor endowments, which are mainly unskilled labor and natural resources. Companies compete on the basis of prices of basic products or commodities and low productivity is accompanied by low wages. At this stage of development, competitiveness depends on a country having decent public and private institutions, acceptable infrastructure, a strong macroeconomic framework and good healthcare and basic education for its population.

As wages rise with growing development, countries move into the efficiency-driven stage of development. In this stage, they must begin to develop more efficient production processes and increase the quality of products they already make. At this point, competitiveness becomes increasingly driven by higher education and training, efficient markets, and the ability to harness the benefits of existing (or impacted) technologies. As countries eventually begin to compete through innovation, they are only able to support higher wages and a higher standard of living if their businesses are able to compete through product innovation as well as novel productivity-enhancing innovations.

Depending on which stage a country is in, the GCI for that country is calculated by giving greater weights to the more relevant pillars. The weights used are the values that best explain growth in recent years. For example, the sophistication and innovation factors contribute 10 percent to the final score in factor and efficiency-driven economies, but 30 percent in innovation-driven economies (values between 10 percent and 30 percent are applied for those economies in transition between stages).

GPI for 2007–08

The United States heads the GCI ranking for 2007–08. The GCR attributes this to its competitive economy, efficiency of its markets, sophistication of its business community, capacity for technological innovation, and its high-quality system of universities and research centers. Despite this ranking, the GCR notes that the United States has serious weaknesses in its macroeconomic structure as evidenced by the sub-prime mortgage crisis and the resulting credit crunch and shocks to the stock market. These problems can pose a risk to the country's future overall competitive potential.

Switzerland and the Scandinavian countries of Denmark and Sweden follow the United States in the GPI ranking. The major European economies—Germany, United Kingdom (UK), and France—rank 5th, 9th, and 15th, respectively. While Germany moved up in the rankings compared to 2006–07, both the UK and France fell, suggesting that the United States has been moving ahead of western Europe in terms of overall competitiveness.

Estonia ranks the highest in eastern Europe (27th), followed by the Czech Republic (33rd). Hungry and Poland rank 44th and 48th, respectively. A number of important eastern European economies have seen their 2006–07 standing erode, including the Czech Republic, Hungary, and Poland, indicating a loss of competitiveness in this region. However, the Baltic region has continued to progress competitively. Estonia, Lithuania, and Latvia have all advanced in their GCI rankings, reflecting their growing integration into the western European economy.

Within Latin America, Chile (26th) ranks the highest. The rest of Latin America trails far behind and, for the most part, in the bottom half of all countries in competitiveness. The highest ranking Latin American countries in terms of competitiveness after Chile are Mexico (52nd), Costa Rica (63rd), El Salvador (67th), Colombia (69th), Brazil (72nd), and Uruguay (75th). Venezuela's competitiveness slipped from 85th in 2006–07 to 90th in 2007–08, testifying to that country's continuing and deep-seated economic and political problems. Within Asia, China (34th) and India (45th) continue to lead the way among large developing economies. However, both countries slipped competitively from their 2006–07 rankings. Indonesia at 54th place also remains formidable as a competitive force in the region. Several countries in the Middle East and North Africa are in the upper half of the rankings. Israel (17th) remains the dominant competitive economy in the region. The remaining countries, while ranking far lower than Israel, still reside comfortably in the top third of all GCI countries, including Kuwait (30th), Qatar (31st), Tunisia (32nd), Saudi Arabia (35th), and the United Arab Emirates (37th). In sub-Saharan Africa, only South Africa and Mauritius stand in the top half of the rankings, with several countries from the region positioned at the very bottom of the GCI, reflecting the persistent economic troubles and political and social dislocations that hinder the region's global competitiveness.

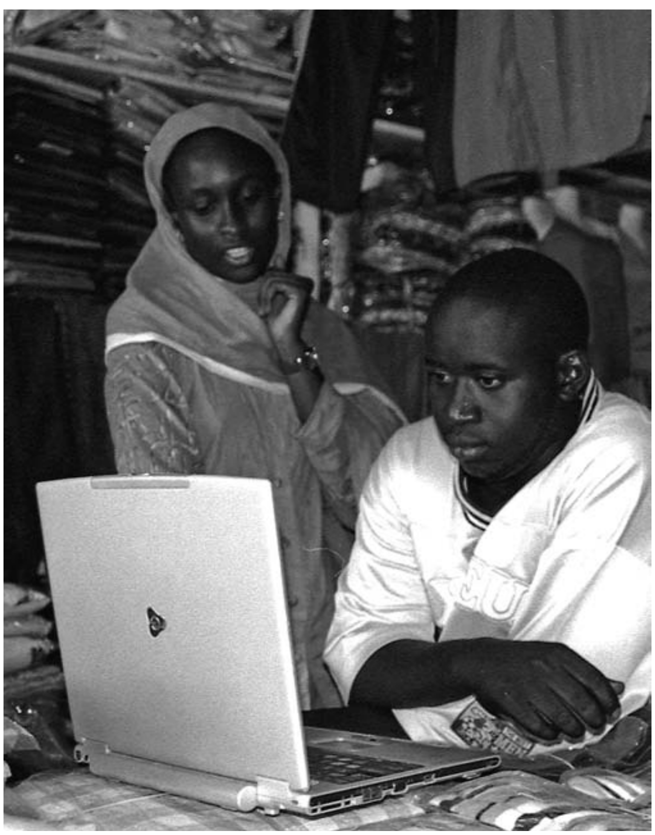
Global Digital Divide

The global digital divide refers to differences in Internet and other telecommunications access and usage across countries. The global digital divide encompasses two concepts. First, there is a divide in access and usage across definable groups within countries, and second, there is a divide in access and usage across countries themselves.

Individual country statistics routinely show an intra-country digital divide. In a Pew Internet and American Life study and nearly all the countries surveyed in a 2008 OECD study, Internet use within OECD countries decreases with the age of the user, increases with the education of the user, and increases with the income of the user. Globally, households with children are more likely to use the Internet and urban/suburban users more likely to have access than rural users. And in many countries men access the Internet more than women. This same study also found that Internet access varies with firm size. Larger firms (firms with more than 100 employees) are twice as likely to have Internet access than smaller firms.

According to Internet World Stats, the latest number of world Internet users in 2008 is 1.5 billion, which represent 21.9 percent of the world population. According to recent studies, there are several major contributors to the inter-country, or global, digital divide among these users including differences in income, literacy, infrastructure, and the regulatory climate. As expected, the lower income developing countries have lower access to the Internet. In these same countries, illiteracy also complicates Internet usage. When the Internet is accessed, users must share a very low bandwidth. As a result, text-based Internet pages are the most likely to be successfully accessed. The irony is that these pages often cannot be read because of low literacy levels and translation difficulties. These users are deprived of the audio and video components of the Web that would be most beneficial to them due to low bandwidth. In 2004 a single user in Japan has access to more bandwidth than the 45 countries with the lowest bandwidth *combined*.



This clothing merchant in Dakar, Senegal, was learning how to use a laptop in his business in 2005.

The focus of reducing the global digital divide has changed over time from expanding landlines to increasing dial-up access to expanding broadband via fiber optic cables. In OECD countries, broadband subscribers increased by 11 times 2000–06. Expanding broadband into developing countries is still a prominent interest of telecommunications companies and governments. A variety of public and private telecommunication structures has developed connecting to one vast network. Public policy analysts fear that monopoly pricing and limited access by private firms will continue to isolate vast geographical areas. One OECD study suggests that the solution to the global digital divide is through liberalizing telecommunications markets while keeping a sound regulatory framework.

Studies of the global digital divide often focus on both Internet access and PC availability. Moves to expand laptop and PC availability to developing third world countries will help increase access to broadband and reduce the global digital divide. However, the popularity of mobile communications in developing countries may suggest that satellite technology is the medium of the future. Mobile phones are less expensive for developing country citizens and providing access is cheaper for firms than building or repairing landline infrastructure. It is therefore easier to use satellite transmission to extend access in these areas. A Nielson report in July 2008 finds that while the United States leads in overall mobile Internet usage (of total users), other nations, such as Russia, Brazil, and India, are now using mobile devices as the primary mechanism for getting online.

Closing the global digital divide requires coordination via companies that produce the broadband and satellite access, telcos and ISPs that provide the access to the consumers, and governments. Provision of access alone will not close the divide. The price of that access for the consumers, their income, their literacy level, and their willingness to learn new technologies are also factors. Continuous technological improvement and competitive markets reduce the price of access. There are many groups seeking to reduce the other burdens of access and provide the tools necessary to equalize access to these markets, such as funds and equipment, accords between governments, and cooperation between private companies.

Globalization

Globalization is the ever-increasing process of integration of local and regional markets into one unitary market of products, services and capital. The main results of this process have been an increase in the interdependence of traditionally national markets on the macroeconomic level and the internationalization of corporate processes, especially production, distribution, and marketing, as well as the adoption of international business strategies on the microeconomic level.

Development

Economists recognize the early signs of globalization in historical phenomena, such as the increased economic activity in the Age of Discovery in the 16th and 17th centuries, which led to the founding of the British and Dutch east India companies; and the new economic opportunities enabled by the scientific discoveries of the 18th and 19th centuries, followed by the 20th century's breaking ground on the Information Age.

The World Bank identifies three waves of globalization, which happened between 1870 and the 21st century. The origins of the process are attributed to the falling costs of transport and the lowering of the politically-driven trade barriers. Trade in commodities developed into trade in manufactured goods. Initially land intensive production became labor intensive. Mass migrations for work became an everyday phenomenon, traveling becoming easier with the development of the more advanced transport technologies. The telegraph allowed more distant countries to benefit from the capital available on the stock exchanges, as stock exchange institutions were brought to new locations, contributing to the growth of financial markets.

Two world wars blocked international trade as individual countries turned protectionist. The situation persisted up till the 1980s, by which time the international exchange between the developed countries was largely freed from the barriers, leaving the developing world outside of the free trade market. It was during the second phase of globalization, when the countries started to specialize in production and the businesses started to function around agglomerations and clusters, that economies of scale started to matter.

A discussion on the wealth inequality and the rising poverty in the developing countries started, resulting in the postulates to allow all the nations to participate in the benefit of a free trade. Interestingly enough, the inequalities of the early globalization era in the 19th century were largely related to the ownership of the land, crucial both for the commodity trade and for the manufactures. However, the inequalities during the second phase of globalization showed a more systemic nature, being driven by the protectionist policies of the developed world.

The third wave of globalization brings the "death of distance" in a traditional geographical sense. It does not matter any more whether the whole business process is situated at the same location, as the service and non-core functions, thanks to communication technologies, can be successfully performed even on different continents.

The third wave of globalization created off-shoring locations in central and eastern Europe and the new, previously developing, economic empires of India and China. Although some of the former developing countries broke their way to the free market and compete successfully for the investments, others remained marginalized and are becoming even more excluded from the benefits of the world economic growth, than ever before. One of the most striking examples of poverty levels and inequality are in the region of sub-Saharan Africa.

Features

The relationship between economic, social, political and cultural aspects of globalization is visible in the main determinants of globalization, which can be attributed to various spheres of human activity. They include but are not limited to

- digitization, which enables easy distribution of data, information and knowledge paired with a parallel advancement and accessibility of communication channels, especially the Internet;
- development and internationalization of mass media, which creates certain convergence of consumer patterns (e.g., mass accessibility of TV such as MTV makes the icons of contemporary pop culture such as McDonald's or Barbie the symbols of capitalist world, which developing societies demand, aspiring to the Western style of life; moreover increasing capital consolidation in the sector of media enables the formation of media empires, like Rupert Murdoch's, which allow a relatively small group of opinion-makers to influence whole societies);
- increasing cross-border and overseas migration trends, caused by people's urge to improve their lives and economic standing;
- longing for freedom in those countries, which suffer internal oppression either from the ruling class or from any other form of political or economic regime; this enables the democratization political systems and in consequence the introduction of economic liberalization and popularization of the free market philosophy (e.g., the spectacular transformation of central and eastern Europe countries from centrally planned economies to the free market);
- advancing skills of global management allowing entrepreneurs to operate in the wider geographical scale (a new category of companies, called transnational corporations, is both a consequence of globalization processes and a response to increasingly tighter competition, stimulating global dispersion of corporate influence, management methods, production patterns and technologies);
- convergence of various economic orders toward a free market and liberal economy and, in consequence, a creation of the unified economic model—the only acceptable economic philosophy;
- technological advancement and dynamics of innovations with their net effects such as a quicker use up of limited Earth resources; this in consequence creates new organizational behavior patterns (i.e., business sustainability, where business models are created on the basis of energy savings and social responsibility);
- new rules of international labor division and, in consequence, creation of geographical competence centers (e.g., information technology [IT] services in India);
- centralization of purchasing by global clients and the economy of scale, which is a direct motivation for global expansion (unit production costs are significantly decreasing with a growing share of B&R, marketing and promotion costs in a total cost of production);
- standardization of production and services being a consequence of adopting certain strategies on the global market (a classical example of such standardization is presented by the quality measurement norms—series ISO—certified by independent bodies such as TUV; getting a certificate, which is determined by adopting

standard procedures in the organization, often determines whether the company can obtain good contracts as the big companies with large international networks of suppliers and distributors often select partners for co-operation on the basis of quality certificates possessed);

- less restrictive trade tariffs;
- strategies adopted by transnational corporations, which aim at gaining more competitiveness on a wider market and which change the rules of labor division as well as internationalization of production process as a result of the complex network of relations between corporate branches in many countries.

Strategy

Among the strategic decisions of enterprises, two have significant gravity in terms of their ability to force further globalization. First, mergers and acquisitions that contribute to enlargement of organizations per se. Second, off-shoring, or locating some business functions and processes in countries that offer cost reductions without compromising on the quality of the service.

Enterprises forced to compete in a tighter and more challenging market seek strategic assets, which are often purchased through takeovers of other companies or through various forms of mergers. Increased mergers and acquisitions activity can be characterized not only by an increased volume of transactions, but also by its significant dynamics (measured by scale of change as compared to the previous year). It is one of the main stimulators of globalization and a response to more demanding and challenging conditions for competition (companies are looking for foreign markets, which are often less saturated than those of the enterprises' origin, however, as foreign markets accept more players and in due course become a global market, entrepreneurs must compete through taking over the strategic assets). In 2006 the value of assets acquired by purchase or through takeovers reached $88.5 billion globally in almost 7,000 transactions.

Off-shoring (or near-shoring in the case of locating operations in the countries in a close proximity to the home country) is a strategic trend stimulating foreign direct investments. Enterprises are largely driven by a paradigm of cost reductions these days. They can achieve it by locating their service functions and non-core activities in the countries that offer significantly lower labor costs and a decent level of skills at the same time. Key criteria used in making such decisions are: local economic and political stability, infrastructure, labor market and the level of education, language attainment, and the real estate market. A typical off-shored operation includes call centers and shared services centers, hosting mostly the IT, administration and accounting functions. As such investments bring many new jobs, they contribute to the growth of local economies.

The most competitive locations, in terms of labor costs and overall investment climate, attract great numbers of investments and as the local market saturates, wages start to increase in a natural way—stimulated by the demand-supply situation. At the same time, local governments tend to encourage the investments in the more complex and sophisticated processes to benefit from a transfer of knowledge and perhaps technologies as well. More sophisticated jobs require higher wages and as the local markets develop toward maturity, as the hosts for off-shoring operations, enterprises move on to the new, less-saturated locations, where they can benefit from the lower costs again. This specific form of colonization is also a part of the globalization loop, where transnational corporations are the reason and the result of the process at the same time.

Last but not least, a change in the very nature of competition remains to be mentioned as a key driver of globalization. Geographic regions compete for resources, for example for the capital and external financing opportunities on the global market. Together with liberalization of capital transfers, new opportunities for obtaining external financing for the projects became available. Companies do not need to apply to banks anymore; they can raise the capital directly on the market, for example through the emission of stock. This phenomena changed the core role of the banks as the sole capital providers. Banking institutions now need to diversify their activity in order to stay competitive. Regions also compete for the investments, specifically foreign direct investments (FDIs), which bring new technologies and jobs.

Globalization should be analyzed in the macroeconomic context—as an aggregated phenomena taking place in the global scale, and in its microeconomic context—at the level of individual enterprises, adopting certain development strategies and making strategic decisions (e.g., locating elements of a value chain in the countries with local advantages or centralizing them in one location).

Economic globalization stimulates a significant institutional evolution. Global institutions are set up to manage certain aspects of activity in the global marketplace. They are equipped with both political and economic tools to control and influence the global market players. The most important include the World Bank, International Monetary Fund, and World Trade Organization.

Commodity, Financial, and Labor Markets

Globalization of various types of markets, i.e. products, services, or financial markets can be characterized by various scale and dynamics, although most clearly it can be observed on the financial markets. It is stimulated by the huge scale of capital being transferred worldwide through the rapidly growing intermediary institutions, e.g., investment funds. The transfer most often happens in virtual terms only, with the use of electronic money and a variety of new financial instruments. For that reason financial markets operate in a fairly autonomic way, relatively independently from the real sphere.

Independence from the real sphere coupled with the inter-relatedness of the whole financial system globally carries the risk of the "domino" effect. A domino effect occurs when dangerous economic trends, such as financial system crises, transfer from one market to another, infecting them. The reason for this is a high sensitivity of the local markets toward the changes in direction of capital flows and a high level of interrelatedness of the whole system.

It is worth noticing that although financial globalization is caused by an increase in the volume of world trade, financial markets globalize much quicker than the market of products. Moreover, the phenomena of financial markets leadership over the market of commodities can be observed in the relation of foreign direct investments toward export. Foreign direct investments show much higher dynamics than the trade volumes.

There are also significant differences in the pace and dynamics of foreign direct investments regionally. To an extent, it is a good measure of the share in the globalization process that respective countries have. For example, there was significant growth of foreign direct investment volume globally in the beginning of the 1970s. However, a change of FDI numbers in the European Union (EU) countries was more dynamic than its overall global trend. A closer look at foreign direct investments trends by region reveals the decreasing attractiveness of the United States and Japan as targeted FDI locations for the benefit of the emerging markets of central and eastern Europe and the former Soviet Union.

The EU countries, both EU-15 and the EU after enlargement, have significant share in world foreign direct investments volume. Although investments in the EU-15 countries, as well as in central and eastern Europe are quite dynamic, the CIS countries (the Commonwealth of Independent States) have recently become more and more attractive for investors (this applies especially to Ukraine and Belarus, although both countries are known to be difficult to navigate because of bureaucracy and low transparency). It is expected, though, that business attention will be naturally drawn to this part of the world, with the maturity of the currently attractive CEE markets getting more advanced and their labor costs increasing as a natural consequence of economic prosperity.

Data from the individual countries provides further information. Within the EU-15 countries, which overtake the United States and Japan by the total volume of FDIs attracted, individually only France and Germany show FDI growth significant enough to be considered a driving force for the whole EU. In the CEE and CIS regions, a similar role is played by Poland, the Czech Republic, and Russia.

Financial Markets

Among the reasons for the globalization of financial markets is the fact that more countries guarantee the exchange of currency (as a result of liberalization of the capital trade) and have deregulated their financial sectors (for example through the cancellation of interest rate limits and opening of the domestic financial sector to foreign capital). This, among other reasons, is happening because of the technological advancement, which on one hand, allows doing transactions on a wide geographical scale and in the real time, while on the other hand, makes them difficult to control, mainly due to the very liquid nature of money.

The fact that there are no significant transport costs related to the trade with use of electronic money, is not unimportant.

Liberalization of capital flows may pose a substantial threat for the stabilization of domestic, local economies, for example a risk of spread of financial crisis, as already mentioned before. The scale of those threats is subject to a wider discussion on the pace and degree of opening the local, national markets for international capital. Economists seem to agree that a high quality of local financial system, determined, among other things, by the existence of effective institutions and measures of the bank governance, is fundamental for this process to be safe for the local economies.

The scale of globalization within countries or regions can be measured in a few ways. For example, the freedom of financial transfers, related to a possibility of investing on the foreign markets, is measured by the Investment Freedom Index, which is a part of a wider Economic Freedom Index. It illustrates how regions differ in globalizing their economies. The majority of the EU countries saw the Index increasing in the last decade, contributing to the overall growth of investment freedom in the EU, which is now at a similar level to the United States. However, global investment freedom decreased in the last decade, mainly because of the situation in countries such as Bolivia, Burma, China, Ecuador, Nigeria, Venezuela, and Zimbabwe. In the central and eastern European countries, the Investment Freedom Index shows a tendency to grow. The wider measure of the Economic Freedom Index is growing on the global scale (5.52 percent in the last 10 years). The main driving forces behind this growth are: growing fiscal and monetary freedom, the freedom of trade, and the decrease in state interventionism.

The markets of commodities and services are the second important sphere where globalization processes can be observed. Globalization in those markets is stimulated by the common membership of countries in the WTO (World Trade Organization), which ensures that liberal rules are adopted by its members in the trade exchange.

The Trade Freedom Index, which measures globalization of the markets of commodities and services, is increasing, showing growth of 22.16 percent in the last decade globally, 11.14 percent in the EU-15 countries and 21.24 percent in the central and eastern European countries and the Commonwealth of Independent States. It decreased only in Japan (–1.23 percent).

The labor market is not immune to globalization, however, it subdues to the process more slowly, although mobility of a labor force is a significant factor in internationalization of domestic economies. It is easily observed in the trans-national corporations, where higher management is characterized by significant mobility.

The freedom to work on the different international markets and the freedom to employ international staff, measured by the Labor Freedom Index, has grown globally only by 0.36 percent since 1997. In some cases such as Finland, Germany, and the United States, it actually decreased (–10.47 percent, –8.78 percent, and –0.85 percent, respectively).

Globalization can be measured by indexes specially constructed for the purpose, such as the KOF Index. Economic globalization, one part of the index, is measured by the scale of financial transfers, which include trade volumes, foreign direct investments, portfolio investments, and wages paid to foreign employees—all as a percentage of gross domestic product (GDP) of a country, and by the scale of restrictions such as tariffs, hidden import barriers, taxes, and import duties. Financial transfers and trade barriers are getting more flexible and loose, leading to growing index values. Economic globalization can be therefore considered to be an ongoing and constantly developing process.

Effects

A single interpretation of globalization would be difficult to offer. The complexity of the process with its net effects is visible in a simple analysis of its benefits and costs. Positive results of globalization may include

- easier participation in international trade and exchange, which enables an export driven economic growth;
- wide access to information and knowledge sharing, which decreases the isolation of whole societies and individuals;
- deconstruction of national monopolies, through new market entries and the enrichment of local economies with new technologies.

On the other side, it is difficult to ignore the costs of globalization, such as

- increasing divergence between the high-income and the low-income countries (the GINI coefficient, measuring inequality in income distribution and/or expense, confirms that the rich countries become even richer, while the poor ones face being marginalized);
- lack of solutions to global poverty and no guarantees for economic stabilization (the number of people living on less than $1 per day is constantly increasing);
- negative social effects related to migrations, e.g., ethnical conflicts and solidifying differences in the economic standing and social status of the immigrants.

One of the obvious aspects of globalization is a deconstruction of the traditional, geographical structure. The distinction between the European Union, the Americas, and Africa, seems to be less significant now, as from the economic perspective, the countries that show the highest participation in globalization come from various countries, e.g., Argentina, Bangladesh, Brazil, China, Columbia, Costa Rica, and India.

Last, but certainly not least, ethical and theoretical doubts cannot be ignored. Noam Chomsky points to the report of Goodland and Dale—the World Bank economists—who discussed the fact that globalization changes the market architecture as understood in conventional economic theory. Individual enterprises, compared to islands in the ocean of the market, where none of them have enough power to influence demand and supply and therefore the price, are growing bigger because of the international expansion and a growth in transactions done within the same organizations (e.g., capital groups, subsidiaries, etc.). Those enterprises resemble continents more than islands. This changes the nature of transactions on the market, which effectively become similar to those that are centrally managed, mainly due to the fact that expanding enterprises are interconnected through complicated international capital structures. Often, a majority of transactions happen within the same capital group or in effect within the same company, operating in the various markets and continents. Market consolidation and an ongoing concentration of capital, together with creation of the huge capital groups, makes governance one of the key problems of contemporary management.

Shrinking of the business environment, caused by the common participation of countries in the trade, based on the liberal rules of capital transfer, paradoxically makes the market tighter and more demanding in terms of competition. Due to the existence of the global market with less and less restrictive rules for economic activity, the distance between the market players is diminishing, which becomes a reason for growing tensions and conflicts.

Paradoxically, what has been overlooked is that the conditions are not those of a “free market” anymore, and despite that many still pursue the liberal philosophy. Joseph Stiglitz describes the hypocrisy and systemic imperfections of the international institutions such as the International Monetary Fund, the World Trade Organization, or the World Bank. They were expected to improve the standing of the developing countries and de facto, in many cases, they caused a negative result (e.g., increasing poverty, the unsolved problem of wealth distribution).

The distribution problem, according to Joseph Stiglitz, is related to the representation rules and a structure of power in the international institutions—there can be no just distribution if the only interest groups represented are those from the commercial, business, and financial environments, while the consumers and taxpayers are largely marginalized. According to Joseph Stiglitz, the institutional background of globalization became the seed of destruction, as the original ideas behind the creation of those institutions and the logic of Keynesian economy were already abandoned in the 1970s.

A theoretical discussion, related to the changing conditions for economic activity, focuses around the paradigm of the “new economy.” The notion was coined in the context of attempts to explain the reasons for the long-term growth in the United States in the 1990s. It describes the economy characterized by massive technology advancement and a development of communication and information techniques enabling the growth of labor productivity. The net result of those factors combined together is a noninflationary growth of wages with a parallel stabilization or even a fall of unemployment (due to the quick pace of creation of new jobs in new areas of production).

Accepting the new conditions for economic activity provokes a natural question of whether the traditional economy has tools enabling a proper description of a new reality. Moreover the question remains, whether it is true that the economic laws are unchangeable and only technologies become new. Perhaps the observed changes in economy demand a brand new theory, which could describe and explain them. The key problems of the new economy include the specifics of new products on the market and so-called network effects. The products of information technology generate benefits proportionally to the number of users. This means that once a given product wins its position on the market, demand for competing products will start to weaken.

The issue of the usefulness of the "invisible hand" paradigm remains also to be determined. The fact that it treats employees' creativity as an exogenous variable does not seem adequate under the conditions of the new, knowledge-based economy, where the share of the knowledge employees create is getting bigger and bigger. Under such circumstances, the paradigm of creative destruction seems to prevail.

The main question related to the new economy, however, is the character and persistence of a positive combination of macroeconomic factors. It seems that in the view of current slowdown of the American economy and the continuously strong economic growth of the central and eastern European countries, the question remains especially valid.

Socio-Cultural Aspects

Cultural globalization is often defined as a homogenization of the norms, standards, and behavioral patterns resulting from consumerism and the influence of American pop culture. It is characterized by three features: it is technologically driven, it is empowered by economic liberalization and the opportunities for international exchange created by free trade, and to a large extent it is dominated by the United States.

It seems that two industries are specifically responsible for the international transfer of behavior patterns and other cultural artifacts: the music industry and film industry. Music became a forerunner of globalization due to its unique ability to be understood without translation—when free trade was still a long way off in the communist countries with centrally planned economies, young people were already imagining Western lifestyles because of music broadcasts from foreign radio stations. Second, the film industry started to increase its output, influencing the public initially through cinemas, then through more and more sophisticated communication channels, i.e., television, cable, and satellite broadcasts, and recently through the Internet. When paired with sociologically underpinned aspirations of people—having one's own television set or a satellite dish is a sign of prestige and better economic standing—broadcasting forms a powerful platform for influencing a wide international audience.

The critics of globalization per se point to the fact that cultural homogenization destroys national identities. Moreover, global culture is accused of being mainly consumption driven. The key question in the current debate over cultural globalization is whether it carries a common, global set of values and what might they might be. One of the concepts proposes democracy as a universal, globally demanded standard, built upon longings for freedom, which can be considered a truly common value. The spread of democracy to countries originally under heavy state control and various forms of oppression, such as communism, is often mentioned as a positive outcome of globalization.

Globalization Index

According to the *Oxford English Dictionary*, the use of the term *globalization* emerged in an article in the October 5, 1962, issue of *The Spectator.* However, it was not until the early 1980s that the term began to take shape within academia. Since then, the term *globalization* has been considered the most quoted, mentioned, and used term in world history so far. The term *globalization* encompasses a range of social, political, and economic changes. Some disciplines including anthropology and sociology focus on cultural changes of growing interconnectedness and the increasing ease of travel. Some disciplines such as political science examine the role of international political institutions like the United Nations and the increasing power of transnational corporations. Other disciplines such as economics track the exchange of finances, goods, and services through expanding global markets.

Theodore Levitt defines globalization as a powerful force driving the world toward a converging commonality. Sociologist Anthony Giddens defines globalization as a decoupling of space and time, emphasizing that with instantaneous communications, knowledge and culture can be shared around the world simultaneously. As one of the most well-known economists and pioneers of globalization, Jagdish Bhagwati claims that globalization is very often used to refer to economic globalization, that is, integration of national economies into the international economy through trade, foreign direct investment, capital flows, migration, and technology via reductions in the barriers to trade, and increased capital flows, stimulated foreign direct investment, technology and knowledge transfer.

World explorations in the 16th century linked continents, economies, and cultures as never before, and that led to a big expansion in international trade and investment throughout the late 19th century. However, Kevin O'Rourke and Jeffrey Williamson demonstrated that there is little evidence of global integration of commodity markets before the early 19th century by utilizing data on commodity price convergence. Their evidence shows that the first wave of globalization began in 1820 rather than the 16th century and it was the period from about 1870 up until World War I that witnessed the most impressive period of globalization.

Then, for Brian Snowdon, the first age of globalization came to an end in 1914 with the beginning of the first world war, and the first age of globalization went into sharp reversal during the 1914–50 period as it collapsed during the gold standard crisis in the late 1920s, the Great Depression in the early 1930s, and World War II between the years of 1939 and 1945. The world economy deglobalized as the world's economies became more protectionist. This was the period when "great reversals" in globalization took place in the goods, financial, and labor markets. Until the end of World War II there were no discussions regarding development with the process of globalization, and it has taken over 50 years to rebuild the global economic system. Finally, the second phase of globalization started in the 1950s, developed with the establishment of the international organizations with the Bretton Woods agreements in 1944, such as the General Agreement on Tariffs and Trade (GATT), World Bank, International Monetary Fund (IMF), World Trade Organization (WTO), and continues today with the liberalization activities in financial markets, international trade, foreign direct investment, and with the innovations in technology and the knowledge economy.

Measurements

The most well-known index for globalization is the KOF index. The KOF Index of Globalization was introduced in 2002 by the KOF Swiss Economic Institute and the index was published by Axel Dreher and his team. The overall index measures the economic, social, and political dimensions of globalization. Now data is available on a yearly basis for 122 countries, and the 2007 index introduces an updated version of the original index. In constructing the indices of globalization, the variables are transformed to an index on a scale of 1 to 100, where 100 is the maximum value for a specific variable over the periods and 1 is the minimum value. Higher values denote greater globalization. According to the index, the world's most globalized countries are Belgium, Austria, Sweden, the United Kingdom, and the Netherlands. The least globalized countries are Haiti, Myanmar, the Central African Republic, and Burundi.

Another very popular measure of globalization is the joint publication of A. T. Kearney Foreign Policy Magazine Index (KFP). The KFP aims to provide a comprehensive measure of the extent of globalization across the world by assessing and ranking 62 countries, representing all the major regions that account for 96 percent of the world's gross domestic product (GDP), and 85 percent of the world's population. The KFP index concentrates on four main dimensions of globalization: economic integration, technological connectivity, personal contact, and political engagement. According to the KFP Index, in 2006, Singapore, Ireland, Switzerland, the United States, the Netherlands, Canada, and Denmark were the most globalized countries, while Egypt, Indonesia, India, and Iran were the least globalized countries in the list.

Key Players

Antiglobalization (mundialism) is a term used to describe the political, economic, and sociological stance of people, groups, and organizations who oppose the neoliberal ideology of globalization. Some antiglobalization groups and organizations are the International Institute for Sustainable Development; the International Forum on Globalization; Greenpeace; the World Wide Fund for Nature; Oxfam; Friends of the Earth International; the Center for International Environmental Law; Public Citizen; Consumers International; the World Conservation Union; Focus on the Global South; One World; the Third World Network; the International Center for Trade and Sustainable Development; and the Center for Research on Globalization. Some antiglobalization individuals are Naomi Klein, George Monbiot, Martin Khor, Mary Robinson, Joseph Stiglitz, Noam Chomsky, Dani Rodrik, and John Ralston Saul.

Pro-globalism (globalism) is a term used to describe the political, economic, and sociological stance of people, groups, and organizations who defend the neoliberal ideology of globalization, such as free trade, economic freedom, libertarianism, and democratic globalization. Some pro-globalization groups and organizations are the International Policy Network; Sustainable Development Network; the Competitive Enterprise Institute; the Cato Institute; the Institute of Public Affairs; the American Enterprise Institute for Public Policy Research; World Growth; the Heritage Foundation; WTO; IMF; World Bank; and the Organisation for Economic Co-operation and Development (OECD). Some pro-globalization individuals are Johan Norberg, Douglas A. Irwin, Jeffrey Sachs, Jagdish Bhagwati, Martin Wolf, Philippe Legrain, and Mike Moore.

Global Leadership and Organizational Behavior Effectiveness Project

A key approach to understanding culture in international management has been to study work-related values as expressed through national culture (a national culture approach assumes that members of a nation share a common ancestry and identity, thereby establishing the basis for a shared culture). Initiated by Robert J. House in 1993, the Global Leadership and Organizational Behavior Effectiveness Project (GLOBE) is a multi-phase study that examines the impact of culture on leadership and organizational practices. The GLOBE team consists of over 200 researchers in 62 cultures/countries collaborating to gather data through multiple research methods. One aim of the project has been to validate and build upon Hofstede's five dimensions of culture, while yet another has been to measure cultural perceptions of leadership.

GLOBE Dimensions of Culture

The GLOBE project presents both societal-level and organizational-level results on nine cultural dimensions. Middle managers were asked to answer questions based on what they perceived in relation to society (a "societal-level" score) and what they perceived in relation to their organization (an "organization-level" score). The GLOBE project also measures culture in two ways, by looking at what is actually done in a society/organization (the culture "as is" or "practices") and by looking at what should be done in a society/organization (the culture "as it should be" or "values").

Nine cultural dimensions were found: Uncertainty Avoidance, Power Distance, Institutional Collectivism, In-Group Collectivism, Gender Egalitarianism, Assertiveness, Future Orientation, Performance Orientation, and Humane Orientation.

1. Uncertainty Avoidance is the extent to which members of an organization or society strive to avoid uncertainty by relying on established social norms, rituals, and bureaucratic practices.
2. Power Distance is the degree to which members of an organization or society expect and agree that power should be stratified and concentrated at higher levels of an organization or government.
3. Institutional Collectivism is the degree to which organization and societal institutional practices encourage and reward collective distribution of resources and collective action.
4. In-Group Collectivism is the degree to which individuals express pride, loyalty, and cohesiveness in their organizations or families.
5. Gender Egalitarianism is the degree to which an organization or a society minimizes gender role differences while promoting gender equality.
6. Assertiveness is the degree to which individuals in organizations or societies are assertive, confrontational, and aggressive in social relationships.
7. Future Orientation is the degree to which individuals in organizations or societies engage in future-oriented behaviors such as planning, investing in the future, and delaying individual or collective gratification.
8. Performance Orientation is the degree to which an organization or society encourages and rewards group members for performance improvement and excellence.
9. Humane Orientation is the degree to which individuals in organizations or societies encourage and reward individuals for being fair, altruistic, friendly, generous, caring and kind to others.

GLOBE Dimensions of Leadership

The GLOBE project also relates dimensions of culture to six global leader behaviors in order to examine in which cultures certain types of leadership styles would be favored. The study shows that there are culturally based shared conceptions of leadership, which the GLOBE team refers to as the "culturally endorsed implicit theories of leadership" (CLT). While they found some leadership styles culturally contingent, the GLOBE team also found evidence for universal support of the charismatic/value-based dimension.

The six global leadership dimensions found are: Charismatic/Value-Based, Team Oriented, Participatory, Humane Oriented, Autonomous, and Self-Protective.

1. Charismatic/Value-Based leadership portrays the ability to inspire and motivate others to perform well based on deeply held values.
2. Team Oriented leadership demonstrates the effective working toward a common goal among members of a work group or team.
3. Participatory leadership suggests the degree to which mangers involve others in making and implementing decisions in an organization.
4. Humane Oriented leadership encompasses a supportive and compassionate stance toward others.

5. Autonomous leadership suggests an independent and individualistic leadership style.
6. Self-Protective leadership is concerned with safeguarding the well-being and security of individual members and the group as a whole.

The GLOBE project provides additional knowledge on cultural dimensions and helps establish cross-cultural leadership as an independent field of inquiry. Until the GLOBE project, such multi-level cultural and leadership data on a large number of countries were not available.

Global Product Divisions

Global product divisions are part of a multinational's organizational structure when the primary division of the firm's activities is based on product (or service) categories. For example, an automobile manufacturing firm may be primarily divided into a truck division, a passenger car division, and an SUV division; or a large professional service firm may be divided into audit, business advising, information technology, and tax divisions. Then each of these "global product divisions" may be divided into several geographic (e.g., Americas, Africa–Middle East, Asia-Pacific, Europe) and/or market subdivisions (e.g., corporate, government, and private clients).

The strategic logic underlying the global product division is the need to concentrate resources at the level of the product (or product group). Thus, in the above automobile example, the firm may feel that these three markets are quite independent, and that appointing a separate management team for each division will allow each to focus on their markets and thus develop their businesses and compete more effectively. Further, C. K. Prahalad and Gary Hamel and other proponents of the resource-based view of the firm would insist that the firm should be structured around the key resources that give the firm sustainable competitive advantage. Thus, for example, a certain set of products could be based on certain technologies and competencies—and a global product division is a natural structure to house these products and resources.

Traditionally a global product division had control over most of value chain relevant to its market. For example, Procter & Gamble (P&G) has three global product divisions, namely Global Beauty, Global Household Care, and Global Health & Well-being (as well as a Global Operations division). Thus, the Global Beauty division would have its own manufacturing facilities, suppliers, brands, distribution network, and service department. However, contemporary managerial and organizational approaches have de-emphasized the advisability of this kind of control for two sets of reasons. First, as stated by Stephen Young and Ana Teresa Tavares, complete autonomy is not necessarily an optimal situation. Along these lines, authors like Julian Birkinshaw have suggested that the overall global firm is better off with coordinating mechanisms across its global divisions that seek to find economies of scale, economies of scope, and other efficiencies and synergies. Thus the normative tendency would be to share information systems, production, facilities, and services across its product divisions; and P&G's Global Operations division would have a mandate to facilitate many of these synergies.

Another popular contemporary approach is "outsourcing" (or off-shoring) of parts of the value chain—such as production of various components or a service call center—to an external service provider. For example, Stanley Holmes writes that Boeing is outsourcing more than 70 percent of the 787's airframe, allowing Italian, Japanese, and Russian engineering concerns to design and build major parts of the fuselage and wings. The benefits of these programs include cutting costs and forging relationships with potential clients. For example, Kristien Coucke and Leo Sleuwaegen report on a recent study whereby off-shoring programs increase the likelihood that Belgian manufacturing firms will survive.

Nevertheless, there is a general acceptance and adoption of global product divisions by multinational firms. This is especially the case in corporations moving away from international division structures—over time, the domestic and international businesses are recombined and then split into either product, market, or geographic structures. However, along the same developmental process, these structures often continue to evolve into some form of matrix—whereby managerial authority descends to the business via two (or sometimes, three) dimensions. For example, one dimension may be like the global product structure responsible for various offerings and the other may be geographic. A more advanced stage of development would be what Chris Bartlett and Sumantra Ghoshal call the "transnational" structure, whereby the firm develops dual capacity to deal with both local (national) as well as global contingencies.

Global Structure

A multinational firm's organizational structure that reflects the "global" philosophy that the world is basically one homogeneous market is called a "global structure." For example, by this philosophy, many large electronics and consulting firms, while allowing for minor local adjustments to packaging and language, basically project the same kinds of products and services around the world. However, there are several differences in terminology and philosophy in this field.

First, a "global" philosophy is characterized by seeing the world as one more-or-less monolithic market with similar tastes and preferences. In contemporary parlance this is opposite to a "multidomestic" (or multinational or multilocal) philosophy by which one sees the world as made up of many more-or-less unique markets, each with its distinct tastes and preferences. A position between these two extremes is called regionalism, whereby one sees the world as being made up of a small number of quite homogenous regions.

These constructs can be applied to industries, firms, and organizational structures, and it is informative to understand how global thinking at industry and strategic levels apply. For example, George Yip sees globalization as a function of the degrees to which the global marketplace is fragmented, local customer needs are distinct, local sourcing imperatives exist, costs are heterogeneous, and trade barriers are significant to cross-border commerce. Thus Randall Schuler, Peter Dowling, and Helen De Cieri and other scholars refer to some industries—like commercial aircraft, copiers, generic drugs, most electronics and computer hardware—as global industries; while retail, the food industry, and most services are considered substantially multidomestic.

Multinationals—and other large firms, for that matter—generally are divided into several parts, units, or divisions that reflect some aspect of their strategy. This link between structure and strategy was made famous in the classic book *Strategy and Structure* by Alfred DuPont Chandler. For example, a firm with five product categories may have been structured into five divisions, each division mandated to manage one of the product categories.

Chris Bartlett and Sumantra Ghoshal build on this logic as they focus on organizational responses to global and local forces; and they describe four organizational types (or mentalities) for the global organization that represent organizational and strategic responses to various industry contingencies. For example, they describe the global firm that views the world as its market, assumes that national tastes are more similar than different, and that believes in standardized products; and these strategic approaches require structural integrative mechanisms that are to coordinate worldwide activities, production, marketing, research and development (R&D), and planning. Thus, it is these structural processes that are implied by the term *global structure.*

Mechanisms

All large organizations need some structures that coordinate and integrate to some degree. However, the global strategy relies on these structures for implementation There are three major aspects to this kind of structure. The first is the locus of strategic responsibility. Second, the way the structure separates reporting relationships and dictates how the firm is divided. This aspect of structure may be called structuring. The final aspect is the kinds of coordination and integration systems—these may be called processes.

Locus of strategic responsibility: A crucial aspect of organization structure is the extent to which decision-making autonomy is delegated from corporate headquarters to parts of the business. In the global firm there is a strategic imperative to centralize important strategic decisions. For example, decisions on product range, research and development, branding, and human resource management tend to be made at corporate rather than subsidiary level. Even customer service, which is the function most likely to be located closer to the customer, may have its major policies and standards set at corporate level.

Structuring: A characteristic of the global structure is that it is relatively blind to geographic distance and instead focuses on one or more other strategic dimensions—like products or markets—that it considers more important (than geography) to its success at implementing a global strategy. Thus a global structure commonly has a major top-level division into product categories (generally called a global product structure), markets (global market structure), or some matrix (global matrix structure). As an example of a global product structure, Procter & Gamble (P&G) has three global product divisions, namely Global Beauty, Global Household Care, and Global Health & Well-being.

However, the distinction between product and market structures is likely to be blurred—for example, Boeing's business units seem like different product divisions (commercial airplanes, integrated defense systems, and Boeing capital corporation), but in effect all three have the aim of marketing various aircraft and aerospace products and services to different market groups—in this case commercial airlines, governments, and financial intermediaries. The global matrix structure attempts to organize activities by two (or more) managerial dimensions—like product, geography, and/or market. For example H. J. Heinz has simultaneously geographic divisions in North America, Europe, Australia/New Zealand, and emerging markets (selected countries in Asia and eastern Europe); several product categories, namely ketchup/condiments/sauces, meals and snacks (including frozen foods), soups/beans and pasta, and infant feeding; and separate operations for retail and food service channels. In a global structure these various departmental and business divisions may have necessary aspects of local focus, but essentially they work together for implementing the firm's global strategy.

Processes: Finally, and very importantly, structure implies processes such as coordination, integration, and information systems. These processes tend to be pronounced in the global structure, and generally very common in contemporary organizations. Kwangsoo Kim and Jong-Hun Park identify four generic integrating mechanisms: (1) people-based integrating mechanisms that use people to coordinate business operations across borders, involving the transfer of managers, meetings, teams, committees, and integrators; (2) information-based integrating mechanisms use information systems such as databases, electronic mail, Internet, intranet, and electronic data interchanges to integrate business operations across borders; (3) formalization-based integrating mechanisms rely on the use of standardized or common work procedures, rules, policies, and manuals across units; and (4) centralization-based integrating mechanisms retain decision-making authority at the corporate headquarters—a similar concept to that in the "locus of strategic responsibility" section above.

The more global the firm, the more it uses these processes. Intel, for example, uses relatively few formal structural mechanisms, but several cross functional teams—including information technology (IT), knowledge management, human resources, finance, legal, change control, data warehousing, common directory information management, and cost reduction teams—as integrating processes that allow them rapid adaptation to changing conditions. Integrating mechanisms can also have negative effects—perhaps tying the hands of local managers, imposing compliance costs (both time and other resources), and creating unintended bureaucratic barriers to efficient decision making. A study by David Brock and Ilene Siscovick, for example, found effects of integrative factors at subsidiary level were often negative.

Gnomes of Zurich

The Gnomes of Zurich is an old tongue-in-cheek term for the Swiss market, and especially Swiss bankers. The term was first used by Harold Wilson, the Shadow Chancellor of the British Parliament in 1964, who believed the Swiss were speculating on the British pound on foreign markets in order to keep its value down. In a speech to the House of Commons, Wilson said:

> Traders and financiers all over the world had listened to the Chancellor. He had said that if he could not stop wage claims the country was facing disaster. Rightly or wrongly, these people believed the Chancellor. On September 5th, when the T.U.C. unanimously rejected wage restraint, it was the end of an era, and all the financiers, all the little gnomes in Zürich and other financial centers, had begun to make their dispensations in regard to sterling.

It is interesting to note that Wilson originally spoke of gnomes "in Zurich and other financial centers," but it was "gnomes of Zurich" that caught on. The use of *gnomes* here implies the secrecy, shadiness, and miserliness associated with both the fairy-tale creature and the stereotypical Swiss banker. Zurich, though not the political capital of Switzerland, is its cultural and commercial capital—a relationship much like that of New York City to the United States. The Swiss stock exchange, SWX, is located in Zurich, and has been since 1873. It is controlled by an association of 55 banks—those Swiss bankers that so concerned Wilson. SWX was the first stock exchange to fully automate its trades, implementing this system in 1995. The economy of Switzerland, once the richest nation in Europe, has steadily slowed since the 1990s, allowing Ireland, Denmark, and Norway to pass it by. The Swiss Market Index (SMI) has tracked the performance of 20 significant stocks on the SWX since 1988. It is calculated in real time, adjusted whenever a trade transpires involving one of the 20 stocks; while many indices adjust their lists quarterly, the composition of the SMI is reexamined annually.

The 20 companies on the SMI are: ABB, an electronics company; Adecco, an employment services company; Baloise, an insurance provider; Clairant, a chemicals company; Credit Suisse, a banking corporation; Holcim, a building materials company; the Julius Baer Group, an investment services provider; Nestlé, the food company; Nobel Biocare, the medical equipment company; Novartis, the pharmaceuticals company; Richemont, a clothing company; Roche, a pharmaceuticals company; Swatch Group, a clothing company; Swiss Life, an insurance provider; Swiss Re, a reinsurance company; Swisscom, a telecommunications company; Syngenta, a chemicals company; Synthes, a medical equipment company; UBS, a banking company; and Zurich Financial, an insurance provider.

Gold Standard

The gold standard was a fixed exchange rate system that operated as the primary monetary regime of the international economy from the late 19th century through to the outbreak of World War I. The apparent virtues of the gold standard lay in (1) its ability to eliminate exchange rate risk, thereby facilitating trade and international investment and (2) its ability as a self-equilibriating mechanism to eliminate balance of payments problems.

The operation of the gold standard required the monetary authorities of each nation to adhere to certain basic principles. First, the money supply of each country (in the form of bank notes and bank deposits) was directly linked to the gold reserves held by the monetary authorities. Second, the monetary authorities would always be willing to exchange a specified weight of gold for any amount of its currency presented to it at a pre-defined fixed rate. Throughout the 19th century, countries such as Great Britain, France, Germany, and the United States all linked their currencies to gold in this manner. The outcome of this was a fixed and stable rate of exchange between the respective currencies. To take one example, the price of one ounce of gold in Britain and the United States was set at £3 17*s.* 10.5*d* and $20.67, respectively. With both currencies permanently equivalent to a definite weight of gold, the price of one unit of sterling expressed in terms of dollars was therefore fixed at £1 = $4.866.

The gold standard not only served as a stimulus to trade and investment by removing the risk of loss from exchange rate fluctuations, but also provided an automatic mechanism for maintaining a nation's balance of payments in equilibrium. We can illustrate this idea by means of a simple example. Let us assume that there are two countries, *X* and *Y*, and that country *X* is experiencing a prolonged balance of payments deficit. How would this problem be resolved?

Given that the gold standard represented a fixed exchange rate system, a downward movement in the exchange value of country *X*'s currency—such as deliberate monetary authority devaluation—would almost certainly be ruled out. If devaluation were pursued, it could undermine confidence in country *X*'s currency if it was expected that *X* would resort to such measures were she to get into future balance of payments difficulties. An alternative method to resolve this excess of imports over exports would be to settle such debts in terms of international gold movements. Based on the above-mentioned relationship between the nation's money supply and her gold reserves, the shipment of gold from country *X* to country *Y* would lead to the contraction of the money supply in *X* and the expansion of the money supply in *Y*.

The contraction of the domestic money supply in *X* would, in turn, lead to reductions in the money cost of production (deflation) that would act to reduce demand for imports and stimulate exports. In contrast, the expansion of the domestic money supply in *Y* would lead to an increase in the money costs of production (inflation) that would reduce exports and stimulate the demand for imports. Thus, under the gold standard, international gold movements appear to be a perfect, self-equilibriating mechanism that brings about changes in expenditure and prices sufficient to eliminate a balance of payments deficit. Yet there are numerous situations that could act to undermine its success. In the above example, the monetary authorities in country *X* could speed up the adjustment process, and so facilitate speedy gold movements, by lowering their discount rate relative to that in country *Y*.

When gold reserves held in banks backed national currencies, exchange rates such as the dollar-to-pound rate were stable.

However, historical research has suggested that few central banks throughout the 19th century actually adhered to the "rules of the game" and did not always vary their discount rates in the prescribed manner. We should also note that there is no guarantee that the necessary relationship between money supply and price level movements would function properly so as to eliminate the trade deficit.

For example, the necessary fall in the money cost of production in country *X* would not take place if labor within the country refused to accept reductions in wage rates.

The gold standard was dealt a severe blow by the economic chaos of World War I, and finally collapsed during the Great Depression of the early 1930s. After World War II, the gold standard was replaced by the Bretton Woods fixed exchange rate system, which lasted from 1947 until 1972. This was essentially a special form of the gold standard, referred to as a gold exchange standard, in which the exchange rates of other currencies were fixed, via the U.S. dollar, against gold.

Government Bonds

A government bond is a security issue by the national government of a particular country that gives the right to the bearer to request the promised interest to be paid in agreed intervals (usually annually). This is a special type of bond, based on the qualities of the issuer. It is like any other "I owe you" (IOU) instrument, but the only specific is that the issuer is the national government, or an authorized agent on behalf of the national government.

National governments issues bonds in order to finance shortfalls in their budgets, and as the level of sovereign debt is growing worldwide, government securities in general, and government bonds in particular, are becoming an increasingly interesting form of investment. As these instruments are, theoretically, highly liquid, they can be used (although they are medium- and long-term instruments) for liquidity management by various economic subjects. As in the case of bonds issued by private companies (nonstate entities) they represent a promise to pay the holder a set level of interest (known as the coupon) during the lifetime of the bond and to repay the money in full on a set date.

This is the general rule, although it is possible to issue a perpetual bond, whose principal will never be repaid, but the government will service them. This is, for instance, the case with consols in the United Kingdom (UK). They are a rare living example of perpetuity in bond issuance, although technically speaking an issuer has an option to redeem them. They have been particularly popular in financing military conflict in the past and there are still some live consols that were issued in order for the UK government to raise funds to finance Napoleonic wars.

Government bonds are, as a rule, denominated in domestic currency and are often referred to as sovereign bonds. A national government is a sovereign power and therefore the bonds have those qualities as well. Government bonds are regarded, in theory, as risk-free bonds, assuming there is a very low or no probability that the national government will default and go bankrupt. Although economists may claim that every economic agent (including the national government) is prone to bankruptcy if insolvent, the legal theorists would (rightly) state that the government can always resort to the unpopular and somewhat immoral option of nationalization and confiscation in order to meet its financial obligations. Most recently, Russia, following the 1998 crisis, declared a moratorium on debt servicing, but the servicing of the public debt resumed after a short while.

Government bonds are regarded as virtually riskless, but one should know that this is only in relation to the credit risk—namely, the risk that the credit will not be returned. All other risks are still present and largely are shared with all other types of bonds, regardless of an issuer, such as foreign exchange, operational, and so on. Government bonds, like other bonds, are also rated by rating agencies, and despite the perception of their stability and inability to go bankrupt, their ratings differ. Only the most advanced industrialized nations have a "triple A" rating, while for instance Japan and Italy (although members of the G7 group of countries) have ratings below the maximum one.

Government bonds being literally default free may be more attractive, especially if the investment is not made at the peak of an interest rate cycle, in which case there is a clear opportunity for capital gain. If the investment is made at the peak of the interest rate boom, then when the interest rate falls, the value of the bond will be reduced and can go well beyond the nominal value. Bonds being fixed-income financial instruments are highly dependent on the (current, market) interest rate, and their market value is linked with the level of interest rates applied. A rise in the price of a bond means a fall in the interest rate, while the reverse applies when the price falls.

Often the issuance of government bonds is centralized at the national level, although often local governments may be empowered by law to raise needed finances in the financial markets. Most recently the debt management function was entrusted to a government agency that would issue securities on behalf of the national government and its finance department/ministry. For instance, in the UK the Debt Management Agency is authorized by law to issue government securities (bonds, or "gilts") and manage servicing of the outstanding stock.

There are also other modalities present. In some countries the central bank, as a fiscal agent of the government, may be authorized to issue bonds, that is, the government securities, while in others the Ministry of Finance may be in charge of issuing securities for the national government. However, as we have already pointed out, the current trend is to organize a separate government agency where the professionals will be entrusted with the task of managing public debt, free from day-to-day political pressures. However, the practice has shown that independence from daily politics is very difficult to sustain.

The importance of government bonds will grow, especially as traditionally debt-averse governments are looking into the issue of public debt, as it is becoming increasingly difficult to finance needs with the budgetary inflows, and monetization of public debt has devastating consequences on economic development and economic and financial stability.

Greece

Greece's official name is the Hellenic Republic and the official form of government is the presidential parliamentary republic. Other conventional names include the names *Hellas* or *Ellada*. It is a Mediterranean country in southern Europe comprising an area of 131,944 sq. km and with an extended coastline of 15,021 km. It consists of a mountainous mainland and thousands of islands and islets scattered in the surrounding Aegean and Ionian archipelagos. According to the latest 2001 census, the population in Greece is 10.93 million people who mostly reside in the major cities of Athens and Thessaloniki.

Greece belongs to the OECD group of developed nations and it has a mixed capitalist economy with gross domestic product (GDP) per capita estimated at around US$29,200. Moreover, annual GDP growth reaches 3.6 percent. Greece is the major business and energy hub for the eastern Mediterranean and southeast European regions with an existing network of thousands of export-oriented and investment companies. It is often the major gateway for investors seeking business access to the region and is rapidly being transformed into the major transit point for oil and natural gas carried from the Caucasus and central Asia to major European markets.

Greece is primarily a service-based economy and major industries of the Greek business landscape include shipping, tourism, food (wines, olive oil, cheese, yogurt, fruits and vegetables, honey, mastic, saffron, organic farming), tobacco, apparel, chemicals, pharmaceuticals, mining products, and financial services.

In this respect, the major trading partners of Greece are mostly western European Union (EU) countries such as Germany, Italy, France, and the United Kingdom plus countries such as the United States, Poland, Bulgaria, and Romania.

An important sector of the economy is the shipping industry—the Greek-owned merchant fleet is the largest in the world. In 2008, Greek-owned ships registered under various flags, including Greece's flag, amounted to 4,173, meaning the Greek fleet represents about 20 percent of the world's tonnage. Greek shipping accounts for about 60 percent of the EU's total shipping; and approximately 23.5 percent of the world's oil tankers belong to Greek ship owners. We can easily estimate the contribution of the Greek shipping sector to the economy of Greece and to international trade given the fact that 90 percent of the world's goods are transported by sea.

Another powerhouse of the Greek economy is the tourism sector, which accounts for almost 15 percent of the nation's GDP. Greece boasts an unparalleled position in the Mediterranean Sea, enjoying a pleasant and healthy climate and a unique combination of mountains (reaching up to approximately 3,000 m. and dominating 75 percent of the territory) and 6,000 islands, of which only 227 are inhabited. The country's position at the crossroads of three continents (Europe, Asia, and Africa) has endowed Greece with the richest variety of flora and fauna in Europe, and its indented coastline of varied seascapes is easily the longest in the Mediterranean. An alluring history dating back to Ancient Greece, a legacy of being the cradle of Western civilization, and a vivid folk culture manifested in culinary traditions and performing arts are also primary reasons for a diversified tourist portfolio that makes Greece a top destination for around 16 million travelers per year.

Greece is a member of various international organizations such as the European Union (since 1979) and NATO (since 1952). A positive outcome of the country's constant involvement with international bodies is its ranking among the world's top 20 countries in terms of pollution control and management policies of natural resources. The country also grants US$362 million annually in foreign aid (Hellenic Aid Service) to Third World countries and holds the 16th place worldwide in Official Development Assistance (ODA).

A major milestone in the country's modern history has been the highly successful organization of the 2004 Olympic Games in Athens. The challenge of managing the largest project on earth was met and, partly due to historical associations, Athens 2004 is considered the most authentic games ever organized. As a result, the Olympic Games projected the modern face of Greece and reinforced the country's competitiveness in the global arena.

The event helped Greece position itself as an exclusive destination for business in a diversified spectrum of industries ranging from energy, construction, and finance to food processing, maritime industry, and tourism. The Greek state and its citizens may have spent a huge amount of money to organize the safest Olympic Games in history, but the legacy that remained in terms of infrastructure is phenomenal. State-of-the-art facilities in sports and urban transportation, accumulation of managerial know-how in organization of mega-events, and a new image for the country and its products are among the many benefits Greece enjoys in the post-Olympics era.

On the downside, Greece, despite its highly skilled workforce, suffers from a high unemployment rate. Unemployment's negative impact is even more reinforced due to the inflation of prices since the introduction of the euro in 2002. More than 8 percent of the population is unemployed, and this phenomenon primarily affects women and the younger population. Part of the problem seems to be the disproportion between employees' supply and the ability of the economy to generate sustainable employment for educated youth. Several sectors such as the food industry and high-tech/telecommunications have shown healthy progress, but traditional industries such as textiles have significantly declined. Moreover, agriculture, which employs more than 12 percent of the workforce, is still characterized by small farms, inadequate marketing techniques for the internationalization of the country's agricultural produce, and low capital investment despite significant support from EU subsidies and structural funds.

Greece is a developed country that looks to the future with optimism and seems eager to exploit opportunities arising from its protagonist role in the region. Its long-standing membership in international bodies such as the EU and NATO and its traditional democratic values ensure a stable political environment in which business can be facilitated and promises for further progress abound.

Green Revolution

The term *Green Revolution* refers to the series of advances in agriculture and agronomy that led to exponentially higher cereal harvests in the 1960s and 1970s, especially in food-scarce nations in Asia and Latin America. Genetic improvement of high-yield plant seed was fundamental to the increases, but synthetic nitrogen fertilizers, pesticides, irrigation, and economic incentives also played important roles. Private foundations initially conducted independent agricultural development research, but, as the Green Revolution spread, the World Bank and the United Nations assisted with funding and organization. Although agricultural production exponentially increased in the second half of the 20th century and ended the immediate threat of famine for millions, critics have cited the adverse social, economic, and environmental implications of the Green Revolution.

Most of the Third World experienced significant population increases during the mid-20th century. This fueled a demand for grain that nations could not meet with domestic production. After World War II, large, once-agriculturally rich regions, especially in South American and Asia, became net importers of American grain. Large surpluses in the United States allowed for direct food aid to other nations. Unfortunately, this aid allowed nations to postpone domestic investment in agricultural improvement, and the increased supply limited the price small-scale, domestic farmers could get for their harvests. In the context of the Cold War, famine represented a threat to social and political stability that American politicians feared would lead to communist revolutions.

In March 1968 William S. Gaud, head of the U.S. Department of State's Agency for International Development, in a speech to the Society for International Development, assessed various international projects that had been working for the past 25 years to limit famine in developing countries. Gaud noted the vast improvements in the agricultural yields of India, Pakistan, the Philippines, and Turkey, and remarked that, unlike wars and coups that required violence to enact change, this agricultural, or "green," revolution was a peaceful yet world-changing development. This was the first time someone used the term *Green Revolution* to describe the series of rapid agricultural developments during the 1960s and 1970s, and the term was almost universally accepted.

Origins

The roots of the Green Revolution can be traced back to 1943, when Mexican president Manuel Avila Camacho and the Rockefeller Foundation, at the urging of vice president–elect Henry A. Wallace established the Office of Special Studies (OSS) to experiment with strategies to avert famine among Mexico's peasant class. The United States had seen rapid agricultural increases since the Great Depression of the 1930s, and the OSS was intended to export these successes to other nations struggling with food scarcity. The OSS grew in importance as an international agricultural research and training center, and by 1966 was renamed the International Center for the Improvement of Corn and Wheat (CIMMYT). J. George Harrar, head of the project, oversaw a group of scientists, most notably Norman Borlaug, who developed a "high-yielding variety" (HYV) of wheat. HYV of all grains have an elevated ability to absorb nitrogen. Since plants with high levels of nitrogen tend to grow tall, bend over, and break before harvest, researchers cross-bred the HYV's with semi-dwarf, or stubby and hardier, wheat varieties that Japanese farmers had cultivated since the 19th century. Unlike traditional varieties that required long growing seasons, responded poorly to fertilizers, and failed to produce consistent yields, Harrar and Borlaug's HYVs responded well to intense fertilization, matured quickly, and were well-adapted to tropical and sub-tropical growing conditions. However, in the absence of fertilizer, irrigation, and pesticides, HYV's may fail to outperform traditional varieties.

In the 1940s, the deserts of northwestern Mexico had recently been opened to irrigation, and the new HYV wheats were planted there on a large scale. In 1962 Pitic 62 and Penjamo 62, the first Mexican dwarf wheat varieties, were commercially released. In conjunction with rational fertilization, Mexican wheat yields dramatically increased. Whereas Mexico produced 300,000 metric tons of wheat in 1950, by 1970 annual national yields had increased to 2.6 million metric tons. The nation achieved wheat self-sufficiency in the late 1950s and even began to export some of its crop. In 1970 Borlaug received the Nobel Prize for Peace for his work that ended the threat of persistent famine for Mexicans.

The Mexican successes were quickly applied around the world, and the search for HYVs extended to other crops. In 1960 the Filipino government founded the International Rice Research Institute (IRRI) with Ford Foundation funds and Rockefeller Foundation scientific staff. The concept of an international research project had been articulated by Harrar and others as early as 1952 and was based on the belief that the basic genetic and biological problems of high-yield agriculture, once solved, could be universally applied with only minor adaptations to local conditions.

Under the direction of Robert Chandler, a university scientist and administrator, IRRI collected indigenous breeds of Asian rice and genetically improved them in the hope of increasing their yields. Early in the process, a cross-breed between an Indonesian rice variety, Peta, and a Taiwanese-Chinese rice variety, Dee-Geo-Woo-Gen, resulted in an HYV of dwarf rice known as IR-8. This "miracle rice," which achieved double and triple yields as compared to traditional varieties, was commercially released in 1966. Cultivation of IR-8 rapidly spread across Asia, allowing farmers' rice yields to increase at a faster rate than population and, in the process, to combat hunger.

The research conducted by CIMMYT, IRRI, and several other regional research centers sponsored by the Ford and Rockefeller foundations not only fostered agricultural innovation but also nurtured an international agricultural research community of experts trained in the tenets of the Green Revolution. Often, these researchers returned to their home countries to take high-level positions in government and therefore influence agricultural policy. Widespread acceptance of the Green Revolution was also promoted by Lyndon Johnson's 1966 reform of the "Food for Peace" program. Johnson announced that food aid shipments would depend on recipient nations' willingness to implement Western agricultural development measures. This meant that nations would be required to accept the Green Revolution if they expected to receive food aid.

The Case of India

The first application of this policy came in the mid-1960s, when India was confronted with droughts and widespread famine and requested not only food but also technical advice. Monkombu Sambasivan Swaminathan, a plant geneticist and Indian minister of agriculture, invited Borlaug to offer advice on improving the food supply and the cultivation of Mexican dwarf varieties provided by the U.S. Department of Agriculture. To the dismay of Indian grain monopolies, Swaminathan, Borlaug, and the Ford Foundation cooperated to import 18,000 tons of wheat seed from the CIMMYT. India selected well-watered and agriculturally successful Punjab as an experimental site, and, after some initial successes, this became another center of innovation. In addition to wheat, India also imported IR-8 from IRRI.

In 1968 S. K. DeDatta, an associate agronomist with IRRI, published his research findings that Indian IR-8 crops produced nearly 10 times the yield of traditional rice strains. This report increased the popularity of IR-8 and promoted its widespread acceptance. Agricultural improvements had direct social and economic implications: Between 1973 and 1974, the average real income of small farmers in southern India rose by 90 percent and the threat of famine accordingly decreased. During the same period, Pakistan also imported CIMMYT wheat seed and experienced a doubling of wheat yield between 1966 and 1971.

Organizations

From 1969 to 1971, the heads of various agencies working on agricultural issues held a series of four meetings, known as the Bellagio conferences, intended to develop strategies to prolong and expand the Green Revolution.

Although the Ford and Rockefeller foundations had successfully established the initial research infrastructure, they realized that they could not bear the increasing financial burden of ongoing research without outside help. Robert McNamara, then president of the World Bank, attended the conference and came away enthusiastic about the Bank's ability to finance

Green Revolution leader Norman Borlaug (left) working with researchers beside a wheat field in Kenya in 2006.

agricultural development. McNamara reached out to the United Nations' Development Programme and the Food and Agriculture Organization, and both agencies agreed to assist with the type of applied research that until then had only been carried out by private foundations.

The Bellagio conferences and McNamara's promotional work resulted in the 1971 founding of the Consultative Group on International Agricultural Research (CGIAR), an informally organized group of donors and experts who shared the goal of eliminating hunger.

CGIAR's primary focus was plant breeding, improved adaptability, and technical advances in cereal, rice, and maize production, but, significantly, the organization's founding resolution also expressed an interest in the "ecological, economic, and social factors" involved with agricultural development. This emphasis anticipated criticisms of the disruptive nature of the Green Revolution. Whereas traditional agriculture required very little investment, HYV agriculture required farmers to purchase fertilizer, pesticides, and even seed.

Through such purchases, farmers accrued debts that, over time, led to the loss of their farmland. This process, along with generally lower food costs, caused greater urbanization. CGIAR recognized the need to deal with the implications of agricultural development, in order to make the system perpetually tenable.

Challenges

The most sophisticated challenges to the Green Revolution have argued that the energy inputs necessary to raise and harvest HYV crops are so great that they outweigh any perceived advantages. Agriculture that relies on intense fertilization and pesticides consumes large amounts of petroleum. Long-term and widespread use of irrigation and chemicals also fundamentally alters the natural environment with unknown and unforeseen health and quality of life consequences. Further, poor transportation, lack of credit, and insufficient education have prevented scientific agriculture from curbing African famines that take millions of lives every year.

Although the most rapid increase in agricultural production took place during the 1960s and 1970s, the Green Revolution continues into the 21st century. The two primary international research centers, CIMMYT and IRRI, the umbrella funding organization, CGIAR, and a network of institutes around the world continued to lead agricultural development research intended to improve crop yields and, ideally, limit the threat of starvation. Plant cross-breeding to achieve HYV crops remains as the fundamental characteristic of the movement, but agricultural rationalization, economic development, education, and technological exchange are also essential to the current Green Revolution.

Grey Market

Grey market (also sometimes known as "gray market") involves the trade of legal goods through unauthorized, unofficial, and unintended channels of distribution. Hence, trademarked products are often exported from one country to another and sold by unauthorized individuals or firms. This practice is also often known as parallel importing, product diverting, and even arbitrage, and typically flourishes when a product is in short supply, when manufacturers resort to skimming strategies in specific markets, or when the products are subject to substantial markups.

For example, even as Apple, Inc., rolled out its latest third-generation iPhone on July 11, 2008, several retail stores throughout the world, including those in China and Thailand, continued to take orders even though this product was not being sold in those markets. Their computer codes were unlocked, so that the phones could be used with different mobile service providers. Even in India, one of the fastest-growing markets for cell phones, Apple delayed the release of the original iPhone until mid-2008, a year after the release in the United States and six months after its release in Europe, for fear of grey market sales.

A wide range of goods and services have been sold through grey markets, including automobiles, broadcasting delivery, college textbooks, pharmaceuticals, photographic equipment, video games, and even wines. Research has demonstrated that every one of the world's eight major export regions has experienced grey marketing activity damaging to their operations. One trade group, the Anti-Grey Market Alliance, in conjunction with a study with the consulting firm KPMG, estimated the global grey market for information technology (IT) products to be over $40 billion.

In the United States, grey market goods are prohibited according to Section 526 of the Tariff Act of 1930, which expressly forbids importation of goods of foreign manufacture without permission of the trademark owner. However, the implementation of regulation by the U.S. Customs Service and the courts' interpretation of the law have not been in line with each other. In a recent study, about 13 percent of the firms in North America have reported some form of grey marketing.

A positive outcome of grey markets is that they form an arbitrage that forces prices down and provides brand-name goods at lower prices to the customer. They can create incremental sales in markets not in direct competition with sanctioned dealers, and sometimes help companies overcome distribution bottlenecks because of local government regulations. Occasionally, it is less expensive to tolerate grey marketing than to shut down the operations completely because of the time and resources required to monitor the violations. Finally, uncovering grey marketing activities can provide a firm with sound marketing intelligence regarding customers in these markets and their buying behavior.

On the other hand, the phenomenon obviously also has several drawbacks for companies. It simultaneously undermines the manufacturer's distribution arrangements and their ability to control quality—it creates the dilution of exclusivity and damages existing channel relationships. Official dealers may not choose to offer significant services in order to compete with the grey market price for the product. There is likely to be an erosion of the brand's global image, and the firm is unlikely to have the ability to use traditional pricing strategies, thus having less control over their overall marketing strategies.

In order to reduce the impact of grey market goods, firms can take pragmatic strategies to evaluate quantity-discount schedules, reduce price differentials between markets and keep them lower than the costs of shipping and inventory holding costs, differentiate products sold to different markets, and sell unique products and names in each market. They can also leverage the Web and Internet technologies to facilitate surveillance of the names and locations of grey marketers. On the demand side, customers can be made aware of the risks of buying goods sold in these markets, refused warranties for the products purchased through these markets, and offered attractive rebates on authorized and legal goods to compensate for the price differentials between those sold through legitimate channels versus those that are not.

Gross National Product

Decisions about allocation of a society's resources require some understanding of how these decisions will affect the welfare of the citizens. The most convenient measure for the welfare of citizens has been found to be the volume of goods and services available in the society. Ideally we would like to assess how the availability of each type of good or service that people enjoy is changing. This, however, makes an overall assessment difficult when the availability of these goods changes by unequal amounts. Are we better off today because we have more of some of these products but less of some others? The concepts of gross national product (GNP) and its very close, and more popular, cousin gross domestic product (GDP) were developed to aggregate and measure the welfare effects of changing supplies of millions of goods and services in a modern economy.

To understand GNP, we start with the concept of GDP, which is the sum of the values of each and every good or service produced within the territory of a society during an accounting period. Every person who works for monetary wages is deemed to produce a good or a service equal to the wages paid to the individual. Every businessperson who coordinates a business activity is deemed to have produced goods or services equal to the value added to the goods and the profits of the business. Aggregate of these wages and profits is the GDP of the society. Divided by the population of the society (measured in the middle of the accounting period), GDP per capita provides an important measure of the average living standard of a country and is a useful measure for comparison of economic performance of different countries. GNP is the aggregate of all goods and services produced by citizens of a society anywhere in the world during an accounting period.

Gross Domestic Product and Gross National Product

GDP includes output of all residents of a country regardless of whether the resident is a citizen of the country or not. Thus the income earned by an American technician who accepts a job with a Japanese firm in Tokyo is counted as part of the Japanese GDP. A Finnish firm that establishes a subsidiary in the United States to manufacture cellular phones is contributing to the U.S. GDP whether it employs U.S. or Finnish workers or managers in its subsidiary. Profits earned by this subsidiary, however, will become part of Finland's GNP even though the value added by this subsidiary will not be part of Finland's GDP. For the measurement of GDP, it does not matter who the producer is—a citizen or a foreigner—as long as the work is done within the economy. U.S. GDP is the value of all goods and services produced within the 50 states and the territories of the United States—regardless who produces it. GNP, on the other hand, measures the output (or income) of all citizens, wherever they may have earned the income.

For most countries, there is only a small difference between GDP and GNP. In the first quarter of 2008, U.S. GDP was $14.1956 trillion, whereas the GNP was $14.3508 trillion, a difference of merely about 1.1 percent. This difference reflects receipts of $796.8 billion as income from abroad by U.S. residents and a payment of $641.6 billion to the rest of the world for income foreigners earned in the United States. For some countries such as Singapore there can be a large difference between GDP and GNP. Singapore's economy depends heavily on foreign workers and Singapore's citizens and firms invest a large part of their savings abroad. Two other countries for which the foreign sector creates a significant gap between GDP and GNP are Ireland and Switzerland.

Interpretation

There are a number of considerations to keep in mind when interpreting concepts such as GDP (or GNP). GDP is a measure of production of goods and services for "final" consumption. Two main categories of final consumption are goods and services used for consumption by the citizens (as well as the government) and goods and services used by business firms to make investments to build the future productive capacity of the society. Two other categories that are included in GDP are sales to foreigners (regardless of the use) and changes in inventories. By definition, therefore, intermediate goods—goods and services that are used as inputs for the production process—are excluded from calculations of GDP. It is sometimes difficult to define whether a product is destined for final consumption or as an input for production of other goods or services. A computer used by an individual for playing games is a final product, one used by a business in an intermediate product.

Treatment of some goods and services deserves special mention. Research and development expenditures are treated as intermediate products and not counted as part of business investments. Purchase of a house by a private citizen is treated as investment whereas purchases of all consumer durable items, including cars, are treated as consumption expenditure.

GDP includes goods and services produced for exchange in a market setup and are aggregated at the price at which the exchange takes place. GDP also includes some goods and services which are produced by governments or nonprofit organizations for citizens and provided to the citizens outside the market framework. These include defense services, educational services, law and order services, and emergency medical services. GDP figures, however, do not include values of care given by family members (looking after our children) or housework (a doctor marrying her cook would lower the country's GDP), voluntary services, black market (unrecorded services paid for in cash), or illegal (street corner drug lord's contributions to fighting emotional slumps), and barter activities (a plumber and a dentist helping each other out) since these activities are difficult to measure accurately. Some countries, however, may accept that such activities are part of the economic life and may adjust their GDP figures by a certain percentage to account for the impact of such activities.

GDP calculations do not make a value judgment as to the usefulness of the products or the services offered for sale in the economy. The assumption is that people have complete freedom of choice and purchase goods and services only when they see a gain from the transaction. All transactions that lead to higher GDP, however, may not be welfare enhancing. Increased level of road accidents will create demand for medical and repair services, giving rise to higher GDP, although a higher GDP in this case does not reflect an increase in society's welfare.

GDP is aggregated by valuing every good or service at the market price—the price at which the exchange may have taken place. This could create anomalies and errors in GDP figures if a citizen or a firm carries out an activity itself replacing what was previously a market transaction. Consider an important "final" consumption product—housing for individuals. If a citizen rents the house, it is clearly a market activity because rent is paid. Should it cease to be included in the GDP if the renter buys the house? The house owner does not pay "rent" anymore, yet the consumption of final products has not decreased. To prevent a possible anomaly arising from situations like this, certain activities like house ownership are "imputed" a value equal to the value of a comparable market transaction (rental of an equivalent house). When comparable market transactions are not available, imputation can be made on the basis of costs of inputs. This type of imputation will be applied, for example, to on-the-job meals provided to employees.

GDP measures values of goods and services when they are produced, not when they are sold. The market transaction is deemed to have taken place at the price at which the goods were produced. Unsold goods at the end of an accounting period are included in the GDP as changes in inventories. Also, when the value of capital equipment that is wearing out or is damaged due to accidents is excluded from the GDP, we obtain the net domestic product.

GDP figures are estimates and not as accurate as, for example, company accounting statements. It is common for GDP figures to be revised by 1–3 percent. On occasions, some countries may revise their GDP figures by more than 15 percent (Italy in 1987, China in 2005).

Measurement of GDP

The national income accounting system divides an economy into four sectors:

- Households. This sector consists of private households, owner-occupants, and nonprofit institutions serving households. Income of this sector arises from wages and returns on investments. In the industrialized countries, household consumption may account for between 60 and 70 percent of the GDP.
- Businesses. This sector produces goods and services and includes private enterprises and government enterprises that engage in providing goods or services to other sectors at close to their cost of operations.
- Government. General government sector provides public goods and services including defense, law and order, infrastructure of the economy, education, etc., and earns revenues through taxes.
- External sector. Rest-of-the-world engages with an economy through trade and capital flows.

While each country has a different approach, there are two important sources of information that form the basis for the assimilation of national accounts. Every country requires that business firms submit detailed information on their activities. This information provides the basis for estimation of flow of goods and services as well as payments made to individuals by the private sector in the economy. Government entities also submit detailed accounts of their activities. This provides the basis for the estimation of the contribution of government to the economy. Data on individual income and expenditures is deduced from data provided by the other two sectors.

GDP is measured in three different ways allowing for more accurate assessment of the level of economic activities in the society. In the expenditure approach, total expenditures made by consumers and public authorities, investment expenditures made by business firms and any increases in inventories are first added and then net imports (imports less exports) and taxes paid to government are subtracted to obtain the value of the GDP.

The income approach adds up the incomes earned by different factors of production. Labor's income is measured as wages, entrepreneurs' income is measured as income from self-employment, and capital's income is measured as profit earned by firms. Values calculated by the income approach are often called gross domestic income. NDI is obtained after depreciation of capital stock of the economy is deducted from the sum of incomes of these factors of production. When income earned by society's factors of production employed outside the country is added, we obtain GNI.

The same result should be obtained by following the output approach, in which value added at each stage of production in basic industries (agriculture or mining), manufacturing, and services and construction are added up. Total value added within the society should add up to the total income of all factors of production as well as to the total expenditures of the society.

GDP Comparisons

We are interested in two types of comparisons of GDP data. First, we would like to compare changes in the GDP of an economy over time. Second, we would like to compare different countries on the basis of their GDPs. For comparison within the same country, we need to differentiate between real GDP and nominal GDP and understand the importance of different ways of aggregating data. For international comparisons, we need to determine an exchange rate at which numbers of one country can be compared to others.

Nominal versus Real GDP: GDP and GNP figures are always collected in terms of current prices. These numbers provide the nominal value of the GDP. For comparisons over time, we would like to know how much of the change in the nominal GDP is due to increased volume of goods and services and how much is due to increase in prices. "Real GDP" figures measure the changes in the volume of production. Along with the value of the real GDP, a "GDP deflator" is calculated that indicates the inflationary component in the rise of the nominal GDP. The U.S. GDP almost doubled between 1990 and 2007, but grew only by about 35 percent in real terms over the same period.

Fixed-weight versus chain-weighted data: GDP figures are aggregated across millions of products and services by calculating their weights in a base year. Over time, however, there may be relative price changes in the economy, that is, prices of various goods and services may change by different amounts. In what is known as the fixed-weight method of aggregation, weight assigned in the base year continues to be used to aggregate GDP figures. This can introduce significant distortions if the relative price changes are large and do not reverse themselves in the future.

This distortion is best explained with the help of an example adapted from the work of Charles Jones. Suppose there are only two products in an economy—oranges and computers—and consumers spend half their income on each of these products in the base year. Further suppose that the number of oranges produced remains the same as in a base year but the number of computers grows by 10 percent a year. Since the real GDP measures the change in the volume of production, the growth of real GDP will appear to be close to 10 percent a year in a few years if we combine the output of the two products in terms of their weights in a base year. This is because the fixed-weight method of aggregation of data ignores the effects of price changes. In reality, as the volume of computers grows, their prices will fall. With a fall in the prices of computers, households will shift their expenditure patterns between computers and oranges. Chain-weighted data attempts to correct for these price movements and shifts in expenditure patterns. This is achieved by assigning weights to different goods and services not according to a base period but by averaging the weights over shorter intervals. Thus, quarterly data may be used to calculate weights and then those weights averaged to yield annual chained-weighted data. All national income accounts data in the United States have been chain-weighted since 1997.

International comparisons: Since each country measures its nominal GDP in its national currency, an exchange rate has to be used to convert each country's information into a common currency for international comparisons. Two exchange rates are used to make such comparisons—one actual and the other an artificial construct. We can use the actual exchange rate between the country's currency and an international currency—usually the U.S. dollar—in which comparisons have to be made.

The actual or market exchange rates are heavily influenced by trade and capital flows of the economy and may distort the real value of goods and services available in that country. To overcome this problem, a concept of "purchasing power parity" exchange rate has been developed to compare national accounts across countries. The "purchasing power parity" exchange rate allows for the fact that due to differences in prices of many products, especially services, one can acquire a significantly different basket of goods in some countries than, say, in the United States for the same number of dollars. A purchasing power parity (PPP) exchange rate is defined as the rate that equalizes the cost of acquiring similar baskets of goods and services in two countries. PPP exchange rate provides a better comparison of the sizes of the economies.

According to the estimates of the World Bank, global GDP in 2006 amounted to US$48.245 trillion. With a world population in excess of 6.5 billion, this implies an average income of $7,439 per capita in the world. There is, however, a great disparity in the average incomes of countries around the world. There are many countries for which GDP calculations based on PPP exchange rates show dramatically different results than those based on actual exchange rates. For some countries, the GDP with PPP exchange rate shows much better results. For others, it shows better results with the actual exchange rate. The per capita income ranges from more than $80,000 (based on actual exchange rate) to only about $120.

Is GNP a Good Measure of Welfare?

The concept of GNP was originally developed to measure the state of welfare of a society. The assumption behind this idea was that the living standard of citizens can be measured by the volume of goods and services available in the society. Has the concept lived up to its expectations? Are other measures of economic activities available that may provide a better indication of the state of a society's welfare? Can this idea be modified to better reflect how well a society is meeting the needs of its citizens?

It is generally recognized that GNP measures only one aspect of human life—material well-being. GNP as a measure of welfare would still be acceptable if we could be sure that other aspects of our lives correlate strongly with the material well-being. Social scientists have always raised questions about this assumption, but the debate seems to have become more serious over the past decade. Some of the glaring omissions of GNP figures include consideration of distribution of income, environmental impact of economic development, and leisure time available to citizens. An OECD study has identified other measures that contribute to human welfare that correlate only poorly with GDP. These measures attempt to identify degrees of self-sufficiency, indicators of health including infant mortality rate and life expectancy, and extent of social cohesion.

The king of Bhutan introduced the concept of Gross Domestic Happiness in 1972 to measure spiritual as well as material development. The United Nations Development Programme has created a human development index that combines economic factors with health, social, and sustainability factors to provide a more balanced view of the state of welfare in countries. In early 2008 President Nicolas Sarkozy of France invited two economics Nobel laureates to develop a measure of economic activity that would take into account quality of life and environment. It is quite likely that the concept of GNP will be modified significantly in the near future.

G20

The Group of Twenty Finance Ministers and Central Bank Governors, or G20, draws its members from 19 of the 25 largest national economies, plus one member representing the European Union as a whole. G20 is used to refer either to that specific group (which has no support staff or institution) or to the member-nations collectively.

The name is a little confusing. The 19 countries represented individually are not necessarily the top 19 economies in any given year, and there are additional members beyond that 19+1: the CEOs of the International Monetary Fund, the World Bank, the International Monetary and Finance Committee, the Development Committee of the International Monetary Fund and World Bank, and the European Central Bank. G20 has been a convenient shorthand emphasizing the number of member-states (plus the European Union), and succeeding the G33 and G22 in 1999.

The countries currently represented in the G20 are: Argentina, Australia, Brazil, Canada, China, France, Germany, India, Indonesia, Italy, Japan, Mexico, Rus-

The economic crisis of 2007–08 brought together these heads of state, along with representatives from the International Monetary Fund and World Bank, at the Summit on Financial Markets and the World Economy in Washington, D.C., on November 15, 2008.

sia, Saudi Arabia, South Africa, South Korea, Turkey, the United Kingdom, and the United States. When the European Union is included with these 19, some 90 percent of the world's gross national product is accounted for, and two-thirds of the population. At annual meetings, the G20 representatives collectively discuss and negotiate international matters of finance and economics.

2008 Summit

In a rare move, the November 2008 meeting was held between heads of state rather than simply the finance ministers, a change suggested by European Union President Nicolas Sarkozy and British Prime Minister Gordon Brown. The work of the 2008 summit, which took place in Washington, D.C., will be continued at the April 2009 summit in London, with the aim of reforming the global finance sector and all international financial institutions (including but not limited to the World Bank and the International Monetary Fund).

The 2007–08 economic crisis precipitated the involvement of heads of state at the 2008 summit. Because of the broad scope and the depth of the problems addressed, the financial media has begun calling the summit Bretton Woods II, though the test of time has yet to be passed; to be as sweeping as Bretton Woods, a conference needs to lead to successful implementation, not just discussion. That said, the spirit of the Mount Washington Hotel was certainly present in the affirmation of free market policies and the prevailing spirit of shoring up those policies in the face of calamity, not abandoning them.

Each country's experience of and reaction to the crisis was reviewed and addressed, and common principles were outlined for financial market reform. Sarkozy, though, argued that the "Anglo-Saxon" approach to the market had failed, that United States–United Kingdom capitalism had proven too free, too unregulated, and this in the end had led to disasters like the subprime mortgage crisis. German Chancellor Angela Merkel concurred that the international financial system had to be rethought from the ground up, and representatives of the European Union emphasized the importance of global standards of regulation and financial crisis response. Manmohan Singh, the Prime Minister of India, was vocal in cautioning against the temptations of protectionism, whereby every country would try to protect its own interests at the expense of the global community.

There was a feeling that the 2008 summit was a preamble to the real work that will be done at, and in preparation for, the April 2009 London summit.

The G20 Developing Nations

G20 is sometimes also used to refer, confusingly enough, to the G20 developing nations, not because the group consists of 20 countries but because it originated on August 20, 2003. Currently consisting of 23 countries, this G20 negotiates with the European Union, the United States, and other powers in the interest of trade liberalization and anti-protectionism. In 2009 the members are Argentina, Bolivia, Brazil, Chile, China, Cuba, Ecuador, Egypt, Guatemala, India, Indonesia, Mexico, Nigeria, Pakistan, Paraguay, Peru, the Philippines, South Africa, Tanzania, Thailand, Uruguay, Venezuela, and Zimbabwe.

Guanxi

Guanxi is a Chinese word for which the closest English synonyms are *connections* and *relationships*, although neither of these words best encapsulates the broader cultural implications that *guanxi* represents. It refers to the dynamic and complex nature of friendships, trust, interpersonal relationships, and the construction of closed family relations, or a joined network, which are all deeply rooted in Chinese society.

One aspect of guanxi *networks that can hinder foreign companies is the requirement for personal introductions.*

Some have described it as "friendships with an exchange or continual exchange of favors," while others have referred to it as "the social interactions within the network place and its members in the equivalent of an infinitely repeated game with a set of people they know." It offers special relationships between people who need something and those that have the ability to give something. In summary, *guanxi* can be regarded as friendship with implications of continued exchange of favors.

Even though the use of *guanxi* networks skyrocketed after the 1979 reforms in China, and the concept started appearing in business publications in the West in the 1980s, the term has deeper roots. It involves a relationship between two individuals or organizations containing implicit agreements that are neither officially acknowledged nor written down. It is based on the fact that there is a high degree of trust and reciprocity involved, i.e., if one offers a favor today, it is with the belief that it will be returned in the near future, whenever the individual needs it.

Guanxi has been identified as one of the most critical factors in doing business in China, regarded as a source of sustainable competitive advantage, acclaimed as aligned to the concept of relationship marketing, and extolled as the future direction of business practices in the 21st century.

The right *guanxi* is shown to be a vital factor in business negotiations, bringing a wide range of benefits, including securing rare resources, bypassing the bureaucratic maze, obtaining information and privilege, selling otherwise unsellable goods, and providing insurance against uncertainty and risk when problems arose.

Tim Ambler describes how *guanxi* systematically unfolds in a business setting. He notes that

> the first part of the "*guan*" is transferable. If A has guan with B and B with C, then B can introduce A to C, or vice versa. Otherwise contact is impossible. For this reason, faxes are unlikely to receive a reply until direct personal contact has been established. In the meantime, A has to fax B, who in turn, if the guan is satisfactory, relay it to C. The "*xi*" part of the word implies formalization and structure. Favors are banked to be repaid when the time is right, if ever. There is no urge to use up the *guanxi* stored; like insurance, one hopes not to need it, but its existence is reassuring.

Guanxi has been shown to have negative consequences as well. Some have viewed this phenomenon simply an emotional desire for the pursuit of self-interest. When such a network violates bureaucratic norms, it can lead to an "under-the-table" form of corruptive behavior. This can lead to, among other things, an "old boys' network," uneven income distribution, briberies, kickbacks and imperfect legal systems. When it takes precedence over civic duties, it has been shown to lead to nepotism and cronyism. Many experts also predict that *guanxi*'s role in business is likely to diminish eventually as China moves to a more open market system in this century.

Cultural differences and language barriers are often an impediment to outsiders in Chinese society, who might find it more difficult to cultivate *guanxi* with the depth possible by Chinese individuals. A foreigner being referred to as an "old friend" by the Chinese is often the first step in developing such relationships. Even in today's China, *guanxi* is imperative to doing business and getting along in life.

Guatemala

Guatemala is a Central American country that shares borders with Mexico, Belize, Honduras, and El Salvador. Its economy is heavily reliant on the agricultural sector, in particular the export of bananas, coffee, sugar, textiles, and fresh vegetables. Its population is over 12.7 million (2007). With a highly unequal distribution of wealth, the average gross domestic product per capita in Guatemala is $2,108 (2004), and about 29 percent of the population lives below the poverty line.

Before the arrival of the Spanish, the Mayan civilization controlled much of present-day Guatemala. It had already gone into steady decline many centuries before the arrival of the Spanish, who conquered the area and, because there were no supplies of gold and silver, established an export economy based on sugar cane, cocoa, and dye from cochineal insects and also from logwood. Many tropical hardwoods such as mahogany were also exported to Spain, where they were used in the construction of churches and palaces. However, the initial Spanish settlements were badly located and faced problems from the elements; the first capital flooded and the second was destroyed by an earthquake. This led to the establishment of Guatemala City as the administrative center, and later the capital of the country. In 1821 the region gained its independence and was incorporated briefly into the Mexican Empire, and then into the United Provinces of Central America. Guatemala gained independence in 1840, when Rafael Carrera caused the end of the federation, with Guatemala firmly in the control of the conservatives and landowners who continued the export trade to Spain and to other countries. Indeed, under Carrera, the crimson natural dye that was produced from insects harvested from the nopal cactus became the principal export of country, with the dye sold largely to Great Britain.

After the "Liberal Revolution" of 1871, the new government of Justo Rufino Barrios wanted to break the control of the supporters of Carrera and the Roman Catholic Church and modernize the country through exports. He developed the infrastructure of the country with the building of railroads and the expansion of the existing ports. His policies led to the introduction of cash crops, and coffee became the major export product in the country, with the alienation of much Indian land that Carrera had resisted.

By 1871 coffee made up half of all the exports from Guatemala. The agricultural sector of the economy still employs about half of the workforce in the country, with coffee still being very important. There are about 12,000 coffee plantations in the country, with about 300,000 metric tons of coffee being produced each year. The importance of coffee can be seen from the fact that it earns about half of Guatemala's income from exports. Debt servitude became important and the wealth of the elite expanded dramatically under the dictatorship of Jorge Ubico from 1931 until 1944.

The other major export income came from bananas, with the United Fruit Company playing a part in the Guatemalan economy. Indeed, the United Fruit Company was involved in the overthrow of the Guatemalan president, Jacobo Arbenz, in 1954. Arbenz had been trying to introduce major reforms to the country that would have eroded the power of the United Fruit Company and U.S. influence, and his overthrow by the Central Intelligence Agency (CIA) has led to many studies of the involvement of the CIA in the promotion of U.S. business interests in Latin America and elsewhere. The events in Guatemala, and also in neighboring Honduras, led to the term *banana republic* entering the vocabulary of politicians, economists, and social commentators around the world.

The coup d'état that overthrew Arbenz also ended the plans for land reform, and there were a large number of right-wing presidents who presided over a desperately poor country whose economy was further adversely affected by the earthquake of 1976 that devastated parts of the country. Following a fraudulent election in 1978, a civil war began, and this only ended in 1996, by which time the economy of the country was totally wrecked, with about a million people being internal or external refugees.

Since then there have been efforts to rebuild Guatemala, and the export of coffee continues to be a major part of the Guatemalan economy. The other major agricultural exports are sugar, bananas, oil, and cardamom, with coconut products, tobacco, tea, cotton, and rubber playing a smaller role. Over half of Guatemala's exports are to the United States, and these now include meat and petroleum.

Hang Seng Index

The Hang Seng Index (HSI) is the internationally recognized stock market indicator of the Stock Exchange of Hong Kong (SEHK). The HSI is a free-float capitalization-weighted index of selected companies listed on the Hong Kong exchange. The index was developed on July 31, 1964, with an initial base level set at 100 for its 30 constituent companies. The HSI was launched as a public service in 1969. The Hang Seng Index is compiled, published, and managed by the Hang Seng Indexes Company Limited, a wholly owned subsidiary of Hang Seng Bank, itself a principal member of the Hongkong and Shanghai Banking Corporation (HSBC). The Chinese characters for Hang Seng translate as "ever growing."

Constituent stocks of the HSI are selected by a rigorous process of analysis. Only companies with a primary listing on the main board of the Stock Exchange of Hong Kong are eligible as components of the Hang Seng Index. Companies in the index play significant roles in the Hong Kong economy as evidenced by the listing requirements: A company must be among those companies that constitute the top 90 percent of the total market value of all eligible shares listed on the SEHK (market value is expressed as an average of the previous 12 months); and must be among those companies that constitute the top 90 percent of the total sales revenue of all eligible shares listed on the SEHK (sales revenue is aggregated and individually assessed for eight quarterly sub-periods over the previous 24 months); and should normally have a listing history of at least 24 months or meet the requirements of a schedule of combinations of market value and listing period.

The Hang Seng Composite Index aims to cover 90 percent of the market capitalization of stocks listed on the main board of the Stock Exchange of Hong Kong. There are currently 200 stocks on the exchange. Constituent stocks must not have more than 20 trading days without sales revenue in the preceding 12 months, excluding days when the stock is suspended from trading ("Turnover Screening"); and after the Turnover Screening, the top 200 stocks in terms of average market capitalization in the previous 12 months are selected as constituents.

The final selection of companies in the HSI is based on the following additional criteria: the market value and sales revenue ranking of the companies; the representation of the sub-sectors within the HSI reflecting the market; and the financial performance of the companies.

Total market capitalization of the HIS stands at about HK$15,000 billion or 10 times the gross domestic product of Hong Kong. The companies (currently 43) in the HSI are divided into four sub-indexes representing particular economic sectors: Commerce and Industry, Finance, Properties, and Utilities. Some of these companies are Hutchinson Whampoa (commerce and industry), the Bank of East Asia (finance), Cheung Kong (properties), and CLP Holdings (utilities).

The Hang Seng Index Composite is calculated as follows:

$$HSI_t = \{ \Sigma [SP_t * IS * FAF * CapF] / \Sigma [SP_{t-1} * IS * FAF * CapF] \} * HSI_{t-1}$$

where:

HSI_t = current Hang Seng Index
HSI_{t-1} = previous closing Hang Seng Index
SP_t = the current day's share price
SP_{t-1} = the previous day's closing price
IS = number of issued shares
FAF = freefloat-adjustment factor
CapF = capitalization factor

As of July 8, 2008, the value of the Hang Seng Index was 23,872.43. Its 52-week high was 24,195.32, and its 52-week low was 23,858.89.

Mainland enterprises (currently 45 companies) that have an H-share listing in Hong Kong are also eligible for inclusion in the Hang Seng Index (HSI) when they meet any one of the following conditions: (1) the H-share company has 100 percent of its ordinary share capital in the form of H shares that are listed on the SEHK; (2) the H-share company has completed the process of Share Reform, with no unlisted share capital in the company; or (3) for new H-share initial public offerings (IPO), the company has no unlisted share capital.

Other Hang Seng Indexes

The Hang Seng Composite Index Series is composed of 18 indexes to gauge the performance of the Hong Kong stock market from different perspectives. In addition to the Hang Seng Composite Index, there are six indexes based on geographical status and market capitalization of the constituent stocks, and 11 indexes based on industry classification.

The Hang Seng Indexes Company appoints an independent advisory committee composed of Hong Kong experts drawn from government, universities, legal professionals, accounting professionals, and investment consultants. The independent advisory committee meets at least four times a year to discuss the composition of the indexes and issues relating to the indexes.

The Hang Seng Composite Industry Indexes cover the following 11 industry sectors: Conglomerates, Consumer Goods, Energy, Financials, Industrial Goods, Information Technology, Materials, Properties & Construction, Services, Telecommunications, and Utilities.

Other important Hang Seng indexes include the following: Hang Seng Hong Kong Composite Index: constituents of the Composite Index that derive the majority of their sales revenue from Hong Kong or places outside mainland China; Hang Seng HK LargeCap Index: top 15 stocks by market capitalization in the Composite Index; Hang Seng HK MidCap Index: companies ranked 16th to 50th in the Composite Index by market capitalization; Hang Seng HK SmallCap Index: companies ranked 51st and below in the Composite Index by market capitalization; Hang Seng Mainland Composite Index: constituents of the Composite Index that derive at least 50 percent of their sales revenue from mainland China; Hang Seng China-Affiliated Corporations Index: non-H share in the Hang Seng Mainland Composite Index with at least 30 percent shareholding by mainland entities such as state-owned organizations, provincial or municipal authorities.

There are also three "Prime Indexes," each with a smaller number of companies, that are designed to facilitate the development of index-derivative products: the Hang Seng 50, the Hang Seng HK 25, and the Hang Seng Mainland 25.

Hanseatic League

The Hanseatic League (the "Hanse") was a regional alliance of North German cities and towns that operated to control trade along the Baltic and North Seas and thrived during the late Middle Ages. Historians point to the Hanse as an early example of regional integration within Europe. Indeed, the Hanse was the most extensive and powerful of regional economic associations within Europe until the rise of the European Union (EU) in the second half of the 20th century. In a manner similar to the EU, the Hanse evolved over time into a more extensive and integrated union in order to more effectively control the economic, commercial, and political forces that threatened individual cities in the region. And, like the EU, the Hanse experienced strong centrifugal forces that limited the degree of integration achieved. Ultimately, by the 17th century, this divisiveness between the German cities, along with unstoppable global economic and political shifts, doomed the Hanse as a viable economic power in Northern Europe.

Economic historians trace the origins of the Hanse to the middle of the 14th century, when the first mention of the existence of such a league appears in commercial documents. The expanding reach and influence of the Hanse was, in fact, not an isolated development, but rather part of a more general penetration of German influence in northern, central, and eastern Europe during the high and late Middle Ages. That the Hanse formed in the region it did is no random development. In other parts of Europe, such as England and France, the rise of the centralized nation-state limited the ability of cities to independently form separate regional alliances. With no central government within the German lands, the commercially important cities in the north virtually ruled themselves. The economic history of Germany in the 13th and 14th centuries is, in fact, no less than the history of its important cities. Consequently, these cities enjoyed great latitude to do as they pleased, including organizing with one another as they saw fit, especially in regard to protecting their regional commercial interests.

The initial impetus for the formation of the "Hanse" was self-protection by merchants participating in commercial trade along the Baltic and North Seas. At that time, the German kings were virtually powerless to uphold laws and regulations of importance to the proper functioning of growing commercial interests. For the most part, this commerce consisted of the carrying by ship of bulky, low-unit-value raw materials obtained from the unindustrialized lands bordering the Baltic. One particular concern of the north German merchants was the disruption in this movement of goods by pirates and brigands. The Hanse first took shape as an alliance between the cities of Luebeck and Hamburg for the purpose of policing the rivers and roads in that part of Germany. Over time, other north German cities joined the alliance.

By the 1350s the number of members reached 50 cities and towns. While the number of towns and cities that were in the Hanse continually fluctuated (since they could enter and withdraw from the league at will), by 1375, the size of the Hanse averaged nearly 100 members. The geographical presence of the Hanse spread as well. At the end of the 13th century, the Hanse's activities extended from Flanders and England to northern Russia. By the mid-14th century, it established its merchants on Latin Christian territory—Bruges, London, Bergen, Stockholm—and in the pagan lands of eastern Europe and Russia.

As the Hanse over time expanded in membership and geographical reach, its functions extended beyond simple policing activities to include wide-ranging commercial agreements. The first of these involved reciprocal trading agreements between the member cities, and eventually included mutual arrangements to secure for members a monopoly in the trade of Baltic and North Sea products including herring and naval stores. Through such agreements, the Hanse effectively coordinated the activities of its members for economic ends and thus operated as a de facto cartel within the region.

While commercial interests remained central to the Hanse throughout its existence, it eventually took on the character of a political-military union. It created its own flag, diplomatic agenda and staff, and

This 1475 building in the medieval port of King's Lynn is the last surviving Hanseatic League warehouse in England.

naval fleet. It also put into place a sort of parliament (or diet) to create and pass laws and executive orders applicable to all the member towns and cities. The most serious political decision faced by the Hanse was entering into a war with Denmark in 1379. The close interdependence between the Hanse's political goals and commercial interests is embodied in the terms of peace demanded by the Hanse (Peace of Stralsund, 1379): free trade for the league cities in Danish territory and free passage of north German merchant shipping through Danish waters. In the century that followed, the Hanse selected economic boycott over war as the more effective—and less destructive—means to gain the advantage in geopolitical disagreements.

The decline of the Hanseatic League began to take place by the late 15th and into the 16th centuries. Internally, the weakening in the coherence of the Hanse set in with growing dissension and commercial rivalry among the members. Then, too, developments in the world within which the Hanse operated rendered the group's position untenable. The Hanse could not stand against the rise of capitalism in Europe. Indeed, the Hanseatic League's commercial operations were quite rudimentary compared with the more sophisticated capitalistic instruments and mentality that were overtaking other parts of Europe; the strict regulations imposed by the Hanse on its members seriously hindered the acceptance of the more innovative capitalistic methods. As critically, effective support—financial, commercial, and military—from their central governments gave England, France, and Holland the means to break the centuries-old monopoly of the Hanse in the Baltic. In any case, the emergence of the profitable Atlantic trade in the 16th and 17th centuries that signaled the beginning of the early modern period in world history relegated trade activity in the Baltic to secondary importance.

Harmonized System

The harmonized system, or as it is more formally known, the harmonized commodity description and coding system, is an international classification system designed to facilitate the collection of trade statistics as well as to assist in the collection of tariffs and customs duties. For decades, individual nations used their own systems for classifying goods and services. Without a universal standard, it was difficult or impossible to categorize correctly merchandise for collecting tariffs, customs duties, or for reporting purposes. To resolve this problem, the World Customs Organization (WCO) developed the harmonized system. In this system, the WCO describes all products through a standardized six-digit harmonized system (HS) code. The six-digit number classifies goods by chapter, heading, and subheading. The United States and other developed countries have added additional commodity codes increasing the number to 10 digits.

The system is quite complex; the complete harmonized tariff schedule has approximately 5,000 item descriptions grouped into 22 sections and 97 chapters (the U.S. version has 99 chapters). In addition to customs use, HS codes provide a data set for international market research. HS codes are not the only system for comparing data on industry structure and trade. In the United States, the Standard International Trade Classification (SITC) and North American Industry Classification are also used. For purposes of trade documentation and trade data, however, the harmonized system is the world standard.

History

Prior to the development of the harmonized system, each country maintained its own system. Exporters needed specialized staff whose role was to properly code goods for entry into different markets. Specialty publishers created concordances that linked one country's system to another. The complexity of the system made it difficult for small companies to trade without employing customs brokers or other intermediaries.

In 1970 a group known as the Brussels Tariff Nomenclature Group published a study that found that a uniform system of coding was both desirable and possible. That original group became the Customs Cooperation Council (CCC) and, with the help of more than 45 countries, implemented the first Harmonized Commodity Description and Coding System. In 1994 the CCC changed to its current name, the World Customs Organization. The WCO engages representatives from its nearly 200 member countries to maintain and update the HS code system and to provide advice and policy recommendations for national customs services.

System Organization

The 10-digit HS code number classifies goods by chapter, heading, subheading, and commodity codes. Each chapter begins with a domain statement that describes goods that are included in the chapter and then goods one would exclude. As an example, Chapter 92 of the code describes musical instruments and accessories. The domain indicates the instruments are acoustic (not amplified), are not toys, would not be considered collectibles or antiques, and do not include any instrument cases. Under Chapter 92 are discrete four-digit headings (e.g., HS 9201 for pianos, HS 9202 for stringed instruments, HS 9205 for wind instruments).

The WCO refers to the six-digit HS code as the subheading—a classification that provides more information. If we consider the heading HS 9202 for stringed instruments, we discover that HS 9202.10 describes instruments played with a bow (violin, viola, cello), where HS 9202.90 describes non-bowed instruments (guitars). The last digits help provide very specific information for use with the importing country's tariff schedule. For example, HS 9202.90.20 informs a customs official that the acoustic guitar in question costs less than $100.

Commodities from the same chapter (same 2-digit HS chapter) can have differing tariffs depending on its country of origin or its value. Consider the importation of guitars to the United States. Acoustic guitars (HS 9202.90.20 00) at a value of less than $100 excluding the cost of the case (HS code, 4202.92.50 00 for cases not made of leather or plastic) have a tariff of 4.5 percent for most countries. If the guitars originate in Mexico or Canada as part of the NAFTA agreement, they enter free of tariffs. If the guitar is more than $100, the HS Code is 9202.90.40 00 and the guitars have a tariff of 8.7 percent (again, zero for NAFTA countries). Electric guitars (HS code 9207.90.00) regardless of price enter the United States from non-NAFTA countries at a tariff of 5 percent. The subtle differences in tariffs are important when you realize that over the past six years, the United States has imported more than $1 billion in acoustic guitars.

Since countries base tariff revenues on imports, most countries have more specific import codes than those for exporters. In the United States, that ratio is about two to one; there are approximately 9,000 export codes and more than 18,000 import codes. To keep from confusing businesses with different exporting and importing codes, the United States calls the export classification system Schedule B and names the import codes the Harmonized Tariff Schedule of the United States. The United States bases all import and export codes explicitly on the harmonized system. The U.S. Census Bureau manages Schedule B while the U.S. International Trade Commission manages import codes.

Research

Market researchers have found HS codes to be a powerful source for international market research. Firms can access publicly available databases like the United Nations "Comtrade" system to track imports and exports for all member countries by four-digit HS code. A researcher can enter an HS code for any country and determine how much of a particular commodity that nation imports. The source of imports provides the researcher with a proxy for competition. While further research is often necessary, in many cases this information alone can help firms rank market entry prospects.

In addition to HS codes, researchers employ two other common trade data classification systems: the Standard International Trade Classification (SITC) and North American Industry Classification (NAICS). The need to classify commodities precisely to match tariff schedules can make the harmonized system unwieldy for comparing trade data. The SITC system allows for easier aggregate analysis of commodity trade data. While closely related to HS codes, the SITC classifies data into fewer code numbers than the harmonized system.

In order to manage the economic analysis required by the North American Free Trade Agreement (NAFTA), Canada, Mexico, and the United States jointly implemented the North American Industrial Classification System (NAICS). Unlike the harmonized system that focuses upon trade and customs compliance, the developers built NAICS around a production supply-chain model. NAICS groups businesses into industries based on the processes firms use to transform materials and assemblies into goods and services. The advantage of the NAICS system is that it allows the three member countries to compare information on employment, labor costs, productivity, industry performance, and other measures of political economy. All three systems—SITC, NAICS, and HS codes—undergo additions and changes to accommodate the exponential growth of new technologies and their related industries.

HBOS

The HBOS group provides business, corporate, and retail banking, insurance, and investment services to 23 million customers in both the United Kingdom (UK) and internationally. While 86 percent of its profits are currently generated in the UK, the balance is provided from operations in Australia, North America, Ireland, and Europe. HBOS has the biggest private shareholder base of any UK company, and employs approximately 72,000 people. Via its 23 million retail customers, HBOS claims to have some sort of relationship with 40 percent of UK households. The company is the UK's largest mortgage (21 percent of the market) and savings (16 percent) provider and is, additionally, a leading general insurer. It also offers both business banking and corporate finance facilities. Somewhat unusually, the company is registered in Scotland.

HBOS plc was established in 2001 from the merger of the Bank of Scotland and the Halifax to thereby become the fifth-largest financial services company in the UK. Both of the merged businesses have a significant pedigree. The Bank of Scotland was created in 1695 by an act of the Scots Parliament, making it Scotland's oldest bank. Over the three centuries since, Bank of Scotland became significantly acquisitive, absorbing other household names such as the Union Bank of Scotland in 1955 and the British Linen Bank in 1971. Although not as old, the Halifax (which was stabled as a building society and only later became a bank) can still boast a history spanning one-and-a-half centuries from its establishment in 1853. Notable acquisitions over the years included the Leeds Permanent Building Society in 1995 and the Birmingham Midshires Building Society in 1999.

HBOS aims to "deliver a better deal" than its competitors (especially the UK's "big four"), and its attitude toward corporate responsibility is a key element. It thus endeavors to align the interests of its customers (80 percent of the company's small shareholders are also customers), "colleagues" (employees, in other words, a significant proportion of whom are also shareholders), and its other shareholders. Over and above the interests of these three parties, the pressing aspects of the environment (regarding such things as carbon reduction—HBOS claims these days to be carbon neutral—paper management, and water management) and the community (where the company is involved in both local and national community programs) are also recognized. Dealing fairly with suppliers is another aspect of the espoused social responsibility.

Given that HBOS's driving philosophy is "what gets measured gets done," it is not surprising that it has developed a set of key performance indicators (unique among British banks) to underpin its statement of business principles. These originally amounted to no less than 48 items, although recently reduced to only 28 so as to give prominence to the major issues the company faces. Other "firsts" the bank claims are publishing an annual financial inclusion report (as a direct response to stakeholder feedback), and the publishing of a target for new social banking accounts. HBOS is one of only two UK banks to receive the highest AAA rating from the Innovest Global Sustainability Review and to be included in the Global 100 Most Sustainable Corporations in the World. Other inclusions are in the 2006 Accountability Rating, Business in the Community Corporate Responsibility Index, Dow Jones Sustainability Index, FTSE4Good Index and Carbon Disclosure Project Climate Leadership Index.

There are five strands to HBOS's strategy to create enduring value for its shareholders. Interestingly, these appear on the first page of the company's Annual Report and Accounts, so despite the corporate responsibility "hype," it remains clear that owners' interests remain paramount in this business: (1) a clear focus on franchise growth across UK financial services; (2) targeted international growth to enhance earnings' diversity; (3) cost leadership to enable competitive pricing; (4) capital discipline so as to ensure both sufficiency and value allocation; and (5) achievement, through team development, of consistent outstanding performance.

The worldwide banking crisis of 2008 affected HBOS, the UK's biggest mortgage lender and generally considered to have consistently been at the center of the British "meltdown." The bank's problems can be traced back to the merger in 2001 of Bank of Scotland (reliant for wholesale funding to finance at least half its lending) and the Halifax (possessing a larger balance sheet) to increase its corporate lending. This enabled the making of huge loans to property developers in the midst of the global credit crisis, and led to record losses of £10 billion during 2008. HBOS was forced into a hastily constructed merger in October 2008 with Lloyds TSB. The merger created Lloyds Banking Group, in which the British public (courtesy of government financial injections) became a large shareholder. In 2009 fears grew that Lloyds would itself become nationalized if matters did not rapidly improve.

Healthcare Benefits/Systems

The organized provision and delivery of healthcare services constitutes a healthcare system. The 2000 World Health Report states the goals for healthcare systems to include good health; making the health status of the entire population as good as possible across the entire life cycle; responsiveness to the expectations of the population; and fair financial contribution:

ensuring financial protection for everyone with costs distributed according to one's ability to pay.

Systems

There are several types of healthcare system models. Entirely private healthcare systems are relatively rare. Where they exist, they are usually for a comparatively well-off subpopulation in a poorer country with a poorer standard of healthcare, for instance, private clinics for a small, wealthy expatriate population in a poor country. Yet there are countries with a majority private healthcare system with a residual public healthcare system. Other major health system models are primarily public insurance systems. These include a social security healthcare model whereby workers and their families are insured by the state; a publicly funded healthcare model wherein the residents of the country are insured by the state; or a social health insurance healthcare model in which case the whole population or most of the population are members of a sickness insurance company. Almost every country that has a government healthcare system allows private healthcare systems as well. This is sometimes referred to as a two-tier healthcare system. The scale, extent, and funding of these private systems vary.

In most developed and many developing countries, healthcare is provided to everyone regardless of their ability to pay. The United States is the only country among developed nations except South Africa that does not have a universal healthcare system. However, healthcare in the United States has different and significant publicly funded components. The United States spends more on healthcare, both as a proportion of gross domestic product (GDP) and on a per capita basis, than any other nation in the world. Current estimates put U.S. healthcare spending at approximately 16 percent of GDP. The health share of GDP is expected to continue its historical upward trend, reaching 19.5 percent of GDP by 2017. In 2007, the United States spent a projected $2.26 trillion on healthcare, or $7,439 per person.

A few U.S. states have taken serious steps toward universal healthcare coverage, most notably Minnesota and Massachusetts, with the most recent example being the Massachusetts 2006 Health Reform Statute. Other states, while not attempting to insure all of their residents, cover large numbers of people by reimbursing hospitals and other healthcare providers using what is generally characterized as a charity care scheme. New Jersey demonstrates the best example of a state that employs the latter strategy. Normally, most forms of general liability insurance sold in the United States, like home, automobile, or business insurance, have a significant premium allocation for medical damages. The U.S. legal system, which has the highest number of attorneys per capita of any country in the world, is available to assist in proving liability and collecting the money for medical bills from such insurances.

Benefits

Healthcare benefits were introduced into the United States marketplace in the 1940s. They include medical coverage, dental and vision insurance, prescription drug plans, some type of disability coverage, employee assistance programs, and in some cases, flexible spending accounts, which allow the subscriber to pay for certain medical and dependent care expenses from pre-tax dollars. Most people cannot afford to pay the full amount of their healthcare costs. Healthcare benefits are a mechanism for people to protect themselves from the potentially catastrophic costs of healthcare in case of severe illness, and also to assure that people have access to healthcare when it is needed.

Health benefits are provided by a variety of both public and private sources in the United States. Public sources include Medicare, Medicaid, the State Children's Health Insurance Program, federal and state employee health plans, the military, and the Veterans Administration. Medicare covers the elderly and disabled with a historical work record, Medicaid is available for some, but not all of the poor, and the State Children's Health Insurance Program (SCHIP) covers children of low-income families. The Veterans Health Administration provides healthcare directly to U.S. military veterans through a nationwide network of government hospitals, while active duty service members, retired service members, and their dependents are eligible for benefits through TRICARE. The Indian Health Service provides publicly funded care for indigenous peoples. Together, these tax-financed programs cover about 27 percent of the population and make the government the largest health insurer in the nation. These programs also account for 45 percent of healthcare expenditures in the United States.

Private health benefits, on the other hand, are obtained primarily through jobs or covered through a family member's insurance. Employer-based health insurance is rather common with larger employers. About 60 percent of Americans receive health insurance through an employer, although this number is declining, and the employee's expected contribution to these plans varies widely and is increasing as costs escalate. About 158 million non-elderly people were insured through employer-sponsored health plans in 2006.

Workers injured on the job are covered by government-mandated worker compensation insurance and wage replacement benefits. These benefits vary considerably state to state, and employers bear the cost of this insurance. Businesses with considerable risk, such as bridge-building, mining, or meat processing, face far higher worker compensation insurance costs than do office-based clerical businesses. Although medical colleges and research institutes form a backbone structure for providing healthcare, private hospitals and nursing homes also are becoming an increasingly necessary part of the healthcare structure in the United States.

Insurance

Employer-sponsored health plans are known as group insurance. With group insurance, very often the employer pays most or all of the costs. It is estimated that the spending on employer-sponsored health insurance will hit $355.9 billion this year, of which employers contribute about 83 percent, while employees and retirees contribute the rest. Some organizations offer only one health insurance plan and others offer a choice of plans: a fee-for-service or indemnity plan, a health maintenance organization (HMO), or a preferred provider organization (PPO). Individual policies can be purchased when the employer does not offer group insurance or if the insurance offered is inadequate. Individual plans may not offer benefits as extensive as those offered under the group policy. About 14 million non-elderly people bought individual health insurance directly in 2006.

A significant and growing number of people cannot obtain health insurance through their employer and are unable to afford individual coverage. The U.S. Census Bureau estimates that about 16 percent of the U.S. population, or 47 million people, are uninsured. More than one-third of the uninsured are in households earning $50,000 or more per year. Sixty percent of the uninsured work in businesses with less than 500 workers or are family members of those who do. Some uninsured are people under age 30 who don't believe they need to purchase healthcare; others are eligible for Medicaid but have not applied.

Indemnity or fee-for-service health insurance plans allow one to go to the doctor of one's choice and pay for services at the time of the visit. The amount that the health insurance company will pay is a predetermined benefit level of covered medical expenses, based on the deductible and co-insurance amounts. To receive payment for medical expenses, one may have to fill out forms and send them to the insurer. There is also need to keep receipts for prescription drugs and other medical costs. With this type of coverage, the patient is responsible for keeping track of all their medical expenses. This type of plan is rare these days.

Unlike an indemnity plan, managed care is a health insurance plan like a health maintenance organization, preferred provider organization, or point of service plan (described below) that encourages or requires insured individuals to use certain providers. The theory underlying managed care is that by improving the overall health of the entire population, primarily through prevention, the employer gains through reduced absenteeism, increased productivity, and employee retention. The goal of the managed care organization is to keep costs down, while having broad coverage. The managed care plan requires or creates incentives for an insured person to use providers that are owned, managed, or under contract with the insurer. These incentives may be financial incentives or additional benefits. Coverage usually includes routine physicals, pediatric immunizations and checkups, emergency care, hospitalizations, surgery, X-rays, lab tests, maternity and newborn care, and mammograms. While managed healthcare plans differ widely in their details, they all direct the patient toward a preapproved network of doctors and facilities, as well as limit coverage of any treatment sought outside the network.

In an effort to reduce healthcare costs, many organizations switched from the traditional indemnity plans to a health maintenance organization (HMO) in the late 1980s. HMOs require that a fixed monthly fee is paid, called a premium. In return, the health insurance company and its physician network provide a variety of medical benefits. From this network, a primary care physician is chosen who is then responsible for the subscriber's overall healthcare as well as for making referrals to specialists and approving further medical treatment. Usually, one's choice of doctors and hospitals is limited to those within the network, since they have agreements with the HMO to provide healthcare. However, exceptions may be made in emergencies or when medically necessary. Generally, the healthcare services offered will require a copayment to be made at each visit. The drawback of any HMO policy is that care received outside the healthcare network is not covered. The benefits of HMOs include reduction in paperwork, broad coverage for a range of medical services, including routine physicals as well as regularly scheduled preventive care visits.

Preferred provider organization (PPO) healthcare plans operate like an HMO in that a fixed monthly premium is paid, and the health insurance company and its healthcare network provide medical benefits to the subscriber. However, under a PPO insurance plan, a primary care physician is not required. As a result, seeing a specialist does not require a referral. Healthcare provided from outside the network incurs a higher copayment or co-insurance than if the provider were from within the PPO network. Thus, the subscriber gets to decide between a higher-cost plan with freedom of choice and a lower-cost plan that restricts care to within a network.

A point of service plan (POS) attempts to combine the freedom of a PPO with the lower cost of an HMO. The POS is based on the basic managed care foundation: lower medical costs in exchange for more limited choices. When enrolled in a POS plan, the subscriber is required to choose a primary care physician from within the healthcare network, who becomes the "point of service" for the subscriber. The primary POS physician may then make referrals outside the network, but then this will incur higher copay and deductibles than for the network provider. For medical visits within the healthcare network, paperwork is completed for the subscriber. However, if care is sought outside the network, it is the subscriber's responsibility to fill out the forms, send bills in for payment, and keep an accurate account of healthcare receipts.

New Developments

Recent changes in federal law have led to establishment of new types of healthcare benefits. These include health savings accounts (HSAs) and health reimbursement accounts (HRAs). These are tax-exempt accounts that can be used to pay for current or future qualified medical expenses. Employers may make these savings mechanism available to the employees, and if the employer contributes to the HSA, these amounts are not included in the employee's gross income. To be eligible to open a health savings account, the employees must have health coverage under an HSA-qualified high-deductible health plan (HDHP).

HDHPs can be provided by the employer or purchased from any organization. HRAs are employer-established benefit plans funded solely by employer contributions that are excluded from the employee's gross income, with no limits on the amount an employer can contribute. HRAs are often paired with HDHPs, but are not required to be. Many employers also offer consumer-directed health plans (CDHPs). CDHPs usually have lower health insurance premiums for the employees.

Long-term care insurance (LTCI) is the emerging healthcare benefit for the aging population to provide healthcare costs associated with skilled or custodial care. It provides benefits for nursing facility care, assisted living, and adult day care as well as personal services needed in the home and hospice care. Medicare and Medicaid will not pay for most of these services, and importantly, individuals with this type of insurance can protect their assets.

The Consolidated Omnibus Budget Reconciliation Act of 1985 (COBRA) allows employees to purchase extended healthcare coverage. Extended healthcare coverage can be purchased under COBRA if one's job ends for any reason other than gross misconduct, or if work hours are reduced. To qualify, the employer must have 20 or more employees, and the employee must have been a participant in the employer's group health plan, and the employer must continue to maintain a health benefit plan. In these circumstances, when a job ends, the insurance plan must provide written notice explaining the employee's rights under COBRA. The employee has 60 days from the date the notice is provided or from the date coverage ends—whichever is later—to elect COBRA coverage.

It begins the day the healthcare coverage ends and lasts for up to 18 months (and longer in some cases). Under COBRA the group rate premium may be paid for healthcare coverage.

The Health Insurance Portability and Accountability Act of 1996 (HIPAA) protects the employee and their family from discrimination because of pre-existing medical conditions. Enacted in 1996, HIPAA requires that most plans provide coverage for pre-existing medical conditions after 12 months, in most cases. Further, HIPAA requires a new employer's plan to offset this 12-month exclusion period by providing credit for the number of days the employee had previous coverage—unless there was a major break in coverage. The former employer is required to provide a certificate that documents the employee's "creditable coverage."

Heckscher-Ohlin Model

The Heckscher-Ohlin model (H-O model) was constructed to understand the role of productive resources in international trade, analyzing an economy in which two goods are produced using two factors of production. It is a general equilibrium model that extends some important results of the comparative advantage theory developed by David Ricardo. One of the principal results of the model is that the countries export the products that employ their abundant factors of production intensively, and import commodities that utilize scarce factors of production. That result is known as the Heckscher-Ohlin theorem. The model was developed in the 1920s by Swedish economists Eli Heckscher and his student Bertil Ohlin (winner of the Nobel Prize in Economics in 1977), and has been extended since by other economists like Paul Samuelson, Wolfgang Stolper, Jaroslav Vanek, and Ronald Jones.

The original formulation of the H-O model refers to the case of two countries, two factors of productions—capital and labor—that have unlimited supplies, and two final goods (for that reason, sometimes the model is called the 2x2x2 model). In the model, the economies use the same technology of constant returns of scale, and the production of the goods differs between countries in the intensity of utilization of inputs. The intensity is about the proportions in which the two factors of production (capital and labor) are used. There is private ownership of the productive capital (that is, the physical machines and equipment that are used in production) and perfect mobility of factors within a country, but controls in the mobility of labor and capital between nations. Additionally, each commodity has the same price everywhere and its production takes place under perfect competition in both countries.

These assumptions widen the conception of the basic Ricardian model of international trade, because this model only supposes the existence of one factor of production—labor—that is required to produce all the goods and services in the economy. The productivity of labor is assumed to vary across countries, which implies a difference in technology between nations. It was the difference in technology that motivated advantageous international trade in the model.

In the H-O model the specialization of the production is incomplete, because of differences in factor endowments. A capital-abundant country is one that is well endowed with capital relative to another country. This gives that country the possibility to produce the good which uses relatively more capital in the production process (the capital-intensive good). As a result, if these two countries were not trading initially, i.e., they were in autarky, the price of the capital-intensive good in the capital-abundant country would be offered in a minor quantity (due to its extra supply) relative to the price of the good in the other country. Similarly, in the labor-abundant country the price of the labor-intensive good would be bid down relative to the price of that good in the capital-abundant country.

Once trade is allowed, profit-seeking firms will move their products to the markets that temporarily have the higher price. Thus, the capital-abundant country will export the capital-intensive good since the price will be temporarily higher in the other country. In the same way, the labor-abundant country will export the labor-intensive good. Commercial flows will rise until the prices of both goods are equalized in the two markets.

The Heckscher-Ohlin theorem is the main result of the model. It states that a capital-abundant country will export the capital-intensive good while the labor-abundant country will export the labor-intensive good. Thus, the H-O theorem shows that differences in resource endowments, as defined by national abundance, are one reason for international trade to take place. Another important conclusion is about the prices of the final goods and the distribution variables: a rise in the relative price of a good will lead to a rise in the return to that factor which is used most intensively in the production of the good, and conversely, to a fall in the return to the other factor.

At the time of the appearance of the original model, the empirical evidence for the 19th century and the first 20 years of the 20th century coincided with the results of the model. In 1953, economist Wassily Leontief developed an empirical test of the H-O model to analyze the case of the United States economy in the 25 years after World War II. Leontief found that the United States, despite having a relative abundance of capital, tended to export labor-intensive goods and import capital-intensive goods; this result is known as the Leontief paradox. There is not a unique explanation for the paradox, and alternative trade models and several alternative explanations have emerged as a result of the Leontief's conclusion. Recent estimates have shown some difficulties with the empirical verification of the model, associated with the key assumption that technology is the same everywhere. However, to change this assumption would mean abandoning the pure H-O model altogether.

Hedging

Hedging is a strategy applied to minimize risk. It also involves the synthetic insurance, i.e., the implementation of a dynamic trading strategy that determines the lower bound on the value of a position. Market participants in the 18th century realized the importance of avoiding uncertainty and created futures markets for certain agricultural commodities. The first futures clearing system that set the foundation for modern futures markets was authorized by Tokugawa Yoshimune, the 8th shogun of the Tokugawa era, in the Dojima District of Osaka, Japan, in 1730. The only traded commodity was rice and speculations were welcomed by the shogunate in order to support the rice price during deflation. In addition, the Dojima rice market was setting the trading standards for all of Japan. In modern financial markets, participants hedge in a multitude of both financial and real assets for various reasons such as taxes, bankruptcy and financial distress costs, managerial contracting with information asymmetry as well as the lack of diversification faced by large ownership blockholders.

Following an increase in market volatility in the last quarter of the 20th century, firms were exposed to new hedging requirements. With the breakup of the Bretton Woods system in the 1970s currency market volatility increased, which has created additional problems for both exporters and importers in planning the cost structure throughout the fiscal year. If imported goods/services are to be paid with foreign currency, the value of which is expected to decline after the expiration of the trade credit period, the exporter cannot determine with certainty what will be the exchange rate and thus the total income in domestic currency. Vice versa, importers will not be able to determine the cost in domestic currency for the payment to be made at a future date to foreign trade partners. This exposure can be hedged with the use of forward contracts that will determine the future exchange rate at which foreign currency can be bought (for the importer) or sold (for the exporter). The impending future cost will be known today, but the company is not protected against any foreign exchange movements that could benefit them, such as the higher (lower) future spot rates for exporting firms (importing firms).

This dilemma could be addressed by balancing assets and liabilities in currencies that have high positive correlations. The so-called exposure netting is routinely applied by multinational corporations' (MNCs') treasury departments and provides substantial cost savings. The Swiss franc, Swedish krone, and euro have high positive correlations, and generally demonstrate negative co-movements vis-à-vis the U.S. dollar and some Asian currencies that closely track it (e.g., the Malaysian ringgit or Hong Kong dollar).

Another effective response is the use of call or put options due to their attractive feature of providing the right, but not the obligation, to be exercised in the future. If a call option is in the money, the importer will buy foreign currency at a lower price, and the total cost will increase by a premium paid for the call option. The exporting firm will exercise a put option and sell foreign currency at a higher-than-prevailing exchange rate. The total benefits will be reduced by a premium initially paid for the put option. Third, an exporter expected to sell foreign currency at a future date can borrow foreign currency and convert it immediately into domestic currency. The total amount can be freely used for other investment purposes, because the debt will be paid on the due date after the receipt of the foreign currency. Importantly, the future principal and interest payments must equal the amount of foreign currency to be received. By contrast, importers will purchase foreign currency and invest it at a market rate until the prospective purchase date. Therefore, the final payment for imported goods will be executed without the involvement of any future forex transactions. Fourth, companies may decide not to hedge if they expect that foreign exchange rate movements will be beneficial to them. Finally, companies can request payments in their own currencies, which is a strategy routinely applied in countries with internationally traded hard currencies.

Oil shocks in the 1970s and financial deregulation in the 1980s associated with a strong globalization drive in the 1990s were characterized by market instability and interest rate swings. Market participants can lock in a short-term interest rate by entering a forward forward contract or a forward rate agreement. The forward forward contract comprises the borrowing and lending of the same sum of money over unequal time periods. The interest rate differential and the length of the net investment horizon will determine the interest rate payment. In the forward rate agreement, the interest rate is determined for a notional amount of principal.

Innovations

As part of the drive to increase returns to shareholders and adequately address the newly created market environment, financial institutions have created a whole stream of new financial innovations. Unfortunately, companies sometimes think of derivatives as a source of extra income, instead of a risk-reducing vehicle that could lead to significant losses. In addition, hedging can provide market participants with protection against downside risk, but prevent them from profiting if new market opportunities have been created. Therefore, the risk management team has to carefully plan whether or not it is justifiable to apply a hedging strategy. If so, the frequency of adjustments in instruments used to hedge the underlying instrument should be determined. This process is called dynamic hedging and determines the success of a company's risk management. Too-frequent changes impose a cost burden, while their infrequency leads to discrepancies that could ultimately result in unexpected losses.

Hewlett-Packard

Hewlett-Packard (HP) is a technology company headquartered in Palo Alto, California, that operates in more than 170 countries worldwide. It was founded in 1939 and is a Fortune 11 company with $91.7 billion in revenue, generating $7 billion in organic growth for fiscal year 2006. It produces and sells a wide portfolio of technological products ranging from handheld devices to some of the world's most powerful supercomputer installations. Additional product categories include digital photography, digital entertainment, computing, and home printing.

HP's corporate objectives have guided the company in the conduct of its business since 1957, when first written by co-founders Bill Hewlett and Dave Packard. These objectives were and still are, according to the firm's mission, to provide products, services, and solutions of the highest quality, and deliver more value to the firm's customers in order to earn their respect and loyalty. Underlying principles supporting this objective include that continued success is dependent on increasing the loyalty of its customers and responding to customers' needs.

Therefore, a strong customer-centric orientation is the dominant philosophy of the firm, which helped it in addressing technology-related problems and challenges that individuals and firms face. It has applied innovative thinking and generated ideas that create value for its customers. The result has been increasing growth and profitability, greater value for shareholders and customers, and a stronger competitive position in global information technology (IT) markets. Between the company's 2004 and 2007 fiscal years, HP's revenues grew from $80 billion to $104 billion and more than doubled its earnings per share. For the most recent four fiscal quarters, HP's revenue totaled $110.4 billion.

The chief executive officer and president of the company since early 2005 is Mark Hurd. In September 2006, he was also named chairman of the board of directors. Prior to joining HP, Hurd spent 25 years at NCR Corp., where he held a variety of management, operations, sales, and marketing roles. He is also a member of the News Corp. board of directors. Hurd's mission is to establish HP as the world's leading technology company and in this respect, he concentrated its investments on three long-term growth opportunities: next-generation enterprise data center architecture and services; technologies for always connected, always personal mobile experiences; and a broad transition from analog to digital imaging and printing across the consumer, commercial, and industrial markets. HP's three business groups drive industry leadership in core technology areas: (1) the Personal Systems Group includes business and consumer PCs, mobile computing devices, and workstations; (2) the Imaging and Printing Group includes inkjet, LaserJet, and commercial printing, printing supplies, digital photography, and entertainment; and (3) the Technology Solutions Group includes business products such as storage and servers, managed services, and software.

Such a related diversified portfolio forms the basis for further growth, which is a major objective of the firm. Hewlett-Packard wishes to expand into new areas that build on its existing technologies, competencies, and customer interests and are enhanced by its size and diversity of businesses. The dynamic, ever-changing environment in the technological sector is seen as an opportunity by the firm to develop and produce innovative products, services, and solutions that satisfy emerging customer needs. This objective is underlined by the belief that growth stems from taking calculated risks based on the state of the industry. This requires both a conviction in studying the trends, but also in inducing change in the industry.

Central to HP's operations is the welfare of its employees. Customer loyalty is a key imperative for the firm and satisfactory performance at this level can only be achieved through loyal, motivated employees. Therefore, the firm has tried to create a stimulating work environment that reinforces invention and urges everyone to contribute to daily and strategic operations. Such an approach that values and respects the individual can be seen as part of the corporation's overall sense of social responsibility, which is manifested in its efforts toward good citizenship. Hewlett-Packard strives to be socially responsible by being an economic, intellectual, and social asset to each country and community in which it operates.

Summarizing, HP is a firm that has managed to achieve a leading position in the international technology sector. Its original vision has turned into action and, today, it is a global firm that delivers value to millions of demanding customers globally and meets its popular brands' promises.

Hitachi

Hitachi, Ltd., a global Japanese company whose products include electronics equipment, home appliances, train cars, elevators, escalators, computers, mobile devices, power plants, and industrial machinery, originated in 1910 in the electric repair shop of Namihei Odaira. The company's first product was three 5-horsepower (hp) motors, and in 1915, it produced a 10,000-hp water turbine. It went on to manufacture electric locomotives, cells, refrigerators, and generators in the first five decades of its history.

In 1959 transistor-based electronic computers were produced and Hitachi America, Ltd., was founded. Between 1969 and 1979, Hitachi built cars and added computerized control systems for the *Shinkansen* (bullet trains), constructed elevators, produced transistors

This E257 series Hitachi train served the busy Shinjuku station in Tokyo, Japan, in 2008.

for color televisions, and developed Japan's first nuclear power station. There was further expansion of the company in the last two decades of the 20th century with the establishment of Hitachi Europe, Ltd., Hitachi Asia, Ltd., and the Hitachi Foundation for Japanese American cultural, educational, and scientific cooperation.

A milestone in Hitachi's progress was the development of the world's fastest superconductive computer in 1989 and building computers with the world's fastest processing speed the next year. The bullet train of Japan attained a maximum speed of 162 miles per hour due to upgrades by Hitachi in 1993. The company opened a branch in China in 1994. In 1995 Hitachi manufactured the 10 Gbit/s fiber optic transmission equipment. After three years it produced the optical data transmission system of 320 Gbit/s. A perpendicular magnetic recording system was developed in 2000.

At the beginning of the 21st century, Hitachi turned its attention toward developing Web gateways and processors for mobile phones. The world's first liquid-cooled notebook computers were produced by Hitachi in 2002. The credit for producing the smallest contactless IC chip also went to Hitachi. It also improvised equipment that was helpful in medical diagnosis. The development of compact DNA analysis and mapping brain functions of babies was successfully performed in 2002 and 2003, respectively. In 2004 Hitachi produced the world's smallest sensornet terminal with batteries running for about a year. In the same year, Hitachi produced lead-free solder paste. In 2005 Hitachi set up a research and development center in China. The next year, the company produced the 2.5-inch HDD on a mass scale.

With revenue of $94.998 billion and 384,444 employees, Hitachi is headquartered at 6-6; Marunouchi 1-chome, Chiyoda, Tokyo, and its present chief executive officer (CEO) and president are Etsuhiko Shoyama (1936–) and Kazuo Furukawa (1946–), respectively. Hitachi was listed on the stock exchanges of New York, Tokyo, and Osaka. The Power and Industrial Systems Information sector of Hitachi was the highest earner for the company, contributing 26 percent of the total revenue. The share of Information and Telecommunication Systems, High Functional Materials and Components, Digital Media and Consumer Products, and Electronic Equipment sectors contributed 21, 15, 13, and 11 percent, respectively. Logistics, services, and other sectors earned 10 percent of total revenue, whereas the financial service segment's share was 4 percent.

Hitachi's success as a global enterprise has been recognized with many awards and honors. The company received in 2007 Asia Pacific Entrepreneurship Awards from Enterprise Asia and Investment in People Award. Hitachi was ranked number 371 of the *Forbes* Global 2000 list for the year 2007. Much of Hitachi's success can be traced to research and development, which has kept Hitachi goods competitive. The company's laboratories in Cambridge, Dublin, and Sophia are on par with similar institutions of other organizations. It has also managed its branches in different parts of the world effectively. On April 1, 2008, Hitachi established a new company called Hitachi Information and Telecommunications System Global Holding Corporation at Santa Clara, California, to supervise two Data Systems Solution holding corporations founded in Dallas, Texas (2000), and Santa Clara (1989), respectively.

Hofstede's Five Dimensions of Culture

Geert Hofstede identifies five cultural dimensions, which assign mathematical scores designating a particular country's beliefs about each of the dimensions. The five cultural dimensions are power distance (PDI), individualism (IDV), masculinity (MAS), uncertainty avoidance index (UAI), and long-term orientation (LTO). These ideas were first based on a large research project into national culture differences across subsidiaries of a multinational corporation (IBM) in 64 countries. Subsequent studies by others covered students in 23 countries, elites in 19 countries, commercial airline pilots in 23 countries, up-market consumers in 15 countries, and civil service managers in 14 countries. These studies together identified and validated five independent dimensions of national culture differences.

The first is power distance, that is, the extent to which the less powerful members of organizations and institutions (like the family) accept and expect that power is distributed unequally. This represents inequality (more versus less), but defined from below, not from above. It suggests that a society's level of inequality is endorsed by the followers as much as by the leaders. Power and inequality, of course, are extremely fundamental facts of any society and anybody with some international experience will be aware that "all societies are unequal, but some are more unequal than others."

The second dimension is individualism on the one side versus its opposite, collectivism, that is, the degree to which individuals are integrated into groups. On the individualist side we find societies in which the ties between individuals are loose: Everyone is expected to look after him/herself and his/her immediate family. On the collectivist side, we find societies in which people from birth onward are integrated into strong, cohesive in-groups, often extended families (with uncles, aunts, and grandparents) that continue protecting them in exchange for unquestioning loyalty. The word *collectivism* in this sense has no political meaning: It refers to the group, not to the state. Again, the issue addressed by this dimension is an extremely fundamental one, regarding all societies in the world.

The third dimension of masculinity versus its opposite, femininity, refers to the distribution of roles between the genders that is another fundamental issue for any society to which a range of solutions are found. The IBM studies revealed that (a) women's values differ less among societies than men's values and (b) men's values from one country to another contain a dimension from very assertive and competitive and maximally different from women's values on the one side, to modest and caring and similar to women's values on the other. The assertive pole has been called "masculine" and the modest, caring pole "feminine." The women in feminine countries have the same modest, caring values as the men; in the masculine countries they are somewhat assertive and competitive, but not as much as the men, so that these countries show a gap between men's values and women's values.

The fourth dimension, uncertainty avoidance, deals with a society's tolerance for uncertainty and ambiguity; it ultimately refers to man's search for Truth. It indicates to what extent a culture programs its members to feel either uncomfortable or comfortable in unstructured situations. Unstructured situations are novel, unknown, surprising, and different from usual. Uncertainty-avoiding cultures try to minimize the possibility of such situations by strict laws and rules, safety and security measures, and on the philosophical and religious level by a belief in absolute Truth; "there can only be one Truth and we have it." People in uncertainty avoiding countries are also more emotional, and motivated by inner nervous energy. The opposite type, uncertainty accepting cultures, are more tolerant of opinions different from what they are used to; they try to have as few rules as possible, and on the philosophical and religious level they are relativist and allow many currents to flow side by side. People within these cultures are more phlegmatic and contemplative, and not expected by their environment to express emotions.

Long-term versus short-term orientation: this fifth dimension was found in a study among students in 23 countries around the world, using a questionnaire designed by Chinese scholars. It can be said to deal with Virtue regardless of Truth. Values associated with long-term orientation are thrift and perseverance; values associated with short-term orientation are respect for tradition, fulfilling social obligations, and protecting one's "face." Both the positively and the negatively rated values of this dimension are found in the teachings of Confucius, the most influential Chinese philosopher, who lived around 500 B.C.; however, the dimension also applies to countries without a Confucian heritage.

Scores on the first four dimensions were obtained for 50 countries and 3 regions on the basis of the IBM study, and on the fifth dimension for 23 countries on the basis of student data collected by Bond. Power distance scores are high for Latin, Asian, and African countries and smaller for Germanic countries. Individualism prevails in developed and Western countries, while collectivism prevails in less developed and Eastern countries; Japan takes a middle position on this dimension. Masculinity is high in Japan, in some European countries like Germany, Austria, and Switzerland, and moderately high in Anglo countries; it is low in Nordic countries and in the Netherlands and moderately low in some Latin and Asian countries like France, Spain, and Thailand. Uncertainty avoidance scores are higher in Latin countries, in Japan, and in German-speaking countries, lower in Anglo, Nordic, and Chinese culture countries. A long-term orientation is mostly found in east Asian countries, in particular in China, Hong Kong, Taiwan, Japan, and South Korea.

The grouping of country scores points to some of the roots of cultural differences. These should be sought in the common history of similarly scoring countries. All Latin countries, for example, score relatively high on both power distance and uncertainty avoidance. Latin countries (those today speaking a Romance language, i.e., Spanish, Portuguese, French, or Italian) have inherited at least part of their civilization from the Roman Empire. The Roman Empire in its day was characterized by the existence of a central authority in Rome, and a system of law applicable to citizens anywhere. This established in its citizens' minds the value complex that we still recognize today: centralization fostered large power distance, and a stress on laws fostered strong uncertainty avoidance. The Chinese empire also knew centralization, but it lacked a fixed system of laws: it was governed by men rather than by laws. In the present-day countries once under Chinese rule, the mindset fostered by the empire is reflected in large power distance but medium to weak uncertainty avoidance. The Germanic part of Europe, including Great Britain, never succeeded in establishing an enduring common central authority, and countries that inherited its civilizations show smaller power distance. Assumptions about historical roots of cultural differences always remain speculative, but in the given examples they are quite plausible. In other cases, they remain hidden in the course of history.

The country scores on the five dimensions are statistically correlated with a multitude of other data about the countries. For example, power distance is correlated with the use of violence in domestic politics and with income inequality in a country. Individualism is correlated with national wealth (per capita gross national product) and with mobility between social classes from one generation to the next. Masculinity is correlated negatively with the share of their gross national product that governments of the wealthy countries spend on development assistance to the Third World.

Uncertainty avoidance is associated with Roman Catholicism and with the legal obligation in developed countries for citizens to carry identity cards. Long-term orientation is correlated with national economic growth during the past 25 years, showing that what led to the economic success of the east Asian economies in this period is their populations' cultural stress on the future-oriented values of thrift and perseverance.

Holidays

The term *holiday* is derived from medieval Christian religious festivities that were collectively called "Holy Days." General usage of the word has transcended from Christian days of religious observance to include other religions' and secular celebrations and individual vacations. International business operations can be significantly impacted by national or religious differences in the adherence of holidays.

Weekly days of rest known as the weekend are not called holidays any more. Yet, they are the original religious Holy Days. Jews, Christians, and Muslims believe that God rested on the seventh day after having worked for six days to create the heavens and the earth. To the Jews, this day is Saturday, the Shabbat. For most Christians it is Sunday, and for Muslims it is Friday, called El-Gumah or Gathering Day. Muslims celebrate it with noon prayers at the mosque but often consider Friday a workday—in Muhammad's time, it was the market day in Medina. Hebrew and Muslim days last from the previous evening's sunset to that day's sunset, while Christian days last from midnight to midnight. International travelers are well advised to check in advance which days are observed as weekend in a specific country or region.

Most religions structure their year around certain spiritual holidays, some of which are rooted in older pagan traditions: Christmas happens near the winter solstice, Easter and the Hebrew Pesach are connected to the spring equinox, and St. John's Day follows Midsummer. The Hebrew Sukkot and many Thanksgiving-related festivities surround the fall equinox.

The feast of Christmas is often seen as synonymous with the word *holiday*—the weeks leading up to it are commonly called the "holiday season." Christmas traditions and dates vary internationally. Gift-giving, for example, traditionally happens on December 6 (Sinter Claas, St. Nicolas Day) in the Netherlands, but on December 24 (Christmas Eve) in other Protestant countries. Catholics celebrate on December 25, and the Orthodox on the Julian calendar's Epiphany (January 6), which currently translates to January 19 in the Gregorian calendar.

Many religious holidays do not have fixed dates. Islamic holidays, for example, are based on a lunar calendar and, in some countries, on actual sightings of the moon. Cloudy nights can delay important celebrations like Eid al Fitr, the last day of the lent month Ramadan. The dates for Chinese, Hebrew, and Hindu holidays as well as Christian holidays like Good Friday, Easter, and Pentecost follow lunisolar rules that mix a lunar and a solar year. In consequence of this and the different calendars used, dates of movable holidays do not only differ between years but also internationally.

Originally public holidays coincided with religious festivities. Until the early 19th century, the Bank of England, for example, closed on selected saints' and anniversary days, making these days "bank holidays." With the advent of nation-states, celebrating anniversaries of important historic events became part of the national folklore or self-conception. One example of such a secular public holiday is the 4th of July in the United States, honoring the signing of the Declaration of Independence. Other public holidays commemorate important persons: In Japan, the Emperor's Birthday is a public holiday. The current 125th *tenno* (emperor) was born Akihito Tsugonimaya on December 23, 1933.

There are multiple secular holidays designated by the United Nations or other organizations, e.g., International Children's Day (June 1) or World AIDS Day (December 1). These are usually not celebrated as public holidays, with Labor Day (May 1 in most countries) and International Women's Day (March 8, especially in Russia) being notable exceptions.

Around the world many other unofficial holidays are designated to celebrate or promote a cause, event, or person. This ranges from well-known days like Mother's Day (in most countries celebrated on the second Sunday in May) to obscure celebrations like "Talk Like a Pirate Day" on September 19. Sometimes holidays get postponed to the subsequent Monday if their normal date falls on a weekend. Detailed lists of the dates of religious and secular holidays can be found on sites like www.bank-holidays.com, www.interfaithcalendar.org, or www.timeanddate.com.

The British English term *holiday* (in American English, *vacation*) is also used to describe a non-illness-related leave of absence from work for relaxation and recovery. Labor laws or collective agreements in most countries include provisions for such periods of rest and vacations. Most countries require employers to give two to six weeks of paid leave for annual holidays. This has allowed tourism to become one of the world's largest industries.

Home Country

The home country is the country in which a firm was founded and/or is considered to be the firm's traditional base. This is generally a simple concept and remains simple as long as the firm retains its headquarters in the original home country. Thus BMW considers Germany to be its home country, General Motors looks to the United States, Hyundai to South Korea, and Toyota to Japan. The allied term *host country* refers to the nation in which a foreign subsidiary is based.

Cross-border mergers complicate the picture, with the acquired firm changing from being at home to being a foreign subsidiary now hosted by its former home country. Thus, in the case of Jaguar—acquired by Ford in 1989—the United Kingdom serves as merely the host country for this subsidiary of a corporation with an American (home country) parent. And the United States became a host country for Chrysler Corporation after it was acquired by Germany's Daimler-Benz AG. Finally, simple home-host classifications lose their salience for truly global companies with multiple significant footholds. For example, South African Breweries acquired Miller Brewing Company in 2002, but after several other acquisitions in Asia, Europe, and South America, it identifies itself with United Kingdom companies listed on the London Stock Exchange.

Researchers in the international management area have generally considered home country effects to be significant to managerial (and strategic) decisions taken at headquarters; and host country effects more significant to those decisions taken at the subsidiary level. These assumptions are grounded in the logic that either level of organization—headquarters or subsidiary—is grounded in its local culture and institutional framework. Authors such as Erin Anderson and Hubert Gatignon note, however, that there are two possible approaches to understanding how a multinational corporation may tend to exert control over a foreign subsidiary: First, the corporation may choose to lessen control as a way of compensating for its lack of knowledge concerning the distant location, relying on subsidiary management to contribute local knowledge; or, it may opt for stronger managerial controls as a way of reducing potential risk and dependence upon affiliates whose actions may to be regarded as opportunistic or poorly understood. Similarly, Yaping Gong shows that headquarters management may opt for close monitoring of a culturally distant subsidiary, but this very distance makes monitoring less effective due to information asymmetry. Other researchers argue that these divergent predictions may explain the inconsistent findings regarding the relationship between cultural distance and entry mode, and go on to show how home country effects generally eclipse host country effects in crucial decisions concerning expatriate deployment. Another study by David Brock and David Barry argues that home country effects tend to overshadow those at host country level in choices and design of planning processes.

It may well be that forces of globalization are having their effect on the balance of home country and host country effects on multinational subsidiaries. Traditionally, forces for localization were stronger, and multidomestic mindsets were more common, and thus one can understand the traditional consideration of the significance of host country forces on foreign subsidiaries. However, as forces for integration are increasingly enabled and strengthened (inter alia, by technology) and global mindsets are increasingly predominant, it is inevitable that home country effects would gain the upper hand.

Home Depot, The

The Home Depot, Inc., a large American retailer specializing in home improvement products, claims to be the largest retailer of its type in the world. Their stores offer building materials, home improvement supplies, and lawn and garden products that are sold to do-it-yourself customers, do-it-for-me customers, home improvement contractors, trades people, and building maintenance professionals. The company also operates EXPO Design Center stores that provide products and services primarily related to design and renovation projects. Apart from 1,950 stores in all 50 states and U.S. territories, in mid-2008 The Home Depot had 34 EXPO stores, five Yardbirds stores, and two THD Design Center stores in the United States, as well as 165 stores in Canada, 12 stores in China, and 66 stores in Mexico. In early 2009, The Home Depot announced it would be closing all 34 EXPO stores and five Yardbirds stores. The company, however, expressed its intention to keep open all of its namesake stores.

The company was founded in 1978 and is based in Atlanta, Georgia. The founders' vision is one of one-stop shopping for the do-it-yourselfer. In order to compete with traditional hardware stores, The Home Depot offered a very wide product range and economies of scale. Quality customer service is considered a major strength. Customers lacking in hardware skills and knowledge were helped to select tools, paint, and other materials, and also advised how to approach projects such as laying tile, changing valves, or using a certain power tool. To implement these service standards, staff were given rigorous product-knowledge training. Further, clinics were offered so customers could learn how to use The Home Depot products.

The business model was successful and early growth impressive. It went public on NASDAQ in 1981, moving to the New York Stock Exchange in 1984. Growth was rapid in the 1980s and 1990s, with 1989 marking the celebration of its 100th store opening. The Home Depot entered the Canadian market in 1994 with the acquisition of Aikenhead's home improvement centers, and the Mexican market in 2001 through the acquisition of Total HOME. In 2006 the company extended its reach to China by acquiring Home Way, a 12-store chain. From the start, The Home Depot developed strategic product alliances directly with industry-leading manufacturers. For example, through a combination of national brands and proprietary products like Ryobi tools, Ridgid tools, Behr paint, LG appliances, and Toro and Cub Cadet lawn equipment.

Some key financial indicators at mid-2008 were: revenue, $76.7 billion; total assets, $56.9 billion; total stockholder equity, $27.7 billion; profit margin, 4.8 percent; operating margin, 8.2 percent; return on assets, 7.7 percent; return on equity, 16.7 percent; market capitalization, $42 billion; price/book ration 2.4; stock beta .39; operating cash flow, $5.5 billion; dividend payout ration, 45 percent. The company is profitable and has sustained a good growth rate. However, growth and profitability are both in decline in the past few years, with several analysts forecasting continued decline through 2009.

A strategic case written by Thomas Wheelen depicts The Home Depot as being highly successful in the do-it-yourself/buy-it-yourself market, but struggling to enter the professional contractor market. One crucial set of issues to the case is that the company has several key resources that make it successful

With challenges facing its nearly 2,000 U.S. stores, The Home Depot is increasingly looking to international markets.

in its traditional markets—such as its customer service, range of products, and locations of stores—but that these resources are not necessarily relevant to the professional contractor market, who need to buy in larger quantities, require credit facilities, demand delivery to building sites, and have little use for attractive stores in residential shopping areas.

The Home Depot continues to target the professional contractor market via, inter alia, a division called "contractor services." As further indications of the company's commitment to market development, the corporate internet sites mention export services, including a free exporter's catalogue and an international sales department; and also a welcome to governmental buyers. In fact, recent statements by Chairman Bob Nardelli indicate a continued commitment to these market developments, with over 40 percent of growth coming from the professional market and 25 percent from international do-it-yourself markets.

Honda Motor

The growth of the Honda Motor Corporation is inseparable from the explosive surge of the Japanese automotive, truck, and motorcycle manufacturing sector in the aftermath of World War II. That expansion is remarkable. In 1950 the combined total for production of cars, trucks, and buses was around 29,000 units; by 1960 this number had multiplied 15-fold; by 1978 it exceeded 9,260,000 units. Within this massive industry Honda is a second-tier player. A world leader in engine manufacturing (its engineers made a major breakthrough with their development of the water-cooled Compound Vortex Controlled Combustion engine in 1973), its volume of vehicles produced is far overshadowed by other Japanese automobile manufacturers, most notably Toyota and Nissan.

As the industry blossomed, especially during the 1960s and 1970s, its major players developed a two-pronged strategy relying upon domestic sales for their core business, simultaneously pursuing export opportunities especially in the relatively high income per capita American market, eventually building a North American production base. For instance, Honda established its first American factory site near Marysville, Ohio, laying the groundwork for Honda of America Manufacturing during the late 1970s.

These two features of the postwar Japanese automobile industry can be neatly captured in the theory of international trade in manufactures rooted in twin concepts of geographic distance and monopolistic competition within national economies. As the costs of shipping goods fall—in the case of automobile shipments over the seas due to the growing use of specialized roll-on/roll-off ships—consumers seeking variety find they can satisfy this demand by purchasing from a menu of choices including both foreign and domestic manufactures. Since there are strong economies of scale and scope in manufacturing and distributing automobiles—unit costs falling with volumes fabricated and sold—relatively few companies can enter and survive within individual national markets. Those that do so differentiate themselves from one another through branding and advertising. While relatively few automobile producers exist in individual countries, considerable variety of choice exists for consumers in these countries due to international trade.

Honda shares with most of its Japanese rivals—Toyota, Nissan, and Mazda—a cluster of characteristics that help explain the phenomenal growth of the industry: building quality into all of the components of its vehicles; the ability to rapidly and flexibly adjust to changing regulations and consumer tastes; and a fierce commitment to improving productivity. Exemplifying these principles is Honda's BP Program—"best position, best productivity, best product"—perfected in Japan during the 1970s and introduced into its North American operations during the 1990s. One of the principal goals of BP is to induce firms in its supplier network—in the case of Honda of America Manufacturing over 80 percent of its manufacturing parts are sourced from its supplier network—to continually drive down costs and to upgrade component quality, never forgetting that the battle to cut costs and improve quality is best fought at the shop floor plant level.

A second characteristic that Honda shares with companies like Toyota is rapid response to constraints on exports. When the American and Japanese governments negotiated voluntary export restraints (VERs) on the volume of Japanese automotive exports to the United States, both companies diversified into luxury cars—each luxury vehicle containing more value added than their less expensive cousins. Honda introduced the Acura, and Toyota the Lexus.

While Honda shares with companies like Toyota a commitment to drive down costs and enhance quality through a focus on the way components are actually manufactured on the shop floor, its evolution from its birth in 1948 exemplifies features that are idiosyncratic. One is Honda's initial concentration on producing motorcycles. Beginning with motorized bicycles, Honda diversified into standard motorcycles, offering consumers first the Dream and Cub, later on the Super Cub that sported a "step through" design that generated enthusiasm among women. It was only after a full decade in the motorcycle market that Honda moved into the automobile business with its fuel-efficient Civic.

A second aspect of Honda's early evolution setting Honda apart from other Japanese firms is its dependence on the entrepreneurial energy of two radically different individuals, Soichiro Honda and Takeo Fujisawa. Honda was the inventor, attempting to mold Honda Motors into a "paperweight" type structure, granting the title chief engineer or executive engineer to a large number of individuals promoted because of their innovative creativity and drive, not because they were needed as supervisors for other employees, eschewing the "pyramid" style of management favored by most Japanese firms. Fujisawa's genius lay in other fields, notably marketing. He promoted the idea of differentiating dealership networks on the basis of the particular product being sold. For instance, when Honda introduced the Cub it avoided distributing it through dealerships already committed to the Dream who might naturally resist selling the Cub because they already had a backlog inventory of Dream motorcycles on hand. The dynamic duo of Honda and Fujisawa put an indelible stamp on the early history of Honda Motors that sets the company apart from its competitors.

Testimony to Honda's success in both automobiles and motorcycles are the following figures for fiscal year 2007: global automobile sales close to 4 million units (slightly less than half occurring in North America); global motorcycle sales slightly above 9 million units; and an operating profit of around US$8 billion. While Honda is overshadowed by Toyota and Nissan, it is a major player in global vehicle markets, carving out a remarkable trajectory of business success rooting in continuous ongoing innovation in both production and marketing.

Hong Kong

Hong Kong is one of two special administrative regions of the People's Republic of China. It is located on the eastern side of the Pearl River Delta. The territory includes Hong Kong Island, Lantau Island, the Kowloon Peninsula, and the New Territories. Its total area is 1,104 sq. km. The population was recorded as 6.99 million in 2006. Over 90 percent of the population are Chinese. The second half of the 20th century saw dramatic growth in Hong Kong's population, beginning with an influx of refugees from the mainland following the communist victory and the founding of the People's Republic of China (PRC). Thus, most Hong Kong residents are first- or second-generation immigrants. Hong Kong is one of the world's leading financial centers and was said to be the most economically free in the world from 1995 to 2008 according to the Heritage Foundation's Index of Economic Freedom.

Hong Kong was a small fishing community early in the 19th century. Its development began when it became a British colony following the signing of the Treaty of Nanking on August 29, 1842, when Hong Kong Island was ceded to Britain "in perpetuity." In 1860, after China's defeat in the second Opium War, Britain claimed the areas south of Boundary Street on the Kowloon Peninsula and Stonecutter's Island. These were ceded to Britain under the Convention of Peking. On June 9, 1898, the New Territories, including part of Kowloon and over 200 islands, were leased to Britain for 99 years. Hong Kong's administration followed the pattern for a British colony, with a governor nominated by Whitehall. In the late 19th century, Hong Kong was a major trading port of the British Empire in Asia. The Hong Kong and China Gas Company developed in 1861, the Peak Tram in 1885, and the Hong Kong Electric Company in 1889; China Light and Power followed in 1903, the electric tramways in 1904, and the Kowloon-Canton Railway in 1910.

Hong Kong's population suffered under Japanese occupation during World War II, but recovered quickly as mainland immigrants, fearing communist reprisals, sought refuge in the colony following the capitulation of the Nationalist forces and the establishment of the PRC in 1949. Many companies in Shanghai and Guangzhou shifted their operations to Hong Kong. Thus, the textile and other manufacturing industries grew and Hong Kong's population dramatically increased in the 1950s as people flocked to Hong Kong for jobs and security. Thousands of immigrants lived in squatter areas all over the colony, the most infamous of which became Shek Kip Mei. The Christmas Day fire of 1953 left 53,000 people homeless and galvanized the British rulers into developing Hong Kong's first public housing program. From its very humble beginnings, this program has developed to include general public housing (rent only) and home ownership schemes covering a wide range of salaries and needs in a territory where home purchase is out of financial reach of the majority.

During the 1960s, the textile industry made up about half of Hong Kong's domestic exports in value. From the 1960s to the 1980s, the manufacturing sector gradually moved from simple labor-intensive products to high–value added products. At that time, secondary production included manufacturing and construction, which made a significant contribution to the gross domestic product (GDP), while primary production became insignificant. The open door policy and economic reforms adopted by China in the 1980s provided (and continue to provide) Hong Kong's industrialists with cheaper labor and land. Using the cheaper supply of land and labor in the Pearl River Delta, industrialists gradually expanded their production bases across the border into mainland China while retaining their offices in Hong Kong. This operation mode enables the continuous economic development in Hong Kong.

In addition, Hong Kong's economy has become increasingly service-oriented since the 1980s. The share of the tertiary services sector in GDP rose from 71 percent in 1985 to 91 percent in 2005. The wholesale, retail, and import/export trades and hotels is the largest services sector and accounted for 29 percent of GDP in the services sector, followed by finance, insurance, real estate, and commercial services, which account for 22 percent; financial services, 13 percent; professional services, 11 percent; logistics, 10 percent; and tourism 3 percent. Hong Kong's total services trade amounted to US$13.8 billion in 2006, which is the world's 16th largest trading entity in value.

The largest share of total imports is electrical machinery, apparatus, and appliances, which was in total US$80.7 billion in 2006. This is followed by telecommunication equipment (US$43.0 billion) and office machines (US$36.5 billion). China, Japan, and

Taiwan are Hong Kong's major suppliers. Export figures in 2006 were US$17.2 billion, mainly from clothing and office machines. China, the United States, and the Netherlands are Hong Kong's largest markets. Re-exports are the most important trade for Hong Kong. The main origin primary re-export countries are China and the United States. Re-exports increased by 11.6 percent to US$333.3 billion in 2006. Electrical machinery, apparatus, and appliances are the main items. The Chinese mainland has long been Hong Kong's largest trading partner, accounting for about half of Hong Kong's total trade. Almost all re-export trade is related to mainland China.

Hong Kong's per capita GDP was US$27,680 in 2006, one of the highest in Asia. Hong Kong has a well-established and efficient infrastructure. It operates one of the busiest container ports and airports in the world. Hong Kong is the sixth-largest foreign exchange market in terms of turnover in the world and second-largest stock market in Asia in terms of market capitalization. Total market capitalization was US$1,710 billion at the end of 2006.

The Hong Kong stock market is an important fund-raising platform for mainland China companies. There are 367 China enterprises listed on the Stock Exchange of Hong Kong. In 2006 equity funds raised by China enterprises totaled US$49.3 billion. About US$39 billion were raised in initial public offerings (IPO) on the stock exchange, which constitutes 91 percent of total equity funds raised in IPOs. The total annual trading turnover of China enterprises accounted for 60 percent of the total annual trading turnover of the whole Hong Kong stock market. Moreover, Hong Kong's financial markets are operated in line with international standards, and ease of entry for professionals from outside contributes to the development of financial markets.

The Hong Kong government continues to improve Hong Kong's transport system to strengthen its competitive advantage in the city, especially the railway system. Rail travel constitutes about 35 percent of the total daily public transport volume. Hong Kong's Mass Transit Railway (MTR) has been in operation since 1979. The Light Rail system started operation in 1988 in the northwestern New Territories. A new international airport has been in operation at Chek Lap Kok since 1998. The Tseung Kwan O MTR line has been in operation since 2002, and the Disneyland Resort Line began operation in 2005. The Ma On Shan rail link between Tai Wai and Ma On Shan in the New Territories was opened in 2004, providing rail transport to the population in the eastern New Territories. The Sheung Shui to Lok Ma Chau line opened in 2007 to relieve the congestion at Lo Wu and shorten the travel time between Hong Kong and Shenzhen, one of the special economic zones in China and the closest to Hong Kong.

The tourism industry is one of Hong Kong's major sources of income. Tourist hot spots include Hong Kong Disneyland, Ocean Park, Hong Kong's Wetland Park, the Ngon Ping 360 cable car ride on Lantau Island, and the Peak Tram and Victoria Peak Tower. Over 25 million tourists visited Hong Kong in 2006 and the number of arrivals has continued growing steadily. Mainland China tourists account for over half of Hong Kong's visitors due to the opening and simplification of policies in certain cities in China on travel applications to Hong Kong. In addition, Hong Kong is recognized as providing some of the world's best convention and exhibition facilities. In 2006 there were over 200 international conventions and nearly 100 exhibitions, in turn attracting nearly one million attendees.

Hospitality Sector

The hospitality sector of the economy comprises two distinct but related industries, the hotel industry and the restaurant industry. The term is also often used to describe a larger system of companies that are interrelated conceptually or operationally in the food, beverage, travel, tourism, transportation, cruise, casino, theme park, leisure, and real estate industries. Globally this larger travel system employs more than 75 million people and represents almost 4 percent of aggregate gross domestic product.

The traditional value proposition for the hospitality sector is the provision of temporary lodging and prepared food away from home, but this has gradually expanded to include a variety of service and entertainment offerings. The term *hospitality* refers to the relationship between companies and consumers, which serves as a substitute for the rapport between hosts and guests in private homes.

The business of hospitality can be traced to early recorded history, for example, the *tabernae* (taverns or inns) of ancient Rome. Until recently, the hospitality sector was highly fragmented and lacked sophisticated management systems. However, as the demand for hotel and restaurant services expanded during the 20th century, several hospitality companies developed significant scale and scope, and the principles of managerial capitalism were gradually institutionalized. The multi-unit "chain" concept became increasingly dominant, and franchising was widely adopted as an expansion and financing technique. The late 20th century was characterized by the increasing segmentation of the industry, by the entry of chain operators into upscale segments, and by significant acquisition and consolidation activity. Notable moments include the listing by Sheraton on the New York Stock Exchange in 1947, and the inclusion of McDonald's in the Dow Jones Industrial Average in 1985.

Worldwide, 75 million people work in hospitality, and there are over four million guest rooms in the United States alone.

The hotel (or lodging) industry provides accommodations for travelers and related services such as onsite restaurants and spas. In the United States, the hotel industry generates annual revenues of more than US$125 billion and comprises more than 47,000 separate locations or "properties" with more than four million guest rooms. The industry is segmented vertically by price and amenity level (from "luxury" to "economy") and horizontally by usage patterns (such as "transient" or "extended stay").

The largest global hotel companies include Accor, Best Western, Carlson, Choice, Hilton, Hyatt, InterContinental, Marriott, Starwood, and Wyndham. With the exception of Best Western, each of these is a holding company with a portfolio of subsidiary brands. Examples include Marriott (which owns brands such as Ritz-Carlton and Courtyard) and Starwood (which owns brands such as Sheraton and Westin).

The restaurant (or foodservice) industry offers prepared food and beverage products away from home. In the United States, the restaurant industry generates annual revenues of more than US$500 billion and comprises more than 945,000 separate locations or "units." The industry is segmented vertically by price and amenity level (from "fine dining" to "quick service") and horizontally by style of cuisine (such as "French" or "barbecue").

The largest global restaurant companies include Brinker, Darden, McDonald's, OSI, Wendy's, and Yum. Several of these are holding companies with portfolios of subsidiary brands. Examples include Darden (which owns brands such as Olive Garden and Red Lobster) and Yum (which owns brands such as Kentucky Fried

Chicken and Pizza Hut). The restaurant industry also includes specialty food retailers (such as Starbucks) and contract foodservice operators (such as Aramark, Compass, and Sodexho). Restaurants within hotels are considered part of both industries, and therefore are doubled-counted in many industry statistics.

A Complex Industry

The structure of the hospitality industry is complex, with five distinct components. The first component is the ownership of the business itself. "Independents" are single-unit companies owned by independent entrepreneurs. "Chains" are multi-unit companies that often have a mixed ownership structure, with both "company-owned" locations and "franchised' locations in the same system.

The second component is the brand or name that appears on signage at each location, which is also called a "flag" in the hotel industry. For independents, the brand is owned by the independent business associated with each location. For chains, the brand is owned by a central corporate entity and loaned to each location for a specific period under a franchise or licensing agreement.

The third component is the daily operation of the hotel or restaurant. Independent locations are either self-managed by owners or managed under contract by an independent management company. Company-owned chain locations are usually managed by employees of the chain. Franchised chain locations may be self-managed by the local franchisee, managed under contract by a "third-party" management company, or managed by employees of the franchisor under a "management contract" arrangement.

The fourth component is the underlying real estate for each location, including both land and building. In the restaurant industry, leasing is more common than owning and many restaurants are located within retail space. In the hotel industry, most companies emphasize branding and operating activities, and rarely hold significant ownership interests in the real estate underlying their hotels. Most hotels are owned by the real estate developers who originally initiated the hotel projects, or by real estate investors and syndicates (such as "real estate investment trusts" or REITs).

The fifth component is the distribution system used to connect supply and demand within the marketplace. In the restaurant industry, this function is disorganized and informal. In the hotel industry, the distribution system is quite complex and sophisticated. Independent hotels typically operate their own reservations activities, but may also engage independent reservations services or join independent marketing consortia. Chain properties rely on the central corporate entity to provide distribution through its "central reservation system" (CRS) or proprietary Web site. Separate companies known as "global distribution systems" (GDS) provide interconnectivity between the various hotel reservations systems, travel agents, airline reservations systems, and internet travel sites.

Management and Measures

Professional management is now standard in many parts of the hospitality industry, especially within upscale segments and chain companies. Managers are recruited from undergraduate business schools, specialized hospitality management schools (such as the Cornell Hotel School), or culinary management programs (such as the Culinary Institute of America). Principles of management, control, and finance are similar to those used in other industrial sectors with four notable exceptions.

First, although hospitality offerings represent a hybrid of both intangible services and tangible products, elements of service and experience tend to dominate the value proposition, especially in upscale segments. As a result, the principles of service management (including human resource management and the design of service delivery systems) are critical to the success of any hospitality venture.

Second, regardless of the exact nature of ownership, real estate is embedded within the hotel industry. Hotel properties are capital intensive and purpose-built, meaning they cannot be converted easily for other uses. As such, real estate finance expertise is critical for corporate executives, asset managers, and senior operational managers in the hotel industry. Real estate finance expertise is less important in the restaurant industry.

Third, the hotel industry is characterized by constant supply (over the short term) and variable demand (due to factors such as seasonality), making synchronization of supply and demand difficult. As a result, the hotel industry has adopted variable pricing or "yield management" systems from the airline industry. This has evolved into an integrated system of forecasting, capacity analysis, variable pricing, and promotional marketing known as "revenue management." Variable pricing is less important in the restaurant industry.

Fourth, the hospitality sector has several specialized performance measures. These include capacity utilization calculations (such as "occupancy" percentage in the hotel industry and "turns" ratio in the restaurant industry), revenue per transaction calculations (such as "average daily rate" or ADR in the hotel industry and "average check" in the restaurant industry), and calculations that compare revenue to capacity (such as "revenue per available room" or REVPAR in the hotel industry and "revenue per available seat" or REVPAS in the restaurant industry).

Host Country

International business is a scientific discipline that is rapidly evolving in parallel with the efforts of most firms to engage themselves in foreign operations. It researches business activity in an international context at the country, firm, or consumer levels. In particular, the international activity of firms presupposes the transfer of production mechanisms and/or market practices from one country to another. Local corporations that eventually go international may build a manufacturing plant or assembly lines in a foreign country, they may be supplied with raw materials and resources, or they may establish an office of business associates who are responsible for the successful marketing of products in their respective countries of operation. These foreign countries that host production, sourcing, or market activities of internationalizing firms are referred to as "host countries" in the international business literature.

Especially, countries with high rates of unemployment or less developed countries (LDCs) compete intensively to make their national contexts a more promising ground for foreign direct investments (FDI) by international firms. Means through which prospective host countries compete to attract FDI include tax incentives, fair competition, skilled labor, or the elimination of bureaucracy. Thus, governance structures and regulatory schemes in both the private and public sectors must be aligned in such a way as to offer transparency and equal treatment within host countries.

Apart from LDCs, almost all countries in the world try to achieve a certain status of hosting international firms' activities. This is because the benefits for local economies' welfare and societies' well-being are well documented and have a lasting effect. The most apparent and much-wanted implication for a host country is the generation of employment through the creation of local marketing subsidiaries or opening of factories. Equally important are the increased cash flows to the host country through tax payments by foreign firms.

Another major advantage is the transfer of technical and managerial know-how from the home to the host country. Firms that choose to operate in a host country often collaborate with local corporations for such reasons as becoming acquainted with the local market's specificities or granting access to valuable resources and raw materials. As a result of this collaboration, firms learn from each other and have access to bits of knowledge, which would otherwise be impossible to get. In particular, Japan and Korea benefited greatly as host countries from such exchanges of technological know-how between local companies and Western counterparts; part of the last century's Japanese miracle is attributed to such fruitful collaborations.

Increasing competition between host and home firms also increases learning potential and the competitive stance of the host country. Local firms must increase their learning capacity and become even more proactive and competitive against an often more sophisticated foreign firm. Such an increase in local firms' competitiveness results in better servicing and needs-fulfilling products for the local population. A closed local market that does not encourage foreign competition may not provide the environmental inducements for economic growth and corporate sophistication.

Moreover, firms that want to invest in a host country are sometimes legally obliged to collaborate with a local business or they cannot assume a majority of ownership. Such collaborations also increase learning benefits for local firms that do not possess the resources to acquire knowledge elsewhere. An example of such a positive implication for the host country is the case of the Philippines. Major shipping firms that invest in that country for reasons of crew recruitment for their ships must collaborate with a Philippine business if they want to establish a branch there. In this way, local firms of the host country have been greatly advantaged through increased cash flows and managerial know-how.

Apart from the aforementioned benefits (corporate growth, seats of employment, financial inflows, and knowledge generation), international operations also generate disadvantages that may inhibit societal welfare in the host country. For example, many resource-seeking firms exploit local raw materials for their own benefit and, thus, significant natural resources become extinct without apparent benefits for the host country. The depletion of the rain forest in the Amazon basin is a characteristic example of unilateral foreign investment in a host country. Foreign timber or oil corporations have largely benefited while the turnover for the local economy is disproportional.

Additional drawbacks of FDI for the host country include the worsening of the balance of payments due to the repatriation of profits or the competitive pressures on local firms. Host country's business units may not afford to compete with often larger, market-seeking foreign corporations. As a result, an increasing number of local businesses cease to exist due to their inherent inability to compete against a multinational giant. Hyper-retailers, in particular, have been rightfully or not accused of destroying local retailing structures and are held accountable for the closure of many local small and medium enterprises (SMEs).

Summarizing, we can claim that a significant body of the international business literature suggests that governments should strive to make their countries host countries for FDI. However, benefits are not generated without establishing a proper platform of policies for hosting international activities. Knowledge sharing and dialogue with experienced host countries must be facilitated if countries want to alleviate poverty or reap aforementioned benefits as host countries. Otherwise, the drawbacks of being a host country will prevail and national competitiveness and well-being may be in jeopardy.

Hostile Takeovers

A hostile takeover is a corporate acquisition that is forcefully resisted by the target firm's top management and board of directors. Although they constitute less than 3 percent of all merger and acquisition (M&A) activity, hostile takeovers have long garnered a disproportionately large share of attention from the news media, the general public, and business scholars for many reasons. Compared to so-called friendly M&As, which are generally planned and negotiated in relative secrecy, hostile takeovers tend to unfold in a more public arena, where representatives of both the acquirer (popularly called a "raider") and target firm vie for the favor of shareholders, regulators, and other influential parties. Sociologists note how the intensity and ritualized nature of these contests has contributed to the unusually colorful terminology used to describe hostile takeovers. More than virtually any other corporate activity, hostile takeovers bring about abrupt and dramatic changes to a firm's strategy, structure, and leadership.

Hostile takeovers have remained a highly controversial practice since their inception in the United States during the early 1950s. While proponents argue that hostile takeovers serve an important corporate governance function that helps maximize shareholder value, critics emphasize their potentially damaging effect to such stakeholders as workers, the local community, and managers of the target firm.

Tender Offers and Proxy Contests

Within the United States, hostile takeovers are most frequently attempted through a financial and legal mechanism known as a tender offer (i.e., a public solicitation to purchase shares of the target company at a fixed price, within a given time period, and usually contingent upon shareholders tendering sufficient shares for the bidder to gain control of the firm). To convince shareholders to sell their shares, the tender offer price is usually set at a significant premium over the current market price (frequently 50 percent or more). Prior to announcing a tender offer, a raider will often purchase shares in the open stock market at prevailing market prices. Such purchases enable the raider to minimize the cost of a successful acquisition, and to sell these shares (often at a significant profit) if the hostile takeover attempt is not completed. Once accumulating more than 5 percent of a voting class of a company's equity, however, the acquirer is required by United States law to file a Schedule 13D (beneficial ownership report) within 10 days. Since the acquirer must disclose the purpose for the share purchase within Schedule 13D, the filing of this report often marks the beginning of the takeover battle.

With the extensive reporting requirements defined by federal law, particularly the Securities Exchange (1934) and Williams (1968) Acts, it would be very difficult in the United States for a party, or group of parties acting together, to gain control of a company solely by accumulating shares gradually in the open market (a practice known as a "creeping tender offer"). Some international business experts suggest that this approach may become an increasingly frequent and less costly alternative to traditional tender offers in countries with less stringent reporting requirements. At present, however, tender offers continue by far to be the most common hostile takeover mechanism worldwide.

Raiders may also initiate a proxy contest, an attempt to convince target firm shareholders to replace existing board members with a new group that will approve the acquisition. While tender offers and proxy contests can be used in tandem, they are often regarded as alternative mechanisms for accomplishing hostile takeovers. Empirical evidence suggests that proxy contests are more prevalent when there is greater evidence of managerial ineffectiveness, as measured by stock market performance and return on assets. Tender offers are used more frequently when the target is highly leveraged.

Anti-Takeover Measures

Companies can take several precautionary steps to curb the threat of a hostile takeover. The most famous anti-takeover measure is the "poison pill," which was first conceived by the attorney Martin Lipton in the 1980s. While there are many variations, the basic poison pill grants shareholders the option to purchase additional shares at a significant discount in the event of a hostile takeover bid, thus diluting the raider's ownership and making the acquisition more costly. Firms can also implement a "staggered board" in which directors serve multiyear terms with only a portion of members coming up for election each year. Another popular anti-takeover practice involves amending the corporate charter so that a "supermajority" of shareholders (often two-thirds or more) is needed to approve major strategic changes, including mergers. All of the anti-takeover practices highlighted above face rigorous opposition by shareholder rights activists.

Somewhat less controversially, a firm may include a provision in its charter that authorizes its directors to consider the well-being of stakeholders other than just shareholders when evaluating major strategic decisions. Once a hostile bid has been announced, the target firm may take on additional debt or sell off a valuable asset ("the crown jewels") to make itself less attractive. In a practice known as "greenmail," the target might buy back its shares from the raider at a premium. Thus, a failed hostile takeover could easily leave the target firm weaker, both competitively and financially, than prior to the bid. The target firm might also enlist a third party "white knight" to acquire sufficient shares to block the hostile takeover, or to initiate a friendly acquisition. Many target firms begin to pursue the types of practices most commonly associated with hostile acquirers, such as laying off workers, outsourcing, rationalizing operations through facility closures, and refocusing on core markets. Target firms will also commonly lobby governmental regulators and legislators to oppose the acquisition.

Effects

The use of hostile takeovers as a means for achieving good corporate governance was originally outlined by Henry Manne in 1965. According to his theoretical premise of a market for corporate control, stock prices are not only efficient but they also provide a critical indicator of managerial effectiveness. When a company's share price falls relative to the overall market, it signals that the firm's managers are underperforming. This, in turn, provides an incentive for an outside party to gain control of the company and implement changes that will increase shareholder value. Advocates of a market-based corporate governance system find this theoretical framework particularly appealing since monitoring managers directly is considered very costly and frequently ineffective. Regardless of whether managers are underperforming due to incompetence or self-interested behavior, the market for corporate control promises that the fault will become readily apparent via the firm's share price. Conversely, critics of hostile takeovers argue that the practice forces managers to focus too narrowly on short-term stock performance to the detriment of long-run shareholder value.

Another important debate involves whether the benefits of hostile takeovers are sufficient to offset their harmful effects. Hostile takeovers tend to lead to workforce reductions in both the target and acquiring organization that are even greater in magnitude than those of friendly acquisitions. The negative impact of facility closures on a local economy can be profound and enduring. Hostile takeovers have also been argued to reduce average wage levels by shifting employment away from older, longer-tenured workers.

Empirical findings support the contention that weak stock market and accounting performance increases a firm's likelihood of becoming a hostile takeover target. Shareholders of target firms generally experience substantial financial gains from hostile takeovers, as they also do from friendly acquisitions. While some studies suggest that the performance of the target generally improves after a hostile takeover, it is not clear that the acquirer benefits financially from these gains after accounting for the purchase premium.

Prevalence

The level of hostile takeover activity differs dramatically across countries. According to a 2004 study by William Schneper and Mauro Guillén, there were 478 hostile takeover attempts in the United States from 1988 to 2003, compared to 273 in the United Kingdom, 19 each in France and Sweden, seven in Germany, three each in Japan and Malaysia, and one in China. Hostile takeovers are relatively less common in countries characterized by high ownership concentration and where state ownership of firms is commonplace. While the corporate cross-ownership of shares has traditionally stifled the hostile takeover market in Japan, the unraveling of these arrangements during recent years has been accompanied by an increase in predatory activity.

From a more sociological perspective, hostile takeovers have been found to be more frequent in countries with strongly individualistic national cultures and where the corporate legal code privileges shareholder rights. Hostile takeovers are less common in countries where workers and commercial banks receive a stronger degree of legal protection. Despite the German system of codetermination, which guarantees workers a significant role in the control of firms, the recent movement toward *Unternehmenswertsteigerung* (increasing shareholder value) appears to have been accompanied by a nascent, but still growing, hostile takeover market. The hostile bid of €124 billion ($128 billion) for Germany's Mannesmann by the UK firm Vodafone in 1999 was the world's largest hostile takeover attempt to date. The deal was later completed as an amicable merger in 2000.

During 1993, China's first hostile bid resulted in Shanghai Bao gaining a 20 percent share of the Yanzhong Industrial Company. Whether hostile takeover activity will continue to spread in these and other countries remains an open question. Regardless of the answer, hostile takeovers will remain an important topic of discussion and spirited debate for the foreseeable future.

Housing Allowance

Typically an allowance paid to expatriates on long-term international assignments, a housing allowance is a financial benefit included in an expatriate's remuneration package to cover the costs of housing in a new location. With the possible exception of foreign taxes and school fees, housing is usually the most expensive portion of an expatriate's international assignment costs. The cost of renting overseas is usually higher than in one's home country because in many popular expatriate destinations, the presence of foreigners drives up rental costs for housing likely to be chosen by expatriates. Temporary rentals on a two-to-three-year lease also tend to be more expensive than permanent housing in one's home country.

A housing allowance is usually included in an expatriate's remuneration package to ensure that expatriates pay no more for housing while abroad than they would have paid had they stayed at home. This is commonly referred to as the "balance sheet" approach. However, inherent in the concept is the expectation that expatriates should still contribute a portion of their salary toward foreign housing costs, just as they would for housing in their home country. To determine the amount of housing allowance to be paid, most organizations base their decision on knowledge of a location's rental market, experience in that market with other expatriates, and advice from external data sources (e.g., housing guidelines from consulting firms). Seniority, salary, and family size may also influence the amount of housing allowance paid or offered. Housing allowances are then set either at a fixed amount per month/year or using rental cost guidelines that allow for some flexibility if a specific need exists.

In addition to the above, other approaches to housing allowances may also be adopted. For example, some organizations share the cost of housing with expatriates by paying an approved amount and permitting an expatriate to pay the extra portion if he/she wishes to live in more expensive accommodations. Many organizations also prefer to hold the lease in the company's name for tax purposes, as most countries consider cash payments for rent to expatriates (through remuneration) as taxable. When the organization holds the lease, it is treated as a business expense, which can substantially reduce the amount of tax due. There are also some locations where rental property owners require that a lease be held in a company's name to ensure that if the expatriate moves out before the lease has expired, the rental income can still be obtained. In these locations, rental-property owners prefer to enter into a contract based on the security of a company's continued presence in that location rather than risk leasing their property to nonpermanent expatriates. In some cases, particularly in remote locations, a company may provide accommodation in residences owned by the organization. This typically occurs in locations where a company may have a long-term presence, but it is more cost-effective to own homes or apartments for expatriates' use.

Utility costs may or may not be included in a housing allowance. Since rental charges do not include utilities, it has become common practice in some locations (particularly in locations where utility charges are high) for organizations to pay all utility costs or a fixed monthly utility allowance. Utilities can include electricity, gas, wood, heating oil, water, septic tank or sewage connection, garbage collection, and cable television. If utility charges exceed a fixed monthly allowance, the expatriate is expected to pay the difference. If utility charges do not exceed a fixed monthly allowance, expatriates typically are not entitled to receive the shortfall.

The issue of maintaining an expatriate's primary home-country residence is also of interest in calculating a housing allowance. As most organizations discourage expatriates from selling their home-country residence (due to the temporary nature of most assignments; expatriates will likely return to their home-country after two or three years), expatriates during an assignment will therefore continue to incur costs associated with their primary residence that may or may not be compensated via their housing allowance (especially if a housing allowance is shared between expatriate and employer). This additional cost can be of concern to expatriates. Most organizations overcome this problem by encouraging expatriates to rent out their primary residence during their absence overseas at a cost that will cover all or much of the mortgage payment. Where a shortfall exists, organizations often subsidize the interest payment of a mortgage, with the knowledge that full replacement of these payments is not necessary given that mortgage payments contribute toward a family's overall equity position.

When rental of the home-country residence is not practical or advisable, organizations may adjust a housing allowance if the expatriate can present legitimate reasons. These reasons can include that the expatriate is required to leave his family at home due to the nature of the assignment (e.g., the children must remain in school), or that the assignee is unable to rent their primary residence and will thereby incur additional costs beyond their control. In these situations, organizations might not adjust a housing allowance but instead might increase an expatriate's salary.

HSBC Holdings

Promoting its slogan "the world's local bank," HSBC is one of the largest banking and financial services organizations in the world. While HSBC Holdings plc is incorporated in England and headquartered in London (although only from 1993; it was previously based in Hong Kong), it has operations throughout Europe (pre-tax profits in France alone exceeded US$1 billion for the first time in 2007), the Asia-Pacific region, the Americas, the Middle East, and Africa. Indeed, the company's emerging markets of Asia, the Middle East, and Latin America now contribute more than 60 percent of group pre-tax profits. There are around 10,000 offices located in 82 countries and territories; 312,000 employees worldwide; and 125 million customers (35 million of whom are registered for internet banking). This is, therefore, a significant undertaking by any measure.

HSBC Holdings is listed on the stock exchanges of London, Hong Kong, New York, Paris, and Bermuda.

There are over 200,000 shareholders spread across 100 countries and territories.

Not surprisingly for a banking colossus, HSBC's growth has been both organic and via numerous acquisitions. The bank's origins can be traced back to 1865 with the establishment in that year of the Hongkong and Shanghai Banking Corporation Limited, which even though founded in Hong Kong, very early on had offices in both Shanghai and London, as well as an agency in San Francisco. Numerous acquisitions followed over the years, although in the European case these were principally those of the grossly mismanaged Midland Bank plc (now HSBC Bank plc) in the United Kingdom (whose shares were acquired over many years, and the remaining equity purchased in 1992); and, in France, one of that country's largest banks, CCF (now HSBC France) in 2000. Other acquisitions over the last half-century have taken HSBC into the Middle East (1959) in general and Saudi Arabia in particular (1978), the United States (initially in 1980, although more acquisitions followed), Germany (1980), Canada (1981), Egypt (1982), Australia (1986), Malaysia (1994), Brazil and Argentina (1997), Luxembourg and Malta (1999), Turkey (2001), Mexico (2002), China (2003), Bermuda (2004), and Central America (2006).

As would be expected in the case of a major force in the world's banking industry, HSBC offers products in many domains, including personal financial services (including consumer finance); commercial banking; corporate and investment banking; and private banking (for individuals with high net worth).

As with many other "household name" businesses, HSBC has proven itself anxious to establish its corporate social responsibility credentials, which it has attempted along a number of dimensions. As an illustration, the company has established the HSBC Climate Partnership, which is a five-year agreement between itself, the Climate Group, the Earthwatch Institute, the Smithsonian Tropical Institute, and the World Wide Fund for Nature. At US$100 million, HSBC's investment (the largest ever to each of the specified environmental charities) aims to combat climate change, through all of the activities of individuals, businesses, and governments, on a worldwide scale.

HSBC additionally supports the local communities in which it operates through both financial donations and via the various involvements of its employees, with the principal objectives being education (particularly of the young) and the environment. In fact, three-quarters of HSBC's charitable giving is directed toward just these two specified areas.

Commitment to the environment (particularly climate change) is evidenced by HSBC's intention to become "the first major bank to go carbon neutral" (although it has to be said that becoming "less of a carbon contributor" might be a more realistic objective for which to aim. Hence the "offsetting" of any "remaining" [i.e., after energy efficiency and green electricity initiatives have been pushed to the limit] carbon dioxide emissions using carbon "allowances" or "credits" would not appear per se to represent much of a "solution" to the carbon emission problem).

Elsewhere, HSBC has been concerned to develop a "sustainable approach to banking" that includes such things as the adoption of the Ecuador Principles (a set of voluntary guidelines that addresses the environmental and social issues that arise in project financing), and the avoidance of certain types of business (such as financing weapons manufacture, dealing with countries the subject of international sanctions, or the laundering of earnings from crime or tax evasion).

As HSBC has maintained, the group's "goal is not, and never has been, profit at any cost" because it is aware that tomorrow's success depends upon the trust it builds today. HSBC Holdings plc fared better than most banks in the 2008 banking crisis.

Hudson's Bay Company

North America's oldest continuously operating commercial enterprise, the Hudson's Bay Company (HBC), officially known as The Governor and Company of Adventurers of England trading into Hudson's Bay, was founded on May 2, 1670, to trade with aboriginals in Canada, mostly for furs. At one time the HBC was the world's largest landowner, controlling the massive drainage area around the Hudson's Bay known as Rupert's Land. The company's head, styled a Governor, was, in essence, in control of most of what is now northern Canada, chiefly through overseeing aspects of trade with the aboriginal peoples. Today the company is a retail entity in Canada.

Granted a charter by King Charles II of England in 1670, the company set up its first trading post in what is now northern Manitoba. Competing with the French-controlled fur trade out of Montreal, the HBC focused on using its access through the bay to establish links with the interior, and to build forts that allowed it to control as much of the fur trade as possible. By the end of the 18th century, the HBC had a string of forts called factories, managed by "factors" (the head of each factory), and acted as the de facto authority of state, notwithstanding the constant fighting between the HBC and French traders and French imperial forces.

The French were eventually defeated in North America, ceding all of Canada to Great Britain in 1763. However, Montreal fur trading interests persisted, establishing the North West Company in 1779. In 1821, following decades of conflict between the two entities, the HBC and the North West Company merged, giving the HBC a monopoly on the entire fur trade for northern North America. This period was overseen by George Simpson, who ran the company from 1821 to 1860. During this time, the company issued its own currency and played a key role in the administration of affairs over much of western Canada and the northwestern United States. Its traders and administrators were responsible for charting and settling much of the region.

Eventually, aboriginals and other traders protested and challenged the HBC's monopoly over all trade in the North West. By the 1860s, the monopoly was no longer enforceable, and in 1869 the company sold Rupert's Land for £300,000 to the young Canadian government, which had itself only been established in 1867. The handover took place in 1870, following an uprising in the Red River Colony by the Métis, the mixed aboriginal and European offspring of the original fur traders. The Métis and their charismatic leader Louis Riel challenged the transaction and forced the creation of the province of Manitoba. Donald Smith, later known as Lord Strathcona, a leading figure in Canadian business and politics, who worked for the HBC for 75 years from 1838 to 1914, negotiated the transfer. This marked the end of the HBC's role as the de facto government of the North West, though its influence remained through its real estate holdings and stores.

The Hudson's Bay Company's activity is now primarily retail—and included this The Bay department store in Toronto in 2007.

By the 20th century, the company had become essentially a retail operation, known as "The Bay." It ended its involvement with northern stores, sold most of its real estate holdings, and largely cut its ties with the fur trade. Its first department store had opened in Winnipeg, Manitoba, in 1881, and the company developed a chain across the country. In 1970, on the company's 300th anniversary, the HBC's headquarters were transferred from London, England, to Winnipeg. In 1979 Canadian Ken Thomson brought the firm into Canadian control by purchasing it for $641 million. Until that time, it had been controlled by British investors. In 2006 the company was purchased by American Jerry Zucker, who became the first U.S. citizen to become governor of the company. In 2008 the company was again sold, this time to U.S. firm NRDC Equity Partners, which owns U.S. retailer Lord and Taylor. In recent years the company has faced difficulties in the very competitive Canadian retail sector, especially against newer entrants such as Wal-Mart.

Because of its age and its place in Canadian history, the Hudson's Bay Company retains significant corporate and emotional symbolism as North America's oldest company, and the last major Canadian-based (but not Canadian-owned) retailer and department store. While many Canadians were unhappy to see the company purchased by an American, they recognized that this may have been its only choice if it wished to continue as an entity.

Hungary

Hungary is a small, landlocked, central European country, capital Budapest, with a population of 10 million. Although its international economic reputation suffered in the first decade of the new century, it has established a positive image as a progressive post-communist state. The modern Hungarian state is a product of the defeat in World War I of the Austro-Hungarian Empire. Although Hungarian nationalists saw themselves as victims of Vienna, the creation of a dual monarchy in 1867 gave Budapest considerable power. It was not used wisely. Many other peoples within the larger Hungarian kingdom saw themselves as oppressed. The Treaty of Trianon much reduced the size of the new Hungary. The largest loss was the transfer of Transylvania to Romania. Inter-war Hungarian politics were reactionary and embittered, especially after the failure of the revolution in 1919. Hungary supported the Nazis during World War II. The country was liberated by the Red Army, and it became a communist state in 1948–49.

In 1956 a revolution, led as much by workers as by intellectuals, broke out. It was suppressed by Soviet forces. After several years of repression, the communist leadership under Janos Kadar made an attempt to compromise. Market-style "socialism" was created and the basis laid for more positive social provision and a more tolerant political atmosphere. This gave Hungary a special place in the communist bloc, which augured well for the country when the communist system collapsed in 1989–90.

Today the idea of restoring a greater Hungary is restricted to the fringes. But claims to a special Hungarian distinctiveness, whether in terms of the assertion that the state's history goes back to the crowning of King Steven in 1000 A.D. or speculation about the uniqueness of the language, or other peculiarities remain, even if some scholars remain skeptical. Conflicts with Hungary's neighbors have been removed, but a major issue remains with Slovakia over Hungarian opposition to a major hydroelectric dam project that is of enormous symbolic significance in Hungarian politics.

In the 1990s, Hungary was a relative success story. It had the highest per capita foreign direct investment (FDI) in the transition bloc and at one stage received around one-third of the FDI in the whole region. It still holds a prominent FDI position today. Budapest gained a reputation as a welcoming and modern European capital. Privatization was undertaken relatively rapidly.

Today agriculture plays a small part in the Hungarian economy, providing only 3 percent of output. Industry produces around 32 percent and services 66 percent of output. The leading industries are telecommunications equipment and electrical and other kinds of machinery. Hungarian trade was quickly refocused on the West in the 1990s, and today Germany, within the EU, is the dominant trading partner, with some 30 percent of imports and exports. However, Hungary still depends on energy imports from Russia.

But beneath the surface there were many difficulties. A black economy continues to be important, and Hungary has one of the lowest labor-force participation rates in the former Soviet bloc. There are serious regional inequalities, with a rust belt of decaying iron and steel, machinery, and ex-mining towns, while the local wealthy and foreigners have second homes on the shores of Lake Balaton in the west of the country. The country is 65 percent urban, with more prosperous Budapest looming disproportionately large.

Hungary quickly joined Western organizations, including NATO in 1999. The key focus, however, was European Union accession. This was gained in 2004, although the accession referendum produced an 84 percent yes vote on the basis of a turnout of only 46 percent. Hungary's leaders have also looked to develop links with Washington. Hungary, along with Poland and the Czech Republic, gave prominent support, despite opposition at home, to the U.S. invasion of Iraq.

In recent years, Hungary's reputation has suffered as its previously ailing neighbors like Slovakia began to recover. Gross domestic product growth has been less impressive and there have been concerns about both the current account deficit and the budget deficit. The government eventually responded to the latter by austerity measures that cut subsidies and raised taxes.

There is a tradition of political opposition and change. While some commentators attack Hungary's relatively high corporate, income, and social security taxes, Hungarians tend to value the higher spending that results. So do many leading foreign companies. The higher level of productivity and style of life continues to be attractive. This includes the facility with English that marks the most educated (although it can be a misleading guide to the wider population). This reduces the tendency of FDI to relocate further east.

Hyundai Motor

Hyundai was founded by Chung Ju-yung and became one of largest conglomerate companies in South Korea. As a family-run Korean business group (chaebol), the most well-known Hyundai organization is the Hyundai Motor Company, the world's fifth-largest automaker. Hyundai Heavy Industries is the world's largest shipbuilder, and Hynix is a top semiconductor producer

The Hyundai Group was established in 1947 with the initial construction company, named Hyundai Togun. After the Korean War, the company displayed spectacular growth and rapid expansion as a result of the postwar government-led reconstruction programs. Since its founding, it also expanded rapidly into car manufacturing, construction, shipbuilding, electronics, and financial services. The company was involved in the early stages of the country's recovery following World War II. After the Korean War, development intensified, and Hyundai was quick to take on a key role, working on civil and industrial projects as well as housing programs. Consequently, Hyundai worked with the government in rebuilding the economy and formed an integral part of Korea's economic strategy.

One of the most significant moves was made in 1975, when the group began constructing an integrated car factory. It was the foundation of South Korea's largest auto company, one that was to dominate Korea's home and export markets. The vehicle was launched in 1975. By the following year, Hyundai was producing 30,000 cars, and by 1979 the total had risen to 110,000.

Hyundai kept expanding its business activities into more various areas. It created Dongsu Industrial Company, a construction-material manufacturer in 1975, and Seohan Development Company, a welding and electrode carbide maker in 1976. For trading arms of these companies, the group also set up Hyundai Corporation. At the same time, it created Hyundai Merchant Marine Company, which concentrated on cargo services, chartering, brokerage, and related services, and Koryeo Industrial Development Company and Hyundai Housing and Industrial Development Company, whose operations included construction design and property development. Hyundai also expanded into the business of precision industry, timber, and heavy and chemical industries, including iron and steel manufacturing.

Hyundai's influence stretched far beyond the Korean peninsula as the company won contracts to build an expressway in Thailand and a major port in Saudi Arabia. Hyundai dominated the Korean market and quickly became a major player on the international scene. By the 1970s, Hyundai began to build vessels as well as shipyards and by 1986, Hyundai produced its first vehicle made entirely from Korean components. From the 1980s, Hyundai added additional specialties including the building of semiconductors and magnetic levitation trains.

Following the creation in 1983 of Hyundai Electronics, Hyundai stepped up its presence in the electronics field and produced semiconductors, telecommunication equipment, and industrial electronic systems. The group as a whole had proven itself capable of taking diverse markets and was determined to maintain and expand its markets by stepping up research-and-development spending focusing on technology.

The South Korean economy took a turn for the worse during the late 1990s. In order to restore the nation's financial health, President Kim Dae Jung, who took office in 1998, launched a series of restructuring programs designed to reform the chaebols, many of which had become heavily debt-burdened. His reforms aimed at dismantling large, often corrupt, chaebols and included changing the ownership, business, and financial structures of the region's large conglomerates. By this time, the Hyundai Group was responsible for approximately 20 percent of Korea's gross domestic product. As such, its financial health was directly related to South Korea's overall economic condition.

As a result of government pressures, Hyundai and other South Korean chaebols set plans in motion to sell off many of their businesses in order to pay down debt and shore up profits. Upon Chung Ju-yung's death in 2001, much of the Hyundai Group was dismantled. In August 2001 nine core Hyundai companies, including Hyundai Engineering & Construction and Hynix Semiconductor, Inc. (formerly known as Hyundai Electronics Industries), left the chaebol. Hyundai Motor Co. was prospering as Korea's largest car maker, but officially separated from the Hyundai Group in September 2000. After the separation, Hyundai Group focused on elevators, container services, and tourism to Mount Kumgang located in North Korea.

Iceland

Iceland is an island in the North Atlantic, divided into eight regions by geographical orientation and/or geographical characteristic, e.g., the Southwest Peninsula, all of which add up to an area of approximately 102,819 sq. km (39,698 sq. mi.). Its capital is Reykjavik (pronounced “rake-a-vik”). The climate is a cool temperate oceanic, but it is changeable and mild because of the Gulf Stream and southwest winds. The present constitution came into force on June 17, 1994, and has been amended four times since, with the most recent amendment on June 24, 1999. The parliament (Alpingi) is elected in accordance with the electoral law of 1999, which provides an Alpingi of 63 members. The current president (a largely ceremonial office) is Olafur Rafnar Grimsson, who was reelected in 2004 by a direct popular vote.

The current prime minister is Geir Hilmar Haarde, who promised to reduce inflation, confirmed Iceland’s contribution to peacekeeping forces in Afghanistan, and reasserted the aim to secure a seat on the United Nations Security Council in 2008. However, Iceland possesses no armed forces, since under NATO, U.S. forces were stationed in Iceland as the Iceland Defense Force until an agreement was signed in September 2006, withdrawing all U.S. forces from the island.

Iceland is a member of over 10 organizations such as the World Trade Organization, the Council of Europe, and the European Free Trade Association. The economy has grown since the mid-1990s as a result of privatization and deregulation. Per capita income has doubled over the last two decades, and in 2005, gross domestic product per capita was US$54,427. The growing economy spurred Iceland’s aim to become the world’s first “hydrogen economy,” which it initiated by converting its buses into fuel cell–powered vehicles in 2003. Iceland intends to run all its transport and fishing fleet on hydrogen produced on the island.

Fishing is vital to Iceland’s economy. The per capita consumption of fish and fishery products is the second highest in the world, after the Maldives. Iceland’s main imports in 2005 were industrial supplies, transport equipment, fuels and lubricants, and food and beverages. Its main exports in the same year were fish, crustaceans, mollusks, mineral and chemical products, health care and toilet articles, and transport equipment.

Corruption is very limited in Iceland; it is generally considered one of the least corrupt nations in the world. There are three levels of courts in Iceland: district, appellate, and the supreme court, which has eight judges. The justices elect the chief justice for a period

A salmon fishery in Iceland, where fish, crustaceans, and mollusks are three of the top exports.

of two years. The penal population in September 2005 was 40 per 100,000 of the national population.

Primary education is compulsory and free from 6 to 15 years of age. Optional secondary education from 16 to 19 is also free. The adult literacy rate is at least 99 percent. Iceland has one of the lowest alcohol consumption rates in Europe. The national church is the Evangelical Lutheran, which is endowed by the state. There is one World Heritage Site in Pingvellir National Park, located on an active volcano. The Reykjavik Arts Festival is held every May–June, which features international artists and performers. Iceland publishes more books per person than any other country in the world. There were 258,000 internet users in 2005, or 88 percent of the total population, which is the highest percentage in the world.

Overall, literacy, longevity, income, and social cohesion are on par with world standards. In fact, Iceland is rated number one on high human development by the United Nations Development Programme and life expectancy is third in the world at 81.5 years.

Iceland became independent on June 17, 1944. Long before independence, Iceland was settled in 874 by Ingólfir Arnarson, who came from Norway to where Reykjavik is today. Most of the 400 migrants who followed him arrived from other Nordic countries and from Norse settlements located in the British Isles. In 930, the first-ever democratic national assembly, the Alpingi, was established. In 1000, Christianity was adopted as the island's official religion. Iceland's only indigenous wood, birch wood, which was in abundance, was valuable in making charcoal. However, in the 14th century birch wood became depleted and this, combined with soil erosion, led to a halt in crop growth. In the 15th century, the Black Death expanded to Iceland on two occasions, killing half the population. Iceland was independent for over 300 years before it was ruled by Norway and Denmark. In 1875, the Askja volcano erupted and damaged the Icelandic economy to the point of widespread famine. Shortly after, 20 percent of the island's population emigrated, mostly to Canada and the United States.

Economic Crisis

Iceland was an early victim of the global financial crisis as its currency plunged and its financial system all but collapsed in October 2008. This was mainly caused by the billions of dollars of foreign debts incurred by its banks. Iceland's banking system had collapsed as a culmination of a series of decisions the banks made that left them highly exposed to disruptions in financial markets. The top three commercial banks were ultimately nationalized.

On November 19, 2008, Iceland and the International Monetary Fund (IMF) finalized an agreement on a $6 billion economic stabilization program supported by a $2.1 billion loan from the IMF. Following the IMF decision, Denmark, Finland, Norway, and Sweden agreed to provide an additional $2.5 billion. New laws have been passed and restructuring of the financial system implemented to prevent a recurrence.

The economic meltdown had a devastating effect on the Icelandic economy. External debt increased threefold from being one of the lowest in the world and unemployment and inflation are affecting people's lives. The government feels, however, that the foundation of Iceland's economy remains strong and its clean energy, marine resources, strong infrastructure, and well-educated workforce provide a firm basis to overcome these severe economic difficulties.

Impact Financial Statements

Impact financial statements, financial impact statements, or fiscal impact statements are documents prepared to analyze and summarize the financial impact of an event or decision. They are prepared not only by corporations, but by governments contemplating the foreseeable financial effects of a policy decision.

Financial statements called for by the Generally Accepted Accounting Principles can include balance sheets, which summarize a business's current financial position; profit and loss, or income, statements, which report the income and outgo over a specified period of time; retained earnings statements, which calculate changes to the business's retained earnings (the amount of income kept by the corporation instead of being paid out in dividends); and cash flow statements. Federal governmental financial statements are governed by the 1990 Chief Financial Officers Act, part of an effort to reform federal fiscal management, and the Federal Accounting Standards Advisory Board.

Impact financial statements focus this information specifically on the consequences of a determination that needs to be made by the organization. There may be some speculative element involved, such as if a corporation is considering a reduced price for its product in anticipation of an increase in demand and total profits.

Fiscal impact statements are especially associated with government ballot measures. Such statements estimate the cost to a state or municipal treasury of implementing a proposed measure; interested voters and other parties can then have a sense of the effect on their taxes or other government spending areas of this measure. Depending on the measure, this can of course be a highly politicized matter. Some states have adopted formal procedures for the preparation of impact statements related to ballot initiatives. Alaska requires that simplified impact statements be included in initiative petitions, so that those petitioning to get a measure included on the ballot have been informed of the cost. The attorneys general of California and Montana evaluate each proposed measure to determine if it will have a fiscal impact; if it does, they order an analysis prepared by a state government body. In California's case, this is the executive branch's Department of Finance and the legislature's Joint Legislative Budget Committee. Montana gives the matter to the state budget director, who works in conjunction with the state agencies affected by the ballot measure.

Florida has a state commission, the Financial Impact Estimating Conference, that produces impact statements within 45 days of a measure's final revision, submitting the statements to the attorney general and secretary of state. The conference includes a member from the governor's office and representatives from the Senate, House of Representatives, and the Office of Economic and Demographic Research. Meetings are open to the public.

Import

It has been argued that importing is simply the opposite of exporting. An organization or an individual in one country purchases goods and services from a seller in another country with the aim of making a profit in the transaction. There are certain aspects of importing that are unique. For example, tariffs and import quotas are only relevant for the importers. The basics of importing involve customs brokers, import restrictions, terms of sale, foreign commercial payments, foreign trade zones, and customs bonded warehouses.

Customs Brokers

A customs broker is often a private company that operates as a middleman between the department of customs in a country and the importing public. Such a relationship will continue to proliferate as long as there are legal requirements regarding the movement of merchandise between countries. Just like a freight forwarder, the customs broker is a private service company licensed to assist importers in the movement of their goods.

Worldwide, billions of dollars in duty collections are filed each year with the customs departments of numerous countries, and they are all predominantly filed and prepared by customs brokers on behalf of importers. Some brokers are sole proprietors with a single office at one port of entry; others are multinational corporations with branches in many ports throughout the world. Customs brokers may be required to be licensed and regulated, for example, in Australia.

The customs broker is employed as an agent by the importer and is often the only point of contact the importer has with the Department of Customs in the respective countries. It is not necessary for an importer to employ a broker to enter goods on its own behalf; however, a bond is required if the importer chooses to handle entry. Most importers who have been in the business for a long time usually engage the services of customs brokers because of the additional services they offer and provide. These include satisfaction in the knowledge that an organization that knows what needs doing with respect to legislation and government bureaucracy is dealing with those issues for you and can provide the answers to many technical questions. Additionally, the importer's time is more valuable and better spent in managing their organization than dealing with the paperwork involved for the product to gain entry into a country.

A customs broker's duties include advising on the technical requirements of importing, preparing and filing entry documents, obtaining the necessary bonds, securing the release of products, arranging delivery to the importer's premises or warehouse, and obtaining drawback refunds.

Drawback involves refunding import duties that have been paid on imported goods if those goods end up being exported out of the country. For example, re-exporting goods that were originally imported; exporting items that contain imported merchandise; or, exporting items that contain wholly imported components. For each of these different scenarios, an importer could be eligible to claim a drawback of the original tariffs paid when first imported. The key to this opportunity is good inventory management and being able to track and keep a record of the movement of inventory. The broker often consults with customs officials to ascertain the correct rate of duty. If the broker is dissatisfied with the rate, the broker will pursue the appropriate remedy on behalf of the importer.

Import Restrictions

When an importer plans a sale to a foreign buyer, it is necessary to examine the import restrictions and regulations of the importing country as well as the export restrictions of the home country. Although the responsibility of import restrictions rests with the importer, the exporter does not want to ship goods until it is certain that all import regulations have been met. Goods without proper documentation will be denied entry. Some of the import restrictions imposed by foreign countries include tariffs, import quotas, exchange control, and invisible tariffs to name but a few.

A tariff is a tax on products imported from other countries. The tax may be levied on the quantity, such as $.10 per kilogram, liter or meter, or on the value of the imported goods, such as 10 or 20 percent ad valorem. A tariff levied on quantity is called a specific duty and is used especially for primary commodities. Ad valorem duties are generally levied on manufactured products.

Governments have two purposes in imposing tariffs: They may wish to earn revenue and/or make foreign goods more expensive in order to protect national producers. Tariffs affect pricing, product, and distribution policies of the international marketer as well as foreign investment decisions. If the firm is supplying a market by exports, the tariff increases the price of its product and reduces its competitiveness in that market. This necessitates a price structure that minimizes the tariff barrier. The product may be modified or stripped down to lower the price or to get a more favorable tariff classification. For example, watches could be taxed either as time pieces at one rate or as jewelry at a higher rate. The manufacturer might be able to adapt its product to meet the lower tariff.

Another way the manufacturer can minimize the tariff burden is to ship the products completely knocked down (CKD) for assembly in the local market. The tariff on unassembled products or ingredients is usually lower than that on completely finished goods. The importing country employs a tariff differential to promote local employment.

Quantitative restrictions, or import quotas, are barriers to imports. They set absolute limits on the amount of goods that may enter the country. An import quota can be a more serious restriction than a tariff because the firm has less flexibility in responding to it. Price or product modifications do not get around quotas the way they might get around tariffs. The government's goal in establishing quotas on imports is obviously not revenue. It gets none. Its goal instead is the conservation of scarce foreign exchange and/or the protection of local production in the product lines affected. About the only response a firm can make to a quota is to assure itself a share of the quota or to set up local production if the market size warrants it. Since the latter is in accord with the wishes of the government, the firm might be regarded favorably for taking such action.

The most complete tool for the regulation of foreign exchange is exchange control, a government monopoly of all dealings in foreign exchange. Exchange control means that foreign exchange is scarce and that the government is rationing it according to its own priorities. A national company earning foreign exchange from its exports must sell this foreign exchange to the control agency, usually the central bank. In turn, a company wishing to buy goods from abroad must buy its foreign exchange from the control agency.

Firms in the country have to be on the government's favored list to get exchange for imported supplies. Alternatively, they may try to develop local suppliers, running the risk of higher costs and indifferent quality control. The firms exporting to that nation must also be on the government's favored list. Otherwise, they will lose their market if importers can get no foreign exchange to pay them. Generally, exchange-control countries favor the import of capital goods and necessary consumer goods, but not luxuries. While the definition of "luxuries" varies from country to country, it usually includes cars, appliances, and cosmetics. If the exporter does lose its market through exchange control, about the only option is to produce within the country if the market is large enough for this to be profitable.

There are other government barriers to international trade that are hard to classify, for example, administrative protection, the invisible tariff, or non-tariff barriers. As traditional trade barriers have declined since World War II, the non-tariff barriers have taken on added significance. They include such things as customs documentation requirements, marks of origin, food and drug laws, labeling laws, anti-dumping laws, "buy-national" policies, and so on.

Terms of Sale

International terms of sale indicate how the importer and exporter divide risks and obligations and, therefore, the costs associated with specific international transactions. When quoting prices, it is important to make them meaningful. The most commonly used international trade terms include the following:

- Currency of Settlement: Some exporters always set their prices in U.S. dollars, which results in the importer bearing the foreign exchange risk arising from the transaction.
- Shipping Terms: It is essential that both the exporter and the importer are clear as to exactly what is included in the price quotation. There are five primary alternatives with regard to shipping terms. These are (a) Delivered Duty Paid: the export price quoted includes the costs of delivery to the importers' premises; (b) Cost, Insurance, Freight (CIF): the exporter quotes a price that includes coverage of transport and insurance charges to a named overseas point of disembarkation; (c) Free on Board (FOB): the exporter's price quote includes coverage of all charges up to the point when the goods have been loaded onto the designated transport vehicle; (d) Free Alongside Ship (FAS): the exporter's price quote includes coverage of all charges up to delivery of the goods alongside the vessel at the named port of shipment; and (e) Ex-Works: the price quoted by the exporter applies at a specific point of origin, usually the factory, warehouse, mine,

or plantation, and the buyer is responsible for all charges from this point.

Foreign Commercial Payments

The sale of goods in foreign countries is complicated by the risks encountered when dealing with foreign customers. There are risks from inadequate credit reports on customers; problems of currency exchange controls, distance, and different legal systems; and the cost and difficulty of collecting bad debts that a require a different emphasis on payment systems. When conducting transactions in the domestic market the typical payment procedure for established customers is an open account. However, the most frequently used term of payment in foreign commercial transactions for both export and import sales is the letter of credit. The five basic payment options for both importers and exporters in decreasing order of attractiveness for foreign commercial transactions are as follows:

1. Cash in Advance: The exporter receives payment before the shipment of goods. This minimizes the exporter's risk and financial exposure since there is no collection risk and no interest cost on accounts receivable. However, importers will rarely agree to these terms since it ties up their capital and the goods may not be received.
2. Letter of Credit: These are widely used in international trade since they minimize the risk for both exporter and importer. A letter of credit is a document issued by the importer's bank guaranteeing to pay the exporter so long as conditions relating to the sale, which are specified in the letter of credit, have been met. An irrevocable letter of credit, where cancellation or modification of the original terms is not possible without the mutual agreement of both importer and exporter, is usual and best. Confirmed letters of credit, which are supported by not only a foreign bank but also a bank in the exporter's country, are often used. With a confirmed letter of credit, the exporter is guaranteed payment even if the foreign bank does not honor its commitments.
3. Draft: This is an order, addressed to the importer by the exporter, specifying when a given sum of money is due from the importer or its agent. Sight drafts are payable immediately upon presentation to the importer or its agent, for example, a bank. Time drafts are payable at a specified future date. Because of the lag between acceptance and payment, they are a useful financing device.
4. Open Account: The exporter ships the goods first and bills the importer later in accordance with the agreed credit terms. Since evidence of the importer's obligations is not as well specified as with other instruments of payment, payment is often difficult to collect if the importer defaults.
5. Consignment: The exporter retains title to the goods until the importer has sold them. It is a highly risky method of payment, usually restricted to dealing with affiliated companies. These terms are only offered to very trustworthy importers.

Foreign Trade Zones

The number of countries with foreign trade zones (FTZs) has increased as trade liberalization has spread throughout the developed and developing world. Most FTZs function in a similar manner regardless of the host country.

In the United States, FTZs extend their services to thousands of firms engaged in a multitude of international trade-related activities. More than 150 FTZs are located throughout the United States. Goods subject to U.S. customs duties and quota restrictions can be landed in these zones for storage or such processing as repackaging, cleaning, and grading before being brought into the United States or re-exported to another country. Merchandise can be held in an FTZ even if it is subject to U.S. quota restrictions. When a particular quota opens up, the merchandise may then be immediately shipped into the United States. Merchandise subject to quotas may also be substantially transformed within an FTZ into articles that are not covered by quotas, and then shipped into the United States free of quota restrictions.

In cases where goods are imported into the United States to be combined with locally made goods for re-export, the importer can avoid payment of U.S. import duties of the foreign portion and eliminate the complications of applying for "duty drawback," as discussed earlier, that is, a request for a refund from the government of the duties paid on imports that are later re-exported.

Other benefits for companies using FTZs includes lower insurance costs due to greater security required in FTZs; more working capital, since duties are deferred until the goods leave the FTZ; the opportunity to stockpile products when quotas are filled; significant savings on goods or materials rejected, damaged, or scrapped for which no duties are assessed; and, exemption from paying duties on labor and overhead costs incurred in an FTZ which are excluded in determining the value of the goods.

Customs Bonded Warehouse

A customs bonded warehouse is a secure area within a customs territory where dutiable foreign merchandise may be placed for a period of up to five years without payment of duty. Only cleaning, repacking, and sorting may take place. The owner of the bonded warehouse incurs liability and must place a bond with the local customs department and abide by those regulations pertaining to control and declaration of tariffs for goods on departure. The liability is cancelled when the goods are removed.

Import Substitution

Import substitution was a strategy for economic development that was popular in the 1950s and 1960s. Advocates of import substitution development strategies believed that industrialization was the key to economic development and looked for policies that would encourage domestic industries to grow. Although it is now largely discredited as an economic development strategy, it has been resuscitated in recent years by antiglobalization and environmental activists as an alternative to free trade not because it can bring about economic development but because of a preference for locally produced goods.

To use import substitution as an economic development strategy, a country would erect tariff and other trade barriers to raise the cost of goods and services imported from elsewhere. The trade barriers would provide a sheltered market in which a domestic company could learn the business without competition. For example, a country lacking a domestic automobile industry might place a high tariff on imports of automobiles. A domestic auto manufacturer would then be established and, protected by the tariffs from international competition, could compete for domestic market share despite its higher costs. In practice, import substitution policies proved largely ineffective at fostering economic development. India aggressively pursued an import substitution strategy during the 1950s through the 1970s and as a result developed a locally based industrial sector, but did not significantly raise living standards until it began to dismantle trade barriers in the 1980s and 1990s.

In practice, import substitution strategies were difficult to implement. In theory, once the local industry had developed, the tariff barriers could be lowered and the domestic company would then compete with the foreign companies both domestically and internationally. In practice, a flaw in the import substitution policy was that the protected industries rarely agreed that they were ready to face international competition and lobbied fiercely to maintain the trade barriers. India's example demonstrates this as well. Import substitution strategies produced what some economists have termed near-autarky by the mid-1970s, with ever-tightening controls. Only when the inability to import domestically unavailable machinery and other supplies began to hamper Indian business generally did the business community begin to support reducing the protective trade barriers.

An additional problem with import substitution as a development strategy was that the sheltered firms were not competitive internationally. As a result, to the extent countries diverted resources into industries producing substitutes for imports, they harmed their competitive position in export industries. This effect can be seen in the stagnation of Brazilian exports at the end of the 20th century. Brazil's economic program for much of the 1970s and 1980s was built around import substitution. During that same period, Brazilian exports remained at roughly 7 percent of gross domestic product.

A final problem with import substitution strategies is that they introduced significant rigidities into economies where they were pursued. This made the economies less able to respond quickly to economic change. For example, Latin American economies recovered much more slowly from the 1970s oil price shock than did many east Asian economies, in part because Latin American economies were burdened more heavily with debt relative to their exports than were east Asian economies, with the extra debt from investment in uncompetitive industries as part of import substitution strategies.

Today, import substitution is largely promoted by organizations seeking to produce local development rather than economic growth. Rather than focusing on increasing economic growth through trade, the modern proponents of import substitution take a mercantilist view of economies and look to retain resources within the local economy. By providing local substitutes for imported goods, import substitution theorists argue, local economies will prevent money from leaving the local economy. Because their goals are different, the modern proponents argue that import substitution strategies' historical record is not relevant to evaluating the merits of the policy today.

India

One of the fastest growing of the world's major economies, India witnessed rapid transformation from a socialist economy of the post-independence era to a globalized one from the 1990s. With a population of about 1.1 billion (July 2006 estimate), it is the second most populous nation of the world, and the seventh largest nation in land area, covering 3,287,590 sq. km, stretching from the Bay of Bengal in the east to the Arabian Sea in the west.

It was Prime Minister Jawaharlal Nehru (1889–1964) who formulated most of India's post-independence policy. A planning commission was set up in 1950 with him as chairperson to modernize large sectors of economy. Increase in agricultural productivity and industrialization within the framework of a socialist pattern of society was emphasized. The mixed pattern of economy saw private ownership of agriculture and industrial firms. Manufacturing, railways, aviation, electricity, communication, infrastructural activities and more were under state control. About four decades of a socialist economy with centralized planning brought about economic woes in various sectors.

The Nehru model slowed down the economy and hampered business acumen due to the prevailing License Raj, or control system. There were innumerable hurdles for private enterprise, and foreign direct investment (FDI) was abhorred by Indian think tanks. In the three decades after independence, the annual economic growth was about 1 percent per capita. The growth of industry was 4.5 percent a year. The centralized planning put a damper on productivity and profitability of industries. The trade deficits increased. Import was not encouraged with all the tariffs and controls. India played a negligible role in world trade. It was high time for Indian policy makers to abandon the decades-old centralized planning model and join the mainstream of globalization with a market-driven economy.

Reform

During the premiership of Rajiv Gandhi (1944–1991), India moved toward economic reforms with far-reaching results pertaining to India's economy and business. During the congress ministry of P. V. Narasimha Rao (1921–2004) with the present premier Manmohan Singh (1932–) in charge of finances, economic reforms accelerated. These formed a watershed in the history of independent India, and their impact was felt in politics, society, and the economy. Privatization encouraged business. Private enterprise, both indigenous and foreign, began to play an important role. State control and public sectors ceased to be important actors in Indian business. A liberalization policy did away with the rigid license system, making starting a business comparatively easier. Import substitution was not emphasized and exports were encouraged. Multinational corporations (MNCs) began to invest in the Indian market.

India shifted to a market-driven economy from its decades-old centralized planning model and joined the mainstream of globalization at the international level. India marched ahead with business process outsourcing (BPO), and Indian technical personnel were sought after in information technology (IT) globally. Indian companies went on a corporation-buying spree on a worldwide basis.

India surged ahead in the Human Development Index (HDI) as a country in the category of medium human development. Per the report of the United Nations Development Programme for 2007–08, its rank was 128, with an HDI value of 0.619 in 2005. The HDI value was only 0.419 in 1975. With a population of more than 1.1 billion, India is expected to take its place in the global economy in the future. Despite 29 percent of its people living below the poverty line, India has become the world's fifth-largest economy in terms of purchasing parity. India became the world's fourth-largest foreign currency holder in January 2008 with a $285 billion reserve. With a gross national product (GNP) of $450 billion, the country has become a leading player in the global economy. The gross domestic product (GDP) in 2006 was $911.8 billion, with growth of 9.2 percent.

India has attracted private investment in various sectors of Indian economy. This along with BPO to the Indian labor market resulted in economic growth. Indian industry benefited immensely from the availability of skilled labor. The emergence of a nouveau riche class generated demand for consumer goods. Earlier, access to imported goods was difficult. But trade liberalization has witnessed import of high-quality consumer items from foreign countries. The sale of these items, which were earlier prohibited in the open market, was possible in malls and various outlets. Indian companies have not lagged behind. They are endeavoring to produce quality goods that will compete on an equal footing with imported goods. An economic expansion in various sectors has put India in the forefront of international economics.

Foreign Trade

The foreign trade regime of India changed dramatically in the last few years after the onset of the liberalization process. A beginning was made in the 1970s, but its impact was not significant. From the 1990s, the trade scenario of India changed a great deal. Exports accelerated in relation to GDP and world trade. Within a decade after 1991–92, it increased from US$18 billion in 1991–92 to $44 billion in 2000–02. India had total export earnings of $43.1 billion in 2000. It created a record of $80 billion in 2004–05. Indian exports had tripled between 2001–02 and 2006–07.

The composition of India's exports was transformed as emphasis was given to diversification of exports as well as manufactured goods. There was a perceptible fall in agricultural products, ores, and minerals, whereas manufactured items like pharmaceuticals, chemicals, leather goods, paints, enamels,

Trimming woven mats by hand in India. Indian exports reached $125 billion in 2007–08 and are growing more sophisticated.

plastic, glass, rubber, textiles, engineering equipment, jewelry, and computer software were on the rise.

Industrial policy changed a great deal with virtual abolition of licenses and the earlier practice of getting permission under different acts was not required. With competition from internal as well as external players, Indian businesses produced quality goods in domestic and foreign markets. Indian business became competitive worldwide; consumers were offered quality products and exports surged ahead.

The government of India did not remain complacent. It wanted a twofold increase in the country's share of global trade and took further steps in August 2004 to cover five years. This Foreign Trade Policy (FTP) had two motives: doubling India's share in world merchandise trade and giving emphasis to employment-generating industries. With a target of average annual growth rate of 16 percent in merchandise trade, the government established an Inter State Trade Council, Export Promotion Capital Goods Scheme, duty-free import of jewelry samples, advance licensing scheme, and bank guarantees, and worked toward procedural simplification. A target of $150 billion was set at the end of the FTP, which was within reach as the figure was $125 billion in 2007–08, notwithstanding an appreciating rupee ($111 billion in April–December 2007). The value of exports had been increasing continuously after the start of the free trade policy. The growth rate of India's share in the world market was increasing, although it lagged behind China, Thailand, and Brazil.

Economic Growth

With the growth of the Indian economy, free trade, and World Trade Organization (WTO) commitments for lowering trade barriers, import demand for consumer goods, raw materials, capital goods, edible oils, petroleum and its products, fertilizers, cereals, and precious stones had increased. The quantitative restrictions had become a historical relic of the socialist path of development. Quotas, tariffs, and import duties had been significantly slashed in Indian trade and commerce so as to keep pace with globalization. The five-year Export Import (EXIM) Policy for 1992–97 took substantial measures in these directions. Imports were free, but subject to a Negative List of imports, which was removed in the EXIM policy of 1999–2002. The country witnessed an increase in merchandise imports to the tune of 24 percent with a value of $185.7 billion in 2006–07. There was a rise in share of capital goods imports of about 4.9 percent in 2006–07; it was 3.7 percent in 2000–01.

Concomitant with the information highway's development worldwide, it became easier to access different services. With a growth rate of 29 percent in import services in 2006, India commanded the top position, closely followed by Saudi Arabia's 27 percent. Commercial services had reached $44.4 billion in 2006–07, having a growth rate of 28.7 percent. Business services had a phenomenal growth rate of 120.6 percent in 2006–07. India surged ahead in import of services like transportation, travel, finance, and software. Total imports that amounted to about $60.8 billion in 2002–03 increased to $168 billion in 2007–08.

Foreign Investment

The development and growth of India's business also can be measured by other indicators like capital inflow, investment, and industrial growth. The net foreign investment in India had remained a steady part of capital inflows. After the 1990s, the FDI as a part of globalization had helped in the growth of GNP, balance of payments, and employment. From 1991, the government of India introduced the Structural Adjustment Prrogram (SAP), changing a great many regulatory policies. Public sector areas were thrown open, registration requirements became easier, the ceiling of 40 percent of foreign-held equity was abolished, and tax rates were reduced.

Foreign companies were no longer required to obtain prior approval of the Reserve Bank of India. It became common for foreign investors in mutual funds, pension funds, and investment trusts and asset management companies to invest in the Indian stock market. Foreign capital flowed into the stock markets of India. The Indian economy was gradually being integrated into the global economy. Net capital flows increased from $25 billion in 2005–06 to $46.4 billion in 2006–07—a growth of 85.8 percent. FDI in India was $6.2 billion in 2001–02, but ballooned to $23 billion in 2006–07. It was spread over various sectors like manufacturing, banking, information technology, finance, and construction. This was the result of a vibrant economy. Nonresident Indians (NRI) also contributed a lot.

It was not only foreign companies that invested in India. Indian companies were turning to international markets. Indian business magnates undertook trans-border operations—investing abroad, buying companies, and starting joint collaborations. Tata Motors took over the luxury brands Jaguar and Land Rover from Ford for about $2.3 billion. Tata Tea purchased Tetley, Britain's largest tea company, and thus became the second-largest tea manufacturer globally. Reliance Communications discussed mergers with the MTN group of South Africa. L. N. Mittal (1950–), the London-based Indian steel magnate and the fourth-richest person in the world, brought his company to the forefront. The juggernaut of Mittal Steel acquired companies all over the world, one after another, the latest being European steel giant Arcelor SA. Four Indians had made it into the *Forbes* list of world's 10 richest persons. In the *Forbes* Global 2000 List, 48 Indian firms were named. India had placed second after Brazil as far as growth of the world's largest public companies was concerned.

Indian business was shining in every respect inside the country as well as outside. But there were also dark clouds in the otherwise rosy picture in Indian business. There remained many hurdles to doing business in India. Its ranking in "ease of doing business" was 120 out of 178 economies of the world in 2008, well behind neighboring Pakistan's 78th rank. Corruption, bureaucratic impediments, and difficult entry procedures were to be removed. There had been enormous amassing of wealth, with different groups controlling resources of the country. The per capita consumption of about 836 million persons was less than a dollar per day. With an HDI ranking of 128 and 29 percent of the people living below the poverty line, India has to do much more to alleviate the living conditions of its people as a whole. Policy makers need to both increase the pace of reforms and provide India's citizens the basic amenities of life.

Indian Oil

The Indian Oil Corporation is India's largest corporation, the 18th largest petroleum company in the world, and was ranked 116 on *Fortune* magazine's 2008 Global 500. It is a *public sector undertaking*: an Indian term for a publicly traded company in which a majority share of the stock is government-owned (at any or all levels of government). Shares are traded on the two major stock exchanges of India: the Bombay Stock Exchange and the National Stock Exchange. A great many of the PSUs in India deal with energy or public transport. Like Indian Oil, its two main competitors are also PSUs: Bharat Petroleum and Hindustan Petroleum. The government's controlling interest in oil companies limits the circumstances in which and extent to which they can raise the price of fuel, which is compensated with subsidies.

Indian Oil products cover the spectrum of petroleum products: gasoline and diesel fuel, aviation fuel, lubricants, naphtha, bitumen, and kerosene, all under a variety of brand names and formulations. It also supplies liquefied natural gas to homes, and operates about 18,000 fueling stations throughout India. Indian Oil employs about 36,000 workers directly.

Subsidiaries and Refineries

Subsidiaries include the recently begun Indian Oil Technologies Limited (IOTL), a marketing firm that works with Indian Oil's Research and Development Center (IOR&D), based on a similar initiative at BP. IOTL and IOR&D share a headquarters in Faridabad. Lanka IOC is Indian Oil's Sri Lankan operation, offering many of the same services there that Indian Oil offers in India, with a recent history of friction with the Sri Lankan government (with whom Lanka IOC is a joint venture) over the issue of subsidy payments. The Chennai Petroleum Corporation and Bongaigoan Refiner and Petrochemicals Limited are similar joint ventures. Indian Oil has participated in several joint exploration ventures with other PSUs.

Indian Oil's refineries include Digboi Refinery, India's oldest refinery and the world's oldest continuously producing oilfield. Oil was discovered at Digboi, in northeastern Assam, in 1889 by the Assam Railway and Trading Company (ARTC), 30 years after the drilling of the world's first oil well, a result of the extensive worldwide search for black gold. Previous exploration of Assam had discovered the presence of oil below the surface, but the Digboi discovery led to the first commercial derrick, in the midst of the wilderness.

The ARTC began a separate company to carry out the drilling at Digboi, which soon became the Assam Oil Company. At the time, such enterprises were still operated and managed by the British, with native labor and middle-management. It may have been the British experience with delegation, at the height of their imperial presence in the world, that led the London-based ARTC to spin off its oil concerns into a separate company, devoted to oil instead of making it one of many multilateral pursuits; at the time, the Assam Oil Company was not unique in its focus but was uncommon.

The Digboi success led to intensified exploration of India, as the potential for reward had been proven. In the coming decades, Royal Dutch Shell and the Anglo-Iranian Oil Company (ancestor of BP) applied for licenses to search for and exploit petroleum resources in India, and the country now has many oil companies, both PSUs and in the private sector. The Assam Oil Company was acquired by Indian Oil in 1981, and is now operated as a division of the larger company; Digboi remains one of the company's most important refineries.

Indirect Export

Exporting to foreign markets takes two forms. Direct exporting means setting up expensive subsidiaries or establishing contractual relationship with foreign companies. Direct exporting does give greater control over sales channels and intellectual property protection, but the entry costs, time to market, and ongoing costs are higher.

The other type is indirect exporting, which means selling goods to foreign buyers through third parties such as export agents, export merchants, or buying houses. This is an especially good mode of entry for the novice exporter or for a manufacturer who lacks country knowledge.

China is a good example. Many exporters do not have the expertise to enter the Chinese market successfully. But when they use indirect exporting, they offer their products through intermediaries who take the product directly to the markets. This way time to entry in the Chinese market is shorter and more flexible. Exporters can receive payment earlier and risks are minimized, particularly volatile foreign exchange markets and credit risks.

One of the greatest benefits is the ability to obtain export know-how and personal contacts through the export merchant or agent. The exporter can possibly realize greater sales volumes since the foreign export agent often represents several different related products or product lines and thus can deliver on economies of scale. Also, exporters find it easier to ascertain whether their products will sell well in a foreign market without the effort, financial investment, or risk. They do not have to worry about all the complexities; they merely give instructions to the agent about packing, labeling, and transportation, and so forth.

However, there are quite a few disadvantages. Perhaps the biggest is that the indirect exporter has very little contact with the foreign agents or distributors, let alone with end users and customers. That means it is more difficult for them to acquire the needed experience in entry into the foreign market. Indirect exporters, especially from smaller firms and smaller countries, may find it difficult to get an export trading house to take on the products without a great deal of paid promotion and advertising. What is worse, the exporter may lose control of pricing and marketing, and even of intellectual property. In addition, the exporter receives a smaller profit margin than through direct exporting.

There are several basic channels for indirect exporting.

1. The export merchant buys the local firm's product outright and assumes the risk of being able to resell it profitably abroad. The type of company typically has expertise in a particular product line and/or in a special geographical market.
2. The export agent usually represents several non-competing manufacturers and receives a commission. The agent does not take title of the goods directly and so does not assume the risk of not being able to sell them abroad. The function of the export agent is to appraise the export potential of the local manufacturer's products, advertise them abroad, look for foreign buyers, obtain export orders, and advise on or arrange for the documentation, shipping, and insurance once a sale has been made
3. The export management company, also known as a trading house, is a private firm that serves as an export department for several manufacturers. This company solicits and transacts export business on behalf of its clients in return for a commission, salary, or retainer plus commission. In addition, some export management companies will purchase the product and sell it themselves to foreign customers. Export management companies can facilitate the export process by handling all of the details—from making the shipping arrangements to locating the customers.
4. Foreign distributors have similarities with the trading house. The distributor takes title to the goods and has to resell them down the distribution chain. The big difference is that transaction (transfer of ownership) may take place in the home country of the distributor. This means that the producer must do the packaging and delivery and assume more risk, but is in a better position to capture more value from the transaction.
5. Foreign agents require the exporter to retain title until the goods are delivered to the buyer or even to the consumer. The agent merely "represents" the producer but never takes ownership of the goods. Motivated agents like to work on a commission basis because they capture an agreed-upon percentage of every transaction, often even with an escalator clause for great sales. That gives them the incentive to maximize sales volumes.

Indirect Foreign Direct Investment

Indirect foreign direct investments (indirect FDI) are foreign direct investments of a multinational enterprise (MNE) that are carried by a foreign subsidiary located in a third country. The MNE obtains a lasting interest in a foreign market, being the ultimate owner of the investment made, but the actual investment operation is carried out by a subsidiary located in a country that is different from its original country.

According to the Organisation for Economic Co-operation and Development–published benchmark definition, foreign direct investment (FDI) is defined on the basis of the objective of an entity that is resident in an economy of establishing lasting interests in an enterprise that is resident in a foreign economy, implying a long-term relationship between them. FDI can be direct, made up by the entity in the target market directly, or indirect, when a third country is involved.

The *Balance of Payments and International Investment Position Manual* of the International Monetary Fund (the IMF Manual), in its 6th edition, states that

> indirect direct investment relationships arise through owning of voting power in one direct investment enterprise that owns voting power in another enterprise or enterprises, that is, an entity is able to exercise indirect control or influence.

Three different countries are involved in an indirect FDI relationship. One is the origin country, where the parental company is located. Another is the destiny country, where the investment is made. There is a third country, in which the parental company owns an entity, and the latter is the one that actually makes the investment in the destiny country. The key difference between direct and indirect investment is that, in the first type, the operation is straight from the origin to the destiny and, in the second type, there is the intermediate country. It is noteworthy that indirect FDI may be viewed as part of two direct FDI flows: one from the origin to the intermediate, where the parental company sets up an interest in the intermediate country; and another from the intermediate county to the destiny.

For data recording, a threshold of 10 percent of ownership is generally taken as the minimum evidence of a long-lasting FDI relationship. Such threshold refers to both direct and indirect ownership. Therefore, if data on foreign direct investment were to follow the ownership criterion, there should be included both the direct and indirect interests of the parental MNE. However, balance of payments statistics usually take into account the location of the origin and destiny enterprises so that countries may not be able to trace back the actual ownership of the companies. Countries may require companies to detail their entire worldwide consolidated accounts.

The most typical motives for indirect FDI include public policies and corporate strategy. Public policies that may induce or discourage indirect FDI include the different national patterns of taxation, which may stimulate or discourage some forms of corporate property and control. In addition, countries vary in terms of their specific forms for treatment of foreign investments. There are other public policies that may affect incentives to use a direct investing company located in a country that is different than the original investing group. Embargoes on investments may also play a role in inducing indirect FDI, so that the interested investor may overcome the restriction by investing through a base country not affected by the embargo.

Corporate strategy may induce indirect FDI. One of the typical situations may include the decentralization of the investment decisions of a company with international presence, by empowering a specific subsidiary for doing the investments in a particular region or group of countries, on behalf of the parental MNE. In certain types of corporate networks, one subsidiary may gain autonomy for prospecting regional opportunities and deciding on the target markets that will be chosen in a region. In such case, the subsidiary benefits from its advantages in geographical and cultural proximity, including the costs for moving executives, more detailed market knowledge and information availability, and several other advantages. The strategy may include the formation of regional hubs for investments, which may be responsible for identifying and exploiting potential business opportunities in the vicinity countries. Other corporate strategies may also require the formation of decentralized investing companies, leading to indirect FDI.

One of the consequences of the existence of indirect foreign direct investment is that outward FDI figures for a given country may not accurately reflect the country's actual investment, but may rather include figures for investment of affiliate enterprises, which ultimately belong to another foreign-based company. In that situation, those figures will be overestimated in relation to the actual outflows, but may also come to be underestimated as long as the nonresident affiliates of the country's companies may also have their own investment abroad channeled through subsidiaries. In the latter case, national statistics may not be able to fully register the amount of direct investments of the resident companies that were carried out through non-resident affiliates.

Therefore, indirect foreign direct investment may bring difficulties for an assessment of the consolidated stock of direct investments of a specific country. One may face difficulties in evaluating the actual stock of a county's foreign direct investment, when only direct FDI is accounted for.

The growing importance of global corporate networks together with the increasing sophistication of direct investment forms and vehicles are reasons behind the boost in importance of indirect FDI.

Individualism/Collectivism

"Individualism/Collectivism" is one of the five cultural dimensions identified by Geert Hofstede in his book *Cultures and Organisations: Software of the Mind*, where he presents the results of research on cultural variability or national cultural differences using survey data collected from IBM in 50 countries. In a similar categorization, Fons Trompenaars and Charles Hampden-Turner classified cultures based on a combination of patterns of behavior and values; one of these categories is communitarianism/individualism value orientation, which is very similar to Hofstede's individualism/collectivism. This dimension relates to the degree of integration of individuals within groups by focusing on the role of the individual versus the role of the group. The main assumption underlying this dimension is that there is cultural variability on the degree of emphasis given to individuality/uniqueness or conformity/interdependence in societies. As such, societies where the interests of the individual prevail over group interests are individualist, and those where the interests of the group prevail over individual interests are collectivist.

Hofstede argues that individualism "pertains to societies in which the ties between individuals are loose: everyone is expected to look after himself or herself and his or her immediate family" while collectivism "pertains to societies in which people from birth onwards are integrated into strong, cohesive ingroups, which throughout people's lifetime continue to protect them for unquestioning loyalty." Therefore, at the core of this dimension is the assumption that culture impacts the mindsets of individuals in society. Hofstede defines culture as "the collective programming of the mind which distinguishes the members of one human group from another." As such, culture impacts both individuals and groups by defining (un)acceptable and (un)desirable behaviors and attitudes; it establishes categories of importance and levels of acceptability toward individualism and collectivism. Consequently, dynamics that prioritize the individual or group are identified based on how culture defines these categories and levels.

In line with the previous, the dimension opposes "I" (individualism) to "we" (collectivism), where highly individualist cultures would have characteristics such as emphasis on individual achievement, self-orientation, and focus and decisions based on individual needs. Highly collectivist cultures, on the other hand, have a group orientation and prioritize aspects such as group dependency, loyalty, belonging, and generally the well-being of the social system. In Hofstede's work, this dimension was measured using an Individualism index (IDV).

Hofstede's Evidence

Using an Individualism Index (IDV) based on measurement of work goal items such as personal time, freedom, challenge, training, physical conditions, and use of skills, participants in 50 countries were asked to think about factors that would be important to them in their ideal job (regardless whether these factors were present at their actual job). The rationale for using these items was the perceived dichotomous spectrum they show by illustrating employees' independence from the organization versus employees' dependence on the organization.

The score results represent the importance attached to these factors. Along the lines of the distinction previously made regarding individualist and collectivist characteristics, responses that prioritized personal time, freedom, and challenge were considered to reflect individualism, whereas responses that prioritized training, physical conditions, and use of skills were considered to reflect collectivism. The index used a range between zero and 100, where zero represented the highest form score of collectivism and indicated high importance of training and low importance of freedom. Conversely, lower importance of training and high importance of freedom increased the score, hence higher individualism. Factor scores for each country were calculated using a statistical procedure where each score was multiplied by 25 and a constant number of 50 points was added.

Findings suggested that the country with the highest IDV was the United States with a score of 91; this was closely followed by Australia with a score of 90 and Great Britain with a score of 89. The country with the lowest MAS was Guatemala, with a score of 6. A list of developing countries dominates the main lowest scores; for example, Ecuador (8), Panama (11), Venezuela (12), Colombia (13), and Indonesia (14). Hofstede's score results suggest that developing countries move within notable collectivism, while industrialized countries move within notable individualism, which sustains his argument that there is a strong relationship between national wealth and the degree of individualism.

In countries with high IDV (or high individualism) scores, such as the United States, Great Britain, Canada, and the Netherlands, individuality is of core importance and there is an ideology of individual freedom, with principles of society that prioritize individual rights; for example, everyone has the right to privacy and everyone is expected to have a private opinion. On the other hand, in countries with low IDV (or high collectivism) scores, such as Guatemala, Venezuela, Pakistan, South Korea, and Thailand, while ideologies of equality sustain societal dynamics, actions and decisions are influenced by interest groups and group membership. For instance, political power is sustained by interest groups and opinions are predetermined by group membership. In that sense, group interests are prioritized over individuals. In view of the general patterns of individualism/collectivism orientation, Hofstede deduces how dynamics operate in the workplace, within occupations, in the family, and at school.

Trompenaars and Hampden-Turner's Work

As mentioned above, Trompenaars and Hampden-Turner categorized cultures based on a combination of patterns of behavior and values. The dimension of individualism/communitarianism is the equivalent of Hofstede's individualism/collectivism, and it poses the question of whether it is more important to focus on the enhancement of each individual or rather the advancement of the corporation. However, the focus in Trompenaars and Hampden-Turner's work is set on the individual and the organization as a community, particularly looking at how culture impacts business. As such, it is fair to say that it builds on Hofstede's work, yet aims to highlight that an organization's adequate functioning depends on the degree of compromise between individualism of different actors, such as stakeholders, employees, and clients, and communitarianism of the larger organizational system.

To measure the degree of individualism versus communitarianism, Trompenaars and Hampden-Turner asked participants (a total of 30,000 managers completed the question) to choose one from two possible options to a scenario that addressed improvement of quality of life, which was included as part of a wider cross-cultural questionnaire. One answer

(a) proposed individual freedom and opportunity to develop, while the other answer (b) proposed taking care of the group and reaching group well-being even if sacrificing individual freedom and opportunity. Findings indicated that the highest individualist were Israelis with a score of 89 percent. Others following this score were Romania (81 percent), Nigeria (74 percent), Canada (71 percent), and the United States (69 percent). The lowest-scoring countries (highest communitarianist) were Egypt (30 percent), Nepal (31 percent), Mexico (32 percent), India (37 percent), and Japan (37 percent).

Aside from differences both in scoring and aims measurement, there are some noticeable differences in response distribution between Hofstede's results and Trompenaars and Hampden-Turner's. Whereas Hofstede's asserted that national wealth was associated with individualism; these assertion cannot be conclusively made in the case of Trompenaars and Hampden-Turner's findings. For instance, while it is the case that there is an observable distribution that somehow resembles Hofstede's findings, Nigeria, a developing country, is the second-highest individualistic value orientation country in Trompenaars and Hampden-Turner's scale while France, an industrialized country, is located in the scale alongside developing and transitional economies such as such China, Brazil, Singapore, and Bahrain, which are culturally, socially, and politically different.

Indonesia

Indonesia is made up of 17,507 islands, 6,000 of which are inhabited, covering about 730,030 sq. mi. Indonesia, with its capital at Jakarta, has the fourth-largest population in the world, estimated at 223 million people in 2005 (after China, India, and the United States). The political system is based on *pancasila*, in which deliberations lead to a consensus. The constitution was amended in 2002 to allow for direct elections for both the president and the vice president. Indonesia is a member of the United Nations, World Trade Organization (WTO), Islamic Development Bank, Organization of the Islamic Conference (OIC), Asian Development Bank, Asia-Pacific Economic Cooperation (APEC), Association of Southeast Asian Nations (ASEAN), Mekong Group, Colombo Plan, and Organization of Petroleum Exporting Countries (OPEC).

Indonesia's 2008 gross domestic product (GDP) can be broken down as follows: agriculture, 13.5 percent; industry, 45.6 percent; services, 40.8 percent. Indonesia was the country worst hit by the Asian financial crisis that commenced in 1997. The banking and foreign exchange crisis caused real GDP to shrink by over 13 percent in 1998. However, in 1999 the economy stabilized, and in 2000 it managed to resume growth at a solid pace. On the other hand, its recent growth performance does not match the high single-digit percentage growth it once experienced.

The currency is the rupiah, and since 1992 foreigners have been permitted to hold 100 percent of the equity of new companies in Indonesia with more than US$50 million capital. Indonesia is the world's largest Muslim country, with 185.1 million Muslims, but religious freedom is granted to all denominations. Indonesia is also the world's largest archipelago state. There are seven UNESCO sites in Indonesia, with the first four being inscribed in 1991. Independence from the Dutch is celebrated on August 17 with cultural events, and military parades on Armed Forces day, which is October 5. Women are celebrated on Kartini Day, in memory of Raden Ajeng Kartini, a symbol of female emancipation.

The Dutch began colonizing the islands in the 17th century, but the islands were occupied by Japan from 1942 until 1945; shortly after the Japanese surrendered, Indonesia declared independence. However, it was not until four years later, after negotiations and

UN mediation, that the Netherlands gave up its stake in the islands and recognized Indonesia.

The official language is Bahasa Indonesia, a form of Malay, and there are an estimated 583 other languages and dialects spoken in the nation. Pancasila is a five-point state philosophy (belief in a supreme being, humanitarianism, national unity, democracy by consensus, and social justice). Education is under the control of the Ministry of National Education, but the Ministry of Religious Affairs is in charge of Islamic religious schools at the primary level. President Susilo Bombang Yudhoyono took office in 2004, promising an agenda close to his predecessor's, assuring actions such as curbing corruption, combating terrorism, and promoting economic growth.

Economy

The disparity in income has been widening, regardless of extraordinary world prices for petroleum. In 2005 and 2006, the annual rate of inflation exceeded 10 percent, and the unemployment rate continued to stay high. A Corruption Eradication Commission (Komisi Pemberantasan Korupsi—KPK) was established by the government to promote investment. According to critics, KPK was too apprehensive in its approach to major cases. Indonesia's stock market has been one of the best three performers in the world in 2006 and 2007. The government recently introduced tax and customs reforms, introduced Treasury bills, and increased capital market supervision in order to reduce risk. Indonesia passed a new investment law in March 2007 that addressed some of the concerns of foreign and domestic investors alike.

Tsunami relief projects such as this USAID-supported road repair in 2005 have helped Indonesia's economy rebound.

Indonesia still has the challenges of poverty and unemployment to overcome. Also, there is inadequate infrastructure, an intricate and complicated regulatory environment, and corruption, and resources are distributed unequally among the 30 regions. Over 100 state-owned enterprises have been slowly privatized, and several of those enterprises have monopolies in key sectors. Pension funds and insurance services remain weak as a result of underdeveloped capital markets. The rising price of oil in 2007 affected Indonesia by driving up the cost of domestic fuel and electricity subsidies. These rising costs are also contributing to concerns about higher food prices, a concern the whole world currently shares.

Foreign Relations

Although avoiding taking positions in quarrels among major powers, Indonesia has wanted to be prominent in Asian affairs. However, due to President Sukarno's assertion between the "old established forces" and the "new emerging forces" that a basic world conflict existed, he tried to project Indonesia to the forefront. While Indonesia was independent in foreign affairs, President Sukarno's regime became close with the People's Republic of China and the Soviet Union. Indonesia had also attained the capitulation of West New Guinea (Irian Jaya/West Papua), and enforced a "confrontation" policy against the new state of Malaysia. Only after diplomatic relations with Malaysia and Singapore were asserted in 1966 did the "confrontation" with Malaysia conclude.

As a tool of regional cooperation, Indonesia took the lead in forming ASEAN. In 1966 Indonesia's membership in the United Nations, as well as other related agencies, resumed. But, in the commotion leading to the resignation of Suharto, relations with China suffered due to attacks against the Chinese. Later in 1999, President Habibie issued an order outlawing ethnic discrimination. At the same time, he terminated the ban against teaching or using Mandarin Chinese.

A security cooperation agreement was signed by Indonesia and Australia in December 1995. Mutual notification in case of emergency was provided for within this agreement. By 1997, they established a treaty for mutual maritime boundaries. In 2001–02, there was criticism from the government of Prime Minister John Howard about how Jakarta had failed to discourage a stream of boats transporting asylum-seekers to Australia's outer territories. Jakarta's actions have caused conflict in relations with Australia. Reluctance to recognize the presence of Jemaah Islamiah (a terrorist organization) until October 2002 led to the bombing of a Bali tourist resort, which took 202 lives; 88 of those lives were Australian.

Australia's $1 billion pledge of relief for the December 26, 2004, earthquake and tsunami disaster was acknowledged in 2005 by President Yudhoyono. The worst-hit area of the country was Aceh, and more than 220,000 people were killed or are missing in Indonesia. The earthquake originated off the coast of Sumatra. A framework partnership agreement was signed by the two countries, which included stipulation of closer military cooperation. Since Indonesia is located in the Pacific "Ring of Fire," it continues to remain vulnerable to natural disasters. The rebuilding of Aceh after the December 2004 tsunami has been progressively successful; there is now more economic growth in the region than before the tsunami struck.

Indonesia suffered new disasters in 2006 and early 2007. In 2006 there was a major earthquake near Yogyakarta, and in 2007 there was an industrial accident in Sidoarjo, East Java, that created a "mud volcano," major flooding in Jakarta, and a tsunami in South Java. These disasters caused additional damages in the billions of dollars to an already hard-hit region. Indonesia is receiving assistance with its disaster mitigation and early warning efforts from the international community. Also, in early 2007, more than one-third of all Avian influenza (bird flu) (H5N1) cases were in Indonesia.

Throughout the 1980s, relations between the United States and Indonesia were strengthened, partly because President Ronald Reagan viewed Indonesia as a powerful counterweight to the spread of communism in the region. However, in 1991, the U.S. Congress cut off direct military funding. Similarly, President George W. Bush has described Indonesia as a key ally in the global war on terror. By 2005 full military links had been restored by Washington. That same year, Indonesia made peace with Muslim separatists in Aceh (partly as a result of the 2004 tsunami) and democratic elections were held in 2006.

Law

The Indonesian press was restricted under the Sukarno regime, and had relative freedom under President Suharto until 1974 when riots in Jakarta prompted a strict government crackdown on freedom of press. As a result, more than 200 newspapers and periodicals were shut down or ordered not to report in accordance with the Ministry of Information. In 1999 President Abdurrahman Wahid abolished the Ministry of Information and replaced it with the State Information Dissemination Bureau. However, in 2002, the Indonesian legislature passed a restrictive media law that established a regulatory body to oversee regulation of media.

The Supreme Court is part of the judiciary of the state and is complemented by the legislative and executive branches, but it is free and independent from government intervention. The justices are appointed by the president from a list of candidates selected by the legislature. In 1989 the Muslim sharia courts were given jurisdiction over civil matters. There are 30 provinces in Indonesia, with two special regions and one special capital city district (Jakarta Raya). Its law is based on Roman-Dutch law, but it has been modified by indigenous concepts and by new criminal procedures and election codes. Indonesia has not accepted compulsory International Court of Justice (ICJ) jurisdiction. Indonesia is a temporary member of the United Nations Security Council.

Industrial and Commercial Bank of China

The Industrial and Commercial Bank of China was founded on January 1, 1984, as the result of a major banking system reform in China. It inherited the industrial and commercial credits and savings businesses from People's Bank of China and developed into one of the four major state-owned commercial banks in China (the other three being the Bank of China, Agricultural Bank of China, and China Construction Bank). On October 28, 2005, the Industrial and Commercial Bank of China was restructured into a joint-stock limited company and officially changed its name to Industrial and Commercial Bank of China Ltd. (ICBC). On October 27, 2006, ICBC was listed on both the Shanghai Stock Exchange and the Stock Exchange of Hong Kong Limited, making it an international public shareholding company. In 2007 ICBC had 81.99 billion yuan (RMB) after-tax profits; total market value rose to US$338.934 billion, making it the largest bank in the world.

ICBC provides diversified financial services that include, structurally, Corporate Finance Business, Personal Finance Business, Bank Card Business, Funds Business, and Internet Bank Business. The Corporate Finance Business of ICBC served 2.72 million corporate customers by the end of 2007. Its domestic corporate loans balance amounted to 2.914993 trillion yuan (an increase of 15.2 percent from the previous year), and domestic corporate deposits balance amounted to 3.402683 trillion yuan (an increase of 20.1 percent).

ICBC also provides financing services covering international and domestic trading financing procedures for customers, and works out international settlement and trade financing centralized operation schemes. In 2007, trading finance from domestic branches accumulated to 223.646 billion yuan, an increase of 132.9 percent; accumulatively transacting international settlement business 593.3 billion dollars, an increase of 48.5 percent. The Personal Finance Business of ICBC served 170 million individual customers through 1,112 financing centers, 95,588 telephone banking, internet bank, and other electronic channels by the end of 2007. Its domestic deposit balance amounted to 3,244.074 billion yuan and domestic personal loans balance amounted to 752.113 billion yuan. The Bank Card Business of ICBC issues euro credit card, Peony Express Business Card, Peony UnionPay Card, Peony Sports Card, and new Peony Traffic Card. By the end of 2007, the overdraft balance of credit cards amounted to 8.241 billion yuan, with an increase of 59.5 percent. The issuing volume of debit cards amounted to 187 million, an increase of 8.58 million, and the yearly consumption reached 454.3 billion yuan, with an increase of 71.4 percent. The Funds Business of ICBC operates domestic and foreign currency in various financial markets. In 2007 domestic institutions had financed RMB inwardly and outwardly 6,096.7 billion yuan, an increase of 27.6 percent. The trade volume of foreign currency market amounted to US$868.2 billion, an increase of 43.5 percent.

The success of ICBC should be largely attributed to the growing economy in China, its strategic focus on sustainable market growth, and a relatively stable management team. Specifically, the optimized deposit structure has enabled the bank to keep the growth of deposits at a low cost in the cycle of rising market interest rates. With an optimized credit structure, the bank has managed to increase credit revenue while complying with macroeconomic policies and maintaining moderate credit growth. Improvement in the investment structure and comprehensive development of the financial market business have brought about substantial increase in income from treasury operation. The rapid development of the intermediary business has further diversified the drivers of growth in income.

In 2007 ICBC successfully acquired 79.9333 percent of Seng Heng Bank, the largest local bank in Macau, and 20 percent of Standard Bank of South Africa, the largest commercial bank in Africa. The bank also entered into new markets in Russia and Indonesia. With 112 overseas institutions, it has formed a global service network covering major international financial centers and the main regions trading with China. The inter-market and global businesses have created synergies and are becoming new drivers for its growth in profit.

ICBC's operation performance has been consistently acknowledged by domestic and foreign banking industry. In 2007 it was awarded "Best Bank in China," "Best Trading in the World," and "Best Management Company in China" by the Bankers, Global Finance, The Assets, Finance Asia, and was appraised by Economic Observer as the "Most Honored Corporation in China." The international professional certificating institutions have raised the ranks of ICBC continuously, among which Moody's raised its long-term credit rank to "A1," and Standard & Poor's raised it to "A-." Relatively unscathed by the banking crisis of 2008, ICBC initiated a new branch in New York and also opened its first bank in the Middle East (in Dubai) that same year.

Industrial Espionage

Industrial espionage (IE) is defined as the illegal acquisition of secrets from business competitors. It is an enigmatic phenomenon in business practice. IE is distinguished from all legal activities of competitive intelligence and scanning of the organizational informational environment. In addition to the distinction between legal and illegal activities, industrial espionage differs from environmental scanning with respect to the focus of the activities. The latter ones are systematized by three methods of managerial information gathering: (1) discovery: gathering of new information, at best largely unguided by the given a priori knowledge and predispositions; (2) expansion: incorporating well-defined information needs and being, thus, more focused on particular aspects that are considered to be worth investigating in further detail; and (3) monitoring: shifting from detection to a permanent observation of relevant developments.

With respect to this scheme, IE activities fit into the category of expansion. Because the spying organization usually has prior knowledge of the rival firm, it uses IE activities to complement this prior knowledge. Therefore, IE is unlikely to reveal "new" developments in the competitive arena, as proposed by the mass media.

Several historical examples clarify the importance of the IE problem: For instance, the Russian supersonic airplane TU-144 is suspected to have been constructed on the basis of the Anglo-French Concorde project. More recently, Oracle took SAP to court because of the illegal download of internal documents. Another prominent case is the 2007 "unauthorized intrusion" into computer systems of the TJX Companies, where 45.7 million credit and debit card numbers were hacked, along with 455,000 merchandise return records containing customers' driver's license numbers, Military ID numbers, or Social Security numbers. Apart from the sheer number of customers affected, this case is remarkable because even after disclosing the fraud, the company was unable to stop the intrusion immediately.

Besides machinery construction and software engineering, the pharmaceutical and the chemical industries are frequently the targets of espionage attacks. The Economic Crime Survey, conducted in 2007, summarizes data from 5,400 companies located in 40 countries. More than 43 percent of these companies admitted that they had been a victim of one or more significant economic crimes during the previous two years, although not all the frauds were IE-related. According to these data, China, Russia, India, Indonesia, Brazil, Mexico, and Turkey are high-risk countries because they harbor many aggressive IE offenders. Notably, in some nations, IE activities are supported or even initiated by governmental administrations. According to the U.S. National Counterintelligence Center, a total of 109 nations were identified as having conducted IE activities in order to steal U.S. corporate intellectual property in 2005. Thus, the distinction between IE and national security activities does not hold for business practice. Proceedings, methods, and technologies are similar; only the legalization differs.

Targeted Information

Secrets acquired by IE are typically divided into three data qualities: (1) customer data, particularly transactional details like prices, discounts and order volumes, credit card details, purchase histories, preferences, etc.; (2) technical data, such as formulas, manufacturing process details, etc.; and (3) strategic information, for instance plans for new product introductions, entries into foreign markets, negotiation results on alliances, cost calculations, etc.

According to these data qualities, companies face different IE threats. With respect to strategic information, internal threats arising from negligent employees and related business partners are critical. For instance, employees frequently pass on information about their company to Wikipedia or publish their daily work in Web blogs. The *Chronology of Data Breaches* provided by the *Privacy Rights Clearinghouse* is peppered with entries of lost laptops, backup tapes, and external hard disks. Exploiting this weakness is common practice in IE. Additionally, former or malicious employees are frequently willing to provide the desired information to rival companies.

In order to support private organizations in protecting their data in the United States, the Economic Espionage Act (EEA) was passed in 1996. Under this act, trade secrets are broadly defined as tangible or intangible information that is subject to reasonable measures to preserve its confidentiality and derives independent economic value from not being generally known to or ascertainable by the public. Measures to protect strategic information include the following:

- Establishing and enforcing clear policies about the handling of confidential information.
- Systematically informing employees and all business partners regarding the proprietary information.
- Requiring employees and all business partners to sign confidentiality and nondisclosure agreements.
- Limiting physical and virtual access to storage of trade secrets.
- Restricting the number of copies of critical data sets (e.g., documents or calculation schemes) and numbering these copies.
- Using encryption algorithms for the protection of digital data.

Technical data are frequently subject to IE by tapping e-mail correspondence, voice phone exchanges, or taking photos of production or engineering facilities. Built-in cameras of cellular phones enable almost anybody with physical access to critical areas or documents to take photos and transmit them immediately worldwide. Customer transaction data can be obtained by infiltrating spyware, particularly by e-mail in the digital information processing systems of an organization. These codes are transmitted via e-mail, gadgets from the Web, or digital advertisements.

Various approaches have been used to profile typical internal spies. This is indeed a challenge as the phenomenon is embedded in the organizational context of a company and its complexities. Furthermore, the fact that the interest in secrets comes from competing or partnering organizations adds to the complexity. Consequently, the phenomenon is not captured by simple descriptive or linear statistical methods. A researcher group from Carnegie Mellon University conducted extensive simulations using a dynamic mathematical model specification. With respect to IE, the following results were obtained:

- Stressful events and organizational sanctions increase the likelihood of espionage.
- Espionage is often “pre-announced” by the spies’ behavior.
- Technical actions by insiders hint at malicious acts, such as IE.
- Companies frequently ignore fraud or fail to detect rule violations.
- A lack of access controls facilitates IE.
- Spies have common personal predispositions, particularly in the taking of risks.

The latter result is in line with an empirical investigation of incidences in German companies that revealed that the typical spy in Germany is male (87 percent), between 30 and 50 years of age (70 percent), with at least six or more years working within or affiliated to the organization.

Industrial Spies

Beyond these quantitative results on internal spies, two prototypes of external spies are characterized in the literature: the social engineer and the high-tech digital thief. Basically, the social engineer takes advantage of employees’ ingenuousness through telephone calls. By feigned telephone calls, he pretends to be a supplier, a customer, or service technician and asks for details on his subject of investigation. Using telephone calls is merely a historical part of this description. Nowadays, the smoker-meetings outside the office buildings, after-work happy hours, etc., provide external spies with a variety of opportunities to establish contacts with insiders. The art of this type of external IE is the manner of establishing an intimate interaction, which will not trigger formal identity checks. The attacker first establishes small talk and then distracts the victims with technical jargon and irrelevant details. To worsen the situation, the employees are frequently less concerned about access to draft documents, which embrace the same information as the final documents or put a massive set of carbon copy recipients in their e-mails. As a consequence, additional employees become valuable victims of this type of attacks.

An impersonal extension of this IE strategy is sending *phishing* (short for *password fishing*) e-mails in order to obtain user names, passwords, PINs, etc. The pattern is similar to the feigned telephone calls, but because of the increasing number of phishing attacks in the individual's private life (mostly targeting bank account details and transaction data), an increasing number of employees are aware of the danger, and as a result, this type of IE is about to lose its impact. The term *pharming* refers to the manipulation of the Domain Name System retrieval of Web browsers (DNS-Spoofing). An employee will not recognize that this is passing his or her data not to the organization's information system, but to a different system. Even the Transport Layer Security protocol or the widespread Secure Sockets Layer give the impression of safe data transfer, but offer no confidential protection against pharming.

The high-tech spy does not aim to establish a pretended trustful interaction with employees, but attacks the information processing systems of the target organization. A sophisticated variant is called Van-Eck-Phreaking, which enables eavesdropping of computer monitors up to 100 meters away. Conventional Yagi antennas have been found to provide a good recording of the amplitudes broadcast by monitors, if the broadcasting frequencies are within a narrow range. Otherwise, special broadband antennas are needed, which might disclose the spy attack. The contents, displayed on cathode-ray-tube computer monitors, are clearly read at longer distances or in neighboring buildings. Flat-panel displays can pose an even larger emission security risk than cathode-ray-tube monitors. The eavesdropping is simplified by low illumination of the environment or under office-light conditions by direct line of sight. Office partition walls or windows do not hamper the recoding of the electromagnetic signals.

The increasing spread of LAN networks, wireless phones, and Bluetooth connections in office life provides the spies with additional entries into organizations' information processing systems. Noticeably, many music publishers and movie producers add rootkits to their digital products, even in cases where the products are bought legally. These become effective with the next boot of the system and enable control over the system, including the readout of data. Thus, companies should not allow any entertainment applications in their information processing infrastructure, including laptops, palms, and cellular phones. However, in addition to all these digital attacks on companies' information systems, there are conventional attacks. In particular, "dumpster diving" is still common practice. For instance, Unilever's hair-care business unit fell victim to dumpster diving by Procter & Gamble in 2001. The spies gathered piles of unshredded documents revealing Unilever's plans for this segment.

Using Stolen Information

Another critical question is the alignment of information gathered in espionage to the companies' strategy. As outlined previously, espionage actions occur usually in the expansion modus. Here, the spying organization already has vested solid knowledge on the topic of interest. The use of this additional information in business strategy development can be systematized by Michael E. Porter's five forces framework.

1. Potential entrants: This is the domain of IE that gains most attention by the mass media, if the IE is uncovered and the offender is taken to court. Actually, the amount of loss caused by these activities is difficult to quantify, because the information by itself would have become public in the course of time anyway. This argument holds for the reverse case of declining markets as well.
2. Customers: With respect to the customers, three qualities of information have to be sepa-

rated: first, the transactional details (credit card numbers, etc.,) which damage the reputation of the companies as well as the relationship commitment of the affected customers. Specialized metrics have been developed to quantify both. Second, the fact that a customer buys products and services from a particular company and what prices a customer pays. This weakens the position for future negotiations because the offender is likely to offer a better deal to the customer. Third, knowledge about customers' preferences, perceptions, etc. Here, two scenarios are relevant: The knowledge might be obtainable in market research activities. Then, the damage equals the price of such market research activities. In the other scenario, the stolen information is unique. In this case, the total change of operational profits has to be taken into account.

3. Substitute products and services: Here, the stealing of chemical formulas or details of the production process and information frauds that support product plagiarism becomes relevant. In addition to the loss in sales, the decrease of quality perception, and exclusivity of products, all efforts of product development have to be taken into account to quantify the damage.
4. Suppliers: If information on suppliers is disclosed, the offender might try to bulkhead the organization from indispensable deliveries, or try to take advantage of the suppliers' innovativeness. Moreover, if the supplier is the offender, he might strengthen his position in further negotiations.
5. Industry competitors: Here, the intended actions and reaction plans on competitive threads are relevant. If these are known to the competitors, it might be easy to outsmart the victim in the competitive arena. However, game-theoretic results suggest that this intuitive idea does not generally hold. On the other hand, plans obtained by IE activities are likely to be taken as fact in their strategy development. Consequently, the offender is not coequal in his strategy development. Linking these game-theoretic results with empirical evidence by econometric model-fitting to overcome the limitations of anecdotal evidence is the focus of the New Empirical Industrial Organization, but in this field, much research is pending. Thus, quantification of IE damage in this domain is doubtful.

The latter point foreshadows the power of counterintelligence activities. These are all means of preventing IE actions against one's own company and all measures of feeding fake data into the offender business's intelligence systems. Since a high credibility is likely to be assigned to these data, an identified but not disclosed IE attack can be used to remote control both the offender's tactical maneuvers and the offender's strategic planning. However, this procedure puts the victim on the same level of unethical behavior as the offending organization.

Industrialized Countries

Understanding what constitutes an industrialized country is predicated on both knowing a given nation's level of industrialization as well as understanding the process by which industrialization occurs. A nation's level of industrialization concerns the extent to which its economy is based on manufacturing, construction, and other industrial activity. The process of industrialization most typically entails the transition from a low-tech, small-scale agricultural economy—wherein the majority of persons are engaged in self-sustaining farming activity in rural areas—to one in which high numbers of persons are employed by large-scale, heavily mechanized, and highly efficient goods and/or services manufacturing organizations located in urban areas. An industrialized country is thus one (1) that has undergone the process of industrialization, and (2) that has an economy based heavily on manufacturing, construction, and other industrial activity.

An industrialized country could, at least in theory, be self-sufficient and not heavily involved in trade with other nations. However, given both the fact that any one country is unlikely to possess all resources needed to be self-sufficient as well as the increasingly interconnected and interdependent nature of today's global economic system, the most industrialized nations—for example, Japan, Canada, Germany, the United Kingdom (UK), and the United States—are typically also heavily involved in importing, exporting, and other aspects of international commerce. In fact, it is these highly industrialized nations that comprise what is known as the core of the global economic system—from which emanates the majority of global economic activity.

There are at least three basic reasons why knowing whether or not a country is industrialized is of critical importance. First, level of industrialization is typically closely related to a nation's level of economic development. The relationship is most generally thought to be linear and positive—the higher the level of industrialization the higher the level of economic development. Although it cannot be said with absolute certainty that industrialization causes development it does appear that industrialization is one of several key factors leading to economic growth characterized by: (1) a significant increase in average per-capita gross domestic product, (2) an increasingly widespread and even distribution of income and wealth, and (3) significant increases in consumer demand. In fact, industrialization is typically considered to be both a prerequisite for economic development and the primary driving force behind the recent rise of nations such as Brazil, Mexico, South Korea, India, China, Taiwan, and other newly industrialized countries (NICs) up the ladder of development and toward a place of greater prominence in the global economic system.

A second reason why knowing whether or not a country is industrialized is important is that level of industrialization is the primary factor in the widely used classification scheme devised by the United Nations to group the nations of the world into "more-developed," "less-developed," and "least-developed countries." Finally, and arguably of greatest relative importance, knowing whether or not a given nation is industrialized tells you a lot about the basic character of that nation. If, for example, a country is industrialized one can be fairly certain that the country in question: (1) possesses an economy based on manufacturing, construction, and other industrial activity; (2) is heavily involved in international trade (and the global economic system); and (3) has, as manifest in the United Nations categorization system, at least a relatively high level of economic development.

It should be noted, however, that the nature and consequences of industrialization are not as simple as perhaps suggested above. For example, although the term *Industrial Revolution* is commonly used to describe the industrialization of both the United States and what is today known as the UK beginning the mid-late 18th century, it is appropriate to consider the tumultuous changes that began at that time as but the first of several industrialization-driven revolutions that have significantly altered the economic and social character of many nations over the course of the last 250 years. In addition, the fact that recent and/or ongoing industrialization-driven development of NICs often differs dramatically from that of nations such as the United States and the UK suggests that the process is not as homogeneous as many have long thought. Further, industrialization does not, in and of itself, necessarily lead to rapid widespread prosperity for a nation and its people. Finally, there are typically serious negative consequences associated with the industrialization process that should not be ignored.

Overall, the process of industrialization should be viewed as being highly complex in nature. The consequences of this process should likewise be seen as intricate and, thus, difficult to accurately predict. Perhaps most importantly, it should be understood that neither industrialization nor its development-related (and other) consequences occur overnight—it can take well over a century for the process and its outcomes to be fully realized in any given country. The traditional view of industrialization is based on the process as manifest in both the United States and the UK. This is in contrast to the ongoing industrialization-driven development of China and other NICs.

The United States and the United Kingdom

The first of as many as three periods of industrial revolution—typically referred to as The Industrial Revolution—began initially in what is today the UK and then in the United States in the mid-late 18th century (with 1760 often being considered as the "start date" of the process in the UK). In both nations, the process of industrialization involved (and was fueled by) both the creation and implementation of machinery for the highly efficient mass production of goods as well as dramatic expansions of transportation infrastructures (mainly railroad). Just as importantly, the Industrial Revolution—and the resultant industrialization of both the United States and the UK—involved the mass migration of hundreds of thousands of persons from self-sufficient agrarian existences in rural areas into burgeoning urban environments where they ran the new machines of the new mass production driving industrialization.

The rural/farming-to-urban/mechanized goods production transformation wrought by the original Industrial Revolution was so significant that it is often said that the modern form of capitalism serving as the backbone of today's global economic system began with the start of this revolution. Adequately describing the overall magnitude of the change involved is difficult. However, consider the case of the textile industry in the UK as being exemplary of two key consequences of the Industrial Revolution in that country—the transformation of both (1) the manner in work is done and (2) the way goods are produced. Before the onset of the Industrial Revolution, the majority of clothing was self-produced in homes. This process was tedious and highly inefficient. Think, in this regard, what it would be like today if most people produced their own clothing. Think, for example, about the time and effort involved in finding and acquiring the right raw materials (e.g., raw cotton and wool) and then processing these materials—thread by tedious thread—into the clothing you wear by hand. Now think about this being done in almost every household in the UK. The gross inefficiencies involved in such a scenario should be obvious.

The character of clothing production in what is today the UK changed dramatically in the mid-1760s with the development of the "jenny." This mechanized device allowed the operator to simultaneously work with dozens of threads—and produce a finished piece of clothing in a fraction of the time that could be achieved by an individual working by hand. By the late 1780s, nearly 20,000 "jennys" were in use in factories across the UK. Gone were the days of inefficient domestic production. Highly efficient clothing factories—along with factories in scores of other developing industries—spread across the country. People moved in mass from rural areas to the cities to work in the factories where they could make far more money and live, in at least material terms, better lives.

Suggested above is the fact that industrialization changes both the basis of national economies and the manner in which people in industrialized nations most commonly work (i.e., from self-subsistence agricultural and domestic work in rural areas toward mechanized, third-party manufacturing in urban locales). Quantifying the magnitude of this shift in both the UK and the United States is challenging. Consider, however, that it is estimated that in the United States in 1810 nearly 85 percent of the workforce was engaged in agricultural activities, with only three percent involved in manufacturing. By 1960 only 8 percent of the workforce in the by then nearly fully industrialized United States was engaged in agriculture, with the share for manufacturing rising to almost 25 percent. By 2006 the percentage of U.S. workers involved in agricultural activities had shrunk to under 2 percent—down from 85 percent shortly after the start of the Industrial Revolution.

Needless to say, the transformation involved in the original Industrial Revolution includes major change not only in the way that most people worked, but also in the way they lived. Prior to industrialization, most people in the United States lived in rural areas and produced needed goods and services themselves—and large portions of their time were spent in their homes and immediate communities engaged in this (grossly inefficient) self-production. With industrialization came the onset of urban masses engaged in highly efficient, mechanized manufacturing—and factory work and the means to acquire these third-party–produced goods. In addition, along with the use of machinery in factories all across the United States and the UK came significant increases in demand for and consumption of such factors of production as coal, iron, and transportation—and large industries built around each factor.

The most widely discussed outcomes of the Industrial Revolution for the United States and the UK are great increases in (1) both worker productivity and manufacturing efficiency and (2) national and per-capita income, gross domestic product (GDP), and other measures of material wealth. With regard to the latter, it is often noted that the United States and the UK are today and have for decades been among the wealthiest nations in the world—and that this is an outcome of having been industrialized for a relatively long period of time. Consider, for example, that although only about 5 percent of the world's population resides in the United States, this country accounts for (1) over 25 percent of global wealth and (2) nearly 22 percent of the world's GDP. This is commonly attributed largely to the manner in which people work as well as the way in which goods and services are produced—all products, ultimately, of the Industrial Revolution.

Critiques

However, it is important to note that there was also a clear downside to Industrial Revolution–era industrialization as manifest in both the United States and the UK. Throughout more than the first 100 years of the Industrial Revolution, the urban areas in which more and more people lived became overcrowded and heavily polluted while the factories that hundreds of thousands of people flocked to for work were far from what could be called "worker-friendly." Factories of the period were often largely unregulated, with poor ventilation, dangerous levels of noise, and poor lighting. Much of the highly efficient machinery was also often very dangerous to operate. Workers often worked 12- to 14-hour days in these often horrendous conditions. As a result, critics charge that the positive outcomes of the Industrial Revolution were not evenly distributed. They claim, specifically, that the great material wealth generated landed disproportionately in the hands of factory owners and executive managers for manufacturing corporations—while the workers toiled long hours in poor working conditions for relatively little pay.

Another commonly discussed negative outcome of the Industrial Revolution, particularly in the United States, is the ultimate effect of industrialization on the family. Throughout much of the 20th century, it was widely assumed that industrialization had been the key causal factor leading to the virtual destruction of the traditional family structure in the United States. This "destruction" was seen, for example, in increasingly widespread marital disharmony and instability as well as weakened ties with extended family members.

Although the idea of the industrialization-driven destruction of the U.S. family appears to have been exaggerated by many commentators, industrialization does appear to have indeed created dysfunctional strains on the family—and at least the potential for familial disintegration. These strains most typically arose via industrialization driving the migration of many people from agrarian jobs in rural areas to factory and other goods-manufacturing jobs in urban areas. When this movement occurred, the priority of the father/husband is said to have shifted from the family itself to work. Although it can certainly be said that this work was engaged in for the betterment of the family, the new focus on work—and working for

A 15-year-old girl in a U.S. textile mill in 1916. By 2004 only 17 percent of U.S. nonagricultural workers still manufactured goods.

a company rather than family- or community-based work—is theorized to have changed the essential manner in which fathers/husbands interacted with other family members. It has been noted, in this regard, that industrialization was a significant contributing factor to both (1) a lesser amount of parental control being exercised over children (due to not having as much time to spend with them) and (2) the "early maturity" of children (wherein parents encouraged their children to be independent at an earlier age so as to prepare them for relatively earlier entry into industrialized U.S. society as productive workers).

Newly Industrialized Countries

The recent and ongoing industrialization of Brazil, Mexico, South Korea, India, China, Singapore, Taiwan, and other newly industrialized countries (NICs) is similar to the Industrial Revolution–based industrialization of the United States and the UK in several key ways. First, in a most basic sense, NIC industrialization involves: (1) the transition from a low-tech, small-scale, inefficient agricultural-based economy to one relying heavily on large-scale, heavily mechanized, and highly efficient goods and/or services manufacturing, and (2) the mass migration of persons from rural to urban locales. Similar too is the fact that industrialization drives significant increases in demand for and consumption of raw materials and other inputs to large-scale production and infrastructure development inherent in industrialization. Consider, in this regard, that it is estimated that China now consumes approximately one-third of the total global supply of iron, steel, and coal.

Similarities between industrialization manifest both today and in past centuries also exist with respect to the most commonly discussed outcomes of the process (e.g., increases in productivity, efficiency, and economic development). It is noted, for example, that China, for centuries a relatively isolated, inwardly focused peripheral nation in the background of the modern global economic system, has recently experienced significant industrialization-driven development. In this regard, the Chinese economy has not only become very global in nature but has also doubled in size every eight years over the course of the last three decades. In addition, during this same period of time, nearly 400 million Chinese people have emerged from poverty—many of them by personally becoming part of the global economic system as a result of moving from farms in rural areas to goods manufacturing jobs in large cities.

However, the industrialization of the NICs differs in important ways from previous manifestations of the process. As suggested above with the example of China, but also very much the case with NICs such as South Korea, Taiwan, Hong Kong, and Singapore—often referred to as the "Four Tigers" of southeast Asia—recent industrialization (and industrialization-driven development) often occurs at a much faster pace than in the past. This is, as will be subsequently discussed in greater detail, the result of technological advances employed in the focal industrializing country.

Also at variance with past industrialization is the sheer magnitude of the process today. This is particularly true with regard to China and India. The staggering extent of the industrialization processes in these two countries is without question largely attributable to the fact that they are far and away the two largest countries in the world. The magnitude of China's industrialization is also a function of the fact that ruling members of China's centralized government do not need to be so worried about pleasing constituents and getting reelected (relative to their counterparts in democratically ruled nations. In this regard, China's industrialization had, as of the start of 2007, helped establish the nation as the global leader in the production of steel, coal, cement, TV sets, and cotton fabric—it was also then ranked second in power generation, third in sugar production, and fifth in crude oil output. And, while the magnitude of China's industrialization to date is unprecedented, it should be noted that in late 2007 it was announced by the Chinese National Bureau of Statistics that the country's industrialization was then estimated to be only at its halfway point.

Another important difference between "old" and "new" industrialization involves identification of a set of distinctive factors driving the incidence of the process in some NICs. These factors include

- political stability and the creation and maintenance of foreign investor-friendly environments;
- economic and legal reforms aimed at strengthening definition and enforcement of property and other contractual rights;
- encouraging entrepreneurship amongst domestic businesspeople;
- centralized planning featuring observable and measurable development-related objectives tied to specific policies;
- an outward orientation wherein export production priorities are based on differentiation-based positioning against global competitors;
- careful choice of where and how to access factors of production the country does not have a competitive advantage in;
- the targeting of specific industries for growth via incentive programs and other forms of governmental support;
- providing governmental incentives that encourage a high rate of domestic savings;
- infrastructure spending and development (e.g., in transportation, education, training, and housing);
- making their domestic marketplaces open to foreign marketers (e.g., via reduction or elimination of many tariffs on imported goods); and
- the privatization of state-owned and operated industries (which allowed resources previously tied up in these typically inefficiently run enterprises to be invested in targeted industry development and other strategically important initiatives).

These factors facilitating modern NIC industrialization are based most significantly on analysis of the rapid industrialization-driven development success of South Korea, Taiwan, Hong Kong, and Singapore—the "Four Tigers" of southeast Asia. These countries, long lesser-developed nations with high rates of poverty, began their involvement in the global economic system as export production platforms/goods assemblers for companies and consumers residing in affluent, industrialized nations (e.g., Japan and the United States). Each nation was able, through deployment of different combinations of these key factors, to establish itself as a major global player in selected industries—eventually competing successfully against rivals from highly industrialized and developed nations.

A final major variation in "old" and "new" industrialization concerns the fact that the process today is often based far more heavily on advances in information technology (and their creative application). Fully comprehending the importance of this variance requires a brief historical review. Earlier, it was stated that the Industrial Revolution that began first in what is today the UK in the mid-late 18th century can be seen as but the first of as many as the three periods of industrialization-driven transformation that have reoriented the economic and social character of nations—turning them into industrialized countries. The second such revolution, occurring most notably in the United States starting in the 1960s, involved a marked shift within the manufacturing sector established in the original Industrial Revolution. This shift involved transition toward an (intangible) services manufacturing-based economy—and away from the factory-based production of (tangible) goods. Consider, in this regard, that in 1960 approximately 35 percent of the nonagricultural workforce in the United States produced goods, while about 65 percent were employed in services. By 2004 the percentage of

U.S. nonagricultural workers manufacturing goods had fallen to roughly 17, while the percentage for services production had risen to approximately 83. This transition was driven, in part, by the fact that many goods manufacturing jobs in the United States were relocated to other nations with lower-cost labor (and other factors of production). This second industrial revolution led to what is today referred to as the "service economy" in the United States (and many other industrialized nations previously dominated by goods manufacturing).

What can be called "the third industrial revolution" is still in its early-mid stages. It is a distinctly high-technology revolution often referred to as "the information age." This revolution is driven by the increasingly inexpensive and reliable global exchange of information. This in turn creates the possibility, for the first time in history, to readily transfer the production of certain types of services (e.g., telephone-based customer support, clerical work, and computer programming) to foreign (i.e., "offshore") locations. This is particularly relevant for service marketers in already industrialized countries where the cost of labor is high relative to wages in lesser developed nations where (1) the technological infrastructure is capable of facilitating delivery of the focal service, and (2) an adequately sized workforce possessing the skills required to provide the service can be accessed. Thus, while industrialization today continues to involve the shift from self-sufficient agricultural activities in rural areas to the mechanized production of goods in urban areas, another key component of the process for some nations—most notably India—is a move toward building up the technological infrastructure and increasing the number of technically qualified persons so as to be able to provide "offshore outsourced" services to customers in other countries.

It should be noted that something that has evidently not changed with the recent wave of NIC industrialization is the existence of clear signs of the negative impact of the process. Working conditions in some factories in NICs (and many other lesser-developed nations) rival those of the United States and the UK during the early-mid years of the original Industrial Revolution. Much the same can be said with regard to pollution and its negative impact on the environment. In fact, with regard to the latter and perhaps not surprisingly given the unprecedented speed and magnitude of industrialization in recent years, some have voiced concern that levels of industrialization-driven pollution and environmental degradation are likewise unprecedented.

Take, for example, the troubling case of China, where industrial emissions are often at best loosely regulated and the vast majority of the massive supply of energy fueling industrialization comes from relatively, if not very dirty sources—predominantly coal. Listed below are select findings of a late-2007 *New York Times* report addressing the magnitude of the health-related impact of China's soaring pollution problem.

- In 2006 levels of air pollution in Beijing were more than 300 percent above the level considered safe by the European Union.
- In 2007 two leading international environmental agencies concluded that China had by then become the world's leading producer of greenhouse gases.
- It is estimated that only about one percent of the nearly 600 million persons living in urban environments in China breathe air considered safe by the European Union.
- Air and water pollution are now believed to collectively be the root cause of approximately 750,000 deaths each year in China.
- In 2007 the Chinese Minister of Health officially recognized that soaring levels of pollution had established cancer as the nation's leading cause of death.

Contemplation of these and other similar data and estimates suggests that in order for the development-related potential of China's ongoing and already unprecedented industrialization to ever come close to being fully realized, Chinese governmental leaders face as arguably their greatest single challenge the cessation of practices that have led to the nation's alarming industrialization-driven pollution situation. And, it should be noted that China's problem in this regard is so massive that it has spread well beyond its national borders. It is estimated, for instance, that emissions from industrial operations in China are at least partly to blame for (1) increasing levels of acid rain in South Korea and Japan and (2) much of the air pollution in Los Angeles, California. Finally, perhaps most importantly—and potentially the greatest cause for concern of all—it should be remembered, as previously stated, that China is presently at approximately the mid-point of its industrialization.

Industry Information

The significant role information plays in the success of industry and its participants continues to dominate academic debate, with the growing volume of multidisciplinary literature demonstrating the complexity of not only defining but accessing relevant information. No one clear interpretation of the term *industry information* exists with the variables of country, language, sector, purpose, etc., determining the context of what is looked for and where and how it can be located. What is clear, however, is that information has and will continue to be a vital asset among a manager's skills. For the purpose of this entry, *industry information* will reflect, as E. Ozgen and R. A. Baron write, "the idea that *information* plays a crucial role in opportunity recognition … to identify opportunities for viable new ventures, entrepreneurs must somehow perceive, gather, interpret, and apply information about specific industries, technologies, markets, government policies, and other factors."

Traditional sources of industry information represented by company reports, market research, country, and sector analysis have now been usurped by the digital era, with estimates that by 2011 the digital universe will be 10 times the size it was in 2006. For examples from the digital era, a look at United Kingdom–based industry/business information in the form of information products may be useful. A wide range of industry information sources can be accessed through national, regional, academic, and private library holdings. The sources covered are primarily electronic sources and identify a cross-section of industry information sources from the innovation/ideas phase through to development and marketing:

- COBRA (Complete Business Reference Advisor) database: An encyclopedia covering information relating to start-up, running, and management of a small business, together with examples.
- Business-in-a-box Web site: A free start-up business guide covering such areas as staffing, finance, protecting your ideas, etc.
- Business Link Web site: Sponsored by the DTI Small Business Service: supported through local agencies, providing information, advice, guides, and networking.
- National Federation of Enterprise Agencies: Independent, nonprofit service to advise pre-start and small businesses.
- Startups.co.uk: Contains business planning, finance, etc., together with newsletter and networking facilities for start-ups.

The following sample, using the advertising industry as an example, demonstrates only a small cross-section of the range and content of sources available relating to competitors, suppliers, market evaluation, etc. Within each respective industry sector (pharmaceuticals, retailing, etc.) a similar range of targeted resources can be identified.

- Advertisers Annual (Hollis Publishing): Listing of United Kingdom agencies ordered by location, sector, associations, and sources.
- BRAD Monthly Guide to Advertising Media (EMAP Group): Monthly listing of advertising media in the United Kingdom, new and existing media sources, arranged by sector.
- Advertising Statistics Yearbook (World Advertising Research Center): Covers sales and marketing data for print, radio, and television media in the United Kingdom.
- Business Ratio Report: Advertising Agencies (Key Note Publications): United Kingdom industry overview, profiling over 120 companies relating to finance, league tables, employee growth, etc.
- The European Marketing Pocket Book (World Advertising Research Center): Covers 33 countries including demographics, economic indicators, advertising expenditure.
- Ad Forum Web site: Resources relating to worldwide advertising.
- Advertising Association: Federation of trade bodies covering advertising and promotion activities in the United Kingdom.

Another useful category of industry information sources are market research databases such as the following:

- AMADEUS: Approximately 1.5 million company profiles covering 32 European countries. The searches can be made across countries to include key financial and contact information and lists can be created.
- Business Insights: Provides market research and analysis of several key sectors including healthcare, financial services, energy, telecommunications, high technology as well as consumer markets such as food and drink.
- FAME: Detailed financial data for 2.5 million companies in the United Kingdom and Ireland. Expert searching allows for the creation of company lists that can be sorted by turnover, postal code, and other search variables.
- Key Note: Provides full text access to over a 1,000 reports covering 30 industry sectors such as information technology and food and drink.
- Kompass Worldwide: Covers detailed product and service descriptions of over 1.9 million companies in 70 countries. This represents a key source for manufacturers and suppliers.
- Mintel: Coverage relates to a wide range of consumer and lifestyle markets in the United Kingdom.

What is becoming obvious is that today's contemporary manager still needs additional resources to complement such electronic sources as those identified above. E. Ozgen and R. A. Baron discuss the need to recognize peer support and social networking and suggest that three further sources of key industry information can be found in the nonstandard social sources of mentors, information industry networks, and participation in profession forums.

Understanding and using industry information is essential for survival in today's information economy, yet to attempt to be aware of and be able to use all formal and informal, internal and external information sources is unrealistic. L. Orna argues that to understand what you need, you have to establish

> a "meeting place for minds," in the form of an electronic information product shaped by its users, and arrived at through a co-operative investigation of what's really going on.

Sources of industry information are available, dependent on locality and time spent to identify where and how to access them, but to use them effectively, the key is knowing what the individual and their organization want and why.

Infant Industry Argument

The infant industry argument is used by countries as an economic protectionist measure so that industries (primarily manufacturing) can be protected from other countries' industries that can produce goods or services cheaper than the country enacting the measure. The measure was first argued in the United States by Alexander Hamilton, the country's first Treasury secretary. Prior to the American Revolution, Britain had discouraged its colonies from developing their own industry so that Britain could benefit from its own mercantilism. Additionally, strong tariffs would raise capital for the new republic. Friedrich List (1856) used a similar argument in Germany to protect Germany against British industries. John Stuart Mill eventually went on to formalize the argument in economic terms.

The infant industry argument promotes protectionist measures using tariffs (for a predetermined time) on imported goods of the same type as a particular industry in the host country that has just begun producing those goods (hence the term *infant*). Since the industry is in its infancy, it has not had the opportunity to gain a learning curve in its mass production. Therefore, the argument assumes two things. First, the argument assumes that the industry's leaders will gain a learning curve so that it will be able to match the price of incoming goods after a predetermined period of time. Second, inputs of the country using the infant industry argument (labor, materials, etc.) are the same or near the same as the other countries.

Several flaws in modern-day nation-state economic activity make the infant industry argument implausible, or at least unfair. First, the World Trade Organization (WTO) and regional trade agreements have sought to lower tariffs to increase free trade. Therefore, a country that seeks to use an infant industry argument and is a participant in these organizations could face retaliation by several countries and not just the country against which the first country enacted protectionist tariffs.

Next, the principles of comparative advantage are violated. All things being equal, it is not in a nation-state's best interest to divert resources to an industry in which they have less efficiency or opportunity costs. If a nation-state follows comparative advantage principles, the resources that are being used inefficiently in the protected industry would be distributed to efficient industries (what the nation-state does better than other nation-states).

Also, in today's global economic atmosphere, the cost of labor as an input (dollars/hour wages) in western Europe and the United States is not the same as developing nations such as China or India. In the mid to late 19th century, labor costs were comparable. Therefore, presently only less developed countries could ethically use this argument. Besides labor cost disparities, a country may have other resource inputs that are naturally higher than the country that currently produces the good at a lower cost. Once the tariffs are lifted, these inputs have a normal effect of making the product that is protected under the infant industry argument cost prohibitive in terms of opportunity costs.

Next, determining when the initial tariffs should be lifted becomes less an economic issue and more a political one for the country enacting the tariffs. The infant industry argument presupposes that the protective tariffs will be lifted when the industry is on an even footing with other nation-states' industries and can meet domestic demand, as well as export these goods to other countries. When this "even footing" occurs remains open to debate. Also, the infant industry argument presupposes that the protected industry will continue to invest in the industry to keep up with other nation-states in the same industry. If the industry continually changes due to new investment, the protected industry may need tariff protection for many years. Furthermore, the argument is less clear when other entrants want to get into the industry after a few firms have been protected.

Finally, it is ethically unfair when trade does not occur naturally ("the invisible hand") per Adam Smith. Related to comparative advantage and opportunity costs, resources and manufacturing should naturally flow to nation-states that can produce products most cheaply. The consumer should work with normal cycles of supply and demand to obtain a product at its equilibrium price.

Information Systems

An information system (IS) consists of the people, processes, and data involved in the handling of information in an organization, and as a field, information systems is the study, design, and implementation of such. Nonspecialists often use "information system" to refer specifically to the software used in such systems, likely because that constitutes the bulk of the new information they need to learn if a new IS is implemented in their workplace. But the IS would include, for instance, not simply the new software in use on the store's cash register, but the delegation of authority—who is authorized to issue a refund if a customer asks for one, who counts out the money in the register at the end of a shift or the end of the working day—and the handling of information not accounted for by the software, such as where the receipt from the refund is filed, and where the money from the register is transferred.

In many companies large enough to support the role, the management of information systems falls under the purview of the Chief Information Officer (CIO), the executive in charge of IT-related operations. The CIO typically answers to the chief financial officer, since much of the information systems in use at the company will be devoted to accounting tasks. At tech companies, he or she may answer directly to the CEO. Some companies refer to their CIO as the IT Director, but the CIO title has become preferred because of its parallelism with CEO, CFO, et cetera. Typical CIO qualifications vary greatly according to the company and the nature of their reliance on IT; the CIO may come from a tech field, may be an MBA who picked up IT knowledge on the job, or increasingly may have earned a degree in information systems. With computer expertise no longer as rare a thing as it was in the early 1990s at the dawn of home internet access, nor as niche a field, a great many more CIOs are rising to their positions from the business management part of their industry rather than the IT support side. Duties may or may not include information security; in some organizations, there will be a separate chief information security officer (CISO) who reports to the CIO.

When referring to the software, many people use "information system" to refer to an information *processing* system, a program that turns one kind of information into another. Tax software is a common example most people are familiar with: it takes the user's input (income and certain outgo), processes it according to the algorithms derived from applicable tax law, and outputs the amount of tax owed. These days, computers are flexible enough that when integrated with electronic payment systems and an internet connection, such a system can be used to determine and pay taxes in one fell swoop, and may be used to suggest possible deductions the user may not have considered, thus doing a good deal more than acting as the sophisticated calculator that computers were for so long relegated to.

The three-schema approach was once common in the construction of information systems, though more sophisticated approaches have taken up much of its share as software has become more sophisticated and computer power has increased. A schema—which shares a root with "schematic," "scheme," and "scenario"—is a model consisting of a diagram, usually with both words and images. An obvious example of a schema is the mock blueprints used by schemers in old cartoons, depicting an oblivious mouse in front of a trap, a mouse caught in the trap, and a mouse on a cat's dinner plate, with directional arrows and captions. The three schemas of this particular approach are the external schema that defines how users view the data involved in the system; the internal schema that defines the physical system itself, or storage of the data; and the conceptual schema, which integrates the two.

System Types

Information systems may include transaction processing systems (TPS), which automate the processing of transaction-generated information. Sales and purchases can be handled automatically—such as in online shopping, with systems generating warehouse orders and adjusting inventory, as well as handling the validation of credit card information—with information then recorded, summarized, and stored in appropriate places. The amount of paperwork that can be generated by a TPS has been made infamous by the film *Office Space*'s repeated mention of TPS reports.

Information systems meant to handle especially high-level tasks, such as serving a large corporation, are sometimes called Enterprise Information Systems, extending the modifier from Enterprise software. Enterprise software is that which is intended to be used "at the enterprise level" rather than with a departmental focus. This software is often proprietary, developed specifically for the business (by the IT division or a contracted software developer), or is custom-constructed from a highly customizable software suite. Sun, Adobe, Oracle, and Microsoft all offer Enterprise software and the tools to develop it, but interestingly there is a lot of attention and effort spent on Enterprise software in the Open Source Software community, which not only offers software for free (sometimes charging a fee for tech support or implementation) but puts the code in the public domain so that anyone who wants to can modify it themselves.

The usefulness of the Enterprise software designation is facing diminution, as some vendors push overly complex software suites on businesses too small to benefit from them, while others package relatively ordinary business management software as Enterprise software because of the prestige appeal of the label.

At the information system level, the purpose of an Enterprise Information System is to avoid the conflicts, redundancies, and inconsistencies that can result from using separate segregated information systems in various departments. The entire company's information system is conceived as a whole, with a unified means of handling data and spotting problems. Such systems will usually include a content management system (CMS). A CMS is a software package that handles digital media, including text. Internet and intranet technologies are used to manage content like documents and procedures, structured and unstructured records, and other information, providing interfaces for it to be accessed in-house, by other businesses (vendors, customers, industry agencies), by the general public, and by the government. Often the end-user is unaware of the content management system; it's "middleware," providing infrastructure and a framework that integrates the foundation (content) with the edifice (the interface).

Other subsets of information systems relevant to business are management information systems (MIS), accounting information systems (AIS), and strategic information systems (SIS). Management information systems examine business operations and internal control—the way the business's resources are allocated and recorded. MIS is concerned with making sure that the operations and processes of the business are consistent with achieving the company's objectives and compliant with its standards. Accounting information systems focus on the financial transactions and behavior of the company. Either can include decision support systems, information systems that guide decision making by organizing data in various categories. DSSes can be communication-driven, facilitating the decision-making processes involving multiple people; data-driven, as in the purchasing example; document-driven, when the relevant data is "unstructured" (in the form of customer letters, for instance, as opposed to manipulable numbers in a spreadsheet); knowledge-driven, when procedures or problem-solving are involved; or model-driven, when the current situation can be compared to others.

Executive information systems are subtype of decision support systems, and are specifically designed for executive-level decision making affecting the whole of the company, and focused on the overall goals of the company more than the day to day transactional operations. The needs of these systems vary by the company's industry, but will include significant data about and evaluations of the other parties the company works with—buyers, vendors, contractors, regulatory agencies, and so on—and relevant industry-wide information.

Strategic information systems are similar to executive information systems, but focus specifically on assisting decision making related to the company's competing in the industry. Ideally, an SIS gives the company a competitive edge by enabling them to react quickly to changes in the industry environment—to maintain this edge, the system needs to be updated regularly in order to keep up with those changes.

Information Technology Auditing

Information technology (IT) auditing collects and evaluates data pertaining to an IT infrastructure. An IT audit may augment a financial audit, but it is specifically designed to test the IT infrastructure's accuracy, efficiency, and security. Though around since the 1960s, IT audits have become especially important in the 21st century, when so much of a business's activity is conducted or assisted electronically.

The first IT audits were necessitated by the use of electronics in accounting systems. Early computers did little more than that—compute—and the combination of their expense with their extraordinarily narrow focus of applications meant that they were adopted slowly. Though General Electric used a computerized accounting system in 1954, computer use was a highly specialized skill, and early input methods (such as punch cards or paper tape) were tedious to error-check.

With the development of specialized office computers in the 1960s and the shift toward developing computers for people who did not work on them for a living, larger businesses began to integrate computers into some of their accounting procedures, especially data storage (such as to keep track of inventory or reservations) and handling large amounts of complicated information. The first IT audits were therefore electronic data processing (EDP) audits, double-checking the accuracy of the software systems in use at a business and the data entered into and derived from them.

This led to the development of specialized accounting software, and in 1968 the American Institute of Certified Public Accountants helped formalize EDP audits, keeping them at the rigorous standards employed by financial audits. The Electronic Data Processing Auditors Association (EDPAA) was formed shortly thereafter, for the growing number of accountants who specialized in EDP audits. EDPAA has since (in 1994) changed its named to the Information Systems Audit and Control Association, and publishes CobiT—Control Objectives for Information and related Technology, the widely accepted list of standards and objectives in IT audits.

IT auditing became especially prioritized in the aftermath of the Equity Funding Corporation of America scandal of 1973, when former EFCA employee Ronald Secrist and analyst Ray Dirks reported that the Los Angeles company—which sold mutual funds and life insurance—was guilty of widespread and organized accounting fraud. At least 100 employees since 1964 had been guilty of deceiving investors and the government, and that deceit included a computer system devoted to the forgery of insurance policies for fictitious policyholders. Determining the extent of the fraud, of course, meant auditing the computer system, as well as all others in use by the company—a process that took over two years. Similarly, in the wake of the 21st-century accounting scandals, the Sarbanes-Oxley Act of 2002 was passed, establishing stricter standards for public company boards and public accounting firms—with a greater emphasis on IT audits.

There are five categories of IT audits:

- Systems and Applications audits test the input, output, and processing at all levels of the company's systems and applications.
- Information Processing Facilities audits test the control of the processing facility under normal and disruptive conditions.
- Systems Development audits examine the systems under development to make sure that they meet the company's objectives and standards.
- Management of IT and Enterprise Architecture audits examine the organizational structure and procedures in use.
- Client/Server, Telecommunications, Intranets, and Extranets audits focus on networking issues, an area where there is particular concern with staying current in security protocols.

Information technology changes rapidly, as does its position in the process of doing business. IT auditors, though they may be CPAs, are generally more versed in information systems, with a general understanding of accounting principles, because the accounting component of their job is the more static ingredient in the mix, while the ramifications, security concerns, and potential for misuse of technology are always in flux.

Infrastructure

Infrastructure is a wide-ranging term that describes the underlying framework and structural characteristics of a location or activity. Generally it refers to such tangible and physical facilities as buildings, equipment, roads, bridges, harbors, rail networks, airports, communications, gas and electrical power, flood control, healthcare, education, police and fire protection, water, and sanitation, but it can also be used to represent more elusive concepts such as organizational structures, knowledge, monetary exchange, property rights, social customs, and other institutional characteristics. By and large the term *infrastructure* is used to represent those assets that facilitate the production and distribution of goods and services, but it can also be used more generically to describe such things as social and institutional practices, literacy, and the flow of information. In the sense that infrastructure is comprised of the vital materials of everyday life, it is fundamentally allied with the routines of both individuals and institutions, since any or all of these issues and factors can affect relative economic, social, cultural, and political conditions.

In historic terms, infrastructure can even be touted as enabling the very development of civilizations in the sense that most societies necessarily occupy particular locations capable of sustaining and fostering life, and each location requires the provision of core necessities. And even though the scale of any particular community will vary, its residents still need to acquire sufficient quantities of food and water as well as the desirability of disposing of its waste in order to make some effort to curb disease. For example, the impressive growth of the world's great metropolises in the late 19th and early 20th centuries (such as London and New York) can be directly coupled with the development and investment in systems that delivered potable water, disposed of sewage, and offered sustainable food supplies by linking urban areas with hinterland regions and markets. Accordingly, both the pace and the model of modern industrial societies can be tied to the establishment and implementation of infrastructure.

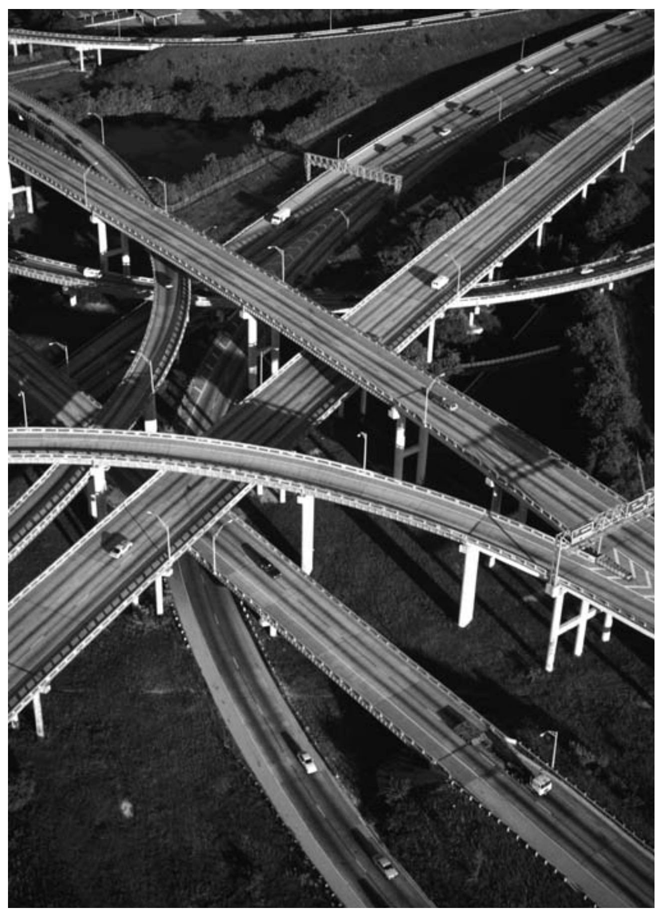
In common application, the term *infrastructure* came into use in the post–World War II era and is sometimes referred to as "social overhead capital." Public capital is also typically not an insignificant proportion of an industrialized nation's entire capital stock. The use of the term *social overhead capital* underscores that many of the more obvious examples of infrastructure (such as roads and bridges) are pervasive assets that are often publicly or socially provided but consumed collectively and individually. They are also social assets that often have substantial initial fixed costs in their creation but relatively low variable costs in their marginal use once provided.

Accordingly, one of the issues around the provision of local public goods such as roads is whether an appropriate amount of the good is being provided relative to its direct and indirect return. The construction of a road will be unambiguously beneficial to the community if it significantly reduces transportation costs and enhances access and exchange. On the other hand, too much or too little of a good is likely to lead to both social and private inefficiencies since both the overproduction and overconsumption of social capital can be inefficient and costly. Unnecessary and duplicative roads are examples of overproduction while traffic congestion is an example of the overconsumption of an existing road network. The availability and relative quality of infrastructure is likely to have significant economic and social impact, not only on many of the costs associated with the production and distribution of any number of goods and services, but it can also define the extent and efficiency of individual markets as well as entire communities.

One of the confounding factors in evaluating the true economic and social influence of infrastructure or social capital is that these are investments that provide benefits across dissimilar industries as well as in diverse time periods. The direct and indirect economic benefits of infrastructure can range from considerable to slight in alternative circumstances and thus may or may not be readily apparent to various consumers and producers that the due influence of social capital on output levels, productivity, and in due course on an area's material standard of living. The social effects of infrastructure, while not necessarily simple to quantify, can likewise range from the obvious to the obscure but all the same can have considerable influence on the manner in which people and institutions subsist and interact. Indeed, communities and individuals are defined and shaped by both the immediate and persistent effects of infrastructure in any number of overt and subtle ways.

Infrastructure and Economic Development

With rising concerns about both the process and the rate of economic development, attention has arisen to explain not only why wealth and poverty are so variable by location and situation but also to identify the probable role of infrastructure in that variation. The notion that infrastructure is directly related to economic development would seem self-evident. Moreover, when you take into account that many of the features most commonly categorized as infrastructure (transportation, communications, and utilities) are organized and function in systems of networks, then the apparent correlation between the availability of infrastructure and economic activity seems fairly straightforward. Nevertheless, economic development is clearly more than a one-dimensional process and consequently any resources, whether publicly or privately invested in the creation of infrastructure, ought to be evaluated



Too much or too little infrastructure can lead to inefficiencies, such as unnecessary or overcrowded roads.

in its appropriate context and relative to alternative investments.

Assuming that some minimal amount of overhead capital is essential for any reasonably sized community to subsist, the development and application of additional appropriate infrastructure is likely to be a necessary condition for further economic growth to occur. To be sure, there may well be some debate about whether or not providing necessary infrastructure would then be sufficient for economic growth to occur, but the notion that social capital can potentially advance the relative economic condition of the community seems reasonable. The adoption of new forms of infrastructure can also be the means by which technological change is diffused through an economy. For example, in both transportation and communications there have been changes not only in the way people move around but also in the means by which they send and receive information. Paved roads permit heavier loads at higher speeds, while fiber-optic cable networks transmit vast quantities of data much more rapidly than did earlier systems. Even though the existence of a technological change does not assure economic growth, most likely the reliance on archaic and inefficient social capital would inevitably engender economic stagnation. On the other hand, if a community's infrastructure were to experience a suitable and sufficient degree of technological change in conjunction with the appropriate institutional responses and policy decisions, then it certainly ought to be an active economy that encourages growth.

While the formation of infrastructure is often associated with public works projects, the production and maintenance of overhead capital does not necessarily involve public financing. Given the diversity of assets and characteristics that are suitably regarded as infrastructure, they can be funded by not only public and private investments but also directly by user fees. With respect to the relative well-being of a community, more pertinent issues include such things as how public capital is utilized in private production and distribution as well as what effect infrastructure ultimately has upon per capita income.

Quantity and Pricing of Infrastructure

Among the concerns of providing social capital goods is choosing an appropriate quantity of the good as well as setting a pricing scheme that efficiently and equitably reflects relative values. Infrastructure reduces costs for both consumers and producers and, as such, there are sufficient incentives on both the demand and supply side of markets to promote the creation and maintenance of infrastructure. Despite these incentives, it is also a potential free-rider problem since it is possible for users to access some of these social capital goods without the necessity of making fair payment. The occurrence of too many free-riders threatens the relative efficiency of providing a local and collectively consumed public good. There are also externalities that mean that potential market failures may well lead to an inefficient provision of social capital.

The relative return on public versus private capital investments is an issue of concern to development economists and policymakers. Private firms clearly have a vested self-interest to pursue private investments that augment their own profitability, but the public nature of infrastructure investments suggests that an equivalent public capital investment would potentially advance overall productivity not only in one product, manufactured by one firm, but simultaneously and consistently across a number of products and industries. Given the pervasiveness of infrastructure, it can be problematical to separate and quantify the real economic value of social capital. For instance, a healthy, literate, and skilled workforce enhances worker productivity, not merely for a particular firm but also across all local industries; accordingly, benefits accrue to employees, employers, and to the entire community.

ING Group

ING Group (Internationale Nederlanden Groep) is a financial services company that provides savings, banking, investments, life insurance, and retirement services to people and companies in over 50 countries. It is a Dutch company with headquarters in the ING House in Amsterdam, the Netherlands. However, it has subsidiaries in nearby Great Britain and in 50 countries and employs over 130,000 people.

The business model that ING uses focuses on accumulating retail savings and pensions, and then investing them in well-diversified assets that have been selected after careful risk management assessments. For its retail customers, the goal is to see that ING's banking, investments, life insurance, and retirement services grow capital while minimizing risk. The mission of ING is to be the standard-setting leader in helping customers to manage their financial futures. Consequently, the strategy of ING is to create value (or wealth) for its customers at a higher rate of return on investments than its competitors over the long term and not just in short-term profits.

ING was created by the 1991 merger of Nationale-Nederlanden and NMB Postbank Group. Both Nationale-Nederlanden and NMB Postbank Group had a long corporate lineage stretching back before the 1800s to the Kooger Doodenbos business begun in Koog, Noord Holland, which was founded in 1743. The group has been involved in business activities such as fire insurance and providing financial security for widows, orphans, and those impoverishment by illness.

The religio-social divisions of Dutch society have played a part in the development of the predecessors of ING, lasting into the formation of ING itself. Catholics, Socialist/Liberals, and Protestants have historically formed subcultures in Dutch society, with separate banks and insurance companies being a consequence. ING inherited these divisions but has sought to overcome them in its subordinate units.

In the early 1990s, regulatory reforms in the Netherlands removed legal restrictions on mergers between insurance companies and banks. Since 1991, ING has become a multinational corporation with a very wide range of international activities. It is no longer simply a Dutch company with an international business.

Since the mid-1990s, ING has engaged in a series of buyouts. Some were acquisitions that sought to increase profits by reselling parts of the buyout after some restructuring. Other acquisitions were intended to increase the size of ING or its presence in a new market. The 1995 acquisition of Barings Bank followed its financial collapse due to the unauthorized speculative trading of Nick Leeson, a trader in Barings's Singapore office who lost $1.4 billion, rendering Barings insolvent. The purchase made ING globally recognized. Some Barings units were integrated into ING; others were closed or were sold.

An important company owned by ING that was sold was Life of Georgia, an insurance company based in Atlanta. It has since been purchased by the Jefferson National Life Insurance Company.

An acquisition that increased the strength of ING's presence in the Benelux countries was the purchase of Bank Brussels Lambert, a Belgian bank. Business activity in the United States was increased with the acquisitions of Equitable of Iowa; Aetna Financial Services; ReliaStar, a life insurance company; and Furman Selz, a privately held New York securities firm, in 1997 for $600 million.

Other acquisitions by ING were into territories in which there was more political risk. In 2001 it bought the Polish Bank Śląski and the Mexican insurer Seguros Comercial America. It has also established working relationships with Asian institutions such as the Bank of Beijing and the Pacific-Antai Life Insurance Company based in Shanghai, and the China Merchants Fund Management Company.

In 2008 the financial crisis that began with the subprime mortgage problem in the United States was signaled by events like the bankruptcy of the Wall Street financial firm Lehman Brothers. ING's exposure was very limited, so it was in a position to acquire several major banks in Iceland that collapsed. In a move to stabilize the situation for British depositors, the British Treasury had ING acquire the Icelandic deposits of Kaupthing Edge, Heritable Bank, and the Landsbanki with obligations of over £6 billion.

Initial Public Offering

An initial public offering (IPO) occurs when a firm for the first time sells securities to the public. Firms going public can be nascent start-ups or old, established corporations engaged in restructuring programs requiring new capital injection. The IPO as a means by which capital is raised became an increasingly common phenomenon in the 1990s when more than 4,000 IPOs were issued in the United States alone.

The process for conducting an IPO generally involves a firm taking the following steps: (1) it registers with the Securities and Exchange Commission (SEC), (2) it seeks the help of one or more investment banks as "underwriters" to pursue a coterie of institutional investors and the general public to purchase the firm's stock, (3) it presents the IPO fact file and prospects to the investor community, (4) it determines the number and price of shares to be offered in the IPO, and (5) it works out the aftermarket position, after observing the "quiet period."

There are a wide variety of reasons for a firm's decision to go public. As the IPO firm faces lower costs for external equity, going public means a lowering of the cost of capital. Moreover, while an IPO broadens the ownership base of the firm, it also allows insiders to cash out. Founder managers, and, in some instances, financial intermediaries such as venture capital and private equity firms can then harvest their investment. Since an IPO attracts the attention of a wider market, a firm operating in a sector such as high technology may conduct its IPO as a reputation-enhancing move. It is also suggested that when a firm reaches a certain point in the business growth cycle and needs capital to support growth, it will decide to conduct an IPO.

The timing of an IPO is deemed crucial because it is generally observed that IPOs come in waves. There are signs of herd mentality in such behaviors, as first-day stock performance of an issuing firm is likely to lead other firms to decide to go public. Firms can then take advantage of better stock market conditions by entering the IPO market. To the extent that the market timing issue is important, a firm will first need to gauge the strength of the IPO market in terms of market and industry stock returns.

There is a difficulty relating to price discovery in an IPO, which is due to the fact that the issuing firm lacks information about the investor demand for its shares, whereas most investors are not certain about the quality of the firm. Therefore, the IPO firm's value must be established without referring to the market value. To alleviate such problems of information asymmetry, investors use a number of mechanisms that signal firm quality. One such mechanism is the choice of underwriters, who have strong incentive to build a reputation as valuation experts as they repeatedly bring firms public. Underwriters are also expected to have an institutional client base, as institutional investors are more willing to participate in an IPO when there is uncertainty about the IPO firm.

When a firm is not able to raise funds through other forms of financing, such as debt or private equity, an IPO provides access to substantial amounts of capital. However, it is generally observed that IPO firms offer prices that are lower than their first-day market closing price, and this is a well-researched area. There is widespread agreement that underpricing is a strategic move designed to compensate investors, especially institutional investors, for taking the risk of investing in the IPO. There are other benefits such as how additional interest in the stock is generated when it first becomes publicly traded.

The risk of the IPO firm is minimized by insiders agreeing not to sell personal shares for a period of time. Because insiders of an IPO have better information about the firm's operations than outside investors, it is expected that the issuing firm commit to a lockup period. A long lockup signals firm quality, and underwriters may use this period to stabilize the aftermarket trading of IPOs via price support. The long-term performance in the returns to stocks that make an IPO has been poor, as demonstrated by studies in the United States and other countries. One factor particularly responsible for this outcome is excessive optimism regarding the firm's earnings potential. A number of studies have found that IPO firms inflate earnings in periods prior to equity offers. Firms also frequently issue IPOs when "exuberant" investors are prepared to pay a relatively high price for issued stock. These factors to some extent explain why firms with income-increasing abnormal accruals at IPO significantly underperform.

Integrated Marketing Communication

The emergence of integrated marketing communication (IMC) introduced a new paradigm into the corporate sphere, promising to make marketing more effective and competitive. The development of IMC constitutes a significant evolution in the areas of corporate marketing, corporate communications and, in particular, marketing communication. While there is no specific definition or common understanding of the concept of IMC, it is widely accepted that it is based on cross-functional processes given that it aims to coordinate corporate and brand messages and communication activities across units and functions. The aim is to increase brand value and to enhance profitable brand relationships by persuading and influencing customers and other stakeholders such as employees, media, suppliers, local community, and/or prospective customers. Soon marketing and communication practitioners and academics began to recognize and apply an IMC approach to their tactics and strategies.

In the 1990s, the concept of integrated marketing communication became increasingly popular. The various reasons that accounted for its relatively quick spread and acceptance included the following: (1) from the outset the notion of integrating the communication and marketing activities of an enterprise originated in—and was soon supported and adopted by—a wide spectrum of practitioners (advertising, direct marketing, and public relations) as well as by advertising agencies and companies alike; (2) the various academics (including Don Schultz of Northwestern University's Medill School, who allegedly coined the phrase), who embarked upon periods of extensive research into (and subsequent publishing of) the concept, soon found an audience both inside and outside the academic world; (3) faced with the challenges (a) of an increasingly globalizing world, and (b) of the growing importance of the internet for daily life and business, the implications for marketing communication appeared stark: It was necessary now to market and communicate more effectively in increasingly fragmented and segmented markets. Simultaneously, mass advertising was renounced in favor of segmented or more personalized communication; (4) a change of focus from an internal (company)-driven to an external (consumer)-driven marketing and communication orientation, and (5) the increased popularity of integrating business functions in order to use synergies resulting in more competitiveness. A combination of the above changed the nature of competition and the process of marketing communications markedly. There were even claims that the new paradigm had revolutionized the marketing discipline in its entirety.

Concept

The precise nature of integrated marketing communication (IMC) is difficult to capture. Popular definitions include Don Schultz's emphasis on the importance of IMC to influence behavior and to address brand and company contacts with audience. Other definitions of IMC range from understanding IMC's role as managing customer relationships to improving brand value, highlighting the cross-functionality of IMC (Tom Duncan) and the importance of aligning corporate messages (on both the corporate and individual brand level) at all contact points of the company with the customer.

Is IMC a tactic or strategy? In line with the alignment and coordination of all messages going out, a transformation from promotion to communication has taken place, i.e., communication not simply between different business units but also between consumer and company. Dialogue such as this will inevitably result in enhanced consumer participation in the processes of communication, marketing, and finally, brand value creation. Knowing more about customers' needs and preferences allows for increased customized communication and a strengthening of the company's relationship with the customer. Today, more than ever before, concomitant with the spread of internet technologies the customer can be treated, integrated, and involved in a more holistic manner.

Glen J. Novak and Joseph Phelps identified three forms of IMC in the body of relevant research: (a) integrated communication, (b) "one voice" communication, and (c) coordinated marketing communication campaign. Integrated communication, that is, the promotion of brand image and the influencing of direct audience behavior, employs all available communication and marketing tools. As regards "one voice" communication, the company makes it clear from the outset that it is committed to a unified and single positioning strategy. In contrast, a coordinated marketing-communication campaign is about synchronizing marketing communication activities in order to address multiple audiences and to introduce multiple brand positions if necessary.

Critiques

Integrated marketing communication's relevance and practice value are being debated vis-à-vis the applicability of both different product types and different business types. On an organizational level, two critical points affect the implementation of IMC: (1) structural barriers (a pronounced business unit mentality including business unit profit centers, functional specialization and lack of IMC budget) can hinder or restrict integrated marketing communication; and (2) the absence of (or limited) horizontal communication would be incompatible with the IMC mindset.

Critiques of the IMC concept are not necessarily limited to the questioning of the technical applicability of IMC: Postmodernists question the ability of IMC to capably address the increased complexity of today's globalizing world. IMC, with its emphasis on control, order, and predictability, is in general terms a somewhat modern concept whereas market fragmentation and consumption practices tend to display postmodern characteristics. To this end, in their discussions of the integrated marketing communication paradigm, postmodernists call for a more fluid, flexible, and open approach to change.

Integrative Bargaining

Integrative bargaining can best be analyzed by comparing it with distributive bargaining, as illustrated by Richard Walton and Bob McKersie's pioneering study. These two approaches differ fundamentally: for example, defining the parameters of what is at stake, the range of possible outcomes, and the indices of a successful outcome. Distributive bargaining is conducted on the basis of win or lose: What one side wins, the other side loses. It is an essentially competitive and adversarial process; and it presupposes a zero-sum game or a fixed-size "pie" that implies limits on what is available for distribution. Successful bargaining, in this type of process, means obtaining as much as possible of the contested "pie" at the expense of "the other side." Given that the priority in this bargaining process is the win/lose dynamic, the parties generally show little concern for the quality of their relationship with each other.

Much of the bargaining conducted in commercial or industrial relations contexts could be characterized as the distributive type. For example, if a buyer can successfully negotiate a lower price than that sought by the vendor, then such an outcome might be at the expense of some of the vendor's profit. Similarly, in pay negotiations, there is usually a conflict between the views of the respective parties as to the share of revenue to be made available for employees' pay relative to employer's profits. In pay negotiations, management typically frames what is at stake as a fixed-size "pie."

By contrast, integrative bargaining is a cooperative approach that emphasizes the quality of the relationship between the parties as well as the substantive matters at stake. It is founded on the assumption that constructive negotiations can enlarge the "pie" by means of such strategies as, for example, identifying areas of common interest. Integrative bargaining is not an approach based on conceding easily to the other side; but it can generate agreements where each party simultaneously considers that it has won something that satisfies some significant interest(s).

For instance, if a buyer can negotiate a lower price per unit, this might be a worthwhile trade-off for the vendor if it is in exchange for the buyer committing to a larger purchase or a longer term: both parties thereby will enjoy increased benefits. Similarly, although distributive bargaining may dominate approaches to negotiating pay, managers and unions can still adopt more integrative, or mutual-gains bargaining approaches when negotiating on other relevant employment matters (e.g., occupational health and safety, work organization, training, and professional development).

Although the distinction between distributive and integrative bargaining was developed in the context of industrial relations, it is also applicable in many other contexts: for instance, political negotiations at both national and international levels. One objective of the proponents of the establishment of what later became the European Union (EU) in the post–World War II period was the prevention of further wars between historically hostile European states by means of an integration of those states within a unifying supranational structure. Subsequent bargaining to develop an expanded EU was predicated on an assumption that this could enlarge the European "pie" to make the EU economy greater than the sum of its national parts. Hence, bargaining about such substantial matters could be seen, in integrative terms, as attempts to achieve win-win outcomes for the respective parties.

Power, or the perception of relative power, is fundamental to bargaining processes and outcomes. This is particularly so for those who try to move from distributive to integrative bargaining. Most bargaining processes involve parties or "reframing" contentious questions to try to influence the perceptions and attitudes of the other party to generate opportunities for achieving consensus.

Intellectual Property Theft

Intellectual property (IP) rights are the rights given to individuals over the creation of their minds. These rights are afforded legal protection for a specified period of time during which the creator of the intellectual property has exclusive rights to this property. Intellectual property has three principal categories: copyrights, which govern the IP of authors of literary and artistic works (books, writings, and musical compositions), as well as the rights of performers (singers and actors) and those responsible for the dissemination of these works (film and record producers); trademarks, which are the indicia (signs, words, or symbols) used by manufacturers to distinguish their products from those of others. These marks may consist of the same mark applied to a number of different products or they may involve the application of different marks to unrelated products. Owners of registered trademarks are entitled to their exclusive use. Finally, there are patents, which govern the IP of those creating industrial property (for example, new technology, processes, and designs) and may be held by individuals or the corporations which employ them.

Protection of IP, in all its forms, is important for a variety of reasons. As far as the creators of IP are concerned, exclusive rights reward creative work in the arts (copyright); they allow trademark owners to enjoy the goodwill associated exclusively with their marks; and patents encourage research and development into new products and processes. Properly enforced, the rights associated with IP ensure that not only do the creators of IP benefit but so does society as a whole; when not properly enforced, misuse of IP affects both the private benefits that accrue to its creators and society at large. Consider, for example, the following potential consequences for society when IP is misused: Research and development are discouraged and therefore economic growth is reduced; new cures for life-threatening diseases are delayed because of the greater uncertainty surrounding future returns; misuse of trademarks on pharmaceutical products can cause serious injury or death; organized counterfeiting exacerbates the problems associated with organized crime.

At the international level protection of copyright was enshrined by the Berne Convention for the Protection of Literary and Artistic Works, 1886 (and subsequently revised, for example, in Paris, 1896; Berlin, 1908; Rome, 1928; and, most recently, by the TRIPS Agreement, 1994). The Berne Convention and its successors established a series of guidelines and the minimum level of protection to be afforded to copyright. For example, works originating in one of the contracting states were to be given the same protection in each of the other contracting states as the former gave to its own subjects. The Convention provided for "moral rights"—the right to claim authorship of the work and the right to object to any modification of the work that was prejudicial to the author's reputation. The Convention stipulated that the duration of copyright protection was to be 50 years after the author's death.

The U.S. movie industry lost an estimated $1.25 billion from piracy, including from counterfeit DVDs, from 1998 to 2002.

During the Uruguay Round negotiations preceding the TRIPS agreement, it was accepted that the Berne Convention generally provided adequate standards of copyright protection and so the focus was on extending the provisions laid down in the last Convention (Paris, 1971). However, signatories do not have rights or obligations under the TRIPS Agreement in respect to "moral rights." Among the key extensions that TRIPS made to the Berne Convention were that copyright would be extended to expressions; the provisions of the Berne Convention that apply to literary works would be extended to computer programs; and databases would be protected even where the data contained on them was not subject to copyright protection. In the case of computer programs, authors would have the right to authorize or prohibit commercial rental to the public of originals or copies of their copyright work. The duration of copyright protection was retained at 50 years (but 20 years for broadcasting organizations).

In the case of trademarks, international agreements covering their registration and protection date back to the Paris Convention for the Protection of Industrial Property, 1883 (and its subsequent extensions, for example, the Hague, 1925; London, 1934; Lisbon, 1958; and the TRIPS Agreement, 1994). The basic guidelines and rights to protection set out in these Conventions were as follows: First, nationals of each of the countries of the Union shall enjoy in all other countries of the Union the advantages that their respective laws now grant; the countries of the Union agree to refuse or to cancel the registration of or to prohibit the use of, any trademark that constitutes a reproduction or imitation of a mark already used by a person entitled to the protection of the Convention, and used for identical or similar goods; restrictions were placed on the use of state emblems, armorial bearings, and hallmarks, as trademarks.

The TRIPS Agreement continued these basic provisions and made a number of extensions. For example, in deciding whether a mark proposed for registration would undermine the exclusive rights of the owner of a registered trademark, the likelihood of consumer confusion was assumed. Additionally, service marks were specifically included in the definition of trademark (the Paris Convention only contained a general obligation to recognize the rights of owners of these marks). TRIPS introduced the first international requirement to provide for cancellation and opposition procedures when a trademark was published prior to registration.

In the case of patents, these, too, were the subject of international protection under the Paris Convention and its successors. The fundamental rights of patent holders established by these Conventions were similar to those of trademark owners (for example, rights to reciprocal protection within the Union), but differed to the extent that they are an intrinsically different form of IP. Among the key rights accorded to patent holders under the Paris Convention were that patents applied for in the various countries of the Union by persons entitled to the benefits of the Union would be independent of patents obtained for the same invention in other countries irrespective of whether they were members of the Union; if examination indicates that an application contains many inventions, the applicant may divide the application into a number of separate applications, and no country of the Union may refuse an application for a patent on the grounds that it contains multiple priority claims.

The TRIPS Agreement extended the Paris Convention in a number of directions. For example, restrictions were imposed on eligibility: inventions may be excluded from patentability if there was a danger that their commercial exploitation would endanger public order/morality (for example, pornography). Additionally, signatories were permitted to exclude from patentability diagnostic and surgical methods for the treatment of animals (to facilitate the free dissemination of new medical techniques). Finally, patent applications would be subject to a precise test governing the description of the invention. Specifically full disclosure was required to ensure that the invention can be exploited without undue difficulty by others after the expiry of the exclusive right (which is nonrenewable).

Misuse of IP continues to be a booming, if illegal, industry, as demonstrated by Nicole Piquero: In the United States, it has been estimated that the motion picture industry lost $1.25 billion between 1998 and 2002 due to piracy; worldwide estimates of the annual amount of pirated software range between $7.5 and $17 billion. One problem is that rapid advances in technology have increased the opportunities for IP theft. For example, the proliferation of photocopying machines has increased concerns about the effectiveness of rights given to copyright holders; these concerns have been exacerbated by the even more rapid proliferation of personal computers and access to the World Wide Web.

Greater international efforts to combat protection of IP rights, as demonstrated by the TRIPS Agreement, have also been matched by reinvigorated efforts at the national level to solve this problem. For example, in the United States, the Department of Justice created a Task Force on Intellectual Property in 2004, to examine how methods for civil and criminal enforcement of IP could be improved. In the United Kingdom, the Alliance Against IP Theft was formed, comprising, for example, British Brands Group; British Phonographic Industry, British Video Association, and the Institute of Trademark Attorneys. These national initiatives are important to combat indigenous IP theft; however, because globalization has increased trade in semi-processed and finished products, all of which contain IP to varying degrees, greater international coordination of these initiatives will become more important if international IP theft is to be eradicated.

Inter-American Development Bank

A regional development institution for the Americas was first proposed in 1890 at the First Inter-American Conference held in Washington, D.C. Not until 1959 did it come into being, as a complement to the World Bank's Latin American activities. The Inter-American Development Bank (IDB) was the first regional development bank and originally included the United States and 19 Latin American nations. It has since expanded to become the largest source of multilateral funds in the Americas, even including European nations as non-borrowing members, and includes 423 member banks. Headquartered in Washington, D.C., the IDB maintains offices in Paris, Tokyo, and every borrowing member nation.

The 26 member nations eligible for IDB loans are Argentina, the Bahamas, Barbados, Belize, Bolivia, Brazil, Chile, Colombia, Costa Rica, the Dominican Republic, Ecuador, El Salvador, Guatemala, Guyana, Haiti, Honduras, Jamaica, Mexico, Nicaragua, Panama, Paraguay, Peru, Suriname, Trinidad and Tobago, Uruguay, and Venezuela. There are, additionally, 21 non-borrowing member nations: Austria, Belgium, Canada, Croatia, Denmark, Finland, France, Germany, Israel, Italy, Japan, the Netherlands, Norway, Portugal, South Korea, Slovenia, Spain, Sweden, Switzerland, the United Kingdom, and the United States. Borrowing countries hold the majority of the shares in the IDB, setting it apart from other regional banks. The majority of the governors on the board come from Latin American and Caribbean nations, and a board of directors handles most functions, including the approval of loans. Historically, the IDB has tended to support U.S. and capitalist-democratic interests—loan applications from Salvador Allende's Chilean administration were routinely refused in the 1970s.

IDB loans are typically granted for infrastructure expenditures (highways, dams, etc.), and since the Latin American debt crisis, have reflected policy-based lending, reshaping economic policy within debtor nations in return for and as part of granting loans. Funding priority is given to projects that integrate a nation's economy with the worldwide economy, reduce poverty, and further sustainable development. The IDB tends to come under criticism from the same corners as the International Monetary Fund (IMF) and the World Bank. In the 21st century, the IDB's pro-American, Washington Consensus leanings have been more prominent, with as much as a third of the loans in any given year being granted for economic reforms and modernization rather than more policy-neutral loans. A special operations fund has also been established for loans to less developed nations at special below-market rates to encourage economic growth and health in the region. In October 2008 IDB announced it would join the Goldman Sachs 10,000 Women Initiative to support and promote women entrepreneurs in the region.

The IDB's funds are raised by selling bonds to institutional investors, backed by the IDB's ordinary capital (about 5 percent of which is paid in, the remainder of which is callable from the non-borrowing member nations). The weakness of Latin American economies has put the IDB's credit rating at risk, but peer pressure has seemed to help to ensure that the borrower nations—which constitute the majority shareholders—will not jeopardize their peers. Argentina did default on its loans in 2001, and there has been concern expressed about Brazil and Mexico.

Interbank Market

The interbank market is a money market that facilitates commercial and noncommercial banks and other nonbank financial intermediaries to lend and borrow to each other. It consists of two tiers: the lending market and the foreign exchange market, which are the biggest and best known over-the-counter financial markets. Unlike the stock market, the interbank market has no physical exchange, and the transactions do not represent any security being traded. Instead, the transactions conducted in the interbank market purely reflect the participants' preferences at the prevailing rate. Also, the interbank market plays a crucial role in the determination of monetary policy.

Banks that have a surplus of funds enter the interbank lending market and lend money to banks that are short of funds. The rate at which banks lend to each other is the London Interbank Offer Rate (LIBOR), which serves as a benchmark for short-term interest rates globally. Since the interbank rate closely monitors the interest rates charged by the biggest institutions, it closely reflects the real interest rate being used by the most prominent market participants.

The interbank rates are maintained and published by the British Bankers' Association (BAA). The BAA maintains a reference panel of banks across a number of countries and institutions; it daily surveys the market activity of the most prominent banks and institutions and classifies their quotes in quartiles. The middle quartiles at which banks lend and borrow are averaged and the resulting rate is the BBA LIBOR rate, which is published in 10 currencies (pound sterling, U.S. dollar, Japanese yen, Swiss franc, Canadian dollar, Australian dollar, euro, Danish kroner, Swedish krona, and New Zealand dollar).

The interbank market is predominantly a short-loan market, with loans ranging from overnight to periods up to six months. The bulk amount of loans, however, is settled overnight. The interest rates charged on the loans is linked to LIBOR plus a margin. So, the loans have the following format: "LIBOR + ¼" or "LIBOR + 10 basis points." While the LIBOR rate constitutes the "sell" side of the interbank market, the London Interbank Bid Rate (LIBOR) constitutes the "buy" side of the market; thus it represents the deposit rate offered by banks to other banks. Similarly, the Japanese Bankers' Association publishes the Tokyo Interbank Offered Rate (TIBOR) and the European Banking Federation publishes the Euro Interbank Offered Rate (EURIBOR), which is the benchmark rate at which Euro interbank deposits are offered. EURIBOR is computed as an average of the quotes provided by 57 of the most active banks in the eurozone. It was first published on December 30, 1998. EURIBOR, however, should not be confused with EUROLIBOR, which is the LIBOR rate quoted in euros.

In the United States, the interbank rate is called the "Federal Funds Rate." The Federal Funds Rate is the rate at which banks and other institutions lend money to each other. However, the mechanism for the Federal Funds Rate is slightly different than the one that prevails in other interbank markets. So, in the U.S. interbank market, banks lend to each other by lending available balances at the Federal Reserve. When banks issue loans, the minimum reserve requirements that should be deposited at any time in the Federal Reserve fall, and the rate at which banks with a surplus of available deposits at the Federal Reserve lend to banks with reserve requirements is called the Federal Funds Rate.

The interbank rate, and accordingly the interbank market, plays a very important role in monetary policy, where an interbank rate target is in essence also a monetary policy target. There is strong correlation between the interbank rate and the rate at which banks borrow from central banks. So, when banks find themselves in need of funds, they can either borrow from other banks at the interbank market and at the prevailing interbank rate or they can instead borrow from the central bank at its rate of interest. Loans offered at the interbank market can mature overnight, while the loans offered by central banks have a minimum maturity of one week. So, provided there is sufficient supply of loans at the interbank market, banks will prefer to borrow at the interbank rate. Yet, if loans are scarce at the interbank market, the interbank rate will increase and banks will have to look for other money alternatives.

The foreign exchange market is also an interbank market where banks can exchange currencies on a 24-hour basis. The foreign exchange market attracts the largest volume at the most competitive quote of any financial market. The market is self-regulated and depends solely on competitive pressures. Transactions in the foreign exchange market can be at the "spot/current," "forward/future," or "swap" price. A swap transaction involves a simultaneous purchase and sale of given amounts of foreign currency. Banks in the foreign exchange market use two forms of quotations when trading foreign currency: The first form states the number of units of foreign currency that are needed to buy one unit of the domestic currency. The second form states the number of units of the domestic currency that are needed to buy one unit of the foreign currency.

Interest Rates

Interest rates are the cost of borrowing money; more specifically, interest rates are the price of credit. They are sometimes defined as the "rent" on borrowed capital, or as a fee on borrowed capital. The rates vary depending upon the risk assumed by the lender of not being repaid the capital. Interest rates are charge in borrowing transactions. To make a loan there must be a borrower who wants to enjoy the use of the principal and a lender who is willing to risk his or her capital. The interest rate is composed of the opportunity costs, the risks of the lender, and general economic conditions. The interest charged may be called interest, or sometimes it is masked as a fee.

One of the justifications for the charging of a fee on borrowed capital is that it makes up for the lost opportunities for investment incurred by the lender. The opportunity costs are experienced by the lender, who is compensated by the fee that is paid for the use of the capital that must be returned. According to this line of thinking, borrowing money and paying interest on those funds is analogous to renting an automobile and paying a fee for its use.

Types and Definitions

There are several types of interest. Simple interest is calculated on the principal or on the amount that remains unpaid. It can be illustrated by drawing a rectangle with interest and principal on the side of the rectangle and the years to pay along its bottom. Then the rectangle is divided from the upper left to the lower right. The area above the line represents the amount principal that has been paid. The area below the line is the amount of interest paid. By the end of the loan most of the payment is going for the return of principal with most of the interest paid in the early years of the life of the loan. In effect the total amount of interest is calculated as a part of the total to be repaid along with the return of principal. This is different from compound interest, which involves charging interest on interest.

Compound interest allows interest to be accumulated as an addition of the principal. It causes rapid growth in the sum of money that has to be repaid. In addition the time periods for compounding may be daily, weekly, or for a longer period of time. Thus, if a borrower has a loan of $1,000 and a compound interest rate of 1 percent per week, then the loan's balance at the end of the first week would be $1,010. Then at the end of the second week it would be 1 percent added to $1,010, which equals $1,020.10. At the end of the third week the amount would be $1,030.30. The resulting progression causes the principal to increase rapidly, making the cost of borrowing much higher than with simple interest.

Prior to the advent of computers several rules of thumb were used for calculating interest and principal repayment schedules. One was the now outlawed "rule of 78". Another rough rule is the "rule of 72," which allows mental math by dividing the interest rate into 72. So if the rate is 7 percent then the amount of time for the lender to double the amount lent is 7 divided into 72 which is a little more than ten years.

Interest rates in finance are commonly viewed as the yield from the investment. The yield is a composite measure. It includes all payments of interest and principal. Retail finance uses annual percentage rates and the effective annual rate as a way of giving the consumer transparency on the loan.

Setting Rates

Interest rates are the result of a number of factors, one of which involves the concept of deferred consumption. If money, which is the savings accumulated by an individual or by savings institutions is loaned, then it is not used by the lender for consumption. Instead the lender defers consumption until the loan is repaid. Part of the cost of borrowing is the price of delayed gratification by the lender.

Another factor involved in setting interest rates is the expectation of inflation. The interest rate reflects the expectation of the lender that the purchasing power of the loan will over time be diminished unless it is recovered through increases in the interest rate. The loan closes the lender to other opportunities. Thus the lender is part of a process where different investments compete for financing. It may be that a lender sees a more profitable investment but is denied the opportunity to invest because of the commitment to one loan over another. Time is an important factor when inflation is a factor because the shorter the life of the loan, the less the principal will be affected by inflation.

Risk is another factor affecting interest rates. The lender always has to risk the chance of not being repaid. The reasons may be due to failure in the investment project. Rapidly changed economic conditions can ruin the possibility of repayment such as a mortgage on a house that drops dramatically in value to well below the value of the loan. Financial malfeasance is also a cause of losses that can stimulate higher interest rates. Taxes can also affect interest rates as can the desire of some investors for a level of liquidity that requires high interest rates in order to induce lenders to lend.

Interest rates in the global economy are set by market forces and by governments as a part of their monetary policy. They factor in the rate of business activity on a macroeconomic scale. In general when interest rates are high the cost of borrowing becomes prohibitive and it dampens business activity. The reduced investment causes national income to fall and for slower economic activity to mark the markets at that time. However, if interest rates are low the reverse happens.

In the United States the Federal Reserve (Fed) acts as a lender to banks and charges a smaller "federal funds rate" for short-term loans than the market price of interest. The latter is the prime interest rate, which is the rate charged to the highest quality customers who have a very high capacity to repay the loan. It uses the open market operations as one of its monetary policy tools for guiding interest rates.

For the Federal Reserve controlling the interest rate for the main body of money that is being lent is a way of stimulating the economy when it lowers the federal funds rate, or of dampening inflation when it raises interest rates. It is not at all usual for the Federal Reserve and the Congress to work at some cross purposes. The case of the latter fiscal policy, the spending that comes from taxation, may have a negative impact on interest rates because the goal of government spending may be to decrease unemployment with inflationary spending. The Fed is able to set rates that influence interest rates in the short run.

Interest rates are usually set competitively by market forces. They are also set in the light of lending conditions. In times of prosperity lenders compete for the business of borrowers. However, there may be times of recession or depression where the cost of lending, the interest rates, are set high. Rates then can be set by circumstance of need or desperation in the financial conditions of the borrower. A lender could then charge "whatever the traffic will bear" as the interest rate. Even in times of prosperity individuals or firms may be subject to high lending rates because of their personal on the firm's circumstances.

Exploitation and Limits

Interest rates may be low or very high. Strictly speaking any charging of interest is usury; however, modern economies thrive on credit financing that charges interest. To protect individuals from unscrupulous lenders, some of whom may be criminal loan sharks, many governments have set limits on interest rates in order to prevent usury. In the United States the states have laws that limit interest charges on a wide variety of loans. However, the credit card industry has been able to charge high interest rates that often range above twenty percent per annum. These rates have encountered objections as usurious, that is, as excessive and exploitative. To prevent these high rates political action is required that sets a lower cap on rates that is more in favor of the consumer. Some see this as an interference with good banking; however, others see it as exploitation that eventually creates economic problems.

In vast areas of the Third World rural people, and especially small farmers, may be subjected to high interest rates because the only lender available is only willing to lend at high rates. The rates may be higher because of drought or other adverse farming conditions. The terms set by the lender could include rates that will mean the loss of the farm and the indenturing of farmers and their families. However, microlending at low rates in many places has allowed women especially to borrow small sums to pay for such items as sewing machines. Or the microloan may be to purchase a farm animal such as a goat that can give milk and can be sold after breeding.

Religious Views

Historically medieval Catholic theology viewed charging interest as usury, which was a sin because in an agricultural economy interest charges were seen as harmful. It was not until the advent of Protestantism that interest was allowed in moral theology. Protestant charging of interest followed John Calvin's view that interest was acceptable. He viewed renting money to be like renting land from which the produce could be used to pay the rent. This was an acceptable practice in medieval Christian moral theology, while charging interest was not. Since Calvin was the spiritual leader of the merchants of Geneva, they favored the practice of charging interest as renting money and as acceptable as renting a house for business or renting farm land.

Today Jews still follow biblical injunctions to not charge their fellow religionists interest. However, it may be charged on loans made to Gentiles. This practice allowed Jews in the Middle Ages to charge interest, which from the Roman Catholic point of view did not matter, because not being Christians they were considered lost souls.

Charging interest is also forbidden in Islam. There are banks run by Muslims that lend at zero interest. The banks actually take deposits and partner with the depositors and the bankers to find projects that pay a profit. The return from the real and carefully studied investment opportunity is seen as a profit and not as interest. Islamic scholars usually cite Sura (Chapter) II.275-278 of the Koran as the ruling text on *riba* (usury). Because of the prohibition, almost all Islamic banks have survived the economic crisis of 2008.

These religious positions on the immorality of charging interest affect interest rates and the practice of applying interest to loans in many areas of the world. Consumer groups, aiming to protect individuals with limited incomes from predatory lenders, also seek to limit the amount of interest charged on loans. Consumer advocates have particularly agitated for government-imposed ceilings on the interest rates charged by credit card companies.

Interest Rate Swaps

A swap is an exchange of one asset (or liability) for another in order to change some of the characteristics of the asset being held by an investor. Usually the objective of the investor is to change only a few, even only one, of the characteristics of the asset. In an interest rate swap, an investor may exchange, or swap, a floating-rate bond for a fixed-rate bond. The bonds being exchanged will be very close in terms of the amounts involved, credit risk, and maturity but may be different only in that the interest rate on one bond may be fixed for the life of the bond while the interest rate on the other may change according to a prearranged formula over the life of the bond. Since the investor who wishes to make such an exchange may find it very difficult to find another investor who wants to make the opposite transaction, that is, be the counterparty to the swap deal, financial institutions usually have to get involved to facilitate the swap transactions.
